W262 Comparison of spring and fall calving beef herds grazing endophyte-infected tall fescue. B. T. Campbell*[1], W. M. Backus[1], M. C. Dixon[2], R. J. Carlisle[2], and J. C. Waller[1], *[1]The University of Tennessee, Knoxville, [2]Research and Education Center at Ames Plantation, Grand Junction, TN.*

Twenty years of production records for spring and fall calving cows were obtained from the Research and Education Center at Ames Plantation. The cow herds were under the same management for the years contained in the study and all cows were strictly culled for reproductive failure and low performance. The cows primarily graze tall fescue (*Lolium arundinaceum* Schreb.) with the wild-type endophyte (*Neotyphodium coenophialum*) that induces the signs of tall fescue toxicosis. The spring herd was comprised of 551 cows and 1548 calves and the fall herd was comprised of 463 cows and 1834 calves respectively. The average age of cows in the spring herd was 4 years old, ranging from 2 to 11; and the average age of cows in the fall herd was 5 years old ranging from 2 to 12 respectively. Data were analyzed for calving interval, number of calves born, birth weight of calves, weaning weight of calves, adjusted 205-d weaning weight, average daily gain (ADG) from birth to weaning, and weight/day of age. The data were analyzed using a randomized block design in SAS 9.2. The spring calving herd had a shorter calving interval by an average of 10 d ($P < 0.05$), and produced fewer calves per cow ($P < 0.05$). The fall calving herd averaged 4 calves per cow while the spring calving herd only averaged 3. Calves born in the spring had higher birth weights than those born in the fall ($P < 0.03$), and spring born calves had higher ($P < 0.001$) adjusted 205-d weaning weights than fall born calves. The calves born in the spring had an ADG from birth to weaning of 1.03 kg/day while the calves born in the fall averaged 0.98kg/day. Fall born calves were lighter at birth than spring born claves and had lower weaning weights than spring born calves. However, spring calving cows had a higher replacement rate than fall calving cows. Higher replacement rates in the spring calving herd could be the result tall fescue toxicosis, a problem during the breeding season of spring calving cows. In contrast fall calving cows are bred during winter when tall fescue is dormant and tall fescue toxicosis is not a problem.

Key words: fescue, calving season, production

W263 Influence of winter and spring pasture allowance on growth and reproductive performance on beef replacement heifers. B. L. Bailey*, K. M. Krause, and T. C. Griggs, *West Virginia University, Morgantown.*

The objective of this study was to compare heifer growth and reproductive performance following 2 pasture allowances during the winter and following spring grazing season. Three 5-ha fields were selected as blocks in a randomized complete block design for application of grazing treatments. All fields had been in long-term hay and/or pasture production and contained cool-season grass-legume mixtures (orchardgrass, tall fescue, smooth bromegrass, quackgrass, red and white clovers). Seventy-two spring born heifers of primarily Angus background and 247 kg mean body weight (BW) were allocated to grazing treatments (12 hd/replicate of a treatment) for the entire developmental period November 12, 2009 - May 24, 2010 (194 d). The treatments consisted of daily herbage dry matter (DM) allocation of 3.5 (LOW) or 7.0 (HIGH) % of BW. The winter grazing period began November 12 and ended December 20. During the winter feeding period (December 21 - April 19) haylage (6.2 kg DM/hd/d) was fed and supplementation of soybean hulls (1.8 kg DM/hd/d) occurred January 20 - April 19. Spring grazing began April 20 and ended May 24. BWs were determined every 2 weeks and blood samples were taken on d 13, 41, 71, 109, 139, 155, 169, and 180. Heifers were subjected to a 58 d breeding season. Average daily gains (ADG) for the entire developmental period were 0.56 vs. 0.63 kg/d ($P = 0.12$) for LOW vs. HIGH heifers. During the winter grazing period ADG were 0.37 vs. 0.63 kg/d ($P < 0.05$) for LOW vs. HIGH heifers. For the winter feeding period ADG were 0.34 vs. 0.39 kg/d ($P = 0.31$) and for the spring grazing period 1.43 vs. 1.36 kg/d ($P = 0.38$) for LOW vs. HIGH heifers. Proportion of heifers who had reached puberty, and BW at the onset of the breeding season did not differ between treatments (60% vs. 60%, $P = 1.0$; and 357 vs. 369 kg; $P = 0.12$, for LOW vs. HIGH). Pregnancy rates did not differ (LOW: 74%, HIGH: 81%). We interpret these results to indicate that delaying the majority of weight gain until late in heifer development may decrease costs of winter feeding without detrimental effects on reproductive performance.

Key words: beef heifers, grazing, reproductive performance

W264 Cow and calf separation to improve reproductive performance of first-calf Nellore beef cows under tropical conditions. P. G. M. A. Martins*[1,2], C. A. A. Torres[1], A. B. Mancio[1], W. F. Souza[1], G. C. Lamb[3], and J. D. Arthington[2], *[1]Universidade Federal de Viçosa, Departamento de Zootecnia, Viçosa, Minas Gerais, Brazil, [2]University of Florida, Range Cattle Research and Education Center, Ona, [3]University of Florida, North Florida Research and Education Center, Marianna.*

Our objectives were to compare the effects of an early Nellore-calf weaning, to cows kept with their calves and a 72-h calf withdrawal on measures of performance of first-calf beef cows. Seventy-six primipa-

rous, Nellore cow-calf pairs were randomly allotted to 3 treatments: EW (early weaned); TW (temporary weaned for 72 h); and CON (control – cows remained with their calves throughout the study). Treatments were initiated at the start of a 90-d breeding season, starting on November 2009. Cow and calf BW, and cow BCS were determined at d 0, 30, 63 and 90 of the study. Blood samples were collected over 90 d, 10 d apart for determination of progesterone concentrations. Resumption of cyclicity was defined as the first sampling day when progesterone concentrations were ≥1.5 ng/mL for 2 consecutive sampling dates. Pregnancy was diagnosed by transrectal ultrasonography on d 63 and 53 d after the end of the breeding season. Cow and calf BW did not differ at the beginning of the breeding season ($P > 0.10$; BW = 365 ± 28.3 and 106 ± 14.5, respectively), as well as cow BCS. However, at the end of the breeding season, cow BW was greater for EW cows, compared with TW and CON ($P < 0.10$; BW = 440 ± 35.4; 404 ± 33.4; 398 ± 30.3, respectively). Cow BCS was also greater for EW cows, compared with TW and CON cows ($P < 0.10$; average BCS = 4.5; 3.8; 3.8, respectively; SEM = 0.10). For calf measures, TW and CON calves had greater BW, compared with EW since December, reflecting on BW at the normal weaning time ($P < 0.10$; BW = 164 ± 19.1; 201 ± 23.7; 196 ± 20.2 for EW, TW, and CON calves, respectively). By d 10 of the breeding season (corresponding to aproximately120 d postpartum), more ($P < 0.05$) EW cows were cycling than TW and CON cows. Pregnancy rate was 84.0 and 96.0% for EW, 60.0 and 84.0% for TW, and 46.2 and 80.8% for CON during and after the breeding season, respectively. In the first year of the study, early calf weaning improved cow pregnancy rate, BW and BCS, but resulted in impaired BW gain of EW calves.

Key words: body condition score, progesterone, weaning

W265 Relationships between performance and residual feed intake in Bonsmara heifers when confinement fed or on pasture. L. M. Wiley*[1,2], T. D. A. Forbes[1], A. N. Hafla[2], C. M. Hensarling[1], B. G. Warrington[1], and G. E. Carstens[2], *[1]Texas AgriLife Research, Uvalde, [2]Texas A&M University, College Station.*

Over 2 years, Bonsmara heifers (n = 60 and 55/yr, yr 1 BW 264 ± 6.1, yr 2 BW 281 ± 5.1) were individually fed a forage-based diet (2.07 Mcal ME/kg DM, 13.1 g CP/kg DM) using Calan gates at College Station, TX. Feed intake was recorded daily, animals were weighed weekly for 70 d, and residual feed intake (RFI) was calculated as the difference between actual dry matter intake (DMIc) and expected DMI from linear regression of DMI on ADG and mid-test $BW^{3}0.75$. Heifers were ranked by RFI, and those with the lowest (n = 12, LRFI) and highest (n = 12, HRFI) RFI were transported to Uvalde TX, and placed on pasture. Animals were weighed weekly over a 56 d period, 3 10-d intake measurement trials (2 trials in yr 1) were conducted using n-alkanes. Estimates of forage DMI were calculated daily and averaged within trials. RFI was computed as described above using forage intake estimates. In both yr, estimates of DMI were lower in LRFI than HRFI animals under confinement feeding (8.4 ± 0.78 vs 11.0 ± 1.11, and 8.5 ± 0.23 vs 10.5 ± 0.22 kg DM/d for years 1 and 2 respectively, $P < 0.01$). On pasture, LRFI animals had lower DMI than HRFI (8.8 ± 0.77 vs 9.1 ± 0.91 and 7.7 ± 0.11 vs 7.9 ± 0.16 kg DM/d, for yr 1 and 2 respectively) but the differences were not significant ($P > 0.1$) Estimates of ADG were not different between LRFI and HRFI within feeding situations or yr. In the confinement trials, F:G was correlated ($P < 0.01$) with ADG (−0.53 and −0.83 for yr 1 and 2. respectively) but not with DMI. During the pasture trials, F:G was correlated ($P < 0.001$) with ADG (−0.88 and −0.88 for yr 1 and 2, respectively) but not with forage DMI. In both yr, RFI during the confinement trials was not correlated with ADG, but was correlated ($P < 0.001$) with DMI and F:G. Forage RFI in yr 1 was not correlated with ADG or FCR, but was correlated with forage DMI, while in yr 2 RFI was correlated with DMI and F:G but not ADG. There were no correlations between RFI measured during the confinement and pasture trials. These data suggest that daily variation in forage DMI prevents accurate forage RFI estimation if using a limited number of estimates of DMI

W266 Effect of birth weight, early feed intake, and average daily gain of calves before weaning on their performance after weaning and during first lactation. C. M. Matuk*[1], M. Chahine[1], A. Bach[2,3], B. Ozer[1], M. E. de Haro Marti[4], J. B. Glaze[1], and T. Fife[1], *[1]University of Idaho, Twin Falls, [2]IRTA, Caldes de Montbui, Spain, [3]ICREA, Barcelona, Spain, [4]University of Idaho, Gooding.*

The effect of birth weight, early feed intake, and average daily gain (ADG) on performance was analyzed in a group of 755 replacement Holstein calves raised on a large commercial dairy operation in southern Idaho. Individual feed intake was recorded 4 times a week during the last 3 wk that calves were individually hutched (56 d of age). Based on their individual feed intake, calves were classified as control (randomly chosen without considering their level of feed intake, CTL, n = 80), ′high eaters′ (highest feeding level quartile, HIGH, n = 200), ′low eaters′ (lowest feeding level quartile, LOW, n = 200) and ′medium eaters′ (the remainder of calves, MED, n = 275). Weight was recorded at birth, and at wk 6, 9 and 12. During data collection, calves were housed at a calf raising facility from birth to approximately 7 mo of age, at a heifer raising facility from 7 mo until heifer reached 247 d of pregnancy and then moved to the dairy where calving occurred. Milk production (305 d mature equivalent, 305ME) records were obtained from the dairy computerized record system for all heifers that calved. Data were analyzed using PROC MIXED and PROC CORR in SAS (SAS Inst. Inc., Cary, NC). Out of the 755 heifers included in the study, 206 were culled (27.3%) and 491 have calved to date (65.0%). Out of the 206 culled heifers, 60 were lost at the calf raising facility (29.1%; 26 sold, 34 dead), 126 at the heifer raising facility (61.2%; 111 sold, 15 dead) and 20 at the dairy (9.7%; 12 sold, 8 dead). Intake classification did not a have a significant effect on cull rate. There was no significant correlation between birth weight and 305ME or between ADG and 305ME. First lactation milk production (305ME) did not differ between feed intake classification and averaged 11553 ± 150 kg for the HIGH group (n = 124), 11483 ± 145 kg for the MED group (n = 123), 11408 ± 174 kg for the LOW group (n = 92) and 11201 ± 255 kg for the CTL group (n = 43). In this study, birth weight, early intake and ADG of calves did not have an effect on their first lactation 305ME milk yield.

Key words: calves, 305ME

W267 Different periods offering chromium oxide (Cr_2O_3) as external marker to evaluate the intake of cattle treated with different diets under feedlot. R. A. Mandarino*[1], F. A. Barbosa[2], I. S. Silva[1], C. F. Lobo[1], S. L. S. Cabral Filho[1], G. A. Carneiro[1], and G. S. Firmino[1], *[1]University of Brasilia, Brasilia, DF, Brazil, [2]Federal University of Minas Gerais, Minas Gerais, MG, Brazil.*

The aim of this study was to evaluate the dry matter intake of cattle using 2 distinct periods of supply of chromium (10 g once daily) as a

marker of consumption of feedlot cattle treated with 3 different diets. The feedlot experiment was conducted from August to November 2009, during 96 d. The herd was composed of 12 zebu cattle with a average age of 23 mo with initial body weight of 364.68 kg. The treatments were the different periods of supply of chromium with 5 d (CR5) and 7 d (CR7) repeated twice in the period of feedlot. The diets were: SIL - corn silage and concentrate (corn grain, soybean meal, soybean hulls, urea and mineral supplement) at a ratio of 25:75 (in dry matter), PEL - exclusive diet of pellets; GRN - diet with whole grain corn and pellets. A randomized scheme in a 2 × 3 factorial divided as follow: CR5SIL, CR5PEL, CR5GRN, CR7SIL, CR7PEL and CR7GRN. The Duncan test at 5% probability level was applied to compare the means obtained. The average final body weight was 471.88 kg. The periods of infusion were not different statistically ($P > 0.05$) for any of the repetitions. The results of dry matter intake showed 2.21%, 2.28%, 1.82%, 2.16%, 1.87% and 1.68% of body weight for CR5SIL, CR7SIL, CR5PEL, CR7PEL, CR5GRN and CR7GRN respectively. All the results showed no interactions either for treatments or the diets ($P > 0.05$) indicating that a shorter period of infusion of chromium can be recommended to reduce the time of this methodology to estimate dry matter intake.

Key words: chromium, markers, supplements

W268 Total and inorganic phosphorus content of an array of feedstuffs. J. P. Jarrett*[1], M. D. Hanigan[1], R. Ward[2], P. Sirois[3], and K. F. Knowlton[1], *[1]Virginia Polytechnic Institute and State University, Blacksburg, [2]Cumberland Valley Analytical Services, Inc., Maugansville, MD, [3]Dairy One, Ithaca, NY.*

Recent investigations suggest that bioavailability coefficients of phosphorus (P) in various feedstuffs may be inaccurate. Surveys of dairy nutritionists suggest that overfeeding of P in dairy rations may stem from a lack of confidence about forms of P and availability of those forms to ruminants. Quantifying variation of P-containing compounds in feed may help improve estimates of P bioavailability. Seventy-two feed samples were received from 2 commercial labs. Total P (TP), inorganic P (Pi), and the percentage of TP that is inorganic were analyzed using the MEANS procedure of SAS. The effect of geographic region and feed class (forages, concentrates, and by-products) was analyzed with the MIXED procedure of SAS. Total P was greater ($P < 0.05$) in concentrate and by-product feeds than in forages but there was no consistent effect of feed class on Pi quantity ($P > 0.10$). However, Pi as a percent of TP was higher ($P < 0.05$) in forages as compared with concentrates and by-products. Region had no effect on TP and Pi concentration. Data characterizing variation of P-containing compounds in feedstuffs may allow better estimations of P availability and more accurate feeding recommendations.

Table 1.

	Total P (μg/g of DM)		Inorganic P (μg/g of DM)		Pi (percent of TP)	
	SD	Mean	SD	Mean	Mean	SD

W269 Protein-energy mineral supplementation of Nellore bulls in the growing phase at *Brachiaria brizantha* 'Marandu' during the rainy season. C. F. Lobo*[1], F. A. Barbosa[2], R. A. Mandarino[1], G. A. Carneiro[1], and S. L. S. Cabral Filho1[1], *[1]University of Brasilia, Brasilia, DF, Brazil, [2]Federal University of Minas Gerais, Minas Gerais, MG, Brazil.*

This experiment was designed to evaluate the effects of 2 types of protein-energy-mineral supplementation and mineral supplementation on the performance of Nellore bulls in the growing phase, during the rainy season, from December to April, in *Brachiaria brizantha* 'Marandu'. A total of 60 Nellore bulls were used, with average initial BW of 227 kg. The treatments were: MS – control, complete mineral supplement; SUP1 – protein-energy mineral supplement with slow release urea, with an average daily intake of 0.36% BW; SUP2 – protein-energy mineral supplement with conventional urea, with an average daily intake of 0.36% BW. The experiment was conducted in a randomized block design with 3 treatments and 4 replications. The Duncan test was used to evaluate animal performance. There was a difference ($P < 0.06$) between SUP1 and MS, with ADG of 0.585 and 0.477 kg/h/d, respectively. The gain obtained with SUP1 in comparison to MS promoted additional gains during the rainy season. There was no difference ($P > 0.06$) in ADG between MS and SUP2, with gains of: 0.477 and 0.496 kg/h/d, respectively. There was no difference ($P > 0.06$) between supplements SUP1 and SUP2, and their ADG equal to 0.585 and 0.496 kg/h/d. There was no significant yield difference between SUP1 and SUP2. As for MS, SUP1 was superior and SUP2 was equivalent, indicating the viability of using SUP1 in the rainy season.

Key words: grass, performance, protein

W270 Requirements for continuous ammonia-NH_3 sampling when using relaxed eddy accumulation from concentrated animal feeding operations. C. D. Gambino*[1], J. M. Ham[2], E. Allwine[1], P. O'Keeffe[1], S. N. Pressley[1], B. K. Lamb[1], and K. A. Johnson[1], *[1]Washington State University, Pullman, [2]Colorado State University, Fort Collins.*

Improved understanding of requirements for measuring ammonia (NH_3) volatilization from concentrated animal feeding operations (CAFO) is needed to design mitigation strategies and better acquire

national NH_3 emission inventories currently required by the United States Environmental Protection Agency. Real time NH_3 concentrations at feedlots can be difficult to measure because ambient temperature, relative humidity (RH), dust interference, and sampling line length can negatively impact the sample stream to the NH_3 analyzer. The compounding effect of these variables increases the potential for imprecise measurements. A review of the literature measuring NH_3 concentrations from feedlots indicates that the necessary concentration range for an NH_3 analyzer to be useful in conjunction with an REA approach to flux measurements must satisfy detection from 194 - 1766 ppbv. One commercial NH_3 analyzer that shows promise to be used for feedlot NH_3 measurements is the Picarro G1103 analyzer for NH_3 and H_2O. The objective of this work was to test the robustness of the Picarro for use in feedlot NH_3 measurements. Laboratory tests were conducted to determine potential interferences to the continuous analyzer's detection sensitivity. A Picarro NH_3 analyzer drew samples from the up or down canister every 30 s. Laboratory tests on the adapted system moved to establish an ideal square wave for analyzer response time. Picarro NH_3 analyzer response time was determined for line loss associated with temperature fluctuations of −20°C - 80°C, concentration differences of 100 ppbv-2500 ppbv, RH ranges from 0% - 100%, and dust interference within the optical cell. Lines, as well as up- and down-eddy canisters were maintained at desired temperatures using heat tape and incubators, respectively. Test concentrations matched extremes found during summer campaigns of 194 - 1766 ppbv- NH_3, corresponding to fluxes 68 - 128 ug- NH_3 m^{-2} s^{-1}. The validation and optimization of the REA-Picarro continuous sampling system provides an option for long sampling periods to improve characterization of NH_3 losses from feedlots.

Key words: ammonia, REA, measurement

W271 Effects of weaning strategy on growth and stress in beef calves. M. E. Howe*, L. B. Krebs, and E. G. Brown, *Stephen F. Austin State University, Nacogdoches, TX.*

The market demands alternative strategies to traditional weaning that will lead to more pounds of product produced and less stress in the weaned calf. To compare alternative strategies with traditional abrupt weaning, 39 crossbred calves and their cows were used to evaluate stress and performance. Cows and calves were assigned to 4 treatment groups based on calf body weight and parity of the cow. Treatments include anti-suckling device (day −4 to 0) followed by fenceline (day 0 to 42; n = 10); anti-suckling device followed by abrupt removal from cow (day 0 to 42; n = 10); no anti-suckling device (day −4 to 0) followed by fenceline (day 0 to 42; n = 10); and no anti-suckling device followed by abrupt removal from cow (day 0 to 42; n = 9). All calves remained with their cows when anti-suckling devices were fitted to the calf. At weaning (day 0), anti-suckling devices were removed. Calves were placed in a pasture adjacent to their cows for fenceline weaning and abrupt calves were moved to a remote location away from their cows at weaning. Cows and calves were weighed on d −4,-2, 0, 2, 4, 14, 28, and 42. Body condition scores (BCS) were determined on cows on d −4, 0, 14, 28, and 42. Blood samples were collected from cows and calves on d −4, 0 and 4 to determine complete blood count. Data was analyzed using Proc GLM of SAS. ADG and BCS was not significantly different ($P = 0.05$) among treatment groups for the cows or calves. There was no difference ($P > 0.06$) in lymphocytes or neutrophils for calves pre-weaning (d −4) or post-weaning (d 4). Results from this study suggest that alternative weaning strategies did not result in an increase in performance of the calves compared to traditional weaning.

Key words: stress, weaning

W272 Whole herd enteric methane emission estimates in three contrasting dairy systems. S. Utsumi*[1], D. Beede[1], S. Zimmerman[2], and P. Zimmerman[2], *[1]Michigan State University, East Lansing, [2]C-Lock Technology Inc., Rapid City, SD.*

Effects of contrasting feeding systems (FS) on diurnal patterns of enteric methane (CH4) emissions per cow, footprint per unit of milk, and frequency of milking of a herd of Holstein cows (n = 61) managed with an automatic milking system (AMS) was quantified in this pilot study. Feeding systems were: pasture grazing (GRASS); total mixed ration (TMR); and, pasture grazing plus TMR (pTMR) lasting 17, 34, and 84 d, respectively. Voluntary milking with one single-stall AMS was applied at variable rates of 4 to 2 milkings/day based on days in milk and milk yield (MY). Cows received in addition to basal diets in the FS, 1 kg of concentrate per 4 kg of milk. The mass flux (MF) of eructed and expired CH_4 during individual milkings (n = 12,584) was estimated with the Greenfeed system (C-Lock Technology Inc., Rapid City, SD), using detected changes in CH_4 concentration, air flow and known amounts of gas tracer. Repeated measures analysis of hourly CH_4 fluxes and ANOVA and Pearson correlation of calculated daily CH_4 fluxes and milking variables were conducted ($P < 0.05$). Hourly CH_4 fluxes were affected by a significant FS by hour interaction likely influenced by differences in daily feed intake patterns among FS. Pasture grazing resulted in greater hourly CH_4 fluxes during night hours (2100 to 0500 h), whereas hourly CH_4 fluxes in pTMR and TMR increased immediately after the TMR feeding at 0500 h. Daily CH_4 fluxes did not differ among FS (average = 389 ± 15 g), but GRASS, pTMR and TMR differed in daily milking frequency (2.6, 2.9 and 3.0; SE = 0.1) and MY (22, 25 and 29 kg/cow per d; SE = 1.2). Differences in MY explained the diluted CH_4 footprint per unit of milk in TMR compared with GRASS (15 vs. 19 gCH_4/kg milk; SE = 1) and the intermediate footprint value for pTMR (17 ± 1 gCH_4/kg milk). No correlation between daily CH_4 fluxes and MY was detected in the 3 FS. However, significant negative correlations between milk yield and CH_4 emissions per unit of milk in GRASS (r = −0.67), pTMR (r = −0.72) and TMR (r = −0.79) highlight the importance of a high milk production as a common strategy to dilute CH_4 emissions among dairy systems.

Key words: methane, dairy systems, automatic milking

W273 Withdrawn

W274 Effect of feeding frequency and protein supplementation on methane production by Holstein cows. P. C. Aikman*, J. A. N. Mills, C. K. Reynolds, and L. A. Crompton, *School of Agriculture, Policy and Development, University of Reading, UK.*

Open-circuit calorimetry and IGER Behavior Recorders were used to measure methane production and eating behavior in 4 Holstein cows (259 ± 13 d in milk) receiving one of 4 treatments in a 4 × 4 Latin Square with 5 wk periods. The frequency of feeding and dietary CP concentration varied between treatments. Treatments consisted of an ad libitum fed TMR (37.5% corn silage, 12.5% grass silage, 50% concentrate; CP, OM, NDF and starch concentrations of 146, 937, 428 and 202 g/kg DM respectively) fed twice daily (CONT2), or the same TMR fed ad libitum with added protein (Amino Green, SCA Nutec, Thirsk, UK) to increase CP concentration (177 g/kg DM), fed once

(PS1), twice (PS2) or 4 times (PS4) daily. Data were analyzed using the Mixed procedure of SAS with period and treatment as fixed effects and cow as a random effect. Mean DMI (18.7 ± 0.45 kg/d), milk yield (27.8 ± 0.78 kg/d) and milk fat, protein and lactose concentrations were unaffected ($P > 0.167$) by treatment. Temporal distribution of eating behavior was affected ($P < 0.001$) by treatment (eating behavior occurring between 10.00 and 16.00 was 43.2, 65.5, 50.8, and 23.9% of 24 h total for CONT2, PS1, PS2 and PS4 respectively) but total time spent eating (mean 305 ± 26.5 min/d) was unaffected ($P = 0.798$). Although number of meals/d (mean 12.1 ± 1.2) did not differ ($P = 0.188$), meal length decreased ($P = 0.008$) as feeding frequency increased (27.9, 31.4, 24.3 and 20.2 min for CONT2, PS1, PS2 and PS4 respectively). Total methane production was lowest in PS1 and highest in PS4 (571, 524, 566 and 576 l/d for CONT2, PS1, PS2 and PS4 respectively, $P = 0.048$). Methane production tended ($P = 0.063$) to be lowest in PS1 and PS2 when expressed as MJ/MJ milk (0.256, 0.223, 0.227 and 0.231 for CONT2, PS1, PS2 and PS4 respectively) but there was no treatment effect ($P > 0.233$) when expressed as L/kg DMI (mean = 29.9 ± 1.1) or L/kg milk (mean 21.0 ± 1.0). Increasing dietary CP concentrations or increasing feeding frequency to encourage animals to distribute feed intake more evenly are not effective strategies to decrease methane yield (L/kg DMI) of lactating dairy cows.

Key words: protein supplementation, feeding frequency, methane

W276 Effect of Quebracho-chestnut tannin extracts at two forage levels on dairy cow lactation performance and emission of methane and ammonia. M. J. Aguerre*[1], M. C. Capozzolo[1], M. A. Wattiaux[1], and J. M. Powell[2], *[1]University of Wisconsin-Madison, Madison, [2]U.S. Dairy Forage Research Center, Madison, WI.*

Our objective was to determine the effects of a tannin mix on lactating cow performance and emission of methane (CH_4) and ammonia-nitrogen (NH_3-N), and whether any responses were affected by dietary forage to concentrate (F:C) ratio. Sixteen multiparous Holstein cows (626 ± 60 kg BW; 120 ± 28 DIM) were randomly assigned to one of 4 air-flow controlled chambers, constructed to fit 4 cows each. Chambers were assigned to dietary treatments sequences in 4 × 4 Latin square designs with 2x2 factorial arrangements of treatments. Dietary treatments, fed as total mixed rations, included the following F:C ratio: 47:53 and 61:39 (DM basis, alfalfa silage and corn silage in a 1:1 ratio) without or with 0.45% tannin (diet DM). Air samples entering and exiting each chamber were analyzed with a photo-acoustic gas monitor. There was no tannin by F:C ratio interaction for any of the measured variables. Overall, DMI (28.5 kg/d), milk fat yield (1.67 kg/d) and MUN (10.6 mg/dL) were not affected by tannin. However, relative to the control, inclusion of tannin reduced ($P < 0.05$) energy corrected milk yield (ECM; 44.6 vs.43.4 kg/d) and true protein yield (1.32 vs.1.28 kg/d). Increasing F:C ratio reduced ($P < 0.05$) DMI (29.5 vs. 27.5 kg/d), ECM (45.5 vs. 42.2 kg/d), milk true protein (1.37 vs. 1.23 kg/d) and fat yield (1.71 vs. 1.63 kg/d), but did not affect MUN. Emission of CH_4 was not affected by tannin (693 g/d), but increased from 15.1 to 17.1 g/kg ECM ($P = 0.03$) relative to control. Although tannin tended to decrease N intake (667 vs. 684, $P = 0.08$), it did not affect NH_3-N emission (28.1 g/d). Increasing the F:C ratio tended to increase CH_4 emission (672 vs. 714 g/d; $P < 0.08$), increased CH_4 per unit of ECM (15.5 vs. 16.7 g/kg, $P < 0.01$), decreased N intake (711 vs. 640 g/d, $P < 0.01$), but increased NH_3-N emission per unit of N intake (3.9 vs. 4.6 g/g, $P = 0.04$). In this study, adding tannin to the diet had negative effects on performance and increased CH_4 emission per unit of milk by 8%, regardless of the dietary content of forage. In addition, F:C ratio altered manure NH_3-N emission and CH_4 emission.

Key words: methane, ammonia, dairy

W277 Effect of fiber on greenhouse gas emissions from stored manure. Q. Huang[1], K. Perano*[2], M. Tenuta[1], C. M. Nyachoti[1], A. Strathe[2], and E. Kebreab[2], *[1]University of Manitoba, Winnipeg, MB, Canada, [2]University of California, Davis, Davis.*

Lagoons from livestock operations emit greenhouse gases (GHG), particularly methane (CH_4) and carbon dioxide (CO_2). Methane emissions result from anaerobic breakdown of volatile solids in livestock excreta during storage in the lagoon. The purpose of the study was to explore the effects of fiber content in the manure on the amount of GHG emitted from pig manure in an anaerobic digester. Pigs were fed 3 different diets (NDF = 12%, 16%, and 20%) to manipulate the amount of fiber in excreta. Manure from the treatments was collected and stored in anaerobic digesters in triplicate for 139 d. The solids concentration was adjusted weekly to keep it at 3%. Each week, 1 L of manure was added and 0.25 L taken out and analyzed for the solids concentration. The resulting increase in volume of the manure in the digester was 0.75 L/wk. The CH_4 and CO_2 emitted by the digesters were collected for each digester daily. A first order model was derived describing the concentration of volatile solids (S) as [dS/dt = (inflow*0.03*0.80 – outflow*S–k*S*V)/V], where k is the rate constant and V is volume. The Arrhenius relationship [CH_4 = k*S*exp(log(A)–E/R*T)] was used to model rate of formation of CH_4 over time. Here A is the Arrhenius constant and E, R and T represent the activation energy, gas constant and temperature, respectively. The parameters k and A were estimated from the time-series using generalized nonlinear least squares. The ANOVA analysis of k and log (A) showed no difference between the 3 treatments ($P = 0.63$). Cumulative emissions over 139 d showed a trend toward higher GHG production as NDF content increases, but it was not statistically significant ($P = 0.55$). Similarly, analysis based on CO_2-equivalent emissions did not show a difference between treatments ($P = 0.55$). Part of the reason for lack of detecting a difference between treatments was the high variation of observed emission values within a treatment. Increased replications per treatment are required to overcome within-treatment variation. Alternatively, GHG emissions from stored manure could mostly be a function of total carbon and may not depend on NDF levels.

Key words: methane, manure, fiber

W278 Evaluation of SF_6 emission for determination of methane in ruminants. A. C. Ruggieri*, N. C. Meister, I. P. Carvalho de Carvalho, N. L. Santos, V. Costa e Silva, F. de Oliveira Alari, and K. T. de Resende, *UNESP-Universidade Estadual Paulista, Jaboticabal, São Paulo, Brazil.*

One requirement of using the technique of inert traced gas sulfur hexafluoride (SF_6) to measure the emission of methane is the determination of emission rate or permeation of gas through the membrane. The aim of this study was to evaluate 2 different thicknesses of membrane permeation (Teflon), and the influence of the use of the washer. We used a factorial (2x3), with 2 thicknesses of film (0.2mm and 0.3mm) and 3 type of assemble: 1- with washer 5mm bore hole (i.d.); 2- with washer 2.5mm bore hole (i.d.); 3- without washer, totalizing 6 treatments with

10 replication each. The capsules were made of brass with the following measures outside diameter (o.d.) 11.1 mm (7 / 16 inch) and 4.76 mm bore role (i.d.), with nut length (Swagelok), were charged with approximately 500mg of SF_6. Compact stick (nylon 6.6) was used to make a washer with 0.8 mm thick. The following capsules were kept at 39°C in the laboratory. They were weighed weekly for 8 consecutive weeks and discarding the first to review the weighing according to the methodology for methane emission from rumen adapted to Brazil. The experimental data were analyzed by SAS statistical software. Analyses of variance were performed using PROC MIXED with repeated measures. The averages of the treatment were compared by Tukey test at 5% probability. The use of film 3 mm resulted in lower emissions ($P < 0.05$) of SF_6 over 2 mm. The emission of SF_6 capsules with or without washer did not different ($P > 0.05$), and they were higher when compared with the capsules inside area with washer lower in 2 thicknesses of film. However the use of the capsules was higher when the washer was used, whereas use of a capsule with emission from 500 to 2000 ng/min.

Key words: membrane permeation, size washer, emission rate

W279 Effect of dietary protein level on ammonia and greenhouse gas emissions from dairy manure. C. Lee*[1], A. N. Hristov[1], C. J. Dell[2], G. W. Feyereisen[3], J. Kaye[1], and D. Beegle[1], *[1]Pennsylvania State University, University Park, [2]USDA-ARS-PSWMRU, University Park, PA, [3]USDA-ARS-SWMRU, St. Paul, MN.*

Experiments were conducted to investigate the effect of dietary crude protein (CP) concentration on ammonia (NH_3) and greenhouse gas (GHG; CH_4, N_2O, and CO_2) emissions from dairy manure in simulated storage (Exp. 1) and from manure-amended soil in lysimeters (Exp. 2). Twenty 4 lactating Holstein cows were grouped and offered randomly one of the following diets: 16.3% CP (HighCP), or 13.5% CP (LowCP). Feces and urine were separately collected from each cow and manure was prepared by mixing feces and urine in a 1.7:1 ratio. Total N concentration and the proportion of ammonium– and urea–N in total N were greater ($P < 0.001$) for HighCP manure compared with LowCP manure (4.4 vs. 2.8% and 51.6 vs. 30.8%, respectively). In Exp. 1, manure was incubated in laboratory conditions for 122 h. The cumulative NH_3 emission from LowCP manure was lower (by 47%, $P < 0.001$) compared with HighCP manure. The emission rates and cumulative emissions of GHG were not affected by type of manure. In Exp. 2, manure was applied to lysimeters (61 × 61 × 61cm; Hagerstown silt loam; fine, mixed, mesic Typic Hapludalf) at 9.5 and 9.1 g N and 1,653 and 2,356 g fresh manure per lysimeter (HighCP and LowCP, respectively). The emission rate of NH_3 was 49% greater (1.53 vs. 1.03 mg/m^2 per min; $P < 0.001$) for HighCP than for LowCP manure. In contrary, the emission rates of CH_4 and CO_2 were greater ($P < 0.001$ and 0.01, respectively) for LowCP compared with HighCP manure, which was explained by the increased manure application rate with LowCP (to achieve similar N application rate). Emissions of N_2O were not affected by treatment. In conclusion, LowCP manure significantly decreased NH_3 emission in simulated storage conditions and from manure-amended soil and increased, due to greater application rate, CH_4 and CO_2 emissions from manure-amended soil compared with HighCP manure.

Key words: dietary protein, gas emission, dairy manure

W280 Use of an activity monitoring system as part of the Cal Poly dairy breeding protocol. T. Nutcher* and S. Henderson, *Department of Dairy Science, California Polytechnic State University, San Luis Obispo.*

Dairy herd reproductive efficiencies have dropped in the past 40 years. Increased milk production, and genetic pull toward more milk production, has led to reproductive rates declining. An advanced breeding program is needed to become more efficient in this area and many options exist such as synchronization programs, pedometers, and other electronic detection aids. The objective of this study was to determine the effectiveness of an activity monitoring system, Heatime by MICRO Dairy Logic, as an integral part of the Cal Poly Dairy breeding protocol. Once installed, the program was kept up to date with the herd, including: pen moves, fresh events, bred events, dry-off events, and collar movements. This was done at least 4 times per week to ensure current information. Pregnancy checks were done every other week to obtain results of previous bred events and were then entered into the system. Pregnancy rates derived by this data were compared with the previous history of the herd. The results of this study yielded a well functioning breeding program. The system continuously monitored activity, stored records, and generated user defined reports with activity and rumination graphs. The system used this data to flag cows to be bred, checked for sickness, or pregnancy checked. Concerns arose with the system being abandoned once the Senior Project was complete. These have been resolved as seen by the breeders and herdsmen having adapted to the new technology smoothly, and using it as an integral part of their management protocol. The system has been established and in use for 5 mo. The pregnancy rates before the system averaged 14.3% compared with the system at 22.5%, which increased the pregnancy rate to a combined 15.3% (12/26/09 – 11/06/10). In conclusion, the Heatime system has shown to be an effective addition to the Cal Poly breeding program; however, further observation is needed to determine effectiveness and consistency over the long-term.

Key words: activity, rumination, estrus

W281 Seasonal and diel changes of air emissions from cross-ventilated dairy freestall barns in Midwestern United States. F. Y. Ayadi*[1], E. L. Cortus[1], L. D. Jacobsen[2], B. P. Hetchler[2], and A. J. Heber[3], *[1]South Dakota State University, Brookings, [2]University of Minnesota, St. Paul, [3]Purdue University, West Lafayette, IN.*

A design feature of the National Air Emissions Monitoring Study was to investigate climate and facility management influence on gaseous and particulate matter (PM) emissions. One monitored site consisted of 2 mechanically cross-ventilated freestall dairy barns in Wisconsin with capacities of approx. 275 and 375 cows. In yr 1, pens were flushed 3 times daily with recycled lagoon effluent; in yr 2, barn floors were scraped with a tractor. The objective of this analysis was to determine variations in ammonia (NH_3), hydrogen sulfide (H_2S), carbon dioxide (CO_2), and PM_{10} attributed to season and time of day over a 2-yr period. Because change in manure removal method had a significant effect on emissions, season and time of day effects were evaluated separately for each yr. Seasons were defined as spring (March–May), summer (June–Aug), fall (Sept-Nov), and winter (Dec-Feb). Time of day influence was evaluated using averages from day (9 a.m.-4 p.m.) and night (10 p.m.-5 a.m.) periods. Yearly ave. values for NH_3 emission were 3.4 g/m^2/d (SE = 0.01) and ranged between 3.5 and 4.4 g/m^2/d during day and 2.8–3.4 g/m^2/d during night. All NH_3 emissions were significantly lower at night ($P < 0.05$). Mean H_2S emission (646 mg/m^2/d, SE = 8.3) during yr 1 was significantly higher than during yr 2 (37.4 mg/m^2/d, SE = 0.5) and showed only minor variations related to season. However, in yr 2, H_2S emissions showed significant differ-

ences based on season; H_2S emissions were highest in summer (63.2 mg/m^2/d, SE = 1.1) and lowest in winter (16.7 mg/m^2/d, SE = 0.2). Differences between years for H_2S were most likely related to the different manure removal systems; a time of day effect on H_2S emissions was not evident. Conversely, PM_{10} emission was significantly lower in yr 1 (121 mg/m^2/d, SE = 3.3) than in yr 2 (187 mg/m^2/d, SE = 3.7 mg/m^2/d) and was significantly higher during the day, most likely as a result of different scraping systems. Emission rates for CO_2 varied due to season and were highest in the winter (1.5–2.1 kg/m^2/d, SE = 0.01). This study demonstrated that season influenced H_2S, and PM_{10} emissions and time of day affected NH_3 and PM_{10} emission.

Key words: manure, cross-ventilated barn, emission

Ruminant Nutrition: Beef Cattle

W282 Effect of oat maturity and variety on yield and nutritive value for grazing cattle. M. L. Drewery*[1], L. A. Redmon[2], and T. A. Wickersham[1], *[1]Texas A&M University, College Station, [2]Texas AgriLife Extension, College Station.*

Oats (*Avena sativa*) often provide earlier grazing, later maturity, and greater forage production during warm weather than wheat or rye, but are often more sensitive to cold stress. Therefore, in warmer climates, oats are often used as a forage resource. However, data are limited on production and nutritive value for many oat varieties when used as a forage source. Accordingly, the objective of this study was to determine the yield and nutritive value of 4 oat varieties (TAMO 405, Harrison, BOB, and Exp 1) at 6 maturities. A prepared seedbed was divided into 4 blocks with each variety randomly assigned to a plot within each block. Plots were established on Oct 20, 2009 in Burleson County, Texas, and were provided with 167 kg/ha of 16–20–0 fertilizer at planting and top dressed with 43 kg N/ha (N-32) on Feb 18, 2010. Samples were clipped from each plot using 0.09 m^2 square on Dec 10, Jan 11, Feb 15, Mar 11, Apr 14, and May 10. All samples were dried at 60°C for 72h, ground to pass a 1-mm screen and subsequently analyzed for OM, N, and NDF. In vitro true digestibility (IVTD) was determined on all samples, except those collected in Dec. Statistical analysis was completed using SAS with variety and maturity in the model and using block as the random term. Maturity linearly ($P < 0.01$) increased DM production while CP content linearly ($P < 0.01$) decreased from 27% in Dec to 8% in May. The largest decrease in CP, from Mar to Apr, corresponded with the greatest increases in DM yield. Nitrogen yield (kg N/ha) increased quadratically ($P < 0.01$), with a plateau occurring at the Mar sampling. Through the Feb sample, NDF content was <29%, then increased rapidly to above 57% for samples collected in Apr and May. Samples collected in Jan and Feb had IVTD above 93%, then linearly decreased ($P < 0.01$) with advancing maturity to <59% in May. There was a tendency ($P = 0.07$) for variety to effect IVTD. Digestible DM kg/ha increased linearly ($P < 0.01$) with advancing maturity from <660 kg in Jan to 2,481 kg in May. Variety did not significantly affect yield or nutritive value. Maturity was the primary driver of forage production, which increased with advancing maturity, while nutritive value declined.

Key words: grazing, oats

W283 Replacing grain and silage with wheat distiller grains: effects on feed intake, daily gain, carcass characteristics, and blood metabolites in finishing beef cattle. W. Z. Yang*[1], T. A. McAllister[1], J. J. McKinnon[2], and K. A. Beauchemin[1], *[1]Agriculture and Agri-Food Canada, Research Centre, Lethbridge, AB, Canada, [2]Department of Animal & Poultry Science, University of Saskatchewan, Saskatoon, SK, Canada.*

A study was conducted to evaluate DMI, daily gain, carcass quality and blood metabolites in feedlot beef steers fed diets that varied in proportion of wheat dried distillers grains with solubles (DDGS) with DDGS replacing barley grain or silage. Two hundred crossbred steers (489 ± 30 kg) were blocked by weight and randomly allotted to 20 pens (5 pens per treatment). Steers were fed one of 4 diets: control, low (25DDGS), medium (30DDGS), and high (35DDGS) wheat DDGS (DM basis). The control diet consisted of 15% barley silage and 85% barley concentrate; the 3 DDGS diets were formulated by substituting 20% barley grain and 5, 10 and 15% silage, respectively, with 25, 30 and 35% wheat DDGS so that the 35DDGS diet contained no silage. Steers were weighed at the start and end and every 21 d during the experiment. In comparing with the control, DMI (10.9 vs. 11.6 kg/d) of calves fed 25DDGS was greater ($P < 0.01$), but final BW tended ($P < 0.06$) to be lower (635 vs. 621 kg), so they were less efficient (130 vs. 113 g gain/kg DMI; $P < 0.01$). With substitution of DDGS for silage, DMI linearly ($P < 0.01$) decreased from 11.6 to 10.7 kg/d without changing final BW or ADG, consequently, feed efficiency linearly ($P < 0.02$) improved from 113 to 128 g/kg DMI. Overall, carcass characteristics were not different among the 4 diets. Plasma glucose averaged 1.0 g/L and was not affected by diet, whereas plasma urea N was doubled from control (95 mg/L) with DDGS diets (195 mg/L). Results indicate that partially replacing barley grain and silage with wheat DDGS in high-grain diets reduces growth and feed efficiency. However, further substitution of wheat DDGS for silage such that the diets contained minimal or no silage did not adversely impact cattle growth or feed efficiency.

Key words: feedlot beef cattle, growth performance, wheat DDGS

W284 Effects of restricted versus conventional dietary adaptation over periods of 14 and 21 days on feedlot performance and carcass characteristics of Nellore cattle. D. D. Millen*[2,3], F. S. Parra[1], J. R. Ronchesel[1], M. D. B. Arrigoni[1], C. L. Martins[1], R. S. Barducci[1], L. M. N. Sarti[1], R. D. L. Pacheco[1], L. C. Vieira Júnior[1], M. C. S. Franzói[1], R. Espigolan[1], J. M. P. Silva[1], M. F. Val[1], F. P. Luiz[1], E. A. Chacon Filho[1], *[1]São Paulo State University (UNESP), Botucatu, São Paulo, Brazil, [2]São Paulo State University (UNESP), Dracena, São Paulo, Brazil, [3]Supported by FAPESP, São Paulo, São Paulo, Brazil.*

This study, conducted at the São Paulo State University feedlot, Botucatu Campus, Brazil, was designed to determine effects of restricting intake of the final finishing diet (REST) as a means of dietary adaptation compared with diets increasing in concentrate (STEPUP) over periods of 14-d and 21-d on overall feedlot performance and carcass characteristics. The experiment was designed as a completely randomized block with a 2 × 2 factorial arrangement, replicated 6 times (5 bullocks/pen), in which 120 18-mo-old yearling Nellore bulls (372.2 ± 21.5 kg) were fed in 24 pens for 84-d according to the treatments: STEPUP for 14-d, STEPUP for 21-d, REST for 14-d, and REST for 21-d. The STEPUP program consisted of ad libitum feeding of 3 adaptation diets over periods of 14-d or 21-d with concentrate level increasing from 55% to 85% of diet DM. The REST program consisted of restricted intake of the final diet (85% concentrate) with programmed increases in feed offered until yearling bulls reached ad libitum access over periods of 14-d or 21-d. No significant ($P > 0.10$) protocols and days main effects were observed for any of the feedlot performance parameters analyzed: final BW, ADG in kg (STEPUP = 1.554, REST = 1.545; 14-d = 1.556, 21-d = 1.539), G:F ratio (STEPUP = 0.147, REST = 0.149; 14-d = 0.148, 21-d = 0.148) and DMI in kg, however a interaction was found ($P < 0.05$) for DMI in % of BW. Animals in STEPUP for 21-d treatment presented greater DMI (% of BW) than yearling bulls in REST for 21-d (2.43% vs. 2.34%). With respect to carcass characteristics, no significant ($P > 0.10$) protocols and days main effects were observed for LM area, 12th rib fat thickness and kidney-pelvic fat, however, yearling bulls in treatments that lasted 14-d presented heavier ($P < 0.05$) HCW (285.61 kg vs. 278.72 kg) and increased ($P < 0.05$) dressing percentage (56.76% vs. 56.13%) when compared with animals allocated in protocols that lasted 21-d. The adaptation in 14-d did not negatively affect feedlot performance of

Nellore cattle and improved HCW and dressing percentage regardless of adaptation protocol.

Key words: adaptation, feedlot, Nellore

W285 Effect of three diets on carcass quantitative traits in cattle Nellore and crossbreed F1 Nellore × Brahman. I. S. Silva*, F. A. Barbosa, S. L. S. Cabral Filho, R. A. Mandarino, and P. C. A. C. Alves, *Faculty of Agronomy and Veterinary Medicine, University of Brasília-UnB, Brasília/DF, Brazil.*

The experiment evaluates the characteristics of carcass in fattening cattle, divided into 2 genetic groups and submitted to 3 diets in a feedlot. The herd was composed of 42 bulls with an average age of 23 mo, 21 were Nellore (NEL) and 21 crossbreed Nellore x Brahman (NBR). Each genetic group was divided and allotted to 3 diets, with 7 animals each. The experimental groups were: SIL-corn silage and concentrate (corn grain, soybean meal, soybean hulls, urea and mineral supplement) at a ratio of 25:75 in dry matter, PEL-exclusive pellets diet; GRN-whole grain corn and pellets diet. The experiment was conducted in a 2x3 factorial, completely randomized design. After slaughter, were evaluated at the half carcass the rib-eye area (REA) and the subcutaneous fat thickness (SFT), and the body composition (muscle, bone and fat) of the section HH (between the 9th and 11th rib). There was no difference to the SFT in comparison of genetics or diets ($P > 0.05$). The REA was similar for the different diets, but differ among the genetic groups ($P < 0.05$), with values 69.25 and 77.15 cm^2 for NEL and NBR. The percentage of bone was not different for diets or genetic groups. The percentage of muscle was similar to the genetic groups but was different for the diets. On the diet PEL the proportion of muscle was higher than in SIL and GRN, 60.43, 55.25 and 57.03%, respectively ($P < 0.05$). The percentage of fat was different for both genetic groups and diets ($P < 0.05$). The NEL was 17.48% while NBR obtained 14.72%. The SIL diet had a high proportion of fat (19.60%), compared with the diets PEL and GRN, 12.98 and 15.96% respectively ($P < 0.05$). The genetic groups did not influence the SFT, or the percentage of bone and muscle in the section HH. The diets did not affect REA, SFT and the percentage of bone in section HH. The REA was higher in NBR in comparison with the NEL. The percentage of fat in the HH section was higher for the NEL compared with NBR. The results indicate that PEL showed a higher percentage of muscle in the HH section between diets, while the SIL and NEL had a greater percentage of fat.

Key words: beef cattle, feedlot, genetic group

W286 Effects of supplementing an exogenous proteolytic enzyme on growth performance in finishing beef steers. J. M. Vera*[1], C. T. Noviandi[1], A.-H. Smith[2], D. R. ZoBell[1], and J.-S. Eun[1], *[1]Department of Animal, Dairy, and Veterinary Sciences, Utah State University, Logan, [2]Danisco USA, Inc., Waukesha, WI.*

An exogenous proteolytic enzyme (EPE) has been previously found to increase in vitro NDF degradability of dried distillers grains with solubles (DDGS). To further investigate the effects of supplementing EPE, 48 Angus crossbred finishing beef steers (473 ± 37.3 kg BW) were used to assess the growth performance when fed a DDGS-based TMR without (control) or with an EPE supplementation in a completely randomized design. The finishing TMR consisted of 5% alfalfa hay, 20% corn silage, 40% barley grain, 30% DDGS, and 5% feedlot supplement (DM basis). The EPE contained 38,622 U/g protease activity with negligible fibrolytic activities. The EPE was diluted with warm water and added at a rate of 0.52 g/kg DM TMR. Four animals were placed in each pen, and 6 pens allocated to each treatment (n = 6). Prior to starting the trial, all steers were adapted to the TMR for a 3-wk period. Feed was offered for ad libitum consumption once daily at 0800 h with free access to water. Feed intake was measured weekly, and individual BW of steers was recorded on 2 consecutive d at the beginning of trial and wk 4, 8, and 12. The experiment lasted 84 d, and data were analyzed using the MIXED procedure of SAS. There were no differences ($P > 0.15$) on BW gain (123 vs. 131 kg) and G:F ratio (0.141 vs. 0.148) between control and EPE treatment, respectively. Intake of DM (12.8 vs. 13.3 kg/d, $P = 0.13$) and ADG (1.75 vs. 1.96 kg/d, $P = 0.11$) tended to increase with EPE supplementation. The positive effects of supplementing EPE on DMI and ADG may have resulted from beneficial modification of ruminal fermentation by EPE. Further investigation is needed to understand if supplementing EPE influences ruminal metabolism of finishing beef steers fed DDGS at relatively high inclusion rate.

Key words: exogenous proteolytic enzyme, finishing beef steers, growth performance

W287 Effects of supplementing an exogenous proteolytic enzyme in beef finishing diets on ruminal fermentation in continuous cultures. J. M. Vera[1], T. Astuti[2], A.-H. Smith[3], D. R. ZoBell[1], and J.-S. Eun*[1], *[1]Department of Animal, Dairy, and Veterinary Sciences, Utah State University, Logan, [2]Faculty of Animal Science, Andalas University, Padang, West Sumatra, Indonesia, [3]Danisco USA, Inc., Waukesha, WI.*

We investigated whether supplementing an exogenous proteolytic enzyme (EPE) would be beneficial on in vitro ruminal fermentation characteristics when supplemented in beef finishing diets without or with dried distillers grains with solubles (DDGS). The finishing TMR consisted of 70% barley grain without DDGS (BT) or 40% barley grain and 30% DDGS (DT) on DM basis. A dual-flow continuous culture system consisting of 4 fermentors was used in a 4 × 4 Latin square designed study with dietary treatment arranged as a 2 × 2 factorial. The 4 treatments were: 1) BT without EPE; 2) BT with EPE; 3) DT without EPE; and 4) DT with EPE. Filtered ruminal contents were allowed 6 d of adaptation to the treatments followed by 3 d of data collection. The EPE contained 38,622 U/g protease activity with negligible fibrolytic activities. The EPE was diluted with warm water and added at a rate of 0.52 g/kg DM TMR. Feeding BT decreased culture pH compared with DT (6.01 vs. 5.82; $P < 0.01$), but supplementing EPE had no effect on culture pH regardless of TMR. Total VFA concentration increased by feeding DT ($P = 0.03$), but EPE supplementation had no effect on the total VFA concentration. While feeding DT increased ($P = 0.03$) or tended to increase ($P = 0.07$) acetate or propionate concentration, respectively, EPE supplementation tended to increase ($P = 0.11$) propionate concentration regardless of TMR. Methane production tended to increase ($P = 0.10$) by feeding DT compared with BT, whereas EPE supplementation increased methane production in BT, but not in DT, resulting in a TMR × EPE interaction ($P = 0.04$). The increased propionate concentration due to EPE supplementation in beef finishing diets may affect growth performance of finishing steers by providing more glucogenic precursor.

Key words: exogenous proteolytic enzyme, ruminal fermentation, continuous cultures

W288 Fecal and urinary excretion of N, P and S with increasing feeding wheat distillers dried grains with solubles (DDGS) in finishing beef heifers. Y. L. Li[1,2], C. Li*[1,3], W. Z. Yang[1], T. A. McAllister[1], and K. A. Beauchemin[1], *[1]Agriculture and Agri-Food Canada, Research Centre, Lethbridge, AB, Canada, [2]Feed Research Institute, Chinese Academy of Agricultural Sciences, Beijing, China, [3]College of Animal Science, Inner Mongolia Agricultural University, Hohhot, Inner Mongolia, China.*

A study was conducted to determine the fecal and urinary excretion of N, P and S with increasing inclusion of wheat DDGS in finishing diet fed to growing beef heifers. Eight ruminally fistulated Angus heifers were assigned to a replicated 4 × 4 Latin square design with treatments: control, low (25%), medium (30%) and high (35%) DDGS. The diets consisted of barley silage, barley concentrate, and wheat DDGS in ratios of 15:85:0, 10:65:25, 5:65:30 and 0:65:35 (DM basis), respectively. Heifers were fed for ad libitum intake. Total collection of feces and urine were conducted for 5 d in each period. Intakes of N were higher ($P < 0.01$) for the DDGS diets (averaged 327 g/d) than for the control (186 g/d). Consequently, total excretion of N was greater ($P < 0.01$) for DDGS (264 g/d) than for control (164 g/d), which were primarily excreted through urine (control vs. DDGS; 104 vs. 185 g/d) and less in feces (control vs. DDGS; 60 vs. 79 g/d). Intake of P quadratically increased ($P < 0.01$) with increasing DDGS in the diets (38, 49, 49 and 43 g/d for control, low, medium and high DDGS, respectively) without affecting P retention. Fecal P excretion quadratically changed (24, 30, 29 and 23 g/d; $P < 0.05$), whereas urinary P linearly increased (3, 10, 11 and 14 g/d; $P < 0.01$) with increasing DDGS from 0 to 35% in the diets. Feeding DDGS diets increased ($P < 0.01$) S intake (control vs. DDGS; 17 vs. 42 g/d), whereas S retention was not affected (2 g/d) by diets. Increased S consumption proportionally increased urinary S excretion (53 to 80% intake) but reduced fecal S excretion (38 to 22% S intake). Results indicate that inclusion 25 to 35% wheat DDGS in finishing diets substantially increased the intakes of N and S, which were then primarily excreted through urine. Influence on intake and excretion of P were relatively small by feeding DDGS.

Key words: wheat DDGS, balance of N, P and S, beef cattle

W289 Effect of Optaflexx when fed as a topdress on performance and carcass traits of finishing steers. G. J. Vogel*, R. L. Botts, J. W. Homm, N. A. Pyatt, and G. D. Hufstedler, *Elanco Animal Health, Greenfield, IN.*

Two-thousand nine hundred forty-nine steers (581 kg) were allotted to 32 pens in a randomized complete block design of 4 treatments with 8 replications to evaluate the effects of differing methods of Optaflexx administration on growth performance. Experimental treatments included: 1) Non-medicated control (Cont); 2) Optaflexx fed continuously (200-C); 3) Optaflexx fed once daily in 0.45 kg topdress pellet (200-P); and 4) Optaflexx fed once daily in 1.8 kg of finisher ration as a topdress (200-FR). Optaflexx was fed at 200 mg hd^{-1} d^{-1} during the final 28 d before slaughter. All cattle were fed their respective basal diets twice daily at 0700 and 1300 h. The basal ration contained Rumensin at 36.7 mg/kg and Tylan at 11.2 mg/kg of the diet DM. Cattle in treatments 200-P and 200-FR were fed their respective medicated topdress, containing the entire daily dose of Optaflexx approximately 30 m after the am feeding. Data were analyzed using a mixed model with treatments fixed and blocks random. Feeding Optaflexx as a topdress resulted in similar live performance ($P > 0.21$) and carcass traits ($P > 0.22$) when compared with feeding Optaflexx continuously. Compared with control, Optaflexx increased ($P < 0.01$) daily gain 0.22 kg/d, live weight gain 6.1 kg/hd, and carcass weight 6.0 kg/hd and improved ($P < 0.01$) feed to gain 12.2%. These data indicate that feeding Optaflexx in a topdress feed once daily is equivalent to feeding Optaflexx continuously in the ration. Feeding Optaflexx increased daily gain, improved feed efficiency and increased carcass weight.

Table 1. Effect of Optaflexx fed as a topdress

	Treatments					
Item	Cont	200-C	200-P	200-FR	SEM	*P*-value
Final BW, kg	623.8[a]	630.5[b]	630.9[b]	628.4[b]	1.2	< 0.01

W290 Effects of crude glycerin on in vitro gas production dry matter disappearance, VFA profiles, and composition of fermentative gasses. E. H. C. B. van Cleef*[2], S. Uwituze[1], and J. S. Drouillard[1], *[1]Kansas State University, Manhattan, [2]São Paulo State University, Jaboticabal, São Paulo, Brazil.*

Two studies were conducted to evaluate effects of glycerin on in vitro fermentation parameters and substrate DM disappearance. Ruminal fluid was collected from 4 fistulated steers fed finishing diets (90% concentrate) of rolled corn, 35% wet corn gluten feed, 20% soybean hulls, 4% supplement, 0 or 15% crude glycerin (2 steers/level), and the balance as dry-rolled corn. Buffered ruminal fluid (150 mL) was placed into 250-mL flasks equipped with pressure monitors. Substrates were added at 1.5 g DM/flask, and consisted of the same ingredient mixture fed to donor steers. The study was arranged as a 2 × 2 factorial, with factor 1 being the diet to which steers were adapted, and factor 2 being type of substrate added to cultures. Gas production, VFA profiles, and composition of head-space gas from each flask were determined after 24 h of incubation, and repeated for 2 d. Data were analyzed using the Mixed procedure of SAS. Study 2 used the same treatments, but measured DM disappearance of substrates using 50-mL in vitro tubes containing 30 mL buffered ruminal fluid and 0.5 g substrate. In study 1, there was an interaction between substrate and diet of the donor steers ($P \leq 0.01$). Differences in gas production for substrates with and without glycerin were negligible when added to cultures containing ruminal fluid from unadapted animals, but were greater for substrate with 15 compared with substrate with 0% glycerin for cultures containing ruminal fluid from steers adapted to glycerin. Prior adaptation of steers to glycerin resulted in greater methane production ($P \leq 0.01$). Adding glycerin as substrate ($P \leq 0.01$), but not as a component of donor diets ($P \geq 0.10$), increased propionate, butyrate, isobutryate, valerate, and isovalerate. In experiment 2, there was a tendency for interacation between substrate and donor steer diet ($P = 0.06$). Glycerin used in conjunction with ruminal fluid from unadapted

animals depressed digestion, but increased it when added to ruminal fluid from adapted animals. These studies suggest that prior microbial adaptation is needed to optimize fermentation of crude glycerin.

Key words: fermentation, glycerin, methane

W291 Effects of ginger root (*Zingiber officinale*) on blood oxidative stability of beef cattle. M. J. Liu*, Z. B. Yang, and W. R. Yang, *Shandong Agricultural University, Shandong, Taian, China.*

Four Lu-xi beef cattle (BW = 420 ± 20 kg) were used to evaluate the effects of different levels of ginger root (*Zingiber officinale*) on serum oxidative stability. The beef cattle were randomly allocated into individual pens and assigned to a 4 × 4 Latin square with the following feeding diets: 1) basal diet (Control), 2) Control diet + 0.5 g/kg ginger powders, 3) Control diet + 1.0 g/kg ginger powders, 4) Control diet + 1.5 g/kg ginger powders. The basal diet was formulated to meet nutrient requirement of NRC (2001). Twenty-milliliter blood samples were obtained from each cattle via jugular vein on d 1, 7 , 14, and 21, subsequently centrifuged at 3,000 r/min for 5 min, and the serum was stored in 1.5 mL Eppendorf tubes at −20°C and analyzed with Assay Kits made by Nanjing Jiancheng. The results showed that supplementation of ginger powder did not affect ($P > 0.05$) total superoxide dismutase (T-SOD) activity on d 1, but reduced ($P < 0.05$) activity on d 7 by addition of 0.5 g/kg ginger powder. Addition of ginger powder at the level up to 1.5 g/kg increased ($P < 0.05$) serum T-SOD activity. Glutathione peroxidase (GSH-Px) activity was significantly decreased ($P < 0.05$) by 0.5 g/kg ginger powder on d 7. Regardless of addition rate, ginger root reduced ($P < 0.05$) MDA content in the serum. Supplemented with ginger powders were not significantly affected ($P > 0.05$) total antioxidant capacities (T-AOC) among treatments ($P > 0.05$). Adding ginger can decline the oxidative stability in serum of beef cattle.

Key words: ginger, oxidative stability, beef cattle

W292 Oro-sensorial preferences for mixtures of protein and energetic ingredients in weaned calves. C. Montoro*[1], I. Ipharraguerre[2], and A. Bach[1,3], *[1]Ruminant Production, IRTA, Caldes de Montbui, Barcelona, Spain, [2]Lucta S.A., Montornés del Vallés, Barcelona, Spain, [3]ICREA, Barcelona, Spain.*

In previous studies with weaned calves, it was determined that soybean meal (SBM) and wheat were the preferred ingredients among 6 protein and 8 energetic ingredients, respectively. On contrary, corn gluten meal (CGM) and corn gluten feed (CGF) were the least desired. The objective of this study was to determine whether these oro-sensorial preferences remain the same when ingredients are part of a mixture. A total of 6 assays involving 60 calves (62 ± 1.3 d of age) were conducted to rank calf oro-sensorial preferences for 4 mixtures at 50%: SBM-CGF, SBM-Wheat, CGM-CGF and CGM-Wheat. To minimize potential interferences with feed texture, all ingredients were ground at 3 mm. In each assay, 20 naive calves were offered a choice ad libitum of 2 mixtures and feed consumption was recorded during 6 h. Each group of calves was used in 2 different assays, which were conducted 3 and 5 d after weaning. No calf was presented twice with the same mixture. Oro-sensorial preference was calculated as a percentage of total feed consumption ((consumption of one mixture / total consumption) x100). Preference data were subjected to one-sample comparison *t*-test using 50% as a reference value (i.e., lack of preference). The most preferred mixture was SBM-Wheat. It was preferred in all assays (Table 1). The CGF-CGM mixture was the least preferred in all assays. No differences were observed between SBM-CGF and CGM-Wheat mixtures. Results indicate that SBM and wheat are still preferred when offered as a part of a mixture. For this reason SBM and wheat could be used to improve starter acceptability by calves. On the other hand, CGF and CGM should be avoided when attempting to improve palatability of starters for calves.

Table 1. Oro-sensorial preferences of weaned calves for different mixtures (50:50%)

Mixture A	Mixture B	Oro-sensorial preferences (%)[1]	SE	*P*-values[2]
SBM-Wheat	CGM-CGF	95.7	2.66	<0.001
SBM-Wheat	CGM-Wheat	83.1	11.37	<0.001
SBM-Wheat	SBM-CGF	80.2	11.42	<0.001
SBM-CGF	CGM-CGF	81.5	5.82	<0.001
SBM-CGF	CGM-Wheat	58.6	11.34	0.130
CGM-Wheat	CGM-CGF	81.8	8.1	<0.001

[1]Percentage of consumption (Mixture A / (Mixture A + Mixture B)) x 100.

[2]Tests whether the relative consumption of mixture A differs from 50%.

W293 Evaluation of cotton ginning by-product value added feed as a supplement for grazing beef cattle. J. D. Rivera*, L. W. Fitzgerald, M. L. Gipson, K. L. Odom, and R. G. Gipson, *South MS Branch Experiment Station, Poplarville, MS.*

A cotton ginning by-product (CPM) was evaluated as a supplemental feedstuff for beef cattle (n = 52, BW = 321 kg ± 15.1 kg) grazing dormant warm-season mixed grass pastures during a 70 d period in 2010. The CPM product was packaged as a 226 kg bale and is a mixture of cotton-gin trash, added protein, molasses and a complete mineral package. These bales are designed to be a self fed complete feed for pasture cattle. In this study, CPM was compared with a limit fed diet (DIET) of soybean hull pellets, dried distillers grains with solubles and a mineral package in a randomized complete design using pasture as the experimental unit. There were 4 pastures per treatment and each pasture was approximately 2.83 ha in area and consisted of dormant warm-season grass mix: bahiagrass (*Paspalum notatum*), bermudagrass (*Cynodon dactylon*), and crabgrass (*Digitaria sanguinalis*), all clipped to uniform height, and were stocked with either 6 or 7 head of predominantly English crossbred steers. Treatments were CPM fed ad libitum and DIET limit fed at the rate of 1.5% of BW and was formulated to be similar in nutrient profile to the CPM bale. At the initiation of the study, cattle were stratified by BW and assigned to pastures, and pastures were randomly allotted to treatment. Data were analyzed with PROC GLM of SAS. Pasture was the experimental unit, and means were separated using the PDFIF option. Cattle fed CPM had greater feed intake compared with cattle limit fed DIET (6.49 kg vs. 4.69 kg, respectively, $P < 0.10$). Nonetheless, cattle fed DIET had greater ADG ($P < 0.05$) compared with cattle fed CPM (0.76 kg vs 0.60 kg, respectively, $P < 0.05$). Additionally, cattle fed DIET had more efficient supplement only feed conversion ($P < 0.05$). Nonetheless, due to the by-product nature of CPM it was less expensive resulting in a cost of gain ($P > 0.10$) that was not different compared with DIET. Results of the study indicated that limit feeding a mixed ration yielded greater daily gain and efficiency, however, did not result in a greater cost of gain in cattle grazing dormant warm-season pastures.

Key words: beef cattle, supplements, pasture

W294 Influence of addition of tannins-extract in low concentration of dietary dry matter on feedlot-performance of bulls. R. Barajas*[1], B. J. Cervantes[2], A. Camacho[1], M. Verdugo[1], M. A. Espino[1], L. R. Flores[1], J. A. Romo[1], E. A. Velazquez[1], and J. J. Lomeli[1], *[1]FMVZ-Universidad Autonóma de Sinaloa, Culiacán, Sinaloa, México, [2]Ganadera Los Migueles S.A. de C.V., Culiacán, Sinaloa, México.*

A 226-d experiment was conducted to determine the influence of addition of tannins-extract in low concentration of dietary dry matter on feedlot-performance of bulls. Forty *Bos indicus* x *Bos taurus* bull-calves (184 ± SE 0.22 kg) were used. The experiment was conducted as a complete randomized block design. Bull-calves were blocked by initial weight and in groups of 5 were placed in 6 × 12 m ground floor pens. Treatments were: 1) Feedlot diets based in dry-ground corn, canola meal and dry distiller grain without additional tannins (CTRL); and 2) Diet similar to CTRL added with 0.32% (DM basis) of a tannins-extract (TE). The tannins-extract was obtained from a commercial blend that contains extracts of condensed-tannins and soluble-tannins (Silvafeed-Bypro; Silvateam-Inudor S.A., Argentina). The final weight of bull-calves fed TE treatment was 7% higher ($P = 0.04$) than CTRL (529.2 vs. 492.4 kg). Average daily gain was improved 11% ($P = 0.04$) by the inclusion of TE in the diet means were 1.37 vs. 1.53 kg/d for CTRL and TE treatments, respectively. Dry matter intake was increased 6% ($P < 0.01$) by TE (8.446 vs. 8.994 kg/d). Feed efficiency was not affected by treatments ($P > 0.15$). Bull-calves that received TE showed a tendency ($P = 0.10$) for best using of dietary NEm, Net energy observed/expected ratio were 0.93 and 0.98 for CTRL and TE, respectively. Hot carcass weight was improved ($P = 0.05$) by TE addition (313.1 vs. 338.6 kg for CTRL and TE, respectively). In blood samples taken at 161-d PUN was 15% lower ($P < 0.01$) in bulls fed tannins (12.79 vs. 10.85 mg/dL for CTRL and TE, respectively). It is concluded, that 0.3% (DM basis) of extract tannins-supplementation in the diet improves feedlot performance of bull-calves.

Key words: feedlot-performance, bull-calves, tannins

W295 Influence of addition of tannins-extract in low concentration of dietary dry matter on carcass characteristics of bull-calves. A. Camacho*[1], B. J. Cervantes[2], M. A. Espino[1], M. Verdugo[1], L. R. Flores[1], J. A. Romo[1], and R. Barajas[1], *[1]FMVZ-Universidad Autonóma de Sinaloa, Culiacán, Sinaloa, México, [2]Ganadera Los Migueles S.A. de C.V., Culiacán, Sinaloa, México.*

Forty *Bos indicus* x *Bos taurus* bull-calves (184 ± 0.22 kg SE) were used to determine the influence of tannins-extract addition in low concentration to dietary dry matter on carcass characteristics of bull-calves. The experiment was conducted as a complete randomized block design. Bull-calves were blocked by initial weight and located in groups of 5 in ground floor pens (6 × 12 m). Treatments were: 1) Feedlot diets based in dry-ground corn, canola meal and dry distilled grain without additional tannins (CTRL); 2) Feeding with a diet similar to CTRL added with the 0.32% (DM basis) of a tannins-extract (TE) from condensed and soluble tannins blend (Silvafeed-Bypro; Silvateam-Inudor S.A., Argentina), along the complete feedlot experiment. Upon the complete feedlot period, animals were sacrificed and carcass weight was measured. Carcasses were chilled during 24 h (0°C), and left half of carcass was cross-sectioned between 12th and 13th ribs to determine carcass traits. Hot carcass weight was improved ($P = 0.05$) by TE addition (313.1 vs. 338.6 kg for CTRL and TE, respectively). Carcass dressing (63.8 ± SE 0.38%) was not affected by treatments ($P = 0.18$). Rib eye area was enhanced ($P = 0.03$) by TE with means of 77.4 and 85.6 cm2 for CTRL and TE, respectively. Adjusted rib eye area (using final weight as co-variable) tended to be higher ($P = 0.09$) in carcass of cattle fed TE (minimum-squares means 79.4 vs. 82.8 cm2 for CTRL and TE, respectively). Back fat thickness (9.2 ± SE 0.54 mm) and KPH-fat (1.9 ± SE 0.11%) were similar between treatments ($P > 0.20$). Meat pH (6.23 ± SE 0.04) was not influenced by treatments ($P > 0.20$). It is concluded that, the addition of a tannins-extract in low concentration of dietary dry matter, enhanced carcass weight and rib eye area without affecting remainder traits of bull-calves carcass.

Key words: carcass-characteristics, bull-calves, tannins

W296 Effect of length feeding additional tannins-extract on feedlot-performance of finishing-bulls. R. Barajas*[1], B. J. Cervantes[2], S. C. Arechiga[1], M. A. Espino[1], L. R. Flores[1], A. Camacho[1], and J. A. Romo[1], *[1]FMVZ-Universidad Autonóma de Sinaloa, Culiacán, Sinaloa, México, [2]Ganadera Los Migueles S.A. de C.V., Culiacán, Sinaloa, México.*

Sixty *Bos indicus* x *Bos taurus* bulls (366 ± 0.39 kg) were used to determine the effect of length feeding additional tannins-extract on feedlot-performance of finishing-bulls. The experiment was conducted as a complete randomized block design. Animals were blocked by initial weight and allotted in groups of 5 in ground floor pens (6 × 12 m). Treatments were: 1) Feeding with a DDG-ground corn based 96% concentrate-finishing diet (12.6% CP, 2.052 Mcal of NEm/kg) without additional tannins during 98 d-complete finishing period (CTRL); 2) Diet similar to CTRL added with the equivalent of 0.32% DM of a tannins-extract (TE) of condensed and soluble tannins blend (Silvafeed-Bypro; Silvateam-Inudor S.A., Argentina), during first 67 d (68%) of finishing period (TE68); and 3) Diet similar to CTRL added with the equivalent of 0.32% DM of a TE during 98 d (100%) of complete finishing period (TE100). Final weight was increased linearly ($P < 0.01$) as length feeding TE was augmented (497.7, 507.1, and 512.6 kg for CTRL, TE68, and TE100, respectively). Average daily gain was increased linearly ($P = 0.02$) as time feeding TE was increasing with means of 1.345, 1.452, and 1.500 kg/day for CTRL, TE68, and TE100, respectively. DMI was not affected by treatments ($P > 0.30$). Gain/DMI ratio was increased linearly ($P < 0.01$) with the increment in days feeding TE (0.145, 0.153, and 0.160 kg gain/kg DMI for treatments CTRL, TE68, and TE100, respectively). Hot carcass weight increased linearly ($P = 0.02$) with the increment in days feeding TE (309.2, 316.4, and 320.1 kg for treatments CTRL, TE68, and TE100, respectively). TE intake reduced ($P = 0.04$) plasma urea nitrogen of bulls relative to no tannins treatment (6.06 vs. 5.25 mg/dL). It is concluded, that as increased the length of feeding additional tannins-extract, improves the feedlot performance of finishing-bulls.

Key words: feedlot-performance, finishing-bulls, tannins

W297 Effect of length feeding additional tannins-extract on carcass traits of finishing-bulls. S. C. Arechiga*[1], B. J. Cervantes[2], M. A. Espino[1], L. R. Flores[1], A. Camacho[1], J. A. Romo[1], and R. Barajas[1], *[1]FMVZ-Universidad Autonóma de Sinaloa, Culiacán, Sinaloa, México, [2]Ganadera Los Migueles S.A. de C.V., Culiacán, Sinaloa, México.*

Sixty *Bos indicus* x *Bos taurus* bulls (366 ± 0.39 kg) were used to determine the effect of length feeding additional tannins-extract on carcass traits of finishing-bulls. The experiment was conducted as a complete randomized block design. Treatments were: 1) Feeding with a DDG-ground corn based 96% concentrate-finishing diet (12.6% CP, 2.052 Mcal of NEm/kg) without additional tannins during 98 d-com-

plete finishing period (CTRL); 2) Diet similar to CTRL added with 0.32% (DM basis) of a tannins-extract (TE) during first 67 d (68%) of the finishing period (TE68); and 3) Diet similar to CTRL added with 0.32% (DM basis) of a TE during 98 d (100%) of the complete finishing period (TE100). TE was supplied as a condensed and soluble tannins extract-blend (Silvafeed-Bypro; Silvateam-Inudor S.A., Argentina). Hot carcass weight increased linearly ($P = 0.02$) with the increment in days feeding TE (309, 316, and 320 kg for treatments CTRL, TE68, and TE100, respectively). Rib eye area was higher ($P = 0.09$) in bulls fed tannins-extract relative to no TE fed-bulls (69.7 vs. 75.6 cm2). Back fat thickness was 13.7% lower ($P = 0.05$) in bulls consuming TE along the complete finishing period (TE100) in relationship to CTRL-bulls that did not received TE. Back fat thickness was decreasing linearly ($P = 0.05$) as time-length in TE was increasing, means were of 10.7, 10.1, and 9.3 mm for CTRL, TE68, and TE100, respectively. KPH values were decreasing linearly ($P = 0.06$) as time-length feeding tannins was augmenting, means were 2.1, 1.9, and 1.6% of carcass weight for CTRL, TE68, and TE100, respectively. Marbling score and muscle pH were not affected by treatments ($P > 0.20$). It is concluded, that feeding tannins-extract along complete finishing period increases carcass weight and decreases fat content in carcass of feedlot-bulls.

Key words: carcass traits, finishing-bulls, tannins

W298 Meta-analysis of the effects of the interaction between copper and molybdenum on weight gain and gain:feed ratio in growing cattle. R. Dias*[1], S. Lopez[2], Y. Montanholi[1], B. Smith[1], L. Haas[1], S. Miller[1], and J. France[1], *[1]University of Guelph, Guelph, Ontario, Canada, [2]Instituto de Ganadería de Montaña (IGM), Universidad de León, León, Spain.*

Copper and molybdenum are essential trace minerals for proper functioning of many biological systems in ruminants. A variety of disease conditions are caused by lack of copper in the feed or by excesses of other minerals such as molybdenum which bind to copper and make it unavailable. Adequate trace mineral supply favors animal performance by improving weight gain and feed efficiency. A meta-analysis was undertaken to summarize and evaluate available data relating to the effects of copper and molybdenum supplementation on weight gain and gain:feed ratio in growing cattle weighing between 120 and 320 kg using 22 studies. The mixed model was applied by considering each study as a random effect. The standard error of weight gain and gain:feed ratio were recorded to give a distinct weight for each study. According to the first model, the interaction between supplementation of copper and molybdenum together, and molybdenum supplemented individually are more influential ($P < 0.05$) to weight gain in growing cattle than copper supplemented individually and DM intake ($P > 0.05$). In contrast, the second model showed that gain:feed ratio was significantly affected by DM intake, copper and molybdenum supplemented individually in the diet, and the interaction between these minerals ($P < 0.05$). The level of copper in plasma and the effects of copper source and animal sex were not significant with either model ($P > 0.05$). The first model indicated that the negative effect of possible excessive molybdenum supplementation on weight gain is more relevant than the effect of copper supplementation. Interaction between copper and molybdenum seems to favor weight gain due to copper neutralizing the negative effect of molybdenum on this parameter. In the second model, gain:feed ratio was negatively affected by copper and molybdenum supplemented individually, but these minerals together favored the gain:feed ratio. The interactions between copper and molybdenum needs to be considered carefully when supplementing these trace minerals individually in diets for growing cattle.

Key words: copper, molybdenum, growing cattle

W299 Effects of restricted versus conventional dietary adaptation over periods of 14 and 21 days on rumen papillae of feedlot Nellore cattle. F. S. Parra[1,3], J. R. Ronchesel[1], M. D. B. Arrigoni[1], C. L. Martins[1], D. D. Millen*[2], R. D. L. Pacheco[1], R. S. Barducci[1], L. M. N. Sarti[1], L. C. Vieira Júnior[1], M. C. S. Franzói[1], R. Espigolan[1], J. M. P. Silva[1], D. Setten[1], F. P. Luiz[1], E. A. Chacon Filho[1], *[1]São Paulo State University (UNESP), Botucatu, São Paulo, Brazil, [2]São Paulo State University (UNESP), Dracena, São Paulo, Brazil, [3]Supported by FAPESP, São Paulo, São Paulo, Brazil.*

This study, conducted at the São Paulo State University feedlot, Botucatu Campus, Brazil, was designed to determine effects of restricting DMI of the final finishing diet (REST) as a means of dietary adaptation compared with diets increasing in concentrate (STEPUP) over periods of 14-d and 21-d on rumen wall absorptive surface area (RASA) of feedlot Nellore cattle. The experiment was designed as a completely randomized block with a 2 × 2 factorial arrangement with repeated measures over time, replicated 6 times (5 bullocks/pen), in which 120 18-mo-old yearling Nellore bulls (372.2 ± 21.5 kg) were fed in 24 pens for 84-d according to the treatments: STEPUP for 14-d and 21-d, REST for 14-d and 21-d. The STEPUP program consisted of ad libitum feeding of 3 adaptation diets over periods of 14-d or 21-d with concentrate level increasing from 55% to 85% of diet DM. The REST program consisted of restricted DMI of the final diet with programmed increases in feed offered until animals reached ad libitum access over periods of 14-d or 21-d. After adaptation one animal per pen was slaughtered for rumen papillae evaluations. The remaining 96 animals were harvested when achieved about 500 kg of BW. At harvest a 1-cm^2 fragment of each rumen was collected from ventral sac. Manually, the number of papillae per cm^2 of rumen wall (NOP) was determined and 12 papillae were randomly collected from each fragment; scanned, and mean papillae area (MPA) in cm^2 was measured by software for image analysis. RASA in cm^2 was calculated as follows: 1 + (NOP*MPA) – (NOP*0.002). No significant ($P > 0.10$) protocols or days main effects were observed for MPA and NOP. Animals in STEPUP protocol had greater ($P < 0.05$) RASA (24.98 vs. 20.52) than animals in REST protocol. A significant ($P < 0.05$) interaction was observed between days and harvesting dates. Animals adapted for 14-d had reduced RASA after adaptation than: 1) after finishing (16.20 vs. 25.58) and, 2) animals adapted for 21-d after adaptation (16.20 vs. 27.78). The STEPUP protocol and 21-d of adaptation led to greater RASA, which could indicate lesser extent of rumen lesions.

Key words: Zebu, papillae

W300 Feedlot performance and carcass traits of yearling bulls fed polyclonal antibody preparations, yeast or monensin. E. Rodrigues[1,3], F. S. Parra[1], M. D. B. Arrigoni[1], C. L. Martins[1], D. D. Millen*[2], R. D. L. Pacheco[1], C. R. M. Andrade[1], R. S. Barducci[1], L. M. N. Sarti[1], J. R. Ronchesel[1], A. L. Campanini[1], and D. Tomazella[1], *[1]São Paulo State University (UNESP), Botucatu, São Paulo, Brazil, [2]São Paulo State University (UNESP), Dracena, São Paulo, Brazil, [3]Supported by FAPESP, São Paulo, São Paulo, Brazil.*

This study, conducted at the São Paulo State University feedlot, Botucatu Campus, Brazil, was designed to test the effects of polyclonal antibody preparation (PAP) against lactate-producing rumen bacteria,

Saccharomyces cerevisiae yeast (YEA) or monensin (MO) on feedlot performance and carcass traits of Nellore yearling bulls fed high concentrate diets for 112-d. One-hundred 20-mo-old bullocks (323.3 ± 21.8 kg) were assigned to 25 pens (4 bullocks/pen) and used in a completely randomized design with a 2 × 2 + 1 factorial arrangement of treatments, replicated 5 times. Factors were inclusion or not of PAP or YEA, both at a dose of 450 mg•kg^{-1} of DM, and the additional treatment was MO at 30 mg•kg^{-1} of DM. Dunnett test was used to compare MO with other treatments. Yearling bulls were weighed every 28-d to calculate ADG and F:G ratio, and DMI was recorded every day. No significant ($P > 0.10$) MO effect was observed for DMI in kg from 0-d to 112-d, however feeding MO reduced ($P < 0.05$) DMI in % of BW from 0-d to 28-d when compared with the other treatments (2.19% vs. 2.29%). Feeding MO from 0-d to 112-d reduced ($P < 0.05$) cost to gain 1 kg of BW (CBW; $2.62 vs. $2.79) and led to greater ($P < 0.05$) amount of kidney-pelvic fat (4.74 kg vs. 4.15 kg) when compared with the other treatments. A significant ($P < 0.05$) YEA main effect was observed for ADG, F:G ratio, CBW and HCW. Feeding YEA from 0-d to 112-d reduced ADG (1.13 kg vs. 1.24 kg), and led to greater F:G ratio (7.16 vs. 6.74) and CBW ($2.88 vs. $2.82) and lighter HCW (252.77 kg vs. 258.46 kg). No significant ($P > 0.10$) PAP main effect was observed for any of the feedlot performance parameters analyzed throughout the study. In addition, no significant ($P > 0.10$) differences between PAP and MO were detected in terms of feedlot performance (ADG, DMI, F:G ratio and CBW) and carcass traits (HCW and dressing percentage) from 0-d to 112-d. Yearling bulls not fed YEA performed better than those animals fed YEA. Feeding PAP did not affect negatively feedlot performance and carcass traits. Thus, the potential of PAP to replace ionophores, such as MO, should be further investigated.

Key words: Nellore, PAP, yeast

W301 Rumen papillae alterations of feedlot yearling bulls fed polyclonal antibody preparations, yeast or monensin. E. Rodrigues[1,3], F. S. Parra[1], M. D. B. Arrigoni[1], C. L. Martins[1], D. D. Millen*[2], R. D. L. Pacheco[1], R. S. Barducci[1], L. M. N. Sarti[1], J. R. Ronchesel[1], C. R. M. Andrade[1], A. L. Campanini[1], and D. Tomazella[1], *[1]São Paulo State University (UNESP), Botucatu, São Paulo, Brazil, [2]São Paulo State University (UNESP), Dracena, São Paulo, Brazil, [3]Supported by FAPESP, São Paulo, São Paulo, Brazil.*

This study, conducted at the São Paulo State University feedlot, Botucatu Campus, Brazil, was designed to test the effects of polyclonal antibody preparation (PAP) against lactate-producing rumen bacteria, *Saccharomyces cerevisiae* yeast (YEA) or monensin (MO) on rumen papillae alterations of Nellore yearling bulls fed high concentrate diets for 112-d. One-hundred 20-mo-old bullocks (323.3 ± 21.8 kg) were assigned to 25 pens (4 bullocks/pen) and used in a completely randomized design with a 2 × 2 + 1 factorial arrangement of treatments, replicated 5 times. Factors were inclusion or not of PAP or YEA, both at a dose of 450 mg•kg^{-1} of DM, and the additional treatment was MO at 30 mg•kg^{-1} of DM. At harvest rumenitis incidence (RUM) was determined, on the entire washed rumen, using a scale of 0 (no lesions noted) to 10 (severe ulcerative RUM). A fragment of 1 cm^2 of each rumen was collected from ventral sac. Manually, the number of papillae per cm^2 of rumen wall (NOP) was determined and 12 papillae were randomly collected from each fragment; scanned, and mean papillae area (MPA) in cm^2 was measured using software for image analysis. Rumen wall absorptive surface area (RASA) in cm^2 was calculated as follows: 1 + (NOP*MPA) – (NOP*0.002). A significant ($P < 0.05$) PAP main effect was observed for RUM, NOP and RASA. Yearling bulls fed PAP presented lesser RUM (1.38 vs. 1.77) and greater NOP (56.42 vs. 44.45) and RASA (21.10 cm^2 vs. 17.30 cm^2) than those animals not fed PAP. Feeding YEA led to smaller ($P < 0.05$) MPA (0.36 cm^2 vs. 0.44 cm^2) and reduced ($P < 0.05$) NOP (48.05 vs. 52.66) and RASA (17.39 cm^2 vs. 21.02 cm^2). Feeding MON led to greater ($P < 0.05$) RASA (25.82 cm^2 vs. 15.99 cm^2) and NOP (57.98 vs. 43.20) when compared with animals fed YEA, but no significant ($P > 0.10$) differences were observed when compared with animals fed PAP. Yearling bulls not fed YEA presented greater development of ruminal epithelia than those animals fed YEA. Feeding PAP reduced RUM and led to greater development of ruminal epithelia. Thus, PAP presents a new technology to control rumen acidification with the potential to replace ionophores, such as MO.

Key words: Nellore, PAP, yeast

W302 Fatty acid profiles in adipose tissue of grazing and feedlot beef steers. C. T. Noviandi*[1], R. E. Ward[2], J.-S. Eun[1], D. R. ZoBell[1], R. D. Stott[1], T. Astuti[3], B. L. Waldron[4], and M. D. Peel[4], *[1]Department of Animal, Dairy, and Veterinary Sciences, [2]Department of Nutrition, Dietetics, and Food Sciences, Utah State University, Logan, [3]Faculty of Animal Science, Andalas University, Padang, West Sumatra, Indonesia, [4]Forage and Range Research Laboratory, USDA-ARS, Logan, UT.*

A livestock study was conducted to evaluate the effects of pasture finishing vs. feedlot finishing beef steers on subcutaneous adipose tissue fatty acid (FA) composition. Twenty-seven Angus crossbred steers were arranged on the following 3 treatments: grazing on tall fescue without N fertilizer (TF–NF), grazing on tall fescue with N fertilizer (TF+NF), and feeding TMR on feedlot (FLT). A total of 168 kg/ha N fertilizer was applied in 3 split applications of 56 kg/ha to the TF+NF. The treatments were arranged in a randomized complete block design with 3 replicates and 3 steers per replicate. The pasture-finished steers grazed on replicated 0.47-ha paddocks from May through September 2010 for total of 16 wk. The steers on FLT were housed in 3 group pens with 3 animals per pen and fed a typical finishing diet containing 83% barley grain. Adipose tissue biopsies were obtained on wk 4, 12, and 16. There were no effects of time and treatment × time interaction on FA composition ($P > 0.10$). Fertilizing N did not affect FA composition, except for C18:1 trans-11 being higher in TF+NF compared with TF–NF ($P = 0.03$). Concentration of C18:2 cis-9, cis-12 tended to increase ($P = 0.09$) in TF–NF compared with TF+NF. Concentrations of C18:3 cis-9, cis-12, cis-15 and C18:2 cis-9, trans-11 were higher in grazing steers compared with those in FLT (0.41 vs. 0.20 and 0.48 vs. 0.25 g/100 g FA, respectively; $P < 0.01$), whereas concentrations of C18:1 cis-9 and C18:1 cis-11 were higher in FLT than grazing treatments. Overall results from this study indicate that 4 wk of grazing resulted in remarkable changes in adipose tissue FA profiles in beef steers, but N fertilization had minor impacts on the FA composition. Grazing beef steers elicited increases in human beneficial FA concentrations compared with steers fed FLT.

Key words: fatty acids, feedlot finishing diet, grazing beef steers

W303 Chromium propionate supplementation on feedlot performance of bulls. M. A. Espino*[1], B. J. Cervantes[2], P. W. Rounds[3], F. Valdez[3], E. A. Velazquez[1], J. A. Romo[1], and R. Barajas[1], *[1]FMVZ-Universidad Autonóma de Sinaloa, Culiacán, Sinaloa, México, [2]Ganadera Los Migueles S.A. de C.V., Culiacán, Sinaloa, México, [3]Kemin Agrifoods, Des Moines, IA.*

With the objective of determine the influence of chromium propionate supplementation on feedlot performance of bulls, a 189 d experiment was conducted. Forty 5 bulls 228 ± 2.84 kg were used. Animals were blocked by initial weight and in groups of 5 were located in ground floor pens (6 × 12 m). The experiment was conducted as a complete randomized block design (CRBD). Treatments were: 1) Feedlot diets without additional chromium (CTRL); 2) Diets added with an equivalent of 0.15 ppm of chromium as Cr-propionate (Cr15); and 3) Diets added with an equivalent of 0.30 ppm of chromium as Cr-propionate (Cr30). Supplementary chromium was provided from Kemin Trace Cr premix (Kemin Agrifoods, Des Moines, IA). The experiment was analyzed by ANOVA for CRBD; CTRL vs. Cr-supplemented diets (Cr15 + Cr30) was compared by orthogonal contrasts; and quadratic trend was explored using polynomial contrasts. In a 189-d experiment, bulls receiving any additional Cr-level were 5% heavier than CTRL (P = 0.03). Ending weight showed a quadratic trend (P = 0.11) toward Cr-level; Cr15-bulls were the heaviest with values of 469.8, 495.9, and 492.2 kg for CTRL, Cr15, and Cr30 treatments, respectively. Average daily gain was improved 10.8% by supplementary Cr compared with CTRL (P = 0.03). Weight gain had a quadratic response to additional Cr-level (P = 0.05), with values of 1.27, 1.42, and 1.40 kg/d for CTRL, Cr15, and Cr30 treatments, respectively; the highest ADG was observed in bulls fed with 0.15 ppm additional Cr. DMI and gain/feed ratio were not affected by treatments (P > 0.20). Cr15 treatment, improved 5.2% hot carcass weight (P = 0.09) comparative to CTRL; carcass weight of Cr30-fed cattle was no different from remainder treatments (P > 0.20). Carcass traits and meat pH were similar across all treatments (P > 0.20). It is concluded, that chromium propionate supplementation improves feedlot performance of bulls, and dosage of 0.15 ppm would result in better response against not Cr addition or 0.30 ppm Cr supplementation

Key words: bulls, chromium, feedlot performance

W304 Creatinine to estimate the quantity of carcass muscle and crude protein in the empty body weight. L. F. Costa e Silva, S. de C. Valadares Filho, P. P. Rotta*, R. F. D. Valadares, and D. Zanetti, *Universidade Federal de Viçosa, Viçosa, Minas Gerais, Brazil.*

The creatinine production is due the protein turnover that occurs in animal muscle. It is possible to determine the muscle and crude protein quantity in carcass and the crude protein quantity in the empty body by the urinary creatinine excretion. The aim of this study was to estimate the urinary creatinine excretion by the body weight (BW) and the muscle quantity in carcass and crude protein quantity in carcass and in the empty body by the urinary creatinine excretion. 32 Nellore bulls with initial body weight of 259 kg and 14 mo were used in this experiment. Four bulls were fed at maintenance and the 28 animals were kept at ad libitum system with corn silage and 40% of diet with concentrate in dry matter. The animals were allocated in 4 groups, which each group was slaughtered in different times of feedlot (42, 84, 126 and 168 d). To estimate the urinary creatinine excretion, 14 animals were kept at Tie Stall system. The others animals were allocated at collective pens with electronic gates to evaluate the individual feed intake. Before each slaughter, collections of urine were realized during 3 consecutive days. From the slaughters the empty body weight and the body composition of the animals were determined. After the slaughter, the left carcass was separated in muscle, fat and bone. The carcass samples were dried and ground to determine the total nitrogen. In urine, the creatinine analyses followed the protocol to high performance liquid chromatography. The creatinine excretion (Y) can be obtained by the equation: $Y = 0.0276 \times BW^{0.9811}$, $r^2 = 0.9761$. The quantity of carcass muscle (Mcarc) and carcass crude protein (CPcarc) estimated by the creatinine (CRE) were: $Mcarc = 15.307 \times CRE^{0.9894}$, $r^2 = 0.9341$ and $CPcarc = 3.2756 \times CRE^{1.0683}$, $r^2 = 0.9312$. The crude protein in empty body weight (CPEBW), estimated by the CRE was: $CPEBW = 6.5563 \times CRE^{0.9502}$, $r^2 = 0.9427$. All the exponents of the equations were near from 1. It allows concluding that the urinary creatinine excretion and the quantity of carcass muscle and carcass and empty body crude protein present near relation.

Key words: excretion, turnover, urine

W305 Effect of glycerin on intake and digestion of bermudagrass hay in beef cattle. T. A. Wickersham*, K. M. Bodensteiner, M. L. Drewery, R. O. Dittmar, and J. E. Sawyer, *Texas A&M University, College Station.*

Glycerin is a byproduct of biodiesel production and has the potential to provide supplemental energy to cattle consuming forage diets; however, the effect of glycerin in these diets has not been determined. Our objective was to determine the effects of increasing levels of glycerin on bermudagrass hay utilization. Four Angus × Hereford steers (BW = 301 ± 18.5 kg) were used in a 3 × 3 Latin square with an additional column for steer. Steers were provided ad libitum access to bermudagrass hay (10.6% CP and 69.0% NDF) and supplemented with cottonseed meal (0.2% of BW per day; 42.5% CP). Treatments consisted of 3 levels of glycerin infusion (0, 0.1, and 0.2% BW). Glycerin was delivered directly into the rumen once daily. Experimental periods were 17d long. Intake was determined from d 11 through 14 to correspond with fecal grab samples collected from d 12 to d 15. Acid detergent insoluble ash was used as an internal marker to estimate fecal production. On d 16 of each period, ruminal fermentation profiles were evaluated. Increasing levels of glycerin resulted in a quadratic (P = 0.04) response in hay OM intake from 6.75 kg/d for 0% glycerin to 5.92 and 6.46 kg/d for 0.1 and 0.2% BW as glycerin, respectively. There was a correspondent quadratic (P = 0.05) response in total OM intake to glycerin provision (7.25, 6.72, and 7.56 kg/d for 0, 0.1, and 0.2%). However, there was no significant (P > 0.12) effect of glycerin on either OM digestion (54.2, 55.6, and 51.5% for 0, 0.1, and 0.2%, respectively) or NDF digestion. When measures of intake and digestion were combined as total digestible OM intake, there was no significant effect (P > 0.35) of increasing glycerin. Intake of total digestible OM was 3.95, 3.74, and 3.92 kg/d for 0, 0.1, and 0.2%. A treatment by time interaction (P = 0.03) occurred for ruminal pH. Increasing glycerin resulted in greater reductions in ruminal pH post feeding; however, all pH values were greater than 6.30. Further work is required to understand why glycerin negatively affected forage intake when provided at 0.1% of BW.

Key words: forage, glycerin, cattle

W306 Effect of methanol on intake and digestion in beef cattle. K. N. Winsco*, N. M. Kenney, R. O. Dittmar, J. A. Coverdale, J. E. Sawyer, and T. A. Wickersham, *Texas A&M University, College Station.*

Methanol is used in biodiesel production, is found in significant quantities in crude glycerin, and has adverse effects on non-ruminants. Currently, the maximum concentration allowed for methanol in ruminant feeds is 150 ppm, but there is little data describing the effects of methanol concentrations in excess of 150 ppm on ruminants. Our objective was to determine effects of methanol concentration on intake and digestion in cattle consuming a grain-based diet. Five ruminally cannulated Holstein steers (BW = 399 ± 34 kg) were used in a 4 × 4

Latin square with an additional column for steer, and provided ad libitum access to a grain-based diet (49% corn, 14.7% CP, 32.1% starch). Treatments consisted of 4 levels of methanol (0, 70, 140, and 210 g/d) infused directly into the rumen to prevent volatilization from feed. Experimental periods were 16 d, with 9 d of adaptation to treatment and 7 d of data collection. Determinations of intake were made on d 10 through 14 of each period to correspond with fecal grab samples collected from d 11 through 15. Titanium dioxide, dosed daily at 10 g/d, was used as an external marker to estimate fecal production. Ruminal fluid was collected on d 16. Methanol intake increased linearly ($P < 0.01$) from 0 to 6,563, 13,356, and 19,831 ppm diet for 0, 70, 140, and 210 g/d of methanol, respectively. Intake was not ($P > 0.71$) affected by methanol infusion (9.93, 9.93, 9.73, and 9.83 kg OM/d for 0, 70, 140, and 210 g/d of methanol). Methanol infusion did not affect ($P > 0.12$) OM or starch total tract digestion, which averaged 75.6 and 93.9%, respectively, across treatments. Our results indicate that levels of methanol consumption in excess of the current recommendation of 150 ppm did not have adverse effects on intake and digestion in cattle. These data suggest minimal risk in allowing ruminant diets to contain greater levels of methanol than non-ruminant diets.

Key words: methanol, glycerin, cattle

W307 Effects of purified lignin on growth performance of feedlot cattle. Y. Wang*[1], J. H. Lora[2], and T. A. McAllister[1], *[1]Agriculture and Agri-Food Canada, Lethbridge Research Centre, Lethbridge, Alberta, Canada, [2]GreenValue Enterprises LLC, Media, PA.*

A feedlot experiment was conducted to assess the effect of purified lignin recovered from wheat straw soda pulping (PL) on the growth performance of feedlot cattle. A total of 60 Hereford-Angus cross weaned calves were randomly divided into 4 groups. The cattle were individually fed a barley grain/barley silage based total mixed ration and randomly assigned to one of 4 diets containing increasing levels of PL (0, 4, 8 and 16 g/kg DM). Cattle were fed once daily for ad libitum intake and had free access to water during a 70-d growing period and a 121-d finishing period. Inclusion of PL in the diet tended to linearly reduce ($P = 0.090$) average daily gain (ADG) during the growing period, but not in the finishing period. Feed intake over the entire experimental period tended to be linearly reduced ($P = 0.100$). Feed efficiency was similar among groups of steers during growing period, but was quadratically improved ($P = 0.059$) during the finishing period with increasing PL in the diet. Supplementation of PL tended to increase ($P = 0.098$) the saleable meat yield, but had no effects on other carcass traits. The quadratic improvement in feed efficiency by adding PL to finishing diet (high grain diet) but not to growing diet is likely due to PL regulating ruminal microbial activity in digestion of starch, as well as modulation of the feed intake. Inclusion of PL at the level of about 8 g/kg DM in diet containing high grain may benefit the feedlot cattle in terms of improving feed efficiency.

Key words: feedlot cattle, purified lignin, growth

W308 Protein balance alters expression of key genes for protein and lysine catabolism in liver of lactating dairy cattle. H. A. Tucker*[1], S. L. Koser[1], P. H. Doane[2], and S. S. Donkin[1], *[1]Purdue University, West Lafayette, IN, [2]Archer Daniels Midland Company, Decatur, IL.*

Lysine supply is often limiting for milk protein production in dairy cattle. The availability of lysine for mammary protein synthesis is a function of metabolizable lysine supply and hepatic lysine catabolism. The objective of this experiment was to examine the effect of protein balance in early lactating dairy cattle on expression of aminoadipate semialdehyde synthase (AASS), a committing step in lysine catabolism by liver, and ornithine transcarbamoylase (OTC), a general indicator of protein utilization and ureagenesis. Thirty multiparous early lactation Holstein cows were fed diets containing either 16.0 or 17.5% crude protein for an 84 d period. Liver samples were collected via percutaneous liver biopsy on d 42 and 84 of the experiment for mRNA analysis. Blood samples were collected on d 42 and 84 and analyzed for blood urea nitrogen. Protein balance was determined for the week preceding sample collection and used to classify cows as either positive or negative with respect to MP balance. AASS expression differed ($P < 0.05$) for d 42 (0.37 ± 0.2 arbitrary units) and d 84 (0.88 ± 0.2 arbitrary units) of the experiment. OTC expression differed ($P < 0.05$) between d 42 (1.43 ± 0.2 arbitrary units) and d 84 (2.62 ± 0.2 arbitrary units). Expression of AASS tended ($P < 0.1$) to be lower in cows experiencing negative protein balance (0.39 ± 0.2 arbitrary units) and was elevated in cows in positive protein balance (0.85 ± 0.2 arbitrary units), while expression of OTC did not differ ($P > 0.05$) between groups. There were no interactions between protein sufficiency and day of experiment for either transcript. Expression of OTC on d 42 was correlated ($P > 0.05$) with metabolizable and rumen undegradable protein intake. Expression of AASS was correlated ($P > 0.05$) with milk urea nitrogen in cows in negative protein balance. No significant correlations between gene expression and positive protein balance were observed. These data indicate that expression of lysine catabolism and ureagenic genes in the liver are responsive to protein balance in early lactating dairy cattle and suggest enhanced sensitivity when protein is limiting.

Key words: lysine, protein balance, gene

W309 Effects of OmniGen-AF on performance and economics of a veal operation. O. Bewley*[1], J. D. Chapman[1], K. P. Zanzalari[1], Y. Q. Wang[2], and N. E. Forsberg[2], *[1]Prince Agri Products, Quincy, IL, [2]OmniGen Research, Corvallis, OR.*

The goal of this study was to evaluate the effects of OmniGen-AF (Prince Agri Products, Quincy, IL) on veal calf performance, immune parameters and economics of production. Two hundred Holstein calves were received at a commercial Pennsylvania veal operation within 48–72 after birth and assigned to 2 treatments: control-fed (n = 50) and OmniGen-AF-fed (n = 150). At trial start, animals on the OmniGen-AF treatment received 10 g OmniGen-AF/head/day. This was added to a commercial milk replacer. The amount of OmniGen-AF was thereafter increased to maintain a dose of 0.09g/kg BW/d. Duration of the study was 137d. Starting weights and final weights were recorded and gain calculated. Whole blood was sampled 4 times during the study (Day 0 and monthly thereafter). Blood RNA was purified with Trizol and used for assay of 2 immune markers: L-selectin mRNA and interleukin-8 receptor (IL8R) mRNA using quantitative reverse transcriptase PCR. Beta-actin mRNA concentration was also assessed to normalize expression of L-selectin and IL8R mRNAs. Treatments and treatment costs were also recorded and economic value of the supplementation program was calculated using on-farm medication costs. Data were analyzed with SAS using least squares means for unequal cell sizes. The Proc GLM procedure was used to compare means for main effects (ration). Mean final weights of control and OmniGen-AF-fed animals were 126.4 and 128.5 kg ($P > 0.05$), respectively. OmniGen-AF reduced ($P < 0.05$) treated calves ($P < 0.05$) from 29 treated calves/50 calves to 18, respectively. Treatment costs were thereby reduced from $2.58/calf to $1.46/calf, respectively. Numbers of calves experiencing severe infections was reduced from 8 to 5.6 severe infections/50 calves by feeding OmniGen-AF. Effects of the additive on blood immune markers were similar to those reported previously (Wang et al., 2007, 2009). Feeding OmniGen-AF tended to increase ($P > 0.05$) L-selectin mRNA and increased ($P < 0.05$) IL8R mRNA during the third and fourth months of the study. Veal calves responded to OmniGen-AF as have most other animal models; including adult dairy cattle, beef cattle, sheep, swine and rodents.

Key words: veal calves, immunity, OmniGen-AF

W310 Determining methionine bioavailability in commercial dairy herds. D. Stucker[1], J. R. Knapp*[2], and N. R. St-Pierre[3], *[1]Venture Milling, Salisbury, MD, [2]Fox Hollow Consulting LLC, Columbus, OH, [3]The Ohio State University, Columbus.*

Our objective was to determine the relative bioavailability of methionine in rumen-protected supplements under field conditions using the selenomethionine dilution approach of Weiss and St-Pierre (2009). Three commercial methionine supplements were fed to 3 pens of approximately 250 cows each in a commercial dairy herd, and methionine bioavailaibility compared with an unsupplemented control in a truncated Latin square design. The selenium yeast and methionine supplements were fed to provide 0.3ppm selenium and 15g methionine per cow per day, respectively. The herd was milked 3x per day, and milk was sampled from each pen during 6 milkings distributed over the last 3 d in each 10-d period. Milk was sampled via an in-line sampling device, mixed extensively, and sub-sampled. Milk components, somatic cell counts, and milk urea nitrogen levels were determined by NIR (DHI Cooperative, Inc.). Milk nitrogen and selenium were determined by micro-Kjeldahl analysis and fluorometry, respectively. Data were analyzed using a mixed model with period and treatment (methionine supplement) as fixed effects and pen and related interaction terms as random effects. Supplementation with selenium yeast increased milk selenium from 19.8 to 36.6 ng/g milk, and is typical of the response observed in previous research. Methionine supplementation increased milk crude protein 0.049% units ($P < 0.05$), decreased milk selenium 6.1 ng/g ($P < 0.0001$), and decreased milk selenium:nitrogen ratio ($P < 0.0001$). No differences were observed in these measurements among methionine supplements ($P > 0.20$). These results confirm that the selenomethionine dilution approach provides an excellent method to determine methionione bioavailability to the mammary glands. However, refinement of the method is required to allow detection of differences between methionine supplements. In this experiment, within-pen variances were larger than expected from prior research conducted on individual animals, indicating that further research is needed to separate components of variances that contribute

to the large within-pen variances, including analytical, sampling, day-to-day, and animal variances.

Key words: amino acid availability, amino acid supplement, methionine

W311 Effect of returned milk (Nutri-Gold) on performance of veal calves. D. Vermeire*, *Nouriche Nutrition Ltd., Lake St. Louis, MO.*

Calves were fed either control (CON) milk replacers (MR) produced with whey and whey protein concentrate or experimental (EXP) MR in which dried milk comprised 30% of the formula (w/w). CON and EXP MR were formulated to contain equal protein and fat concentrations. Dried milk (Nutri-Gold) was within-date returned milk from grocery stores, blended, and dried with drum dryers. Holstein calves (n = 196, 43.5 kg) were fed either CON or EXP pre-starter and starter MR (d 1–52), and either CON or EXP finisher MR (d 53–144) in a 2x2 factorial arrangement of treatments in a completely randomized experimental design. Calves were randomly assigned to individual stalls upon arrival. Calves in odd-numbered stalls were fed EXP while calves in even-numbered stalls were fed CON pre-starter and starter MR treatments, respectively. Calves in stalls 1 and 2, 5 and 6, 9 and 10, etc. were fed EXP while calves in stalls 3 and 4, 7 and 8, and 11 and 12, etc. were fed CON finisher treatments, respectively. All treatment combinations were represented in every 4 stalls throughout the room. Weight (WT) on day (d) 1 or d 52, and gain from d 1–52 were not different due to starter or finisher treatment. Gain from d 52–144 tended ($P = 0.056$) to be greater, and gain from d 1–144 tended ($P = 0.069$) to be greater for calves fed EXP vs CON starter MR. Carcass WT were heavier ($P = 0.023$, 120.9 ‡1.16 vs 117.1 ‡1.17 kg, respectively), and LD color was lighter ($P = 0.031$, 2.25 ‡0.05 vs 2.40 ‡0.05 VUSA score) for calves fed EXP vs CON starter MR, respectively. During the finishing phase, calves fed EXP were heavier on d 144 ($P = 0.002$, 201.0 ‡1.85 vs 192.8 ‡1.86 kg, respectively), had heavier carcass WT ($P = 0.002$, 121.5 ‡1.14 vs 116.4 ‡1.16 kg, respectively) and gained more WT from d 52–144 ($P = 0.002$, 126.7 ‡1.60 vs 119.7 ‡1.63 kg, respectively) than calves fed CON. LD color was not affected by finisher MR. Interaction of MR (CON vs EXP) and phase (starter vs finisher) was significant ($P < 0.001$) for WT on d 144, carcass weight, and gain from d 52–144 indicating that feeding drum-dried returned milk in either starter or finisher phase increased carcass WT, WT on d 144, and WT gain from d 1–144.

Key words: veal, dried milk, calves

W312 Antioxidant activity in milk of dairy cows fed diets containing propolis-based products. S. M. Cottica[1], S. C. de Aguiar[1], E. M. de Paula[1], R. B. Samensari[1], L. P. P. de Moura[1], S. L. Franco[1], J. V. Visentainer[1], G. T. dos Santos[1], R. Kazama[2], O. P. P. do Prado[1], F. J. Maia[1], and L. M. Zeoula*[1], *[1]Universidade Estadual de Maringá, Maringá, Paraná, Brazil, [2]Universidade Federal de Santa Catarina, Florianópolis, Santa Catarina, Brazil.*

The objective was to evaluate the effect of propolis-based products (PBP), which differ in the concentration of propolis, alcohol content, and concentration of flavonoids (PBP1, PBP2, PBP3) in the diets of dairy cows, to verify the antioxidant activity in the milk produced by these animals. Four Holstein cows, with 550 kg of body weight and 147 d of lactation were subjected to 2 daily milkings (0600h and 1500h) and randomly assigned to a 4x4 Latin Square. The diets were formulated with 60.27%:39.73% forage:concentrate to contain 16.9% of CP, 1.49 mcal/kg of NEL, 10.2% RDP and 38.2% NDF, differing with the inclusion or not of PBP, which are: control (no additives), PBP1, PBP2 and PBP3 (with 30.63, 71.88 and 78.45 mg of quercetin equivalents ($QE.g^{-1}$), respectively). The PBP1 and PBP2 differ only in the concentration of propolis and have the same ethanol content, while the PBP3 has the same propolis concentration of PBP2 and higher ethanol content. The PBP, a powder, were introduced into the rumen via ruminal cannula at the time of diets ministration. Analyses of antioxidant activity of milk samples were performed using the ORAC method - Oxigen Radical Absorbance Capacity with fluoresceíne (ORAC-FL), based in the capacity that the sample has to capture peroxyl radicals generated by thermal decomposition of 2.2-azobis (2-amidinopropane) dihydrochloride (AAPH). The results were expressed as mM of Trolox Equivalent (mM TE) and differed significantly between treatments. It was observed that PBP increased ($P = 0.000001$) the antioxidant activity of milk compared with control treatment. Milk samples resulting from treatments PBP2, PBP1 and PBP3 had antioxidant activity of 24.352, 23.640 and 16.075 mM TE, respectively, and the control treatment had antioxidant activity of 14.582 mM TE. It can be concluded that the PBP has antioxidant capacity and its addition in the diet of dairy cows can be positive, due to an increase transfer of antioxidant activity to the milk, preventing, therefore, their lipid oxidation, which will improve quality and lead benefits to consumer health.

Key words: antioxidant activity, milk, propolis ethanolic extracts

W313 Ruminal fermentation of acidosis induced cows treated with monensin or polyclonal antibodies against target ruminal bacteria. D. D. Millen*[2,3], R. D. L. Pacheco[1], C. T. Marino[4], J. P. S. T. Bastos[4], T. A. Barros[4], F. A. Ferreira[4], C. L. Martins[1], M. D. B. Arrigoni[1], and P. H. M. Rodrigues[4], *[1]São Paulo State University (UNESP), Botucatu, São Paulo, Brazil, [2]São Paulo State University (UNESP), Dracena, São Paulo, Brazil, [3]Supported by FAPESP, São Paulo, São Paulo, Brazil, [4]University of São Paulo (USP), Pirassununga, São Paulo, Brazil.*

This study was designed to evaluate the potential of a multivalent polyclonal antibody preparation (PAP) against target ruminal bacteria (*S. bovis*, *F. necrophorum* and *Lactobacillus* ssp.) or monensin (MO) as acidosis preventative feed additive for cattle switched abruptly to high concentrate diets. Nine cannulated cows (677 ± 98 kg of BW) were used in a completely randomized design in 2 periods of 20-d. Treatments were: control (CTL), PAP at a dose of 450 $mg•kg^{-1}$ of DM and MO at 30 $mg•kg^{-1}$ of DM. During first 5 d of each period, animals were fed a 100% forage diet (fresh chopped sugarcane). Ruminal acidosis was induced by abruptly introducing a 74% concentrate diet (based on high moisture corn) during 15-d. An interval of 15-d was considered between the 2 periods as ruminal washout. Ruminal acidosis evaluation parameters were: DMI, DMI fluctuations during the subsequent days after challenge, rumen pH, and VFA, lactate and NH_3-N concentrations. There was no treatment main effect ($P > 0.05$) for DMI. Higher pH was observed ($P < 0.01$) for MO fed cows (6.06) compared with those on PAP (5.89) and CTL treatments (5.91). Ruminal lactate concentration remained low (0.23 mM) and unchanged ($P > 0.05$) throughout the study. The NH_3-N concentration of cows on CTL treatment (11.20 $mg•dl^{-1}$) was lower ($P < 0.01$) compared with cows fed MO (14.74 $mg•dl^{-1}$) and PAP (13.64 $mg•dl^{-1}$). A day x treatment interaction ($P < 0.01$) for molar concentration of propionate was found, in which feeding MO increased propionate concentration during 4 d after challenge. Feeding MO also reduced ($P < 0.01$) acetate:propionate ratio during 3 d after challenge. Molar proportion of butyrate was reduced ($P < 0.01$) when cows were fed MO (15.42

mol•100mol^{-1}) and PAP (16.35 mol•100mol^{-1}) compared with cows on CTL treatment (18.43 mol•100mol^{-1}). The type of ruminal acidosis generated in the present study was not lactic and possibly did not promote adequate conditions for PAP control ruminal lactate-producing bacteria. Nevertheless, MO was effective in increasing rumen pH and improving ruminal fermentation of cows induced to ruminal acidosis.

Key words: acidosis, monensin, PAP

W314 Effect of a combined supplement of vitamin B12 and folic acid on vitamin B12 concentration in milk of dairy cows. M. Duplessis*[1], D. Pellerin[1], and C. L. Girard[2], *[1]Université Laval, Département des sciences animales, Québec, QC, Canada, [2]Agriculture and Agri-Food Canada, Sherbrooke, QC, Canada.*

Increasing folic acid supply could mask vitamin B12 deficiency until neurological damages are irreversible. Consequently, since folic acid fortification of flour became mandatory in many Western countries, there is a renewed interest for vitamin B12 status in human populations. The natural source of vitamin B12 in human diets comes from animal products, especially those from ruminants. Moreover, a recent study showed that vitamin B12 in cow′s milk is absorbed more efficiently than its synthetic form. The objective of this work was to evaluate the effect of a combined supplement of vitamin B12 and folic acid on vitamin B12 concentration in milk of dairy cows. Commercial dairy herds were involved in this study (n = 15). Every 2 mo and within each herd, from February to July 2010, cows (n = 309) were randomly assigned, based on parity, predicted 305d milk yield, and calving interval to weekly intramuscular injections of 5 mL of 1) saline 0.9% NaCl (C) or 2) 10 mg of vitamin B12 + 320 mg of folic acid (V). The treatments began 3 wk before the expected calving date until 8 wk after parturition. Milk samples were taken on average at 28.1 ± 3.9 (T1) and 55.6 ± 3.9 (T2) DIM. Data were analyzed using the MIXED procedure of SAS with block, herd, parity, treatment and time as main effects. Vitamin supplements increased ($P < 0.0001$) average milk concentration of vitamin B12 from 3.1 to 5.2 ± 0.1 ng/g. For V and S, vitamin B12 concentrations were 5.5 and 5.0 ± 0.1 ng/g and 3.1 and 3.2 ± 0.1 ng/g at T1 and T2, respectively (treatment × time, $P = 0.0005$). Vitamin B12 concentration in milk was not affected by parity ($P = 0.13$) but it differed among herds ($P < 0.05$); there was no interaction treatment × herd ($P = 0.23$). Weekly intramuscular injections of vitamin B12 and folic acid increased by 68% milk concentration of vitamin B12 in commercial dairy herds. A glass (250 mL) of milk from supplemented cows provides 54% of the recommended daily allowance (2.4 µg) for adults and children over 13 years of age.

Key words: vitamin B12, folic acid, dairy cow

W315 Effects of cornmeal or molasses supplemented with different protein sources on milk production and nitrogen utilization of organic dairy cows. S. Ross*[1], A. F. Brito[1], H. V. Petit[2], and K. J. Soder[3], *[1]University of New Hampshire, Durham, [2]Agriculture and Agri-Food Canada, Sherbrooke, QC, Canada, [3]USDA-Agricultural Research Service-Pasture Systems and Watershed Management Research Unit, University Park, PA.*

Sixteen lactating organic Jersey cows were assigned to 4 replicated 4 × 4 Latin squares with a 2 × 2 factorial arrangement of treatments to compare the effects of feeding cornmeal (CM) or molasses (MOL) with either flaxseed meal (Flax) or a protein mix [(PM = 11% soybean meal (SB) + 5% sunflower meal (SM)] on milk yield and N utilization. Cows were fed (% diet DM) grass baleage (70%), mineral pre-mix (2%), plus one of 4 concentrates (28% diet DM): 1) 12% CM plus 16% PM (CMP); 2) 12% CM plus 16% Flax (CMF); 3) 12% MOL plus 16% PM (MOLPM); or 4) 12% MOL plus 16% Flax (MOLF). Cows were fed twice a day with concentrates top-dressed on the baleage. Preplanned orthogonal contrasts were used to compare the main effects of: energy source (ES = CM vs. MOL) and protein source (PS = SB + SM vs. Flax), and the ES × PS interaction. A significant PS was observed for milk yield with cows fed Flax diets producing the lowest amounts. Cows fed MOL diets had the lowest ($P = 0.01$) feed efficiency while those fed PM diets the highest ($P < 0.001$). Significant PS effects were observed for yields and contents of milk fat and milk protein. A dilution effect possibly explains the reduced ($P < 0.01$) milk protein content in cows fed CMP and MOLP. A significant ES × PS interaction was found for MUN with cows fed CMF showing the highest and cows fed MOLF showing the lowest values, indicating enhanced N utilization in the latter diet. Cows fed MOL diets had the lowest PUN showing improved N utilization. Increased PUN with PM diets can be explained by their slightly greater CP compared with Flax diets. Overall, diets containing Flax reduced yields of milk and milk components while those containing MOL improved N utilization in organic cows.

Table 1. Performance and N utilization

	Diets					Contrasts		
	CMP	CMF	MOLP	MOLF	SED	ES	PS	ES × PS

W317 Effects of essential oils, yeast and enzyme additive to milk replacer and starter on dairy calf performance. A. D. Kmicikewycz*[1], H. T. Pervis[2], J. Hill[2], and N. B. Litherland[1], *[1]University of Minnesota, St. Paul, [2]Ralco Nutrition Inc., Marshall, MN.*

The objective of this study was to determine the effects of an essential oil blend, yeast cell wall extract, *B. subtilis*, and a source of digestible fiber in milk replacer (MRA) along with a digestible fiber, yeast cell wall extract, an essential oil blend, niacin and enzyme premix additive blend to starter (SA) on calf performance and health. Sixty multi-farm commingled male (n = 15) Holstein calves <7 d of age were randomly assigned to 1 of 4 treatments and balanced by initial body weight

(BW). The treatments (T) were as follows: T1) 20% CP:20% fat milk replacer (MR) and 18% CP texturized starter (control); T2) 20:20 MR with 10 g/d MRA and18% CP starter; T3) 20:20 MR and SA; T4) 20:20 MR with 10 g/d MRA and SA. All MR was non- medicated, reconstituted to 12.5% solids and fed at 1.5% of arrival BW. Calves were weaned on d 42. Water and starter were provided ad libitum from d 1 to 56. Weekly weight and structural measurements and daily starter intake and fecal scores (FS) were recorded. Data were analyzed using Proc Mixed in SAS as a completely randomized design with repeated measures. Starter and total DM intake was not different among treatments. There was a tendency ($P = 0.08$) for an increase in starter intake by week. Least squares means of starter intake (kg/d) from d 1 to 42 were 0.62 for T1, 0.59 for T2, 0.53 for T3, and 0.49 for T4. Average BW gain from d 1 to 42 (T1 = 15.4; T2 = 14.0; T3 = 13.0 and T4 = 10.7) was not different ($P = 0.40$) or was BW gain from d 1 to 56 ($P = 0.47$). Average daily gain (ADG) from d 1–56 was not different ($P = 0.47$) averaging 0.43, 0.36, 0.34 and 0.36 kg/d for T1, T2, T3, and T4. There was no significant T or T × wk interaction for hip width, hip height, wither height or heart girth. FS were not different ($P = 0.95$) between treatments and averaged 2.2. Feeding a combination of essential oils, microbial and enzyme additives did not increase calf daily gain or performance over the 56 d.

Key words: calf, milk replacer, essential oils

W318 Milk production responses of grazing cows to partial mixed rations. M. J. Auldist*, J. L. Jacobs, L. C. Marett, J. S. Greenwood, and W. J. Wales, *Department of Primary Industries, Ellinbank, Victoria, Australia.*

An experiment was conducted to measure milk production responses of grazing dairy cows in late lactation to supplements offered as partial mixed rations (PMR), or as grain in the dairy and forage in the paddock. Three groups of 72 multiparous spring-calving Holstein-Friesian cows had a common pasture intake of 8 kg DM /cow.d. Each group was randomly assigned to 1 of 3 rations to receive the balance of their nutrient intake. Rations were: (i) Control: barley grain in the dairy twice daily at milking times and pasture silage in the paddock. (ii). PMR1: a simple PMR of barley grain and pasture silage. (iii). PMR2: a PMR comprising maize silage, maize grain, barley grain and alfalfa hay. All rations were isoenergetic with grain:forage ratios of 75:25 (DM basis). Both PMRs were fed on a feed pad twice per day aftermilking. The 3 groups were further divided into 8 groups of 9 cows, and offered their supplements at one of 4 rates (6, 8, 10 or 12 kg DM supplement/cow.d) for 25 d. Milk yields measured daily and concentrations of fat and protein measured weekly were used to calculate yields of energy corrected milk (ECM). The ECM response to supplements between 6 and 12 kg DM/cow.d was linear ($P < 0.05$) for PMR2, but not for Control or PMR1. There was no difference between ECM yield of any group except at the highest rate, when cows fed PMR2 produced 1.9 kg/cow.d more ($P > 0.05$) than cows fed the Control and PMR1 diets. These data suggest that feeding grazing cows high rates of supplements as a PMR containing maize grain and maize silage may offer the opportunity to alleviate the diminishing or negative marginal response commonly observed when feeding high amounts of grain in the dairy.

Table 1. Yields of energy corrected milk (kg/cow.d) for cows offered different levels of supplements as a Control system or as one of two different partial mixed rations. Data are means for two groups of 9 cows offered each rate of each diet

Rate of feeding (kg DM/cow.d)	Control	PMR1	PMR2
6	17.5	15.8	16.5
8	19.6	18.1	19.5
10	21.4	20.3	21.0
12	20.1[a]	19.8[a]	22.0[b]

[a,b]Within rates of feeding, means with different superscripts are significantly different. Overall standard error of the difference between means was 1.09.

Key words: pasture, milk response, supplements

W319 Evaluation of a rumen protected carbohydrate supplement prototype feed with fresh lactation dairy cows. J. P. Russi*[1], P. F. Russi[1], J. M. Simondi[2], G. M. Bonetto[2], C. Nasser Marzo[2], J. A. Di Rienzo[3], and A. R. Castillo[4], *[1]Rusitec S.A., Buenos Aires, Argentina, [2]INTA, EEA Manfredi, Cordoba, Argentina, [3]University of Cordoba, School of Agriculture, Cordoba, Argentina, [4]University of California, Cooperative Extension, Merced, CA.*

The objective of this trial was to feed a prototype rumen protected carbohydrate supplement to fresh lactation cows to determine if a patent pending manufacturing product is effective in protecting simple carbohydrates against ruminal degradation. Twenty 7 cows were group fed the same basal diet from −21 d of expecting calving date to parturition. From calving to 28 DIM cows were assigned to 3 treatments in a randomized complete block design and fed a diet of (% DM): 31.4% corn silage, 19.4% alfalfa hay, 22.8% corn grain, 7.4% soybean seeds, 4% extruded soybean meal, 4.3% minerals and vitamins; and 10.7% basal supplement (58.9% solvent soybean meal, 37.4% glucose and 3.7% urea). The 3 treatments consisted on replacing 0% (T0), 50% (T1) and 100% (T2) of the basal supplement with the rumen protected carbohydrate prototype feed. The prototype feed had the same ingredients of the basal supplement. Body weight, BCS, and blood samples were taken once a week. Weekly samples of TMR were taken for feed analysis. Milk yield and milk composition per cow was measured 2 times per week on non-consecutive days. Energy corrected milk (ECM) was calculated based on milk fat, protein, and lactose contents and milk yield/cow/d. DMI and ECM were not different for T0, T1 and T2, averaging 19.0, 20.2 and 21.1 Kg/d. and 28.2, 25.7, and 26.6 Mcal/cow/d. Milk fat, 4.08, 4.06, 4.15% and protein 3.36, 3.47, and 3.48% were similar among T0, T1 and T2. Milk lactose (%) was higher for T1 (4.96) and T2 (4.88), compared with T0 (4.70). Milk ketone bodies were not different averaging 0.73, 0.36 and 0.57 mg/dl for T0, T1 and T2. Blood glucose (mg/dl) was higher for T1 (45.3) and T2 (42.5) vs. T0 (38.8). Body weight loss (kg) during wk 3 was higher for cows in T0 (20.5) compared with T1 (7.3) and T2 (5.7). Based on milk lactose content, blood glucose, and body weight changes, it was concluded that the rumen protected carbohydrate supplement prototype was effectively protected against rumen microbial degradation

Key words: rumen protected carbohydrate, fresh cows′ performance

W320 Effects of balancing for methionine and lysine in a lactation diet containing high concentrations of wet corn gluten feed. C. R. Mullins*[1], D. Weber[2], E. Block[2], J. F. Smith[1], M. J. Brouk[1], and B. J. Bradford[1], *[1]Kansas State University, Manhattan, [2]Arm & Hammer Animal Nutrition, Princeton, NJ.*

Primiparous (n = 33) and multiparous (n = 63) lactating Holstein cows (186 ± 51 DIM) were used to evaluate the effects of balancing for metabolizable amino acids using lysine in a matrix of Ca salts of fatty acids (Megamine-L, Arm & Hammer Animal Nutrition) and the isopropyl ester of 2-hydroxy-4-methylthio butanoic acid (HMBi; MetaSmart, Adisseo Inc.) in diets with high concentrations of wet corn gluten feed. Cows were blocked by production, parity, and pregnancy status, then randomly assigned to 1 of 8 pens and allowed a 7 d adaption period before receiving treatments. The study consisted of 2 28-d treatment phases, in which DMI and production were monitored daily and milk components analyzed 3 d/wk. Phase (P) 1 and 2 data were analyzed separately using mixed models with repeated measures. During P1, pens were offered 1 of 2 rations formulated to differ by amino acid content. The control diet had CPM-predicted values of 181 g/d of metabolizable lysine (6.05% of metabolizable protein [MP]) and 63 g/d of metabolizable methionine supply (2.11% of MP). The treatment diet was similar, with replacement of 190 g/cow per d of Ca salts of fatty acids (Megalac-R, Arm & Hammer Animal Nutrition) with the lysine product, and the addition of 14 g/cow per d of the HMBi product. This yielded CPM-predicted values of 197 g/d of metabolizable lysine (6.58% of MP) and 66 g/d of metabolizable methionine supply (2.20% of MP). No treatment effects were observed for any parameters in P1. For P2, cows remained in the same pens and dietary treatment groups; however, the treatment diet was modified to replace some wet corn gluten feed with corn silage, decrease dietary CP from 17.9% to 17.1% by removing expeller soybean meal, and further increase lysine and methionine supply. The resulting treatment diet had CPM-predicted values of 196 g/d of metabolizable lysine (7.10% of MP) and 69 g/d of metabolizable methionine supply (2.49% of MP). In P2, MUN was decreased in the treated group (10.8 vs. 12.5 ± 0.2 mg/dL, $P < 0.001$) without affecting milk production ($P = 0.51$). No differences were observed in any of the other parameters measured.

Key words: amino acid, dairy, by-product

W321 Effects of subacute ruminal acidosis (SARA) challenges on bacteria in the digestive tract of dairy cows. S. Li*, J. C. Plaizier, E. Khafipour, and D. O. Krause, *University of Manitoba, Winnipeg, MB, Canada.*

Effects of SARA challenges on bacterial populations in the rumen and cecum were determined in 6 nonlactating Holstein dairy cows with cannula in the rumen and in the cecum. A replicated 3 × 3 Latin square was used. During the first 3 wk of the 4 wk experimental periods, cows received a control diet containing 70% forage (DM basis). During wk 4, cows received one of the 3 diets: the control diet, a grain-based SARA challenge (GBSC) diet containing 64% concentrate including 34% wheat-barley pellets, or an alfalfa-pellet SARA challenge (APSC) diet with 56% of forage including 37% alfalfa pellets. Digesta samples were taken at 6 h after feed delivery in wk 4. The starch content in cecal digesta was 2.8, 2.6, and 7.4% of DM for the control, APSC, and GPSC treatments, respectively. Relative qPCR quantification was used to determine the relative changes of bacterial groups during SARA challenges compared with control. Both GBSC and APSC increased *P. bryantii* and *S. ruminantium*, but decreased *S. bovis* in the rumen. Only GBSC increased *M. elsdenii* in the rumen. *E. coli* was undetectable in the rumen. In the cecum, both GBSC and APSC increased *P. ruminicola*, whereas only GBSC increased lactobacillus and *E. coli*, and decreased *S. bovis*. Across treatments, all selected bacteria groups, with the exception of *M. elsdenii*, *S. bovis* and lactobacillus were higher in the rumen than in the cecum. Results indicate that the balance between lactate producers and lactate utilizers and increased *E. coli* numbers in the hindgut may play a role in the inflammatory response commonly associated with grain-based SARA.

Table 1. Relative change (log2) to control

	Rumen		Cecum	
	GBSC	APSC	GBSC	APSC
Prevotella bryantii	2.8*	1.6*	1.0	0.7
Prevotella ruminicola	0.2	−0.2	1.8*	1.9*
Ruminobacter amylophilus	1.8[a]	−0.8[b]	−0.1	2.5
Fibrobacter succinogenes	−0.02	1.0	2.0	2.2
Selenomonas ruminantium	2.5*	1.9*	0.1	0.8

W322 Interactions between mild protein imbalance and taste preference in young ruminants. A. Bach*[1], J. J. Villalba[2], and I. R. Ipharraguerre[3], *[1]ICREA and Ruminant Production-IRTA, Barcelona, Spain, [2]Utah State University, Logan, [3]Lucta, S.A., Barcelona, Spain.*

Thirty-two crossbred lambs (BW = 31.2 ± 4.7 kg) distributed in individual pens were used to determine whether an imbalanced protein supply would alter preferences for feeds containing flavors designed to elicit either umami (U) or a mix (33.3:33.3:33.3%) of umami, sweet, and bitter (M) taste. Lambs were randomly allocated to either a low (LP; 10.9% CP) or a high (HP; 20.4% CP) protein diet for 21 d. Afterward, lambs were presented during 21 d with a choice of the same LP or HP diet unflavored (LPC or HPC) or flavored either with U (LPU or HPU) or M (LPM or HPM) at 0.1% as fed in a 2× 2 factorial design with 8 replicates per treatment. Diets were offered ad libitum and intake was recorded daily. Blood samples were drawn on d 14 to assess blood urea N (BUN). Data were analyzed using a mixed-effects model for repeated measures accounting for random effect of animal within treatment and the fixed effects of treatment, time, and their interaction. During the first 21 d of study, feeding LP decreased ($P < 0.05$) DMI, ADG, and feed efficiency compared with HP. The restricted intake of CP caused by LP was further evidenced by the lesser ($P < 0.001$) BUN concentrations in LP lambs (7.63 ± 1.07 mg/dl) compared with HP lambs (18.81 ± 1.07 mg/dl). When offered a choice, all lambs showed a preference for the unflavored diet except for LP lambs which clearly ($P < 0.001$) preferred LPU (72% of total DMI) over LPC. However, preference for LPU progressively decreased ($P < 0.05$) as time of exposure to the choice increased. In summary, protein-restricted lambs were able to differentiate the umami-flavored feed and increase preference for and consumption of such feed probably in an attempt to fulfill their protein requirements. However, the increase in preference and consumption of the umami-flavored low-CP diet disappeared over time. This response was most likely a consequence of the overriding effects of metabolic control of intake elicited by the absence of a concomitant dietary supply of protein.

Key words: diet selection, sheep, flavor

W323 Evaluation of RumeNext-D and monensin in early lactation diets for dairy cattle. J. P. McNamara*[1], G. Duncan[1], R. Bose[1], S. Rocco[1], J. Kay[1], P. Doane[2], and K. L. Perfield[3], *[1]Washington State University, Pullman, [2]ADM Research, Des Moines, IA, [3]Elanco Animal Health, Indianapolis, IN.*

The plant botanicals eugenol and cinnamaldehyde (RumeNext-D), as well as the ionophore monensin, have been shown to positively affect performance of early lactation dairy cows. To test the effects of RumeNext-D (RND), monensin (MON) and the combination of the 2 (BOTH), on lactation performance of dairy cattle in early lactation as well as the relationship of productive responses and body compositional changes to estimate overall efficiency we used randomized complete block with parity (1 and 2) and genetic merit as blocks, with treatments (n = 15): 1) Control (CTL), 2) RND, 3) MON and, 4)BOTH. Alfalfa and triticale silage based diets with a corn, barley, peas and SBM based grain mix began at 21 DIM and continued to 111 DIM (d 13 through d 20 postpartum were used as a covariate). Monensin was mixed in the TMR at 14 g/ton (targeted 400 mg/d) and RND was included at 600 mg/d into the grain mix of the TMR. There was an effect of parity such that feed intake, milk yield and BW were all greater in 2nd parity animals. For most variables, there was a random effect of the covariate period. Dry matter intake (DMI) was 20.5, 21.0, 22.1 and 20.9 (SEM = 0.4) for the 4 treatments, respectively, 1.5 kg/d greater for the MON group versus CTL and 0.4 kg/d greater than control for RND or BOTH fed groups. However, with the covariate included, there was no significant effect of treatment on DMI. Milk yields were 34.2, 34.2, 36.5 and 34.9 kg/d (SEM = 1.1 kg/d) for the 4 treatments, respectively. Monensin increased ($P < 0.04$) milk yield 2.3 kg/d over the 3 mo experimental period and MON significantly ($P < 0.01$) increased milk protein yield by 0.15 kg/d over the CTL group. There was no effect of any treatment on milk fat or milk protein content or milk fat yield. Rumen pH (22 h after feeding) was approximately 6.2 and declined slightly as lactation progressed, there were no differences among treatments. Body weight and BCS did not change among treatments Monensin increased milk yield and milk protein yield, as previously demonstrated, however there did not appear to be an effect of the plant botanicals eugenol and cinnamaldehyde.

Key words: efficiency, monensin, plant botanicals

W324 Comparing a 40-d dry period with a single close-up diet with a 60-d dry period with far-off and close-up diets on glucose, lactate, and calcium in the blood plasma of dairy cows. H. Khazanehei*, S. Li, D. O. Krause, M. L. Connor, L. Lippins, and J. C. Plaizier, *University of Manitoba, Winnipeg, MB, Canada.*

Effects of a 40-d dry period with a single close-up diet (40-d) with a 60-d dry period with far-off and close-up diets (60-d) on glucose, lactate, and calcium in blood plasma were compared. Twenty-six multiparous Holstein cows were paired based on the expected calving date and within pairs randomly assigned to 1 of 2 treatments. The 60-d dry period was divided into a 39-d far-off period and a 21-d close-up period. The far-off diet contained (DM basis) 1.29 Mcal/kg NEL, 12.0% CP, 38.7% NDF, and 0.79% Ca. The close-up diet contained 1.43 Mcal/kg NEL, 14.7% CP, 34.0% NDF, and 0.78% Ca. After calving, all cows received a diet containing 1.71 Mcal/kg, 17.6% CP, 29.7% NDF, and 0.97% Ca. Blood samples were taken weekly from wk 3 prepartum to wk 9 postpartum. Blood plasma was analyzed for glucose, lactate, and Ca. Data were analyzed as repeated measures under a randomized block design using the MIXED procedure of SAS. Cows on the 40-d treatment had higher blood glucose at 3 wk before calving, and at 1 wk and 5 wk after calving. Cows on the 40-d treatment also had higher blood lactate at 1 wk after calving and higher blood calcium at 3 wk before and 2 wk after calving. The treatment differences at 3 wk before calving may be explained by the switch in diet that cows on the 60-d treatment, but not cows on the 40 d treatment made at that time. Treatment differences at wk 1 and 2 may have been due to the lower milk yields of the cows on the 40-d treatment.

Table 1. Concentrations of glucose, lactate, and calcium in the blood of dairy cows

Relative to Calving	Glucose (mg/dL)			Lactate (mmol/L)			Calcium (mmol/L)		
Week	40-d	60-d	*P*-value	40-d	60-d	*P*-value	40-d	60-d	*P*-value
−3	86	71	0.03	2.51	2.06	0.28	1.06	0.97	0.04

W325 A meta-analysis on the effects of supplementing exogenous fibrolytic enzyme products in dairy diets on productive performance in early lactation. J.-S. Eun*[1], C. M. Williams[2], and A. J. Young[1], *[1]Department of Animal, Dairy, and Veterinary Sciences, Utah State University, Logan, [2]Department of Soil and Crop Sciences, Colorado State University, Fort Collins.*

There have been several studies to examine the effects of exogenous fibrolytic enzyme (EFE) products on milk production of dairy cows. When viewed across all studies the variability in response is high, as a range of different enzyme products and experimental conditions were used. Thus, we performed a meta-analysis to assess production responses when EFE were supplemented in early lactation dairy diets. Supplementing EFE is likely to be more beneficial to early lactating cows than mid- to late lactating cows. Therefore, a database was developed from 10 studies recently published in the J. Dairy Sci. using early lactating dairy cows. In addition, the best responding treatment was chosen if an individual study tested various enzyme treatments, because efficacy of EFE depends on rate of dose, method of providing enzymes, and diet composition. A mixed model regression analysis with random study effect was used to evaluate relationships between supplementation of EFE and lactational performance parameters. Supplementing EFE increased DMI ($P = 0.05$), milk yield ($P < 0.01$), and ECM yield ($P = 0.04$) by 0.5 (2.2% increase), 2.3 (6.6% increase), and 1.7 kg (4.7% increase) units, respectively, but did not affect milk fat ($P = 0.27$) and protein ($P = 0.82$) concentrations. While milk fat yield was not affected by EFE supplementation, milk protein yield increased by 0.06 kg unit (5.5% increase; $P = 0.02$). Milk production efficiency (milk yield/DMI) was improved by 0.07 units (4.6% increase; $P = 0.01$). Although the meta-analysis data set only included 10 studies, it is evident from the positive animal responses that EFE additives can be an effective means to improve productive performance of early lactating dairy cows. A better understanding of the factors affecting animal response to EFE supplementation will help ensure cost-effective use of these additives on-farm.

Key words: early lactating dairy cows, exogenous fibrolytic enzymes, meta-analysis

W326 Evaluation of dietary fat from dried distillers grains in the diet Holstein heifers on growth and dry matter intake. J. L. Anderson*, K. F. Kalscheur, A. R. Hippen, and D. J. Schingoethe, *South Dakota State University, Brookings.*

The objective of this study was to determine how increased dietary fat from dried distillers grains with solubles (DDGS) in diets of growing heifers affects DMI, ADG, and growth. Thirty-three Holstein heifers (133 ± 18 d old) were used in a 24-wk randomized complete block design. Treatments were: 1) control (C) containing ground corn (15.9% of DM) and soybean products (17.9%), 2) low-fat (LF) containing low-fat, high-protein DDGS (21.9%) and ground corn (11.9%), and 3) high-fat (HF) with traditional DDGS (33.8%). All diets contained 39.8% grass hay, 24.8% corn silage, and 1.5% vitamins and minerals. Diets were formulated for 16.3% CP (DM basis) 9.8% RDP and 6.5% RUP. The HF diet contained 4.8% fat compared with 2.8% in the C and LF diets, which were greater in NFC. Diets were 1.0 Mcal/kg of DM and limit-fed at 2.45% of BW. Heifers were weighed every 2 wk and rations adjusted accordingly. Every 2 wk, heart girth, hip height, wither height, body length, and BCS were recorded. No treatment × time interactions were found. Dry matter intakes were similar, averaging 7.01, 7.01 and 6.89 kg/d (SEM = 0.26) for C, LF, and HF, respectively. Body weights were similar among treatments (248.4, 243.9, 244.2 kg, SEM = 8.06), as were ADG (0.92, 0.90, 0.91 kg/d, SEM = 0.07). Heart girth was similar among treatments (137.7, 138.2, 144.7 cm, SEM = 3.51). Hip height was less ($P < 0.01$) for heifers fed HF (118.3 cm) compared with those fed C (119.7) and LF (119.3, SEM = 1.18). Wither height was greater ($P = 0.02$) for heifers fed LF (115.3 cm) compared with HF (114.4), and tended ($P = 0.09$) to be greater compared with heifers fed C (114.6), but C and HF were similar (SEM = 1.01). Body length was longest ($P < 0.01$) for heifers fed C (105.0 cm), shortest for HF (102.6), with LF (103.7) in between (SEM = 1.47). Overall BCS were similar for heifers fed C and LF (3.05), but greater ($P = 0.04$) for HF (3.09, SEM = 0.02). Despite similar BW, ADG, and DMI, feeding diets with additional fat from including DDGS compared with diets with low-fat DDGS or corn and soybean products to growing heifers may result in slightly greater BCS and slightly smaller body frame sizes.

Key words: distillers grains, heifers

W327 Bee pollen and its polysaccharides, the new feed additives in milk replacer of preruminant calves. Y. Tu*, G.-F. Zhang, N.-F. Zhang, C.-G. Jiang, and Q.-Y. Diao, *Key Laboratory of Feed Biotechnology of Ministry of Agriculture/Feed Research Institute, Chinese Academy of Agricultural Sciences, Beijing, P.R. China.*

The experiment investigated the influence of lotus bee pollen and polysaccharides extracted from lotus bee pollen on growth performance and nutrient digestibility in preruminant calves. Twenty-five neonatal Chinese Holstein female calves were randomly allotted to 5 groups, and each group was offered a milk replacer (MR) supplemented with 0 (control, C), 10 (10BP), 25 (25BP) or 50 g (50BP) lotus bee pollen/kg MR, or 5 g (5PS) polysaccharides/kg MR for 63 d. The MR, containing 20.41 MJ digestible energy/kg, 26.16% crude protein (CP) and 15.62% ether extract (EE), was fed at 11.0% of live weight of the calves, and a starter ration was offered ad libitum from 28 d thereafter. Average daily gain (ADG), average daily feed intake (ADFI) and feed/gain ratio (F/G) were measured fortnightly. A 3-d digestion trial by total collection of feed refusals, feces, and urine was conducted from 26 to 28 d and from 47 to 49 d, respectively. The apparent digestibility of dry matter (DM), CP, EE, Ca and total P was calculated. Data were analyzed by GLM procedure of SAS® software. The results showed that, compared with group C, ADG was significantly higher in the calves from group 25BP or group 5PS (656.6 vs 808.7 or 797.5 g/d, $P < 0.05$); F/G was decreased by 12.85% in the calves from group 25BP (1.79 vs 1.56, $P < 0.05$); there was no significant differences in ADFI among the groups. The apparent digestibility of DM during 26 to 28 d was increased by 8.38% and 7.66% respectively in the calves from groups 25BP and 5PS (79.02% vs 85.64% and 85.07%, $P < 0.05$); the apparent digestibility of CP was increased by 18.63% in the calves from group 25BP (66.35% vs 78.71%, $P < 0.05$). No differences in the apparent digestibility of the nutrients were detected among the groups during 47 to 49 d ($P > 0.05$). In conclusion, supplementation of bee pollen or its polysaccharides at 25 or 5 g/kg MR, respectively, improved ADG, F/G and apparent digestibility of DM and CP in preruminant calves.

Key words: bee pollen, calves, growth and apparent digestibility

W328 Effect of lipopolysaccharides on immune parameters and nitrogen metabolism in preruminant calves. N.-F. Zhang, H. Li, Y. Tu*, C.-G. Jiang, and Q.-Y. Diao, *Feed Research Institute, Chinese Academy of Agricultural Sciences, Beijing, P.R. China.*

This study investigated the effect of immunological stress on immune parameters and nitrogen metabolism in preruminant calves. Forty male Chinese Holstein calves of 24 d old were randomly divided into 2 groups with 20 calves each, and one group was injected intraperitoneally with 2.5 μg *E. coli* lipopolysaccharides (LPS)/kg BW at 24, 26 and 28 d of age, and the other was injected with an equivalent volume of sterile saline. Rectal temperature was measured at 30, 90, 150 and 210 min after injection. A total collection of feces and urine was conducted between 25 and 27 d for analysis of nitrogen metabolism. Plasma samples were collected 60, 120 and 180 min after injection for analysis of urea nitrogen, interleukin-1β (IL-1β), tumor necrosis factor-α (TNF-α), complement C3, interleukin-2 (IL-2) and interleukin-4 (IL-4). The body temperature was elevated significantly 150 and 210 min after the challenge of LPS ($P < 0.05$). The plasma concentration of IL-1β and TNF-α was increased significantly 120 and 180 min after the challenge of LPS ($P < 0.05$), the plasma complement C3 was decreased significantly 120 min after the challenge of LPS ($P < 0.05$), and the plasma IL-2 (Th1 type cytokine) ($P < 0.05$), IL-4 (Th2 type cytokine) and the ratio of IL-2 to IL-4 were increased following the challenge of LPS. The plasma urea nitrogen was increased significantly 120 min postinjection of LPS ($P < 0.05$). The urinary concentration of nitrogen was higher ($P < 0.05$), but the nitrogen retention and apparently biological value of nitrogen were lower in the LPS-challenged calves than control. The results suggested that the immunological stress induced inflammatory responses, activated immune responses, and shifted immune responses from Th2 type to Th1 type, and then suppressed the nitrogen retention and decreased the utilization efficiency of nitrogen in the calves.

Key words: immunological stress, nitrogen metabolism, calves

W329 Partially replacing barley grain with wheat factory sewage in the dairy cow diets did not affect digestion and milk production. M. Khorvash[1], S. Kargar[1], G. R. Ghorbani[1], M. Borou-

mand-Jari[2], A. Ghaempour[1], and W. Z. Yang*[3], *[1]Isfahan University of Technology, Isfahan, Iran, [2]Jahad-Agriculture Institute of Scientific-Applied Higher Education, Isfahan, Iran, [3]Agriculture and Agri-Food Canada, Research Centre, Lethbridge, Alberta, Canada.*

The objective of this study was to evaluate whether wheat factory sewage (WFS) could partially replace barley grain in the diet of dairy cows without adversely affecting DMI, rumen fermentation, digestibility, and milk production of dairy cows. Eight multiparous (60 ± 3 DIM) Holstein cows were used in a replicated 4 × 4 Latin square designed experiment with 4 21-d periods. The basal diet was formulated with 22% corn silage, 22% alfalfa hay and 56% barley grain-based concentrate (DM basis); barley grain was partially replaced with 0% WFS (WFS0), 4% (WFS26), 6% (WFS39) or 8% WFS (WFS52). Data were analyzed using the MIXED model procedure of SAS to account for diet as fixed effect and square, cows within square and period within square as random effect. DM content of diets linearly ($P < 0.01$) decreased from 65, 59, and 57 to 54% with increasing the inclusion of WFS due to high water content of WFS (80%). DMI was quadratically changed ($P < 0.04$) to be higher for WFS26 (23 kg/d) than for other 3 diets which were similar (21 kg/d). Rumen total VFA (100 to 103 mM), molar proportion of acetate (65 to 67%), propionate (24 to 25%), and ratio of acetate to propionate (2.68 to 2.89) were not affected with increasing the replacement of barley grain by WFS. Apparent total-tract digestibilities of DM (67%), CP (68%) and NDF (54%) were not different among treatments. Milk yield (averaged 40 kg/d) and milk composition were not affected by the diets. Results showed that partially replacing 26, 39 and 52% of barley grain with WFS in dairy cow diets decreased DM content but had no adverse effects on DMI, rumen fermentation, digestibility, and milk production responses. It suggests that WFS can be used as alternative to grain to feed dairy cattle.

Key words: barley grain, wheat factory sewage, dairy cow

W330 Effects of dietary crude protein level on eating pattern and performance of Holstein calves. G. Araujo[1], M. Devant[1], A. Mereu[2,1], I. Ipharraguerre[2], and A. Bach*[3,1], *[1]Deparment of Ruminant Production, Institut de Recerca i Tecnologia Agroalimentàries (IRTA), Barcelona, Spain, [2]Lucta, S.A., Barcelona, Spain, [3]Institució Catalana de Recerca i Estudis Avançats (ICREA), Barcelona, Spain.*

The objective of this study was to evaluate changes in eating pattern and performance of calves fed 2 isoenergetic concentrates differing in CP concentration. Seventy 5 male Holstein calves (initial BW 246 ± 29 kg and 211 ± 24 d of age) were housed in 4 homogenized groups of 18 to 20 animals each according to ages and weights. One dietary treatment consisted on a concentrate containing 18% CP on DM basis (HP) and the other contained 16% CP on a DM basis (LP). In addition to concentrates, calves had ad libitum access to barley straw on a separate feeder. Animals were weighed on d 0, 14, and 28 of study and individual concentrate intake was monitored daily using an electronic feeding system. Data were analyzed with a mixed-effects model with pen as a random effect and treatment and day as fixed effects, with time entering the model as a repeated measure. Calves receiving HP spent more ($P < 0.05$) time eating concentrate (42 ± 0.7 min/d) than those receiving LP (38 ± 0.7 min/d). However, the number of meals per day was similar for both treatments (9.0 meals/d for HP and 9.3 meals/d for LP) and average meal interval of HP calves (168.1 ± 2.8 min) was longer ($P < 0.01$) than that of LP (161.5 ± 2.8 min). This was mainly due to the greater ($P < 0.001$) meal length observed with HP (5.3 ± 0.1 min/meal) than with LP calves (4.5 ± 0.1 min/meal). Meal size was also greater ($P < 0.001$) in HP (845.4 ± 19.2 g/meal) than in LP (790 ± 19 g/meal) calves. Furthermore, eating rate of HP calves (163 ± 4 g/min) was slower ($P < 0.001$) compared with calves consuming the LP concentrate (185 ± 4 g/min). Although concentrate intake did not differ between both treatments (6.7 kg/d), HP calves tended ($P = 0.05$) to grow more (1.67 ± 0.02 kg/d) than LP (1.56 ± 0.02 kg/d) calves, and as a consequence HP calves were numerically ($P = 0.35$) more efficient (26.6 ± 0.9%) than LP calves (24.9 ± 0.9%) converting consumed nutrients into gain. In conclusion, concentrates containing 18% CP tend to result in improved ADG compared with 16% CP levels due to increased CP supply and changes in eating pattern, mainly increased meal size and length and decreased eating rate, but not due to changes in DMI.

Key words: feeding behavior, intake regulation, efficiency

W331 Feeding distiller′s grains as an energy source to gestating and lactating heifers: Impact on calving and pre-weaning progeny performance. P. J. Gunn*[1], J. P. Schoonmaker[1], R. P. Lemenager[1], and G. A. Bridges[2], *[1]Purdue University, West Lafayette, IN, [2]University of Minnesota, Grand Rapids*.

Angus-cross beef heifers pregnant to a single sire (n = 80; BCS = 5.1 ± 0.03; BW = 518 ± 6 kg) were used to determine the effects of feeding dried distiller′s grains with solubles (DDGS) as an energy source during the late gestation and early lactation on calving parameters and offspring growth through weaning. At 192 d in gestation, heifers were allotted by BW within BCS to receive either a control diet of corn silage and haylage (CON; 10% CP prepartum; 11.8% CP postpartum) or corn residue and DDGS, where DDGS were fed at 1.2% of BW per d (DG; 15.7% CP). Diets were formulated to be isocaloric (1.0 Mcal/kg NEg). Dietary treatments concluded and cattle were commingled 30 d after timed-AI (118 ± 0.1 d postpartum; DPP). Heifer BW and BCS (1–9) were assessed every 28 d. Calving score (1 = no assistance; 5 = C-section) and calf vigor at birth (1 = nursed on own; 4 = died after birth) was evaluated. Calf weights were taken at birth and at weaning (191 ± 0.6 d of age). Milk production was assessed via weigh-suckle-weigh procedure at 66 ± 0.6 DPP. Heifer BW never differed between treatments ($P \geq 0.33$), but BCS was greater before calving (5.8 vs. 5.3; $P < 0.01$) and at conclusion of dietary treatments (5.6 vs. 5.4; $P < 0.01$) for CON than DG heifers, respectively. Gestation length was greater ($P = 0.03$) for DG (278 ± 0.7 d) than CON (276 ± 0.6 d) heifers. Sex ratio and vigor of calves did not differ ($P \geq 0.69$). Birth weight (36.7 ± 0.7 vs. 32.5 ± 0.7 kg) and rate of dystocia (59 vs. 24%) was greater ($P < 0.01$) in DG than CON progeny, respectively. Although dam milk production did not differ between treatments ($P = 0.86$), weaning weight was greater ($P = 0.05$) for DG progeny (244 ± 3.6 kg) than CON (234 ± 3.7 kg). In summary, feeding DDGS at 1.2% of BW per d to gestating heifers resulted in greater birth weights, dystocia rates and weaning weights of the DG progeny without altering milk production, suggesting this dietary strategy induced developmental programming changes that increased progeny pre-weaning performance.

Key words: beef heifers, DDGS, developmental programming

W332 Feeding distillers grains as an energy source to gestating and lactating heifers: Impact on milk production, composition, and fatty acid profile. P. J. Gunn*[1], J. P. Schoonmaker[1], R. P. Lemenager[1], and G. A. Bridges[2], *[1]Purdue University, West Lafayette, IN, [2]University of Minnesota, Grand Rapids.*

Angus-cross beef heifers pregnant to a single sire (n = 80; BCS = 5.1 ± 0.03; BW = 518 ± 6 kg) were used to determine the effects of feeding dried distillers grains with solubles (DDGS) as an energy source during late gestation and early lactation on milk production, composition, and fatty acid profile. At 192 d in gestation, heifers were allotted by BW within BCS to receive either a control diet of corn silage and haylage (CON; 10% CP prepartum; 11.8% CP postpartum) or corn residue and DDGS, where DDGS were fed at 1.2% of BW per d (DG; 15.7% CP). Diets were formulated to be isocaloric (1.0 Mcal/kg NEg). Dietary treatments concluded and cattle were commingled 30 d after timed-AI (118 ± 0.1 d postpartum; DPP). BW and BCS were assessed every 28 d during treatment and did not differ during milk data collection. At 65 ± 0.6 DPP, milk samples were collected to determine composition and fatty acid profile. The following day, milk production was assessed via 24 h weigh-suckle-weigh. Total milk production (8.8 ± 0.4 kg/d), milk protein, and lactose content did not differ ($P \geq 0.38$). However, milk fat (223 ± 15 vs. 121 ± 14 g/d), total solids (1084 ± 44 vs. 951 ± 40 g/d), and energy corrected milk production (7.8 ± 0.4 vs. 6.5 ± 0.3 kg/d) was greater ($P \leq 0.03$) in CON than DG, respectively. Milk urea N (MUN) was greater in DG (16.4 ± 0.5 mg/dL) than CON (7.1 ± 0.6 mg/dL; $P < 0.01$). Short- (3.7 ± 0.2 vs. 2.3 ± 0.2 g/100 g) and medium-chain fatty acids, (17.3 ± 0.4 vs. 10.1 ± 0.4 g/100 g) and SFA (64.3 ± 1.1 vs. 47.5 ± 0.9 g/100 g) content was greater ($P < 0.01$) in CON than DG, respectively. In contrast, long chain fatty acids (87.7 ± 0.5 vs. 79.0 ± 0.6 g/100 g), MUFA (44.7 ± 0.9 vs. 32.0 ± 1.0 g/100 g), PUFA (7.8 ± 0.2 vs. 3.6 ± 0.2 g/100 g), and CLA (3.4 ± 0.1 vs. 0.9 ± 0.1 g/100 g) content was greater ($P < 0.01$) in DG than CON, respectively. In summary, feeding DDGS at 1.2% of BW per d to first-parity heifers resulted in decreased milk fat, milk solids, and energy corrected milk production, but greater MUN, long chain fatty acids, CLA, MUFA, and PUFA in the milk produced.

Key words: beef heifer, DDGS, milk

W333 Effect of extruded flax products on dairy cow milk and steer tissue fatty acid composition. D. A. Christensen*, P. Yu, J. J. McKinnon, and A. Foth, *University of Saskatchewan, Saskatoon, SK, Canada.*

Several benefits have been attributed to omega-3 content of milk and ruminant products. The objective of this research was to determine the effect of extruded flax products on fatty acid content of milk, organs and meat. To determine effect on milk 6 early lactation Holstein cows were fed a barley silage, alfalfa hay, barley grain, canola meal, SBM based ration for 28 d, then 5.8% of DM of an extruded product (Oleet Processing, Regina SK) replacing concentrate for 28 d followed by a second control period of 28 d. The extruded product contained 54% flax, 38% pea grain, 8% alfalfa meal, vitamin E and ethoxyquin. Extrusion temperature was 143°C. Six large frame crossbred steers were fed a similar product as 18% of ration DM which contained 36% flax seed and 20% canola seed for 70 d before slaughter. Three additional steers were fed a control barley grain, barley silage finishing ration. Milk yield in the test feeding period averaged 46.6 kg and 3.36% fat. Milk C18:3n3 (ALA) increased from 0.49% of fatty acid methyl esters (FAME) to 0.83% ($P < 0.01$) in the test period and declined to 0.46 in the second control period. C18:2 c9-t11 (CLA) increased from 0.30 to 0.60 ($P = 0.07$) then declined to 0.32% of FAME in the second control period. EPA, DPA and DHA were 0.07% of FAME or less. Total milk omega-3 fatty acids increased from 0.59 to 1.04% then declined to 0.60% of FAME 28 d after the extruded product was withdrawn. In steer liver ALA increased from 0.71% to 2.28% ($P < 0.01$). Liver EPA increased from 0.71 to 1.61% of FAME ($P = 0.03$). The increase in DHA from 1.74 to 2.04% of FAME was not significant ($P = 0.29$). Total liver omega-3 increased from 7.36 to 12.9% of FAME. Ribeye (L. dorsi) ALA increased from 0.25% to 0.78% of FAME ($P < 0.01$) with no other significant effects. Fatty acids in loin, shoulder and chuck meat samples showed a similar pattern to ribeye with the main effect being an increase in ALA. Substantial extruded product effects on ALA content of liver, milk, and meat samples were observed.

Key words: milk, meat and organ, fatty acids

W334 Grain source and alfalfa hay particle size effects on fecal fermentability and particle size in midlactation Holsteins. A. Nikkhah*[1], S. M. Nasrollahi[2], M. Khorvash[2], and G. R. Ghorbani[2], *[1]University of Zanjan, Zanjan, Iran, [2]Isfahan University of Technology, Isfahan, Iran.*

The objective was to determine independent and interactive effects of alfalfa hay particle size and grain source on fecal fermentability and particle size. Eight Holstein cows (175 d in milk) in a replicated 4 × 4 Latin square design with four 21-d periods were fed 4 diets with either finer (FA) or coarser (CA) chopped alfalfa hay, with either ground barley (GB) or a 50:50 ratio of ground barley and corn grains (BC). Diets were offered ad libitum as mixed rations with forage to concentrate ratio of 40:60 (DM based). Geometric mean particle size was 4.33 and 3.43 mm for CA and FA, respectively; and 3.8, 3.6, 3.7, and 3.4 mm for CAGB, FAGB, CABC, and FABC, respectively. Feces were sampled for 5 d directly from rectum before morning feeding. Acid insoluble ash was used as an internal marker to estimate fecal outputs. Wet sieving was utilized to measure feces particle size. Feed and fecal potential fermentability was measured after 48 h of rumen incubation in situ through cannula. Data were analyzed using Mixed Procedures of SAS with linear models consisting of fixed period, grain source, hay particle size, and grain source × hay particle size effects, plus cow and residuals random effects. Feed potential fermentability was similar among CAGB (84.35%), FAGB (84.33%), CABS (84.35%), and FABC (84.46%). However, fecal fermentability was greater for BC vs. GB (67.8 vs. 64.4%, $P < 0.01$). Fecal fermentable DM as % of DMI was similar among CAGB (33.9), FAGB (34.1), CABC (33.3), and FABC (32.0). Fecal fineness was not significantly different. Rumen pH was higher for CA vs. FA (6.45 vs. 6.27, $P < 0.05$), while similar for GB vs. BC (6.36 vs. 6.37). Data suggest that greater amount of partially digested organic matter escaped the gastrointestinal tract digestion for BC vs. GB, that agrees with greater DMI for BC vs. GB (25.6 vs. 24.3 kg/d, $P < 0.05$). Hay particle size and grain source interactions did not affect fecal properties. Results suggest that dietary grain source and not hay particle size can affect fecal fermentability in midlactation dairy cows.

Key words: fecal fermentability, grain source, alfalfa hay

W335 Textured versus ground starter effects on Holstein calves chewing behavior. A. Nikkhah*[1], S. M. Nasrollahi[2], B. Raad[2], S. Khorsandi[2], M. Forootan[2], and S. P. Emami Panaah[2], *[1]University of Zanjan, Zanjan, Iran, [2]Foeka Agriculture and Dairy Corporation, Isfahan, Iran.*

The objective was to determine effect of calf starter physical form on chewing activity. Thirty-two Holstein calves (16 males and 16 females, 41 ± 2.8 kg body weight) were offered from 4-d of age until weaning an either textured (T) (with steam flaked grains plus peletted non-grains) or fully ground (G) starter feed. Each treatment had 8 male and 8 female calves. Feed composition and calf management were

exactly the same for both groups. On d-60 of age, eating, ruminating and resting times were recorded visually every 5 min. Each activity was assumed to persist for the entire 5-min if occurred. Accordingly, meal size and eating rate per kg of dry mater intake and per minute of eating were calculated. Data were analyzed using Mixed Procedures of SAS as linear completely randomized models with fixed effect of starter physical form, and random effects of calf within treatment plus residuals. Daily starter intake (1.67 vs. 1.55 kg), duration of eating (126.7 vs. 117.0 min/d), ruminating (325.3 vs. 324.6 min/d), and resting (981.5 vs. 991.8 min/d), and per kg starter intake of eating (76.5 vs. 74.3 min) and ruminating (199 vs. 186 min) activities were not significantly different between T and G, respectively. Daily number of eating (24.3 vs. 24.4) and ruminating (15.3 vs. 13.7) bouts, mean eating bout size (68 vs. 64 g), and average bout length of eating (5.5 vs. 5.2 min) and ruminating (21.8 vs. 23.6 min) were also similar for T vs. G, respectively. In summary, results suggest that whether starter is textured or finely ground may not affect young calf eating and chewing behaviors.

Key words: calf chewing, physical form, starter

W336 Changes in long-chain polyunsaturated fatty acid status of dairy cows during the periparturient period based on erythrocyte-membrane fatty acids. C. L. Preseault[1], H. M. Dann[2], and A. L. Lock*[1], *[1]Michigan State University, East Lansing, [2]William H. Miner Agricultural Research Institute, Chazy, NY.*

This study examined shifts in long-chain polyunsaturated fatty acid (LCPUFA) status of dairy cows during the periparturient period using erythrocyte membrane (EM) FA profiles. It was hypothesized that EM FA could be used to assess LCPUFA changes in dairy cows because they have been used previously in human studies to assess long-term FA status. Two groups of cows (11/treatment) were fed a low-energy, high-straw diet during a 40 d dry period, and then fed either a low-starch (22%) diet, or a high-starch (26%) diet for the first 91 DIM. Blood samples were collected at −14 d before projected calving date (DRY), at 21 DIM (EARLY), and at 90 DIM (MID). Data was analyzed as repeated measures using SAS proc mixed. There was no effect of dietary treatment at any time point on EM FA. Sampling time did not affect EM concentrations of total saturated or cis PUFA (47.6 and 22.6 g/100 g FA, respectively). Total cis MUFA concentration was 26.6, 27.7, and 24.9 g/100 g FA for DRY, EARLY and MID, respectively ($P < 0.05$). The ratio of n-6/n-3 FA was 9.9, 9.1, and 11.2 for DRY, EARLY and MID, respectively ($P < 0.01$). There was a trend for total n-6 FA to be lower in EARLY ($P = 0.08$) whereas total n-3 FA were not different across time. EM concentrations of individual n-6 FA were consistently lower at EARLY, whereas individual n-3 FA were consistently lower at MID compared with the other times. Comparing EARLY to MID, the EM concentration of C18:2 n-6 was 11% lower ($P < 0.1$), C20:2 n-6 31% lower ($P < 0.001$), C20:3 n-6 37% lower ($P < 0.001$), and C22:4 n-6 38% lower ($P < 0.001$). Comparing MID to EARLY, the EM concentration of C18:3 n-3 was 11% lower ($P < 0.05$), and C20:3 n-3 30% lower ($P < 0.05$). Neither C20:5 n-3 nor C22:5 n-3 were different across time; 22:6 n-3 was not detected in cow EM. Total trans C18:1 was 19% higher in EARLY and MID compared with DRY ($P < 0.001$). Results demonstrate potential differences in LCPUFA status of cows during the periparturient period. Whether EM FA profiles provide a robust measure of LCPUFA status and if these changes affect animal production and health remain to be determined.

Key words: erythrocyte membrane, long-chain PUFA, transition cows

W337 A 40-d dry period with a single close-up diet and a 60-d dry period with far-off and close-up diets differ in their effects on lipolysis and liver triacylglycerol. H. Khazanehei*, S. Li, D. O. Krause, M. L. Connor, L. Lippins, and J. C. Plaizier, *University of Manitoba, Winnipeg, MB, Canada.*

Effects of a 40-d dry period with a single close-up diet (40-d) with a 60-d dry period with far-off and close-up diets (60-d) on β-hydroxybutyrate (BHBA) and nonesterified fatty acids (NEFA) in blood plasma and triacylglycerol (TAG) in liver samples were compared. Twenty 6 multiparous Holstein cows were paired based on their expected calving date. Cows within pairs randomly were assigned to 2 treatments. The 60-d dry period was divided into a 39-d far-off period and a 21-d close-up period. The far-off diet contained (DM basis) 1.29 Mcal/kg NEL, 12.0% CP, and 38.7% NDF. The close-up diet contained 1.43 Mcal/kg NEL, 14.7% CP, and 34.0% NDF. After calving, all cows received a diet containing 1.71 Mcal/kg, 17.6% CP, and 29.7% NDF. Blood samples were taken weekly from wk 3 prepartum to wk 9 postpartum, and were analyzed for BHBA and NEFA. Liver biopsies were obtained at wk 3 prepartum, and at wk 1 and wk 4 postpartum, and were analyzed for TAG. For both treatments TAG was low at 3 wk before calving, increased at 1 wk after calving, and remained high at 4 wk after calving. At 1 wk after calving cows on the 40-d treatment had higher TAG than cows on the 60-d treatment. NEFA were higher at 1 wk after calving than at 3 wk before calving. Cows on the 40-d treatment had higher NEFA at 1, 2, and 3 wk after calving than cows on the 60-d treatment. BHBA was not affected by treatments on any week before or after calving. The NEFA results mirrored the TAG results. Results suggest that during the 3 wk after calving, cows on the 40-d treatment had a deeper negative energy balance, which caused more intensive lipolysis and the accumulation of a greater amount of TAG in the liver. Results also suggest moderate fatty liver and high lipolysis in early lactation in cows on both treatments.

Table 1. Concentrations of liver TAG, and NEFA and BHBA in blood plasma

Week relative to calving	TAG (% wet weight)			NEFA (mmol/L)			BHBA (mg/dl)		
	60-d	*P*-value	40-d	60-d	*P*-value	40-d	40-d	60-d	*P*-value

W338 Reduced protein for late-lactation dairy cows. A. B. D. Pereira*[1], L. K. Zeringue[1], C. Leonardi[2], M. E. McCormick[1], and V. R. Moreira[1], *[1]Louisiana State University Agricultural Center, Baton Rouge, [2]Louisiana State University - Health Sciences Center, New Orleans.*

Excess protein in dairy cattle diets unnecessarily increases the cost of production and may contribute to environmental pollution. The objective of this experiment was to determine the effect of feeding dairy cows with 2 levels of dietary protein on milk production and manure

characteristics. The experiment was carried out with 24 lactating dairy cows (334 ± 43 DIM and 22.2 ± 3.79 kg milk yield). Cows were randomized to 4 pens in a free-stall barn equipped with Calan gates for individual TMR feeding. Control TMR (HP) was estimated to contain 16.5% CP with soybean meal as the main protein supplement. Treatment TMR (LP; 13.5% CP) was prepared using dry distillers grains plus solubles (DDGS) and rumen protected Lys (AminoShure-L, Balchem) and Met (Metasmart, Adisseo) to offset AA deficiencies in the diet. Rations contained nearly 55% forage as corn silage and Bermudagrass hay. Manure (feces and urine) samples were collected for the last 3 d of each sampling period, twice daily while cows were milked. The experiment was analyzed as a crossover design using the MIXED procedure of SAS with pen as the experimental unit. No significant difference was observed between treatments in DMI (21.0 kg/cow/d for HP and 20.4 kg/cow/d for LP; $P = 0.46$), milk yield (20.7 kg/cow/d for HP and 20.5 kg/cow/d for LP; $P = 0.91$), body weight gain (38.2 kg/cow/period for HP and 37.2 kg/cow/period for LP; $P = 0.91$) and body condition score (0.14 units/period for HP and 0.10 units/period for LP; $P = 0.91$). Water intake tended to be higher (5 L/cow/d; $P = 0.09$) for HP. Percentages of milk components were 4.18 vs. 4.25 (HP vs. LP), 3.73 vs. 3.71, 4.53 vs. 4.55, and 9.18 vs. 9.12, respectively for fat, protein, lactose, and solids non-fat ($P > 0.60$). Milk urea nitrogen decreased ($P < 0.001$) from 17.2 mg/dL with HP to 9.93 mg/dL with LP. Manure pH was significantly higher for HP than LP (7.87 for HP and 7.53 for LP, $P < 0.05$). Both, MUN and manure pH, are indicative of less nitrogen loss to the environment when cows were fed LP. This experiment suggests that performance of late-lactation dairy cows can be maintained with low-protein diets based on DDGS and supplemented with Lys and Met.

Key words: dairy cows, protein, amino acids

W339 Comparison of in vivo and in vitro NDF digestibility data in dairy cows. S. Colombini*, G. Galassi, L. Rapetti, and G. M. Crovetto, *University of Milan, Department of Animal Science, Milano, Italy.*

Aim of the study was to determine, in dairy cows, the relationship between total tract in vivo NDF digestibility (NDFD) and the NDFD predicted by CNCPS model, using the k_d determined in vitro. Six lactating Italian Friesian cows were fed in a Latin square design 3 diets with a different silage basis: corn (CS), sorghum grain (SG) and sorghum forage (SF). Diets were formulated with the CNCPS model and balanced to have a content (% DM) of 11.0, 36.0 and 26.0 of metabolizable protein, NDF and starch, respectively. Due to the different fiber contents, forages were included in the diets in different proportions (41.5, 36.7 and 28.0% on DM for CS, SG and SF diet, respectively). Cows were housed in individual metabolic chambers to allow total collection of feces. TMRs were analyzed for NDF in vitro digestibility (Ankom Daisy Incubator) to predict the k_d according to Van Amburgh et al. (2003). Rumen NDF digestibility was predicted with the model of Waldo et al. (1972) with the k_p calculated according to Seo et al. (2006). According to CNCPS, intestinal NDF digestibility was supposed to be 20% of the NDF which enters the duodenum. The content of NDF was 39.5, 45.2 and 62.5 for corn, sorghum grain and sorghum forage silages. DMI (kg/d) was lower for SF (18.2) than CS and SG (20.0 for both diets) (P=0.07). Milk yield (kg/d) was higher for CS (25.4), intermediate for SG (24.6) and lower for SF (23.6) (P=0.05). In vivo NDFD was higher for SF than SG and SF (table). The predicted NDFD was slightly higher than the in vivo values but with the same rank. The relationship between in vivo and predicted NDFD was: $y = 0.543x + 23.5$ ($r^2 = 0.45$; n = 18).

Table 1. In vivo and in vitro NDF digestibility of TMRs

Diet	CS	SG	SF	SE	P
NDFD 6h[1], %	19.8	15.3	19.2	1.61	0.16
NDFD 24h[2], %	43.0	37.8	44.7	2.25	0.14
k_d[3], /h	0.035	0.032	0.042	0.004	0.21
NDFD vivo, %	51.4	48.6	54.1	0.94	0.01
NDFD predicted, %	53.4[b]	51.8[b]	57.4[a]	1.78	0.15

W340 Effect of two different non-forage fiber sources on performance and feeding behavior of Holstein calves. L. l. Castells*[1], A. Bach[1,2], G. A. Pirisino[1], and M. Terré[1], *[1]Department of Ruminant Production, IRTA, Caldes de Montbui, Spain, [2]ICREA, Barcelona, Spain.*

The objective of this study was to evaluate the effect of 2 different non-forage fiber sources on performance and feeding behavior of Holstein calves. Fifty-nine male Holstein calves (initial BW = 44.5 ± 5.47 kg) were randomly assigned to 1 of 3 different dietary treatments that consisted on a starter (21% CP, 15% NDF) without any other supplementation (CTR) or with an additional bucket with soybean hulls (SBH) or dehydrated citrus pulp (DCP). All calves were offered 2 L of milk replacer (MR) at 12.5% DM twice daily via a bottle until 50 d of age, and then only one daily dose of 2 L of MR at 12.5% DM during the week before weaning (57 d of age). Intakes of starter, MR, and fiber sources were recorded daily and BW was recorded weekly. Calves were individually housed and bedded with wood shavings. Performance data were analyzed with an ANOVA with repeated measures, and behavior data were analyzed with a Poisson regression analysis. There were no differences in ADG and gain-to-feed ratio among treatments. Animals in the CTR treatment consumed (830 ± 44 g/d) more ($P < 0.01$) starter than those receiving SBH (610 ± 44 g/d) or DCP (450 ± 44 g/d). Calves tended ($P = 0.08$) to consume more citrus pulp than soybean hulls (59 vs 25 g/d, respectively). Total DMI tended ($P = 0.08$) to be greater in CTR and SBH than in DCP animals after weaning. Calves in DCP treatment were devoted 17% less ($P < 0.01$) time to eat starter than CTR calves, and 5% less ($P < 0.05$) time to eat non-forage fiber than those in SBH. Animals in the SBH treatment were 13.7 times more ($P < 0.05$) likely to ruminate than those in CTR, and DCP calves were 11% less ($P < 0.05$) likely to develop non-nutritive oral behaviors than CTR calves. In conclusion, providing a choice of a non-forage fiber source in the diet of young calves stimulates rumination and reduces non-nutritive oral behavior, but it reduces starter intake and tends to reduce DMI.

Key words: calves, non-forage fiber, performance

W341 Morphology of the rumen of dairy cows fed high or low grain content diets before parturition. T. S. Teófilo, J. C. Resende Júnior*, S. F. Costa, M. B. Moreira, R. F. Lima, D. O. R. B. Santoro, G. P. Lenzi, P. P. Bueno, T. M. França, and T. A. Dell Vale, *Universidade Federal de Lavras.*

Dairy cows after parturition are fed diets rich in rapidly fermentable carbohydrates in reticulorumen leading to production of VFA at high speed which can to induce ruminal acidosis (RA). A high-energy diet

before parturition is able to induce the proliferation of ruminal epithelium, but some experiments have found conflicting results raising questions about the effectiveness of transition diet. The aim of this study was to examine whether transition diet given in the last weeks of gestation could contribute effectively to the control of RA in the postpartum of dairy cows. Six Holstein cows with cannula in the dorsal sac of the rumen, were allocated to 2 treatments in 3 blocks of 2 cows, defined by the date of the expected parturition. Six weeks before the expected calving, cows were fed a standard diet and 4 weeks before delivery were subjected to diets with high (HGC) or low (LGC) grain content. After delivery, all cows were fed a high energy lactation diet. Fragments of the rumen were collected by biopsy on days –42, –28, –14, –7, 2, 14, 28, 42 and 56 in relation to parturition. Cows that were fed HGC diet had higher ($P < 0.01$) dry matter intake and higher ($P < 0.01$) milk production. The HGC diet induced greater ($P < 0.01$) extension of the rumen absorptive surface than LGC diet. This supports the hypothesis that transition diet improves the ruminal ability to absorb VFA. The extent of the absorptive surface before parturition was lower than after calving, probably reflecting the effect of the highly energetic lactation diet. The provision of HGC diet before parturition may be a good alternative for the RA control after calving of dairy cows. This practice induces further development of the absorptive surface of the rumen avoiding the accumulation of VFA in this compartment. The greater dry matter intake and the greater milk production associated to HGC diet appear to have been a reflection of better physiological conditions of the rumen of these animals.

Key words: acidosis, ruminant stomach, transition diet

W343 Energy efficiency and performance of lactating dairy cows fed ethanol and acetic acid. J. L. P. Daniel*, L. G. Nussio, R. C. Amaral, A. Sá Neto, E. H. C. Garcia, A. W. Bispo, F. C. L. Oliveira, and I. F. Silva, *University of Sao Paulo, College of Agriculture "Luiz de Queiroz", Piracicaba, SP, Brazil.*

Ethanol and acetic acid are common end products from silages. The objective of this study was to determine whether ethanol and acetic acid affect performance and energy efficiency of high producing dairy cows. Heat of combustion from ethanol (kcal/g) is higher than either acetic acid or glucose, thus ethanol fed animals could be more efficient. Thirty lactating Holstein cows were grouped in 10 blocks and fed either: Control (33% Bermuda hay + 67% concentrates); Ethanol (control diet + 5% ethanol); or Acetic acid (control diet + 5% acetic acid, DM basis) diets, during 7 weeks. Ethanol and acetic acid were diluted in water (1:2) and sprayed onto total mixed ration twice daily before feeding. The same amount of solution was replaced with water in the control diet. During the 1st week the cows received half-dose of these chemical compounds. Dry matter intake (DMI) and milk yield were recorded every day and milk composition was determined once weekly. Data were analyzed as repeated measures using the MIXED procedure of SAS. Cows fed ethanol yielded more milk (37.9 kg/d) than those fed control (35.8 kg/d) or the acetic acid (35.3 kg/d) diets ($P = 0.04$), due to the higher DMI (23.7, 22.2, 21.6 kg/d, respectively). The significant diet*week interaction for DMI ($P = 0.02$), mainly during the 2nd and 3rd weeks (when the 5% acetic acid achieved the full dose) was related to the decrease in DMI of the acetic acid diet. Milk fat yield, milk urea-nitrogen and somatic cells counts were unaffected by diets, however protein and lactose yields were higher for ethanol diet, which agrees with the higher milk yield. Energy efficiency showed diet*week interaction ($P = 0.06$) and again, during 2nd and 3rd weeks the acetic acid diet increased NEl milk/DMI ratio due to the lower DMI and body weight loss. Otherwise, energy efficiency was similar across diets (1.1 Mcal NEl milk/kg DMI). Animal performance suggested similar energetic value from ethanol containing diet as compared with the other diets. Volatilization losses of ethanol at feed bunk and rumen conversion to acetate might be reasonable explanations to the deviation on the predicted energetic value.

Key words: volatile organic compounds, alcohol, intake

W344 Effect of an essential oil compound based product on ruminal disappearance of proteins, fiber and starch and fermentation parameters in dairy cow. D. Éclache, P. Etienne, and V. Noirot*, *Phodé Laboratories, Terssac, France.*

An in vivo study was carried out to evaluate the effect of Oleobiotec (Phodé Laboratories, France) containing carvacrol on ruminal disappearance of crude proteins-CP (soybean meal), starch (corn meal), fiber (alfalfa hay) and rumen fermentation parameters. Four non lactating dairy cows with ruminal cannulas were assigned to a 2 × 2 factorial arrangement in a 4 × 4 Latin square design. The product was given orally (0 or 1g/cow/day) and tested on 2 types of diet: one concentrated in fiber (F diet: 42% NDF, 20% starch) and the other in starch (S diet: 42% starch, 27% NDF). The ruminal disappearance of starch, CP and fiber was measured by the nylon bag method, after 4, 8 and 24 h, respectively. Each experimental period lasted 35 d with 15 d for adaptation, 12 d for the treatment and measures and 8 d without additive. A mixed linear model was used for statistical treatment (SPSS). Oleobiotec increased ADF disappearance with the S diet (+6,1 pts, $P < 0.05$) and decreased CP disappearance when associated with F diet (−6.0 pts, $P < 0.05$). There was no significant effect on starch disappearance and total volatile fatty acids concentration on either diet. The proportion of acetate increased with the S diet ($P < 0.05$) and that of propionate tended to increase with the F diet and to decrease with the S diet($P < 0.10$). N-NH_3 concentration decreased with the S diet ($P < 0.05$). Oleobiotec seems to improve fiber utilization with high starch diet and lower CP rumen utilization with high fiber diet.

Table 1.

	F		S		
	Control	Oleobiotec	Control	Oleobiotec	SEM
Disappearance, %					
ADF	28.2^{c}	28.0^{c}	19.3^{a}	25.4^{b}	1.6

W345 Milk fatty acid profile from dairy cows fed tropical forage-based TMR containing increasing levels of sunflower oil. M. A. S. Gama*[1], C. G. S. Ribeiro[4], F. C. F. Lopes[1], M. M. Almeida[2], E. F. Motta[1], M. T. Ribeiro[1], and J. M. Griinari[3], *[1]Brazilian Agricultural Research Corporation, Juiz de Fora, Minas Gerais, Brazil, [2]The Uni-*

versity of Juiz de Fora, Juiz de Fora, Minas Gerais, Brazil, [3]Swedish University of Agricultural Sciences, Uppsala, Sweden, [4]The University of Minas Gerais, Belo Horizonte, Minas Gerais, Brazil.

Due to health concerns associated with milk fat intakes, efforts have been made to decrease medium chain saturated fatty acids (C12 to C16) and increase oleic acid (cis-9 C18:1) as well as CLA (cis-9 trans-11 C18:2) in milk fat. Supplementation of the dairy cow diet with plant oils is a practical way to achieve this goal. Most studies published, thus far, have used temperate grasses or corn silage as forage. In this study, we evaluated the effects of increasing levels of sunflower oil (SO) on milk fatty acid profile in cows fed fresh Elephant grass (*Pennisetum purpureum*) - a tropical forage. Twelve primiparous Holstein cows (95 ± 25 DIM) were assigned to the following dietary treatments (level of SO inclusion, % of diet DM): Control (CTL): 0%; T1: 1.5%, T2: 3.0% and T3: 4.5%. The experimental design was a 4 × 4 Latin Square with 15 d treatment periods (last 5 d for data collection). Diet was fed as a TMR and it was composed of chopped Elephant grass and a concentrate mixture (65:35, DM basis) containing the SO. Milk yield, milk composition and DM intake were unaffected by the treatments. SO supplementation reduced the relative proportion of C12:0 to C16:0 fatty acids from 42.2% to 38.8, 27.8 and 26.8% for CTL, T1, T2 and T3, respectively ($P < 0.05$). C18:0 increased from 9.9% to 14.3, 15.7 and 16.7% ($P = 0.006$), cis-9 C18:1 increased from 21.7% to 24.8, 26.7 and 27.3% ($P = 0.0315$) and cis-9 trans-11 CLA increased from 0.88% to 1.26, 1.62 and 2.14% ($P < 0.0001$) for CTL, T1, T2 and T3, respectively. Interestingly, there was a linear decrease ($P < 0.05$) in desaturase indexes (14:1/14:0, 16:1/16:0, 18:1/18:0 and CLA/trans-11 C18:1) as the level of dietary SO increased. Concentration of C18:0 in milk fat was inversely associated with C18:1/C18:0 and CLA/trans-11 C18:1 ($r = -0.85$, $P < 0.0001$), and with C14:1/C14:0 ($r = -0.69$, $P < 0.0001$). These results suggest that extensive biohydrogenation of dietary PUFA has occurred in the rumen, leading to high levels of C18:0 in milk fat. High level of C18:0 in the preformed fatty acid supply to the mammary gland may have contributed to the observed reduction in desaturase indexes.

Key words: desaturase, milk fat, cows

W346 Effects of grinding or steam rolling of starter grains on nutrient digestibility of Holstein suckling calves. N. Jalali-Farahani, M. Dehghan-Banadaky*, K. Rezayazdi, and M. Ganjkhanlou, *Animal Science Department, Campus of Agriculture and Natural Resources, University of Tehran, Karaj, Tehran, Iran.*

This study conducted to evaluate the effects of grains processing (grinding versus steam rolling) in calf starter diet on nutrient digestibility of Holstein suckling calves. In present experiment, 60 Holstein calves (28 male and 32 female) with average 44 ± 5 kg birth weight were used from 3 until 120 d old. Calves randomly divided to 4 treatments included: 1) ground barley and corn, 2) steam rolled barley and ground corn, 3) ground barley and steam rolled corn, 4) steam rolled barley and corn. Calves were housed in individual hutch and had free access to water and starter diet. Calves weaned at 90 d old. In this experiment a complete blocks randomized design used with 4 treatment (diets) and 15 replicates (calves) and 2 blocks (sex). Feed and fecal were sampled at 90 and 120 d. Acid insoluble ash used as internal markers for nutrients digestibility study. Manure screening was done every other week for evaluation of grain digestion. In diet 1, undigested grain in fecal was significantly different from others treatments ($P < 0.05$). Apparent digestibility of dry matter, crude protein, neutral detergent fiber, organic matter, and ether extract between diets had not significant discrepancy. But apparent digestibility of non fibrous carbohydrates (NFC) was significantly different between treatments ($P < 0.05$). The results indicated that the treatment with grinding corn and grinding barley did the best performance for starter diet in Holstein claves.

Key words: calf starter, grinding, steam rolling

W347 Investigation of grinding or steam rolling of starter grains on growth performance of Holstein suckling calves. N. Jalali-Farahani, M. Dehghan-Banadaky*, K. Rezayazdi, and M. Ganjkhanlou, *Animal Science Department, Campus of Agriculture and Natural Resources, University of Tehran, Karaj, Tehran, Iran.*

This study conducted to evaluate the effects of grains processing (grinding versus steam rolling) in starter diet on growth performance of Holstein suckling calves. In present experiment, 60 Holstein calves (28 male and 32 female) with average 44 ± 5 kg birth weight were used from 3 until 120 d old. Calves randomly divided to 4 treatments include: 1) ground barley and corn, 2) steam rolled barley and ground corn, 3) ground barley and steam rolled corn, 4) steam rolled barley and corn. Calves were housed in individual hutch and had free access to water and starter diet. Calves weaned at 90 d old. In this experiment a block completely randomized design used with 4 treatment (diets) and 15 replicates (calves) and 2 blocks (sex). Measurements of shoulder height, hip width and hip height were recorded every 15 d. In diet 1, hip height and shoulder height were significantly more than other treatments ($P < 0.05$). Width hip between diets did not show any significant difference but hip width was a significant difference between sexes, female calves gad wide hip. Results indicate that the type of grain processing incorporated into calf starter can influence structural growth in suckling calves.

Table 1. Least squares means for structural growth measurements of Holstein calves fed for diet 1-4

	Diets					Sex		*P*-value	
	1	2	3	4	SEM	male	female	sex	treatment
Shoulder Height (cm)	89.9	86.1	88.3	87.8	1.16	88.5	87.6	NS	NS
Hip Height (cm)	92.8[a]	90.6[ab]	91.1[ab]	89.3[b]	1.01	90.4	90.0	NS	0.03
Hip Width (cm)	13.4	13.2	14.8	13.6	0.56	13.0[b]	14.5[a]	0.01	NS

Diets 1-4 included: 1) ground barley and corn, 2) steam rolled barley and ground corn, 3) ground barley and steam rolled corn, 4) steam rolled barley and corn.

Key words: grinding, steam rolling, calf starter

W348 Investigation of chewing activity in cows fed diet with different ratios of alfalfa hay and corn silage. A. Akbai, A. Zali, M. Ganjkhanlou, and M. Dehghan-Banadaky*, *Animal Science Department, Campus of Agriculture and Natural Resources, University of Tehran, Karaj, Tehran, Iran.*

In present study, chewing activity in cows fed total mixed ration based on alfalfa hay and corn silage evaluated. Fifteen Holstein cows (37 ± 10 DIM) were used in a completely randomized design with 3 treatments and 5 replicates during 9 weeks. Treatments included 3 levels of

hay and corn silage included: 1) 10% alfalfa −30% silage corn (CS), 2) 20% alfalfa −20% silage corn (CSAH) and 3) 30% alfalfa −10% silage corn (AH). The ratio of forage: concentrate was 40:60 in all treatments. Cows were fed the total mixed rations (TMR) twice daily. Individual dry matter intake and ort were measured daily. Chewing activity was recorded visual every 5 min during 24 h in 2 periods at 4 and 8 weeks. Eating and ruminating activities were monitored by 2 alternating individuals once every 5 min under the assumption that each activity would persist for the entire 5 min. Total time spent chewing was calculated as the time spent eating plus the time spent ruminating. Dry matter intake was higher when cows were fed CSAH (23.20 kg per day) compared with CS (22.95 kg per day) and AH (18.64 kg per day). Eating time (min/day) and (min/ kg DM, NDF intake) increased in CSAH group. Ruminating time (min/day) and (min/ kg DM, NDF intake) were not affected by treatment. Also, the total chewing time (min/day) decreased with increase alfalfa ratio. Resting time in AH group was more than CS and CSAH. Total pledges during the day and during each meal, ruminate and chewing activity did not significant difference between treatments.

Key words: alfalfa hay, corn silage, Holstein cows

W349 A non activated charcoal reduced diarrhea of calves subject to Escherichia coli compared to a conventional treatment after 9 days of treatment. C. Ionescu*[1], P. Ferretti[2], and D. M. Bravo[1], *[1]Pancosma, Geneva, Switzerland, [2]NanoAgro, Buenos Aires, Argentina.*

Calves post-weaning diarrhea is common in several areas. One of the diarrhea causes is the prevalence of *E. coli*. To treat diarrhea, veterinarian use conventional treatments including antibiotics (ANTIB). The objective of this trial was to check if a non activated charcoal (NAC: CARBOVET) could be used as an alternative, in case of *E. coli* diarrhea in calves. Twelve calves (34.9 ± 3.5 kg) were selected based on diarrhea diagnostic. *E. coli* presence was confirmed by microbiology counts in their feces. Calves were introduced in 2 groups for 20 d as following: NAC calves were given orally 20 g NAC per head per d for 6 d and 10 g NAC per head per d for the remaining 14 d; ANTIB calves were given: orally 30 mL Estreptocarbocaftiazol (ftalisulfatiazol, dihydroestreptomycin sulfate, coffee charcoal extract and dimethylpolyxyloxan) and 40 mL Brebaje (streptomycin sulfate, sodium sulfadimethylpyrimidine and gallotanic acid) for 3 d and injected 5 mL of Diafin (benzetimide hydrochloride and enrofloxacin), 6 mL of Terramycin (oxytetracyclin). Fecal score (FS) and average daily feed intake (ADFI) were measured daily; BW was measured on d 1/2, 5 and 20. Fecal scores were noted on a 5 points scale: 1 being normal to 5 being watery. Two calves died during the trial due to virosis. Data were analyzed using GLM procedure. ADFI was higher in NAC than in ANTIB during the first 4 d (25 vs. 0 g/d, $P \leq 0.05$, respectively). From d 5 to 20, no more differences in ADFI were observed. No differences in BWG were measured between groups. The FS for d 1 to 8 period was numerically higher in NAC than in ANTIB calves (3.47 vs. 2.77, $P = 0.20$) indicating a higher diarrhea intensity in NAC. For d 9 to 20 period, FS was lower in NAC group compared with ANTIB (1.04 vs. 1.63, $P \leq 0.05$, respectively). The percentage of calves relapsed in diarrhea (with FS values over 4) after 6 d where higher in ANTIB than in NAC (83.3% vs. 33.3%, $P = 0.09$,respectively). These results indicate that NAC could be beneficial for calves experiencing diarrhea caused by *E. coli*.

Key words: *E. coli*, charcoal, calves

W350 A new method for individually feeding a supplement to dairy cows in a free stall. E. M. Ramsing*[1], C. M. Shriver-Munsch[1], J. R. Males[1], W. K. Sanchez[2], I. Yoon[2], and G. Bobe[1], *[1]Department of Animal Science, Oregon State University, Corvallis, [2]Diamond V Mills, Cedar Rapids, IA.*

Previously, nutrition research on commercial farms was limited to treatments applied across entire pens or utilization of forced-intake techniques such as bolusing. Our hypothesis was to develop a reproducible, non-invasive procedure for individually feeding supplements to dairy cows on commercial dairy farms. Multiparous Holstein cows, housed in free-stall barns, received *Saccharomyces cerevisiae* fermentation product (Diamond V Original XP) as a top dressing during the morning feeding lock-up period. The supplement consisted of 0, 56, or 112 g of Original XP mixed with 84 g of molasses and 168, 112, or 56 g of corn meal, respectively. After creating an indentation (25 to 30 cm deep and 10 cm diameter) in front of each cow in the newly delivered TMR, the supplement was placed in the indentation so adjacent cows could not consume it. Intake of the supplement and other feed was monitored and given a score on a 5-point scale (0 = no supplement consumption, 1 to 4 = partial consumption, 5 = complete consumption). To prevent supplement consumption by other cows, leftovers of the supplements were removed after 15 min from the feed bunk. Cows accepted the new feeding method within 3 d. The greatest differences in feed consumption between cows were observed at calving (no supplement consumption: 25 cows; partial consumption: 5 cows; complete consumption: 66 cows). Using PROC GLM, complete supplement consumption on the day of calving was associated with lower serum β-hydroxybutyrate concentrations the following day ($P = 0.02$). The impact of the differing supplements on intake behavior is reported in companion abstracts presented at this meeting. In conclusion, the newly developed method is non-invasive to cows, requires minimal investment and no modification to existing facilities, and enables 3 technicians to feed and monitor up to 50 cows during a 30-min lockup period.

Key words: dairy, individual feeding, supplement

W351 Effect of quantity and frequency of colostrum feeding on passive transfer, health, and performance of pre-weaned and post-weaned dairy calves. B. Ozer*[1], M. Chahine[1], C. M. Matuk[1], and M. E. de Haro Martí[2], *[1]University of Idaho, Twin Falls, [2]University of Idaho, Gooding.*

The objective of this study was to determine the effect of quantity and frequency of colostrum feeding on serum IgG concentration, health parameters, and growth in Holstein calves. Two hundred 16 Holstein female calves raised on a commercial facility in southern Idaho were randomly assigned to one of 2 treatments which consisted of maternal colostrum (MC, n = 107) or maternal colostrum+milk (MCM, n = 106). The first feeding of colostrum (3.2 L) was administered to MC and MCM calves using an esophageal tube within 1 h of birth. A second feeding of colostrum (2 L) was administered 12 h following the first feeding to MC calves while MCM calves received 2 L of milk. Blood samples were collected at 24 ± 3 h of age and tested for total serum protein (TSP) and serum IgG concentration. Rectal body temperature was measured twice a week during the first 3 weeks of age. Health evaluations were conducted daily until calves were 3 mo of age. Fecal (FC), dehydration (DH) and respiratory (RS) scores were recorded during the first 4 weeks of age. Average daily gain was measured at 28 ± 1 d of age and at weaning (52 ± 3 d). Data were analyzed using a mixed model in SAS. TSP and IgG concentrations were significantly

greater ($P < 0.0001$) in calves fed MC (TSP = 5.74 ± 0.05 g/dL; IgG = 21.06 ± 0.53 g/L) compared with calves fed MCM (TSP = 5.17 ± 0.05 g/dL; IgG = 17.40 ± 0.53 g/L). Rectal body temperature did not differ between MC and MCM and averaged 38.8°C ± 0.01. No differences were detected in pneumonia or diarrhea incidence which averaged 70.4% and 10.3% respectively. MCM calves had a greater ($P < 0.05$) incidence of abnormal FC (75.0%) and DH (30.0%) compared with MC calves (30.3% and 12.1% respectively). MC calves had a greater ($P < 0.0001$) incidence of abnormal RS (69.7%) compared with MCM (20.0%). Average daily gain did not differ between MC and MCM and averaged 0.60 ± 0.01 kg. Results suggest that feeding Holstein calves 2 separate feedings of colostrum will improve passive transfer and might lead to some health benefits. The effect of colostrum feeding quantity and frequency on RS needs to be investigated further.

Key words: colostrum, immunoglobulin, calves

W352 Odd- and branched-chain fatty acid (OBCFA) composition of plasma in response to N underfeeding and energy source in dairy cows and their distribution among plasma lipid classes. R. Gervais*[1], B. Vlaeminck[2], A. Fanchone[3], P. Nozière[4], M. Doreau[4], and V. Fievez[2], *[1]Département des sciences animales, Université Laval, Québec, Québec, Canada, [2]Lanupro, Ghent University, Melle, Belgium, [3]Unité de Recherches Zootechniques, INRA, Petit Bourg, Guadeloupe, France, [4]Unité de Recherche sur les Herbivores, INRA, Theix, St-Genès-Champanelle, France.*

The objective of the current study was to evaluate the consequences of a strong decrease in dietary N supply in dairy cows and its interaction with the nature of energy on the OBCFA composition of plasma total lipids and to assess the distribution of these fatty acids (FA) among plasma lipid classes. Four Holstein cows (662 ± 62 kg; 71 ± 10 d in lactation), fitted with rumen, proximal duodenum, and terminal ileal cannulas, were used in a 4 × 4 Latin square design, with 28-d periods. Treatments were 2 N levels (low and high) combined with 2 energy sources rich in starch (barley, corn, and wheat) or fiber (soybean hulls and dehydrated beet pulp). The high level of N met 110% of N requirements expressed in the French protein digestible in the intestine (PDI) system from INRA, with an adequate supply in rumen degradable N, whereas the low level covered 80% of N requirements with a shortage in rumen degradable N. The 4 diets had a forage:concentrate ratio of 60:40 (DM basis) and were isoenergetic. A decrease in dietary N supplementation had no effect on total plasma concentration of iso, anteiso, and linear odd-chain FA. The total plasma concentration of iso FA was decreased when cows received starch compared with fiber-rich diets (1.07 vs. 1.25 g/100g FA; $P < 0.05$), whereas energy source had no effect on plasma concentrations of anteiso and linear odd-chain FA. No interaction between level of N supply and energy source on OBCFA plasma composition was observed. Regardless of treatments, proportions of iso and anteiso FA were higher ($P < 0.01$) in cholesterol esters (28.4 and 33.1 g/100g OBCFA, respectively) and triacylgycerols (28.0 and 31.7) compared with phospholipids (23.5 and 27.4) and free fatty acids (23.0 and 26.9). Phospholipids (49.2 g/100 g OBCFA) and free fatty acids (50.1) presented higher ($P < 0.01$) concentrations of linear-odd chain FA compared with cholesterol esters (38.5) and triacylglycerols (40.4). Results from the current study suggest the selective incorporation of OBCFA in different plasma lipid classes.

Key words: lipid class, OBCFA, plasma fatty acids

W353 Effect of dietary escape microbial protein (DEMP) and degradable protein level on fermentation, digestion, and N flow in rumen-simulating fermenters. G. A. Harrison*, M. D. Meyer, and K. A. Dawson, *Alltech Biotechnology, Nicholasville, KY.*

Dietary escape microbial protein (DEMP) is a yeast-derived protein source with a moderate ruminal degradation rate allowing supplementation of high quality protein similar to ruminally synthesized microbial protein. Effects of DEMP in diets differing in calculated ruminally degradable protein (RDP) were examined in single-flow rumen-simulating fermenter cultures. Twelve cultures were used in a 2 × 2 factorial design with 4 treatments and 3 replications per treatment. Cultures were fed 25 g twice daily for 6 d. Factors were DEMP at 0 or 2.64% (600 g/d equivalent at 22.7 kg DM intake) and RDP at 9.9 and 11.4% in diets balanced at 16.5% CP (DM basis). Fermentation samples were collected from cultures before morning feeding during the last 3 d of experiment. Composite effluent samples from each fermenter were used for DM and NDF disappearance and volatile fatty acid analyses. Nitrogen flow measures were estimated by using purine to N ratios for effluent and bacteria. Data were analyzed for treatment effects using GLM procedure of SAS with factor effects determined by orthogonal contrasts. Culture fed higher RDP diets had higher molar proportions of acetate and isoacids (isobutyrate + isovalerate+ valerate) and lower molar proportion of propionate ($P < 0.05$). Ammonia concentration was higher in cultures fed more RDP ($P < 0.01$). Bacterial N yield was 10.3% greater in cultures fed higher RDP and efficiency of bacterial N production based on DM truly digested or fermentable carbohydrate greater ($P < 0.05$). Efficiency of bacterial N production based on DM truly digested tended to be higher in DEMP-fed cultures ($P < 0.10$). Bacterial N yield was numerically greater (+6.6%) in cultures fed DEMP ($P = 0.13$). Cultures fed DEMP and higher RDP degraded more protein and had a greater proportion of effluent N from bacteria but not when DEMP was fed with lower RDP (interaction; $P < 0.05$). DEMP fed at the equivalent of 600 g/d had no impact on fermentation. Interactions suggest that DEMP may have a more positive effect when fed in higher RDP diets.

Key words: dietary escape microbial protein, degradable protein, ruminal metabolism

W354 Effect of level of dietary escape microbial protein (DEMP) on fermentation, digestion, and N flow in rumen-simulating fermenters. G. A. Harrison*, M. D. Meyer, and K. A. Dawson, *Alltech Biotechnology, Nicholasville, KY.*

Dietary escape microbial protein (DEMP) is a yeast-derived protein source with a moderate ruminal degradation rate allowing supplementation of high quality protein similar to ruminally synthesized microbial protein. DEMP has a recommended feeding rate of 600 g/d for lactating dairy cows but effects of DEMP fed at higher levels on ruminal metabolism have not been evaluated. Diets were formulated at 16% CP with inclusion rates of DEMP at 0, 1.76, 2.64, 3.96, 5.95, and 8.92% DM or 0, 400, 600, 900, 1350, and 2025 g equivalent for 22.7 kg DM intake. DEMP primarily replaced soybean meal. Twelve single-flow rumen-simulating fermenter cultures were used in a completely randomized design with 6 dietary treatments, 2 replications per treatment, and 2 experimental runs. Cultures were fed 25 g twice daily for 6 d. Fermentation samples were collected from cultures before morning feeding during the last 3 d of experiment. Composite effluent samples from each fermenter were used for DM and NDF disappearance and volatile fatty acid (VFA) analyses. Nitrogen flow measures were estimated by using purine to N ratios for effluent and bacteria. Data were

analyzed for effects of treatment using GLM procedure of SAS. Culture diet did not affect fermentation pattern or extent of digestion ($P > 0.10$). Bacterial purine content was altered by diet. Bacteria isolated from cultures fed the 0 g DEMP diet had a higher purine concentration than those from all other treatments except the 400 g DEMP treatment. Bacteria from cultures fed the 900 g DEMP diet had a lower purine concentration than those from cultures fed 0, 400, and 2025 g DEMP diets ($P < 0.05$). Bacterial N yield and efficiencies of bacterial N yield production were not significantly affected by culture diet ($P > 0.10$). Numerical increases in bacterial N yield in cultures fed 600 to 2025 g DEMP compared with the 0 g DEMP diet (+6.1 to 8.2%) are in agreement with previous work with fermenter cultures. Inclusion of dietary escape microbial protein (DEMP) at equivalent feed rates of 400 to 2025 g/d did not affect ruminal fermentation.

Key words: dietary escape microbial protein, ruminal metabolism

W355 Effects of abomasal infusion of fish oil, sterculia foetida oil and conjugated linoleic acids on milk yield and composition, and mammary mRNA expression of stearoyl CoA desaturase in dairy cows. M.-P. Dallaire*[1,2], L. Ma[3], B. A. Corl[3], R. Gervais[1], Y. Lebeuf[1], F. J. Richard[1], and P. Y. Chouinard[1,2], *[1]Département des sciences animales, Université Laval, Québec, QC, G1V 0A6 Canada, [2]Institute of Nutraceuticals and Functional Foods (INAF), Québec, QC, Canada, [3]Department of Dairy Science, Virginia Tech, Blacksburg.*

Sterculic acid and t10c12 conjugated linoleic acid (CLA) are both inhibitors of stearoyl CoA desaturase (SCD). This enzyme is active in mammary gland of lactating cows where it plays a key role in the regulation of milk fat composition. The purpose of this study was to determine the effects of sterculic acid, CLA and fish oil (FO) on milk yield and composition and on the mammary expression of 2 isoforms of SCD (1 and 5). Eight multiparous Holstein cows (mean BW 635 ± 34 kg; mean DIM 69 ± 13 d) were used in a double 4 × 4 Latin square design with 28-d periods. For the first 14 d, cows received abomasal infusion of CTL) 406 g of saturated fatty acids (Energy Booster (EB); control); SFO) 7 g of sterculia fetida oil + 399 g of EB; CLA) 36 g of CLA (42% t10c12 CLA) + 370 g of EB; and FO) 406 g of fish oil. Contrasts were used to compare individual effects of SFO, CLA, and FO with CTL. On d 14 of infusion, mammary gland biopsies were harvested and analyzed for RNA transcripts of SCD1 and SCD5. Compared with CTL, SFO decreased milk yield from 38.0 to 33.0 kg/d, and increased milk fat and protein content from 3.79 to 4.45% and 3.30 to 3.63%, respectively ($P < 0.01$). Milk fat content was also decreased ($P < 0.01$) by CLA (2.23%) and FO (3.34%). Milk fat yield was not affected by SFO (1475 g/d) when compared with CTL (1431 g/d), but was decreased ($P < 0.01$) by CLA (774 g/d) and FO (1186 g/d). Compared with CTL, expression of SCD1 was increased ($P = 0.04$) by SFO (30%) and decreased ($P = 0.02$) by CLA (24%), while FO had no effect. The mRNA abundance of SCD5 was not affected by treatments. Results from the current study support the concept that SCD1 and SCD5 present differences in their regulation by dietary FA.

Key words: conjugated linoleic acids, stearoyl-CoA desaturase, sterculic acid

W356 Effect of corn silage inoculation with Sil-All and dietary protein on fermentation, digestion, and N flow in rumen-simulating fermenters. G. A. Harrison*, M. D. Meyer, M. S. Taylor, and K. A. Dawson, *Alltech Biotechnology, Nicholasville, KY.*

Effects of feeding corn silage treated with inoculant (Sil-All) on ruminal metabolism were evaluated in rumen-simulating fermenter cultures. Whole corn plants (CF 738; Caverndale Farms, Danville, KY) were harvested at 6 stages of maturity (90, 94, 98, 105, 108, and 111 d) and ensiled in 125 L black plastic bags. At each harvest date, 5 kg of wet forage was ensiled without treatment (control) and with Sil-All at 200,000 cfu/g (SA). After 35 d, silages were dried at 55o C and ground through a 4 mm screen. Twelve single-flow rumen-simulating fermenter cultures were used in a 2 X 2 factorial design with 4 treatments, 2 replications per treatment, and 6 experimental runs. For each run, diets were formulated at 15 or 18% CP (DM basis) with control or SA corn silage from a single maturity date. Diets consisted of 75–85% silage with soybean meal used to meet protein targets. Cultures were fed 20 g twice daily for 6 d. Fermentation samples were collected from cultures before morning feeding during the last 3 d. Composite effluent samples from each fermenter were used for DM and NDF disappearance and volatile fatty acid (VFA) analyses. Nitrogen flow measures were estimated by using purine to N ratios for effluent and bacteria. Data were analyzed for effects of treatment using GLM procedure of SAS with factor effects determined by orthogonal contrasts. Culture pH was higher when either higher CP diets or SA corn silage were fed (6.40 vs. 6.46, $P < 0.05$). Higher protein diets resulted in higher molar proportions of isoacids (isobutyrate + isovalerate+ valerate) and greater culture ammonia ($P < 0.0001$). Digestion of OM and NDF were increased when cultures were fed more protein ($P < 0.05$). Bacterial N yield tended to be greater with higher protein diets (+3.4%, $P < 0.10$). Cultures fed SA silage produced 3.7% more bacterial N than cultures fed control silage ($P < 0.05$). Both higher protein and SA silage increased efficiency of bacterial N yield based on DM truly digested ($P < 0.05$). Diets based on Sil-All treated corn silage resulted in increased bacterial N production in fermenter cultures.

Key words: corn silage inoculation, ruminal metabolism

W357 Enhancing antioxidant properties of milk using a programmed, nutritional approach. G. A. Harrison*, M. S. Taylor, M. D. Meyer, and K. A. Dawson, *Alltech Biotechnology, Nicholasville, KY.*

The potential to enhance antioxidant capacity in milk was examined in a series of field trials. This programmed approach involved feeding a low inclusion rate pack of bundled, proprietary Alltech technology formulated to meet trace mineral and vitamin needs of lactating dairy cows. Six field trials were conducted using herds in SW Kentucky. Herds were selected on the basis of ability to follow trial protocols including replacement of current trace mineral and vitamin supplementation with an Alltech-Inside Dairy Pack (ATI) for 2–3 weeks and collection of individual milk samples from 12 cows before and during and ATI supplementation period. Bulk tank milk samples were also taken on collection days and approximately 3.5 L of milk was used in the production of mozzarella cheese. Herd was used as the experimental unit and response to ATI supplementation was evaluated using the GLM procedure of SAS. Milk and cheese samples were analyzed for selenium via hydride generation fluorescence (Millennium Excalibur 10.055, PS Analytical). Total antioxidant capacity was estimated by ferric reducing antioxidant power and radical scavenging ability by the DPPH assay (2,2-diphenyl-1-picryl hydrazyl). Se content of individual milk samples was 33% greater when cows were fed ATI Dairy Pack (32 vs. 42 ppb; $P < 0.05$). Total antioxidant capacity of individual milk samples was 9% greater when cows were fed ATI Dairy Pack (934 vs. 1021 μM Trolox equivalent; $P < 0.05$). Radical scavenging ability in milk from individual cows was similar comparing the 2 col-

lection periods (96 vs. 107 μM Trolox equivalent $P > 0.10$). Bulk milk samples collected during the ATI period had higher Se content (33 vs. 39 ppb; $P < 0.05$) and more radical scavenging ability (110 vs. 127 μM Trolox equivalent $P < 0.05$), but did not differ in total antioxidant capacity (1013 vs. 1099 μM Trolox equivalent $P > 0.10$). For mozzarella cheese, feeding the ATI pack resulted in higher Se content (178 vs. 294 ppb; $P < 0.05$) but did not alter in total antioxidant capacity and radical scavenging ability ($P > 0.10$). Antioxidant properties of milk can be enhanced through a programmed, nutritional approach.

Key words: milk, antioxidant capacity, selenium

W358 Mineral metabolism in pregnant dairy goats. C. J. Härter*[1], I. A. M. A. Teixeira[1], L. D. Lima[1], H. G. O. Silva[1], A. R. Rivera[1], D. S. Castagnino[1], K. T. Resende[1], and N. R. St-Pierre[2], *[1]Universidade Estadual Paulista, Jaboticabal, SP, Brasil, [2]Department of Animal Sciences, The Ohio State University, Columbus.*

Although mineral requirements are important to animal nutrition especially during pregnancy there are few studies on mineral metabolism of pregnant goats. Therefore the aim of this study was to determine calcium (Ca) and phosphorus (P) metabolism during pregnancy of dairy goats. After pregnancy confirmation, 32 female goats were distributed into treatments according to a block design in a 2 × 2 × 3 factorial as follows: 2 breeds (Oberhasli and Saanen), 2 types of pregnancy (single and twin) and 3 levels of feed restriction (0, 20 and 40% feed restriction). Blood samples were collected at 1, 35, 50, 65, 80, 95, 110, 125 and 140 d of gestation and serum samples were taken after centrifugation at 4°C for 20 min. at 1370 × g. Serum concentration of Ca, P, magnesium (Mg) and alkaline phosphatase (AP) activity were determined in these samples. Statistical analysis was performed in PROC MIXED using compound symmetry covariance structure. It was observed a significant decrease ($P < 0.05$) in serum concentration of Ca, P and AP activity after 80 d of pregnancy. Regardless the number of fetuses and the level of feed restriction Saanen goats presented higher levels of serum concentration of Ca and P and lower AP activity ($P < 0.01$). The serum concentration of Ca, P and AP activity decreased, and Mg raised as feed restriction increased ($P < 0.01$). Twin pregnant goats were found to have higher serum Ca ($P < 0.05$) than goats pregnant with one fetus . On the other hand, serum P concentration and AP activity ($P < 0.05$) were lower in twin pregant goats. These results show that the mineral demand increases as pregnancy advances, especially in twin pregnancy, and the higher mineral demand is met by calcium mobilization through bone resorption. Under feed restriction the animals might have attempted to meet Ca demand also by increasing intestinal absorption which is related to high ATPase activity and consequently higher Mg serum concentration (ATPase co-factor). (Fapesp project number 2009/10125–0).

Key words: dairy breeds, days of gestation, feed restriction

W359 Effect of various dosages of *Saccharomyces cerevisiae* fermentation product on milk production of multiparous dairy cows. E. M. Ramsing*[1], C. M. Shriver-Munsch[1], J. R. Males[1], W. K. Sanchez[2], I. Yoon[2], and G. Bobe[1], *[1]Department of Animal Science, Oregon State University, Corvallis, [2]Diamond V, Cedar Rapids, IA.*

Feeding 56 g/d of *Saccharomyces cerevisiae* fermentation product (Diamond V Original XP) to transition dairy cows increased milk production in most studies. Doubling feeding rates of Original XP was suggested during times of increased stress such as around parturition, which is an especially challenging time period for older cows. The objective of the current study was to evaluate whether greater dosages of Original XP than 56 g/d are beneficial during the transition period. Multiparous Holstein cows housed in the same pen were given a supplement containing either 0 (control; n = 32), 56 (n = 33); or 112 g (n = 31) of Original XP daily during morning lock-up as a top dressing to their TMR. The supplement consisted of 0, 56, or 112 g of Original XP mixed with 84 g of molasses and 168, 112, or 56 g of corn meal, respectively. Supplement feeding started 28 d before predicted calving date (at least 14 d prepartum) and ended 28 d postpartum. The study was conducted on a commercial dairy. Milk weights and samples were collected twice weekly from the afternoon milking on non-consecutive d and analyzed for milk fat, protein, lactose, and somatic cell counts. Overall, supplementation with Original XP did not significantly increase milk production, however, in second lactation Holstein cows (n = 25; 8 or 9 cows per group), Original XP supplementation, regardless of dosage, increased milk production by 5.5 kg/d ($P = 0.05$). Doubling feeding rates of Original XP (112 g/d) additionally benefitted milk production in the last supplementation wk in fourth or higher lactation Holstein cows (n = 27; 8 to 10 cows per group; +10.6 kg/d versus control, $P = 0.08$, and +9.8 kg/d versus 56 g Original XP; $P = 0.10$). Although there were several potential confounding factors that could not be controlled on the commercial dairy, our results support the original hypothesis that greater dosages of Original XP than 56 g/d may be required to support increased nutritional demands and milk production during time periods of increased stress.

Key words: dairy, milk, yeast culture

W360 Prediction of enteric methane output from milk fatty acid composition, intake and rumen fermentation parameters. R. Mohammed*, S. M. McGinn, and K. A. Beauchemin, *AAFC, Lethbridge Research Centre, Lethbridge, AB, Canada.*

Milk fatty acid (FA) composition has been suggested as a means of predicting enteric methane (CH_4) output in lactating dairy cattle. The objectives of this study were to: i) predict CH_4 from milk FA composition, intake and rumen fermentation parameters and ii) test the reliability of CH_4 prediction equations reported in previous studies. Sixteen lactating Holstein cows were used in a cross over design with four 28-d periods. All diets contained steam-rolled barley, a pelleted supplement and 45% barley silage and were supplemented with crushed oilseeds from sunflower, flax, canola and calcium salts of long chain FA to provide 3.3% added fat on dry matter basis. Methane (g/d) was measured in chambers (2 animals/chamber) on 3 consecutive days (d21–23). Total dry matter intake (DMI, kg/d; d21–23), forage DMI (kg/d; d21–23), milk FA composition (% total FA methyl esters; d18–21), volatile FA (mol/100 mol; d19–21) and protozoal counts (d19–21) were averaged by chamber before including in the model. Forage DMI (r = 0.52; n = 32), DMI (r = 0.52; n = 32) and rumen acetate:propionate (r = 0.66; n = 16) were positively related ($P < 0.01$) to CH_4 (g/d) whereas rumen propionate (r = 0.63; n = 16), milk c9–17:1 (r = 0.64; n = 32) and c11–18:1 (r = 0.64; n = 32) were negatively related ($P < 0.01$) to CH_4. The best regression equation was ($P < 0.001$; $R^2 = 0.90$; n = 16): CH_4 (g/d) = −910.8 (±156.7) x milk c9–17:1 + 331.2 (±88.8) x milk 16:0 iso + 0.0001 (±0.00) x total entodinomorphs + 242.5 (±39.7). Removing rumen parameters from the model also resulted in a reasonably good estimate ($P < 0.001$; $R^2 = 0.83$; n = 32) of CH_4. Step-wise regression analysis within diets resulted in greater R^2 and lower standard error values. Methane predicted using equations from previous studies resulted in a mean over-estimation ranging from 19 – 61% across studies. Thus, milk FA composition and intakes (DMI) can be used to estimate enteric CH_4 under field conditions. However, more accurate

predictions require equations specific to each diet. More studies are required to test the reliability of CH_4 prediction equations under varied feeding conditions.

Key words: methane, milk fatty acid composition, prediction equations

W361 Effect of dietary starch content in early lactation on the lactational performance of dairy cows. B. H. Nelson*[1,2], K. W. Cotanch[1], M. P. Carter[1], H. M. Gauthier[1], R. E. Clark[1], P. D. Krawczel[1], R. J. Grant[1], K. Yagi[3], K. Fujita[3], and H. M. Dann[1], *[1]William H. Miner Agricultural Research Institute, Chazy, NY, [2]Department of Animal Science, The University of Vermont, Burlington, [3]ZenNoh National Federation of Agricultural Cooperative Associations, Tokyo, Japan.*

Multiparous Holstein cows (n = 78) were used to evaluate the effect of dietary starch content in corn silage-based diets fed in early lactation on performance and blood metabolites. Dietary treatments were 1) a low-starch diet (L; 21.0%; 1.65 Mcal NE_L/kg) for the first 91 d in milk (DIM; LL), 2) a medium-starch diet (M; 23.2%; 1.67 Mcal NE_L/kg) for first 21 DIM and a high-starch diet (H; 25.5%; 1.68 Mcal NE_L/kg) for the next 70 DIM (MH), and 3) a high-starch diet (H; 25.5%; 1.68 Mcal NE_L/kg) for the first 91 DIM (HH). Corn meal was replaced partially with soyhulls and wheat middlings in the L and M diets. Cows were housed in sand bedded freestalls, fed in a Calan Broadbent feeding system and milked 3 × daily. Dry matter intake (DMI) and milk yield were measured daily. Milk composition was measured weekly starting at wk 2. Serum was collected every other day (1 to 21 DIM) and was analyzed for nonesterified fatty acids (NEFA) and β-hydroxybutyrate (BHBA). Data were analyzed as a completely randomized design by ANOVA with the MIXED procedure of SAS using treatment and time as fixed factors and cow within treatment as a random factor. Through the first 21 DIM (n = 78 cows), there was no treatment effect ($P > 0.10$) for DMI (20.3 ± 0.6 kg/d), milk yield (40.9 ± 1.6 kg/d), milk fat (4.34 ± 0.11%), milk protein (3.39 ± 0.05%), and serum BHBA (8.8 ± 1.1 mg/dL). Serum NEFA (μEq/L) was higher ($P = 0.02$; SEM = 39) for MH (578) than HH (437); LL was intermediate (452). Through the first 91 DIM (n = 72 cows; Table 1) treatment affected milk yield and milk urea nitrogen (MUN) and tended to affect DMI and milk fat. Diets containing ≤23% starch can be fed successfully to cows in early lactation when corn meal is partially replaced with nonforage fiber sources as long as energy density of the diet is maintained.

W362 A fibrolytic enzyme additive for lactating dairy cow diets: ruminal fermentation, pH, bacterial populations and enteric methane emissions. Y.-H. Chung*[1], L. Holtshausen[1], T. W. Alexander[2], M. Oba[3], and K. A. Beauchemin[1], *[1]Agriculture and Agri-Food Canada, Research Centre, Lethbridge, AB, Canada, [2]Department of Animal Science, University of Vermont, Burlington, [3]Department of Agricultural, Food and Nutritional Science, University of Alberta, Edmonton, AB, Canada.*

The objective was to determine if supplementing a dairy cow diet with a fibrolytic enzyme product (Econase RDE; AB Vista, Marlborough, Wiltshire, UK) alters ruminal fermentation, pH, bacterial populations, the risk of ruminal acidosis or enteric methane (CH_4) emissions. In a companion study this enzyme product improved ($P < 0.05$) efficiency of fat-corrected milk production for early-lactation dairy cows in a dose-dependent manner up to 11.3%. Nine ruminally cannulated, lactating Holstein cows were used in a replicated 3 × 3 Latin Square design with 21-d periods. Dietary treatments were 0 (control), 0.5 (low) and 1.0 (high) mL enzyme/kg TMR DM. Rumen contents were collected on 2 d, ruminal pH was measured continuously for 6 d, and enteric CH_4 emissions were measured for 3 d. The enzyme additive did not alter volatile fatty acids or ruminal pH profiles. However population densities of certain bacteria, calculated as copy number of specific 16S rRNA genes, were affected by enzyme treatment. The ruminal fibrolytic bacterium, *Fibrobacter succinogenes* ($P = 0.11$), and non-fibrolytic bacteria, *Ruminobacter amylophilus* ($P = 0.04$) and *Selenomonas ruminantium* ($P = 0.03$), increased linearly with increasing levels of enzyme in the diet. Increasing the level of enzyme supplement in the diet also increased enteric CH_4 production, even when adjusted for feed intake or milk production (19.3, 20.8 and 21.7 g CH_4/kg DMI or 12.9, 13.6 and 15.1 g CH_4/kg milk for the control, low and high enzyme diet, respectively; $P \leq 0.05$). The improvement in feed conversion efficiency of fat-corrected milk production with this enzyme product was related to a shift in ruminal bacterial communities associated with improved fiber digestion, which resulted in an increase in enteric CH_4 emissions without a change in volatile fatty acids or pH profile of the rumen fluid.

Key words: fibrolytic enzyme, ruminal bacteria, enteric methane emission

W363 Nutritional and seasonal factors causes milk fat concentration variability in dairy cows. A. S. Atzori*[1], P. Carta[2], G. Gaspa[1], and A. Cannas[1], *[1]Dipartimento di Scienze Zootecniche, Università di Sassari, Sassari 07100, Italy, [2]Associazione Regionale Allevatori della Sardegna, Nuraxinieddu, OR, Italy.*

Many animal and dietary factors might affect milk fat concentration (MF) of dairy cows. In this work several of them were studied in cows kept in Mediterranean climatic conditions. From December 2009 to July 2010, 54 samples of different total mixed rations (TMR) and bulk milk were collected from 26 dairy Sardinian farms (Italy). Daily herd DMI intake and milk yield (MY) were also recorded at the day of sampling. TMR were analyzed for chemical composition and sieved with the Penn State Particle Separator (PSPS) to estimate their physical effectiveness (peNDF). In the studied farms MY was 27.3±2.8 kg/cow per d (mean±s.d.; range 20.0-33.3), MF was 3.79±0.26% (range 2.88-4.29), dietary NDF was 37±2.6% of DM (range 32.2-43.9), while peNDF was 31.1±3.0% of DM (range 24.8-38.4). Despite this large variability, no significant associations between MF and NDF, peNDF or DM in the PSPS sieves were found. MF was negatively associated with the DM of TMR ($r = -0.55$; $P < 0.001$) and positively associated

with the concentration of silage in the ration (r = 0.30; $P < 0.05$). MF was lower in hot than in cold seasons ($P = 0.03$). A multivariate factor analysis, which excluded MF, was applied to the dataset and 6 factors were extracted. They indicated: F1) diet energy content (linked to TDNm, NEL3m, apparent digestibility, ADL, lipids in diet), F2) forage to concentrate ratio (linked to starch, NFC, NDF, ADF), F3) silage effects (linked to middle and lower PSPS fractions, silage in diet, DM of TMR), F4) cow performances (linked to MY, DMI, upper PSPS fraction), F5) diet protein balance (related to CP and bottom pan of the PSPS) and F6) season effects (linked to cold and hot season). Silage and season effects were the only factors significantly correlated with MF (r = 0.40, $P < 0.01$ and −0.33, $P < 0.05$, for F3 and F6 respectively). F3 was positively related to MF, with a similar trend both in hot and cold seasons, highlighting the positive effects of silages in the nutritional supply. The results showed that in many instances other factors than peNDF affect MF of dairy cows.

Key words: factor analysis, PSPS, silage

W364 Replacing soybean meal with Upland cottonseed, Pima cottonseed or extruded Pima cottonseed cake on production of lactating dairy cows. G. A. Broderick*[1], T. M. Kerkman[2], H. M. Sullivan[2], M. K. Dowd[3], and P. A. Funk[4], *[1]U.S. Dairy Forage Research Center, Madison, WI, [2]EcoSol, Tucson, AZ, [3]USDA-ARS, New Orleans, LA, [4]USDA-ARS, Mesilla Park, NM.*

Pima cotton production is growing in the US Pima cottonseed contains more gossypol, a toxic compound, than Upland cottonseed; heating cottonseed reduces gossypol absorption. Forty lactating Holstein cows were blocked by DIM into 5 squares in an incomplete 8x8 Latin square. Diets were formulated to (DM basis) 30% alfalfa silage, 30% corn silage, 21–25% corn, 16% CP and fed as TMR for ad libitum intake. Dietary protein was from: 1) solvent soybean meal (SSBM) or SSBM plus equal CP from 2) Upland cottonseed (UCS), 3) cracked Pima cottonseed (PCS), 4) Pima cottonseed cake (PCSC; prepared using experimental extrusion), 5) UCS plus PCS, 6) UCS plus PCSC; or expeller soybean meal (ESBM) plus equal CP from 7) PCS, or 8) PCSC. Periods were 4-wk (total 16 wk); data were from the last 2 wk. Blood plasma was collected on d-28. Data were analyzed using Proc Mixed in SAS. LS-means are in the table. Diet affected DMI ($P = 0.05$), with greatest intake on diet 6 and lowest intake on diet 1. MUN ($P = 0.05$) was lowest on diets 3, 7 and 8. No other production trait was affected. Milk fat ranged from 3.78 to 4.25%, suggesting cottonseed oil had no adverse effects. Plasma gossypol was higher ($P < 0.001$) on PCS, and lower on PCSC, than on corresponding diets with UCS, indicating extrusion reduced gossypol absorption. Performance on all diets supplemented with cottonseed was comparable to that on SSBM.

W365 The effects of feeding high-fiber byproduct feedstuff on productivity of dairy cows in early lactation. Y. Q. Sun* and M. Oba, *University of Alberta, Edmonton, Alberta, Canada.*

The objective of this study was to evaluate effects of a partial substitution of dietary grain with wheat DDGS on DMI, sorting activity, milk production and plasma metabolites of early-lactating dairy cows. Sixty-one Holstein cows were blocked by parity (22 primiparous and 39 mutliparous cows) and assigned to one of 2 experimental diets immediately after calving until 12 weeks in lactation. Experimental diets contained 43.1% barley silage, 21.6% rolled corn grain, and either steam-rolled barley grain (Control) or wheat DDGS (DDGS) at 17% of dietary DM. Both diets were formulated to contain 19.5% CP, 22.6% forage NDF, and 5.4% fat on a DM basis, but dietary NFC contents were 38.1% and 32.3% for Control and DDGS diet, respectively. Because excess fermentation in the rumen often decreases energy intake of ruminants, we hypothesized that reducing dietary NFC content by replacement of barley grain with DDGS would increase DMI and milk production. Cows fed DDGS diet sorted to a greater extent for long (104 vs. 102%, $P = 0.08$) and medium (94.7 vs. 91.4%, $P = 0.004$) particles, which retained on 19- and 8-mm screens of Penn State Particle Separator, respectively, compared with animals fed the control diet. Treatment did not affect body weight, BCS, or plasma concentrations of glucose, NEFA, BHBA, and plasma urea N. We observed parity-by-treatment interactions for DMI ($P = 0.08$), milk yield ($P = 0.05$), and milk protein concentration ($P = 0.05$). Feeding DDGS diet increased DMI (16.5 vs. 15.0 kg/d), milk yield (31.4 vs. 28.7 kg/d) but decreased milk protein concentration (2.71 vs. 2.78%) for primiparous cows. For multiparous cows, feeding DDGS decreased DMI (20.2 vs. 21.2 kg/d) and milk yield (39.1 vs. 41.8 kg/d) but increased milk protein concentration (2.85 vs. 2.77%). In conclusion, wheat DDGS can be used as a substitute for barley grain in the diets of dairy cows in early lactation, but the causes for different production responses between multiparous and primiparous cows warrant further investigation.

Key words: early-lactating cow, DDGS, barley grain

W366 Determination of the metabolizable methionine contributions of three different sources of lipid coated methionine. E. Devillard[1], F. Rouffineau[1], and B. Sloan*[2], *[1]Adisseo France, Commentry, France, [2]Adisseo North and Central America, Alpharetta, GA.*

Lysine and methionine (Met) are the most limiting amino acids (AA) for dairy cow production. To supply the required quantities of metabolizable lysine and Met, dairy rations often need to be supplemented with rumen-protected AA. This study aims at quantifying the metabolizable Met contribution of 3 different rumen-protected products: MethioPlus (Soda Feed Ingredients, protection by encapsulation), Mepron M85 (Evonik Degussa, protection by encapsulation) and Smartamine M (Adisseo, protection by pH-sensitive coating) and 2 experimental products that will not be discussed here. The methodology based on mathematically integrating the increases in blood plasma Met levels following a spot dose of product (50 g of Met), was as described by Graulet et al. (2005). The area under the curve (AUC) was thus used to determine the proportion of Met reaching the blood stream. Eight nonlactating Jersey cows were used in a replicated incomplete Latin square design (Cochran and Cox 1962), with 5 periods of one week. The total quantity of product was introduced in the rumen at 2 p.m. via the rumen cannula of cows receiving a diet composed of 75% hay and 25% concentrate. Blood samples were taken before and after the spot dose (at −22, −6, −3, 0, +6, +10, +14, +20, +24, +28, +32, +38, +48, +72 h) for quantification of Met concentration. An ANOVA with repeated measures was performed on the data using the PROC MIXED of SAS/STAT software. The maximum Met concentrations in plasma were observed 24h after the spot dose for Smartamine M (183 µmol/L) or Mepron M85 (49 µmol/L), and after only 14h (43 µmol/L) for MethioPlus, suggesting that product formulation characteristics influence rumen residence time, rate of release in the rumen and postruminally and Met absorption. From the AUC, the proportion of Met reaching the blood stream was calculated at 81% for Smartamine M, which was significantly higher ($P < 0.001$) than those of Mepron M85 and Methioplus, respectively 30% and 21%. These results suggest that products vary greatly in their ability to deliver metabolizable Met to meet requirements.

Key words: metabolizable methionine, rumen-protected amino acids

W367 In vitro degradation of melamine in rumen liquor. T. Calitz and C. W. Cruywagen*, *Stellenbosch University, Stellenbosch, South Africa.*

Melamine contains 667 g/kg N, which makes it an attractive protein adulterant, as it has the ability to inflate the crude protein content of feed- and foodstuffs artificially. Although melamine has been found to be a poor source of nitrogen for ruminants, its rumen degradability has not been determined previously. The current study was done to measure the in vitro degradability of melamine over time. For each of 5 repetitions, melamine (100 mg) was placed in Erlenmeyer flasks (n = 4/treatment) in a water bath at 39°C. Rumen liquor was collected from 4 ruminally cannulated dairy cows and volumes of 100 mL per cow were transferred to the respective flasks. Initial melamine concentrations were thus 1000 mg/L. Flasks were purged with CO2 and fitted with rubber stoppers equipped with one-way gas release valves. The flasks were then transferred to an incubator and samples were incubated for 6, 24 or 48 h at 39°C. Two control treatments were included where rumen fermentation was inhibited by either killing the microbes with the addition of 1 mL of 10% formaldehyde per 100 mL rumen liquor, or by exposing it to air while placing it on ice for 2 h. Erlenmeyer flasks in the control treatments were not incubated and served as a 0 h treatment and also to calculate the recovery rate of melamine after analysis. The total experimental sequence was repeated 5 times in different weeks in a randomized block design. A main effects ANOVA was done on the data with the aid of Statistica version 10. Main effects were treatment, cow and block. Melamine recovery from the control treatments was 91%. When the control treatments were adjusted to 100% recovery (1000 mg/L), melamine concentrations in the incubated samples were 993 mg/L (6 h), 1003 mg/L (24 h) and 1007 mg/L (48 h). Treatment means did not differ ($P = 0.981$). It was concluded that melamine is not degraded in rumen liquor up to 48 h of incubation.

Key words: degradation, melamine, rumen

W368 Characterization of lipase-producing bacteria in the presence of varying energy substrates in vitro. H. D. Edwards*[1], R. C. Anderson[2], R. K. Miller[1], T. M. Taylor[1], M. D. Hardin[3], S. B. Smith[1], N. A. Krueger[2], and D. J. Nisbet[2], *[1]Texas A&M University, College Station, [2]United States Department of Agriculture/Agricultural Research Service, Southern Plains Agricultural Research Center, College Station, TX, [3]IEH Laboratories & Consulting Group, Lake Forest Park, WA.*

Ruminal lipolysis has long been attributed mainly to *Anaerovibrio lipolyticus* and *Butyrivibrio fibrisolvens*. Conversely, *Propionibacterium* species *avidum* and *acnes* are also known to express lipase activity but little is known regarding the contribution of these prominent anaerobes to rumen lipolysis. To further characterize and understand the lipase activity of these 4 different bacteria, each was grown with 4 different energy substrates: olive oil, corn oil, flax seed oil, and glycerol. The bacteria were cultured in triplicate in tubes containing glass beads (which served as a solid support matrix), 6 mL of anaerobic medium containing minerals, vitamins, yeast extract, trypticase, with or without added glucose and with 0.2 mL of the respective triacylglyceride-derived energy substrates. Tubes were incubated horizontally and agitated at 39°C and growth and enzyme activity was stopped when cells reached early log and stationary phase (based from growth curves done before the study). Free fatty acid accumulation was measured colormetrically with the glycerol treatment acting as the negative control in this study. Results were analyzed using a general ANOVA with Tukey's separation of means. Because findings from studies conducted with or without added glucose supported the same conclusions, we present results from studies conducted with added glucose only. Olive oil and flax seed oil promoted the highest ($P < 0.05$) rates of free fatty acid accumulation for all bacteria, averaging 213.84 ± 37.94 and 245.76 ± 34.82 nmol/ml per h, respectively, when compared with corn oil (76.72 ± 36.93 nmol/ml per h). Compared with the other bacteria, *P. avidum* demonstrated the most rapid rates ($P < 0.05$) of lipolysis, which were 649.99 ± 77.86 and 700.02 ± 69.64 nmol/ml per h for cultures grown with olive oil and flaxseed oil, respectively. The results suggest that diets containing a high content of oleic acid and linolenic acid promote high rate of lipolysis in the rumen and *P. avidum* may contribute to a higher amount of lipolysis than previously considered.

Key words: rumen, lipolysis, energy substrates

W369 Exogenous fibrolytic enzymes: Unlocking nutrients from fiber for ruminant production. W. F. J. van de Vyver* and C. W.

Cruywagen, *Stellenbosch University, Stellenbosch, Western Cape, South Africa.*

Exogenous fibrolytic enzymes (EFE) as additives in ruminant feeds are being researched worldwide, but there is a need for a better understanding of the mode-of-action thereof. Four forages, treated with EFE, were evaluated in vitro and at microscopic level, in an attempt to determine the effect of EFE on tissue degradation. For the histological evaluation, weeping love grass and kikuyu leaf material and alfalfa and wheat straw stem material were used. Simultaneously, the forages were incubated in rumen fluid inoculated media for the determination of the in vitro digestibility. The main focus, however, was a quantitative assessment of the degradation of the plant tissue at histological level. The section to slide technique was used to mount plant tissues on microscope slides for incubation in buffered rumen fluid media. Degradation of cell wall components were quantified using image analysis software. The in vitro digestibility data were subjected to a Factorial ANOVA whereas histology data were analyzed with either a Bonferroni or Newman-Keuls multifactorial test, using Statistica 8.1 (2008). In vitro digestibility was significantly higher for EFE treated alfalfa and kikuyu at 24h of incubation ($P < 0.05$). Clear histological differences were observed for all tissue types over the incubation period. Cell wall of the metaxylem of leaf material were thinner for the EFE treated samples at 12h of incubation ($P < 0.05$). There was also a significant thinning effect of EFE on the cell wall of phloem at 12h of incubation for kikuyu as well as the adaxial epidermis at 24h. The abaxial epidermis at 12h was thinner for weeping love grass due to EFE treatment. Excluding the thinner epidermis of EFE treated alfalfa (at 12h incubation, $P < 0.05$), no significant effects of EFE on stem material was observed. It was concluded that image analysis can be useful to quantify changes in cell wall over an incubation period and that the addition of exogenous enzymes could be quantified by this system. There was a definite, subtle thinning effect of EFE on cell wall thickness of plant material which could be indicative of the mode-of-action of EFE.

Key words: fibrolytic enzymes, plant histology, digestibility

W370 Comparison rumen degradability of *Sedilitzia rosmarinus*, *Halocnemum strobilaceum* and *Kochia scoparia* with wheat straw and alfalfa hay. M. Mahmoodi-Abyane*, R. Valizadeh, A. A. Naserian, and A. Koocheki, *Ferdowsi University of Mashhad.*

Rumen degradability of 3 halophyte species including *Sedilitzia rosmarinus*, *Halocnemum strobilaceum* and *Kochia scoparia* were determined and compared with the measure parameters for alfalfa hay and wheat straw samples. In situ rumen degradability was determined at 0, 2, 4, 8, 12, 24, 36, 48, 72, 96 and 120 h after ruminal incubation. The results of ruminal degradability demonstrated that the "a" fraction (rapidly degradable) of *Halocnemum strobilaceum* was significantly highest ($P < 0.05$) among the halophytes and alfalfa hay or wheat straw, whereas the value "b" fraction (slowly degradable) for wheat straw was higher ($P < 0.05$) than other treatments. The "c" fraction (rate of degradation) of *Sedilitzia rosmarinus* and *Halocnemum strobilaceum* was significantly ($P < 0.05$) higher than that for other treatments whereas lowest level of "c" fraction was absorbed in wheat straw sample. Potential degradability (PD) level of *Sedilitzia rosmarinus* (76%) was significantly ($P < 0.05$) higher than other forage whereas lowest of this factor was observed in wheat straw (60%). Also effective degradability (ED) level in *Sedilitzia rosmarinus* (70%) was significantly ($P < 0.05$) highest among the other treatments whereas lowest level of ED was observed in wheat straw (60%). It was concluded that *Sedilitzia rosmarinus* and *Halocnemum strobilaceum* could be relatively a suitable forage for the dry area of many part of the Iranian wilderness.

Key words: rumen degradability, *Sedilitzia rosmarinus*, *Halocnemum strobilaceum*

W371 Comparison rumen degradability of *Phragmites australis*, *Nitraria schoberi* and *Atriplex canescens* species with wheat straw and alfalfa hay. M. Mahmoodi-Abyane*, R. Valizadeh, A. A. Naserian, and A. Koocheki, *Ferdowsi University of Mashhad, Mashhad, Khorasan Razavi, Iran.*

Ruminal degradability of 3 halophyte species including *Phragmites australis*, *Nitraria schoberi* and *Atriplex canescens* were determined and compared with the measure parameters for alfalfa hay and wheat straw samples. In situ ruminal degradability was determined at 0, 2, 4, 8, 12, 24, 36, 48, 72, 96 and 120 h after ruminal incubation. The results of ruminal degradability indicated that the a fraction (rapidly degradable) of *Atriplex canescens* was significantly ($P < 0.05$) highest among the halophytes and alfalfa hay or wheat straw whereas lowest of this fraction was observed in *Phragmites australis*. The value b fraction (slowly degradable) for wheat straw and *Phragmites australis* was significantly ($P < 0.05$) higher than other treatments, respectively. The c fraction (rate of degradation) of *Nitraria schoberi* was significantly ($P < 0.05$) higher than that for other treatments whereas lowest level of c was absorbed in *Phragmites australis* and wheat straw samples. Potential degradability (PD) level of alfalfa (0.6357) and *Atriplex canescens* (0.6065) were significantly ($P < 0.05$) higher than other forage whereas lowest of this factor was observed in *Phragmites australis* (0.4639). Also effective degradability (ED) level in alfalfa (0.5621) and *Atriplex canescens* (0.5366) were significantly ($P < 0.05$) highest among the other treatments whereas lowest level of ED was observed in *Phragmites australis* (0.2663) and wheat straw (0.5995). It was concluded that ruminal degradability of *Atriplex canescens* similar to alfalfa hay and *Phragmites australis* had similar value with wheat straw.

Key words: alfalfa, ruminal degradability, wheat straw

W372 The comparison of chemical composition of *Pragmates australis* ensiled forage by various feed additives. R. Valizadeh, M. Mahmoodi-Abyane*, and A. Salahi, *Ferdowsi University of Mashhad, Mashhad, Khorasan Razavi, Iran.*

The chemical composition of whole plant of *Pragmates australis* silage treated with different feed additives were investigated. The applied treatments were: 1) *Pragmates australis* (Pa) ensiled without additive, 2) Pa + 4% NaOH, 3) Pa + 4% urea, 4) Pa + 10% molasses, 5) Pa + 4% urea + 10% molasses and 6) Pa + 4% urea + 10% molasses + 4% NaOH (on DM basis). The NDF, ADF, CP, and ash content of initial sample and not ensiled forage were 78, 47, 14, and 12.7%, respectively, that significantly ($P < 0.05$) changed while ensiling by the various feed additives. The NDF content of ensiled sample with urea was highest (72.5%) whereas it was lowest in the NaOH treated forage(62.0%). ADF percent of urea treated forage (44.4%) and as well as ensiled sample without additive (44.8%) were higher than other treatment with various feed additives while NaOH treated forage and molasses ensiled forage decreased to 40.1 and 41.6%, respectively. CP content of the urea treated forage (14.1%) was also higher than that for other samples and lowest was observed in NaOH treated forage (9.7%). Ash content of the NaOH treated forage (19.0%) was significantly ($P < 0.05$) higher in caparison with other treatments

whereas lowest one was seen in ensiled sample with urea (12.3%). It concluded that molasses additive had good efficacy on chemical composition of this forage and higher level of this additive supplemented must be beneficial.

Key words: chemical composition, silage, *Pragmates australis*

W373 The comparison of qualitative characteristics of *Pragmates australis* ensiled forage by various feed additives. R. Valizadeh, M. Mahmoodi-Abyane*, and A. Salahi, *Ferdowsi University of Mashhad, Mashhad, Khorasan Razavi, Iran.*

The qualitative characteristics of whole plant of *Pragmates australis* silage treated with different feed additives were investigated. The applied treatments were: 1) *Pragmates australis* (Pa) ensiled without additive, 2) Pa + 4% NaOH, 3) Pa + 4% urea, 4) Pa + 10% molasses, 5) Pa + 4% urea + 10% molasses, and 6) Pa + 4% urea + 10% molasses + 4% NaOH (DM basis). Initial sample of forage with 25% DM ensiled and silages opened after 60 d. Comparison of DM content silages after ensiling indicated that treatment without additive had lowest level of DM (26.7%) while forage supplemented with tree additives had highest one (32.3%). pH level was significantly ($P < 0.05$) different among the treatment. Lowest level of pH observed in ensiled sample was with molasses (4.2) whereas urea treated forage (8.3) had highest of pH. Highest level of acidity also observed in sample with molasses (12.6%) whereas the NaOH treated forage (4.1%) had lowest of acidity. Ammonia-N (mg/dl) content of the urea treated forage (63.8) was also higher than that for other samples and lowest was observed in molasses treated forage (4,0). It concluded that fresh *Pragmates australis* could be harvested and treated with the appropriate supplement (molasses) and ensiled for subsequent utilization when the availability of forages is limited.

Key words: qualitative characteristics, *Pragmates australis*, silage

W374 A comparison of methods to analyze physical effectiveness fiber. R. S. Goulart*, L. G. Nussio, A. V. Pirez, J. L. P. Daniel, R. C. do Amaral, and V. P. Santos, *University of Sao Paulo/ESALQ, Piracicaba, Sao Paulo, Brazil.*

The physical effectiveness factor (pef) or effectiveness factor (ef) from fiber sources were evaluated in a 6 × 6 Latin square trial using 6 Nellore steers in a bioassay methods (BM) as recommended by Armentano and Pereira (1997). Laboratory methods (LM) were also performed according to Mertens (1997) and Lammers et al. (1996) to estimate the pef of the fiber sources (pef ≥ 1.18 or pef ≥ 8.0mm, respectively). Six diets were formulated with different fiber contents and sources: negative control (NC) (10% of the NDF from corn silage – CS – in TMR), positive control (PC) (CS with 20% of the NDF in TMR) and 4 diets containing 10% of NDF from CS added with 10% of the NDF from each the following sources: sugarcane (SC), sugarcane bagasse (SCB), soybean hulls (SH) and low oil–cottonseed meal (LOCM). By using the BM, differences in pef were observed ($P \geq 0.05$) between the standard fiber source, CS (pef = 100%) and the following fiber sources: SCB, SC, SH and LOCM (116, 106, zero and 68%, respectively) considering chewing time in min/day. When chewing time in min/kg of DMI was considered as target trait higher values of pef were observed for the SCB (250%), following SC (120%), SH (zero) and LOCM (68%). Ruminal mat consistency calculated by method of Welch (1982) showed the following values of pef: 100, 135, 150, 0, and 61% (CS, SCB, SC, SH and LOCM, respectively). The mean ruminal pH values were utilized to estimate the pe values: 100, 162, 145, 66 and 166% (CS, SCB, SC, SH and LOCM, respectively). Estimated values from the LM showed a larger range when compared with the BM. The pef ≥ 1.18 values were: 95, 60, 88, 71, 87% and the pef ≥ 8.0mm values were: 87, 63, 77, 20, 72% for CS, SCB, SC, SH and LOCM, respectively. The LM showed low or no correlation ($P \geq 0.05$) with any animal response parameter utilized in this study. Values of effectiveness can vary significantly within the same method and across methods (bioassay and laboratory). This study demonstrated that particle size analyses were affected by LM. There is a need to achieve standardization and validation of the method for measuring pef and consequently establish its requirements for beef cattle.

Key words: roughage, byproducts, Nellore

W375 Rumen degradability of sugarcane (*Saccharum* spp.) treated with different hydrolysis agents used in Brazilian farms. S. L. S. Cabral Filho*[1,2], D. C. Pinto[1], and R. A. Mandarino[1], *[1]Universidade de Brasília, Brasília, Distrito Federal, Brasil, [2]Fazenda Experimental Agua Limpa, Brasilis, Distrito Federal, Brasil.*

The feeding sugarcane to cattle has been an alternative for Brazilian farmers in Brazil lowering the costs of production. The processing of sugarcane with hydrolysis agents has been promoted as a way to improve the fiber degradability of sugarcane. The aim of this study was to evaluated changes in effective ruminal degradability of the fiber fraction (ENDFD and EDADF) of non-treated sugar cane (SCNT) and sugar cane submitted to treatments of 5% of NaOH (SCT1), 1.5% of CaO (SCT2) and 5% of urea (SCT3). A dose of treatment for SCT1 was based in the recommendations of commercial products used in Brazil, for SCT2 and SCT3 were based in research results. The ruminal degradability was evaluated by in situ using nylon bags incubated in 2 fistulated cattle. The means were compared with Tukey test ($P < 0.05$) in a randomized design scheme with 3 replicates per treatment. The treatments SCT1 and SCT2, promoted a significant improvement in degradability of the fiber of sugarcane, compared with SCNT ($P < 0.05$). The means were 37, 42, 63 and 37% of ENDFD and 35, 39, 61 and 35% of EADFD, for SCNT, SCT1, SCT2 and SCT3, respectively. The treatment SCT3 resulted in no improvements in degradability ($P > 0.05$). The experiment suggests the adoption of treatment with 5% NaOH or 1.5% CaO, since they improved the degradability of the fiber. However, care should be used because they are, especially NaOH, corrosive compound. More experiments are necessary to evaluate the economic advantages of those treatments.

Key words: forage, fiber, in situ

W376 Effect of dietary fish oil level on selected strains of rumen bacteria in continuous culture fermenters. A. Ishlak*, A. A. AbuGhazaleh, P. Gudla, and D. Hastings, *Southern Illinois University, Carbondale.*

Previous studies have shown that adding fish oil (FO) to cows diet increased vaccenic acid (VA) accumulation in the rumen. Therefore, the objective of this study was to evaluate the effects of FO level on selected strains of rumen bacteria involved in trans fatty acids formation. A single-flow continuous culture system consisting of 4 fermenters was used in a 4 × 4 Latin square design with 4 9 d consecutive periods. Treatment diets were: 1) control diet (53:47 forage to concentrate; CON), 2) CON + FO at 0.50% (DM basis; FOL), 3) CON + FO at 2% (FOM), and 4) CON + FO at 3.5% (FOH). Alfalfa hay and grass hay (4:1 DM basis) were used as forage source. Fermenters were fed treatment diets 3 times daily at 120 g/d. Samples were collected

from each fermenter on d 9 of each period at 1.5, 3 and 6 h post morning feeding and then composited into one sample per fermenter. Data were analyzed as a Latin square using the PROC MIXED of SAS. Preplanned comparisons were linear, quadratic, and FO versus control. Increasing dietary FO level resulted in a linear decrease ($P < 0.01$) in acetate and isobutyrate concentrations. Propionate, butyrate, valerate and isovalerate concentrations were not affected ($P > 0.05$) by treatment diets. Concentrations of C18:0 in fermenters linearly decreased ($P < 0.01$) while concentrations of trans-10 C18:1 and VA linearly increased ($P < 0.01$) as dietary FO level increased. The DNA abundance for *Butyrivibrio fibrisolvens* (64.63, 32.20, 18.54, and 27.04 pg/36ng of total DNA for treatment diets 1 to 4, respectively), *Butyrivibrio* VA subgroup (1.54, 1.34, 0.50 and 0.70 pg/24 ng of total DNA), *Butyrivibrio* SA subgroup (39.79, 38.97, 19.16, and 18.89 pg/18 ng of total DNA) and *Butyrivibrio proteoclasticum* (1.46, 1.25, 0.40 and 0.60 pg/18ng of total DNA) linearly decreased ($P < 0.01$) as dietary FO level increased. Fish oil had no effect ($P > 0.05$) on the DNA abundance for *Anaerovibrio lipolytica* and *Ruminococcus flavefaciens*. In conclusion, FO effects on VA accumulation in the rumen may be explained in part by FO influence on *Butyrivibrio* species.

Key words: fish oil, fatty acids, bacteria

W377 Effects of rumen-protected niacin on lipid metabolism, oxidative stress and production of transition dairy cows during summer in Wisconsin. K. Yuan*[1], R. Shaver[1], S. Bertics[1], M. Espineira[1], and R. Grummer[2], *[1]Department of Dairy Science, University of Wisconsin-Madison, Madison, [2]Balchem Corporation, New Hampton, NY.*

The objective of this study was to evaluate the effects of a rumen-protected niacin product (RPN; NiaShure, Balchem Corp., New Hampton, NY) on lipid metabolism, oxidative stress and performance of transition dairy cows during the summer in Wisconsin. Thirty multiparous Holstein cows were paired according to expected calving date and randomly assigned to either RPN at 12/g/cow/d or control (C) un-supplemented diets. Treatment diets were fed from 21 d before expected calving through 21 DIM. Ambient temperature and humidity were monitored weekly to calculate temperature-humidity index, and individual cow rectal temperatures were measured weekly to characterize heat stress conditions during the experiment. Blood samples were taken on d −21, 1, 7, 14, and 21 relative to calving for analyses. Data were analyzed for a randomized complete block design using Proc Mixed of SAS with repeated measures. Pre- (10.2 vs. 11.7 kg/d) and postpartum (15.5 vs. 15.9 kg/d) DMI, milk yield (33.4 vs. 33.3 kg/d), milk fat percent (4.87 vs. 4.54%), milk protein percent (3.19 vs. 3.08%), linear somatic cell score (3.40 vs. 2.34) and rectal temperature (38.7 vs. 38.8°C) were unaffected ($P > 0.05$) by treatment. While body weight and body condition score decreased ($P < 0.01$) during the experimental period, no treatment effects ($P > 0.05$) were observed. Time ($P < 0.01$) and time × treatment ($P < 0.05$) effects were observed for plasma NEFA. On d 1 postpartum, NEFA reached 1138 ± 80 μEq/L for control cows compared with 698 ± 80 μEq/L for RPN cows. Cows in RPN group tended to ($P < 0.10$) have lower plasma NEFA concentrations than control cows on d 7 and 14 postpartum. Plasma glucose concentrations were similar ($P > 0.05$) for RPN and C. Plasma SOD was unaffected ($P > 0.05$) by treatment; a trend for a time effect ($P < 0.10$) on SOD was observed. In conclusion, under summer conditions in Wisconsin, dietary supplementation with 12g/d per cow RPN decreased plasma NEFA concentrations, but did not affect the anti-oxidant enzyme SOD, lactation performance or body temperature of transition dairy cows.

Key words: transition cows, rumen-protected niacin, oxidative stress

W378 Using rumen microbes for consolidated bioprocessing to convert plant fiber to ethanol or other biofuels. R. A. Kohn* and S.-W. Kim, *University of Maryland, College Park.*

Microorganisms that live in the cow's rumen orchestrate the fastest biological degradation of biomass on earth. For example, a strain of *Ruminococcus albus* readily degrades ligno-cellulose without pretreatment to produce acetate and ethanol. The objective of this study was to isolate fiber-digesting microorganisms from the rumen that produce ethanol to a high concentration. Rumen fluid was collected from a fistulated cow and enriched for fiber digesting microbes by incubating in media with timothy grass hay as the main substrate. Every 3 to 5 d a portion of the culture was transferred to new media. For some enrichments, the media contained 6% or 10% ethanol by volume. Individual strains that grew on Avicel, filter paper or cellobiose were isolated on agar from diluted enrichments. Several isolates could digest various types of biomass (e.g., cellulose, hemicellulose, grass) and convert it directly to ethanol. Microbial cultures from the rumen converted 1% cellobiose to 0.5% ethanol increasing ethanol concentration from initial 6.0% to more than 6.5%. A second addition of cellobiose further increased ethanol to more than 7.0%. The 16s rDNA sequences of 20 strains that converted cellobiose to ethanol were >97% homologous with at least one of *Clostridium bifermentans*, *C. sordelli*, *C. sporogenes*, *Enterococcus casselflavus*, *E. muntii*, *E. sangunicola*, *E. faecium*, *E. lactis*, *Pediococcus acidilactici*, *Lactobacillus mucosae*, or *Staphylococcus epidermidis*. Some of these bacteria also produced 1-butanol or 1-propanol from plant fiber. Additional bacteria (*Enterococcus avis*) produced high concentrations of alcohols from H_2 and CO_2 or CO. Microorganisms like these can produce ethanol directly or indirectly from waste biomass or grass (patent pending). The biomass is sterilized with heat and pressure and then simultaneously digested and fermented to ethanol.

Key words: biofuel, fiber digestion, cellulosic ethanol

W379 Fiber-digesting rumen bacteria that predominantly produce propionate or butyrate. S.-W. Kim* and R. A. Kohn, *University of Maryland, College Park.*

Most known fiber-digesting bacteria from the rumen of cattle produce acetic acid as a major end product. The present investigators isolated 2 new species of rumen bacteria that primarily produce propionate or butyrate directly from cellulose. When one strain was incubated with Avicel, 45% of the NDF disappeared within 4 d incubation (n = 2). A control culture of *Ruminococcus albus* (strain 7) resulted in 66% NDF disappearance in the same time frame (n = 2). The molar percentages of VFA produced by the new strain were 45% acetate, 55% propionate and 0% butyrate. A second bacterial strain digested 65% of Avicel NDF in 4 d (n = 2), and produced the molar percentages of VFA of 1.3% acetate, 3.5% propionate, and 86.2% butyrate. Both strains were gram-positive rods and no spores were observed. The propionate-producing strain was 96.08% homologous with *Selenomonas ruminantium*, and the butyrate-producing strain was 94.31% homologous with *Clostridium bifermentans* on the basis of 16S rDNA sequence. Neither closest-related species is known to digest cellulose and homology of 16S rDNA less than 97% suggests the isolates are members of unique species. Further characterization is needed. We propose that such microbes may be useful as probiotics or for conversion of plant fiber to VFA to be used as feeds or to produce other bioproducts.

Key words: fiber digestion, butyrate, propionate

W380 The combination of garlic oil and cinnamaldehyde modify rumen fermentation profile reducing methane production. P. W. Cardozo*[1], M. Blanch[1], M. D. Carro[2], and M. J. Ranilla[2], *[1]Novus International Inc., St. Charles, MO, [2]Deptartamento de Producción Animal, Universidad de León, León, Spain.*

The objective of this study was to analyze the effects of 3 doses (200, 300 and 400 mg/L of product) of NEXT Enhance 300 (NE300; containing cinnamaldehyde and diallyl disulfide) on in vitro ruminal fermentation. Batch cultures (120 mL serum bottles) of mixed ruminal microorganisms (BCRM) were used to test the effects of the additive. Three hundred mg of 60:40 alfalfa hay:concentrate diet was used as a basal substrate. The rumen fluid inoculum was obtained from 4 rumen-cannulated Merino sheep fed the same diet incubated in BCRM, mixed and strained through 4 layers of cheesecloth into an Erlenmeyer flask with an O_2-free headspace. Particle-free fluid was mixed with the buffer solution (no trypticase added) in a proportion 1:4 (vol/vol) at 39°C under continuous flushing with CO_2. Thirty mL of buffered rumen fluid were added into each bottle under CO_2 flushing and were sealed with rubber stoppers and aluminum caps, and incubated at 39°C for 24 h. After incubation total gas production was measured, and a gas sample was removed for methane production. Bottles were then uncapped, the pH was measured immediately, and samples for volatile fatty acid (VFA) and ammonia-N analyses were taken. Incubations were repeated on 4 different days to allow statistical analysis of results. Differences were declared at $P < 0.05$. Doses of 400 mg/L of NE300 decreased total VFA production and apparently fermented organic matter compared with control (CTR, no additive), thus indicating some inhibition of ruminal fermentation. NE300 at 200 mg/L reduced acetate:propionate ratio, methane production and methane/VFA ratio compared with CTR. NE300 at 300 mg/L reduced ammonia-N concentrations, methane production, acetate proportion, and acetate:propionate ratio, and increased propionate proportion compared with CTR. In conclusion, NE300 at 300 mg/L decreased methane production and increased propionate proportion without affecting total VFA production, and this would indicate a higher supply of energy for the host animal.

Key words: cinnamaldehyde, garlic oil, methane

W381 Ruminal kinetics of the diets with increasing levels of crude propane-1,2,3-triol. R. Mello*[1], C. M. M. Bittar[2], L. A. M. A. da Costa[3], R. C. de Araújo[2], and A. L. Abdalla[2], *[1]Universidade Federal de Santa Maria, Santa Maria, Rio Grande do Sul, Brazil, [2]Universidade de São Paulo - Escola Superior de Agricultura 'Luiz de Queiroz', Piracicaba, São Paulo, Brazil, [3]Universidade Federal de Roraima, Boa Vista, Roraima, Brazil.*

The objective was to assess the effect of different levels of propane-1,2,3-triol in the diets on rumen fermentation kinetics. Treatments were 0, 3, 6, 9, 12, 15, 18, 21 and 24% addition levels of crude propane-1,2,3-triol, co-product derived from the production of biodiesel fuels with palm oil (*Attalea maripa*), replacing corn on dry matter of the diets. A randomized block experimental design with 9 treatments and 3 replications was used, considering the incubation as blocking criterion. The ruminal kinetics was analyzed by in vitro gas production technique. Substrates were incubated with ruminal fluid buffered in triplicate. Gas production was followed over time (72h) in an automated system by radiofrequency (Ankom). Data were fitted by dual-pool logistic model and parameters estimated through the Gauss-Newton algorithm implemented in the NLIN procedure of SAS® software. The increase of propane-1,2,3-triol resulted in longest lag time: Lag (h) = 0.220+0.203x; $r^2 = 0.91$; i.e., a delay of 12 min in the latency period to each 1% of propane-1,2,3-triol. The maximum volume of gas produced (mL per gram of incubated organic matter) by degradation of soluble fraction ($V_1 = 84.71–2.415x$; $r^2 = 0.88$) and insoluble potentially degradable fraction ($V_2 = 78.62–2.264x$; $r^2 = 0.87$) reduced, while the specific rates of gas production by degradation of soluble fraction ($k_1 = 0.106$) and insoluble potentially degradable fraction ($k_2 = 0.031$) were constant as the propane-1,2,3-triol level raised in the diets. Total volume of gas produced also reduced, can be represented by equation: VT (V_1+V_2) = 163.34–4.680x ($r^2 = 0.99$). This suggests that propane-1,2,3-triol has an effect in vivo glycogen to be absorbed directly (intact) or indirectly (as propionate) by the ruminal epithelium. Volume of methane produced (mL/g OM) also decreased with increase of propane-1,2,3-triol in the diets ($CH_4 = 43.8633–0.3514x$; $r^2 = 0.56$). Thereby, addition of propane-1,2,3-triol can help in mitigation enteric methane and improve energy supply. Thus, the inclusion of propane-1,2,3-triol in ruminant diets may be an important alternative to mitigate greenhouse gas emissions.

Key words: 1,2,3-propanetriol, glycerol, glycerin

W382 Effect of various semi-arid medicinal plant essential oils on in vitro ruminal methane emission and feed fermentation efficiency. H. Jahani-Azizabadi*[1], M. Danesh Mesgaran[1], A. R. Vakili[1], and K. Rezayazdi[2], *[1]Dept. of Animal Science, Excellence Center for Animal Science, Faculty of Agriculture, Ferdowsi University of Mashhad, Mashhad, Khorasan Razavi, Iran, [2]Dept. of Animal Science, Faculty of Agriculture, University of Tehran, Karaj, Tehran, Iran.*

The objective of the present study was to investigate the in vitro effect of some semi-arid medicinal plant essential oils on ruminal methane emission and feed fermentation efficiency (FFE). A mixed diet of alfalfa hay: concentrate (50:50, based on DM) was provided. It was then ground to pass through a 1- mm screen. Approximately, 500 mg of the diet alone (as control) or plus essential oil of cinnamon, dill, oregano or peppermint (100 µL/ g DM) were placed into a 125 mL serum bottle (n = 6) containing 50 mL of buffered-rumen fluid (2:1). Rumen fluid was obtained from 3 ruminally fistulated sheep (49.5 ± 2.5 kg, body weight), before the morning feeding. Bottles were placed in shaking water bath for 24 h at 38.5°C. Gas produced of each bottle was recorded using a pressure transducer and then sampled. Gas pressure was converted into volume using an experimentally calibrated curve. Then, bottle content was filtered (42 µm) and residual was dried (60°C, 48 h) to determine dry matter disappearance (DMD). Data were statistically analyzed using SAS (V. 9/1) and Dunnett's test was used to compare the means ($P < 0.05$). Feed fermentation efficiency was estimated as FFE = DMD (g/kg)/cumulative gas (ml) produced at 24 h. Methane content of the produced gas was determined using gas chromatography procedure. Results indicated that these essential oils caused a significant ($P < 0.05$) decrease in methane and total gas produced over 24 incubation compared with those of the control (Table 1). The essential oil of Dill enhanced FFE ($P < 0.05$) compared with that of the control. Present results demonstrated a positive effect of the essential oils on ruminal fermentation pattern.

Table 1. In vitro effect of medicinal plant essential oils on total gas produced, methane emission and feed fermentation efficiency

Item	Control	Cinnamon	Dill	Oregano	Peppermint	SEM
Total gas (ml/ g DMD)	276.1	115.4 *	253.1 *	186.5 *	187.8 *	0.61
Methane (ml/ g DMD)	41.28	13.97 *	36.89 *	24.28 *	23.61 *	4.8
FFE	6.1	10.6 *	5.9	6.0	6.5	0.5

*Within a row, means with an asterisk differ significantly from the control (P< 0.05).

W383 Rumen parameters and digestibility of diets with different levels of crude propane-1,2,3-triol. R. Mello*[1], C. M. M. Bittar[2], L. A. M. A. da Costa[3], P. B. Costa[4], J. K. Kirinus[1], and J. L. Nörnberg[1], *[1]Universidade Federal de Santa Maria, Santa Maria, Rio Grande do Sul, Brazil, [2]Universidade de São Paulo - Escola Superior de Agricultura 'Luiz de Queiroz', Piracicaba, São Paulo, Brazil, [3]Universidade Federal de Roraima, Boa Vista, Roraima, Brazil, [4]Universidade Estadual do Oeste do Paraná, Marechal Cândido Rondon, Paraná, Brazil.*

The objective was to assess the effect of increasing levels of propane-1,2,3-triol in the diets on rumen fermentation parameters and digestibility. Treatments were 0, 3, 6, 9, 12, 15, 18, 21 and 24% addition levels of crude propane-1,2,3-triol, co-product derived from biodiesel production with palm oil (*Attalea maripa*), replacing corn on DM of the diets. A randomized block experimental design with 9 treatments and 3 replications was used, considering the incubation as blocking criterion. Substrates were incubated with ruminal fluid buffered in triplicate. The digestibility was evaluated after 48 h and ruminal parameters were measured after 72 h of in vitro incubation. Data were analyzed in the SAS software. The table below shows the least squares means of dependent variables. The acetate and butyrate concentrations, acetate: propionate ratio, in vitro true digestibility (IVTD) of DM, organic matter (OM) and NDF coefficients decreased ($P < 0.05$); and the pH values increased ($P < 0.05$) as the propane-1,2,3-triol level raised in the diets. Thus, the inclusion of propane-1,2,3-triol with 35.6% purity in substitution of non-fibrous carbohydrates on DM of ruminant diets negatively affect the ruminal fermentation parameters and digestibility, but can be an important alternative of destination to the surplus generated from biodiesel chain.

W384 Dose response effects of a garlic oil chemical compound propyl-propyl thiosulfate (PTSO) on rumen microbial fermentation in a dual flow continuous culture system. A. Foskolos*[1], A. F. De Souza[1], M. Rodriguez-Prado[1], A. Ferret[1], D. Bravo[2], and S. Calsamiglia[1], *[1]Animal Nutrition, Management and Welfare Research Group, Universitat Autònoma de Barcelona, Bellaterra, Spain, [2]Pancosma, Geneva, Switzerland.*

Oxy-propyl-thiosulphate (PTSO) is an active molecule purified from garlic bulb. The objective of this experiment was to investigate the effects of increasing doses of PTSO on ruminal fermentation in vitro. Eight dual flow continuous culture fermentors inoculated with rumen liquid from a dairy cow were used in 2 replicated periods (blocks). Temperature (39 ◦C), pH (6.4), and liquid (0.10/h) and solid (0.05/h) dilution rates were maintained constant. Fermenters were fed 95 g DM of a diet (21.6% corn silage, 43.6% dehydrated alfalfa, 11.4% soybean meal, 31.6% corn grain and 0.83% vitamin-mineral mix, DM basis) in 3 equal portions daily and treatments were no additive (CTR) and 50, 100 and 150 mg/L of PTSO. Each experimental period consisted of 5 d for adaptation and 3 d for sampling. Samples were collected 2 h after the morning feeding and from the 24-h effluent of the 3 sampling days. Results were analyzed with PROC MIXED and significance was declared at $P < 0.05$. Contrasts were used to analyze for linear, quadratic and cubic responses. Total VFA and molar proportions of acetic and propionic acids concentrations and the acetate to propionic acid ratio responded quadratically with higher total VFA and propionic acid and lower acetic acid concentrations and acetic to propionic ratio in the intermediate doses. Branch-chained VFA decreased linearly by increasing doses of PTSO and ammonia-N concentration was not affected by treatments. In the samples from the 24-h incubations, only the total VFA and BCVFA concentrations responded quadratically and linearly by increasing dose of PTSO, respectively. Results suggest the potential of PTSO to modify rumen fermentation in a direction consistent with better energy utilization.

W385 Estimation of protein fractions of tropical grasses by near infrared reflectance spectroscopy. R. G. Basurto[1], G. Buendia-Rodriguez[1], E. R. Ramírez[1], M. A. Barron[2], J. J. G. Bustamante[3], R. E. Santos[4], J. J. M. Maldonado[5], and S. S. Gonzalez-Muñoz*[6], *[1]CENID Fisiologia Animal-INIFAP, Queretaro, Mexico, [2]CE Huimanguillo-INIFAP, Tabasco, Mexico, [3]CE Santiago Ixcuintla-INIFAP, Nayarit, Mexico, [4]CE Iguala-INIFAP, Guerrero, Mexico, [5]CE Rosario Izapa-INIFAP, Chiapas, Mexico, [6]Colegio de Postgraduados, Montecillo, Estado de Mexico, Mexico.*

The aim of the study was to investigate the use of near infrared reflectance spectroscopy (NIRS) as an alternative method to estimate crude protein (CP), degradable (DIP) and undegradable (UIP) intake protein of tropical grasses. A total of 945 samples of 13 species were collected by clipping at different ages of re-growth (28, 42, 56, 70 and 84 d) in plots in 4 states (Chiapas, Guerrero, Nayarit and Tabasco) in Mexico. The grass species included were *D. aristatum*, *C. dactylon*, *H. altissima*, *U. brizantha*, *D swazilandensis*, *C. plectostachyus*, *U. maximum*, *B. humidicola*, *C. echinatus*, *A. gayanus*, *B. brizantha* x *ruziziensens*, *D. eriantha* and. DIP was estimated as the protein fraction that disappeared after incubation with a protease ofand UIP was the remaining protein in the sample. Samples were scanned using a spectrophotometer Nicolet FT-IR 6700 (Thermo Fisher Scientific, Inc.) over a wavelength range of 1000 to 2500 nm in reflectance. Data were stored as log (1/R) at intervals of 4 nm. Calibration equations were developed using modified partial least squares with the TQ Analyst

program (v8.0). The selection of the equations was based on: the coefficient of determination of calibration (R^2cal), the minimization of the standard error of calibration (SEC), the standard error of cross validation (SECV), and the ratio SECV/SD. If the ratio was >0.33, then calibration had a low predictive power. The best NIRS models obtained are shown in Table 1. It is concluded that NIRS calibration for PC has good precision, but DIP and UIP calibrations are less precise.

Table 1. Laboratory data and calibration and validation statistics of NIRS models

ITEM (% of DM)	N	Mean	Range	SD[1]	R^2cal	SEC	SEP	SECV	Ratio
CP cal[2]	675	7.98	2.7 - 20.7	3.01	0.94	0.79

W386 Commodity blood meal variation: digestible RUP and amino acids. R. Brown*[1], D. Stucker[1], J. R. Knapp[2], and N. R. St-Pierre[3], *[1]Venture Milling, Salisbury, MD, [2]Fox Hollow Consulting, LLC, Columbus, OH, [3]The Ohio State University, Columbus.*

The objective was to determine the variation in nutrient availability of commodity blood meal as a source of rumen undegradable protein (RUP). The nutritional value of RUP sources is based on their ability to deliver amino acids for absorption in the small intestine and is affected by the protein content, the rumen degradability of the protein, and the post-ruminal digestibility of the RUP. To date, a modification of the procedure of Calsamiglia and Stern (1995) appears to be the best in predicting the nutritional value of ingredients rich in RUP. This 3-step procedure consists of an in sacco incubation in rumen-fistulated cows followed by sequential in vitro protease digestions with pepsin and pancreatin. The residues from the incubation and digestions can be analyzed for amino acids, and amino acid digestibilities determined. The procedure has been modified in our laboratory by partial standardization of enzymes, use of fuzzy standards, and Bayesian statistics to adjust for inter-assay variation. Amino acid analyses were performed by the University of Missouri Agricultural Experiment Station Chemical Laboratories. Commodity blood meal samples (n = 265, porcine and bovine) were obtained over the past 5 years from commercial sources across the US The results using this procedure showed reasonably consistent crude protein contents (90.1 ± 3.7%, mean ± S.D) on an as fed basis. However, RUP (% of CP) was more variable (76.8 ± 14.8%CP) and RUP digestibility was highly variable (64.6 ± 23.1%RUP). No relationship between RUP and RUP digestibilities was observed. Also, average RUP digestibility was lower than the 80% reported for ring-dried blood meal in the 2001 NRC Requirements for Dairy Cattle. Amino acid digestibilities were generally similar to RUP digestibility (65 ± 24%), with the exception of lysine digestibility, which was consistently lower (56 ± 27%). Lysine digestibility approached 0% at RUP digestibility of 20%. These data provide a significant improvement in our knowledge regarding the digestibility and nutritional value of commodity blood meal and should improve feed library values found in ration formulation software currently used throughout the dairy industry.

Key words: blood meal, lysine, RUP

W387 Tannin content and rate of ruminal protein degradation of legume hays. S. Colombini*[1], G. A. Broderick[2], J. H. Grabber[2], and W. K. Coblentz[3], *[1]University of Milan, Milan, Italy, [2]U.S. Dairy Forage Research Center, Madison, WI, [3]U.S. Dairy Forage Research Center, Marshfield, WI.*

This study evaluated ruminal protein degradation rates of legume hays that varied in tannin content. Two cuttings of 5 varieties of birdsfoot trefoil (*Lotus corniculatus*) that were selected for different tannin contents, but similar NDF and CP, and Spredor-4 alfalfa (control) were conserved as hay. Samples were ground (1 mm) and analyzed for chemical composition and tannin content. Protein degradation rate was determined using ruminal inocula in the Michaelis-Menten inhibitor in vitro method; 3 incubations were performed. Extent of degradation was estimated from net release of N in ammonia (phenol-hypochlorite colorimetry) plus amino acids and small peptides (o-phtaldialdehyde colorimetry). Samples also were incubated in situ to estimate RDP. Data were analyzed using mixed procedure of SAS and are in the table. There were differences among trefoils in tannin content with the greatest values for Dewey and Goldie and lowest for Exact. Within cut, alfalfa had the most rapid degradation rate and Exact had the numerically greatest rate among trefoils. Rate was significantly affected ($P < 0.001$) by variety and cutting; there also was a variety*cutting interaction ($P = 0.017$). Regression between degradation rate and tannin content was: $y = -0.0027 (\pm 0.0007) x + 0.231 (\pm 0.019)$ ($r^2 = 0.61$). Regression between in situ RDP and tannin content was: $y = -0.194 (\pm 0.024) x + 84.0 (\pm 0.68)$ ($r^2 = 0.87$). Soluble N content must be determined to compute RDP within the in vitro method. Degradation rates were more rapid for second cutting hays; this may be explained partly by greater NDIN content in hays from first vs. second cutting (21 vs. 18% of total N).

Table 1. Results

Variety	Cut	Tannin (g/kg DM)	NDF (% DM)	Total N (% DM)	NDIN (% total N)	In vitro rate(/h)
Dewey	1	36.8	36.7	3.05	26.9	0.126
Georgia	1	23.0	37.1	3.07	20.8	0.140
Exact	1	15.6	38.2	3.13	18.2	0.150
Lotanova	1	27.8	38.2	3.00	20.7	0.134
Goldie	1	36.7	38.1	2.91	23.2	0.137

Alfalfa	2	0	38.7	3.16	15.4	0.290

Key words: protein degradation, birdsfoot trefoil, tannins

W388 Evaluation of acid-insoluble ash and indigestible neutral-detergent fiber as total tract digestibility markers. C. Lee*, A. N. Hristov, T. Cassidy, and K. Heyler, *Pennsylvania State University, University Park.*

The objective of this experiment was to evaluate acid insoluble ash (AIA) and indigestible NDF (INDF) as intrinsic digestibility markers in comparison with total fecal collection (TC). The experiment was part of a larger experiment, which involved 8 Holstein cows (102 ± 28 DIM; 26.0 ± 0.79 kg/d DMI; 40.9 ± 1.46 kg/d milk yield). The experimental design was a replicated 4 × 4 Latin square with the following treatments: 15.6% crude protein (CP) diet (HighCP), 14.0% CP diet (LowCP), 14.0% CP diet supplemented with a ruminally protected Lys (AminoShure-L, 100 g/cow/d; LowCPLys), and 14.0% CP diet supplemented with ruminally–protected Lys plus a ruminally–protected Met (Mepron, 24 g/cow/d; LowCPLysMet). Each period consisted of 14 d of adaptation and 7 d of sample collections. Total feces were collected for 5 consecutive days during each period. Composite TMR and fecal samples were analyzed for nutrients, AIA (digestion with 2 N HCl) and INDF (12 d ruminal incubation in 25μm pore size bags). Apparent total tract digestibilities of all nutrients were greater for AIA compared with INDF and TC (Table 1). Digestibility estimated using INDF or TC were not different. There was method × treatment interaction (TC and INDF) for all nutrients (P = 0.02 to 0.07), except CP. Examination of the method × treatment mean comparisons revealed no significant differences between TC and INDF. In conclusion, using AIA as a digestibility marker yielded lower fecal output estimates and consequently greater apparent digestibility values for all dietary nutrients compared with TC or INDF. Apparent total tract digestibility of nutrients did not differ between TC and INDF. In the conditions of this experiment, INDF was a more appropriate intrinsic digestibility marker than AIA.

Table 1. Comparisons of methods for determining total tract apparent digestibility

	Method				
Item	TC	INDF	AIA	SEM	*P*-value
DM	61.0[b]	59.4[b]	67.9[a]	1.10	<0.001
OM	62.2[b]	60.8[b]	69.0[a]	1.13	<0.001
NDF	40.4[b]	38.2[b]	51.1[a]	1.21	<0.001
ADF	35.5[b]	33.0[b]	47.0[a]	1.35	<0.001
CP	52.4[b]	50.4[b]	60.8[a]	1.66	0.002

W389 Nutritional value of *Smallanthus sonchifolius* and *Moringa oleifera* tropic forage as alternative in ruminant feeding. L. C. Bernal Bechara*, *Universidad de La Salle, Bogotá, Colombia.*

The aim objective was to evaluate the nutritional quality of *Smallanthus sonchifolius* and *Moringa oleifera* to determinate their physical and chemical properties as a tool to predict its nutritive value. Two treatments were evaluated: a. *Smallanthus sonchifolius* leaves and b. *Moringa oleifera* leaves; with 4 replications per forage type. Physical properties evaluated were density (g/ml), solubility (%), the water holding capacity (g/g) and buffering capacity (meq). The samples were reduced to a particle size of 1 mm. Chemical fractions were analyzed for dry matter (DM, %), crude protein (CP, %), neutral detergent fiber (NDF, %), acid detergent fiber (ADF, %), ether extract (EE; %), total digestible nutrients (TDN,%), net energy NE of lactation, maintenance and gain (NEl, NEm, NEg; Mcal/kg) and in vitro digestibility of dry matter IVDDM (%). A completely randomized was evaluated experimental design. The data of the selected variables was analyzed using by procedure a GLM model and differences between means treatments were analyzed using Tukey in the SAS Statistical package. Density, water absorption capacity and buffering capacity did not difference (P > 0.05) between forages types, but solubility was greater (P < 0.001) in *Smallanthus sonchifolius* (14%) than *Moringa oleifera* (7%). There was no difference in DM, CP and EE between forages, but NDF and ADF were greater in *Moringa oleifera* than *Smallanthus sonchifolius* (61.24% vs. 42.77% FDN; 38.96 vs. 26.33% FDA, respectively). TDN, net energy and IVDDM was in *Smallanthus sonchifolius* than *Moringa oleifera* (69.47 vs. 60.56% TDN; 57.6 vs. 48% IVDDM; 1.5 vs. 1.3 Mcal/kg NEl; 1.7 vs. 1.4 Mcal/kg NEm; 1.0 vs. 0.7 Mcal/kg NEg). These physical and chemical characterization results suggest that leaves of *Smallanthus sonchifolius* are potential forage to be used in cattle feeding, because of its low fiber content and greater IVDDM than *Moringa oleifera*.

Key words: *Moringa oleifera*, nutritional quality, *Smallanthus sonchifolius*

W390 Postprandial hypoglycemia after feeding of alcohol-fermented apple pomace silage. M. Kondo, H. Moriuchi, J. Fang, H. Suzuki, and M. Matsuzaki*, *Hirosaki University, Hirosaki, Aomori, Japan.*

Four Suffolk ewes were used to study the effect of feeding apple pomace silage (APS) with different ethanol content on postprandial glucose homeostasis in a 4 × 4 Latin square design trial. Ewes were fed alfalfa hay cube and either a concentrate (Ctrl), low-ethanol APS (L-APS), high-ethanol APS (H-APS) or the concentrate supplemented with equal amount of ethanol in H-APS (+EtOH). Alfalfa hay cube and the concentrate or APS provided half of TDN requirement for maintenance. The 70% apple pomace, 6% soybean meal, 12% wheat bran and 12% beet pulp (as FM basis) were mixed for APS preparation to contain equal amount of TDN and CP as the concentrate. Ethanol content of APS was manipulated by ensiling with either fresh apple pomace, which has slight amount of ethanol, or alcohol-fermented apple pomace, which left on 2-mo after production. The resultant L-APS and H-APS contained 1.4 and 3.3% of ethanol, respectively. At the end of each 14-d period, blood samples were collected via catheters before and after the morning feed for 120 min and then another 120 min after intravenous insulin challenge (0.1Î1/4U/kg BW). Plasma glucose was assayed for all samples and the concentrations of Insulin, glucagon, ethanol and D-3-Hydroxybutyric acid (DHBA) were assayed for samples for the first 120 min. The area under or upper the curve (AUC) of each plasma measurement was calculated. Plasma glucose was decreased and ethanol level increased after ingesting ethanol in the L-APS, H-APS and +EtOH treatments (P < 0.05). The AUCs of plasma glucose and ethanol in H-APS treatment were greater (P < 0.05) than the Ctrl, with the L-APS and +EtOH intermediate. Plasma insulin level was elevated only in the L-APS after feeding (P < 0.05) while glucagon level was unchanged by feeding in all treatments. Plasma DHBA was gradually increased after feeding and that in the L-APS was higher than other treatments (P < 0.05). The glucose AUC after insulin challenge was greater (P < 0.05) in the Ctrl than other treatments. A significant correlation between the AUCs of plasma glucose and ethanol (P < 0.05) suggest that postprandial hypoglycemia after APS feeding is due primarily to ingestion of ethanol.

Key words: apple pomace, glucose, ethanol

W391 Inclusion of substrate of *Pleurotus ostreatus* on kinetics of in vitro fermentation of *Brachiaria* hay. S. L. S. Cabral Filho*[1,2], R. S. Oliveira[1], R. A. Mandarino[1], and C. A. Lobo[1], *[1]Universidade de Brasília, Brasilia, Distrito Federal, Brasil, [2]Fazenda Experimental Agua Limpa, Brasilia, Distrito Federal, Brasil.*

The demand for increased and faster production of food in the world makes the production of mushrooms an important alternative. However, each 80g of mushrooms produced resulted in 100g of substrate residue. The aim of this study was to assess the inclusion of the substrate production of *Pleurotus ostreatus* on in vitro fermentation of hay-based diet of *Brachiaria brizantha* for ruminants, as well as measuring gas production and rumen kinetics for different levels of inclusion of substrate. The experiment was conducted using a semi-automatic gas production technique, the rumen inocula were collected from 3 fistulated bovines, grazing *Brachiaria* pasture. We used a *Brachiaria brizantha* hay and exhausted substrate for *Pleurotus* production, for the composition of the treatments, which were defined as: ES (100% of exhausted substrate), BH (100% *Brachiaria* hay), ES5 (5%ES +95% BH), ES20 (20%ES +80%BH) and SE30 (30%ES +70%BH). The experiment was conducted in a 5 × 3 factorial with 5 treatments and 3 inocula (3 donor animals). The dry matter degradability (DMD) was determined after 96h of fermentation. No significant differences among treatments were observed on the potential gas productions (A) BH, ES5, ES20 and ES30. The averages were 262.6, 284.3, 256.6 and 261.7 mL, respectively ($P > 0.05$), showing that the inclusion of the substrate did not affect the fermentation of *Brachiaria* hay. The ES treatment presented a lower potential gas production and DMD (165.9 mL and 52%, $P < 0.05$) demonstrated the lower quality of the exhausted substrate compared with hay, despite the presence of enzymes that degrade the cellulose in the mycelium of *Pleurotus*. The ES treatment had a shorter lag phase (L = 2.6 h, $P < 0.05$), which can be attributed to higher concentration of soluble carbohydrates due to higher proportion of wheat meal and mycelium in this treatment. The inclusion of the exhausted substrate did not impair microbial degradation of hay and it by-product can be used in ruminant feed.

Key words: gas production, roughages, mushrooms

W392 Evaluation of protein fractions of tropical grasses by near infrared reflectance spectroscopy. R. G. Basurto[1], G. Buendía-Rodríguez[1], S. S. González-Muñoz*[6], R. E. Ramirez[1], M. A. Barrón[2], G. J. J. Bustamante[3], R. E. Santos[4], M. J. J. Maldonado[5], and C. J. A. Bonilla[3], *[1]CENID Fisiología y Mejoramiento Animal, Ajuchitlán, Querétaro, [2]CE Huimanguillo–CIRG, Huimanguillo, Tabasco, [3]CE Santiago Ixcuintla–CIRPAS, Nayarit, [4]CE Iguala–CIRPAS, Iguala, Guerrero, [5]CE Rosario Izapa–CIRPAS, Tapachula. INIFAP–México, [6]Colegio de Postgraduados, Montecillo, Estado de México, México.*

The aim of study was to evaluate the use of near infrared reflectance spectroscopy as alternative method to determine CP, and degradable (DIP) and undegradable (UIP) intake protein of tropical grasses. Nine hundred and 23 samples of 13 species were collected by clipping sampling at different ages of re-growth (28, 42, 56, 70 and 84 d) in plots in the states of Chiapas, Guerrero, Nayarit and Tabasco, México. The species were *D. aristatum*, *C. dactylon*, *H. altissima*, *U. brizantha*, *D swazilandensis*, *C. plectostachyus*, *U. maximum*, *B. humidicola*, *C. echinatus*, *A. gayanus*, *B. brizantha* × *ruziziensens*, *D. eriantha*, and *U. mutica*. DIP was estimated as the protein fraction that disappeared after incubation with a protease, and UIP was equal to the remaining protein in the samples. The samples were scanned at a spectrophotometer Nicolet FT-IR 6700 (Thermo Fisher Scientific, Inc.) over a wavelength range from 1,000 to 2,500 nm in reflectance; data were stored as log (1/R) at intervals of 4 nm. Calibrations equations were developed using modified partial least squares with TQ Analyst program (v8.0). The selection of the equations was based on: coefficient of determination of calibration (R^2 cal), the minimization of standard error of calibration (SEC) and standard error of cross validation (SECV) and ratio SECV/SD; if the ratio is >0.33, then calibration had a low predictive power. It is concluded that NIRS calibration for PC showed good accuracy, but calibrations were less accurate for DIP and UIP.

Table 1.

		Chemical analysis			Statistics				
Item	N	Mean	Range	SD	R^2 cal	SEC	SEP	SECV	Ratio
Crude protein (DM)									
Calibration	677	7.98	1.0–8.6	3.01	0.94	0.79			
Validation	244	3.01	1.2–7.5	2.05			0.90	0.94	0.31
DIP (% DM)									
Calibration	681	3.44	1.0–8.6	1.32	0.91	0.39

W393 The effect of storage structure on haylage and corn silage fermentation. C. Rasmussen*, D. Petri, S. Jens, and A. H. Smith, *Danisco USA, Waukesha, WI.*

Decreasing nutritional and dry matter losses of ensiled forages has always been an important topic of research and debate. Many factors contribute to silage quality (time of harvest, packing density, aerobic exposure, etc.), but one factor often overlooked is storage structure. The objective of this study was to determine if certain storage structures produce better quality silage and if certain storage structures are better suited for specific crops. Samples used in this study included 170 haylage and 242 corn silage stored in bunkers, bags, upright silos, or piles received from 2009 and 2010 and originating from commercial farms within the United States, primarily the upper Midwest. Samples were analyzed for pH, dry matter, lactate, acetate, ethanol, yeast, and mold. Data was analyzed as a 2 × 4 factorial Anova using Proc Mixed procedure as well as Proc corr procedure for correlation analysis (SAS 9.1.3). The mean pH for corn silage and haylage at 3.96 ± 0.031 and 4.76 ± 0.036 respectively would be considered high for well-ensiled crops reflecting the fact that samples received for analysis were generally those of questionable quality. All other measured parameters were within normal ranges. The pH was significantly higher for silos ($P \leq 0.05$), which was correlated with significantly higher levels of spoilage organisms, both yeast and mold ($P \leq 0.05$). Further investigation is needed to determine whether fermentation is more effective in bunkers, piles and bags and if the samples obtained for analysis from these structures are from deeper regions with less oxygen exposure than silo samples.

Key words: silage, corn, haylage

W394 The effect of direct fed lactic acid bacteria combined with monensin. R. C. de Souza*[1], R. B. Reis[1], J. Holliday[2], E. Rabelo[4], and R. A. Filho[3], *[1]Federal University of Minas Gerais, Belo Horizonte, Minas Gerais, Brasil, [2]Chr. Hansen - Animal Health and Nutrition, Hørsholm, Denmark, [3]Chr. Hansen - Animal, Valinhos, São Paulo, Brasil, [4]Rehagro Team Consultation, Belo Horizonte, Minas Gerais, Brasil.*

Monensin is widely accepted in the American cattle industry, but alternatives to ionophores such as direct fed microbials (DFM) are receiving increased awareness. The question is, if the 2 combined can have a synergistic effect. To address this issue, both a continuous culture experiment and an in vivo study were conducted. The in vivo study included 40 multiparous Holstein cows (milk yield between 8.000 and 10.000 kg) which were supplemented with monensin and a DFM (contaning *E. faecium* and *S. cerevisiae*, Probios TC, Chr. Hansen). The continuous culture trial included a diet with a forage:concentrate ratio of 50:50 combined with four treatments (No additive, DFM, Monensin, and DFM+Monensin). The in vivo trial tested the effect of the DFM on milk yield and milk composition following three alternative applications: included solely pre-partum, solely post-partum or both pre and post-partum. Post-partum, the cows were fed a diet containing corn silage (forage:concentrate ratio of 50:50) and sufficient monensin to supply 16 ppm in the diet DM. The results from the continuous culture showed that monensin significantly ($P < 0.05$) reduced NDF digestibility compared to control, while adding the DFM diminished this effect. There were no treatment effects on the molar proportion of the VFA of any of the treatments. In the in vivo study, supplementing the DFM on diets with monensin, resulted in an additional increase ($P < 0.01$) in milk yield (32.27, 28.37, 35.65 and 36.20, respectively for treatments no additive, DFM pre-partum, DFM solely postpartum and DFM pre and post-partum), milk fat and protein production in both the post-partum and the post and pre-partum period. A negative effect on milk yield ($P < 0.01$) was observed when feeding DFM solely pre-partum. The DFM supplementation only after parturition was better for the increasing milk production and its quality according to composition compared to treatments with no additive and DFM pre-partum.

Key words: transition, DFM, monensin

W395 Morphological response of the ruminal and omasal mucosae to the variation in the energy of the diet. R. F. de Lima, J. C. de Resende Júnior*, J. L. P. Daniel, S. de F. Costa, M. B. Moreira, and M. G. Cardoso, *Universidade Federal de Lavras.*

The rumen capacity to absorb volatile fatty acids (VFA) is proportional to the extent of their absorptive surface which responds positively to the direct and indirect stimulation of VFA. There are indications that the wall of the omasum, which in dairy cows is responsible for about 40% of absorption of VFA, also could respond to the same stimuli of proliferation of the rumen wall. Aiming to test this hypothesis we compared the morphology of fragments of rumen and omasum obtained by biopsy. Four nonlactating cows and not pregnant, not defined breeds and unknown ages were sequentially fed 2 diets. One diet only of chopped grass (CG) and other with concentrate plus chopped grass (CCG). In the first 18 d of the experiment the animals were fed CG diet. In subsequent 18 d the cows received the CCG diet. Then were fasted for 72 h. Biopsies of the ventral sac of the rumen were made at the end of the period of the CG diet, at 4 and 18 d of the CCG diet and at end of fasting period. After fasting the cows were fed with the CCG diet again by 18 d with biopsies on d 4, 12 and 18. Data were analyzed as repeated measures considering the effect of cow, compartment, diet, possible interactions and error. The DMI and the TDN intake were higher ($P < 0.001$) in periods in which the animals were fed with the CCG diet. The mitotic index (MI) of the basal layer in the epithelium of the rumen and of the omasum were higher ($P = 0.01$ for interaction between compartment and diet) in the fourth days of CCG diet and the same occurred with the VFA concentration in the rumen ($P <$ 0,001). There was positive correlation between MI of the rumen and the omasum ($R^2 = 0.66$; $P < 0,01$) . The width of the rumen papillae varied among treatments and was greater at 18 d of CCG diet ($P < 0.001$), which revealed proliferative stimulus of the rumen wall. The similarity ($P = 0.67$) in thickness of the not keratinized layers of the epithelium and the positive correlation between the MI of the rumen and of the omasum, indicate that the stimulation of cell division caused by the energy content of the diet has simultaneous effect in both compartments. However the omasum seems respond more quickly to the stimulus.

Key words: acidosis, ruminant stomach morphology, transition diet

W396 Determination of solubility of alternate magnesium sources and their impact on pH with an optimized in vitro rumen fermentation protocol. S. J. Taylor*[1], J. Apajalahti[2], E. Pennala[2], C. Murphy[1], and T. Rinttilä[2], *[1]Celtic Sea Minerals Ltd., Cork, Ireland, [2]Alimetrics Ltd., Espoo, Finland.*

Absorption of Mg from the rumen of mature ruminants is dependent on its concentration in the liquid phase. An in vitro model of rumen function modified to investigate the mode of action of materials known to affect pH (Taylor et al. 2011) was used to investigate the solubility of different sources of Mg. Simulation protocol. The simulation used 1 g (DM) feed (50% grass silage, 40% barley meal, 10% soy). The bicarbonate and phosphate buffer (Agriculture Handbook, Vol 379, USDA 1970) was diluted 1:4 with 0.9% NaCl. The simulation was inoculated with 5% of fresh, strained rumen fluid from a fistulated cow on a high energy diet and continued for 9 h in triplicate. Anaerobic techniques were applied throughout. Ten treatments included negative control, Acid Buf alone (50 mg/40mL) and Acid Buf plus 8 different sources of Mg oxide (15mg/40mL). Products referred to as country codes in the table were obtained from international feed industry. Analyses. Mg and pH were determined at indicated time points from inoculation. Soluble Mg was analyzed by ICP. Results were compared with the volume of 0.1N HCl consumed by 0.25 g of product in 2 h at pH 5.5 using Titrino Automated pH meter. Inclusion of Acid Buf reduced the drop of pH. Mg was released into solution at a rate dependent on the source and correlated with the titration. Release of Mg significantly suppressed the decline of pH.

Table 1. Results

	2 h	9 h	9 h		Titration with 0.1 *N* HCl
Treatment	Mg (mg/L)	Mg (mg/L)	% Mg solubility	pH	ml*

W397 Influence of *Salix babylonica* and *Leucaena leucocephala* extracts on ruminal fermentation activities in growing lambs. R. P. Hernández[1], A. Z. M. Salem*[1], R. R. Rojo[1], and D. L. Camacho[2], *[1]Universidad Autónoma del Estado de México, Centro universitario UAEM – Temascaltepec, Km 67.5 Carr. Toluca – Tejupilco Estado de México CP 51300, México, [2]Universidad Autónoma de Guerrero, Facultad de Medicina Veterinaria y Zootecnia, Carretera Altamirano – Iguala Km 3 CP 40660 Cd. Altamirano Guerrero, México.*

Sixteen Katahdin × Pelibuey crossbreed male lambs 3 to 4 mo of age and 24 ± 0.3 kg BW were used to study effects of administration of extracts rich in secondary compounds from *Salix babylonica* (SB) and *Leucaena leucocephala* (LL) on ruminal pH and protozoal account as well as total and individual VFA and ammonia N concentrations. After 2 wk of adaptation consuming a total mixed ration (TMR; 219 and 141 g/kg of crude protein and NDF, respectively), lambs were weighed and distributed by BW into 4 groups of 4 lambs/group in a completely randomized design with: Control group TMR; SB group TMR (as Control plus *S. babylonica* extract at 30 mL/ lamb /d); LL group TMR (as Control plus *L. leucocephala* extract at 30 mL/ lamb/d); SBLL group TMR (as Control plus 30 mL/lamb/d of *S. babylonica* and *L. leucocephala* extracts in a (1:1, v:v) mixture) for a 63-d experiment. Data were analyzed using the MIXED procedure for repeated measures. A weekly stock volume of the individual extracts as well as their 1.1 mixture were prepared for daily administration. Extracts were orally administered before the 08:00 h feeding to each lamb. pH values were increased ($P = 0.004$) with SBLL (1:1, v:v) compared with other groups. Protozoal amounts were no affected ($P = 0.531$) by the administration of extracts to lambs. Individual extracts (SB or LL) increased ($P = 0.0435$) the propionic acid concentration versus control or SBLL groups. Ruminal acetic acid ($P = 0.5053$) and total VFA ($P = 0.2709$) were not affected by extracts administration, while butyric acid ($P = 0.0435$) and ammonia N concentrations ($P = 0.032$) were increased with the SB or LL extracts vs. SBLL or control. In conclusion, individual extracts of SB or LL had effective impacts on ruminal fermentation activities and increased the propionic acid concentrations that suggested an improvement in animal daily gain.

Key words: extracts, lambs, ruminal fermentation

W398 Effect of live yeast *Saccharomyces cerevisiae* (strain Sc 47) on ruminal parameters of growing Mehraban lambs. N. Baleghi[1], A. Taghizadeh[2], A. FarahAvar[3], and H. Khalilvandi-Behroozyar*[3,4], *[1]Islamic Azad University, Maragheh Branch, [2]University of Tabriz, [3]University of Tehran, [4]Urmia University.*

Yeast (*Saccharomyces cerevisiae*) products may exert beneficial effects on ruminant productivity by either increasing fermentability of fiber and/or allowing rumen microbes to more effectively metabolize end products of ruminal starch fermentation. The objective was to evaluate the possible effects of live yeast on different ruminal parameters in fattening Mehraban lambs. Twelve male lambs (average BW 34 ± 4.2 kg) randomly assigned to 3 groups: a) control, without additive b) 1 g/ day/head and c) 1.5 g/day/ head S. cerevisiae (strain Sc 47) with 8 × 10^9cfu per gram. Additives supplemented via gelatin capsules to TMR ration (alfalfa hay, wheat straw, barley grain, canola meal, wheat bran, Mineral-vitamin mix, calcium carbonate and salt) formulated for 200 g/d weight gain using CNCPS-S. Animals fed experimental rations for a period of 70 d in 2 equal meals. Ruminal fluid samples were taken from rumen at 4 h after morning meal in the last day of experiment to determine rumen pH and concentration of NH3-N and VFA. Gas chromatography was used to determine VFA profiles equipped with a packed column. Protozoal counts were determined using light microscopic numeration with hematocytometer. Data were analyzed by GLM procedure of SAS 9.1 with CRD design and Duncan test ($P \leq 0.05$). Treatments were failed to have statistically significant effects on measured variables, but there was a tendency ($P \leq 0.1$) for higher total VFA, acetate and ammonia nitrogen concentrations and protozoa counts in lambs receiving 1.5 g/head/ day compared with control.

Table 1. Characteristics of ruminal fermentation in sheep fed Saccharomyces cerevisiae

	1	2	3	SEM
Mean pH	6.32	6.38	6.61	0.081

W399 Intake and digestibility by wethers fed a fresh ryegrass-based diet intraruminally infused with *Acacia mearnsii* tannins. F. Hentz*[1], C. J. Härter[2], G. V. Kozloski[1], S. C. Àvila[1], and D. S. Castagnino[2], *[1]Universidade Federal de Santa Maria, Santa Maria, RS, Brazil, [2]Universidade Estadual Paulista, Jaboticabal, SP, Brazil.*

Eight Polwarth × Texel wethers (30 ± 4.8 kg BW), housed in metabolic cages and offered fresh ryegrass (*Lolium multiflorum*) ad libitum (10% refusals) were used in a 4 × 4 Latin Square-designed experiment to evaluate the effects of infusing *Acacia mearnsii* tannin extract (containing 0.625 g/g of condensed tannins) on intake and whole tract apparent digestibility. Treatments consisted of no tannin (0) or intraruminal infusion of 20, 40 or 60 g tannin/kg of ingested DM, according to the DMI of the previous day. Experimental periods lasted for 15 d (10 d adaptation, 5 d collection periods). Feed, orts and fecal output were recorded daily on d 10 to 15 and samples collected and composited within animal and period. Data was analyzed using the MIXED procedures of SAS. When the treatment effect was significant ($P < 0.05$) or tended to be significant ($0.05 < P \leq 0.10$), the means of different treatments were compared by orthogonal contrast (0 vs. tannins), and the effect of levels of tannin infusion was analyzed by regression for linear and quadratic effects. There were no quadratic effects for any variable. Total DM, OM and digestible OM intake and digestibility were greatly reduced ($P < 0.05$) with tannin infusion (Table 1). Moreover, this negative effect increased linearly at increased levels of tannin infusion for OM digestibility and digestible OM intake ($P < 0.05$). Although N intake tended to decrease ($P = 0.077$) and N digestibility decreased ($P < 0.01$) with tannin infusion, they did not vary ($P > 0.05$) within the levels of tannins. In conclusion, dietary inclusion

of Acacia meanrsii extract in concentrations above 20 g/kg of DMI negatively affect nutrients supply to wethers fed a temperate grass-based diet.

Table 1. Intake and total tract digestibility by wethers fed a fresh ryegrass-based diet intraruminally infused with Acacia mearnsii tannins (n=8 per treatment)

W400 Effect of sorghum grain supplementation on glucose metabolism 2: Ovine. M. Aguerre*[1], C. Cajarville[2], A. L. Astessiano[3], M. Carriquiry[3], and J. L. Repetto[1], *[1]Departamento de Bovinos, Facultad de Veterinaria, Universidad de la República, Montevideo, Uruguay, [2]Departamento de Nutrición Animal, Facultad de Veterinaria, Universidad de la República, Montevideo, Uruguay, [3]Departamento de Producción Animal y Pasturas, Facultad de Agronomía, Universidad de la República, Montevideo, Uruguay.*

Corriedale × Milchschaf lambs (n = 12; 45.6 ± 6.2 kg), blocked by BW, were used to evaluate the effects of sorghum grain supplementation (0 vs. 1.5% BW, S0 vs. S1.5, respectively) on plasma glucose, insulin and glucagon concentrations, and on hepatic expression of genes related to glucose metabolism. Lambs were fed ad libitum fresh *Lotus corniculatus* (31.8% DM, 12.4% CP, 41.8% NDF). At the end of treatments (31 d) blood samples were taken every 2h from 0 to 6h post-supplementation, to determine glucose by colorimetry and insulin and glucagon by RIA. Liver biopsies were collected to quantify abundance of pyruvate carboxylase (PC), phosphoenolpyruvate carboxykinase (PCK–1) and insulin receptor (IR) mRNA by SYBR–Green real time PCR, using hypoxanthine-guanidine phosphoribosyltransferase as endogenous control. Data were analyzed with MIXED procedure (SAS). No differences on glucose levels were found between treatments (60.0 vs. 58.3 ± 5.61 mg/dL, P = 0.756; for S0 and S1.5 respectively) and the shape of the curves was similar over the 6h post-supplementation. Mean insulin concentrations were not different between treatments (10.1 vs. 8.80 ± 2.04 µUI/mL, P = 0.404; for S0 and S1.5 respectively), recording a 2-fold increase from 0 to 2h in S0 group (5.55 vs. 12.3 ± 2.51 µUI/mL, P = 0.028) and from 0 to 4h in S1.5 group (6.06 vs. 14.2 ± 2.88 µUI/mL, P = 0.026) returning to baseline at 6h in both groups. Glucagon concentrations were lower in S0 than S1.5 (50.1 vs. 63.7 ± 5.27, P = 0.053) but no interaction between hour and treatment was found (P = 0.415). Plasma glucagon tended to be negatively correlated with OM intake (r = –0.52, P = 0.101). The IR and PC mRNA did not differ between treatments (11.3 vs. 12.8 ± 2.23, P = 0.663 and 38.9 vs. 35.9 ± 7.82, P = 0.758 for S0 and S1.5 respectively), but PCK–1 mRNA was greater in S0 than S1.5 (11.2 vs. 8.60 ± 2.66, P = 0.048). In conclusion no major changes were observed in the glucose metabolism of lambs after sorghum grain supplementation. The results were consistent with a decrease in OM intake in supplemented lambs.

Key words: grazing sheep, hormones, liver mRNA

W401 Inter-individual variability in in vitro methane production by ruminal microorganisms from sheep fed different diets. M. J. Ranilla*[1,2], M. L. Tejido[1,2], C. Saro[1,2], and M. D. Carro[1,2], *[1]Dpto. Producción Animal. Universidad de León, León, Spain, [2]IGM (CSIC-ULE), Finca Marzanas s/n, Grulleros, León, Spain.*

A large variability in methane emissions between individual sheep and cattle has been repeatedly reported. The aim of this study was to investigate the inter-individual variability in methane production in batch cultures of ruminal microorganisms (BCRM) inoculated with ruminal fluid from sheep fed different diets. Our hypothesis was that potential differences between inocula may be masked by the homogeneous conditions (pH, temperature, retention time) in the BCRM. Six rumen-fistulated sheep (S1 to S6) were fed 4 diets differing in their forage:concentrate ratio and type of forage in a partially replicated 4 × 4 Latin square design. In each period, ruminal fluid from each sheep was used to inoculate BCRM containing 500 mg of the same 4 diets as substrate. Cultures were incubated at 39°C, and methane production was measured after 8 and 24 h of incubation. Mean values of methane production for each sheep (pooled values for all diets and substrates) at 8 h of incubation ranged from 299 to 519 µmol, with a coefficient of variation of 0.241. Methane production at 24 h of incubation was rather consistent in BCRM inoculated with ruminal fluid from S1, S4, S5 and S6 (mean values of 650, 716, 669 and 671 µmol, respectively), with a mean value of 677 µmol and a coefficient of variation of 0.041. Values for S2 and S3 were 552 and 858 µmol, respectively. When data from all 6 sheep were pooled together, the mean value (686 µmol) was similar to the one obtained for S1, S4, S5 and S6, but the coefficient of variation increased to 0.155. Because the study was conducted in vitro, differences between BCRM inoculated with ruminal fluid from different sheep fed the same diet can only be attributed to differences in microbial populations in the inocula and the survival of microbes over the incubation. These results support previous observations on the considerable variation in the amount of methane produced by individual animals, despite of the homogeneous incubation conditions in the BCRM, and illustrate the importance of using mixed inocula from more than 1 single animal for in vitro studies.

Key words: methane, in vitro ruminal fermentation, inter-individual variability

W402 Influence of sugar cane molasses levels on apparent digestibility of diets for finishing lambs. L. R. Flores*[1], J. J. Lomeli[1], I. A. Vazquez[1], I. Quintero[1], J. E. Borbolla[1], J. E. Guerra[2], and R. Barajas[1], *[1]FMVZ-Universidad Autonóma de Sinaloa, Culiacán, Sinaloa, México, [2]FA-Universidad Autónoma de Sinaloa, Culiacán, Sinaloa, México.*

Four Katahdin lambs 24.8 ± 0.9 kg were used to determine the influence of sugar cane molasses levels on apparent digestibility of diets for finishing lambs. In agreement with a Latin Square Design lambs were assigned to the following dietary treatments: 1) Corn-soybean meal based-diet with 87% of concentrate and 13% of roughage (16% CP; 2.45 Mcal of DE/kg), and no cane molasses added (CTRL); 2) Diet similar to CTRL with 8% of sugar cane molasses substituting corn in dry matter basis (M8); 3) Diet similar to CTRL with 16% of sugar cane molasses substituting corn in dry matter basis (M16); and 4) Diet

similar to CTRL with 24% of sugar cane molasses substituting similar proportion of corn in the dry matter of the diet (M24). Data was analyzed by ANOVA; CTRL (0 molasses added) vs. all other treatments (8, 16, and 24% of molasses) were compared by orthogonal contrast; linearity of increasing molasses levels on dietary digestibility was tested using polynomial procedures. Molasses inclusion at any tested-level increased ($P < 0.05$) fecal excretion of DM and organic matter. CP excretion was increased linearly ($P < 0.05$) as cane molasses level was augmented in the diet. Cane molasses inclusion decreased ($P < 0.05$) apparent digestibility of dry matter (80.3 vs. 75.7%), organic matter (82.0 vs. 77.1%), and crude protein (78.0 vs. 70.6%). Observed/expected CP digestibility was 9% lower in molasses diets compared with CTRL ($P < 0.05$). By substitution method using corn as reference, energetic value of sugar cane molasses was estimated to be 2.92 Mcal/kg of DM that is 85% of its expected value, and complete digestive tract digestibility of crude protein of Molasses was calculated in 17%. It is concluded, that sugar cane molasses substitution for corn in finishing diets for lambs, decreases diet-digestibility, and the expected energy content of sugar cane molasses would be near of 2.9 Mcal of DE kg of DM^{-1}.

Key words: digestibility, lambs, sugar cane molasses

W403 Influence of additional tannins-extract level on feedlot-performance of finishing lambs. R. Barajas*[1], B. Ortiz[1], A. Camacho[1], N. E. Villalba[2], L. R. Flores[1], J. J. Lomeli[1], and J. A. Romo[1], *[1]FMVZ-Universidad Autonóma de Sinaloa, Culiacán, Sinaloa, México, [2]Agricola Ganadera Mojolo, Culiacán, Sinaloa, México.*

An experiment was conducted to determine the influence of additional tannins-extract level on feedlot-performance of finishing lambs. Thirty 6 weaned lambs 24.5 ± 0.36 kg, 18 lambs of 3/4 Katahdin x 1/4 Pelibuey breed ; and remainder 18 lambs of 3/4 Dorper x 1/4 Pelibuey Breed, were used. Animals were blocked by breed and weight and placed in groups of 3 in 12 elevated pens. Lambs were assigned in a complete randomized block design to be fed with a 5:95 roughage:concentrate corn-soybean meal based-diets (14% CP; 2.07 Mcal of NEm/kg) containing DM basis 0, 0.3 or 0.5% of a tannins-extract (TE). Tannins extract was supplied from a blend of condensed-tannins of quebracho trees, with soluble-tannins of cheese-nut trees (Silvafeed-Bypro; SilvaTeam-Inudor, S.A., Argentina). Lambs fed with 0.3% tannins diet had the highest final weight ($P = 0.02$), and a quadratic response ($P < 0.01$) of final weight to tannins-extract level was observed. Final weight values were 36.7, 38.8 and 37.7 kg, for tannins-extract levels of 0.0, 0.3, and 0.5%, respectively. Average daily gain was improved in 12% ($P = 0.02$) by 0.3% of tannins-extract level compared with no additional tannins treatment. ADG of lambs fed 0.3% of TE was 7% higher than observed in 0.5% of TE fed-lams ($P = 0.08$). Average daily gain shown a quadratic response ($P = 0.03$) to tannins-extract level in the diet, mean values were 0.32, 0.35, and 0.33 kg/day, for treatments with 0.0, 0.3, and 0.5% of TE, respectively. Dry matter intake and gain/intake ratio were not affected by tannins extract level ($P > 0.20$). It is concluded, that addition of an extract-blend of condensed and soluble tannins in concentrations close to 0.3% of dietary DM improves performance of finishing lambs

Key words: feedlot-performance, lambs, tannins

W404 Carcass evaluations of sheep supplemented with brewer waste (ensiled and dried) grazing under the rainy season in tropics. F. P. Portilho*[1,2], S. L. S. Cabral Filho[1], H. Louvandini[1], A. M. Menezes[1], and B. S. L. Dallago[1], *[1]University of Brasilia, Brasilia, DF, Brazil, [2]Agrodefesa, Rio Verde, GO, Brazil.*

At reduced costs, industrial wastes enable usage of protein and mineral mixtures as ingredients in the formulation to improve the productive capacity. The aims of this study were to evaluate the carcass parameters of finishing sheep in pasture during the rainy season and to evaluate the effect of replacement of traditional protein source (soybean meal) by sources of low degradability in the rumen like cotton meal and brewery waste (dried and ensiled). We used 40 male sheep of Santa Inês breed, with average weight of 22.0 ± 3.14 kg, grazing on Aruana grass (Panicum maximum), receiving supplementation of 100 g/animal/d for 4 treatments, plus a control without supplementation. Treatments were represented by supplementation offered for sheep grazing at the end of the rainy season during 30 d (between March and April). The treatments were composed as follows: T1– mostly of dried brewer grain (DBG), T2– silage of brewer grain (SBG), T3– cotton meal (CM), T4– soybean meal (SBM) and T5– without supplement (control–C). The experiment was designed with randomized blocks, with 2 blocks (n = 20), 4 repetitions by treatment. Differences were not observed for carcass among the treatments evaluated ($P > 0.1$) with respect to pH of the carcass (5.14 ± 0.77), weight of thoracic organs (1.44 ± 0.31 kg), carcass length (55.5 ± 2.96 cm), body condition (2.52 ± 1.03), skin thickness (0.40 ± 0.09 cm), length of ham (50.9 ± 2.21 cm), ham weight (1.72 ± 0.35 kg), leg circumference (33.1 ± 2.15 cm), loin weight (0.32 ± 0.091 kg), palette (0.90 ± 0.23 kg), rib (1.33 ± 0.39 kg), neck (0.49 ± 0.10 kg) and diaper (0.19 ± 0.54 kg), water loss (16.1 ± 2.61 mL), tenderness (2.79 ± 0.95 kgf). The hot and cold carcass weight varied among the treatments ($P < 0.05$) comparing the supplemented and control. They were 12.3 and 11.9 kg (DBG), 10.6 and 10.4 kg (SBG), 8.5 and 8.2 kg (CM), 9 and 8.7 kg (SBM), 11.5 and 11.2 kg (C), respectively. The carcass weight had better trend for DBG and the worst one for the CM treated animals. Therefore the usage of brewer waste showed that it can be employed to replace protein sources without disparity in the carcass parameters.

Key words: brewer grains, supplementation, sheep

W405 Feed efficiency and carcass traits in crossbred Katahdin lambs supplemented with hydroponic green wheat. M. Guerrero-Cervantes*[1,4], M. A. Cerrillo-Soto[1,4], F. G. Ríos-Rincón[2,4], A. Estrada-Angulo[2,4], A. S. Juárez-Reyes[1,4], and H. Bernal-Barragán[3,4], *[1]Universidad Juárez del Estado de Durango, Durango, Durango, México, [2]Universidad Autónoma de Sinaloa, Culiacán, Sinaloa, México, [3]Universidad Autónoma de Nuevo León, Monterrey, Nuevo León, México, [4]Red Internacional de Nutrición y Alimentación en Rumiantes, Durango, Durango, México.*

Hydroponic green fodder is considered an important alternative to conventional protein sources in semiarid regions. This study was carried out to determine the effect of supplementing hydroponic green wheat (HGW) on feed efficiency and carcass traits in crossbred Katahdin lambs fed an oat-straw based diet. Thirty lambs (120 ± 15 d of age; 17.7 ± 0.250 kg BW) were fed during 13 weeks, placed in individuals pens and separated in 3 groups of 10 lambs each. The animals received 1 of 3 oat straw-based diets supplemented with 3 levels of HGW (TI 23% HGW; TII 19% HGW and TIII 13% HGW), which substituted corn grain and soybean meal of the diet. Experimental diets were isonitrogenous (13% CP). Data of daily weight gain, dry matter intake, feed efficiency and carcass traits were analyzed by ANOVA according to a completely randomized block design, using the initial body weight as covariate. No differences in the studied variables ($P > 0.05$) were determined; however, numerical increments were registered in daily weight gain, carcass yield, muscle percentage and feed efficiency in animals fed TI. Animals fed TII had a higher fat percentage than their counterparts. Lambs receiving TIII had slightly larger ($P > 0.05$) rib eye area. It is concluded that the utilization of HGW might improve feed efficiency and be cost-effective in growing lamb nutrition practices.

Table 1. Daily weight gain, feed efficiency and carcass traits

Item	Treatments			Mean
	T I	T II	T III	
Daily weight gain (g)	150±12	136±12	124±12	138±38
Daily DM intake (g)	1076±10	1091±10	1021±10	1063±60
Feed efficiency*	7.4±0.7	8.5±0.7	8.6±0.7	8.9±2.2
Carcass yield (%)	64.8±2.2	64.2±2.2	63.5±2.2	64.2±4.9
Rib eye area (cm^2)	13.0±1.0	12.8±0.9	13.7±0.9	13.2±2.1

W406 Effect of diet and finishing weight on performance and carcass traits of meat goat kids. A. Gaesser*[1], G. Rentfrow[2], T. K. Hutchens[2], J. Schoonmaker[1], K. Andries[3], J. E. Tower[1], M. E. Einstein[1], and M. K. Neary[1], *[1]Purdue University, West Lafayette IN, [2]University of Kentucky, Lexington, [3]Kentucky State University, Frankfort.*

The objective of this study was to evaluate 2 diets differing in starch and fiber content fed to 2 different target finishing weights (TW) on growth performance and carcass traits of meat goat kids. Diets were isocaloric (0.9 Mcal/kg NEg) and isonitrogenous (15% CP) and differed in the primary energy source (corn (C) vs. soybean hulls (SH)). The TW of kids were 27 kg and 34 kg. Intact male crossbred (n = 32) kids that had been weaned (initial weight of 22 ± 0.7 kg) for 30 d were individually fed and housed until reaching the TW. Kids were randomly assigned to one of 4 2 × 2 factorially arranged treatments of C, SH, and TW of 27 and 34 kg and data were analyzed by a linear ANOVA model that included diet (C vs SH), target weight (27 vs 34 kg) and the interaction. There was no ($P > 0.05$) interaction between diet and TW for any of the goat response variables. Goats fed SH based diets had higher ($P < 0.05$) ADG (0.162 vs 0.119 ± 0.01 kg), higher ($P < 0.01$) feed intake (1.26 vs 1.02 ± 0.05 kg/d), and tended ($P = 0.07$) to have higher Gain to feed (G:F) (0.14 vs 0.12 ± 0.01 kg) than goats fed C. Dressing percent did not ($P > 0.05$) differ between goats fed SH (51 ± 0.5%) or C (50.3 ± 0.5%), but HCW was higher ($P < 0.05$) for

SH (15.8 ± 0.34 kg) than C (14.7 ± 0.34 kg) fed goats. Goats fed to a TW of 27 kg had higher ($P < 0.05$) G:F (0.14 vs 0.11 ± 0.002 kg) and tended ($P = 0.09$) to have higher ADG (0.152 vs 0.129 ± 0.009 kg) than goats fed to 34 kg. Dressing percent was higher ($P < 0.05$) when goats were fed to 34 kg (51.5 ± 0.49%) as compared with 27 kg (49.8 ± 0.49%). The quality grade and fat score were not ($P > 0.05$) influenced by feeding C or SH or finished weights of 27 or 34 kg. These results show that feeding SH as the primary dietary energy source resulted in higher growth performance than C, with no affect on carcass traits. Feeding goats to 34 kg as compared with 27 kg resulted in higher dressing percentage, with lower G:F.

Key words: goat, finishing weight, carcass

W407 Feedlot productive performance and carcass traits by hybrid lambs. M. T. Espinoza[1], M. A. Cerrillo-Soto[2,3], A. Estrada-Angulo[1,3], J. F. Obregon[1,3], J. J. Portillo[1,3], and F. G. Rios*[1,3], *[1]FMVZ-UAS, Culiacan, Sinaloa, Mexico, [2]FMVZ-UJED, Durango, Durango, Mexico, [3]Red Internacional de Alimentacion y Nutricion de Rumiantes, Durango, Durango, México.*

Genetic diversity by lambs should be considered when looking for diet optimization. To determinate productive response and carcass traits in hybrid lambs,a 70 d feedlot trial was conducted using 54 lambs (27 males and 27 females) with 73 ± 7 d initial age; and 15.7 ± 3.0 kg initial BW, from each genotype Pelibuey (100PB), Dorper × Pelibuey (50DR x 50PB) and Dorper × F1 dams Katahdin × Pelibuey (50DR × 25KT × 25PB) fed a 17% CP, 3.4 Mcal/kg DE (growth) and 15% CP, 3.4 Mcal/kg DE (finishing), concentrate-based diet. At slaughter carcass traits only from males were recorded. Data of growth performance were analyzed using ANOVA with repeated measures and means comparisons were performed using orthogonal contrasts. Carcass traits were analyzed using slaughter weight as covariate, and adjusted averages compared with Tukey-Kramer test. Average daily gain (ADG) throughout the experiment was 18.4% higher ($P < 0.01$) in hybrid lambs at d 28. ADG was higher ($P < 0.01$) for hybrid 50DR x 25KT × 25PB (301 g), than for F1 50DR × 50PB (276 g) and 100PB (236 g). Weight gain was 31% higher in males ($P < 0.01$) at d 28, 56 and 70 than female lambs. No differences among racial groups ($P > 0.05$) were observed in feed intake throughout the feeding periods. However males ate more feed than their counterparts (1146 ± 38 vs. 1018 ± 31 g/d). There were no differences in carcass characteristics among the evaluated racial groups. According to our data, it is concluded that growth performance and carcass characteristics of hybrid lambs, 50DR × 25KT × 25PB are similar than F1 50DR × 50PB.

W408 Evaluation of carcass characteristics of feedlot lambs receiving repeated doses of zeranol. L. Carlos-Valdez*, A. Grado-Ahüir, G. Corral-Flores, L. González-Aguilera, L. Barron-Limón, G. Villalobos-Villalobos, D. Dominguez-Diaz, and I. Anguiano-Cardona, *Universidad Autónoma de Chihuahua, Facultad de Zootecnia y Ecología, Chihuahua, Chih., México.*

The objective of this study was to evaluate the effect of repeated doses of zeranol implant in carcass characteristics and dressing percentage. We used (n = 20) crossbred finishing male lambs (average 54.5 ± 3.6 kg) from a 70 d performance trial. During the trial the lambs were randomly allocated into 3 treatments: no implant (0ze, n = 6), 12 mg of zeranol (Ralgro, Schering-Plough) on d 0 (12ze, n = 7), and 12 mg of zeranol on d 0 with a second implant at d 28 (24ze, n = 7). The lambs were harvested at the Universidad Autonoma de Chihuahua slaughterhouse following the slaughter Mexican Government regulation NOM-006–200–1996. The carcasses were cut in half and put in a cold room (4°C) for 24 h, then were transferred and stored in a freezing room (−24°C), until processed. Chilled right halves were cut into primary cuts and weighed. Rib eye area and fat depth were determined; all variables were analyzed adjusting a linear model with treatment as the fixed effect. Lambs 24ze had greater dressing percentage ($P < 0.05$; 53.6 ± 0.55%) compared with 0ze and 12ze (50.33 ± 0.60 and 51.91 ± 0.55%, respectively). The hot carcasses and cold carcasses were heavier for 24ze ($P < 0.05$; 29.22 ± 0.69 and 28.8 ± 0.67kg, respectively), compared with 0ze (27.17 ± 0.74 and 26.73 ± 0.72kg, respectively), but there was no difference ($P > 0.05$) between 24z and 12ze. Leg weight expressed as a percentage of carcass weight was also greatest for 24ze ($P < 0.01$; 7.4 ± 0.19%), compared with 0ze and 12ze (6.6 ± 0.20 and 6.3 ± 0.19%, respectively). The rib eye area was greater for 24ze ($P < 0.04$; 7.96 ± 0.35) compared with 12ze (6.86 ± 0.35cm2). Back fat deposition was greater for 24ze ($P < 0.02$; 4.17 ± 0.67mm) and 12ze ($P < 0.01$; 4.42 ± 0.62mm) compared with 0ze (1.83 ± 0.67mm). There were no differences ($P > 0.05$) among treatments for loin, rack, shoulder and ribs weights. We concluded that repeated doses of zeranol implants have an advantage over non implanted and single implant doses, increasing dressing percentage and economical carcass characteristics such as leg muscle accretion and rib eye area, while back fat deposition was significantly greater for both implant treatments.

Key words: lambs, zeranol, carcass characteristics

W409 Performance and carcass characteristics of lambs fed with diets including protected fat and vitamin E. A. P. P. Pinto[1], I. F. Furusho-Garcia*[2], I. Leopoldino Junior[2], J. R. O. Pérez[2], V. A. A. Reis[2], S. P. Greca[2], N. G. Alves[2], and I. G. Pereira[1], *[1]Universidade Federal dos Vales do Jequitinhonha e Mucuri, Diamantina, Minas Gerais, Brasil, [2]Universidade Federal de Lavras, Lavras, Minas Gerais, Brasil.*

The experiment was conducted at the Federal University of Lavras to evaluate the effect of the use of protected fat, with presence or absence of vitamin E on the performance and carcass characteristics of lambs in confinement with different weights. Thirty-two of Santa Ines lambs fed roughage: concentrate ratio of 40:60%, ad libitum, with the absence or presence of protected fat (calcium soaps) totaling 6% ether extract in the complete diet; and presence or absence of vitamin E (α-tocopherol acetate DL), resulting in 4 experimental diets. The 2 live weights at start confinement: lightweight (23.05 kg ± 1.62) and heavy (32.63 kg ± 1.72). All animals were slaughtered at 84 d of confinement. The experimental design was completely randomized in a 2 × 2 x 2 (2 levels of protected fat (0 and 4%), 2 levels of vitamin E (0 and 0.05%) and 2 live weight). Data were analyzed by General Linear Methods Procedure (Proc GLM) of SAS (Statistical Analysis System); and means compared by *t*-test at 5% probability. The daily weight gain was not influenced by the factors evaluated ($P > 0.05$). The feed conversion of lambs lighter was worse ($P < 0.05$) for lambs fed diet containing no fat protected as shown in the table. The inclusion of vitamin E improved ($P < 0.05$) carcass dressing percentage (52.29%) compared with animals that were fed vitamin E (49.00%). Lighter lambs had lower ($P < 0.05$) carcass dressing percentage (48.13%)

compared with the heaviest lambs (52.29%). The addition of fat in the diet reduced ($P < 0.05$) dry matter intake and increased ($P < 0.05$) ether extract intake. The average weights of intestinal contents were higher ($P < 0.05$) in the absence of dietary fat (7.87 kg) compared with lambs fed fat (6.93 kg), this may be due to increased consumption of diets that contained no protected fat. In conclusion, lambs that start in the feedlot heavier weights have better performance and carcass characteristics, the use of protected fat improves the performance of lambs, and vitamin E improves carcass yield.

Table 1. Mean feed conversion due to the interaction between experimental weight and the presence of protected fat in diet

	Protected fat in diet		
Experimental weight	0%	4%	Mean
30-35 kg	4.487^{A,b}	4,725^{A,a}	4.606^{a}
20-25 kg	5,918^{A,a}	4,163^{B,a}	5.041^{a}
Mean	5,203^{A}	4,444^{A}	

Means followed by different letters, uppercase letters in rows and lowercase in columns, differ statistically by t test ($P < 0.05$).

W410 Feeding system and breed affect goat kid growth and carcass composition. M.-E. Brassard*[1], L. Tessier[1], R. Gervais[1], E. Pouliot[1], C. Gariepy[2], G. F. Tremblay[3], R. Berthiaume[4], P. Y. Chouinard[1], and D. Cinq-Mars[1], *[1]Département des sciences animales, Université Laval, Québec, QC, Canada, [2]AAFC, Food Research and Development Centre, Saint-Hyacinthe, QC, Canada, [3]AAFC, Soils and Crops Research and Development Centre, Québec, QC, Canada, [4]AAFC, Dairy and Swine Research and Development Centre, Sherbrooke, QC, Canada.*

Forty weaned male goat kids (25.9 ± 1.4 kg) from meat (Boer) and dairy (mostly Alpine and Saanen) breeds were used to evaluate the effects of 2 feeding systems on growth and carcass composition. Twenty kids from each breed were blocked according to body weight in 10 groups and kids were randomly allotted to an intensive pasture system or a concentrate-based diet. Grazing kids from each breed were raised in group and had access to a mineral supplement. Kids receiving concentrates (corn, soybean meal, and vitamin and mineral premix) and grass hay were reared indoor in individual pen. Kids were slaughtered when they reached 44.5 ± 0.6 kg live weight. Weight for carcasses and body components were recorded and the left side of each carcass was cut into 7 commercial joints (foreshank, neck, shoulder, flank, rib, loin, and leg). Each joint was weighed and dissected into fat, muscle and bone. No interaction was observed between feeding system and breed unless specified otherwise. Average daily gain was greater for meat than dairy kids (156 vs. 116 g/d; $P < 0.01$). Kids fed the concentrate-based diet attained slaughter weight in 131 d while those fed intensive pasture required 149 d ($P < 0.05$). Breed and feeding system did not affect dressing percentage (48 ± 3%). Meat kids ($P < 0.01$) and kids fed concentrate-based diet ($P < 0.05$) showed greater values for fat weight and percentage in neck, foreshank, rib and leg. Concentrate feeding also increased fat values for shoulder, loin and flank especially when fed to meat kids (Feeding × Breed: $P < 0.05$). Muscle weight for loin and leg were greater for meat than dairy kids whereas the opposite was observed for neck and shoulder joints ($P < 0.05$). Pasture-fed kids had greater muscle percentage in shoulder and neck ($P < 0.05$). Feeding pasture also increased muscle percentage in loin and rib specifically when fed to meat kids (Feeding × Breed: $P < 0.05$). Dairy breed kids had higher bone percentage and weight for foreshank, leg, loin, and rib than meat breed kids ($P < 0.01$). Results from this study showed that breed and feeding system influence carcass quality in growing kids.

Key words: goat kid, carcass composition, commercial cuts

W411 Molecular survey of *Trypanosoma vivax* infection in Nigerian goats. T. Sanni[1], A. Yakubu*[2], M. A. Adefenwa[3], B. O. Agaviezor[4], C. O. N. Ikeobi[1], M. Wheto[1], M. Okpeku[5], M. I. Takeet[6], M. De Donato[7], and I. G. Imumorin[7], *[1]Dept of Animal Breeding and Genetics, University of Agriculture, Abeokuta, Nigeria, [2]Dept of Animal Science, Nasarawa State University, Lafia, Nigeria, [3]Dept of Cell Biology and Genetics, University of Lagos, Lagos, Nigeria, [4]Dept of Animal Science and Fisheries, University of Port Harcourt, Port-Harcourt, Nigeria, [5]Dept of Livestock Production, Niger Delta University, Amassoma, Nigeria., [6]Dept of Veterinary Microbiology and Parasitology, University of Agriculture, Abeokuta, Nigeria, [7]Dept of Animal Science, Cornell University, Ithaca, NY.*

Trypanosomiasis is a major protozoan parasitic disease that is endemic in Nigeria and much of Sub-Saharan Africa. To gain better understanding of the distribution of this disease in goats, a cross-sectional study was conducted in 3 geopolitical zones of Nigeria to determine the prevalence of trypanosomiasis in the 3 indigenous breeds of goats. Blood samples and some physiological parameters (rectal temperature, body temperature, respiratory rate and pulse rate) were collected from a total of 205 randomly selected animals from across the country. *Trypanosoma vivax* detection was carried out using *T. vivax*-specific polymerase chain reaction (PCR) primers that amplifies 400 bp of the trypanosome genome. Results showed that 71.22% of the total goats were infected with *T. vivax*, comprising 19.51% males and 51.71% females, respectively. Among the breeds examined, 21.46%, 42.44% and 7.32% of West African Dwarf, Red Sokoto and Sahel goats respectively were found to be infected with this parasite species. The prevalence rate was 30.73%, 20.00% and 20.49% in the northeastern, northwestern and southwestern parts of the country respectively. Breed-sex-zone interaction effect was significant ($P < 0.05$) for *T. vivax* score; indicating the separate rankings of the 3 genotypes under the 2 sexes and 3 zones investigated. The logistic regression analysis revealed that among the physiological indices, respiratory rate was the trait of utmost importance in predicting the presence of *T. vivax* with Hosmer-Lemeshow goodness-of-fit. The present information could aid management and conservation strategies toward attenuating the rate of trypanosomiasis prevalence in Nigerian goats.

Key words: *Trypanosoma vivax*, Nigeria, goats

W412 Gene expression changes in goat testes during development and in sperm during the breeding and nonbreeding seasons. A. N. Faucette*[2], P. K. Riggs[2], D. W. Forrest[2], L. Nuti[1], G. R. Newton[1], and N. H. Ing[2], *[1]Prairie View A&M University, Cooperative Agriculture Research Center, Prairie View, TX, [2]Texas AgriLife Research, College Station.*

Current clinical tests to screen for fertility include analyses of sperm number, morphology, motility, chromatin quality, and acrosomal integrity in semen. These endpoints fluctuate due to many factors unrelated

to overall fertility. Our working hypothesis is that regulated genes involved in spermatogenesis may be useful predictors of male fertility. Our goals were to analyze alterations in gene expression in the goat testes during development and analyze alterations in gene products in sperm from mature bucks between breeding and non-breeding seasons. For the former, testes were harvested from 5 Alpine bucks at 0, 2, 4, 6, and 8 mo of age. Northern blotting and in situ hybridization indicated that the largest changes in gene expression during testes development happen in the first 4 mo in the goat. Sertoli cell marker Sex determining region Y-box 9 (SOX9) mRNA peaked at 2 mo of age then declined. At 4 mo, expression of Stimulated by Retinoic Acid gene 8 (STRA8) and Protamine 1 genes was strongly upregulated in early and maturing germ cells, respectively. RNA from ejaculated sperm collected from 3 mature Alpine bucks in October (peak breeding season) and April (not peak breeding) was interrogated for 44,000 gene products on Bovine Gene Expression Microarrays (Agilent). 43 gene products were expressed 3-fold or more highly in peak breeding season, while concentrations of 12 mRNAs decreased 3-fold or more ($P <$ 0.01). Discovery of 5-fold greater levels of glycerol kinase 2 (GK2) mRNA in sperm from the peak breeding season and 6-fold lower levels of Sperm Adhesion Molecule 1 (SPAM1) mRNA are being confirmed and extended to more Alpine and Boer goat sperm samples with real time PCR. Results of these experiments may be useful in developing novel fertility tests based on mRNA levels in testes and ejaculated sperm that will assist improving reproductive efficiencies in animal production systems. W413 Feeding management affect the occurrence of self-suckling in dairy goats. J. Martínez-de la Puente, I. Moreno-Indias*, A. Morales-delaNuez, L. E. Hernández-Castellano, M. D. Ruíz-Díaz, N. Castro, and A. Argüello, *Universidad de las Palmas de Gran Canaria, Arucas, Las Palmas, Spain.*

Self-suckling, an animal suckling on its own teats, is an abnormal behavior observed in dairy livestock. To investigate the effect of feeding management on self-suckling, the occurrence of this behavior was recorded in 21 dairy goats during periods of 20 min at 3 different times per day (immediately after milking and the first feed (10:30), immediately after the second feed (13:30) and in the afternoon (17:00)) along 3 consecutive experimental periods of 9 d each. During the first (PRE) and the third (POST) periods goats were fed with corn, soy 44, dehydrated lucerne, dehydrated beetroot, lucerne hay and a vitamin-mineral corrector. During the second period goats were supplemented ad libitum with wheat straw in addition to their ordinary diet. Statistical analyses were conducted using Wilcoxon Matched Pairs Tests and a Friedman ANOVA (a nonparametric alternative to one-way repeated measures ANOVA). During each 20 min period, an average of 6.9 ± 2.5, 5.1 ± 1.9 and 7.5 ± 2.9 goats suckled on their own teats during the PRE, ad libitum and POST periods respectively. During each 20 min period, a lower number of self-suckling goats were observed during ad libitum than during both PRE ($Z = 3.26$; $P = 0.001$) and POST periods ($Z = 3.74$; $P < 0.001$). Moreover, during PRE, ad libitum and POST experimental periods, each goat suckled on their own teats at least one time during an average of 8.9 ± 8.7, 6.6 ± 7.4 and 9.6 ± 8.6 20 min periods respectively. These differences reached significance (n = 21; Chi Sqr. = 9.34; d.f. = 2; $P < 0.01$) with a lower self-suckling frequency during ad libitum than during POST period ($Z = 2.66$; $P <$ 0.01). The same trend was found comparing PRE and ad libitum periods ($Z = 1.91$; $P = 0.06$). Overall, this study strongly supports the role of feeding management as a major factor affecting the occurrence of self-suckling in dairy goats.

Key words: behavior, feeding management, self-suckling

W415 Finishing performance of lambs fed fresh or dehydrated spineless cactus (*Opuntia ficus-indica*). M. I. Aguilar-Yañez[1], O. Hernadez-Mendo[1], G. Aranda-Osorio*[2], J. E. Ramirez-Bribiesca[1], S. S. Gonzalez-Muñoz[1], and M. M. Crosby-Galvan[1], *[1]Colegio de Postgraduados, Montecillos, Estado de Mexico, Mexico, [2]Universidad Autonoma Chapingo, Chapingo, Estado de Mexico, Mexico.*

The objective of this study was to evaluate the effect of cactus (*Opuntia ficus-indica*) supplementation on finishing lambs performance, during an 11-week period. For this purpose, 27 male commercial crossbred lambs were used, with initial body weight (BW) mean of 21.4 ± 2.18 kg. They were distributed homogeneously into 3 groups of 9 each (each lamb being an experimental unit), and randomly assigned to the following treatments: (T1) control diet (representative lambs finishing diet for the central region of Mexico), (T2) diet with 17% dehydrated cactus (dry basis), and (T3) diet with 17% fresh cactus (dry basis). Variables were in situ dry matter digestibility (ISDMD), dry matter intake (DMI), average daily gain (ADG), feed:gain ratio (F:G) and gain:feed ratio (G:F), backfat depth (BFD), hot and cold carcass yield (HCY and CCY), biological hot and cold carcass yield (BHCY and BCCY), and carcass pH at slaughtering and 24 h post mortem. The experimental design was completely ramdomized, analyzed under the Proc GLM of SAS, and means were compared with Tukey test ($P \leq 0.05$). There ISDMD was higher (42.0%) for T1 at 6 h and for the T3 (88.6%) at 48 h ($P \leq 0.001$). No differences ($P \geq 0.05$) were found between treatments for average final BW (37.7 ± 1.21 kg). Backfat (BFD) was lower ($P \leq 0.001$) in lambs fed dehydrated (4.1 mm) or fresh (3.3 mm) cactus diets, compared with those fed the control diet (7.8 mm). Average values for hot and cold carcass yield, biological hot and cold carcass yield, and carcass pH at slaughtering and 24 h post mortem, were 50.6 and 47.0%, 55.4 and 49.5%, and 6.6 and 5.8, respectively ($P \geq 0.05$). Feeding lambs a diet including cactus seems to be a viable alternative for finishing systems in Mexico where cactus is readily available all around the year at a low cost. Besides, cactus could have a beneficial effect on meat traits.

Key words: cactus, sheep, productivity

W416 Finishing performance of Pelibuey sheep fed with different levels of alfalfa. V. Resendiz-Cruz[1], O. Hernadez-Mendo[1], J. Gallegos-Sanchez[1], P. A. Martinez-Hernandez[2], G. Aranda-Osorio*[2], C. Sanchez-Del Real[2], and S. S. Gonzalez-Muñoz[1], *[1]Colegio de Postgraduados, Montecillos, Estado de Mexico, Mexico, [2]Universidad Autonoma Chapingo, Chapingo, Estado de Mexico, Mexico.*

The objective of this study was to evaluate the effect of feeding different levels of alfalfa to sheep on animal performance, during a period of 11 weeks. For this purpose, 36 Pelibuey male sheep were used indoors, with initial body weight (BW) mean of 22.3 ± 0.3 kg. They were distributed homogeneously into 4 groups of 3 each, with 3 replicates per group, and then randomly assigned to each of the following treatments:

0, 20, 30 and 40% alfalfa (dry basis). Dry matter intake (DMI), average daily gain (ADG), feed:gain ratio (F:G) and gain:feed ratio (G:F), hot and cold carcass yield (HCY and CCY), biological hot and cold carcass yield (BHCY and BCCY), and carcass pH at slaughtering and 24 h post mortem, and in situ dry matter digestibility (ISDMD), were evaluated. A completely random design under Proc GLM of SAS was used, and a mean comparison using the Tukey test was done. There were not differences ($P \geq 0.05$) between treatments on animal performance, except on dry matter intake, which increased ($P \leq 0.05$) from 1.2 to 1.4 kg DM per animal when increasing alfalfa level from 20 to 40%, even though diets including alfalfa had less ($P \leq 0.05$) digestibility compared with the control one. ADG, F:G and G:F averaged 271 g animal^{-1} d^{-1}, 4.7 and 0.212, respectively($P \geq 0.05$). The average for hot and cold carcass weight, and hot and cold carcass yield, were 19.3 and 18.8 kg, and 54.4% and 53.0%, respectively ($P \geq 0.05$). Including alfalfa to sheep diets offers no benefits on animal performance; however, including up to 40% of it, could be a viable feeding strategy, since it increases dry matter intake, which in a way, could have a positive effect if alfalfa is fed as meal or whole plant.

Key words: lambs, alfalfa, productivity

W417 Evaluation of feedlot male lamb performance receiving repeated doses of Zeranol. L. Carlos-Valdez*, A. Grado-Ahüir, L. González-Aguilera, D. Barron-Limón, P. García-Montoya, G. Villalobos-Villalobos, and D. Domínguez-Díaz, *Universidad Autónoma de Chihuahua, Facultad de Zootecnia y Ecología, Chihuahua, Chih., México.*

The objective of this study was to evaluate the effect of repeated doses of zeranol implant on the performance of male lambs. Fifty 5, post-weaning Charollais crossbred male lambs (BW = 25.2 ± 5.42 kg) were randomly allocated into 3 treatments: no implant (0ze, n = 15), 12 mg of zeranol (Ralgro, Schering-Plough) on d 0 (12ze, n = 15), and 12 mg of zeranol on d 0 with a second implant at d 28 (24ze, n = 15). The lambs had a 10 d acclimation period to a new diet and individual pens. During this time they were also vaccinated (Bobact-8, Intervet) and de-wormed (Baymec 1% Hidrofilico, Bayer). The diet was formulated to equal or exceed the nutrient requirements (NRC Sheep, 1985). The lambs were fed ad libitum twice a day (0800 and 1300h) with a TMR (85:15, concentrate:forage) that contained 2.9 Mcal/kg of ME and 13.7%CP, with free access to fresh water all day. Offered feed and refusals were weighed and recorded daily to estimate feed consumption. The lambs were weighed every 14 d for 70 d. All data was analyzed adjusting a linear model with treatment as the fixed effect. There were no differences found among treatments for final weight and DM intake ($P = 0.8$). However, numerically, 24ze had the greatest final weight (51.5kg). The ADG was greater for 24ze ($P < 0.03$; 0.37 ± 0.023kg) compared with 0ze and 12ze lambs (0.31 ± 0.020, 0.31 ± 0.020kg, respectively). For G:F 24ze lambs were more efficient ($P < 0.05$; 0.34 ± 0.02) compared with 0ze lambs (0.28 ± 0.03) but not different from 12ze lambs. These results show that repeated doses of zeranol implant increase the feed efficiency and ADG in male lambs post-weaning.

Key words: zeranol, lamb, performance

W418 Effect of using different performance traits to estimate residual feed intake. R. R. Cockrum*, R. H. Stobart, S. L. Lake, and K. M. Cammack, *University of Wyoming, Laramie.*

Predictive models for residual feed intake (RFI) have used ADG, feed intake, ME, mid-body weight (MWT), metabolic mid-body weight (MMWT$^{0.75}$), and various carcass traits. For RFI to become adopted by producers as an indicator of feed efficiency, relevant performance traits should be incorporated into the model to increase accuracy. Carcass traits typically measured in a ram performance test include back fat (BF) and loin eye area (LEA); scrotal circumference (SC) is another typical measurement that is indicative of growth. We hypothesized that incorporation of these biological measures into the prediction model would provide a more accurate measurement of feed efficiency in sheep. Our aim was to determine if the use of BF, LEA, and SC in the predictive equation affected RFI ranking. Individual feed intake measurements were collected on rams submitted to the University of Wyoming Western Whiteface Ram Test (n = 62) for 140 d using the GrowSafe System, an automated system that collects individual feed intake data from group-housed animals. Feed samples were collected and analyzed for DM, ADF, and IVDMD to determine ME, a measurement often preferred over actual feed intake as it accounts for individual digestibility. Using the GLM procedure in SAS, predictive equations were generated to estimate RFI, and the CORR procedure was used to evaluate relationships among these alternative predictive equations. An α of 0.05 was assumed. The base model used was $Y = \beta_0 + X_1\beta_1 + X_2\beta_2 + e$ where Y = ME, X_1 = ADG, and X_2 = MMWT$^{0.75}$ or MWT. An R^2 of 0.43 was generated for this equation regardless of use of MMWT$^{0.75}$ or MWT. Further analyses used only MWT for estimating RFI. When BF and LEA predictors were added to the equation, R^2 increased to 0.45, and SC further increased R^2 to 0.46. Additional performance traits in the model had no effect ($P = 0.985$) on individual RFI ranking, and the predictive equations analyzed were highly and positively correlated ($P < 0.001$). Adding performance data to the RFI predictive equation had limited effect on accuracy, and did not produce rankings different from the base model.

Key words: efficiency, predictive models, residual feed intake

W419 Increased nutritional level positively influences the onset of the breeding season and the reproductive performance of native male goats in northern Mexico. A. Olán-Sánchez[1], E. Carrillo[2], L. M. Tejeda[1], J. M. Guillén-Muñoz[1], P. A. Robles-Trillo[1], C. A. Meza-Herrera[3], F. G. Véliz[1], R. Rodríguez-Martínez*[1], and M. Mellado[4], *[1]Universidad Autónoma Agraria Antonio Narro, Torreón, Coahuila, México, [2]Instituto Tecnológico de Torreón, Torreón, Coahuila, México, [3]Universidad Autónoma Chapingo, Unidad Regional de Zonas Áridas, Bermejillo, Dgo., México, [4]Universidad Autónoma Agraria Antonio Narro, Buenavista, Saltillo, Coahuila, México.*

To determine whether feeding influences the onset of sexual activity in native bucks in northern Mexico (26° N), adults native bucks (n = 10) were divided into 2 homogeneous groups in relation their body condition (1.5, scale 1–4) and body weight (27 kg). Before the trial, bucks were kept in an extensive production system with predominant native vegetation consisting of *Prosopis glandulosa*, *Acacia farnesiana*, *Atriplex acantocarpa*, *Agave scabra*, *Mimosa biuncife*, *Heliantus ciliaris*, *Salsola kali*, *Solanum elaeagnilolium* as well as *Chloris virgata*, *Setaria verticillata*, *Eragrostis pectinacea*, *Bouteloua curtipendula*, *Aristida purpurea* and *Bouteloua barbata*. Sometimes, bucks had available some agricultural crop residues such as sorghum (*Sorghum vulgare*) and corn (*Zea mays*), among others. On May 19, 2010, a group of males (Well fed, n = 5) received a diet to cover 150% of their nutritional requirements for maintenance, while another group of males (Control, n = 5) was fed a maintenance diet. At the end of the

trial (June 19) a sexual behavior test was carried-out, in which males of both groups were exposed to 2 females in estrus during 15 min, for 2 consecutive days. Percentage of anogenital sniffing, nudging, mounting attempts, and complete mounts were compared with Chi-squared test, while the ejaculation latency time was compared with a Student *t*-test. All the tests were performed by means of the statistical package SYSTAL 12. Well-fed bucks had more anogenital sniffing, nudging, mounting attempts, and full mount than controls (Table). In addition, ejaculation latency time in well-fed bucks was shorter (57.8 ± 7.1 s) than Control bucks (419 ± 116 s). These results show that feed supplementation of range mixed-breed goat bucks in spring elicits a strong sexual behavior.

Table 1. Sexual behavior of native bucks, well and poorly fed, exposed to estrogenized females for two days during 15 min, at the onset of sexual activity season in northern Mexico (26° N)

Groups	Anogenital sniffing	Nudging	Mounting attempts	Complete mounts
Poorly fed	69[a]	258[a]	13[a]	27[a]
Well fed	102[a]	378[b]	22[a]	65[b]

W420 Response of sexually inactive French Alpine bucks to the stimulus of estrous goats. L. M. Tejada*[1], E. Carrillo[2], R. Rivas-Muñoz[2], M. Guillén-Muñoz[1], C. A. Meza-Herrera[3], G. Arellano-Rodríguez[1], M. Mellado[1], and F. G. Véliz[1], *[1]Universidad Autónoma Agraria Antonio Narro, Torreón, Coahuila, México, [2]Instituto Tecnológico de Torreón, Torreón, Coahuila, México, [3]Universidad Autónoma Chapingo, Unidad Regional Universitaria de Zonas Áridas, Bermejillo, Durango, México.*

This study was designed to investigate whether sexually inactive French Alpine bucks stimulated with estrous does are capable to induce estrus and ovulation in anestrous does. Two goats were subcutaneously injected, every 2 d, with 2 mg estradiol cypionate (Estradiol, Qro., México) in 1 mL vegetable oil. These goats in permanent estrus were placed with 2 sexually inactive bucks (stimulated) in May and another 2 bucks in June, during 3 weeks before breeding. Fifty-nine adult anestrous French Alpine goats were randomly assigned to one of 4 treatment groups: exposure to stimulated (n = 14) or nonstimulated (n = 15) bucks in March, or with stimulated (n = 15) or nonstimulated (n = 15) bucks in June. All goats received a single I.M. injection of 25 mg progesterone (Progestelas E, Qro., Mexico) before the buck exposure. Does were considered in estrus when copulation occurred. Once bred, goats were removed from the breeding pens and pregnancy was diagnosed by transrectal ultrasonography using a 5.0 MHz transducer (Supply, Inc., Tequesta, FL) 50 d after mating. Additionally, the sexual behavior exhibited by bucks in contact with penned does was recorded during 2 consecutive observation sessions lasting one h each. The estrus response was 79 and 100% for goats exposed to stimulated bucks in March and June, but none of the goats joined with the nonstimulated bucks showed estrus in both breeding seasons. Pregnancy rate based on ultrasonography 50 d post copulation was lower ($P < 0.01$) in goats joined to stimulated bucks in March (50%) compared with goats bred in June (80%). For both breeding seasons none of the goats joined to nonstimulated bucks kidded. Interval to estrus was shorter (68 ± 2 vs 141 ± 13 h) and more synchronized in goats exposed to stimulated bucks in June than goats exposed to bucks in March. Frequency of flehmen, nosing, and approaches were higher ($P < 0.01$) for simulated bucks than nonstimulated bucks. It was concluded that the exposure of sexually inactive bucks to estrous goats is an inexpensive, practical and efficient way to elicit sexual active in bucks, which subsequently triggers breeding activity of anestrous goats.

Key words: male effect, goat, estrous goats

W421 Contact with estrogenized female goats influences the end of sexual activity of young bucks but not adult bucks in northern Mexico. A. Olán-Sánchez*[1], E. Carrillo[2], R. Rivas-Muñoz[2], L. M. Tejeda[1], J. M. Guillen-Muñoz[1], R. Rodríguez-Martínez[1], P. A. Robles[1], C. A. Meza-Herrera[3], F. G. Véliz[1], and G. Arellano-Rodríguez[1], *[1]1Universidad Autónoma Agraria Antonio Narro, Torreón, Coahuila, México, [2]Instituto Tecnológico de Torreón, Torreón, Coahuila, México, [3]Universidad Autónoma Chapingo, Unidad Regional Universitaria de Zonas Áridas, Bermejillo, Durango, México.*

In the present study it was determined if the contact of estrogenized female goats with bucks promotes the end of sexual activity of young or adult Alpine bucks in northern Mexico (26° N). Alpine adult (n = 8, 4-yr-old) and young bucks (n = 10, 1-yr-old) were divided into 2 homogeneous groups regarding their body condition score and body weight. All animals were reared in an intensive system and had free access to alfalfa hay and 200 g commercial concentrate (14% CP). On January 15, 2010, a first group of adult bucks (Experimental-Adult, n = 4) was daily exposed during 4 weeks to 2 goats permanently in estrus (does received 2 mg estradiol cypionate every 3 d). During this period, another group of adult bucks (Control-Adult, n = 4) had no contact with estrogenized does. A third group of young bucks (Experimental-Young, n = 5) was daily exposed during 4 weeks to 2 estrogenized does. A fourth group of young bucks (Control-Young, n = 5) did not have contact with does in estrus. At the end of the study (16 February, 2010) a sexual behavior test was carried out; males of both groups were exposed to 2 females in estrus for 15 min, for 2 consecutive days. Percentage of anogenital sniffing, nudging, mounting attempts, and complete mounts were compared with the Chi-squared test, whereas latency to ejaculation was compared with a Students *t*-test. All statistical tests were performed with the statistical package SYSTAL 12. The results of sexual behavior tests are indicated in Table 1. These results indicate that exposure of young bucks to estrogenized does elicited a strong sexual response in these animals; on the other hand, nonstimulated adult bucks displayed the same sexual performance as that showed by adult bucks in contact with estrogenized does.

Table 1. Sexual behavior of adult or young French Alpine bucks, previously isolated or exposed to goats permanently in estrus during two evaluations at the end of the breeding season

Groups	Anogenital sniffing	Nudging	Mounting attempts	Complete mounts	Latency to ejaculate	Aggression
Control-Young	28[a]	18[a]	1[a]	0[a]	901[a]	16[a]
Experimental-Young	66[b]	47[b]	23[b]	7[a,b]	484[b]	2[b]
Control-Adult	35[a]	37[a,b]	0[a]	9[b]	15[c]	0[b]
Experimental-Adult	38[a]	23[a]	1[a]	9[b]	26[c]	0[b]

W422 NCSynch: A protocol for ovulation synchronization and timed artificial insemination in goats. E. C. Bowdridge*, W. B. Knox, C. S. Whisnant, and C. E. Farin, *North Carolina State University, Raleigh.*

The study objective was to compare overall pregnancy rates achieved using a combined ovulation synchronization-timed artificial insemination protocol (NCSynch-TAI) with those obtained using estrus synchronization and artificial insemination (AI). Multiparous Boer and Boer-cross does (n = 132) were randomly assigned within age (Year 1) or parity (Years 2, 3) to one of 2 treatments. Control does received 15 mg prostaglandin F (PGF; Lutalyse®) on Days 1 and 10 of treatment. Estrus onset was checked twice daily with separately penned, intact bucks (Year 1) or a vasectomized buck penned with the does (Years 2, 3). Controls were bred by AI 12 h after estrus onset using frozen semen. NCSynch-TAI does received 15 mg PGF on Day 1 of treatment. On Day 8, does received 50 μg GnRH (Cystorelin®) and on Day 15, 15 mg PGF was given. On Day 18, NCSynch-TAI does were appointment bred (TAI) using frozen semen and received 50 μg GnRH at breeding. All AI/TAI procedures were performed in late September by experienced inseminators using a transcervical technique. Pregnancy was monitored by transabdominal ultrasonagraphy at 50 and 85 d after insemination. In Year 1, 13 of 15 control does (87%) were detected in estrus with 8 pregnant to AI (53% overall pregnancy rate). For NCSynch-TAI, 15 does were bred and 11 (73%) became pregnant. In Year 2, 24 of 26 controls (92%) were detected in estrus with 19 pregnant to AI (73% overall pregnancy rate). For NCSynch-TAI, 26 does were bred and 20 (77%) became pregnant. In Year 3, 21 of 25 controls (84%) were detected in estrus with 8 pregnant to AI (32% overall pregnancy rate). For NCSynch-TAI, 25 does were bred and 14 (56%) became pregnant. Across Years 1–3, the overall pregnancy rate for NCSynch-TAI does (45/66, 68%) did not differ ($P = 0.075$, Chi^2 df = 1) compared with controls (35/66; 53%). In summary, overall pregnancy rates using NCSynch-TAI were comparable to those for does bred by AI based on estrus detection. Use of NCSynch-TAI eliminates the need for heat checking before AI and allows breeding to be scheduled on a predetermined date. Supported by NC Ag Research Service.

Key words: ovulation synchronization, estrus synchronization, timed artificial insemination

W423 Comparison of two ovulation synchronization methods for timed artificial insemination in goats. N. C. Whitley*[1], C. E. Farin[2], W. B. Knox[2], L. Townsend[3], J. R. Horton[3], K. Moulton[1], and S. Nusz[4], *[1]North Carolina A&T State University, Greensboro, [2]North Carolina State University, Raleigh, [3]NCDA, UMRS, Laurel Springs, NC, [4]Redlands Community College, El Reno, OK.*

The objective of this experiment was to compare 2 potential estrus and ovulation synchronization protocols for timed artificial insemination (TAI) in goats. Thirty-eight mixed parity meat goat does (Spanish and Boer-crossbred) were used at 3.4 ± 0.3 years of age and 47.4 ± 1.3 kg body weight. Half of the does underwent the "NCSynch" protocol in which does were injected with 15 mg dinoprost tromethamine (3 mL Lutalyse) im on d 0, or start of the protocols, and d 14 and 50 μg gonadorelin diacetate tetrahydrate (1 mL Cystorelin) im on d 7 as well as on d 17 at TAI. Remaining does were administered a CIDR protocol in which sheep CIDRs were inserted on d 4 and removed on d 15. The CIDR group received 3 mL Lutalyse and a combination of 200 IU eCG and 100 IU hCG (2.5 mL PG600) im at CIDR removal; TAI occurred on d 17. Does were housed together throughout the study and were allowed fence-line access to an intact buck on d 15. Trans-cervical insemination was conducted by 2 experienced technicians alternating between groups such that equal numbers of does from each treatment were inseminated by each technician. One doe from the CIDR group was removed at insemination due to an unknown physical problem making it impossible to penetrate the cervix. An intact buck wearing a marking harness was introduced at 21 d after TAI. Blood samples were collected via jugular vein puncture at 31 d after insemination to determine pregnancy status (bioPRYN®; BioTracking, LLC). Pregnancy rates were higher ($P < 0.009$) for animals treated with the CIDR protocol (50%) than the NC-Synch protocol (10.5%) based on Chi-Square analysis. However, bioPRYN levels for one of the CIDR treated does was indicative of an early pregnancy loss and the doe was later marked by the buck. The buck marked more ($P < 0.005$) NCSynch treated does than CIDR-treated does (84% vs 39%, respectively). Previous use of the NCSynch protocol with the same inseminators resulted in higher pregnancy rates than seen with either protocol in this study; however, because both protocols are costly and labor intensive to use, more research will be required.

Key words: estrus synchronization, goat, timed artificial insemination

W424 Effect of flushing and (or) exposure to estrogenized does upon reproductive performance of anovulatory range goats exposed to male effect. M. A. De Santiago-Miramontes*[1], J. R. Luna-Orozco[1], F. G. Véliz-Deras[1], R. Rodríguez-Martínez[1], P. A. Robles-Trillo[1], C. A. Meza-Herrera[1], and M. Mellado[1], *[1]Universidad Autonoma Agraria Antonio Narro, [2]Centro de Bachillerato Tecnologico Agropecuario N° 1, [3]Universidad Autonoma Chapingo, Unidad Regional Universitaria de Zonas Aridas.*

The objective is to determine if flushing around mating or the stimulus of estrogenized goats is necessary to achieve a high reproductive response in anestrous mixed-breed rangeland goats (arid region of Mexico; 26° N). On May 21, 78 goats grazing on natural rangeland (1.6 ± 0.2 points, BCS, 1–4 scale) were randomly assigned to 1 of 4 experimental groups: (1) Flushed (F; n = 20) does received nutritional supplementation 1 week prior joining and 2 weeks after, receiving 1.0 kg of alfalfa hay (17% CP), 310 g rolled corn grain (8.5% CP) and 220 g soybean meal (48% CP) per animal. (2) Stimulated (S; n = 20) does was exposed to 4 estrogenized females. (3) Stimulated-Flushed (S-F; n = 20) does was supplemented and stimulated as mentioned. (4) Control (C; n = 18) does only grazed on the rangeland. All the does were exposed to 2 bucks/group. Regardless of treatment, 100% of does showed luteal activity. S and S-F groups depicted estrus during the first 5 d of joining (45 and 60%, respectively) compared with C or F group (11 and 5%, respectively; $P < 0.05$). Hours to estrus was greater ($P < 0.01$) in C (225 ± 18 h) and F (271 ± 19 h) groups than in S (130 ± 22 h) and S-F group (104 ± 16 h). Pregnancy rate did not differ at d-70 post-breeding among groups ($P > 0.05$; C, 72%; F, 80%; S, 70%; S-F 65%). However, kidding rates were lower ($P < 0.05$) in F and S-F groups, (40% and 35% respectively) compared with C (67%) and S (55%) groups. These results demonstrate that the presence of estrogenized does shortens the interval to estrus induced by the male effect. Nonetheless, the short-term nutritional supplementation around joining promoted the fertilization-implantation, did not improve the reproductive performance because of the failure to maintain gestation, probably due to the adverse nutritional conditions in the rangeland after the 2/3 of gestation. Therefore, alternative food resources must be offered to those supplemented-goats showing an increased ovulatory outcome around breeding once these females arrive to the 2/3 and 3/3 of gestation, if abortions or stillbirths is tried to be avoided.

Key words: feed supplementation, rangeland, kidding rate

W425 Exposure of does in estrus to bucks subsequently induces estrus in anestrus females. S. Marcelino-León*[1], J. R. Luna-Orozco[1], F. G. Véliz-Deras[1], L. Gaytán-Alemán[1], C. A. Meza-Herrera[1], R. Rodríguez-Martínez[1], M. Mellado[1], and M. A. De Santiago-Miramontes[1], *[1]Universidad Autonoma Agraria Antonio Narro, [2]Centro de Bachillerato Tecnologico Agropecuario N° 1, [3]Universidad Autonoma Chapingo, Unidad Regional Universitaria de Zonas Aridas.*

The objective of the present study was to determine if the stimulus exerted by the exposure of estrogenized does to bucks would stimulate the estrous behavior in mixed-bred anovulatory goats in the arid region of northern Mexico, also, determine if an increased percentage of estrogenized does would modify such response. A total of 93 pluriparus anovulatory goats were divided in 3 experimental groups (n = 31, each) and exposed to 2 males per group. Thereafter, one group was also exposed to 6 estrogenized does (G20%), a second group was exposed to 3 estrogenized does (G10%), and the third group was exposed to 6 non-estrogenized does (G0%). Proportions of does in estrus were analyzed with chi-squared test while hours to estrus was compared with a Student *t*-test. Systat 12 statistical package was used. The proportion of does displaying estrous behavior during the study was similar in both the G10% and G20% groups (93%, 90%, respectively; $P > 0.05$), although different in the G0%, where no female demonstrated estrous behavior (P 0.01). In addition, hr to estrus was greater in G10% (167.8 ± 17 h) than in G20% (142 ± 20 h; $P < 0.001$). These results indicate that estrogenized does exposed to "effected" male goats positively affected the percentage of goats depicting estrous behavior of anovulatory goats exposed to the male effect. In addition, an increased percentage of anovulatory goats depicting estrous behavior of female goats during the anestrous season.

Key words: female effect, seasonal anestrous, sexual activity

W426 Influence of sexually inactive bucks subjected to either long photoperiod or testosterone upon the induction of estrus in anovulatory goats. J. M. Guillén-Muñoz*[1], J. R. Luna-Orozco[2], L. M. Tejeda-Ugarte[1], M. A. De Santiago-Miramontes[1], M. Mellado[1], F. G. Véliz[1], R. Rodríguez-Martínez[1], and C. A. Meza-Herrera[3], *[1]Universidad Autónoma Agraria Antonio Narro, Torreón, Coahuila, México, [2]Centro de Bachillerato Tecnológico Agropecuario No 1, Torreón, Coahuila, México, [3]Universidad Autónoma Chapingo, Unidad Regional de Zonas Áridas, Bermejillo, Dgo., México.*

The objective of this study was to evaluate the efficacy of exposing sexually inactive bucks to either artificial long photoperiod or testosterone upon the induction of estrus of anovulatory goats under rangeland conditions. Multiparous mixed breed anestrous goats (n = 91) were randomly assigned to one of 3 treatment groups: I. Joining with bucks subjected to 2.5 mo of artificial long days (16 h of light/d; PHOTO; n = 31), II. Joining with testosterone-treated bucks (TESTO; n = 30), and iii. Joining with untreated bucks (CONTROL; n = 30). Two bucks were assigned to each treatment group. The breeding season was from August to February and estrus response was measured twice a day (0800 to 1000 and 1800 to 2000 h). Percentages of goats in estrus and conception rates were analyzed with the Fisher exact test, interval to estrus was analyzed by PROC-GLM, and buck sexual behavior was analyzed with the Fisher exact test. While no differences where observed ($P > 0.05$) between the light-treated (100%) and testosterone-treated (93%) bucks in their ability to induce estrus of anovulatory does, none of the goats exposed to the CONTROL-buck exhibited estrus behavior ($P < 0.05$). The interval from the onset of mating to estrus was shorter ($P < 0.05$) in those goats exposed to the light-treated bucks (37.9 ± 4.8 h) as compared with those exposed to the TESTO-treated bucks (58.3 ± 8.7 h). Overall pregnancy rate in goats joined to PHOTO, TESTO and CONTROL bucks was 84, 77, and 0%, respectively, with no differences ($P > 0.05$) between the first 2 groups. Ano-genital sniffing, approaches, mounting attempts and mounts were highest ($P < 0.01$) in the PHOTO-group and lowest in CONTRO-group. Both PHOT and TESTO treated bucks were equally effective in synchronizing estrus in anovulatory goats and resulted in similar levels of fertility under rangeland-extensive conditions.

Key words: male effect, photoperiod, reproductive outcomes

W427 Nutritional supplementation before or after the breeding season does not improve the productive and reproductive response of goats managed under a marginal production system in Northern Mexico. C. G. Orta-Castillón[1], C. A. Meza-Herrera[2], G. Arellano-Rodríguez[1], P. A. Robles-Trillo[1], M. A. De Santiago-Miramontes[1], R. Rodríguez-Martínez[1], M. Mellado[3], and F. G. Véliz*[1], *[1]Universidad Autónoma Agraria Antonio Narro, Torreón, Coahuila, México, [2]Universidad Autónoma Chapingo, Unidad Regional Universitaria de Zonas Áridas, Bermejillo, Durango, México, [3]Universidad Autónoma Agraria Antonio Narro, Saltillo, Coahuila, México.*

The aim of this study was to determine if feed supplementation before or after the breeding season improves both productive and reproductive performance of mixed-breed goats under rangeland conditions in northern Mexico. Three groups of goats grazed (11:00 to 17:00 h) on rangeland and field crop residues. Goats in one group were offered feed supplement 5 d before and 20 d after breeding (SS, n = 37; 2.2 ± 0.1, CC scale 1.4, and 39.7 ± 1.2, kg BW), other group (SS-After, n = 40; 2.2 ± 0.1, CC and 39.9 ± 1.0 kg) received feed supplement only 5 d before breeding. Both groups were fed a ration which provided 75% of their energy and protein requirements for maintenance. The control group (n = 24; 2.3 ± 0.4, CC and 39.5 ± 0.9 kg BW) received no feed supplementation during the experimental period. On March 20th 2010, experimental groups were exposed to 4 bucks which were induced to an intense sexual activity by means of a photoperiodic treatment of 2.5 mo of long day photoperiod scheme (16 h light/day) starting on November first. Differences in the proportion of does showing estrus activity and diagnosed pregnant were detected by using the exact probability test of Fisher. Differences in litter size were compared with the Kruskal-Wallis test. The statistical analyses were carried out with the Systat 10 program (Evenston, IL, USA). The results are shown in Table 1. Overall 83% of goats showed estrus during the experimental period with no difference between groups ($P > 0.05$). Percentage of pregnancy (mean 70% across groups) and ovulatory rates (1.5 ± 0.1 across groups) were similar between groups ($P > 0.05$). These results suggest that mixed-breed multiparous goats in good body condition under extensive-range production systems in northern Mexico, did not benefit from feed supplementation before or after breeding in spring.

Table 1. Reproductive performance of mixed-breed goats supplemented before or after breeding[1]

Goats	Estrus activity (%)	Pregnancy rate (%)[2]	Kidding rate (%)	Litter size (mean±SD)
CG	(88) 38/43	(70) 30/43	(63) 27/43	1.4 ± 0.1
SS-After	(85) 33/39	(74) 29/39	(69) 27/39	1.4 ± 0.1
SS	(79) 33/42	(67) 28/42	(60) 25/42	1.6 ± 0.1

[1]For all variables no statistical differences were detected among groups ($P > 0.05$).

[2]Pregnancy rate at 50 days after the last copulation.

587 Comparison of porcine cathelicidin expression between Jinhua and Landrace pigs. Y. Gao*, S. An, Y. Xie, Y. Liu, F. Han, C. Luan, and Y. Wang, *Institute of Feed Science, Zhejiang University, Hangzhou, Zhejiang Province, China.*

Cathelicidins are important antimicrobial peptides with both antimicrobial and immunomodulatory functions in porcine innate immunity. However whether the expression levels of cathelicidin genes contribute to the disease resistance capabilities between different pig breeds still remains unclear. Therefore the present study was aimed to investigate the tissue-specific and developmental expression of Protegrin-1, Prophenin-2 and PR-39 genes in Jinhua pigs, in addition compare the baseline differential expression of these 3 cathelicidin genes between Chinese local Jinhua pigs and foreign landrace pigs at 20-d of age (before weaning) and 40-d of age (after weaning) by using quantitative real-time PCR. The results showed that cathelicidin genes were expressed in bone marrow, spleen, liver, lung, mesenteric lymph node, kidney and duodenum in both Jinhua and landrace pigs at 20- and 40-d of age. Bone marrow is the major expression site for the above 3 cathelicidin genes and the expression levels in bone marrow were significantly higher than in other tissues ($P < 0.05$). Spleen, liver, mesenteric lymph node and lung had moderate expression of cathelicidin genes. Jinhua pigs showed higher expression of Protegrin-1, Prophenin-2 and PR-39 in bone marrow, spleen, liver, mesenteric lymph node compared with landrace pigs at 20- and 40-d of age, and the difference were significant in bone marrow between breeds ($P < 0.05$). Moreover, cathelicidin genes were developmentally regulated in Jinhua pigs from neonatal to 120-d of age. Taken together, those results indicated that bone marrow was the major expression site of cathelicidin genes in both Jinhua and Landrace pigs, and the higher baseline expression of cathelicidin in Jinhua pigs may contribute to the better disease resistance capabilities, suggesting the expression of cathelicidin genes could relate to the disease resistance capabilities between different pig breeds.

Key words: cathelicidin, gene expression, Jinhua pigs

588 The effect of prenatal stress and dominance order on immune function in response to a DTH and LPS challenge in pigs. B. L. Davis*[1], M. A. Sutherland[1,2], and M. A. Ballou[1], *[1]Texas Tech University, Lubbock, [2]Ruakura Research Centre, AgResearch, Hamilton, New Zealand.*

Prenatal stress (PNS) is caused by elevated maternal glucocorticoid concentrations crossing the placenta to the fetus, resulting in potentially long-term physiological, immunological and behavioral changes in the offspring. The objective of this research was to determine the effects of PNS and dominance order on the cell mediated and acute-phase immune responses. Sows were either injected with adrenocorticotropic hormone or sham handled 3 times a week, from d 76 to 115 of gestation. At weaning, barrows from the stressed (PNS; n = 15) and sham (PNS; n = 15) sows were housed in groups of 3 within the same treatment. At 28 d of age, a food deprivation test was used to determine the dominance order of pigs within each pen. Pigs were denoted as being dominant (DOM), intermediate (INT) or submissive (SUB). A delayed-type hyperresponsivity (DTH) test was performed to assess the cell mediated immune response. One week after the DTH test, each pig was injected intraperitoneally with (include the dose) lipopolysaccharide (LPS) to stimulate an acute phase response. Blood samples were collected from pigs before and 60, 120, 360 min and 24 h after the LPS challenge to measure complete leukocyte counts and differentials; as well as plasma concentrations of cortisol and C-Reactive protein. Rectal temperatures were taken at the same time blood samples were collected. Data were analyzed using the MIXED procedures of SAS. Prenatally stressed pigs had a greater ($P < 0.05$) DTH response than CON pigs and DOM pigs had a lower ($P < 0.05$) DTH response than SUB pigs. Rectal temperature and total leukocyte counts changed ($P < 0.05$) over time in response to the LPS challenge; however, neither prenatal stress nor dominance order influenced the response. Cortisol concentrations following the LPS challenge were greater ($P < 0.05$) in DOM compared with INT pigs and tended ($P = 0.084$) to be greater than SUB pigs. The neutrophil to lymphocyte ratio was greater ($P = 0.05$) in SUB pigs than INT pigs. In conclusion, prenatal stress and dominance order affected both cell mediated immune function and the physiological response to an LPS challenge in barrows.

Key words: pigs, prenatal stress, immune

589 Effects of *Lactobacillus fermentum* I5007 on the redox state of healthy and oxidative-stressed piglets. C. J. Cai*, A. N. Wang, L. C. Chu, S. Y. Qiao, and D. F. Li, *China Agricultural University, Beijing, China.*

The study was conducted to investigate the effects of *Lactobacillus fermentum* I5007 (LF) on the redox state of healthy and oxidative-stressed piglets. A total of 24 weaned barrows (7.19 ± 0.22 kg) were randomly assigned to 1 of 4 treatments: control group (T1), stress group (T2), control group orally administrated LF (T3), and stressed group orally administrated LF (T4). The trial period lasted 21 d. Pigs in T3 and T4 were orally administrated with 20 mL/d (10^8 cfu/ml) LF. On d 8, pigs in T2 and T3 were injected intraperitoneally with diquat at 10 mg/kg body weight, while pigs in T1 and T4 were injected the same volume of isotonic saline. Following the injection, blood was collected at 0.5 h, 1.5 h, 3.5 h, 7.5 h and 14.5 h. At the end of the experiment, all pigs were killed and the liver was sampled. Data were analyzed using the GLM procedure of SAS. The effects of diquat, LF and their interaction were included in the statistical model. The results showed that compared with saline-injected pigs, the diquat-injected pigs had decreased growth performance ($P < 0.05$) during 2 wks after injection, and the increased levels of cortisol (26.90 vs 144.72 pg/ml, $P < 0.01$), adrenaline (3.68 vs 27.90 ng/ml, $P < 0.01$), the free fatty acid (67.02 vs 186.75 μmol/L, $P < 0.01$), glucose (26.90 vs 144.72 mg/dl, $P < 0.01$), malondialdehyde (MDA, 3.67 vs 4.03 nmol/ml, $P < 0.01$), and carbonyl (0.93 vs 1.06 nmol/mg protein, $P < 0.05$) in the plasma from 1.5 h to 14.5 h. Regardless of diquat, supplementation of LF improved the ADG (416 vs 446 g, $P < 0.05$) and ADFI (630 vs 667 g, $P < 0.05$); increased superoxide dismutase (105.23 vs 120.89 U/mg protein, $P < 0.05$), glutathione peroxidase (93.94 vs 103.54 U/mg protein, $P = 0.05$) and the ability to inhibit superoxide anion production (AISP, 316.90 vs 351.34 U/g protein, $P = 0.05$), and reduced the levels of MDA (3.66 vs 3.45 nmol/mg protein, $P < 0.05$) in pig liver. In conclusion, this study indicated that LF increased the growth performance of pigs, improved the antioxidative defense system, and alleviated the oxidative damage caused by oxidative stress.

Key words: *Lactobacillus fermentum*, piglet, oxidative stress

590 In vitro antibacterial activity, cytotoxicity and mechanisms of cathelicidin peptides against enteric pathogens in weaning pig-

lets. Y. Liu*, S. An, C. Luan, and Y. Wang, *Institute of Feed Science, Zhejiang University, Hangzhou, Zhejiang Province, China.*

In the last few decades, long-term and high-dose usage of antibiotics in livestock diets induces the emergence of antibiotic resistance bacteria, antibiotics residues in animal products and environmental pollution, which have adverse effects on animal health and well-being. This study investigated 5 cathelicidin peptides from different animal origins (i.e., protegrin-1[PG-1], PMAP-23, LL-37, indolicidin and cathelicidin-BF[C-BF]) as antibiotic replacements with higher antimicrobial activity and lower cytotoxicity and to study their mechanisms of action toward enteric pathogens in vitro. The antibacterial activity was evaluated via minimum inhibitory concentration (MIC) determinations, killing kinetics and synergy assays. The morphology of peptide-treated bacteria was observed by transmission electron microscopy and intracellular function was determined by DNA binding and cell-free protein synthesis assays. Finally, cytotoxicity was assessed by hemoglobin release, cell viability and lactate dehydrogenase release assays. PG-1 from porcine and C-BF from snake had the most effective bacteriocidal properties and widest spectra of activity, with the MIC values equal to or lower than commonly used antibiotics toward several *Escherichia coli* isolates and Salmonella strains, and showed a synergistic effect with aureomycin. Mechanism studies for PG-1 and C-BF suggested the C-BF killing mechanism was based on membrane permeability, while multiple targets existed for PG-1, including membrane and intracellular biomacromolecules. Cytotoxicity tests showed PMAP-23 and C-BF exhibited the lowest cytotoxic effects, while PG-1, LL-37 and indolicidin displayed cytotoxicity by dose. Although PG-1 showed strong cytotoxic activity, there was less than 20% lysis at 8 Î1/4g/mL at which there was remarkable antimicrobial activity. This study demonstrated that C-BF has the capacity to inactivate enteric pathogens with lower cytotoxicity and is potentially a novel anti-bacterial agent. The activity of PG-1 is highly efficient, with the potential to reduce cytotoxicity using molecular design.

Key words: cathelicidin peptides, antibacterial activity, mechanism of action

591 Microbial transmission and assembly of the gut microbiota in neonatal pigs on day 7 and 14 postfarrowing. E. E. Hinkle*, I. Martinez, J. Walters, P. S. Miller, and T. E. Burkey, *University of Nebraska-Lincoln, Lincoln.*

The gastrointestinal microbiota (GM) effects gut maturation, nutrient metabolism, host immunity, and protection from pathogens. We employed 454-pyrosequencing of 16S rRNA tags to evaluate 1) effect of dam parity (P) on microbial ecology, and 2) microbial transmission from sows to their progeny. Fecal samples were collected from P1 and P3 sows (n = 6/P; d 7 postfarrowing) and 1 piglet/litter on d 7 and 14 postfarrowing. Microbial DNA was extracted and pyrosequenced (Roche Genome Sequencer GS-FLX Titanium). Quality controlled, chimera checked sequences were taxonomically assigned (Classifier, Ribosomal Database Project). An α diversity (Shannon) measure was determined using Qiime. Phylogenetically blasted β diversity was obtained (UniFrac). There were no P effects on GM composition or diversity. The phyla Firmicutes and Bacteroidetes dominated in P1 (83.8% and 5.6%, respectively), and P3 sows (91.0% and 3.1%, respectively). A parity × d ($P < 0.05$) interaction was observed within the phylum Firmicutes. Specifically, P1 sows (83.8%) and d 7 progeny (81.48%) had increased Firmicutes compared with their d 14 progeny (61.7%), and P3 sows (91.0%) had increased Firmicutes compared with their d 7 (60.8%) and 14 (63.0%) progeny. Time effects ($P < 0.05$) were observed for Bacteroidetes, Fusobacteria, and Proteobacteria among progeny from both parities. Bacteroidetes were increased ($P < 0.001$) in piglets compared with sows (11.0 and 25.4% vs. 5.6% for P1, 22.8 and 27.4% vs. 3.1% for P3; respectively, for d 7 and 14 vs. sows on d 7). Fusobacteria and Actinobacteria in progeny were greater on d 7 compared with d 14 (Fusobacteria, 4.13 and 0.17%, Actinobacteria, 4.49 and 0.45%; respectively). Proteobacteria in progeny was increased on d 14 (5.8 and 7.4% for P1 and P3 piglets, respectively) compared with d 7 (0.76 and 3.70% for P1 and P3 piglets, respectively). Sows had increased ($P < 0.001$) Shannon's index compared with progeny. The GM of progeny had greater β diversity than sows ($P < 0.001$). These results represent an initial investigation into transmission and establishment of microbial populations from sows to their progeny.

Key words: parity, gut microbiota, swine

592 Viability of *Parascaris equorum* eggs intermittently exposed to the interior of a windrow composting system. J. C. Gould*, E. T. Lyons, L. M. Lawrence, and M. G. Rossano, *University of Kentucky, Lexington.*

Parascaris equorum generally infects horses less than 18 mo; its pathological effects can be severe. The purpose of this study was to examine the effects of windrow composting on the viability of *P. equorum* eggs intermittently exposed to the interior of a windrow. ANKOM F57 filter bags were used as sentinel chambers and spiked with manure confirmed positive for *P. equorum* eggs. Starting on d 0, chambers were placed within the center of the windrow at 5 different locations, then alternated between resting on top of, or inside, the windrow whenever it was turned. Chambers from each location and control chambers were removed at d 2, 4, 6, 8, 10, 12, 14, and 18; chambers incubated for 21 d at room temperature (24°C). After incubation, chamber material was diluted with a 10% bleach solution, subsampled, and eggs were recovered using double centrifugation with Sheather's solution. Eggs were evaluated using a microscope and classified as viable or nonviable. Efficacy was assessed by 2-tailed *t*-test; a *P*-value of <0.05 was deemed to be significant. The average % viability of *P. equorum* eggs exposed to composting were 10.77, 0.31, 0.00, 0.00, 0.00, 0.00, and 0.00 on sampling d 2, 4, 6, 8, 10, 12, 14, and 18 respectively. The average % viability of control *P. equorum* eggs were 91.34, 79.97, 90.37, 89.93, 81.30, 86.74, 83.29, and 86.94 on sampling d 2, 4, 6, 8, 10, 12, 14, and 18 respectively. Intermittent windrow composting treatment reduced the percent viable eggs compared with the control on d 2 and 4 ($P < 0.000002$). By d 6, percent viable eggs for sentinel containers under the intermittent windrow composting treatment dropped to 0.00 and remained this way for d 8, 10, 12, 14, and 18. The results of this study demonstrate that a well maintained windrow composting system is capable of rendering *P. equorum* eggs nonviable even under intermittent exposure within the windrow.

Key words: parasite, *Parascaris equorum*, compost

593 Effect of a yeast nucleotide product on performance and health status of broilers. A. Ganner*, S. Schaumberger, J. Uhlik, and G. Schatzmayr, *BIOMIN Research Center, Tulln, Lower Austria, Austria.*

Nucleotides are involved in various essential biochemical processes; in animal studies dietary nucleotide supplementation has been shown to exert positive effects on performance, growth, gut health and the immune system. Yeasts as feed additives are an economical and practi-

cal way to provide concentrated nucleotides to the animal. The present study was conducted to evaluate the efficacy of a product, consisting of purified nucleotides, on performance and health status of broilers. The nucleotide product contained 27% RNA-monomers (AMP 9%, GMP 6%, CMP 5%, UMP 4%, nucleosides 3%). In a 35-day study, 675 1-d-old mixed sexed broilers were distributed into 3 experimental groups with 8 replicates: control group A, group B and C with 0 kg, 0.2 kg and 2 kg of nucleotide product per ton feed. Directly after housing the chicks were supplied with the experimental diets. Feed and water were provided ad libitum, feeding was done manually several times a day. Chicks were group weighed at day 1, day 14 and single weighed at day 35. On day 14, statistical significant differences ($P < 0.05$) for weight and average daily weight gain could be observed in group C (2 kg per ton feed) compared to group B (0.2 kg per ton feed) and the control group. At the end of the trial no more statistical differences could be observed in group C ($P > 0.05$), but group B showed positive trends over all parameters (weight day 35, $P = 0.5$; average daily weight gain (ADWG) day 15-35, $P = 0.1$; ADWG d 1-35, $P = 0.5$; FCR d 15-35, $P = 0.09$; FCR d 1-35, $P = 0.2$) compared to group C and the control group. Mortality was slightly reduced in both trial groups with 1.3%, compared to the control (1.8%). Our results indicate that proper nucleotide dosage and supplementation period may have beneficial effects on broilers growth and performance; however over-dosage of nucleotide additives which could cause loss in performance through potential over-reaction of the immune system should be avoided.

Key words: yeast nucleotides, broiler performance, growth

594 The effect of *Vernonia amygdalina* leaf extract on Alloxan-induced diabetic rats. A. H. Ekeocha*, P. C. Ekeocha, and T. Fashola, *University of Ibadan, Ibadan,Oyo,Nigeria.*

The hypoglycaemic or sugar reducing effect of the bitter leaf extract (BLE) was determined using Alloxan-induced diabetic rats. Thirty male Albino rats were divided into 6 groups of 5 rats. Four groups with basal blood sugar levels of 38 ± 0.16, 39.2 ± 0.23, 35.2 ± 0.27, and 35.8 ± 0.25 mg/dl were injected with 10% alloxan in saline to make them diabetic (277.6Â ± 6.55, 284.8 ± 3.80, 256.4 ± 1.39 and 265.6 ± 4.41 mg/dl fasting blood sugar (FBS) respectively). The 4 diabetic groups were then treated with different doses (g/kg body weight, BW) of an aqueous extract of dried bitter leaf herein referred to as BLE. A fifth group (non diabetic) was treated with 400mg BLE /kg BW. BLE was administered twice daily for 2weeks using an oral cannula. The sixth group (non-diabetic) received no BLE as a positive control. Blood was collected from the tail to determine blood on a glucometer. The FBS levels of the 6 albino rat groups were recorded every 2 days for 2 weeks. At the end of wk 2, the rats were slaughtered and their liver, kidney and pancreas examined. Data were analyzed using ANOVA (SAS, 1999). All the rats injected with alloxan became diabetic as their fasting blood sugar (FBS) levels exceeded the normal range of between 80 and 100 mg/dl. The FBS of the diabetic albino rats significantly ($P < 0.05$) decreased as BLE levels increased from 50 to 400 mg/kg BW on days 2, 4, 6, 8, 10, 12 and 14 (Table 1). The plant extract was observed to have a hypoglycemic effect on each group of diabetic rats as it reduced FBS levels (mg/dl) from 277.6 ± 6.55 to 92.0 ± 1.68 (Group 1), 284.8 ± 3.80 to 68.8 ± 0.41 (Group 2), 256.4 ± 1.39 to 55.8 ± 0.49 (Group 3) and 265.6 ± 4.41 to 38.4 ± 0.21 (Group 4) over a period of two weeks. The extract reduced the level of damage to the kidney, liver and pancreas when administered on diabetic rats. The rats were considered treated when their FBS returned to almost their basal blood sugar (BBS) levels. *Vernonia amygdalina* has anti-diabetic properties as it reduced the blood sugar level of albino rats.

Table 1. Fasting blood sugar (mg/dl) of normal and induced-diabetic albino rats administered with varying doses of *Vernonia amygdalina* leaf extracts

Breeding and Genetics Symposium: Is There Space for Genomic Selection in Small Populations?

595 Is genomic selection a one size fits all? I. Misztal*, *University of Georgia, Athens.*

Several methods are used for genomic selection (GS). A multi step method in dairy involves a regular BLUP, creation of pseudo-observations for animals with genomic information, genomic prediction (GP) for genotyped animals, and creation of an index with parent average. This method is successful when models for prediction are simple, genotyped animals include high accuracy bulls, and the number of genotypes is >2000. When genotyped animals have low or variable accuracy, approximations in pseudo-observations, GP and the index reduce the accuracy of prediction and create biases. Lack of the index results in lower accuracy especially for animals farther from the reference population. Another method of GS applies GP directly to phenotypes and genotypes of reference populations. The resulting equations are used for prediction, either directly or as a correlated pseudo-trait in a regular evaluation. This method is simple but less accurate because it ignores information from ungenotyped ancestors and from correlated traits. Also, accuracy of predictions for animals far from the reference populations may be very low. The newest method for GS is single-step GBLUP (ssGBLUP), which is conventional BLUP except that the pedigree-based relationship matrix is modified by SNP-derived relationships. In tests, ssGBLUP seems to be the most accurate one as it utilizes all the information with few approximations. Issues implicitly present in the other methods but explicit in ssGBLUP are proper scaling of genomic relationships, removal of genotype and pedigree conflicts, realistic approximation of accuracies, and optimal selection of animals for genotyping to minimize costs. The additional accuracy due to GS is approximately $\sim\sum[(a^{ij}-g^{ij})^2\ acc_j^2]$, where a_{ij} (g_{ij}) are pedigree (genomic) relationships between animal i and j, and acc_j is accuracy for animal j. The additional accuracy is maximized by selection of reference animals with high accuracy who are strongly related to candidates for selection. In populations where an individual is inexpensive, expanding progeny sizes may be more cost effective than extra genotyping.

Key words: genomic selection, accuracy, single step

596 Is there value in maintaining small populations? Example of the Dual-Purpose Belgian Blue breed. N. Gengler*[1,2], H. Soyeurt[1,2], C. Bastin[1], B. Buske[1], S. Vanderick[1], and F. Colinet[1], *[1]Ulg - GxABT, Gembloux, Belgium, [2]FNRS, Brussels, Belgium.*

Current status of thinking on genomic selection in dairy cattle is mostly major breed centric (e.g., Holstein) and only for traditional traits (e.g., milk yields). Once you depart from this, it becomes obvious that different, often related, issues appear (e.g., lack of large training populations, need for expensive recording of new phenotypes). Also, there is an urgent need to rethink issues that are important for sustainability of dairy production (e.g., added value foods, animal robustness). In this context, small populations (breeds/lines) could represent a potential source of extra information to justify their maintenance. As marker densities increase, efficient dissection of different selection histories of divergent breeds or lines, potentially identifying pockets of unexploited variability will increase. A current example from the Belgian (Walloon) perspective is the Dual Purpose (DP) line of the Belgian Blue Breed (BBB), with presently around 4500 breeding females, for historical reason of which only 1500 have good pedigrees, and which is present in Belgium and northern France. Recent research, done on this line, showed its tendency to produce less saturated milk fat and to have better fertility. Results indicated that it could stay competitive in specific markets, especially because of largely increased meat value. Currently, the myostatin mutation is largely used for breeding purposes. To assess the genetic diversity of the breed, recently, over 200 genotypes (SNP50K) for nearly all breeding bulls of the last 20 years became available. HD genotypes should be available in the near future, also allowing to access selection history of this breed as being in between the 2 extreme breeds: Beef BBB (with which it shares a recent history) and Holstein-Friesian (which is related through its geographic proximity over centuries). Finally, genomic selection for DP-BBB will need to consider a single step type approach without the need of reference population and potentially relying heavily on SNP3K of cows, also with the objective to recreate relationships between animals of interest.

Key words: genomic selection, milk quality, robustness

597 Overview of genomic selection in dairy cattle populations. P. M. VanRaden*[1] and J. R. O'Connell[2], *[1]Animal Improvement Programs Laboratory, ARS, USDA, Beltsville, MD, [2]University of Maryland School of Medicine, Baltimore.*

Genomic selection is most successful for traits recorded over many years in large populations. Holstein breeders have reference populations >10,000 proven bulls via cooperation among major countries, and countries with smaller Holstein populations can contribute additional bulls. Scandinavian red dairy cattle breeders have 8,000 reference bulls, and Brown Swiss breeders have a global population of 4,500 reference bulls at Interbull. Jersey breeders have genotyped but have not yet merged their 6,000 reference bulls. Denser chips can transfer genomic information across breeds if all breeds are in the same data set. Less dense chips with imputation to higher densities allow affordable selection for smaller populations or more recently recorded traits. The North American database now includes Illumina 2,900 marker (3K) or 50,000 marker (50K) genotypes for 74,389 Holsteins, 8,905 Jerseys, and 2,008 Brown Swiss, plus 777,000 marker (HD) genotypes for 435 animals. To determine how many HD animals within each breed may be needed for imputation, 600,000 marker genotypes were simulated for either the youngest animals or for older bulls with highest reliability, and the other animals had 40,000 markers. After imputation using findhap.f90 version 2, percentages of estimated genotypes that matched true genotypes ranged from 96.1 to 98.7% when numbers of HD genotypes ranged from 250 to 1000 within each of the 3 breeds. Imputation accuracy was about 1% less if the youngest animals instead of the older bulls had HD. The value of matching cow phenotypes to their own genotype instead of to their sire's genotype was demonstrated by excluding bulls and using only the 13,935 cows in the Holstein reference population instead of all 25,131 reference bulls and cows (official). For milk yield of young animals, the correlation was 0.86 between cow-only and official evaluations vs. 0.71 between parent average and official. Smaller populations can increase genomic reliability by exchanging information with large populations and by lower cost genotyping.

Key words: genomic evaluation, reference populations, breeds

598 Overview of genomic selection in small populations of beef cattle. G. L. Bennett*, W. M. Snelling, R. M. Thallman, J. W. Keele, and L. A. Kuehn, *USDA, ARS, US Meat Animal Research Center, Clay Center, NE.*

Efficiency and reproduction are important to beef production and are enhanced by using breeds adapted to specific management strategies and environments and by crossbreeding. Thus dozens of breeds are currently used in the US Genomic prediction of breeding value (MBV) needs large trait and genotypic data sets which favors breeds with many cattle. Breeds with small effective population sizes have longer blocks of linkage disequilibrium which they should exploit. Using equations for MBV trained in one population and applied in another has had limited success. New sources of data and analyses are needed to improve MBV. New genotyping assays with more than 10 times the SNP on current assays are expected to yield more robust associations across breeds but this is not proven yet. Using multi-breed data to train MBV predictions identifies markers with consistent associations across breeds but limits the proportion of variation that can be predicted within populations because population specific associations are often not detected. Analyses that utilize both general and breed specific marker associations need to be developed. Identifying the breed origin of an allele is a prerequisite for these analyses and haplotypes may have stronger associations across breeds than SNP alleles. Phenotypic data, especially for expensive or difficult traits, is particularly limiting in less numerous breeds. Breeds that are genetically less diverse (e.g., European Continental) are more likely to have consistent marker associations and might benefit from combining SNP data and expensive phenotypes. Some traits are difficult because they are measured on commercial animals that are not usually genotyped. A strategy of genotyping pools of cattle in from the tails of a trait distribution and using genomic relationships to these pools may be useful for some traits, particularly disease and reproduction, measured in unpedigreed progeny. Basic research to develop and use MBV has been done and is being used in the beef cattle industry, but there is a strong need for innovations that will make this progress accessible to more of the industry.

Key words: breeds, genotype, phenotype

599 Overview of genomic-assisted selection in swine populations. S. Forni*, *Genus Plc, Hendersonville, TN.*

Swine breeders have been successfully using genetic markers since the early 1990s. Marker assisted selection has been applied in the past 20 years and genetic gain was increased for several performance traits. Recent studies have shown that a relatively small number of markers can improve the predictive ability of breeding values by 40–60% for challenging traits such as scrotal hernia, mortality and litter size. Genomic information on a large reference population of swine is not available. Genomic-assisted selection in swine imposes large computational and statistical challenges because information is accumulated and selection decisions are made as often as weekly. The single-step genomic evaluation proposed recently for dairy cattle has appealing features for the swine industry. The method allows for the use of an unrestricted number of markers independent of the trait and accounts for non-genotyped animals in the population. Increases in accuracy of 30% for genotyped selection candidates have been observed in lowly heritable traits with the single-step evaluation. Accuracy improvement was also obtained when only the parents of selection candidates were genotyped. Different weights for specific markers can be incorporated in the method, and this is expected to improve predictive ability. Kernel-based methods can have similar properties regarding computational efficiency and can be used to include the effects of gene interactions in genomic-assisted evaluation. The outcomes of blending genomic information from different lines or swine breeds have not yet been well exploited. Results with simulated data have indicated that genomic information on parental lines could significantly impact the evaluation of performance in the commercial level, if non-additive effects are contemplated. Multi-breed genomic evaluation may also benefit from genotype imputation procedures because higher marker density is important for increasing evaluation accuracy. Methods to reduce genotyping costs and computation time are imperative for the full implementation of genomic-assisted selection in the swine industry.

Key words: genomic-assisted selection, single-step genomic evaluation, swine

600 Delivering livestock genetic improvement in a genomics era: Evolving roles and responsibilities. W. Herring* and K. Andersen, *Pfizer Animal Genetics, Kalamazoo, MI.*

Genomic usage in the genetic improvement business has rapidly evolved over the past 5 years. Until recently the research pipeline has been funded by government/university sources and commodity groups. However, due to the delivery of genetic improvement in each of these species and regional differences in the livestock production structure, the timeline of genomic utilization has and is varying differently. Poultry breeding companies have pursued a consortium approach involving breeding companies and university partners to provide their initial products. Retail swine genetics providers have relied primarily on their own funding to add value to their products. Dairy and beef represent the most diverse examples of utilization of genomic technologies. In the US, U.S.D.A. has heavily funded dairy genetic improvement and is also the source of the industry's genetic evaluations. Due to the heavy use of A.I. and recent efforts of aggressive genotyping, dairy has provided the most visible utilization of genomic technologies into genetic improvement platforms available to dairymen in North America. Conversely, beef cattle genetic evaluations are managed by breed societies and service providers that have been challenged with limited budgets and relatively small resource populations from which to grow their knowledge base. As a result, the largest beef breed societies maintain a position of more advanced execution, with smaller societies struggling to keep pace. Entrance of animal health companies as providers of genomic-based evaluations (primarily beef and dairy), into a space traditionally occupied only by societies and academic institutions that provide genetic evaluation services, is causing shifts in the culture and delivery of genetic improvement. These companies bring networks of expertise across disciplines, customer service, access to development funding and relationships with livestock producers. As shifts in regional production competitiveness are occurring in real-time, all with collaborative influence should be motivated to deliver the most rapid access to genetic improvement such that constraints to its utilization are removed.

Key words: genomics, genetics

Dairy Foods: Impact of Salt Reduction on Cheese

601 Influence of salt-in-moisture of full fat and low fat Cheddar cheese on microflora and flavor. D. J. McMahon*[1], C. J. Oberg[2], L. V. Moyes[2], R. E. Miracle[3], and M. A. Drake[3], *[1]Western Dairy Center, Utah State University, Logan, [2]Department of Microbiology, Weber State University, Ogden, UT, [3]Southeast Dairy Foods Research Center, North Carolina State University, Raleigh.*

Low fat (LF) cheddar cheese develops flavor during aging uncharacteristic of full fat (FF) cheese, such as rosey and burnt/brothy flavors and bitter taste. Our objective was to determine if this is a function of differences in salt-in-moisture (S/M) content. Full fat and LF curd was made (in triplicate) using 700 kg of milk and salted to produce cheese with S/M typical of LF cheese. Half the curd was pressed into blocks, and further salt was added to the remainder to make cheese with S/M typical of FF cheese. For FF cheese, high salt (HS) levels were 2.1–2.5% salt (5.4–6.4% S/M) and low salt (LS) levels were 1.4–1.6% (3.5–4.0% S/M). For LF cheese, HS levels were 2.4–3.1% (4.3–5.6% S/M) and LS levels were 1.6–2.0% (3.0–3.6% S/M). Cheese was stored at 6°C and analyzed monthly for total lactic acid bacteria (LAB), lactococci, and nonstarter LAB (NSLAB) using selective media. Sensory profiles and volatile compounds of cheeses were analyzed after 2, 5 and 7 mo using descriptive sensory analysis and gas chromatography mass spectrometry. In general, initial NSLAB levels were $< 10^4$ and NSLABs became dominant after 3 mo storage. The HS cheeses had the expected die-off of lactococci during storage to $< 10^4$ cfu/g, with this occurring faster at the highest salt level (6.4% S/M) and slower at 4.3% S/M. For LS-FF and LS-LF cheeses, lactococci remained at ~10^5 cfu/g throughout storage. All flavor attributes except milkfat were impacted by age ($P < 0.001$). Both FF and LF cheese with LS levels tended to have higher flavor attributes of sulfur, brothy, rosy, and bitter flavors. In general, LF cheese with HS level had similar flavor scores (except for milkfat flavor) to the FF cheese with LS levels. Volatiles were generally higher in FF than LF cheeses. When comparing salt levels, both LF and FF cheeses had higher concentrations of phenyl and furanone compounds known to be sources of rosy and burnt off flavors. Thus, development of undesirable flavor attributes in LF cheese was not just a function of its lower S/M content but fat content also played a role in sensory perception of flavorants.

Key words: Cheddar, low fat, flavor

602 Manufacture and sensory analysis of reduced and low sodium Cheddar cheeses. B. Ganesan*, K. Brown, D. Irish, C. Brothersen, and D. J. McMahon, *Western Dairy Center, Department of Nutrition, Dietetics and Food Sciences, Utah State University, Logan.*

Salt is used for moisture control during Cheddar cheese manufacture and also restricts off flavors from bacterial metabolism during aging. To address the technical challenges associated with making acceptable reduced salt Cheddar cheese, we made Cheddar cheese in triplicate with final salt levels of 0.75%, 1%, 1.25%, 1.5% and 1.75% (w/w) with similar post press moisture and pH ($P > 0.05$) by altering current manufacture protocols. We conducted texture profile analysis at 0 and 6 mo and initially, cheeses at different salt levels varied in hardness, springiness, and chewiness, but exhibited similar properties by 6 mo of age. The changes in properties however varied at different salt levels. For example, cheese containing 1.8% salt was initially ~40% harder ($P < 0.05$), but became softer and comparable to the others ($P > 0.05$) at 6 mo. In contrast, the 0.75 and 1.5% salt cheeses did not soften during aging. Cheese adhesiveness decreased with salt content between 1.25% and 0.75% and with age ($P < 0.05$), but varied at higher salt levels. Consumer preference (9 point hedonic scale) and descriptive (15 point intensity scale) sensory panels were conducted to evaluate liking and flavor attributes as a function of salt content, respectively. Cheese was served in the consumer panel on separate occasions either cold as cubes or melted as a quesadilla. Cubed Cheddar cheese containing 0.75% salt received ($P < 0.05$) lower liking scores at 0 or 6 mo than the other cheeses. Consumers were able to distinguish cheeses at alternate salt levels at 0 and 6 mo age ($P < 0.05$) irrespective of serving style. Salty and buttery attributes were perceived more ($P < 0.05$) with increasing salt levels by the descriptive panel at 0 mo, whereas bitter, brothy and umami attributes were perceived less ($P < 0.05$) at the higher salt levels. However, this trend reversed at 6 mo, when salty, sour, bitter, buttery, lactone/fatty acid, and umami attributes' perception all increased ($P < 0.05$) along with salt level. Our study highlights that salt plays a multi-faceted role in shaping the physical attributes and flavor perception of Cheddar cheese.

Key words: Cheddar cheese, reduced sodium, flavor

603 Growth and metabolism of *Lactobacillus casei* in a ripening Cheddar cheese model varying salt, lactate, and lactose concentrations. J.-H. Oh*[1], M. F. Budinich[1], M. A. Drake[3], R. E. Miracle[3], J. R. Broadbent[2], and J. L. Steele[1], *[1]Department of Food Science, University of Wisconsin-Madison, Madison, [2]Department of Nutrition, Dietetics, and Food Sciences, Utah State University, Logan, [3]Department of Food Science, North Carolina State University, Raleigh.*

This study focused on how varying the composition of a cheese ripening model system affects the growth and metabolism of *L. casei* M36, UW1, UW4, 32G, and 12A. The conditions that were varied included salt (1.2% and 4.8%), lactate (2.7% and 4.3%), and lactose (0.2% and 1.0%). The Cheddar cheese ripening model system employed a water extract of Cheddar cheese, Cheddar cheese extract (CCE), as the growth media, and 10-week incubation was conducted at 8°C and pH 5.2 in the absence of oxygen. During the 10-week ripening period, there were 12 time points during which the culture was enumerated and the pH determined. At select time points, organic acids and volatile compounds were quantified by high performance liquid chromatography (HPLC) and gas chromatography (GC), respectively. *L. casei* UW4 reduced the concentration of phenylacetaldehyde, a compound responsible for rosy and metallic off-flavors in Cheddar cheese, 78% relative to the control. *L. casei* M36 enhanced the accumulation of diacetyl and sulfur containing volatiles, compounds thought to enhance Cheddar cheese flavor development. Additionally, these 2 strains exhibited fast growth in CCE under the conditions examined. The results obtained suggest that UW4 and M36 strain may have utility in enhancing the flavor of reduced-sodium and reduced-fat Cheddar cheeses. This study has demonstrated that salt in the moisture is a key variable in determining the volatiles produced by non-starter lactic acid bacteria and identified 2 strains to be examined in subsequent Cheddar cheese trials with reduced salt in the moisture. Screening of a collection of genetically diverse *Lactobacillus casei* strains will allow us to select a subset of strains to be examined for their ability to dominate the microbiota and positively influence flavor development in ripening reduced-fat and reduced-sodium Cheddar cheeses.

Key words: *Lactobacillus casei*, reduced-fat Cheddar cheese flavor, volatile compounds

604 Manufacture and sensory analysis of reduced and low sodium pasta filata style Mozzarella cheeses. B. Ganesan*, K. Brown, D. Irish, C. Brothersen, and D. J. McMahon, *Western Dairy Center, Department of Nutrition, Dietetics and Food Sciences, Utah State University, Logan.*

High sodium intake negatively impacts consumer health, thus there is active interest in lowering sodium levels in dairy foods. Toward developing a healthier cheese and tackling the challenges associated with reduced sodium cheese manufacture, we made low moisture part skim Mozzarella cheese with total salt levels at 0.7, 0.9, 1.25, 1.35, and 1.8% (w/w) in triplicate, thus reducing sodium by 25 to 60%. Our manufacturing protocols yielded cheeses with similar moisture and pH ($P > 0.05$) independent of the final salt levels in cheese that allowed us to study the effect of salt on cheese properties. Further, we evaluated mozzarella cheese functionality by characterizing stretch and melt properties, and also studied flavor and acceptance using descriptive (15-point intensity scale) and consumer (9 point Hedonic scale) taste panels. At wk 2, all Mozzarella cheeses melted similarly, but by wk 8, the meltability of all cheeses increased by ~2-fold ($P < 0.05$), with the 0.9% salt cheese showing the greatest increase. Stretchability also increased 4 to 8-fold ($P < 0.05$) with storage, but varied with salt content. At wk 2, 1.8% salt cheese required the greatest stretch force, while other cheeses had similar stretch properties. Taste panels conducted at 3 wks with cold shredded cheese showed that consumers liking for Mozzarella cheese was low at 0.7 and 0.9% salt, but equally ($P > 0.05$) preferred all cheeses containing higher salt levels (1.25, 1.35, and 1.8% salt). All cheeses had acceptable liking scores when served as pizza toppings, and consumers were able to differentiate cheeses ($P < 0.05$) at alternate salt levels, e.g., 1.8% and 1.5% salt cheeses scored similar ($P > 0.05$), as did cheeses at 1.5% and 1.35% salt, but 1.35% salt cheese scored lower ($P < 0.05$) than and was discernible from 1.8% cheese. Descriptive panelists identified salty, sour, umami, bitter, brothy, lactone/fatty acid, and sulfur attributes as different across the cheeses, with the perception of each significantly ($P < 0.05$) increasing along with salt level. To our knowledge, this is the first study that investigates the role of salt as the chief variable in mozzarella cheese physical properties and flavor attributes.

605 Informatic prediction of alterations to Cheddar cheese flavor reactions and pathways due to sodium substitution. B. Ganesan* and K. Brown, *Western Dairy Center, Department of Nutrition, Dietetics and Food Sciences, Utah State University, Logan.*

Increased interest in reduced and low sodium dairy foods due to health implications generates novel issues for product manufacture. As an alternate to reduction, Na may be partly replaced with potassium or calcium, but the role played by the substituting cations in flavor development is unclear. For example, NaCl addition to Cheddar cheese induces a general stress response at the gene level in lactic acid bacteria and restricts microbial outgrowth and metabolism and consequently reduces off flavors. Once Na is reduced or replaced the metabolic routes and the resulting flavors may also be altered. For example, Ca substitution beyond 10% total salt causes bitterness in Cheddar cheese. The roles of other cations in bacterial stress are unknown, but the effect of some cations on metabolic enzymes has been characterized. K, for example, is an activator of over 40 enzymes and inhibits 25 enzymes. Similarly Ca activates 29 enzymes but also inhibits 55 enzymes. Currently we can visualize the effects of these cations only as lists inside metabolic databases. By visualizing the impact of these activating and inhibitory activities as biochemical pathways inside a metabolic database we can analyze, predict, and eventually dictate the aging process of cheeses with non-sodium cations. Henceforth, we reconstructed new metabolic databases that illustrate the effect of different salt cations on flavor-related enzymes as microbial pathways. After metabolic reconstruction and analysis we found that nearly 100 pathways of lactic acid bacteria are affected due to enzymes likely to be activated/inactivated by K and Ca. These pathways are primarily linked to sugar metabolism, acid production, and amino acid biosynthesis and degradation. Notably, some pathways controlled by K also link to assimilation of other minerals such as magnesium and iron, suggesting that K addition will also affect additional cation inclusions currently being considered. This approach will allow us to identify and tackle metabolic routes induced and inhibited by cation replacements and their effects on Cheddar cheese flavor.

Key words: reduced sodium, Cheddar cheese, flavor

606 The effect of NaCl substitution with KCl on Nabulsi cheese: Chemical composition, total viable count, microstructure and texture profile. N. P. Shah* and MM Ayyash, *School of Biomedical and Health Sciences, Victoria University, Melbourne, Victoria, Australia.*

Sodium chloride is traditionally added to cheeses as a preservative and to improve flavor. However, a positive correlation between high level of sodium and osteoporosis, kidney stones and hypertension has been found. Hence, there has been an increased interest to reduce salt in foods. This study aimed at examining the impact of NaCl substitution with KCl on characteristics of a high brined white cheese (Nabulsi). Nabulsi cheese was made and kept in 4 different brine solutions at 18% including NaCl only (A; control); 3NaCl: 1KCl (w/w; B); 1NaCl: 1KCl (w/w; C); and 1NaCl: 3KCl (w/w; D) and stored for 5 mo. Chemical composition, proteolysis, total viable count (TVC) and texture profile analysis (TPA) were assessed at monthly intervals for 5 mo. No significant effect was found among experimental cheeses in terms of chemical composition and TPA profiles. Proteolytic activities were higher in cheeses kept in brine solutions that contained higher KCl (B, C, and D) as compared with the control. At the end of the storage period, water soluble nitrogen (WSN) and 12% trichloroacetic acid (TCA)-SN in Nabulsi cheeses stored in B, C and D was higher than the control (A). Also, TVC increased significantly after 1 mo of storage for all salt treatments. Hardness and gumminess decreased significantly during storage at the same salt treatment. ESEM micrographs showed a compact and closed texture for cheeses at same storage period. Microstructure of all cheeses became more closed and compact with storage period. Calcium content negatively correlated with hardness and sodium and potassium contents during storage at same salt treatment. The results showed that KCl could partly replace NaCl without any significant effect on the general characteristics of Nabulsi cheese.

Key words: salt substitution, TPA, TVC

607 The effect of NaCl substitution with KCl on low moisture mozzarella cheese: Chemical composition, organic acid profile, soluble calcium content, functional properties, proteolysis, lactic acid bacterial population, and ACE-inhibitory peptides. N. P. Shah* and M. M. Ayyash, *School of Biomedical and Health Sciences, Victoria University, Melbourne, Victoria, Australia.*

NaCl is traditionally used as a preservative and is added to cheeses to control bacterial growth, enzymatic activities, and to improve flavor. The recommended daily intake for sodium is 2.4 g, which is equivalent to 110 mmol Na or 6.0 g NaCl; the daily sodium intake in developed countries is substantially higher than the RDI. There is a positive asso-

ciation between hypertension and salt which in turn causes cardiovascular diseases. The effect of NaCl substitution with KCl on chemical composition, organic acids profile, soluble calcium and functionality of low moisture Mozzarella cheese LMMC) was investigated. Four batches of LMMC were made, and after milling cheeses were dry salted using 4 combinations of NaCl and KCl (only NaCl (A; control), 3NaCl:1KCl (B), 1NaCl:1KCl (C), and 1NaCl:3KCl (D) at 46 g/Kg. Functionality (meltability and browning), organic acids profile and chemical composition, proteolysis, lactic acid bacteria, and ACE-inhibitory of LMMC were measured. Chemical composition showed no significant difference between experimental cheeses at same storage period, and same salt treatment. Meltability of LMMC with treatment B, C and D was higher compared with the control. The amount of soluble Ca and P increased significantly during storage with no significant difference between salt treatments. There was no significant difference in organic acid profile between salt treatments at same storage period. Substitution of NaCl with KCl had similar effect on chemical composition, organic acids profile and functional properties. In addition, LMMC salted with NaCl/KCl mixture (treatments C and D) improved functionality of LMMC compared with the control. pH value of LMMC salted with NaCl/KCl mixture (C and D) was generally higher compared with the control. ACE-inhibitory peptides in treatment D increased significantly compared with other batches. WSN, TCA-SN showed no significant difference between experimental cheeses; however, PTA-SN significantly differed.

Key words: LMMC, substitution of NaCl, functionality

608 The impact of pectin types on the rheological and physical properties of yogurt. S. S. Mohamed*[1,2] and J. A. Lucey[1], [1]*University of Wisconsin, Madison,* [2]*University of Kafrelsheikh, Egypt.*

Pectin is commonly used as a gelling agent in the manufacture of yogurt. The objective of our study was to evaluate the impact of 4 different types of pectin that had different degrees of esterification (DE) and amidation (DA), on the physical properties of set type yogurt. The pectin samples included 2 types of low methoxyl (LM) pectin with 38% and 45% DE, one type of low methoxyl amidate (LMA) with 39% DE and 14% DA, and one of high methoxyl (HM) with 72% DE. Other pectin types resulted in phase separation in milk. Pectins were added to heated reconstituted skim milk at various concentrations (0.005, 0.05, 0.1 and 0.2%). Gelation properties were monitored using dynamic low amplitude oscillatory rheology and infrared light backscatter. Microstructure was studied using fluorescence microscopy. Wheying off and permeability (porosity) were analyzed at pH 4.6. At pectin concentration of 0.005% no significant differences were observed in yogurts. Yogurt made with 0.05 or 0.1% LMA, LM with 38% DE, and LM with 45% DE, had significantly lower storage modulus (G'), light back scatter ratio at pH 4.6 (RpH4.6), wheying off and permeability compared with control yogurt (no pectin). Permeability and wheying off increased with increasing LMA concentration from 0.1 to 0.2%, while the G' and RpH4.6 values were reduced. Complete inhibition of wheying off was observed when 0.2% LM (38% DE) pectin was used in yogurt and this sample also had the lowest permeability. In yogurt made with 0.2% of HM pectin, the R value gradually decreased after gelation pH until pH 4.6. Wheying off and permeability increased with an increase in the concentration of HM (from 0.005 to 0.2%). HM pectin produced yogurt with the lowest G' and RpH4.6 values compared with other treatments. The microstructure results indicated that yogurt made with HM pectin had an open network, especially at 0.2% pectin, while yogurt made with LM (38% DE) had higher degree of interconnectivity of strands. In conclusion, pectin types greatly impact gelation behavior and yogurt texture. LM pectin with low DE value and without amidation gives the best gelation properties.

Key words: yogurt, pectin, rheology

609 Engineering yogurt texture: Interactions between texturing lactic acid bacteria and processing conditions in low fat stirred yogurt. K. B. Qvist*, C. Gilleladen, J. Trihaas, and C. Svane, *Chr. Hansen, Hoersholm, Denmark.*

Recent years has seen increasing use of highly texturizing cultures in yogurt manufacture, and also a rapid diversification regarding protein ingredients used. This caused us to question whether the current understanding of yogurt technology is adequate, given that most of it was derived before widespread use of new protein ingredients and highly texturizing cultures. To study effects and interactions of the following factors we executed a so-called D-optimal design experiment with 168 yogurts samples (representing 1134 samples of a full factorial): protein type used for fortification (skimmilk (SKM), or PM500G (fortified in whey protein compared to SKM, from IDI); protein addition level (0.7, 1.05, 1.4%); fat content (0.5, 1.0, 1.5%); back pressure during cooling in plate heat exchanger (0, 0.1, 0.2 MPa); filling temperature (12, 18.5, 24°C); and 7 commonly used yogurt cultures differing in EPS production and other properties. Shear stress assessed at a shear rate of 300 s^{-1}, and complex modulus at 1 Hz (StressTech rheometer), were used to represent mouth thickness and gel stiffness, respectively. Major variables determining shear stress and complex modulus were culture used, protein addition level and type, and back pressure. Shear stress and modulus increased substantially when raising protein addition from 0.7 to 1.4%, but decreased when back pressure was increased from 0 to 0.2 MPa. The most important new insight was that interactions between culture, protein type, and amount of protein added can be complex. For instance, the effect of amount of protein added on shear stress can depend strongly on which culture is used. Also, with some cultures, PM500G increased shear stress much more efficiently than SKM. Regarding the modulus, with a highly texturizing culture, adding SKM did little to increase the modulus, while addition of PM500G was highly effective. In conclusion, a much higher level of process optimization can be achieved by exploiting interactions between cultures, ingredients and technology, than by thinking of these factors independently of each other.

Key words: yogurt texture, cultures, interactions

610 Yogurts made from milk where heating was performed at different pH values. T. Ozcan[1,2] and J. Lucey*[1], [1]*University of Wisconsin-Madison, Madison,* [2]*Uludag University, Bursa, Turkey.*

It is well known that the pH of milk during heat treatment has significant effect on level/type of whey protein interaction with casein micelles. As the pH of heating decreases there is an increase in the proportion of denatured whey protein associated with casein micelles (bound aggregates) and less soluble denatured whey proteins. The objective of this research was to investigate the effects of heating milk at different pH values, with or without readjustment to pH 6.7 after heating, on the properties of yogurt gels. Reconstituted skim milk was adjusted to pH values 6.2, 6.7 or 7.2 and heated at 85°C for 30 min. Another set of milks were heated as above but readjusted to pH 6.7 after heating. Milks were inoculated with 3% yogurt culture and incubated at 40°C until pH 4.6. Gel formation was monitored using dynamic oscillatory rheology and light backscattering. Fluorescence microscopy was used to observe gel microstructure. The G′ values at pH 4.6 were highest in gels made from milk heated at pH 6.7 and lowest in milk heated at pH 6.2, with or without pH adjustment after heating. The G′ values at pH 4.6 were lower in samples adjusted to pH 6.7 after heating. No maximum in the loss tangent parameter was observed during gelation for yogurts heated at pH 6.2 but a maximum was observed at pH~4.8 for milks heated at pH 6.7 or 7.2, with or without pH adjustment after heating. Profiles for the light backscatter ratio (R) during gelation indicated that higher R values were observed in samples heated at higher pH values, with or without pH adjustment after heating. The first derivative of light backscatter ratio (R') also revealed differences between samples. The R' profiles for samples heated at pH 6.7 and 7.2 had 2 peaks during gelation but the pH 6.2 sample had only one. Higher peak values in the R' profiles were observed with an increase in the pH of heating. No clear differences were observed in the microstructures of gels between treatments. Heating milk at pH 6.7 created an optimum balance of bound and soluble denatured whey proteins, which resulted in yogurt with the highest gel stiffness.

Key words: yogurt, rheology, gelation

611 Dextran addition to model acid gels to explore the mechanism by which EPS influence yogurt texture. U. Pachekrepapol* and J. A. Lucey, *University of Wisconsin - Madison, Madison.*

Exopolysaccharides (EPS) are biopolymers produced by lactic acid bacteria and EPS production can impact the rheological properties of yogurt. It is not clear when EPS is produced during the yogurt fermentation process. We believe that the point in the fermentation process when EPS are produced could greatly impact gelation and rheological properties of yogurt. Our objective was to use a model acid gel system to explore the impact of biopolymer addition at various pH values. High molecular weight dextran (2×10^6 Da) was used as a simple model biopolymer instead of bacterial EPS. Reconstituted skim milk was acidified to pH 4.4, 4.6, 4.8 and 4.9 at ~0°C by addition of 3N HCl. Dextran solution was then added into cold acidified milk to give a dextran concentration of 0.5% (w/w). Milk was then warmed up in a rheometer at a rate of 0.5°C/min until the temperature reached 30°C and it was held for 17 h at 30°C. The cold acidified milks gelled as they were warmed to 30°C. The rheological and microstructural properties of these gels were determined by small amplitude oscillation rheology and confocal scanning laser microscopy (with image analysis), respectively. No significant difference in the gelation time or storage modulus (G′) was observed in gels with or without dextran addition for gels made at the same pH value. Image analysis was used to determine the percentage of area of the protein aggregates in gels. Image analysis indicated that there was no significant difference in protein aggregate area in gels made at the same pH with or without dextran. However, gels made at different pH levels had different area of protein aggregates. At pH 4.4 and 4.6, the areas of protein aggregates were similar and higher than those of gels made at pH 4.8 and 4.9. In conclusion, we did not find that the addition of dextran had any significant impact on gel properties. Although, we added a high concentration (0.5%) of a high molecular weight dextran, possibly other physical characteristics of EPS (e.g., branching or charge) could be important in the ability of EPS to impact yogurt texture.

Key words: EPS, yogurt, Dextran

612 Effect of the addition of glucose/glucose oxidase and packagings with different permeability oxygen rates on some characteristics of probiotic yogurts. A. Cruz[1], J. Assis*[1], D. Granato[2], S. Bogusz Junior[1], and H. Godoy[1], *[1]University of Campinas (UNICAMP), [2]University of São Paulo (USP).*

The use of the enzymatic complex glucose/glucose oxidase has been presented as a potential option for removal of the dissolved oxygen in stirred probiotic yogurt. In this research, the stability of probiotic yogurt packaged in plastic material with different values of oxygen permeability was investigated during 28 d. Probiotic yogurts supplemented with *Lactobacillus acidophilus* La14, *Bifidobacteria longum* BL05, 62.32 ppm of glucose oxidase and 4.35 ppm glucose were manufactured and packaged in conventional polypropylene cups (PP) or PP coextrused with different levels of vinyl ethylene alcohol (VEOH), presenting the following permeability oxygen rates (TPO2): 0.09 (P1), 0.20 (P2), 0.39 (P3) and 0.75 (P4) ml O2/cup*day. Postacidification, dissolved oxygen, proteolysis, viable count of yogurt and probiotic bacteria, carbohydrate consumption (glucose and lactose), organic acid production (acetic and lactic acid) and aroma compounds (diacetyl and acetaldehyde) were monitored weekly (1, 7, 14, 21, and 28 d). A significant ($P < 0.05$) effect of the packaging system was observed for all analyzed parameters. P1 and P2 presented the lowest values of dissolved oxygen, reflecting in an increased metabolism of probiotic cultures. These samples also presented a greater postacidification, proteolysis, carbohydrate consumption, organic acid levels and aroma compounds, suggesting a continuous performance of the enzymatic system. P3 and P4 had the opposite trend, maybe due to the difficulty of the enzymatic complex in removing the oxygen in the product. As a conclusion, if plastic materials with a low barrier to oxygen are used a higher concentration of glucose should be added into the yogurt to guarantee the best enzymatic efficiency and, hence, the functionality of the stirred probiotic yogurt during the shelf life.

Key words: probiotic yogurt, glucose oxidase, stability

613 Effect of increased concentration of glucose oxidase in probiotic stirred yogurt on functionality, proteolytic pattern, and metabolic products. A. Cruz, W. Castro, and J. Assis*, *University of Campinas (UNICAMP).*

The addition of increased concentrations of glucose oxidase, a potential oxygen remover, in probiotic stirred yogurt was evaluated. Probiotic yogurts supplemented with *Lactobacillus acidophilus* La-14 and *Bifidobacteria longum* BL 05, added with 0, 200, 400, 600, 800 and 1000 ppm glucose oxidase were manufactured and packaged in 200 mL polypropylene cups. Post acidification, dissolved oxygen, proteolysis, viable count of yogurt and probiotic bacteria, carbohydrate consumption (glucose and lactose) and organic acid production (acetic and lactic acid) were monitored weekly during 1, 7, 14, 21, and 28 d refrigerated storage. Independent of the amount of added enzyme, a rapid consumption of the substrate (glucose) was observed and also an increase of dissolved oxygen during the storage time, probably because of the high oxygen permeability of the package. Consequently, the count of viable probiotic microorganisms (mainly *B. longum*) decreased as function of storage time as well as lower carbohydrate consumption, lower proteolysis and lower ph values ($P < 0.05$). No effect was observed in the lactic acid production ($P > 0.05$). However, at the of shelf life the counts of *Lactobacillus acidophilus* and *Bifidobacteria longum* were still 7 and 6 log cfu/g, respectively. Based on such results it was concluded that it is necessary to improve the oxygen barrier of the package to benefit from the use of glucose oxidase and prolonging the shelf life of probiotic stirred yogurt.

Key words: probiotic yogurt, glucose oxidase, stability

614 Impact of adding galactooligosaccharides on the physical and optical characteristics and sensory acceptance of vanilla ice cream. A. Cruz, J. Faria*, W. Castro, R. Cadena, and H. Bolini, *University of Campinas (UNICAMP).*

Prebiotic and conventional dairy foods should present similar technology and sensory performance. The research aimed to evaluate the effect of adding galactooligosaccharide (GOS) on the physico-chemical and optical characteristics and sensory acceptance of ice cream. Vanilla ice creams supplemented with 0, 1.5% and 3.0% w/w (0G, 1.5G, 3G) galactooligosaccharides (GOS) were subjected to physico-chemical analysis (pH, firmness, melting rate, and overrun) and optical analysis (instrumental color). Simultaneously, vanilla ice creams supplemented with 1.5% or 3% w/w (1.5F, 3F) fructooligosaccharides (FOS) were also produced and submitted to the same analyses. In addition, a consumer test (30 consumers, triangular test) was performed. The 3G ice creams were characterized as firmer and with lower melting rates as compared with the others samples ($P < 0.05$) while absence of effect was observed in the pH and instrumental color values. The results from the consumer test indicated that the 3G ice creams were perceived as different from the 0G ice creams ($P < 0.05$), whereas the 1.5G, 1.5F, and 3F ice creams were perceived as similar ($P > 0.05$) to the control sample. The findings suggest it is possible to manufacture ice creams

supplemented with 1.5% GOS, which presented more stable and with a sensory perception similar to the conventional ice creams.

Key words: ice cream, galactooligosaccharides, stability

615 Physical properties and functionality of probiotic vanilla ice creams manufactured with different overruns levels. A. Cruz, J. Faria*, W. Castro, R. Cadena, and H. Bolini, *University of Campinas (UNICAMP)*.

The effect of different overrun levels on the physical properties and functionality of probiotic ice creams was investigated. Vanilla ice creams supplemented with *Lactobacillus acidophilus* were manufactured with 45, 60 and 90% (O45, O60, O90) overruns levels. Physical analysis (pH, viscosity, melting rate) were performed. In addition, *L. acidophilus* counts were performed during 60 d of frozen storage at −20°C. Probiotic ice creams manufactured with higher overrun levels showed better stability ($P < 0.05$), presenting lower melting rate and improved viscosity, while no effects on pH were observed. Overrun levels also influenced the survival of *L. acidophilus* ($P < 0.05$). O60 presented viable probiotic counts ranging from 8.10 and 8.02 log cfu/g while for O90 this parameter ranged from 7.00 to 6.06, respectively. However, O45 presented viable probiotic counts ranging from 8.06 to 8.04 log cfu/g ($P > 0.05$), during storage. These findings suggest it is important to optimize the overrun levels during the probiotic ice cream processing to keep its functionality, without negative impact on its intrinsic parameters of quality.

Key words: probiotic ice cream, overrun, functionality

Extension Education Symposium: Enhancing Educational Approaches for Future Changes in Biosecurity and Antibiotic Use in Animal Agriculture

617 Overview–The importance of biosecurity and animal production. E. R. Jordan*, K. J. Lager, and R. G. Bruno, *Texas AgriLife Extension Service, College Station.*

Many factors, including religion, personal income, commodity price, traditions and personal preference, influence demand for animal protein provided by livestock production. Frequently, as affluence in developing countries improves, demand for animal protein expands. According to the World Health Organization worldwide per capita consumption of livestock products increased from 24.2 kg/yr in 1964–66 to 36.4 kg/yr in 1997–1999 and was projected to reach 45.3 kg/yr by 2030. During the same period worldwide per capita milk consumption increased from 73.9 to 78.1 kg/yr and was projected to reach 89.5 kg/yr in 2030. Yet, despite increases in total caloric intake and animal protein intake, the Food and Agriculture Organization (FAO) of the United Nations estimated that 925 million people were undernourished in 2010. The world population is expected to grow from 6.8 billion today to 9.1 billion in 2050, requiring 200 million tonnes of additional meat production. As the world has become more intertwined, disruptions to food production, processing and distribution as a result of natural disasters, disease, economic constraints or terrorist actions can have far reaching effects on food insecurity, further destabilizing the World. For example, the 2001 Foot and Mouth Disease Outbreak in Britain resulted in 6 million animals (4.9 million ovine, 0.7 million bovine and 0.4 million porcine) being culled, resulting in an economic loss of £3.1 billion to agriculture and the food chain plus a significant loss of animal protein to the food supply. A global threat for poultry as well as humans is the H5N1 highly pathogenic avian influenza virus, which emerged in 1997 in SE Asia and has subsequently infected the wild bird population. To protect the food supply for an expanding world population, increased emphasis has been placed on biosecurity, which encompasses the various measures taken to secure a population from exposure to harmful biological agents. Preventing animal disease and the spread of those diseases once introduced into an animal population is one of the keys to fighting hunger, malnutrition and poverty. Furthermore, having biosecurity measures in place so that food supply chain disruptions resulting from a disease outbreak can be minimized is imperative for the well-being of the animal industry, as well as to the human population to which it provides nourishment.

Key words: biosecurity, livestock

618 Biosecurity at the farm level: The role of extension in preventing animal disease introduction. R. Daly*, *South Dakota State University, Brookings.*

Biosecurity can be defined as interventions that prevent the introduction of novel infectious diseases into an area such as a farm, state or country. While extension personnel should be aware of and assist state and federal disease control programs where appropriate, it is at the farm level where extension programming has potential for great impact. A wealth of publications that address biosecurity have been published and distributed by extension and other groups. These publications are primarily directed toward general livestock, dairy, beef and poultry operations. Common subjects addressed are use of footbaths/disposable boots, quarantine of new animals, equipment disinfection and visitor/vehicle access. A recent review of these resources revealed that there are discrepancies among recommendations. For example, recommended isolation time for new animals entering beef operations varied from 14 to 60 d. Producers may become discouraged when trying to account for these differences, and may "cherry-pick" procedures that are most convenient for them or avoid them entirely. Another pitfall of many biosecurity recommendations is that they are often too general to be useful. An individual, farm-specific approach to biosecurity is more desirable than dependence on general recommendations. Tools are available to extension personnel for conducting individual risk assessments, in concert with herd veterinarians, regarding infection control practices. Practical and effective biosecurity measures can then be developed for the operation. Comprehensive materials for beef, dairy and equine facility risk assessment are available through the Center for Food Security and Public Health at Iowa State University. Extension personnel have a unique role in educating youth about biosecurity measures. Animal exhibitions present ideal opportunities to emphasize infection control practices and proper management of animal movements to prevent novel disease back at home. Assisting producers in development of biosecurity plans is an appropriate function of extension personnel. Tools are available to formulate specific, useful recommendations for farms and ranches.

619 Extension and outreach programs that address contemporary issues in food animal production. P. D. Ebner*, *Purdue University Department of Animal Sciences, West Lafayette, IN.*

Most Americans are far removed from animal agriculture. There is an increasing demand by the general public, however, for information regarding various technologies used in modern livestock production. Both consumers and non-consumers of animal products have questions on topics ranging from antimicrobial use to manure application and its potential environmental impact. The land-grant universities, where many of these technologies were developed, are uniquely positioned to provide these individuals with research-based information. In recent years, the Department of Animal Sciences at Purdue University has focused on the development extension programs that examine contemporary topics in food animal production, but target less traditional audiences. These programs have mixed traditional media such as fact-sheets and symposia with newer media including YouTube-hosted educational videos, social networking sites and other web-based tools. Examples of such programs include the Purdue University Concentrated Animal Feeding Operation Team (www.ansc.purdue.edu/CAFO) which brought together experts in various fields to identify and research public health, environmental and social/economic issues surrounding the expansion of animal agriculture in Indiana. The team developed a series of educational materials and programs targeted to the state and local officials charged with making decisions regarding proper siting of larger livestock facilities. Purdue University more recently developed the Food Animal Education Network (www.ansc.purdue.edu/FAEN), which is targeted to individuals who may have no connection to livestock production, but have questions or concerns regarding how their meat is produced. The program answers a wide range of questions from 'why are antibiotics used in livestock production?' to 'who is in charge of meat inspection?' and provides the information in accessible and appropriate forms. Together, these programs provide information to all of our stakeholders so that they can better determine the impact that food animal production has on their lives and their communities.

620 Novel approach to measuring internal scrotal temperature in stallions utilizing a thermal sensory device. J. D. Mawyer*, R. K. Gordon, C. A. Cavinder, M. M. Vogelsang, C. C. Love, S. P. Brinsko, T. L. Blanchard, and S. R. Teague, *Texas A&M University, College Station.*

Past studies investigating testicular heat stress due to exercise or insulation in the stallion have utilized thermistor probes to measure scrotal surface temperatures (SST). Although such devices are effective, a more efficient measurement of testicular thermal stress would be subcutaneous scrotal temperature (SQST). The objective of this study was to utilize a thermal sensory device to measure SQST in the stallion during exercise and correlate it with subcutaneous neck (SQNT), rectal (RCT), and ambient temperatures (AMBT), as well as % humidity (HUM), and temperature-humidity index (THI). Thermal sensory microchips (Digital Angel, Inc., St. Paul, MN) were surgically implanted into the subdermis of the necks and scrotums of 8 miniature stallions. Stallions were assigned to a non-exercised (Non-Ex; control; n = 4) or exercised (Ex; n = 4) group. A motorized equine exerciser was used to work stallions 30 min/d for 4 d/wk during a 12-wk period from July–October. Temperatures (SQST, SQNT, RCT, and AMBT) were recorded before exercise, immediately after intense exercise, and 1 and 2 h post-exercise. Humidity data was obtained later to determine THI. Data were not normally distributed; therefore, a Spearman′s Rank Order correlation analysis was used. No deleterious effects were observed from implantation of thermal sensory microchips. Subcutaneous scrotal and RCT showed the highest correlation (R = 0.761). Scrotal temperature was also correlated to SQNT, AMBT, and THI ($P < 0.0001$) (Table 1). Thermal sensory microchips are a safe and effective way to measure SQST to monitor testicular heat stress.

Table 1. Mean correlations (Rs) of SQST, SQNT, RCT, AMBT, HUM, and THI

	SQST (°C)	SQNT (°C)	RCT (°C)
SQNT (°C)	0.476*		
RCT (°C)	0.761*	0.453*	
AMBT (°C)	0.625*	0.513*	0.558*
HUM (%)	−0.074*	−0.263*	−0.025
THI (°C)	0.629*	0.453*	0.573*

* indicates $P < 0.0001$.

Key words: stallion, subcutaneous scrotal temperature, exercise

621 Electrolyte and pH response to submaximal training in Quarter and Miniature Horses. R. M. Legere* and J. S. Pendergraft, *Sul Ross State University, Alpine, TX.*

Plasma electrolyte concentration and pH response was compared in Quarter Horses (QH) and Miniature Horses (MH) to evaluate the miniature horse as an exercise physiology model for full size horses during submaximal exercise and training. Four QH, 8 to 16 yr of age (439 ± 14 kg), and 4 MH, 10 to 17 yr of age (95 ± 16 kg), with each size consisting of 2 mares and 2 stallions, were blocked within breed by age and initial body weight. Horses were subjected to 2 standardized exercise tests (SETs) in a 2 × 2 factorial design. Between SETs horses performed 6 weeks of biweekly submaximal training bouts, with 3 2-week stages of increased training time. The SET and training bouts were scaled using the Froude pendulum model to provide equivalent workouts for all horses at customized speeds, based on height at the withers, and performed on the Kagra Mustang 2200 high speed equine treadmill. Whole blood was sampled via jugular venipuncture into lithium heparin treated tubes at 11 points before, during, and in recovery after each SET. Plasma was immediately separated using the Iris Statspin centrifuge and analyzed by the Idexx VetStat Electrolyte and Blood Gas Analyzer. Differences in plasma pH, bicarbonate (HCO_3), chloride (Cl), potassium (K), and sodium (Na) were analyzed using a PROC MIXED procedure for repeated measures (SAS Inst. Inc., Cary, NC). No sex effect or horse size difference was observed for pH, HCO_3, Cl, K, or Na. As expected, all parameters varied ($P < 0.001$) over time before, during, and after exercise bouts. No difference was seen for Cl between SETs. Na was higher ($P < 0.001$) and K was lower ($P < 0.001$) for SET2 than SET1. Both pH and HCO_3 were numerically higher ($P < 0.001$) for SET2 compared with SET1, which suggests adaptations to training. Results suggest that miniature horses could be used as a research model to measure electrolyte and pH response during submaximal training for full size horses.

Key words: miniature, submaximal, electrolyte

622 Effects of intra-articular lipopolysaccharide injection on circulating leukocyte population in yearling horses. C. L. Mueller*, D. H. Sigler, J. A. Coverdale, N. D. Cohen, M. M. Vogelsang, C. A. Cavinder, and J. L. Lucia, *Texas A&M University, College Station.*

The immature skeletal structure of a young horse in training is subject to repeated stress which induces inflammation and may ultimately lead to articular degradation. Further characterizing this process may allow for development of preventative strategies to improve future performance and longevity. Intra-articular injection of lipopolysaccharide (LPS) has been used successfully as a method of inducing temporary inflammation in skeletally mature horses to mimic progression of joint disease. However, little information exists regarding its application to the young equine. The objective of the current study was to evaluate the circulating leukocyte population in yearling horses following an intra-articular LPS injection. Nineteen yearling Quarter Horses were utilized in a randomized complete block design. Horses were blocked by age, sex, and BW and treatments were randomly assigned within block. Treatments were an injection of 0.25 ng (n = 7) or 0.5 ng (n = 6) of LPS or sterile lactated Ringer′s solution (n = 6; control). The LPS was obtained from *Escherichia coli* 055:B. Blood was collected at pre-injection hr 0 and at 2, 6, 12, and 24 h post aseptic injection of the left radial carpal joint. Peripheral blood smear slides accompanied plasma samples for determination of total leukocyte count and differential. Leukocyte analysis was performed by Texas Veterinary Medical Diagnostic Laboratory (College Station, TX). Data were analyzed using PROC MIXED (SAS v 9.1; SAS Inst. Inc., Cary, NC). No treatment effects were observed; however total circulating leukocytes increased over time ($P = 0.04$) with highest values at 6 and 12 h post injection. Similarly, an increase over time was observed in subpopulations of monocytes ($P = 0.002$) beginning at 12 h post injection and in platelets ($P = 0.01$) at 12 and 24 h post injection. The results indicate that regardless of treatment a mild immune response was elicited, likely due to repeated arthrocentesis. Future experiments need to consider effects of arthrocentesis, even in control animals, and dosage of LPS injections for young horses.

Key words: joint inflammation, leukocyte, horse

623 Role of cellular sodium transport in nonglandular equine gastric ulcer disease. F. Andrews*[1], A. Peretich[2], R. Reese[2], L. Abbott[2], and M. Dhar[2], [1]*Louisiana State University, Baton Rouge,* [2]*University of Tennessee, Knoxville.*

Gastric ulcers are common in horses. Volatile fatty acids (VFAs), from bacterial fermentation of carbohydrates, decrease sodium transport (NAT), by inhibiting NA-K ATPase (NAKA) across nonglandular (NG) mucosa, which leads to ulceration. The purpose of this study was to determine the role of NAT and NAKA in NG ulcers. NG gastric mucosa were collected from 10 euthanatized horses. NG tissue bioelectric properties were measured in Ussing chambers while exposed to normal Ringer's solution (NRS, control), a VFA mixture containing concentrations found 2 h after feeding sweet feed (0.5 Kg/Kg BW) (VFA-AF) and a VFA mixture containing high acetic acid (40 mM) (VFA-HAc) at pH 1.5, 4, or 7 for 330 min. Tissues were removed and examined under light microscopy and frozen in liquid nitrogen for determination of NAKAβ1 subunit gene mRNA-expression RT-PCR. Unpaired *t*-tests were used to determine differences in relative expression of NAKA using standard software. $P < 0.05$ was considered significant.NG mucosa exposed to the VFA mixture-AF, showed a decrease in bioelectric properties (PD and Isc), similar to tissue exposed to NRS at the same pH. However, NG mucosa exposed to VFA mixture-HAc showed an immediate decrease in bioelectric properties and NG cell swelling was noted in tissues exposed to the VFA mixture-HAc. When tissues were grouped together there was no difference in relative expression of mRNA for NAKA. However, relative expression of mRNA for NAKA was significantly decreased in horses (n = 5) < 5 years of age when compared with horses (n = 5) > 12 years of age and controls. Results suggest that VFAs present in gastric juice from excessive grain feeding, at pH ≤4.0, result in changes in barrier function and may be related to alternations in NAKA and may be age-dependent. This may account for the age bias in NG gastric ulcer disease.

Key words: horse, gastric ulcers, volatile fatty acids

624 Effect of concentrate form on gastric ulcer syndrome in horses. L. R. Huth*, D. H. Sigler, C. A. Cavinder, and N. D. Cohen, *Texas A&M University, College Station.*

Equine gastric ulcer syndrome (EGUS) is common among equine athletes of various disciplines and has been linked to decreased performance. Incidence among racehorses has been reported to be over 90%, performance horses at 60%, and endurance horses at 67%. In swine, concentrate form and smaller particle size increase ulceration; thus, the objective of this study was to investigate the effect of concentrate type on EGUS. Quarter Horse yearlings (n = 19; 12–18 mo) were blocked by initial EGUS score on a scale of 0 to 4 (0 = no ulceration or hyperkeratosis, 4 = extensive, deep ulceration) and sex, and utilized in a 77-d crossover design with 2 28-d periods separated by a 21-d washout period. During the first 28-d period, horses were separated into 1 of 2 treatment groups that were all fed Bermuda grass hay and either pelleted or textured concentrate. After the initial 28-d period, horses were all fed pelleted feed and Bermuda grass hay for a 21-d washout period and then treatment groups were switched for the final 28-d period. The rations were a commercially available, pelleted 14.3% CP concentrate and 14.4% CP textured concentrate formulated for this study. Data were analyzed using PROC MIXED (SAS) and effects of horse, treatments (pelleted or textured), period (1st vs 2nd; switchback) and all interactions were considered. Results were considered significant at $P < 0.05$. At the beginning of the study, baseline EGUS scores were not different between horses assigned to either treatment (mean EGUS scored of 1.1); however, upon treatment, horses fed textured feed acquired a reduced incidence of ulceration as compared with those fed pelleted (mean EGUS score of 1.1 vs 1.6, respectively; $P = 0.02$). Degree and incidence of ulceration was influenced by concentrate form as yearlings fed pelleted feed had higher mean ulcer scores then those fed textured feed. Textured feed reduced the EGUS score, possibly due to larger particle size. Also, EGUS scores for both groups in the second period (switchback) were lower, which may be attributed to yearlings being accustomed to the housing, feeding, and management practices during the second period.

Key words: horse, ulcer, diet

625 Development of a nutritional model to predict digestible energy requirements for broodmares based on body condition changes. V. V. Cordero*, C. A. Cavinder, L. O. Tedeschi, and D. H. Sigler, *Texas A&M University, College Station.*

Nutritional models have been developed for beef and dairy cattle to estimate energy balance based on changes in body condition score. These models have not been developed or fully evaluated in horses to date. The objective of this study was to develop a model to predict changes in body weight (BW), rump fat (RF) thickness, and overall % body fat (BF) to maximize profitability and productivity by accurately predicting energy balance of mares. The evaluation of the model was performed using non-lactating Quarter Horse mares (n=20; 4 to 18 yr of age). The initial BW ranged from 376 to 553 kg, with an initial body condition score (BCS) of 3.5 to 7.0 (scale of 1 - 9; 1 = emaciated, 5 = moderate, and 9 = obese). The BCS, RF thickness, and BW were measured for each mare prior to the commencement of the feeding trial and once/wk thereafter for the duration of a 30 d feeding trial. The pre-trial BCS was used to assign mares to 1 of 4 treatment groups (n=5/group) and fed to alter BCS by 1 unit as follows: Group 1, 4 up to 5; Group 2, 5 down to 4; Group 3, 6 up to 7; and Group 4, 7 down to 6. Initial BCS, target BCS, %BF, and BW data was collected from each mare and input into the model. Mares (non-lactating; 10 open, 10 early gestation) were individually fed according to the DE suggestions proposed by the model in order to achieve the targeted BCS change within 30 d. The forage provided was a Coastal Bermudagrass hay and the concentrate was a 12% CP pelleted horse feed (Brazos County Producer's Co-Operative Association, Bryan, Texas). Results showed a 79.8% correlation between BCS and BF in which for every change in 1 BCS (either increasing or decreasing) a change in the same direction of 1.05 percentage units of BF can be expected. All mares' observed final %BF values finished with less than a 20% variation from the model-predicted values (r2=0.61), less than 10% variation from BCS values (r2=0.91), and less than 32kg variation from final EBW values (r2=0.94). An equine nutritional model will enhance feeding management and also reduce the costs of unnecessary overfeeding while maintaining broodmares at a nutritional level to achieve optimum reproductive efficiency.

Key words: body condition score, digestible energy, broodmares

626 Equine grazing preferences of twelve cool season grasses. K. Martinson*, E. Allen, and C. Sheaffer, *University of Minnesota, St. Paul.*

The objective was to evaluate the relationship between equine grazing preferences and forage quality of 12 perennial, cool season grasses. The experimental design was a randomized complete block with 4 rep-

licates. Grasses included tall fescue (*Schedonorus phoenix*), meadow fescue (*Festuca pratensis*), quackgrass (*Elytrigia repens*), smooth bromegrass (*Bromus inermis*), meadow bromegrass (*Bromus biebersteinii*), reed canary grass (*Phalaris arundinacea*), perennial ryegrass (*Lolium perenne*), timothy (*Phleum pretense*), Kentucky bluegrass (*Poa pratensis*), creeping foxtail (*Alopecurus arundinaceaus*), and orchardgrass (*Dactylis glomerata*). Four adult horses were grazed on May 18, June 16, July 19, August 16, September 14, and October 11. Horses grazed 2 replicates (21 × 31-m) for 8-h on day one, and 2 replicates for 8-h the following day. Forage subsamples were harvested to a 9 cm height from duplicate 0.25 m square areas to assess crude protein (CP), neutral detergent fiber (NDF), acid detergent fiber (ADF), and non-fiber carbohydrates (NFC). Grass removal on a scale of 0 (no grazing) to 100 (100% grazed) was visually assessed by 2 trained researchers to determine preference. Forage quality and removals were averaged throughout the season. Data were analyzed using MIXED, ANOVA or PROC REG procedures of SAS. Grasses differed in ADF, NFC ($P < 0.01$) and in palatability ($P < 0.01$). Timothy was most preferred (82%), while orchardgrass and meadow bromegrass were least preferred (47 and 38%, respectively). Timothy had lower ADF (240 g/kg) and higher NFC values (217 g/kg), while orchardgrass and meadow bromegrass had higher ADF (281 and 298 g/kg, respectively) and lower NFC values (142 and 154 g/kg, respectively). To investigate the relationship between grass removal and forage quality, univariate regressions of percent grass removal on forage quality components were performed. ADF ($P < 0.01$) was negatively and NFC ($P = 0.02$) was positively associated ($R^2 = 0.53$ and 0.43, respectively) with horse preference. Grasses differed in forage quality and palatability to grazing horses. Horse preference for specific grasses was partially explained by lower ADF and higher NFC forage levels.

Key words: forage quality, horse, preference

627 A comparison of two conventional horse feeders with the Pre-Vent feeder. M. Carter*, T. Friend, J. Coverdale, S. Garey, A. Adams, and C. Terrill, *Texas A&M University, College Station.*

Feed waste, choke, and sand colic are economic and health issues that present concerns for horse owners across the industry. A new feeder on the market claims to reduce these issues by reducing the speed at which a horse can eat, and the amount of feed dropped and eaten off the ground by the horse. This study compared the Pre-Vent feeder (PV) with commonly used rubber tub (T) and hanging bucket (B) feeders. The PV has 8 cup-like structures 12.7 cm in diameter with a depth of 8.89 cm molded into the bottom of the feeder. It is claimed that the cups will make the horse use its lips and tongue to retrieve the feed, and hence reduces the amount of feed that a horse can eat at one time. Nine Quarter Horse geldings were used to determine time spent eating and feed wastage from the 3 types of feeders. Each horse was fed a 12% crude protein pellet diet at 0.75% bodyweight per day from one of the 3 feeders twice a day for 3 d, and then switched to the next feeder following a 3 × 3 replicated Latin square design (n = 9). The horses were brought from pasture twice daily, and placed in individual 3 × 3 m concrete-floored feeding stalls. Data were analyzed using a GLM with individual animal, day fed, time fed, and feeder type as independent variables to predict time spent eating and feed wastage (dropped on stall floor), followed by pair-wise comparisons. Horses spent more time eating (31.15 ± 0.72 min, $P < 0.0001$) from PV than B (19.39 ± 0.72 min), and T (18.87 ± 0.72 min) feeders. When fed from PV, horses wasted significantly less feed (3.2 ± 0.98% of their ration) than when fed from B (10.2 ± 0.98%, $P < 0.0001$), and from T (7.0 ± 0.98%, $P < 0.007$). One of the 9 horses was particularly wasteful, losing 22.6 ± 1.7% of his feed overall. When fed from the PV, he lost a mean of 8.7% of his ration, compared with 32.8% when fed from B, and 26.2% when fed from T. Residual feed left in PV could not be compared statistically with the other treatments because PV had the only recoverable residuals, which averaged 0.20 ± 0.04% of each horse's ration. The PV is a useful device for increasing time spent eating and reducing feed wastage.

Key words: Pre-Vent feeder, horse, time eating

628 Evaluation of a granulated paper waste product as a suitable bedding material for horses. A. G. Youngblood*[1], B. J. Rude[1], J. D. Davis[1], D. L. Christiansen[1], C. Mochal[1], P. M. Ward[2], and P. L. Ryan[1], *[1]Mississippi State University, Starkville, [2]Rutgers University, New Brunswick, NJ.*

Twelve mares (BW = 540 ± 46.8 kg) were used for three 14 d trials comparing granulated paper-clay mix (GP) to pine pellets (PP) and wood shavings (WS) as a bedding for horses. After each trial, mares were re-randomized for each subsequent trial. During d 1 through 5 stalls were cleaned daily of feces only. On d 6 stalls were re-bedded with clean bedding and feces and saturated bedding (wet spots) were removed daily through d 14. If needed, clean bedding was added to maintain depth of bedding. Additional GP and WS were needed, but not PP. Due to apparent decreased absorptive capacity, WS were added; however, GP was added mostly because of loss of bedding during the removal of feces and wet spots. Horse and stall (AM and PM) cleanliness scores were assigned daily (1 to 5; 1=clean and 5=heavily soiled). Horses were subjected to a nasal swab (d 5 and 14) and tracheal wash (d 14) during each trial. Tracheal washes were scored from 1 to 5 (1=none and 5=chronic) for cytology, aerobic bacteria and fungal growth. Piled bedding was used to acquire NH3 and pH (5 d and 14 d). Individual horse was considered the experimental unit, and data was analyzed as a complete random design, using the GLM procedures of SAS. Horse cleanliness was not different ($P > 0.10$) among bedding types. For A.M. and P.M. stall cleanliness, PP (2.79, 3.12; respectively) was cleaner ($P = 0.0014$) than both GP (3.30, 3.74; respectively) and WS (3.09, 3.47; respectively). Initial pH was greater ($P = 0.0001$) for both GP and WS compared to PP and all bedding types increased with use. No differences ($P > 0.10$) were found for ammonia on d 5 (between 3.3 and 88.5 ppm) or d 14 (between 7.3 and 42.7 ppm). Amount of bacteria (cfu) found in the nasal cavity was not different ($P > 0$ .05) among bedding types on d 5 (between 107,413 and 148,575 cfu) or d 14 (between 152,500 and 191,775 cfu). No differences ($P > 0.05$) were found for cytology and aerobic bacteria scores within the tracheal wash. However, WS (1.67) and PP (1.67) had less ($P = 0.0474$) fungal growth than GP (2.17). Results indicate the use of GP as a bedding material for horses has potential.

Key words: equine, bedding material, granulated paper-clay mix

629 Evaluating varying dietary energy levels for optimum growth and early puberty in Sahiwal heifers under sub tropical environment. M. Abdullah*[1], M. Fiaz[2,1], M. Nasir[1], M. E. Babar[1], J. A. Bhatti[1], T. N. Pasha[1], and M. A. Jabbar[1], *[1]University of Veterinary & Animal Sciences, Lahore, Punjab, Pakistan, [2]Buffalo Research Institute, Pattoki, Pattoki, Punjab, Pakistan.*

To study the effects of different energy levels for optimum growth and early puberty, 20 Sahiwal heifers (Age = 12 ± 2 mo and wt = 120 ± 10 kg) were assigned to 4 dietary treatments having 5 animals on each treatment. Iso-nitrogenous (CP = 13.7%) diets having varying energy, viz; ME 100% (Control), ME 88%, ME 112% and ME 124% of NRC recommended level for small breed non bred heifers were fed to the respective groups until onset of puberty. The collected data was analyzed through ANOVA techniques using SAS 9.1.3 potable software. Average daily gain (ADG) during the time phase from 13 to 18 mo of age was found optimum. The overall ADG was higher (571 ± 15 g/d) in ME 124% than of ME 100, 88 and 112%, whereas ADG was lowest in ME 88% (397 ± 07 g/d). Similar trend was observed in feed efficiency for different treatment groups. Heifers fed dietary level of ME 124% of NRC acquired higher body length, height and heart girth as compared with those fed other dietary energy levels. The digestibility of nutrients, age at puberty, age at 1st conception and serum progesterone were not influenced by dietary treatments ($P > 0.05$). It is concluded that higher dietary energy level (ME 124% of NRC) enhanced growth parameters and feed efficiency but reproductive performance of Sahiwal heifers in terms of age at puberty and age at 1st concenption was optimum even at lower dietary energy level (ME 88% of NRC recommended level) under sub tropical regions.

Key words: dietary energy, Sahiwal heifers, puberty

630 Performance of Sahiwal calves raised on whole milk, blend or milk replacer with or without calf starter supplementation. M. Abdullah*[1], J. A. Bhatti[1], Z. Iqbal[1], and K. Hayat[2], *[1]University of Veterinary and Animal Sciences, Lahore, Pakistan, [2]Livestock Experiment Station, Jahangirabad, Khanewal, Pakistan.*

Young dairy calves are severely deprived of the milk allowance during pre-weaning period for obvious monetary reasons. This leads to stunted growth, high mortality and ultimately late age at puberty. The objective of the present study was to compare the performance of Sahiwal calves fed whole milk, blend or milk replacer with or without calf starter. The study was conducted using 40 8 newly born Sahiwal calves, maintained at Livestock Experiment Station Jahangirabad, having mean birth weight of 20.40 ± 0.18 kg to determine the affect of feeding whole milk, milk replacer or blend of whole milk and milk replacer with or without calf starter supplementation on their performance. At 14 d age the calves were randomly allotted to whole milk (W), WM+ calf starter (WC), W+ Milk replacer (WR), WM+MR+CS (WRC), Milk Replacer (R) and MR+CS (RC) diets up to 120 d of age. Data thus obtained were analyzed using ANOVA technique under completely randomized design (CRD) and differences among treatment means were compared through least significant difference (LSD) test. Mean daily intake was highest ($P < 0.05$) in calves on treatment WC (2.33 ± 0.21 kg) followed by W, R, WR, WRC and RC, respectively. Highest daily weight gain ($P < 0.05$) was observed in the calves on treatment WRC (0.38 ± 0.02 kg). Fortnightly mean body height increase in calves on W, WC, WR, WRC, R and RC was 0.70 ± 0.07, 1.08 ± 0.10, 0.75 ± 0.09, 1.14 ± 0.09, 0.74 ± 0.09and 1.13 ± 0.10 inches, higher ($P < 0.05$) in the groups fed either whole milk, milk replacer or blend but supplemented with calf starter. Similar trend was observed in body length and heart girth increase at fortnightly intervals. Differences in mean WBCs, RBCs values and hemoglobin level varied ($P < 0.05$) between treatments and differences among total protein and albumin contents were non-significant. Cholesterol and triglyceride levels were highest ($P < 0.05$) in calves fed R. Cost to gain ratio was lowest on treatment RC. It was concluded that early introduction of calf starter during pre-weaning period improved the growth performance of Sahiwal calves

Key words: milk replacer, calf starter, weight gain

632 Financial and energy analysis spanning the first decade of the pioneer organic beef enterprise in the Mexican tropics. P. Fajersson*[1] and P. Parada[2], *[1]EcoAgroPec, Hueytamalco, Puebla, Mexico, [2]Carnes La Rumorosa, Poza Rica, Veracruz, Mexico.*

Ten years ago a strategic alliance was formed between academia, a certification agency and a rancher to establish the first organic beef enterprise in the Mexican tropics. The sustainability and rentability of a 761 ha pasture based 550 head traditional beef cattle system (TBCS) converted to an organic beef cattle foodchain (OBF), with 685 head of cattle and marketing beef in 8 states in 2010, was evaluated using a financial and energy analysis. Continuous collaboration and interviews with the rancher and a questionnaire were used to obtain production costs, quantify inputs and collect data from yrs 2000, 2006 and 2010. In the energy analysis, the inputs used were identified, quantified, each assigned a value and transformed into energy units, compared and also used to determine critical points of the foodchain to identify opportunities to improve resource use. An analysis of 6 future economic scenarios identified strengths and weaknesses in a dynamic environment. The fixed costs were similar, USD 460933–466603 over time, while variable costs were less in the TBCS than in the OBF, USD 25123, 59608 and 75778 respectively. The marginal gain of the fixed costs remained negative, while the difference between return on investment, 16.6% in the TBCS and 36.6% and 31.2% in the OBF, represents the real gain from the conversion. Using only the variable costs, the marginal gain was USD 43912 for the TBCS and USD 132725 and 93339 for the OBF over time. The OBF remained profitable in all future scenarios, USD 37139–144074.The organic certification and integration of the foodchain increased production and commercialization costs, but guarantee the product quality and access to value added markets. The energy flow reflected the use of natural resources and their direct and indirect use in generating beef for society. The OBF was more energy efficient, 37.9% and 49.6% in yrs 2006 and 2010, than the TBCS with 18.3%. The efficiency and stability, indicating improved sustainability of the OBF, have increased as external inputs have declined. Increased beef production is possible without deterioration of natural resources in this low input organic agroforestry system, but economic gain depends more on the value added, 25% in 2010, to the organic beef.

Key words: organic beef, profit margin, energy efficiency

633 Expansion of meat rabbit projects in disaster-stricken Haiti. S. D. Lukefahr*[1], M. Kaplan-Pasternak[2], J. I. McNitt[3], and B.

Migny Jasmin[4], *[1]Texas A&M University, Kingsville, [2]PO Box 587, Nicasio, CA, [3]Southern University Agricultural Research and Extension Center, Baton Rouge, LA, [4]PO Box 80, Cap Haitian, Haiti.*

Following the recent devastating earthquake in Haiti in January of 2010, humanitarian efforts have been made to expand small-scale rabbit farming enterprises to over 1,000 resettled rural families. The rabbit program was initiated in the mid-90s. The study objective was to evaluate rabbit program status, based on a USAID consultancy visit in July–August, 2010. In the townships of Cap Haitian and Grand Boulage, several farms were visited to determine production status. In general, farmer enthusiasm toward the project was perceived to be high. Shed and cage designs as promoted by the host organization (Makouti Agro-Enterprises; MAE) were sound. Rabbit health problems associated with pathogens were minor. Contrary to the objective of farmer's achieving low-cost, on-farm feed security, only one feed species was typically fed each day, rather than a broad variety of grass and legume forages and garden and kitchen "wastes." With one exception, poor feeding practices were observed on all farms visited. In response, reproductive performance on farms was low and body condition of does was poor to fair. Average litter size was 3.71 kits, well short ($P < 0.05$) of the target standard of 5.5 fryers at market age per litter. Also, fryer body weights were light considering age. A frequency distribution of does on farms that were present with litter revealed a mode of 0%, a mean of 23.3%, and a median of 22.2%. Further, the distribution was sharply skewed to the right with one-third of farmers having no does with litters. Over one-half of farmers fell short of the 50% target (based on 6 litters per doe per annum). During the visit, rabbit training that emphasized proper feeding practices was conducted in both townships involving a total of 63 students, professionals, and farmers from many project locations. Several recommendations were made including that MAE make more frequent routine visits to farmers and also explore rabbit meat market opportunities. In conclusion, despite the discouraging present status, good progress has been made since project initiation, and people have accepted the practice of rabbit farming and the consumption of rabbit meat in their diets.

Key words: rabbits, development, international

Meat Science and Muscle Biology Symposium: Biochemical Mechanisms influencing Postmortem Proteolysis and the Identification of Protein Markers for Predicting Tenderness

634 The role of the muscle cell microenvironment on postmortem proteolysis. E. Huff-Lonergan* and S. Lonergan, *Iowa State University.*

Muscle cell metabolism reacts quickly to stimuli in living muscle and in the early postmortem period, thus the microenvironment of the muscle cell is very dynamic. Some of the changes in microenvironment that occur include loss of energy stores, a decline in pH, an increase in ionic strength, and a change in the oxidative status. The postmortem development of these changes can be influenced by genetics, ante mortem metabolism state, and postmortem handling of carcasses and muscle/meat. The resulting interplay between the intracellular environment and muscle enzymes and structural proteins is a large factor governing the amount and extent of postmortem proteolysis and meat tenderness that occurs. One family of enzymes in muscle that is sensitive to changes in pH and oxidative conditions is the calpain family. Both the rate and the extent of pH decline have a significant influence on the activity of μ- and m-calpain. In addition, oxidative changes in their environment can modify the activity of the calpain enzymes as well as their interactions with specific proteins, including their inhibitor, calpastatin. Structural proteins are also susceptible to oxidation and to denaturation by alterations in early postmortem pH. For example, oxidation of myosin, particularly the heavy chain region, has been shown to promote its aggregation and may potentially lead to cross-linking with other proteins in the myofibril, most notably titin. These changes in myosin may promote toughening of meat. Another microenviromental factor that may play a role in governing tenderness is the process of protein nitration. Nitrosylation is a potent signaling mechanism in living muscle and its effects are still evident in postmortem muscle. For instance, the activity of the protease μ-calpain is influenced by nitrosylation events. This posttranslational modification is among many that need to be examined in detail in early postmortem muscle. Understanding how the microenvironment of muscle cells influences changes like protein degradation, denaturation, oxidation and nitration is key to ultimately developing methods to predict and potentially control meat quality

Key words: calpain, skeletal muscle, meat tenderness

635 Orchestration of postmortem proteolysis following apoptosis onset. B. Yasmine[2], B. Samira[2], G. Mohamed[2], and O. Ahmed*[1], *[1]INRA de Clermont-Theix, St Genes Champanelle, France, [2]Unversity of Constantine, Constantine, Algeria.*

Meat tenderness variability is still a major problem for meat industry. All scientists agree that tenderization of meat upon storage results from a proteolytic degradation of myofibrils and associated components by endogenous muscle proteases. Progress in that domain thus followed the discovery of different proteolytic systems and their ability to mimic biochemical and structural changes affecting postmortem muscle. Despite the large controversy about the nature of the major proteolytic system responsible of meat tenderization, accumulating evidences support that this process is mutienzymatic in nature and involves a large set of endogenous proteolytic enzymes acting in a synergistic manner. The recent proposal that the first step of the conversion of muscle into meat is the onset of apoptosis is a real revolution in the meat science field. Apoptosis is a finally regulated process allowing elimination of excessive, damaged or potentially dangerous cells from an organism without damaging surrounding cells and contributing to the normal development of a multicellular organism during embryogenesis and the maintenance of tissue homeostasis in adults. Apoptosis is mediated by a particular group of cysteine peptidases called caspases, an acronym of cyteine aspartyl proteases. In that presentation we will overview different aspect of the apoptotic process: 1) how we came to that conclusion; 2) mechanisms and regulation of the process; 3) apoptosis is an energy dependent process but how the cell can provide enough energy for the onset of apoptosis in postmortem muscle?; 4) we will finely overview the consequences of apoptosis on muscle structure and how proteolytic systems may act all together.

Key words: apoptosis, muscle, proteolysis

636 Understanding postmortem proteolysis and identification of protein markers for tenderness using proteomics approaches. E. Veiseth-Kent* and K. Hollung, *Nofima Mat AS, Ås, Norway.*

Tenderness is a critical factor determining consumer acceptance of meat. Despite substantial research efforts aimed at revealing the critical factors determining meat tenderness, today′s level of understanding remains unable to explain a significant amount of the observed variation. Historically, research into postmortem proteolysis was conducted using techniques such as Western blotting and protease activity assays. While sensitive and specific, these techniques only provide insight into the actions of those specific proteins. A proteomics approach allows for a more global analysis of the dynamic process occurring with postmortem proteolysis. By expanding our focus beyond a limited set of candidates, new relationships and key players can be identified. Proteomics approaches in meat science have provided us with a better understanding of postmortem proteolysis and its relation to meat tenderness. This includes discovery of degradation products from proteins thought to be unaltered during postmortem storage and the involvement of heat shock proteins. Not surprisingly, proteomics has also been used by several groups to identify potential protein markers for tenderness. The power of these candidate markers to explain variation remains unclear, but it is certain that they will contribute to building a better picture of this complex process. However, applying this new knowledge to improve tenderness is a significant challenge. It is unlikely that online measurements of protein markers will ever be introduced as standard into meat processing plants. Fortunately, recent advances in technology and reduction in costs mean that today′s potential sires are routinely genotyped and data is being used to improve stock by genomic and marker-assisted selection. The success of genetic breeding programs is dependent upon access to high-resolution phenotype data, and if our efforts to detect potential protein markers for tenderness are successful and they have a sufficient genetic contribution, then it should be possible to associate these with genetic markers and improve breed and meat tenderness through selective breeding.

Key words: proteomics, proteolysis, tenderness

637 Growth and physiological responses of growing pigs to co-fermented wheat and corn distillers dried grains with solubles. D. Ayoade*, E. Kiarie, B. Slominski, and CM Nyachoti, *University of Manitoba, Winnipeg, Manitoba, Canada.*

Gaining a detailed knowledge on the impact of a feedstuff on pig growth and physiological responses is critical for its effective utilization in swine nutrition. Thus, the purpose of this study was to investigate the effect of distillers dried grains with solubles derived from co-fermentation of wheat and corn (wcDDGS) on performance, carcass and viscera organ weights, whole body O_2 consumption and heat production (HP) in growing barrows. The experimental diets were: (1) corn-soybean meal diet (Basal) (2) Basal + 15% wcDDGS, and (3) Basal + 30% wcDDGS. All diets were formulated to meet the NRC 1998 nutrients specification for 20–50 kg pigs. In Exp. 1, 48 pair-housed pigs (18.5 kg BW) were alloted based on BW to the 3 diets (n = 8). Pigs had free access to water and feed for a 28-d period during which ADG and ADFI were monitored weekly. On d 28, 1 pig/pen was killed to measure carcass and viscera organ weights. Overall, wcDDGS linearly decreased ($P < 0.001$) ADFI and ADG but had no effect on G:F ($P > 0.10$). The ADFI was 3.1, 2.9 and 2.7 kg/d for diets 1, 2 and 3, respectively; corresponding values for ADG were 0.79, 0.75 and 0.67 kg/d. A linear decline ($P = 0.04$) in eviscerated hot carcass weight was observed as wcDDGS increased, specifically, pigs fed 30% wcDDGS had 11.2% lower carcass weight relative to the pigs fed the basal diet. However, diet had no effect ($P > 0.10$) on the weights of any of the viscera organs. In Exp. 2, 18 pigs (20.4 kg BW) individually housed in metabolism crates were fed the 3 diets (n = 6) at 550 kcal ME/kg $BW^{0.60}$/d for a 15-d period followed by measurement of O_2 consumption and CO_2 production over a 24-h period using an indirect calorimeter system. There was no effect of diet ($P > 0.10$) on whole body O_2 consumption and CO_2 production and HP. In conclusion, increasing wcDDGS content in growing pig diets linearly reduced ADFI, ADG, and eviscerated hot carcass weight but had no effect on G:F, viscera organ weights and heat production.

Key words: co-fermented wheat and corn DDGS, physiological responses, pigs

638 High-protein distillers dried grains can replace soybean meal in the diets for growing-finishing pigs. L. Ma*[1] and G. Allee[2], *[1]Chia Tai Investment Co., Ltd., Beijing, China, [2]University of Missouri, Columbia.*

The information on the use of high-protein distillers dried grains (HP-DDG) to replace soybean meal (SBM) in swine diets is limited. Additionally, previous studies from our lab determined that the optimal SID Trp:lys ratio of pigs fed diets containing HP-DDG was 16%. Thus, the objectives of this study were to determine the effects of HP-DDG replacing SBM in grower-finisher diets on growth performance and to evaluate the validity of 16% SID Trp:Lys ratio for pigs. Pigs (n = 108; initial BW = 29.1 kg) were blocked by BW and allotted to one of 3 dietary treatments: 1) Corn-SBM control diet, 2) diet with HP-DDG replacing 37% of SBM, 3) diet with HP–DDG replacing 70% of SBM, in a 4-phase study (21 d/phase). Each treatment had 6 replicate pens with 6 pigs per pen. In this study, the SID Trp:Lys ratios of the control diets were above 17%. The diets including HP–DDG contained SID Trp:Lys ratios of 16%. In phase 4 (99–123 kg), ractopamine (Paylean, Elanco Animal Health) was added in the diets. At the beginning and the end of each phase, pigs were individually weighed and feed disappearance was recorded. There were no differences in ADG, ADFI, and G:F ($P > 0.05$) during any phase and the entire 84 d among the 3 treatments. In conclusion, HP–DDG (35.5% CP) can be used to replace up to 70% of SBM in growing-finishing pigs diets without any detrimental impact on performance. In addition, 16% SID Trp:Lys ratio is suitable for growing-finishing pigs fed diets containing HP–DDG.

Table 1.

	Control	2	3	SE	*P*-value
D 0 WT, kg	29.13	29.00	29.37	0.66	0.65
D 84 WT, kg	124.94	123.52	124.04	1.36	0.56
D 0 to 84					
ADG, kg	1.14	1.13	1.13	0.01	0.61

Key words: high-protein distillers dried grains, pigs, growth performance

639 Effects of including tallow, palm kernel oil, corn germ, or glycerol to diets containing distillers dried grains with solubles on pork fat quality of growing-finishing pigs. J. W. Lee*, B. D. Keever, J. Killefer, F. K. McKeith, and H. H. Stein, *University of Illinois, Urbana.*

Thirty 6 barrows and 36 gilts (initial BW: 43.7 ± 2.0 kg) were used in an 88-d experiment to determine effects of including tallow, palm kernel oil, corn germ, or glycerol to diets containing distillers dried grains with solubles (DDGS) on pork fat quality of growing-finishing pigs. Pigs were individually housed and randomly allotted to 1 of 6 dietary treatments using a 2 × 6 factorial design with 2 genders and 6 diets and 12 replicate pigs per diet. A corn-soybean meal control diet with no added fat and a diet containing corn, soybean meal, and 30% DDGS were formulated. Four additional diets were formulated by adding 15% corn germ, 3% tallow, 3% palm kernel oil, or 5% glycerol to the DDGS-containing diet. At the end of the experiment, pigs were slaughtered, belly characteristics were measured, and backfat and belly fat samples were collected. Fatty acids were analyzed in all ingredients, diets, and fat samples, and iodine value (IV) was calculated. Dietary IVP was calculated using either the sum of the analyzed IVP of each ingredient in the diet (IVP 1) or the analyzed IVP of dietary fat (IVP 2). There were no effects of diet on belly length, width, and weight. Pigs fed the control diet had greater ($P < 0.05$) flop distance than pigs fed the DDGS-containing diets. There were no differences in flop distance among the diets containing DDGS. Barrows had greater ($P < 0.05$) flop distance and heavier ($P < 0.05$) bellies than gilts. Diet did not affect belly fat IV. However, gilts had greater ($P < 0.05$) belly fat IV than barrows. Dietary IVP 1 was positively correlated (r = 0.80; $P = 0.06$) to backfat IV; however, there was no correlation with belly fat IV. Dietary IVP 2 was not correlated with either backfat or belly fat IV. Back fat IV can be predicted using the following equation: IV = 0.11 × dietary IVP 1 + 70.29 (R2 = 0.63, $P < 0.06$). In conclusion, the negative effects of DDGS on pork fat quality were not ameliorated by supplementing diets with corn germ, tallow, palm kernel oil, or glycerol.

Key words: fat quality, DDGS, pigs

640 The impact of feeding corn distillers dried grains with solubles to sows on plasma and milk vitamin E and selenium levels. S. A. Crowder* and M. E. Johnston, *JBS United Inc., Sheridan, IN.*

Corn distillers dried grains with solubles (DDGS) were fed to gestating and lactating sows to determine the impact on milk and plasma vitamin E (vit E) and selenium (Se) levels. One hundred thirty-eight sows (PIC-C29) were blocked by parity and body condition score and allotted to 1 of 4 treatments. Diet 1 (Control) contained 0% DDGS in gestation and lactation, diet 2 contained 15% DDGS in gestation and 7.5% DDGS in lactation, diet 3 contained 30% DDGS in gestation and 15% DDGS in lactation. Diets 1, 2, and 3 were formulated to contain 66 IU/kg of vit E. Diet 4 contained 15% DDGS in gestation and 7.5% DDGS in lactation with supplemental vit E (110 IU/kg total). Plasma samples were collected from sows on d 100 of gestation and at weaning. Milk samples were collected from sows and plasma samples from a subset of pigs at weaning. All samples were analyzed for vit E and Se levels. Sow performance was not affected by the inclusion of DDGS with or without added vit E; including number of pigs born live and weaned, birth and wean weight, and lactation feed intake ($P > 0.05$). There was no negative impact of DDGS inclusion with or without added vit E on plasma Se levels at d 100, weaning, in the pig, or the milk. There was no negative impact of DDGS inclusion on sow plasma vit E levels at d 100 (Control = 1.69 μg/ml, 15% DDGS = 1.90 μg/ml, 30% DDGS = 2.10 μg/ml, 15% DDGS + vit E = 2.35 μg/ml) or at weaning. Milk vit E levels for Control, 15% DDGS, 30% DDGS, and 15% DDGS + vit E were 3.57, 3.24, 3.35, and 3.90 μg/ml respectively. There was no difference in milk vit E level between the Control and the DDGS treatments ($P > 0.05$). The 15% DDGS + vit E had a higher milk vit E level ($P < 0.05$) compared with the 15% and 30% DDGS treatments. Pig vit E level was greatest for the 15% DDGS + vit E treatment ($P < 0.05$). There was no difference in pig vit E level between the Control and DDGS without added vit E treatments ($P > 0.05$). These data suggest the addition of up to 30% DDGS in gestation and 15% DDGS in lactation diets with 66 IU/kg of vit E had no negative impact on vit E and Se levels.

Key words: sow, DDGS, vitamin E

641 Evaluation of various corn distillers dried grains with solubles (DDGS) feeding strategies in nursery pigs. N. L. Horn*, C. R. Little, and J. D. Spencer, *JBS United Inc., Sheridan, IN.*

An experiment was conducted to determine the performance response of nursery pigs fed various corn DDGS feeding strategies. There were 11 replicates per treatment with 11 pigs per pen. Four hundred and eighty-four pigs (PIC C29 × 337, BW = 6.21 ± 0.16 kg, 19-d old) were blocked by gender and BW, and pigs within each block were randomly assigned to one of 4 dietary treatments. Pigs were fed a 4-phase nursery program with a common phase 1 pellet containing no DDGS from d 1 to 6 post wean and the phase 2, 3, and 4 experimental diets from d 7 to 13, d 14 to 20, and d 21 to 41 post wean, respectively. Dietary treatments were 1.) No DDGS throughout, 2.) 0, 10, and 20% DDGS d 7 to 13, d 14 to 20, and d 21 to 41 post wean, respectively (slow step-up), 3.) 10, 20, and 30% DDGS d 7 to 13, d 14 to 20, and d 21 to 41 post wean, respectively (moderate step-up), and 4.) 20 and 30% DDGS d 7 to 13 and d 14 to 41 post wean, respectively (aggressive step-up). Experimental diets were formulated to contain equivalent true ileal digestible lysine (1.36%) during phases 2 and 3 and an equivalent true ileal digestible lysine to ME ratio (3.75) during phase 4. Introducing DDGS to pigs in phase 2 did not affect ($P > 0.05$) growth performance. DDGS supplementation in phase 3 increased ($P < 0.05$) ADG and G:F compared with the no DDGS program. Furthermore, 20 and 30% DDGS supplementation increased ($P < 0.05$) ADFI compared with the no DDGS program during phase 3. In phase 4, the pigs fed the aggressive DDGS program gained less weight ($P < 0.05$) than the other dietary treatments. Cumulatively (6 wk), use of DDGS in diets for nursery pigs had no effect ($P > 0.05$) on final BW or ADG, but did result in reduced ($P < 0.05$) feed intakes and increased ($P < 0.05$) G:F, with no difference among the DDGS utilization strategies. These results suggest that 20% DDGS can be used as early as 7-d post weaning and up to 30% DDGS by 14 d post weaning without negatively affecting growth performance; however, all these results will depend on DDGS quality and accurate characterization of nutrient values.

Key words: DDGS, nursery, swine

642 Effects of distillers dried grains with solubles in the diet of gestating sows on nutrient excretion. H. J. Kim*, S. D. Carter, T. M. Walraven, M. R. Bible, and K. F. Coble, *Oklahoma State University, Stillwater.*

A total of 88 sows (212 kg; parity = 2.5) were used to determine the effects of distillers dried grains with solubles (DDGS) on nutrient excretion during the gestation period. Sows were stratified by BW, parity, and status of gestation, and housed in one of 2 identical environmentally-controlled buildings (experimental unit) with shallow pit, pull-plug systems. Dietary treatments were randomly assigned to one of 2 buildings in a 2 (trt) x 2 (building) crossover design. The control diet consisted of a fortified corn-soybean meal based diet formulated to 12% CP, 0.47% SID Lys and 0.39% digestible P. The experimental diet (DG40) contained 40% DDGS (89.2% DM, 26.1% CP, 0.8% P, and 2.2 ppm DON) and was formulated to 16% CP, 0.47% SID Lys and 0.39% digestible P. DDGS replaced corn, soybean meal and dicalcium phosphate and Lys HCl was used to adjust dietary levels of CP and SID Lys. Each of 2 phases consisted of a 6-wk period which included a 2-wk adjustment period followed by a 4-wk slurry collection period. At the end of the initial 6-wk period, treatments were switched between buildings to allow for another 6-wk period. There was no difference ($P > 0.10$) in feed intake (2.28 vs. 2.20 kg) for sows fed control vs. DG40. Also, slurry pH (7.66 vs. 7.65), temperature (16.6 vs. 17.2°C), and volume (38.4 vs. 42.7 L) were similar ($P > 0.10$). Daily intakes of DM, P, Ca, K, Fe, Zn, Cu, and Mn were similar ($P > 0.10$) for both dietary treatments. However, daily N intake (46 vs. 55 g) tended to increase ($P = 0.10$), but Mg (3.1 vs. 4.5 g), Na (4.8 vs. 7.5 g), and S (4.1 vs. 7.6 g) intake increased ($P < 0.05$) for sows fed 40% DDGS. Inclusion of DDGS in the diet increased ($P = 0.04$) daily excretion of DM (199 vs. 255 g) and S (2.7 vs. 4.4 g) by 28 and 68%, respectively. The daily excretion of Ca and Mg tended to increase ($P < 0.08$) with DDGS. Daily N excretion increased by 20% with inclusion of DDGS in the diet; however, this was not significant ($P = 0.12$). In conclusion, 40% inclusion of DDGS in the diet of gestating sows markedly increases DM and S excretion, and may influence N, Ca, and Mg excretion. This work was partially funded by NPB.

Key words: Sows, DDGS, nutrient excretion

Nonruminant Nutrition Symposium: Nutrition's Role in Environmental Management and Meeting Government Regulations

643 An update on current environmental regulations and standards for livestock facilities. D. Porter*, *Environmental Protection Agency, Region 7, Kansas City, KS.*

In 1972 Congress enacted the Clean Water Act which defined Concentrated Animal Feeding Operations or CAFOs as point sources. Subsequently, the EPA established National Pollution Discharge Elimination System or NPDES permit regulations for livestock facilities defined as CAFOs. These regulations created effluent limitation guidelines that permitted discharges from the CAFO production area during a 25-yr, 24-h rainfall event, assuming the CAFO was in compliance with the conditions of its NPDES permit. In 2003, EPA revised the regulations to require effluent limitation guidelines for land application areas through development of nutrient management plans (NMP) and require all CAFOs that discharge to obtain a permit. In 2005, the 2nd Circuit Court of Appeals Decision vacated the duty to apply for all CAFOs and required that all NPDES permits and NMPs must be available for public review and comment before issuance. In the CAFO Rule that became effective in December of 2008, EPA revised the duty to apply for an NPDES permit to CAFOs that discharge or propose to discharge to waters of the US; based on the CAFOs design, construction, operation, and maintenance. The 2008 CAFO Rule also established additional NMP-related requirements to be included as enforceable terms of the permit. Several site-specific terms to be included in the permit and NMP include: 1) fields available for land application, 2) outcome of a phosphorus risk assessment, 3) crops to be planted, 4) a realistic yield goal for each crop, and 5) nitrogen and phosphorus removal rates for each crop. Substantial revisions to the NMP, such as changes to land application fields, crops, and increases in the risk of phosphorus runoff, must be changed in the permit and public noticed.

Key words: CAFO regulation, nutrient management plan

644 Environmental management regulations in Europe. N. Penlington*, *BPEX, Warwickshire, UK.*

Environmental regulations in Europe are comprehensive and developed to address existing pollution issues such as water and air quality. Farmers and agri-businesses have to work within a complex regulatory framework including the need for some to have permits and licenses, minimum facilities, restrictions on how and when some activities can be carried out. Regulators and the public are demanding higher levels of performance from farmers and scrutinize proposals for new or expanding operations. Conflicts arise between regulations often developed in isolation for a specific purpose and economic viability. Cross media effects, factors including animal welfare, consumer requirements and local conditions become the issue rather than the Best Solution. Recent world events and significant rises in food costs, government focus on reducing greenhouse gas emissions, food security and a growing world population has changed the dynamic in which agri-businesses have to operate. The emphasis is shifting, the drivers being efficiency and increased production, but not at any cost. Businesses embracing this change are finding that environmental regulations become less of an issue, those who run their business to comply with regulation are unlikely to thrive. Regulations will change to allow pig and poultry producers working with processors to convert resources efficiently into meat and other products with minimal waste or loss from the system.

645 Nutritional practices that affect the environment-excretion of nitrogen, phosphorus, and sulfur; and emissions of odors and greenhouse gases from swine production facilities. B. J. Kerr*, *USDA-ARS-NLAE, Ames, IA.*

In growing swine, whole-body retention of nitrogen, phosphorus, and sulfur is approximately only 50% of total dietary intake. Consequently, excretion of these compounds in urine and feces (i.e., manure), and subsequently into the environment, can be relatively extensive, especially in areas where large numbers of livestock are produced on relatively small areas of land. Air, surface water, and ground water are 3 natural resource components that can be impacted by livestock production facilities. Although generally depicted separately, many avenues for nutrient or gaseous abatement in any of one these components are directly interrelated and can simultaneously increase, or decrease, the impact on the environment. From animal production facilities, release of nitrogen (NH3), carbon (CO_2 and CH_4), phosphorus, sulfur (H_2S), volatile organic compounds (primarily short chain fatty acids, SCFA), particulates, and greenhouse gasses (CH_4, CO_2, and N_2O) are of highest interest since reduction in any of these compounds have short-and long-term environmental impact. Because a reduction of these compounds from animal production facilities will have a multiplicative effect on the total excretion process, these compounds need to be evaluated simultaneously and methods to reduce these compounds must be considered in diet formulation, especially because feed costs account for approximately 70% of the total cost of livestock production. The bottom line is that undigested feed products, endogenous animal secretions, and nutrients in excess of the needs of the animal are ultimately the nutrient input (carbon, nitrogen, phosphorus, sulfur, etc.) in manure storage systems, and subsequently, are potential contaminants into the environment; either air or water. Data will be summarized and new data will be presented evaluating diet modifications (focusing largely on dietary carbon, nitrogen, and sulfur) relative to nutrient excretion and the impact that these nutrients on the environment.

Key words: environment, nutrient excretion, gas emissions

646 Practical application of manure management plans of a swine production system to row crop production agriculture. B. S. Borg*, *Murphy Brown LLC, Ames, IA.*

During the past several years there has been tremendous change in the methodology, equipment used for application and regulatory emphasis on the accurate use of animal waste. Farmers have always understood the "value" of manure being applied to crop land but this understanding has grown to include intricate detail about the inputs and outputs of the fine balance of crop nutrient requirements, current soil nutrient content and manure nutrient content. Sustainable agriculture programs circulate around the balance of nutrient application and nutrient use. Environmental concerns about the leaching of nutrients into underground water reservoirs as well as nutrient run off have led to regulations in many states that now monitor and direct the use of manure more intelligently than the use of more nutrient dense, commercially available nutrients. Murphy Brown LLC, and former ownership entities, have included manure management plans as an important part of our hog production system since the early 1990s. Historical records of soil nutrient content that span over a 17 year period, with every other year manure application, show phosphorus and potassium content of

the soil to be on a slight decline over time. During this period of time, significant changes have occurred in feeding programs to include a greater use of crystalline amino acids, phytase as well as other ingredients that have a direct impact on the nutrient content of the manure. Understanding and monitoring soil nutrient content, waste nutrient content and the changing requirements of the crop being raised allow for a balanced system to occur. Animal waste is an excellent source of highly available nutrients and can be very effectively used as a cost efficient source of nutrients while maintaining adequate focus on environmental concerns relating to nutrient loading of the land and surface waters.

Physiology and Endocrinology II

647 Can prenatal social stress impact sex characteristics in piglets? L. A. Mack*[1], S. D. Eicher[2], A. K. Johnson[3], D. C. Lay Jr.[2], B. T. Richert[2], and E. A. Pajor[4], *[1]Purdue University, W. Lafayette, IN, [2]LBRU, USDA-ARS, W. Lafayette, IN, [3]Iowa State University, Ames, [4]University of Calgary, Calgary, AB, Canada.*

Prenatal stress (PNS) alters sex traits in rodents by androgenizing offspring resulting in reduced reproduction. In production, gestating sows are often exposed to social stress of mixing. This study examined if mixing gestating sows alters sexual development in piglets. At 34 ± 10 d of gestation, 6 groups of 18 sows (n = 108) were put in 1 of 4 treatments: stable (S), hydrocortisone acetate (HCA), unstable (U) or unstable companion (UC). In an incomplete block design, 18 sows were housed in 6 pens of 3 sows for 3 wk. Each pen contained 3 S, 3 HCA, or 1 U and 2 UC sows. Stable, HCA, and UC sows did not move; unstable sows moved weekly into a new pen with unknown UC sows. To simulate stress, 70 mg HCA was orally given twice daily to HCA sows for 3 wk. Data were analyzed in SAS using Mixed Model Procedure. Cortisol concentration was greatest in HCA sows ($P < 0.0001$) and after initial mixing ($P < 0.05$). Sows' progesterone level did not differ by treatment or time. Lesion scores increased after mixing in all treatments ($P < 0.05$). On wk 3, U sows had more head and upper leg lesions than the other treatments ($P < 0.05$). Sow's treatment had little effect on piglets: litter size, sex ratio, BW, and mortality did not differ. Pigs were weighed on d 1, d 3, weaning (d 19 ± 8), and 5 mo post-weaning (6 mo). There was no treatment effect on weight from birth to weaning but at 6 mo HCA and UC pigs tended to weigh more ($P < 0.10$) and from weaning - 6 mo had greater ADG than S pigs ($P < 0.05$). Testes weight, teat number, and teat asymmetry did not differ by treatment or gender. Males born from dominant sows, defined by feeding behavior, tended to have more teats than those of low ranked sows ($P < 0.10$). Anogenital distance (ANO) in male pigs was greater in UC than U pigs ($P < 0.05$) with the other treatments intermediate. Female ANO showed no differences. Social stress induced by weekly mixing had little impact on sexual, morphological measures of the offspring in this study.

Key words: prenatal stress, swine, reproduction

648 Heat stress increases small intestinal permeability and circulating endotoxin in growing pigs. S. C. Pearce*, V. Mani, L. H. Baumgard, and N. K. Gabler, *Iowa State University, Ames.*

Heat-stress causes a decreased intestinal integrity and induces "leaky" gut. This may lead to reduced growth performance and bacterial sepsis, but whether this occurs in pigs and the mechanisms responsible for it, are ill-defined. Crossbred gilts (n = 48; 35 ± 4 kg BW) were housed in constant climate controlled rooms in individual pens and exposed to 1) thermal neutral (TN) conditions (20°C; 35–50% humidity) with ad libitum intake (n = 18), 2) HS conditions (35°C; 20–35% humidity) with ad libitum intake (n = 24) or 3) pair-fed (PF in TN conditions [PFTN], n = 6: to eliminate confounding effects of dissimilar feed intake [FI]). Pigs were sacrificed at 1, 3, or 7d of environmental exposure and freshly isolated jejunum samples were mounted into modified Ussing chambers. Segments were then analyzed for transepithelial electrical resistance (TEER) and intestinal fluorescein isothiocyanate (FITC)-labeled lipopolysaccharide (LPS) transport expressed as endotoxin apparent permeability coefficient (APP). Additionally, circulating concentrations of endotoxins were measured in plasma blood samples. Irrespective of day, plasma endotoxin concentrations increased 46% ($P < 0.05$) in HS pigs compared with TN pigs, while TEER decreased 24% ($P < 0.05$) and endotoxin APP increased 81% ($P < 0.01$), respectively. Furthermore, d 7 HS pigs tended to have increased APP ($P = 0.06$) compared with PFTN controls. These data indicate that HS decreases intestinal integrity and increases endotoxin permeability. Together, this translated into an increase in circulating endotoxin. We hypothesize that these events lead to increased acute inflammation which is responsible for reduced pig performance during warm summer months.

Key words: heat stress, pig, intestinal permeability

649 The effect of naloxone on reproductive behavior and plasma prolactin levels in third lactation sows. V. O. Fuentes Hernadez*, R. Orozco Hernandez, and A. Bernal Canseco, *Centro Universitario de los Altos, Universidad de Guadalajara, tepatitlan Jalisco, Mexico.*

The present study was undertaken to study the effect of small doses of naloxone on behavior, prolactin plasma levels, interval of weaning to first estrus, and duration of estrus in third lactation sows. Thirty York × Landrace sows weaned at 25 to 27 d pospartum, were selected and separated at random in 2 groups of 15. One group served as control and the other received every 12 h 2 mg of naloxone im. Treatment with small doses of naloxone started 3 d before and continued for 3 d after weaning similarly the control group was injected with 2 mL of a saline solution. Naloxone treated sows showed estrus 88.8 ± 6.2 h after weaning ($P < 0.01$), control sows estrus was evident 102.37 ± 7.2 h after weaning. Duration of estrus in treated and nontreated was 85.6 ± 3.8 and 42.6 ± 3.7 h respectively. Prolactin levels decreased rapidly after weaning in both groups, but plasma PR in naloxone treated sows were below control levels (15 ± 2 and 7 ± 0.3 ng respectively $P < 0.1$). Behavior scores showed that naloxone treated sows accepted mounting with a significant reduction in aggressive behavior as compared with controls. It was concluded that endogenous opioids are important modulators of sow sexual behavior.

Key words: sow, naloxone, behavior

650 Differential expressed proteins in porcine follicular fluid during folliculogenesis. J. M. Feugang*[1], K. Pendarvis[2], S. T. Willard[3], and P. L. Ryan[1,4], *[1]Department of Animal and Dairy Sciences, Mississippi State University, Mississippi State, [2]Life Science Biotechnology Institute, Mississippi State University, Mississippi State, [3]Department of Biochemistry and Molecular Biology, Mississippi State University, Mississippi State, [4]Department of Pathobiology and Population Medicine, Mississippi State University, Mississippi State.*

Ovarian follicular fluid (FF) is a dynamic and suitable microenvironments for growth and acquisition of oocyte developmental competence. Disparities in oocyte quality of diverse follicle sizes are partly attributed to FF composition, whose changing contents during folliculogenesis are still not well-characterized. Follicular fluid is an optimal source for identifying determinants of oocyte and follicle growth. Therefore, we compared proteome profiles of porcine FF of various follicular developmental stages. Follicles were dissected from healthy sow ovaries and classified as small (SFF; ≤3mm), medium (MFF; 4-6 mm), and large (LFF;7-12mm). Follicular fluid was aspirated from individual follicles, centrifuged and collected for protein quantification and estradiol assay. All procedures were performed at 4°C and

repeated 4X. Samples with highest estradiol content were selected for a non-gel based proteome analyse. Peptides significantly detected ($P \leq 0.05$) were subjected to protein identification, and highly differentially detected (DD) proteins ($P \leq 0.05$) were selected for functional annotation. Approximately two thousand proteins were detected in each FF group. Significant protein numbers (1,493-1,656) were specific to each FF group, and 23-26% of proteins (558-570) were common amongst groups. Of these shared proteins, 28 to 33% were significantly differentially detected ($P \leq 0.05$). Gene ontology (GO) analyses of highly significantly DD indicated associations with various cellular components, molecular functions and biological processes. Pairwise comparisons indicated that MFF vs SFF had the highest total GO annotation number (184) compared to LFF vs SFF (61), and LFF vs MFF (48). Based on their abundance in FF, few proteins such as fibronectin 1, inhibitor of carbonic anhydrase precursor, and histidine rich glycoprotein were highly DD in LFF, MFF, and SFF, respectively. In conclusion, the study indicates important quantitative and qualitative changes in FF composition during folliculogenesis, and whose specific components may serve as candidate markers of follicle and oocyte growth. Work supported by USDA-ARS Biophotonics Initiative #58-6402-3-0120.

Key words: follicular fluid, proteome, oocyte growth

651 Effects of glucuronic acid supplementation on the in vitro maturation and fertilization of pig oocytes. A. R. Clark* and B. D. Whitaker, *The University of Findlay, Findlay, OH.*

The objective of this study was to assess the in vitro maturation and fertilization (IVF) of pig oocytes supplemented with glucuronic acid during the last 24 h of maturation. Oocytes were transferred after 20 h from the beginning of maturation into hormone-free maturation media containing glucuronic acid (0, 0.01, 0.1, 1 mM) for an additional 24 h of maturation. Oocytes (n = 300) were evaluated for thickness of the zona pellucida, size of the perivitelline space, fertilization characteristics at 12 h after IVF, and embryo development at 48 h and 144 h after IVF. There were no significant differences between treatment groups when comparing zona pellucida thickness, however supplementation of 0.1 and 0.01 mM glucuronic acid significantly increased ($P < 0.05$) the size of the perivitelline space compared with no supplementation. Supplementation of 0.01 mM glucuronic acid significantly increased ($P < 0.05$) the size of the perivitelline space compared with 1.0 mM glucuronic acid supplementation. There were no significant differences between the treatment groups when evaluating sperm penetration or male pronucleus development but 0.01 mM glucuronic acid supplementation significantly decreased ($P < 0.05$) polyspermic penetration compared with the other treatment groups. Although there were no significant differences in cleaved embryos at 48 h after IVF, there were significantly higher ($P < 0.05$) numbers of embryos derived from oocytes supplemented with 0.01 mM glucuronic acid (38.78 ± 5.50%) at the blastocyst stage by 144 h after IVF compared with 0 mM (22.00 ± 5.68%), 0.1 mM (25.00 ± 5.81%), and 1.0 mM (18.60 ± 5.87%). The results of this study suggest that there are positive effects of 0.01 mM glucuronic acid supplementation during the oocyte maturation on successful IVF and subsequent embryo development in pigs.

Key words: glucuronic acid, swine, embryo development

652 Vitrification versus freezing for cryopreserving bovine embryos. S. G. Kruse* and G. E. Seidel Jr., *Colorado State University, Fort Collins.*

Our objective was to compare vitrification and freezing for cryopreserving bovine embryos. Crossbred, nonlactating beef cows were superovulated and embryos recovered 7d post estrus. Embryos of quality #1 or #2 per IETS standards were cryopreserved via vitrification (VIT; n = 40) or slow freezing (SLF; n = 42). For VIT, embryos were exposed to 5 M ethylene glycol in SynGro for 3 min at 22°C and moved to 6.5 M ethylene glycol + 0.5 M galactose + 18% Ficoll in SynGro at 22°C, and in 20 µl, immediately loaded in 0.25 mL straws between 2 columns of 1 M galactose in SynGro. After 35 s, embryos were vitrified by cooling for 2 min via contact of straw walls with columns drilled into an aluminum block immersed in liquid nitrogen; straws were then plunged into liquid nitrogen. Embryos frozen via SLF were exposed to 1.36 M glycerol in modified Dulbecco′s PBS + 0.4% BSA (PBS) for 10 min at 22°C, loaded in 0.25 mL straws, and placed into a freezing machine. Straws were cooled to −6°C at 4°C per min, held at −6°C for 5 min, seeded, held at −6°C for 10 min, and cooled to −30°C at 0.5°C per min and plunged into liquid nitrogen. Embryos were warmed/thawed by holding straws in air at 22°C for 8 s and placing them in 37°C water for 20 s. VIT embryos were mixed with 1 M galactose in SynGro in the straw for 2 min and directly transferred. SLF embryos were expelled, and glycerol was removed in steps: 0.8 M glycerol + 0.3 M sucrose for 6 min; 0.4 M glycerol + 0.3 M sucrose for 6 min; 0.3 M sucrose for 6 min; and PBS for 2 min, then loaded in 0.25 mL straws. Embryos were nonsurgically transferred into cows culled for unknown reasons, but with normal-appearing reproductive tracts. Recipients were d 7 ± 0.5, and each received 2 embryos into the uterine horn ipsilateral to the CL. Pregnancy diagnosis was at d 37 ± 2 via ultrasonography. Survival rate per embryo (normal fetus with heartbeat) did not differ (Fisher′s Exact; $P \geq 0.1$) between methods (VIT = 47.5%; SLF = 38.1%; 16 of the 19 pregnant cows carried twins). Therefore, VIT was similarly efficacious to SLF for cryopreservation of bovine embryos, and simpler, requiring less equipment, time, and expense.

Key words: embryo transfer, vitrification, bovine

653 Effects of cyanocobalamin supplementation on frozen-thawed boar spermatozoa. A. M. Hyde, L. E. Elsea*, and B. D. Whitaker, *The University of Findlay, Findlay, OH.*

The objective of this study was to assess the in vitro fertilization (IVF) of pig oocytes using frozen-thawed boar sperm supplemented with cyanocobalamin to the incubation media. Frozen semen pellets were thawed and incubated for 1 h in fertilization media containing cyanocobalamin (0, 0.5, 1.0, 2.0 µM) then evaluated for forward progressive motility and viability. Forward progressive motility of the 0.5 and 1.0 µM cyanocobalamin supplements were significantly higher ($P < 0.05$) than the 0 and 2.0 µM cyanocobalamin supplements. Viability of sperm supplemented with 0.5 µM cyanocobalamin was significantly higher ($P < 0.05$) than all other groups. Oocytes were matured and fertilized with frozen-thawed boar semen that was previously incubated for 1 h in fertilization media containing cyanocobalamin (0 or 0.5 µM; 100 oocytes/treatment). Fertilization characteristics were evaluated 12 h after IVF of oocytes and embryo development was analyzed at 48 h and 144 h post-IVF. There were no significant differences between treatment groups when evaluating sperm penetration, polyspermic penetration, or male pronucleus development. Embryos derived from the oocytes fertilized with 0.5 µM cyanocobalamin supplemented sperm had a significantly higher percentage ($P < 0.05$) of cleaved embryos compared with those without cyanocobalamin supplementation at 48 h after IVF. There were no significant differences in the percent of embryos reaching the blastocyst stage by 144 h after IVF

between treatment groups. The results of this study suggest that there are positive effects of 0.5 μM cyanocobalamin supplementation during incubation of frozen-thawed boar semen on early development of IVF derived pig embryos.

Key words: cyanocobalamin, in vitro fertilization, swine

654 GnRH therapeutics to advance the timing of pregnancy in the seasonally anovulatory mare. J. F. Thorson*[1,2], L. D. Prezotto[1,2], R. D. Cardoso[1,2], B. R. C. Alves[1], M. Amstalden[1], and G. L. Williams[1,2], *[1]Texas AgriLife Research, Beeville, [2]Texas A&M University, College Station.*

Onset of the winter anovulatory period in mares is associated with a marked diminution in adenohypophyseal synthesis and release of LH. Native GnRH, unlike its synthetic agonists, stimulates the synthesis and secretion of LH in mares without pituitary refractoriness. Herein we tested the hypotheses that 1) the average Julian day of conception can be accelerated by up to 50 d in winter anovulatory mares treated continuously with native GnRH beginning on February 1 and 2) mares will sustain luteal function and pregnancy following treatment withdrawal. Forty-two winter anovulatory mares were stratified by age and BCS across 2 locations in a randomized block design and assigned to 1 of 3 groups (n = 14/group): 1) Control: untreated; 2) GnRH-14: GnRH delivered subcutaneously in saline at a rate of 100 μg/h for 8 wk (Feb. 1–Mar. 29) using 4 consecutive 14-d pumps (Alzet 2ML2), or 3) GnRH-28: GnRH delivered as in 2, but using 2, 28-d pumps (Alzet 2ML4). Upon development of a 35 mm follicle and expression of estrus, mares were bred the following day and treated with hCG. Pregnancies were confirmed by ultrasonography on d 14, 24, 33, and 45, with blood samples collected to assess luteal function. Mares treated with GnRH (GnRH-14 and GnRH-28) exhibited marked increases ($P \leq 0.04$) in the frequency of development of a 35-mm follicle, submission rate for live cover/AI, ovulation, and pregnancy compared with Control mares on treatment d 28 (March 1, 2010) and 56 (March 29, 2010). Interval to first 35 mm follicle was 51.8, 15.1, and 16.0 d for Control, GnRH-14 and GnRH-28, respectively, excluding 2 GnRH-28 mares that failed to develop 35-mm follicles during the treatment period. By the end of the treatment period (Mar. 29), only 14% of Control mares were confirmed pregnant compared with 75% of GnRH treated mares. Further, serum concentrations of progesterone were similar to ($P \geq 0.07$) or greater than ($P \leq 0.05$) that of Control mares from d 14 to 46 post-breeding for GnRH-28 and GnRH-14, respectively. These data illustrate that continuous administration of native GnRH is a practical and highly efficient option for managing seasonal anovulation in mares.

Key words: GnRH, mare, seasonality

655 Adaption of a kinetic chromogen LAL test system to investigate the incidence of endotoxins on pig farms. S. Schaumberger*, C. Ratzinger, L. Krüger, and G. Schatzmayr, *BIOMIN Research Center, Tulln, Austria.*

Endotoxins cause a stimulation of the immune system and since they are ubiquitous in the environment their contribution to pig diseases has been repeatedly discussed. The objective of this study was to evaluate a test for measuring endotoxins in the farm environment and to determine the incidence of endotoxins on swine farms. Feed, water and air samples were taken from 16 pig farms and 32 sows were sampled (milk, feces and urine) between the first and third lactating week. All samples were tested with the kinetic chromogen Limulus-Amoebycat-Lysat test (LAL). Feces, air and feed were extracted with Tween20 for 1 h and dilution rows of all samples were prepared within 12 h after sampling. Predefined dilutions were used for testing. Tests were evaluated valid with a r^2 of the calibration line > 0.97 and the recoveries ranging between 50 – 200% of added LPS. Data were statistically analyzed using PASW 18.0 (formerly SPSS Statistics). The first step was to identify the lowest valid sample dilution to use, since using high dilutions can lead to a rise in endotoxin activity in the sample. Reproduction of endotoxin measurements with the LAL test over a period of time revealed a deviation of 15% compared to the first measurement. Nevertheless, endotoxin values of the different matrices showed high variation among farms. Problems concerning the sensitivity of the test system and sample preparation could be overcome. Interferences in samples were inhibited by diluting and heat inactivation before testing. These steps in addition with routine handling led to valid and reproducible results. This study demonstrated the prevalence of endotoxins in pig farms; however, we were unable to draw any conclusions about the correlation between occurrence of endotoxins in the farm environment and impairment of pig health. Therefore, additional resarch is needed.

Key words: endotoxin, swine, environment

656 Effect of day of mixing gestating sows on measures of reproduction and animal well-being. M. Hopgood*[1], L. Greiner[2], J. Connor[2], J. Salak-Johnson[1], and R. Knox[1], *[1]University of Illinois, Urbana, [2]Carthage Veterinary Service, Carthage, IL.*

Available data provides limited evidence that mixing gestating sows during certain periods, including peri-implantation, disrupts pregnancy establishment and reduces litter size. We designed a study to test the effect of day of mixing on reproduction and measures of sow well-being. Mixing was conducted in replicates (n = 5) on a commercial farm in Illinois. Mixed parity (2–6) sows (n = 1,436) were assigned to treatment during June through August. At estrus sows were assigned to one of 4 treatments: 1) housed in crates from weaning until d 110 of gestation (Crate n = 20/replicate); 2) housed in crates after weaning and mixed in a pen at d 3 of gestation (D3 Mix, n = 58/pen/replicate); 3) housed in crates after weaning and mixed in a pen at d 14 of gestation (D14 Mix, n = 58/pen/replicate); and 4) housed in crates after weaning and mixed in a pen after d 35 gestation (D35 Mix, n = 58/pen/replicate). On d 3, 6, 9, 12 and bi-weekly after mixing until d 110, all sows were observed for lesion and body condition score. Sub-sample populations (n = 15/treatment) were identified from d 3 high, moderate, and low lesion score sows to collect serum for cortisol and progesterone. All sows were assessed on d 30 by ultrasound for pregnancy status. Binomial data were analyzed using GENMOD and continuous data by the MIXED procedures of SAS for the main effects of replicate and treatment. Conception rate differed ($P < 0.001$) by treatment with D3 (87%) and D14 (90%) reduced compared with D35 (94%) and Crate (95%). Preliminary data for the first 3 replicates indicates total born (12.2 pigs), born alive (11.6), mummies (0.1) and stillborns (0.6) were not affected by treatment ($P > 0.10$). Future data will include additional measures for reproduction and animal well-being. Our preliminary analyses suggests that mixing sows at d 3 and d 14 is associated with lower conception but not litter size. The effect of treatment on the key reproductive measures of farrowing and litter size in addition to the critical measures of animal well-being will be needed for accurate interpretation of this experiment.

Key words: reproduction, sow, well-being

657 A pig growth model for assessment of environmental footprint from swine operations: Effect of dietary energy and lysine supply. A. B. Strathe*[1], A. Danfaer[2], H. Jorgensen[2], and E. Kebreab[1], *[1]Department of Animal Science, University of California, Davis, [2]Department of Animal Health and Bioscience, Faculty of Agricultural Sciences, Aarhus University, Blichers Allé, Tjele, Denmark.*

In swine operations, greenhouse gas emissions are mostly from stored manure. Accurate prediction of manure composition is required to estimate environmental footprint from swine operations. Pig growth models are often used to optimize profitability of swine production facilities; however, their application may be more valuable through assessment of environmental footprint from swine production. The study aims to describe and evaluate nutrient partitioning and excretion in a pig growth model to be used in predicting manure volume and composition. From a biological perspective, nutrient excretion can be viewed as the "residual" and hence prediction of nutrient partitioning between protein (PD) and lipid deposition (LD) is central. The model represents the partitioning of digestible nutrients from intake through intermediary metabolism to body protein and body fat. The model contained 3 state variables: Amino acids, fatty acids and a central pool of metabolites that supplies substrate for lipid synthesis and oxidation. Body protein and fat represented the body constituent pools. It was assumed that fluxes of metabolites follow saturation kinetics depending on metabolite concentrations. The feed intake can either be defined by the user or ad libitum intake may be simulated by means of an algorithm for metabolic regulation. The model was developed using the open source software R. The data of Bikker et al. (1994, 1995 and 1996) [J. Anim. Sci. 72:1744–1753, 73:2355–2363 and 74:817–826] was used to evaluate model predictions. The data had 48 different feeding regimens with contrasting energy and lysine intakes at 2 different stages of growth. The overall observed and predicted mean were 109, 112, and 132 and 136 g/d for PD and LD, respectively, suggesting minor mean bias. The overall mean square prediction error was 2.2 g/d and 4.1 g/d for PD and LD, respectively.

Key words: simulation modeling, nutrition, sustainability

658 Evaluating the biological and economic differences between light- and heavy-birth weight piglets. D. A. Widmar*, N. J. Olynk, A. P. Schinckel, B. T. Richert, and K. A. Foster, *Purdue University, West Lafayette, IN.*

Not all piglets are created equal. A host of genetic and environmental influences create biological variation in the growth and production of hogs. Variation begins at birth and follows the piglet throughout its life, ultimately creating variation in the economic performance of individual hogs. The objective of this research was to evaluate how light-birth weight (birth weights less than 1.0kg) piglet's biological growth and economic performance differs from heavy-birth weight (birth weights greater than 1.0kg) piglets. A bioeconomic model was constructed to simulate individual piglet growth and performance. Implications resulting from sow parity, litter size, competition while nursing, crowing while in feeding pens, and survivability were included. The stochastic model simulated each piglet's daily bodyweights, daily feed intake, carcasses characteristics, and market value to track its unique revenues and costs. By tracking individual piglet performance, it was possible to analyze the average performance of different groups of piglets, in this analysis piglets sorted into light- or heavy-birth weight groups. Under the assumptions of the model, the initial difference in bodyweights for the average light- and heavy-birth weight piglet, or the difference at birth, between the two groups was relatively small. Over their lifespan however, the differences between the groups becomes increasingly pronounced. Costs, revenues, and returns on an individual piglet basis were calculated. Heavy-birth weight piglets were more profitable, on average, than light-birth weight piglets. Light-birth weight piglets were found to have a greater probability of zero or negative returns. However, it was observed that the relationship between the two groups is not static. The difference between the group's expected profitability, and the probability of achieving an expected level of return, was impacted by the growth curves of the piglets in the two groups and changing values of pigs at time of market. This research provides producers with insight about the biological and economic performance of piglets with varying birth weights.

Key words: farm management, stochastic modeling, piglet birth weight

661 Doe reproductive rates among Boer F_1 and four purebred genotypes including Myotonic in the southeastern United States. A. Nguluma*[1], R. Browning Jr.[1], A. Pellerin[1], J. Groves[1], and M. Leite-Browning[2], *[1]Tennessee State University, Nashville, [2]Alabama A&M University, Huntsville.*

This study evaluated primiparous does produced in a diallel of Boer (B), Kiko (K), and Spanish (S) meat goat breeds. An assessment was also made on Myotonic (M) purebred does. Straightbred and reciprocal BxK and BxS F_1 crossbred (BX) does (n = 192) born across 2 yr were evaluated. All does were exposed to M bucks. Rate of does kidding was higher ($P < 0.01$) for BX does than for B does but not different from S or K does. Kidding rate was affected by maternal grandsire breed ($P < 0.01$) and maternal granddam breed ($P < 0.05$). Kidding rate of daughters of B dams was lower (39.7 ± 21.0%) than for S (59.7 ± 21.3%) and K dams (61.7 ± 21.0%). Kidding rate of B-sired daughters was lower (34.0 ± 21.0%) than from K (63.3 ± 21.2%) or S sires (64.0 ± 21.0%). Rate of does weaning kids did not differ among BX, B, K, and S. Weaning rate was affected by maternal grandsire breed ($P < 0.05$) and maternal granddam breed ($P < 0.001$). More daughter of K (55.0 ± 17.4%) or S dams (50.6 ± 17.4%) weaned a kid than from B dams (29.1 ± 17.3%). Higher proportion of K-sired (55.9 ± 17.6%) and S-sired daughters (52.0 ± 17.4%) weaned a kid than from B sires (26.8 ± 17.3%). Stayability through 1 yr did not differ among BX, B, K, and S genotypes. A higher proportion ($P = 0.06$) of K-sired (78.1 ± 6.7%) and S-sired daughters (85.1 ± 6.2%) stayed in the herd than from B sires (63.7 ± 6.2%). Heterosis level was important ($P < 0.05$) for kidding rate, but not ($P > 0.2$) for weaning or stayability rates. Among purebreds, kidding rate was lower ($P < 0.02$) for B does (1.7 ± 22.0%) than for K (65.0 ± 19.2%), M (45.9 ± 18.8%) and S does (67.7 ± 19.2%); the later 3 did not differ. Weaning rate was lower ($P < 0.01$) for B (2.7 ± 17.7%) than K (62.9 ± 13.6%) and S does (55.3 ± 13.7%); M (30.5 ± 13.1%) only differed from K ($P < 0.05$). Stayability for B, K, M and S does was 54.6 ± 16%, 93.6 ± 6.9%, 82.5 ± 6.0% and 76.7 ± 7.0%, respectively. Only B and K differed ($P < 0.05$). In summary, BX performed better than B but did not differ from S and K. Heterosis was only evident for fertility. Among purebreds, M had relatively better stayability, but lower reproductive rates.

Key words: meat goats, crossbreeding, reproduction

662 Survival rates within a breeding population of Boer, Kiko, and Spanish does managed in the southeastern United States. A. Pellerin*[1], R. Browning Jr.[1], M. Leite-Browning[2], and M. Byars, Jr.[1], *[1]Tennessee State University, Nashville, [2]Alabama A&M University, Huntsville.*

Straightbred Boer (n = 132), Kiko (n = 92) and Spanish (n = 79) does were evaluated to determine if meat goat breed influences doe survival rates. The herd was semi-intensively managed on humid subtropical pasture in central Tennessee. Annual herd records across 6 production years (2003–04 to 2008–09) were used to assess survival rates and determine the reasons for doe exits. Does entered the herd in each year except Year 6. Regardless of entry year, records for all does remaining in the herd at the conclusion of Year 6 were considered censored (n = 106) and all does that exited the herd were considered failures (n = 197). All does that entered the herd had the opportunity to complete at least 2 yr of production. Does were bred to kid once each year. All culling from the breeding herd was involuntary. Does were culled if they failed to wean a kid for any 2 yr on study. Survival analysis to compare breeds within the herd was done by the product-limit method using the LIFETEST procedure of SAS (SAS Inst. Inc., Cary, NC). There were significant differences between the Boer and Kiko ($P < 0.001$) and between the Boer and Spanish ($P < 0.001$) for survival rate. No significant difference ($P = 0.285$) was found between the Kiko and Spanish. Overall survival rates and survival rates up to 2 yr in the herd were lower for Boer does (10.54 ± 0.03%, 58.33 ± 0.04%) than for Kiko (39.08 ± 0.06%, 85.87 ± 0.04%) and Spanish (31.99 ± 0.06%, 83.54 ± 0.04%) does. Individual doe exits were categorized into health, reproductive and accidental causes. Health-related failures constituted the largest proportion of whole-herd exits (78.68%) followed by reproductive failures (14.72%) and accidental losses (6.60%). These proportions were similar within each individual breed population. Breed of doe significantly influenced survival rates. Boer does demonstrated a lower level of fitness than the Kiko and Spanish does as evidenced by relatively higher exit rates under the management conditions of this study.

Key words: meat goats, breed, survival rate

663 The effect of increasing the nutrient and amino acid concentration of whole milk diets on dairy heifer individual feed intake, growth, development and lactation performance. J. K. Margerison*, *IFNHH Massey University, Palmerston North, New Zealand.*

Whole milk is known to less than an ideal feed for growing animals, while increasing the early (<3 mo.) growth rate of calves has been found to increase the milk production potential of dairy heifers. The aim of this research was to compare the effect of offering whole milk with added carbohydrate and amino acids on the growth, development and weaning age of Holstein Friesian dairy heifers. A total of 60 calves were selected at random and allocated (24 h of age) according to; birth date, breed, stature and live weight to one of 3 treatments; 0 to 18 d all were offered milk and probiotics and at 21 d of age calves were offered either; 4 l/h/d of whole milk (M), 4 l/h/d of whole milk, plus 200 g plant extracts (MP) 200 g plant extracts with amino acids (MPA). All calves weaned at set target weight of 90 kg, when calves were limited to 2 kg/h/d and pasture. Total milk used (l) was; M: 333, MP: 315.4, MPA: 302.1 and plant extract used (kgFM) was; M: 0, MP: 11.6, MPA: 10.9. Pelleted feed intake was significantly lower for calves offered MPA during the milk period (kgFM) (M: 68.3 a, MP: 60.9 a, b, MPA: 56.9 b, (sem 2.57) $P = 0.012$) as was total pellet intake (kgFM) (M: 82.3 a, MP: 74.9 a, b, MPA: 70.9 b, (2.57) $P = 0.012$), while straw intake (kgFM) did not differ (26.8, 24.5, 22.5 (1.4) $P = 0.098$). Calves offered MPA had significantly higher mean weight gain (g/d) (M: 765.5 b, MP: 814.9 a, b, MPA: 876.3 a (25.25) $P = 0.008$) and had a lower number of days to weaning from milk (M: 83.26 a, MP: 78.84 a, b, MPA: 75.53 b (1.88) $P = 0.012$)) and a higher mean hip width gain (mm) (M: 6.1 b, MP: 6.6 a, b, MPA: 7.4 a, (0.34), $P = 0.033$), while mean gain in hip height did not differ (M: 14.0, MP: 15.6, MPA: 15.9 (1.16) $P = 0.476$) compared with calves offered milk. Live weight, maturity levels and hip height and width was not significantly different at parturition, but milk yield and milk fat and protein yield were significantly higher in animals offered additional carbohydrates and AA with whole milk.

Key words: lactation, heifer nutrition, milk production

664 Integration of cyclic GMP-dependent protein kinase (PKG) and phosphatidylinositol 3-kinase (PI3K) on rumen protozoal chemotaxis to glucose and soluble peptides. H. L. Diaz* and J. L. Firkins, *The Ohio State University, Department of Animal Science, Columbus.*

Insulin (Ins) was hypothesized to activate PI3K, increase growth rate, deplete substrate, and increase protozoal chemotaxis. Wortmannin (WORT) is a specific inhibitor of PI3K, and sodium nitroprusside (SNP) activates PKG to polarize cells toward a chemoattractant gradient. We expected chemotaxis for both isotrichids (IS) and entodioniomorphids (EN) toward glucose and for peptides only by EN but hypothesized interactions with the following modifiers at higher dosages. Rumen fluid was collected 3 h after feeding and pre-incubated for 0 and 3 h with Control, 2.5 or 25 μM Ins, 50 or 500 μM SNP and 20 or 200 μM WORT. Two capillary tubes (75 mm) were not filled and uncapped (UN) (control for the protozoal count in beakers) or filled with either saline (Sal; control for random swimming), 1 M glucose (Glc), 1 g/L soluble peptides (Pep), or Glc+Pep and capped before insertion in beakers. In a randomized incomplete block design (blocked for 3 replicate runs), data were analyzed by protected LSD. For EN, the log10 counts in capillary tubes (20 minus 0 min) differed ($P < 0.05$) for UN by pre-incubation treatment, so data were covariate-adjusted to the mean UN (3.54 log10 counts). Main effects means were 2.31, 2.91, 2.81, and 3.22 for SAL, Glc, Pep, and Glc+Pep, respectively. Glc+Pep were additive at increasing chemotaxis, regardless of SNP or WORT. The interaction ($P < 0.05$) between pre-incubation beaker treatments and capillary chemoattractant treatments was from log10 counts being 2.41, 2.48, 2.28, 2.37, 2.05, 2.52, and 2.06 for Sal but 2.70, 2.86, 2.70, 2.92, 3.04, 2.92, and 3.22 for Glc for CONTROL, Ins2.5, Ins25, SNP50, SNP500, WORT20, and WORT200, respectively. For Sal, the SNP500 and WORT200 counts were decreased ($P < 0.05$) vs. CONTROL, but Glc increased ($P < 0.05$) chemotaxis for SNP500 and WORT200 vs. CONTROL. For IS, main effects means (log10, no pre-incubation treatment effect) were 1.56, 2.33, 1.11, 1.62, and 1.96 for Sal, Glc, Pep, Glc+Pep, and UN; Pep decreased ($P < 0.05$) chemotaxis. These data justify future experiments to integrate chemotaxis and growth rate.

Key words: rumen protozoa, chemotaxis, glucose

665 Evaluation of specificity of hydrolysis methods for separation of water-soluble carbohydrates. M. B. Hall*, *US Dairy Forage Research Center, USDA-ARS, Madison, WI.*

Various hydrolysis methods have been recommended to convert oligo- or polymeric water soluble carbohydrates to monomers for detection in reducing sugar assays, but responses and specificity for different carbohydrates have not been well characterized. The study objective was to evaluate reducing sugar responses of sucrose (SUC), maltose (MAL), lactose (LAC), raffinose (RAF), and inulin (INU) to hydrolysis (HYD) by invertase, 0.5 M HCl, or 0.037 M H_2SO_4 or a mixture of sucrase/maltase/pullulanase/β-amylase (Sucrase Mix). The p-hydroxybenzoic acid hydrazide reducing sugar method was used for detection. Hydrolyzed and unhydrolyzed samples were analyzed in 2 runs for each method. The statistical model included carbohydrate (WSC), HYD method, and the interaction (INT). Values presented are least squares means for reducing sugars as a percentage of sample DM. Unhydrolyzed carbohydrates differed in reducing sugar values ($P < 0.01$; SUC = 1.1%, MAL = 54%, LAC = 42%, RAF = 2.0%, and INU = 7.4%, SED = 1.5%). LAC and MAL values reflect reactivity of the reducing end hexose in both molecules, whereas RAF and SUC lack reactive reducing end hexoses. The value for INU may reflect presence of a small amount of damaged molecules. Hydrolyzed minus unhydrolyzed values describe the amount of reducing sugar released by hydrolysis. This difference differed by WSC ($P < 0.01$), HYD ($P < 0.01$), and INT ($P < 0.01$) (Table 1; SED = 3.5%). LAC was largely unaffected by HYD. Because of complete or partial hydrolysis of SUC, RAF, and INU by the same treatments, and responses of unhydrolyzed LAC and MAL, it is concluded that these hydrolyses do not allow separation of specific WSC.

Table 1. Hydrolyzed minus unhydrolyzed reducing sugar values by hydrolysis method, % of DM

	Hydrolysis Method			
Carbohydrate	Sucrase Mix	Invertase	HCl	H_2SO_4
Sucrose	84	103	101	102
Maltose	35	2.2	4.6	2.2
Lactose	0.6	3.1	2.8	1.4
Raffinose	0.4	91	89	92
Inulin	4.0	19	97	99

666 Effect of dietary protein level and rumen-protected amino acid supplementation on dietary amino acid apparent digestibility and recovery in milk in lactating dairy cows. C. Lee*[1], A. N. Hristov[1], T. Cassidy[1], K. Heyler[1], H. Lapierre[2], G. A. Varga[1], and C. Parys[3], *[1]Pennsylvania State University, University Park, [2]Agriculture and Agri–Food Canada, Sherbrooke, QC, Canada, [3]Evonik Degussa GmbH, Hanau, Germany.*

This study investigated the effect of dietary CP level and rumen-protected Lys and Met (RPLys and RPMet) supplementation on apparent total tract digestibility (ATTD) of amino acids (AA) and recovery in milk protein in dairy cows. The experiment was conducted with 8 Holstein cows (102 ± 28 DIM; 26.0 ± 0.79 kg/d DMI; 40.9 ± 1.46 kg/d milk yield) in a replicated 4 × 4 Latin square design trial with 21–d periods. Treatments were: 15.6% CP diet [HighCP; metabolizable protein (MP) balance: –24 g/d], 14.0% CP diet (LowCP, MP balance: –283 g/d), LowCP supplemented with RPLys (AminoShure–L, estimated 24 g/d digestible Lys supply; LowCPLys), and LowCP diet supplemented with RPLys plus RPMet (Mepron®, estimated 15 g/d digestible Met supply; LowCPLysMet). Data were analyzed using the mixed procedure of SAS with diet, square and period in the model and animal within group as a random effect. Plasma Met concentration was increased (30%; $P = 0.02$) by LowCPLysMet compared with LowCP. RPLys supplementation had no effect on plasma Lys. LowCPLys and LowCPLysMet increased ($P < 0.001$) Lys ATTD compared with HighCP and LowCP (51, 47, and 39%, respectively). Met ATTD was higher ($P < 0.001$) for LowCPLysMet compared with the other diets (54 vs. average of 44%). His, essential AA (EAA), and total AA ATTD were higher ($P = 0.001$ to 0.04) for HighCP compared with the LowCP diets. All AA secretion in milk was not affected by diet. RPLys and RPMet supplementation decreased ($P < 0.001$) milk Lys (by 25%) and Met (by 30%, respectively) recoveries (milk ÷ intake) compared with LowCP. Lys, His, EAA and total AA recoveries in milk were greater ($P < 0.001$ to 0.07) for the LowCP diets compared with HighCP. In conclusion, supplementation of LowCP with RPLys and RPMet increased ATTD of total intake Lys and Met, respectively. Supplementation, however, reduced the apparent efficiency of utilization of total intake Lys and Met for milk protein secretion. The apparent efficiency of utilization of all dietary AA for milk protein secretion was increased by decreasing dietary protein intake.

Key words: dietary protein, amino acid utilization, dairy cow

667 Microbiome analysis of the rumen, cecum, and feces of dairy cows with subacute ruminal acidosis. E. Khafipour[1], S. Li*[1], J. C. Plaizier[1], S. E. Dowd[2], and D. O. Krause[1], *[1]University of Manitoba, Winnipeg, MB, Canada, [2]Medical Biofilm Research Institute, Lubbock, TX.*

Subacute ruminal acidosis (SARA) is a metabolic disease common to high producing dairy cattle that is characterized by daily episodes of low rumen pH. It has been assumed that SARA primarily afflicts the rumen, but it may also affect the large intestine. The effects of SARA on the rumen, cecum and fecal microbiome were determined using next-generation sequencing. Six nonlactating Holstein cows with cannula in the rumen and the cecum were used in a replicated 3 × 3 Latin square. During the first 3 wk of each 4 wk experimental period, cows received a control diet containing 70% forage (DM basis). During wk 4 of each period, cows received one of the 3 diets; a control diet, a grain-based SARA challenge (GBSC) diet containing 64% concentrate including 34% wheat-barley pellets, or an alfalfa-pellet SARA challenge (APSC) diet containing 56% forage of which 37% was alfalfa pellets. Rumen, cecum and fecal samples (n = 54) were collected at 6h after feed delivery in wk 4. DNA was extracted from the samples and subjected to pyrosequencing of 16S rRNA. Sequence coverage was assessed with rarefaction and was 74.8%, 81.0%, and 77.7% for the rumen, cecum and fecal samples, respectively. In all compartments, the number of operational taxonomic units was highest in controls followed by APSC and GBSC ($P < 0.05$). Species richness and diversity was lowest in GBSC ($P < 0.05$). A total of 10 phyla were represented in all data sets. If a phylum was present in all animals at 1% or higher, it was considered a core-phylum. Bacteroidetes and Firmicutes were core phyla in all compartments. Proteobacteria and Spirochaetes only core to the rumen, and Fusobacteria only core in the cecum. The Bacteroidetes population was most abundant in the rumen (40% compared with 25% in the cecum and 17% in the feces) while Firmicutes were lowest (53% compare with 65% in the cecum and 80% in the feces). The increases in Rikenella, Butyrivibrio, and Treponema in the rumen were associated with APSC. The loss of Fusobacteria in the cecum and Lentisphaerae in the feces was associated with GPSC ($P < 0.05$). The cecum and fecal microbiome of GBSC was clearly distinct from other groups.

Key words: SARA, gastrointestinal tract, microbiome

668 The effect of diet on milk fatty-acid profiles in Holstein dairy cattle on commercial dairy farms. R. W. Swidan*[1], Y. Chouinard[2], R. Lacroix[1,3], D. Lefebvre[3], and K. M. Wade[1], *[1]McGill University, Montreal, QC, Canada, [2]Laval University, Quebec City, QC, Canada, [3]Valacta, Ste. Anne de Bellevue, QC, Canada.*

Milk samples were collected from 14 commercial dairy farms in Québec with a view to investigating the effects of diet on fatty-acid (FA) profiles. Data represented 284 individual cows covering the period 2006 to 2008. Feed information was obtained from the Québec DHIA (Valacta). The objective of the study was to determine the effects of main forage source (corn silage, grass silage, legume silage, and hay), main energy source (corn, barley, both corn and barley, mixed meal and "other concentrates"), and the presence or absence of both corn silage and corn grain, on the FA profile of Holstein milk. More specifically, the 3 groups investigated were omega-3 FA, conjugated linoleic acids (CLA), and trans FA. Samples were analyzed in a repeated-measure model using the PROC MIXED (SAS). Farms feeding grass silage and corn silage as a main source of forage were found to have lower concentrations ($P < 0.001$) of total omega-3 FA (0.59 and 0.63 g/100g FA, respectively) in the milk versus farms feeding legume silage or hay (0.85 and 1.11 g/100g FA, respectively), while farms feeding hay produced milk with more CLA (0.77 g/100 g FA) compared with those fed grass silage (0.44 g/100g FA). The presence of any corn silage in the diet versus no corn silage resulted in a significant decrease ($P < 0.005$) in total omega-3 FA (0.75 vs. 0.91 g/100g FA, respectively).

Corn silage also tended to decrease both CLA and trans FA concentration, but neither was significant ($P > 0.01$). Different sources of energy in the diet had no significant effect on total omega-3 FA in the milk fat. With regard to CLA, mixed-meal based diets led to a significant increase ($P < 0.001$) in the concentration, while the presence of any corn yielded significantly lower concentrations ($P < 0.001$) than all other energy sources. "Other concentrates" were intermediate in their effect on CLA. The results suggest that changing the diet of dairy cows on commercial farms may affect the fatty acid profile of milk fat, which may have an impact on its processing quality or nutritive value.

Key words: concentrates, forages, milk fatty acids

669 Effects of close-up dietary energy strategy and prepartal dietary monensin on production and metabolism in Holstein cows. J. A. Vasquez*[1], K. L. Perfield[2], H. B. Green[2], and J. K. Drackley[1], *[1]University of Illinois, Urbana, [2]Elanco Animal Health, Greenfield, IN.*

Effects of higher-energy close-up (CU) diets compared with single-group controlled energy (CE) diets remain controversial. Benefits of prepartal monensin (M) in each dietary strategy have not been determined. In a randomized design, multiparous (n = 70) and primiparous (n = 32) cows were assigned to 1 of 4 treatments in a 2 (dry period diet) x 2 (monensin supplementation) factorial arrangement. Dry period diets were either a single CE diet (1.30 Mcal NEL/kg DM) or CE in the far-off period followed by 21 d of CU (1.49 Mcal NEL/kg DM). Diets were either unsupplemented or supplemented with M (22 g/T). Cows received diets for a target of 50 d prepartum. After parturition all cows received a common lactation diet (1.70 Mcal NEL/kg DM) that contained M (14 g/T); data were collected for 84 d. Dry period diet did not affect DMI during the far-off period ($P = 0.21$), but DMI was greater ($P < 0.001$) during the close-up period for cows fed CU; DMI was unaffected by M in either period. Neither diet nor M affected DMI, BW, or BCS postpartum. Prepartum diet did not affect milk yield, milk protein percent, yields of milk components, or FCM but milk fat percent was lower ($P = 0.03$) for CE than for CU. Prepartal M tended ($P = 0.06$) to increase milk yield and increased ($P < 0.01$) lactose content in milk. Contents of fat, protein, and total solids were not affected by M, but yields of fat ($P = 0.01$), lactose ($P = 0.03$), and total solids ($P = 0.03$) as well as FCM ($P = 0.01$) were greater for cows fed M prepartum. Prepartal NEFA were greater ($P < 0.01$) but postpartum NEFA were lower ($P = 0.05$) for cows fed CE. Concentrations of NEFA and BHBA were not affected pre- or postpartum by prepartal M. Concentrations of total lipid, triacylglycerol, and glycogen in a subset of mature cows at d −10 and d 7 were unaffected by diet or M. Other than increasing milk fat content, probably due to greater NEFA, feeding a higher-energy CU diet did not benefit production or metabolism. Prepartum supplementation of M increased yields of milk fat, lactose, total solids, and FCM.

Key words: monensin, prepartum dietary energy, metabolism

670 Effects of close-up dietary energy strategy and prepartal dietary monensin on rumen dynamics and fermentation in Holstein cows. B. F. Richards*[1], J. A. Vasquez[1], K. L. Perfield[2], H. B. Green[2], M. R. Murphy[1], and J. K. Drackley[1], *[1]University of Illinois, Urbana, [2]Elanco Animal Health, Greenfield, IN.*

Concern exists about postpartal rumen adaptation in cows fed single-group controlled energy (CE) diets prepartum rather than traditional close-up (CU) diets. Effects of prepartal monensin (M) on rumen adaptation with these diets are unknown. Multiparous cows (n = 16) with ruminal cannulas were assigned to treatments in a 2 (diet) x 2 (M supplementation) factorial arrangement. Prepartum diets fed for 50 d were either a single CE diet (1.30 Mcal NEL/kg DM) or CE in the far-off period followed by 21 d of CU (1.49 Mcal NEL/kg DM). Each diet was fed without and with M (24.2 g/tonne). Postpartum all cows received a common lactation diet (1.70 Mcal NEL/kg DM) containing M (15.4 g/tonne) for 84 d. Rumen measurements were made at d −14, 2, 14, and 28 relative to parturition. Neither diet nor M affected DMI or BW pre- or postpartum. Supplemental M increased ($P < 0.01$) milk yield. Mass of rumen contents decreased ($P < 0.05$) from d −14 (59.4 kg) to d 2 (45.9 kg) but did not differ among treatments. Rumen fluid dilution rate decreased when M was added to CE but increased when M was added to CU (diet x M interaction, $P < 0.01$). Rumen particulate passage rate did not differ among diets or days. Ruminal pH was higher ($P < 0.01$) at d −14 (6.58) than postpartum (6.23, 6.30, 6.23 for d 2, 14, 28) but did not differ by diet or M. Total VFA concentration tended to increase when M was fed with CE but decreased slightly when M was fed with CU (diet x M, $P = 0.09$). Total VFA decreased at d 2 for cows not fed M (96.9 mM) but increased at d 2 (132.1 mM) when M was fed (M x day, $P < 0.01$). Acetate (% of total VFA) tended to decrease when M was fed with CE but increased when M was added to CU (diet x M, $P = 0.10$); propionate followed the opposite trend ($P = 0.10$). Butyrate tended ($P = 0.09$) to be greater for CE. Mean papillae length was decreased by M at d 2 mainly in cows fed CE (diet x M x day, $P = 0.02$). Feeding a CU diet had few effects on rumen characteristics compared with the single CE diet. Supplemental M shifted rumen fermentation differently between diets and modulated changes in rumen environment across the transition.

Key words: monensin, prepartum dietary energy, rumen

Ruminant Nutrition Symposium: Modulation of Metabolism Through Nutrition and Management

671 Optimizing production of the offspring: Nourishing and managing the dam and the calf early in life. A. Bach*[1,2], [1]*Department of Ruminant Production, IRTA, Barcelona, Spain,* [2]*ICREA, Barcelona, Spain.*

On several mammalian species, it has been shown that fetal and early life nutrition has a role in long-term lipid and glucose metabolism of the offspring, and thus it may also have consequences on milk yield in the dairy cow. For instance, high-energy diets during the last weeks of pregnancy may result in elevated glycemia, which in turn, may alter fetal adipose tissue development. However, most research efforts on management and nutrition of dry cows have focused on minimizing metabolic disorders of the postpartum cow without devoting any attention to potential consequences for the offspring. Similarly, nutritional needs for proper placental development and early fetal growth have received little attention, despite the fact that alterations in placental and fetal development may alter expression of genes participating in homeorhesis of the offspring. Similarly, newborn calves and young heifers are fed to ensure a particular growth target without compromising mammary development, however, data linking growth targets with future milk yield are scarce, and the impact of plane of nutrition on mammary development during prepubertal periods has been shown to be less important than initially thought. However, milk yield not only depends on mammary development, but also on nutrient partitioning, which is regulated by the endocrine milieu. There are some periods of time during development where nutrition may have long-lasting effects on milk production. For instance, the first months of life seem to be critical as recent data from both retrospective and controlled studies indicate that elevated growth rate (or plane of nutrition) during this phase is positively associated with future milk production. Growth rate during early life depends on nutrition (a necessary but not sufficient condition) and management (i.e., grouping strategies and housing systems), and thus optimal rearing programs should be designed considering long-term consequences on milk yield. Likewise, nutrition of the pregnant cow, both while lactating and dry, should also consider aspects of placental and fetal development that may affect milk performance of the progeny.

Key words: epigenetics, metabolism, imprinting

672 Optimizing production of the dairy cow: Nutrition and management during late pregnancy. J. K. Drackley*, *University of Illinois, Urbana.*

Nutrition and management during late gestation impact occurrence of peripartal health problems and influence subsequent milk production. Obesity at calving is a serious risk factor for health problems and suboptimal production. Likewise, extreme under-nutrition may adversely affect postpartum outcomes. The accumulated evidence is that higher energy-density close-up diets do not increase subsequent milk production or energy balance. Evidence from our laboratory indicates that even modest overfeeding results in changes analogous to obesity, with elevated insulin and NEFA before calving, poor DMI before calving, substantial body fat mobilization, increased fat deposition in the liver, prolonged increases in ketone bodies in blood after calving, and, if severe, impairment of liver function. The liver of modestly overfed cows displays a greater specific metabolic capacity for NEFA esterification and a decreased capacity to oxidize NEFA during the periparturient period. A modest energy excess during the dry period can lead to substantial internal fat deposition even in the absence of detectable changes in body condition. Adipose tissue of overfed cows undergoes marked changes in expression of enzymes and other gene products, including inflammatory responses. On the basis of available data, we conclude that requirements for energy (and other nutrients) should be met but not greatly exceeded during the dry period. This concept may be applied via several approaches, ranging from limit-feeding of moderate-energy diets to ad libitum feeding of high-roughage low-energy diets. Requirements for energy for dry cows and first-gestation heifers are modest (ca. 100 MJ ME or 14 Mcal NE per cow daily) and can be met with relatively low-energy diets. Conversely, diets high in starch from corn silage or whole-crop cereals and supplemented with additional concentrates result in excess energy intake relative to requirements, as cows do not regulate intake to meet energy needs over the short-term. Careful feeding management is critical to ensure that formulated nutrient intakes are actually achieved in practice.

Key words: periparturient period, transition period, management

673 Optimizing production of the dairy cow: Nutrition and management during early lactation. J. P. McNamara*, *Washington State University, Pullman.*

Optimal production of the dairy cow entails selecting top overall genetic attributes, not only of milk and component production but for fertility and longevity. Management of these animals from birth and through multiple cycles of pregnancy and lactation will help bring genetic efficiency to full fruition. We must take into account not only feed intake and milk production, but also metabolic flux in body tissues, primarily in visceral, muscle, and adipose tissues. Metabolic processes are affected by genotype, phenotype, and intake, processes that are usually under control of hormonal and neural systems. Reproductive processes leading to additional timely pregnancies must also be understood; as well as the interactions of the genome and transcriptome with the environment in terms of immune function and resistance to disease. A systems approach must be taken to lead to better genetic selection and management. We have continued our work with the objective of identifying the patterns of metabolic flux in the most efficient dairy cattle, using an existing mechanistic metabolic model (Molly, UC Davis) and have expanded that to integrate transcriptional control aspects and reproductive functions to identify the patterns of the most efficient animals. The combination of the transcriptomic and modeling analyses identified key differences in control of nutrient metabolism in the most efficient dairy cattle, rates of adipose tissue metabolism were directly related to overall efficiency. Feed intake was a major component of overall feed efficiency, while the ability of body tissue to support milk production and recover after peak production was another major contributor. We have created the first mechanistic model of control of estrogen and progesterone dynamics, early embryonic development and control of these processes by metabolic rate and genetic selection in the dairy cow. This systems approach can focus our research to make faster and large advances in efficiency, and show directly how this can be applied on the farms.

Key words: dairy cattle, systems biology, metabolic control

674 Optimizing production during heat stress: Nutrition and Management. L. H. Baumgard*[1] and R. P. Rhoads[2], [1]*Iowa State University, Ames,* [2]*University of Arizona, Tucson.*

Heat stress (HS) compromises efficient animal production by marginalizing efforts to reduce food production inputs while negating genetic selection for performance endpoints. Modifying farm infrastructure has yielded modest success in mitigating HS-related losses yet HS remains arguably the costliest issue facing livestock producers. Reduced output (milk yield, muscle growth, egg production, etc.) during HS was traditionally thought to result from decreased nutrient intake (a classic biological response shared by all animals during environmental-induced hyperthermia). Our recent observations have begun to challenge this belief and indicate heat-stressed animals employ novel homeorhetic strategies to direct metabolic and fuel selection priorities independently of nutrient intake or energy balance. Alterations in systemic physiology support a shift in carbohydrate metabolism, evident by increased basal and stimulated circulating insulin levels. Cellular metabolism of the hepatocyte and myocyte also show clear differences in glucose production and use, respectively due to HS. The apparent dichotomy in intermediary metabolism between the 2 tissue types may stem from factors such as mitochondrial function and antioxidant capacity. Perhaps most intriguing given the energetic shortfall of the heat-stressed animal is the apparent lack of basal adipose tissue mobilization coupled with a reduced responsiveness to lipolytic stimuli. Thus, the HS response markedly alters post-absorptive carbohydrate, lipid and protein metabolism independently of reduced feed intake through coordinated changes in fuel supply and utilization by multiple tissues. Interestingly, the systemic, cellular and molecular changes appear conserved among different species and physiological states as we have characterized similar events in growing and lactating ruminants, pigs, poultry and adult rodents. Ultimately, these changes result in the reprioritization of fuel selection during HS which appears to be primarily responsible for reduced animal productivity during the warm summer months.

675 Toxicokinetic and carry-over of ochratoxin A in lactating goats. R. Blank*[1], M. Looff[2], M. Mobashar[2], A. Westphal[1], and K.-H. Südekum[2], *[1]University of Kiel, Germany, [2]University of Bonn, Germany.*

The aim of the present study was to investigate the effects of chronic feeding of 2 different doses of ochratoxin A (OTA) on feed intake, milk yield as well as systemic availability, urinary excretion and carry-over of OTA into milk in lactating goats fed high concentrate diets. Additionally, the effect of sodium bicarbonate (NaHCO3) supplementation was evaluated. For the experiment, 10 mid-lactating goats, divided into 2 groups of 5 animals each, received a diet consisting of 70% concentrate (1.5 kg/d) and 30% hay (0.65 kg/d). After feeding the OTA free diet for 2 weeks, the animals received a concentrate containing 1.5 or 2.8 mg/kg of OTA. After 3 weeks of feeding the OTA-concentrate, animals were switched for a period of 2 weeks to the same compound feed, except that it was supplemented with 15 g/kg NaHCO3. During the entire experiment, feed intake, milk yield, and urinary output was measured. Additionally blood samples from the jugular vein were drawn. Blood, urine, milk, and casein samples were analyzed for OTA and ochratoxin α (OTα). No toxic effects due to OTA could be detected. Feed intake of goats fed the high OTA concentrate was marginally lower ($P < 0.05$) compared with the low dosage group. Milk yield decreased slightly ($P < 0.05$) during the entire experiment but was unaffected by OTA feeding. Concentration of OTA in blood was lower ($P < 0.05$) in the low compared with the high dose group. Renal excretion of OTA (1.2–1.6% of OTA intake) was not affected by dose or NaHCO3 supplementation. Carry over of OTA into milk was unaffected by the dose (0.016 and 0.017% of intake) fed, while NaHCO3 supplementation reduced carry over of OTA (0.006 and 0.009% of intake). In the casein fraction, being the most relevant for cheese making, only OTα and no OTA could be detected. In conclusion, daily intake of 2–4 mg OTA in lactating goats fed high concentrate diets has no impact on milk performance, but may lead to marginally carry-over of OTA into milk. Supplementation of NaHCO3 has some potential to reduce carry-over of OTA in ruminants.

Key words: lactating goats, carry over, ochratoxin A

676 Effects of replacing rolled barley grain with wheat dried distillers' grains with solubles in Merino sheep rations. A. S. O'Hara*[1], A. V. Chaves[1], E. Jonas[1], A. Tanner[2], D. Palmer[1], and R. D. Bush[1], *[1]Faculty of Veterinary Science, The University of Sydney, Sydney, NSW, Australia, [2]Faculty of Agriculture, Food and Natural Resources, The University of Sydney, Sydney, NSW, Australia.*

Three experimental trials were conducted to determine the effects of replacing rolled barley grain with either 20% or 40% diet DM of wheat dried distillers' grains with solubles (DDGS) in Merino wether diets. Effect on ruminal fermentation from the experimental diets was measured using by a batch culture in vitro incubation trial. Nutrient degradability of dry matter (DM), neutral and acid detergent fiber (NDF and ADF) and crude protein (CP) in the diets was measured with an in situ study using 2 cannulated Holstein dairy cows. Finally, an in vivo experiment was conducted using 36 Merino wethers in a complete randomized design over a period of 50 d to determine the effect of feeding pelleted diets containing either 0%, 20% or 40% diet DM of wheat DDGS on wool production and growth performance. Diets were provided ab libitum to the Merino wethers by 9 automatic feeders. The data were analyzed using the mixed model procedure of SAS. In the in vitro study, gas and ammonia production were not affected by dietary treatment ($P = 0.34$). The addition of wheat DDGS in the diet increased total volatile fatty acids (VFA), in vitro dry matter digestibility, propionate production and slightly lowered culture pH ($P < 0.01$). In the in situ study, the wheat DDGS diets demonstrated faster ($P = 0.04$) rate of NDF degradation (k, h^{-1}) compared with control diet. All diets had high proportions of soluble CP (above 90% of total CP). In addition, replacing rolled barley grain with wheat DDGS increased ($P < 0.01$) the ruminal degradability of crude protein. The inclusion of wheat DDGS in the diets did not effect wool yield, fiber diameter or wool softness traits, however wool growth, staple length and the coefficient of variation were improved by feeding wheat DDGS to the Merino wethers ($P \leq 0.03$). This study showed up to 40% dietary DM of wheat DDGS can be used to replace rolled barley grain in Merino sheep rations to improve wool production, maintain growth performance and promote efficient rumen fermentation.

Key words: by-products, ruminal fermentation, wool

677 Effects of dried distillers grains with solubles on feedlot lamb performance and carcass characteristics. T. L. Felix*, H. N. Zerby, S. J. Moeller, and S. C. Loerch, *The Ohio State University, Wooster.*

Dried distillers grains with solubles (DDGS) may be a cost effective source of energy and protein for feedlot lambs. However, the S content of DDGS may affect animal health, performance, and mineral metabolism. Information is lacking on the negative effects of elevated DDGS inclusion in lamb diets. The objectives of this study were to determine the effects 0, 20, 40 or 60% dietary DDGS on growing lamb performance, carcass characteristics, and tissue minerals. Ninety-six lambs were blocked by gender (ewes, n = 48; wethers, n = 48) and weight, housed in 24 pens (4 lambs per pen), and used in a 92 d feedlot trial (initial BW = 26.4 ± 16.7 kg). Lambs were fed 1 of 4 dietary treatments: 1) 0% DDGS, 2) 20% DDGS, 3) 40% DDGS, and 4) 60% DDGS. Dietary S was 0.12, 0.22, 0.36, and 0.47%, respectively. The DDGS replaced primarily corn and diets were fed as a complete pellet. There was a quadratic effect of DDGS inclusion on ADG; lambs fed the 20% DDGS diet had the greatest ($P = 0.04$) gains at 0.358 kg/d. This effect on ADG led to a quadratic ($P = 0.03$) effect of DDGS on final BW. There was no effect ($P > 0.05$) of treatment on DM intake. There was a linear ($P = 0.02$) effect of treatment on G:F (means: 0.216, 0.232, 0.206, and 0.209 for 0, 20, 40, and 60% DDGS, respectively). In the liver, S increased linearly ($P = 0.05$) while Cu decreased linearly ($P < 0.01$) with increasing dietary DDGS. No other liver minerals were affected ($P > 0.05$). In the kidney, increasing dietary DDGS increased ($P < 0.04$) P, Mg, and S concentrations linearly but did not affect ($P > 0.05$) other minerals. There was no effect ($P > 0.05$) of dietary DDGS on muscle mineral concentrations. Lamb HCW were 65.9, 71.6, 64.1 and 63.3 kg for 0, 20, 40, and 60% DDGS, respectively (quadratic; $P = 0.03$). Yield grade was not affected ($P > 0.05$) by dietary DDGS. Yield grade means were 3.10, 3.58, 2.97, and 2.86 for 0, 20, 40, and 60% DDGS, respectively. Lambs fed 20% DDGS had optimum performance in this study. Lambs fed 40 or 60% DDGS had similar performance as those fed 0% DDGS. Sulfur increased in the liver and kidneys of lambs fed DDGS reflecting the increase in S intake.

Key words: dried distillers grains, lambs, sulfur

678 Estimation of milk yield of West African Dwarf (WAD) ewe fed Mexican sunflower leaf meal (MSLM) based diets. A. H. Ekeocha*, K. D. Afolabi, and A. O. Akinsoyinu, *University of Ibadan.*

A study was carried out to estimate the milk yield of West African Dwarf (WAD) ewe fed Mexican Sunflower Leaf Meal (MSLM) on a basal diet of Panicum maximum(Pm). Sixteen WAD ewe weighing 19.50 to 22.46kg on a basal diet of Pm were allotted into four treatment groups such that each treatment had four replicates of four ewes. The MSL replaced wheat bran (WB) gravimetrically at 0, 15, 30 and 45%. Diets were formulated on a DM basis. Animals on treatment A served as control while animals in treatments B, C and D received Mexican Sunflower Leaf Meal (MSLM) at 15, 30 and 45% respectively. The experiment lasted for thirteen weeks (91 days). Assessment of milk yield started in day 2 after lambing to enable lambs suckle colostrum. Lambs were kept separately from ewes and were only allowed together at periods of suckling. Milk production of the ewes were estimated by the indirect method of weighing lambs before and after suckling using a sensitive weighing balance thrice daily. Animals were weighed from day 2 to day 91 of lactation. Data were analyzed using descriptive statistics and ANOVA. From parturition there was an increase in milk production from 422.75g/day at first week to a peak of 570 g/day at third week and thereafter a gradual decline to 281.25 g/day at 13th week of lactation. Treatment effects on the variations in obtained yield (g/day) at week 2 and then from 6th week to 13th week of lactation were not significantly ($P > 0.05$) different. Overall total milk yield (kg) for the entire lactation period of 13 weeks were 36.7, 37.9, 37.3 and 35.6 kg for treatments A, B, C and D respectively. Variations observed were not significant ($P > 0.05$). Maximum daily milk production of 0.57 to 0.50 kg was obtained for WAD ewe. The total milk yield of 35.6 to 37.9 kg/ewe was obtained during the entire lactation period of 91 days. Feeding up to 30% Mexican sunflower leaf meal to West African dwarf ewe enhanced milk yield without deleterious effect.

Key words: milk yield, West African dwarf ewe, Mexican sunflower leaf meal

679 Iron carbonate supplementation of lambs administered high-sulfur water. A. M. Jons*[1], K. L. Kessler[1], K. J. Austin[1], C. Wright[2], and K. M. Cammack[1], *[1]University of Wyoming, Laramie, [2]South Dakota State University, Brookings.*

Drinking water with high sulfur (S) concentrations can reduce the performance and cause health problems such as polioencephalomalacia in livestock raised in the western US Monitoring and treating water for high levels of S are both expensive and often impractical; therefore, an alternative method of controlling this problem is needed. Our objective was to determine if supplemental Fe, commonly used in water treatment plants to bind S, prevents reduced performance and poor health caused by administration of high-S water. We hypothesized that dietary supplementation with an Fe compound would bind excess S in ruminant animals, preventing the negative effects associated with high-S drinking water. Wether lambs (n = 80) were assigned to one of 4 treatments in a randomized complete block design with 20 lambs per treatment replicated over 2 pens per treatment. Treatments included: 1) control feed and low-S well water; 2) control feed and high-S water (2,500 mg SO_4^{2-}/L); 3) low-Fe (250 ppm Fe as $FeCO_3$) feed and high-S water (2,500 mg SO_4^{2-}/L); and 4) high-Fe (500 ppm Fe as $FeCO_3$) feed and high-S water (2,500 mg SO_4^{2-}/L). All lambs received ad libitum access to feed and water. Body weights and blood samples were taken on d −1, 25, and 50, and H_2S gas in the rumen was measured on d −1 and 50. Effects of dietary treatment were estimated using the MIXED procedure of SAS. There were no differences in ADG ($P = 0.668$), daily water intake ($P = 0.795$), or daily feed intake ($P = 0.659$) between treatments. Trace mineral analysis showed no treatment differences in serum concentrations of Cu ($P = 0.199$), Fe ($P = 0.590$), Mo ($P = 0.119$), Mn ($P = 0.549$), or Zn ($P = 0.422$). Production of H_2S gas was less ($P \leq 0.001$) in low-S control lambs compared with lambs in the high-S treatment groups; no differences in H_2S gas production were detected between high-S treatment groups. These results indicate that supplementation of an Fe compound to lambs exposed to high-S water was not effective at preventing the reduced performance associated with elevated dietary S.

Key words: lambs, sulfur, water

680 Effect of supplementing ewes during late gestation with metabolizable protein on wether lamb feedlot performance, carcass characteristics, and nitrogen balance. M. L. Van Emon*[1,2], K. A. Vonnahme[1], S. E. Eckerman[1], L. A. Lekatz[1], K. R. Maddock Carlin[1], M. M. Thompson[2], and C. S. Schauer[2], *[1]Department of Animal Sciences, North Dakota State University, Fargo, [2]Hettinger Research Extension Center, North Dakota State University, Hettinger.*

The objective was to determine the effect of metabolizable protein (MP) supplementation to ewes during the last 50 d of gestation on wether offspring nitrogen (N) balance, feedlot performance, and carcass characteristics. Maternal dietary treatments were isocaloric and contained 100% (CON), 80% (MED), and 60% (LOW) of MP requirements for ewes bearing twins during the last 50 d of gestation. Feedlot (29 ± 2 kg) and N balance wethers (32 ± 0.4 kg) were fed a common feedlot ration (84.4% whole corn, 15.6% commercial market lamb pellet). Initial and final feedlot BW, ADG, and G:F were not affected ($P \geq 0.17$) by maternal dietary treatment. Wethers born to ewes fed the LOW diet had increased ($P = 0.01$) DMI compared with the wethers born to ewes fed the MED diet during the feedlot phase. Wethers born to CON had reduced ($P = 0.10$) days on feed compared with wethers born to MED ewes. Wethers born to CON ewes had increased ($P = 0.04$) percent boneless, closely trimmed, retail cuts compared with wethers born to the LOW and MED ewes, with all other carcass characteristics not affected ($P \geq 0.13$). Nitrogen balance trial DMI, NDF intake, total tract digestibility of DM, NDF, and N, fecal N excretion, and N balance were not affected ($P \geq 0.12$) by maternal dietary treatment. Wethers born to LOW ewes had increased ($P = 0.08$) daily N intake and reduced ($P = 0.08$) daily digested N retained compared with wethers born to CON and MED ewes. Wethers born to LOW ewes had increased ($P = 0.03$) daily urinary N excretion compared with wethers born to the MED and CON ewes. A treatment × day interaction was observed ($P = 0.004$) for serum urea N concentrations. On collection d 2, 4, 5, and 6 of a 7 d collection period, the wethers born to LOW ewes had increased ($P \leq 0.001$) serum urea N concentrations compared with the wethers born to MED and CON ewes. These results suggest that wethers born to ewes fed below MP requirements are less efficient in N retention, require more feed to finish in the feedlot, and have decreased retail product.

Key words: feedlot, metabolizable protein, nitrogen balance

681 Effect of increasing dietary inclusion of dried distillers grains with solubles on nutrient digestion and retention in growing lambs. T. L. Felix* and S. C. Loerch, *The Ohio State University, Wooster.*

Dietary inclusions of dried distillers grains with solubles (DDGS) greater than 40% have been shown to decrease lamb performance. This may be due in part to dietary S in excess of the maximum tolerable limit. Recent data suggest that feeding 60% DDGS to growing cattle decreases digestibility of DM, NDF, and fat. The effects of DDGS on nutrient digestibility and retention in lambs are not known. Therefore, the objectives of this study were to determine the effects of increasing dietary inclusion of DDGS on nutrient and mineral digestibility and retention in growing lambs. Twenty-four Dorset × Suffolk lambs (initial BW = 43.0 ± 4.4 kg) were used in a metabolism study. Lambs were adapted to experimental diets for 17 d before a 5 d sampling period during which total feces and urine were collected. The treatment diets were fed for ad libitum intake and were: 1) 0% DDGS, 2) 20% DDGS, 3) 40% DDGS, and 4) 60% DDGS. The DDGS replaced primarily corn and diets were fed as a complete pellet. Dietary S concentrations were 0.12, 0.21, 0.35, and 0.45%, respectively. The apparent digestibility of dietary DM decreased linearly ($P < 0.01$) with increasing dietary inclusion of DDGS (79.6, 78.4, 75.2, and 72.7% for treatments 1 through 4, respectively). Digestibility of fat, followed a similar pattern, whereas, N, S, and P digestibility increased linearly ($P < 0.03$) with increasing dietary DDGS. The digestibility of NDF was not affected ($P > 0.05$) by dietary treatment. Apparent retentions (as a percentage of intake) of N, K, Mg, Cu, Fe, and Zn, were not affected ($P > 0.05$) by dietary DDGS inclusion. The retention of S and P was decreased ($P < 0.04$) with increasing dietary DDGS. Daily urine output increased linearly ($P < 0.01$) with increasing dietary inclusion of DDGS. Urine pH decreased linearly ($P < 0.01$) with increasing DDGS (7.46, 5.86, 5.52 and 5.32 for treatments 1 to 4, respectively). These data suggest urine is a major route for excretion of acid when high S diets containing DDGS are fed. Increases in dietary DDGS resulted in decreased digestion of DM and fat which may affect lamb feedlot performance.

Key words: dried distillers grains, lambs, metabolism

682 Performance of growing West African Dwarf ewe fed Mexican sunflower leaf meal based diets. A. H. Ekeocha*, *University of Ibadan, Ibadan, Oyo, Nigeria.*

Studies were conducted using 16 lambs weighing 13–15kg on based diet of *Panicum maximum* were allotted into 4 treatments. The experiment was conducted using completely randomized design with 4 replicates. The Mexican sunflower leaf meal (MSLM) replaced wheat Bran (WB) gravimetrically at 0, 15, 30, 45%. Animals on diet A served as control while animals in diets B, C and D received Mexican sunflower leaf meal (MSLM) at 15, 30 and 45% respectively. The experiment lasted 84 d. Parameters measured included voluntary dry matter intake (VDMI) which comprised concentrate DMI (CDMI) and grass DMI (CDMI), changes in body weight (BW) and feed conversion ratio (FCR). Data were analyzed using descriptive statistics and ANOVA. The VDMI (g/d) varied from 351.0 to 621.9 for ewe-lambs. CDMI (g/d) varied from 162.70 to 480.30 and GDMI (g/d) varied from 116.90 to 193.22 for ewe-lambs. Approximately 75.5 ± 1.1 of the VDMI came from the supplement. Diets containing 30% MSLM was superior to others for GDMI (116.9–193.2 g/day) and CDMI (162.7- 480.3g/day) during the growth phase ($P < 0.05$). BW gain (Kg) varied from 3.50 to 3.58 and FCR varied from 8.42 to 14.92 and these were similar. Inclusion of up to 45% MSLM based-diets enhanced the performance of ewe-lambs in terms of BW gain, growth and feed conversion ratio.

Key words: Mexican sunflower leaf, West African Dwarf ewe

683 Use of *Megasphaera elsdenii* NCIMB 41125 during introduction of sheep on corn crop residues and un-harvested corn lands. P. H. Henning* and F. M. Hagg, *MS Biotech, Centurion, South Africa.*

Ruminants are often grazed on corn crop residues to utilize grain wasted during harvesting. They may also be grazed on un-harvested corn lands. In both cases rumen acidosis is a problem due to the sudden high intake of starch-rich grain. *Megasphaera elsdenii* is a rumen bacteria which utilizes lactic acid, thus preventing rumen acidosis. Its numbers are low on grass diets and only increase slowly when animals change to high starch diets. It is hypothesized that supplying *Megasphaera elsdenii* as a DFM when placing animals thus may benefit adaptation and production. The objective of this study was to determine the benefit of drenching sheep with *Megasphaera elsdenii* NCIMB 41125 (Me) just before introduction onto intact or harvested corn lands. In Trial 1 300 recently weaned male and female lambs (average live-weight 25 kg), on grass pasture, were randomly divided into 2 equal groups. Both groups were subsequently placed on the same newly harvested corn land for 50 d. One group (Me-treated) received a single 70 mL oral dose of Me (10^8 cfu ml^{-1}) 60 min before this placing, while the other group (control) received none. In Trial 2 184 castrated male lambs (average live-weight 47 kg), on grass pasture, were randomly divided into 2 equal groups. Both groups were subsequently placed on the same un-harvested corn land for 50 d. One group (Me-treated) received a single 70 mL oral dose of Me (10^8 cfu ml^{-1}) 60 min before this placing, while the other group (control) received none. In Trial 1 Me-treated male and female sheep gained 16.2 and 9.3 kg live-weight, respectively, which was significantly ($P < 0.01$) more than the corresponding 15.9 and 8.3 kg for the control group. In Trial 2 Me-treated lambs gained 6.64 kg, which was significantly ($P < 0.05$) greater than the 5.92 kg gain for the control group. It is concluded that a single oral dose of *Megasphaera elsdenii* NCIMB 41125 given to sheep just before placing them on harvested or un-harvested corn land can benefit production, probably by controlling rumen acidosis.

Key words: corn crop residues, *Megasphaera elsdenii*, rumen acidosis

684 White blood cell populations in goat kids and lambs during the first four days of life, with special reference to CD4 and CD8. A. Arguello*[1], L. E. Hernandez-Castellano[1], A. Morales-delaNuez[1], I. Moreno-Indias[1], J. Capote[2], and N. Castro[1], *[1]Universidad de Las Palmas de Gran Canaria, Arucas, Las Palmas, Spain, [2]Instituto Canario de Investigaciones Agrarias, La Laguna, Tenerife, Spain.*

To investigate the white blood cell populations (including CD4 and CD8) in goat kids and lambs, 10 goat kids (Majorera dairy breed) and 10 lambs (Canaria dairy breed) were used. Blood samples were obtained at birth, and at 2 and 4 d of life in Lithium heparin containers. Immediately after collection, 50 μL of unclothed blood were added with 5 μL of CD4 (FITC) and 5 μL of CD8 (RPE) monoclonal antibodies (Serotec, Dusseldorf, Germany) and the reaction ran for 15 min at room temperature. After that, 50 μL of Optilyse (Beckman Coulter, Brea, CA) were added and the reaction ran for 15 min at room temperature to lyses red blood cells. Subsequently, 150 μL of saline serum were added to clarify the solution. Fifteen minutes later, the samples were redden using an FC500 flow cytometry device (Beckman Coulter, Brea, CA). An ANOVA (with repeated measures) procedure from SAS was used. Two white blood cell populations were observed clearly, lymphocytes plus macrophages (L+M) and polymorphonuclear (PMN), in both species at all tested times. L+M population was higher ($P \leq 0.05$) in goat kids than in lambs at all tested times (75.5, 63.5 and 74.0% in goat kids and 53.2, 45.7 and 59.5%, at birth, 2 and 4 d of life respectively). Concomitantly, the PMN population was greater ($P \leq 0.05$) in lambs than in goat kids. Goat kids CD4 population (expressed as a L+M percentage) was lower ($P \leq 0.05$) than in lambs at all tested times (29.3, 30.4 and 22.6 for goat kids and 53.7, 41.4 and 40.2 for lambs at birth, 2 and 4 d of life, respectively). No significant differences were observed for CD8 between species (ranged from 9.8 to 18.1% of L+M). There was no breed effect on CD4/CD8 ratio but a trend was observed, being goat kid CD4/CD8 ratio lower than lamb ratio (2.7, 2.1 and 2.4 for goat kids and 3.7, 3.0 and 2.8 for lambs at birth, 2 and 4 d of life, respectively). In conclusion, goat kids and lambs are different in the innate immune system during the first days of life.

Key words: goat kid, lamb, CD4 CD8

685 Immune status of goat kids fed cow′s milk with an exogenous source of DHA. I. Moreno-Indias*[1], L. E. Hernández-Castellano[1], A. Morales-delaNuez[1], A. Torres[2], D. Sánchez-Macías[1], N. Castro[1], and A. Argüello[1], *[1]Universidad de las Palmas de Gran Canaria, Arucas, Las Palmas, Spain, [2]Instituto Canario de Ciencias Agrarias, La Laguna, Santa Cruz de Tenerife, Spain.*

As the main role of dairy goat farming is to yield marketable milk, artificial rearing is closely linked to the intensification of these farms. Therefore, the use of milk replacers has been suggested. Classic works did not recommend the use of cow′s milk to feed goat kids, due mainly to problems with diarrhea. Recently, the benefits of the use of omega-3 fatty acids in nutrition such as the docosahexaenoic acid (DHA) have been presented. In this study different diets were supplied to 3 groups of goat kids: goat milk (GM), cow milk (CM) and cow milk with a supplemented source of DHA (DHA-gold) (CM-DHA). Animals were fed ad libitum twice a day. Blood samples were collected from the jugular vein until d 10 of life, and after that, each 5 d until animals weighed 8 kg (animals were weighed twice a week). IgG, IgM, total and alternative pathway complement system activity and chitotriosidase activity were measured to establish the immune status of goat kids. The MIXED procedure of SAS (version 9, SAS Institute Inc., Cary, NC) was used to evaluate the effects of the treatments on immune status of goat kids. When goat kids reached 8 kg, concentrations of IgG were 3.855, 4.002 and 3.662 mg/mL and concentrations of IgM were 0.802, 0.736 and 0.730 mg/mL for GM, CM and CM-DHA, respectively. Differences did not reach significance among treatments. When dairy kids weighed 8 kg, complement system activity did not show significant differences among treatments neither in total (GM: 58.54%, CM: 56.69% and CM-DHA: 55.09%) nor in the alternative pathway (GM: 37.94%, CM: 37.47% and CM-DHA: 34.91%). However, significant differences were found ($P = 0.03$) in the alternative pathway between GM (39.76%) and CM-DHA (23.30%) treatments when goat kids weighed 7 kg, although without continuity in the time. Finally, the chitotriosidase activity in goat kids at 8 kg did not differ significantly among treatments (GM: 1867.67 nmol/mL/h, CM: 1895.83 nmol/mL/h and CM-DHA: 1893.10 nmol/mL/h). In conclusion, CM is a good option to feed goat kids instead GM. However, DHA at this concentration did not show any effect on goat kid immune status.

Key words: DHA, milk replacer, cow milk

686 Effects of feeding sericea lespedeza as a natural anthelmintic for *Haemonchus contortus* in lactating does. J. L. Vest*[1], M. A. Brown[4], J. D. Kohler[1], M. D. Hudson[1], S. R. Nusz[5], J. M. Burke[3], J. E. Miller[2], C. T. Mackown[4], and E. L. Walker[1], *[1]Missouri State University, Springfield, [2]Louisiana State University, Baton Rouge, [3]Dale Bumpers Small Farms Research Center, USDA-ARS, Booneville, AR, [4]Grazinglands Research Laboratory, USDA-ARS, El Reno, OK, [5]Redlands Community College, El Reno, OK.*

In the United States, infection with the gastrointestinal nematode *Haemonchus contortus* is the leading cause of goat mortality. Use of alternative parasite control methods, including forages containing condensed tannins (CT), has been found to reduce the effect of gastrointestinal nematode parasites. During the last 30 d of gestation, 37 Boer-cross does kidding from April to June were randomly assigned to diets of alfalfa (*Medicago sativa*; 21% CP; n = 16) pellets (Alf) or sericea lespedeza (*Lespedeza cuneata*; 16% CP; n = 21) pellets (SL) and allowed to graze on 0.61 ha bermudagrass pasture. Does were fed pellets at a maximum of 3% of BW throughout the study. At parturition, BW and gender of kids was recorded. On d 7, 21, 35, 49, and 63 postkidding, doe fecal samples, BCS, blood samples, and measurements of milk yield and composition were obtained. To account for environmental changes during the 62 d kidding period, does were grouped in 2 kidding periods, early (those kidding from d 1 to d 31) and late (d 32 to d 62 of the trial). The climate during the later kidding period included increased rainfall and high humidity compared with the early period. The later kidding does had greater fecal egg counts (FEC) on d 7, 21, 35 and 49 ($P < 0.003$) and greater packed cell volume (PCV) on d 21, 49, and 63 ($P < 0.05$) compared with early kidding does. SL-fed does had lower FEC ($P < 0.05$) than the Alf does on d 35. On d 63, does with singles had lower FEC ($P \geq 0.03$) and greater PCV levels ($P \geq 0.006$) than does with twins. Doe FAMACHA scores gradually increased from d 7 to d 49 with an improvement by d 63 ($P < 0.0001$). Does with singles tended to have lower FAMACHA scores ($P = 0.08$) and greater BCS ($P = 0.0002$) than does with twins. Does raising twins produced more milk on d 7 and 21 becoming similar to single parity does by d 35 ($P = 0.0001$). Alf-fed, later kidding does had the lowest milk production ($P = 0.0089$). In conclusion, SL decreased FEC at d 35

but not at other times. It is possible the minimal differences in FEC and PCV between alfalfa and SL may have been influenced by treatment differences in crude protein.

Key words: goats, sericea lespedeza, parasite

687 Polymorphisms in the melanocortin-1 receptor (MC1R) gene in Nigerian indigenous goats. M. A. Adefenwa[1], B. Oboh[1], G. O. Williams[1], M. Wheto[2], C. O. N. Ikeobi[2], K. Adekoya[1], M. Okpeku[3], M. De Donato*[4], and I. G. Imumorin[4], *[1]Dept of Cell Biology and Genetics, University of Lagos, Lagos, Nigeria, [2]Dept of Animal Breeding and Genetics, University of Agriculture, Abeokuta, Nigeria, [3]Dept of Livestock Production, Niger Delta University, Amassoma, Nigeria, [4]Dept of Animal Science, Cornell University, Ithaca, NY.*

Coat color is an adaptive trait in mammals with implications for physiological efficiency. The extension locus, which encodes the melanocortin-1 receptor (MC1R), is known to control the synthesis of the pigment granules, eumelanin and pheomelanin, which in turn affects coat color. Functional mutations is said to cause black coat color while inactivating mutations is said to cause red coat color. There is paucity of information regarding the genetics of coat color in indigenous livestock species in Nigeria and Sub-Saharan Africa. In this study, we examined polymorphisms in the caprine MC1R gene in the 3 major Nigerian goat breeds which exhibit different coat colors: (West African Dwarf, black; Red Sokoto, brown/red; and Sahel, white). We amplified and sequenced a 716 bp fragment spanning part of the coding region of the MC1R gene (716 bp) in 69 Nigerian goats (17 West African Dwarf, 23 Red Sokoto, and 29 Sahel), sampled from across the country, using genomic DNA obtained from whole blood samples. Sequences were aligned using CLUSTALX and DnaSP version 5.10.01 was used for identifying single nucleotide polymorphisms (SNPs). Four single nucleotide polymorphisms were identified: 2 silent mutations (g.T125C and g.G128A) and 2 missense mutations (g.C126G, p.R30G and g.A729C, p.I231L). Our results in this pilot experiment showed no association between coat color and the identified SNPs as none of the variants seem to be fixed in any of the breeds. The SNPs g.T125C, g.G128A and g.C126G were identified in the same set of animals, 7 out of 69, which were cut across the 3 breeds (3 West African Dwarf, 3 Red Sokoto and 1 Sahel). The allele C for the g.A729C polymorphism occurred with a frequency of 0.029. Additional work to genotype these polymorphisms in a larger number of animals for population genetic analysis are in progress.

Key words: MC1R gene, goat, coat color

688 Molecular identification of *Trypanosoma vivax* Infection and physiological indices in Nigerian sheep. G. O. Onasanya[1], M. A. Adefenwa[2], B. O. Agaviezor[3], C. O. N. Ikeobi[1], M. Wheto[1], M. Okpeku[4], A. Yakubu*[5], M. I. Takeet[6], M. De Donato[7], and I. G. Imumorin[7], *[1]Dept of Animal Breeding and Genetics, University of Agriculture, Abeokuta, Nigeria, [2]Dept of Cell Biology and Genetics, University of Lagos, Lagos, Nigeria, [3]Dept of Animal Science and Fisheries, University of Port Harcourt, Port Harcourt, Nigeria, [4]Dept of Livestock Production, Niger Delta University, Amassoma, Nigeria, [5]Department of Animal Science, Nasarawa State University, Lafia, Nigeria, [6]Dept of Veterinary Microbiology and Parasitology, University of Agriculture, Abeokuta, Nigeria, [7]Dept of Animal Science, Cornell University, Ithaca, NY.*

Trypanosomiasis remains a major challenge to livestock production in endemic areas of Sub-Saharan Africa. Nationwide prevalence of *Trypanosoma vivax* (*T. vivax*) infection was estimated in 4 extant sheep breeds using 161 samples collected from across Nigeria and to ascertain associations of parasite presence with physiological indices. The presence of *T. vivax* was determined by polymerase chain reaction to amplify a 400 bp DNA fragment of the parasite genome. Results showed that 73.9% of sheep sampled were infected with *T. vivax* with geographical locations showing prevalence rates of 73.5% (Southwest), 71.7% (Northwest) 73.5% (Northeast) and 88.0% (Northcentral). Breed prevalence were Balami (85.4%), West African Dwarf (75%), Uda (62.5%) and Yankasa (72.5%). There was a significant ($P < 0.05$) interaction of *T. vivax* and sex status on pulse rate with non-infected females showing higher pulse rates of 129.138 ± 5.57 beats per minute (bpm) compared with infected rams (111.8 ± 5.96 bpm) and infected females (122.6 ± 3.00). Also, non-infected females had higher respiratory rate with 64.4 ± 4.04 bpm compared with infected rams with respiratory rate of 51.217 ± 3.25 bpm. The interaction of *T. vivax* infection and breed on pulse rate was significantly different ($P < 0.5$) between non-infected Balami (159.3 ± 9.98 bpm) compared with infected West African Dwarf (106.7 ± 6.18 bpm) goats. Similarly, respiratory rates differed significantly ($P < 0.05$) between non-infected West African Dwarf (71.6 ± 11.31 bpm), while infected Uda had the lowest respiratory rate (53.560 ± 3.33 bpm). The interaction effect of *T. vivax* infection and sex was also significant on body weight with non-infected males weighing more (39.962 ± 4.43 kg) than infected females. Molecular diagnosis using PCR seem effective and the presence of trypanosome appears to have important implications for physiological efficiency of sheep in Nigeria.

Key words: *Trypanosoma vivax*, Nigeria, sheep

689 Polymorphism in the ovine TNXB gene and association with morphological traits and physiological status in Nigerian indigenous sheep. O. Ajayi[1], M. A. Adefenwa[2,6], B. O. Agaviezor[3,6], C. O. N. Ikeobi[1], M. Wheto[1], M. Okpeku[4], A. Yakubu[5,6], M. De Donato[6], and I. G. Imumorin*[6], *[1]Dept of Animal Breeding and Genetics, University of Agriculture, Abeokuta, Nigeria, [2]Dept of Cell Biology and Genetics, University of Lagos, Lagos, Nigeria, [3]Dept of Animal Science and Fisheries, University of Port Harcourt, Port Harcourt, Nigeria, [4]Dept of Livestock Production, Niger Delta University, Amassoma, Nigeria, [5]Dept of Animal Science, Nasarawa State University, Lafia, Nigeria, [6]Dept of Animal Science, Cornell University, Ithaca, NY.*

The major histocompatibility complex (MHC) plays an important role in the adaptive immune response of vertebrates and tenascin XB (TNXB) localizes to the MHC class III region and encodes a member of the tenascin family of extracellular matrix glycoproteins. The tenascins have anti-adhesive effects and are thought to function in matrix maturation in connective tissues such as blood vessels. Given the role of blood vessel function in adaptive physiological response, we aimed to determine the influence of variation in the ovine TNXB gene on physiological variables in Nigerian indigenous sheep in the hot humid tropics. We sequenced a 450 bp fragment of the ovine TNXB gene in 150 randomly sampled indigenous sheep, comprising 30 West African Dwarf and 40 each of Yankasa, Uda and Balami from 4 geographical zones of Nigeria, and genotyped the identified SNP using PCR-RFLP. The frequencies of genotypes TT, Tt and tt were 40.0%, 48.0% and 12.0%, respectively. While morphological traits did not significantly differ among TNXB genotypes, there were significant ($P < 0.05$) differences for pulse rates in beat per minute (bpm) [129.28 ± 6.64 (tt) versus 111.93 ± 4.05 (TT) versus 110.38 ± 3.82 bpm (Tt), respectively] and in body temperature (35.82 ± 0.65 (tt) versus 37.94 ± 0.40 (TT) versus 38.81 ± 0.370C (Tt); $P < 0.05$, respectively]. Breed x TNXB

genotype and zone x TNXB genotype interaction effects were significant ($P < 0.05$) for heart girth and body temperature, while the interaction effect of breed x sex x TNXB genotype was significant ($P < 0.05$) for body weight, rump height, heart girth and rump width, respectively. Variation in TNXB may be mediated through a possible role in connective tissue biology such as blood vessels which may in turn be a potential genetic marker for heat tolerance traits, as well as for disease resistance when validated in a larger population supported by functional studies.

Key words: Tenascin XB gene, sheep, Nigeria

690 Lean lamb production during the process of grading up to hair sheep genetics. D. K. Aaron*, D. G. Ely, E. Fink, B. T. Burden, M. E. Hoar, M. M. Simpson, and A. K. Lunsford, *University of Kentucky, Lexington.*

The overall objective of a long-term grading-up project was to track changes in production as breed composition of the flock changed from Polypay (PP) to White Dorper (WD). This portion of the project evaluated carcass characteristics of a sample of wether lambs selected for harvest from lamb crops produced from 2003 through 2010. Percentages of WD breeding in harvested lambs were 0 (PP; n = 50), 50 (1/2 WD; n = 50), 75 (3/4 WD; n = 50), 87.5 (7/8 WD; n = 35) and 93.75% or higher (WD; n = 48). Each year lambs were born in April, creep fed on pasture, and weaned at 70 d of age. Lambs were managed postweaning on pasture and supplemented with grain at 2 to 3% BW. Lambs were harvested at a live target weight of 54 kg. Data were analyzed using mixed model procedures. Orthogonal polynomials were used to partition differences among lamb genetic types (0, 50, 75, 87.5 and 93.75% or higher WD). Polypay lambs were youngest at harvest (197 d) and age increased (Linear, $P < 0.01$) as percent WD increased with 93.75% or higher WD lambs being oldest (220 d). Harvest weights decreased as percent WD increased (54.2, 54.3, 53.2, 51.3 and 52.3 kg; Linear, $P < 0.01$). Carcass weights responded quadratically (26.5, 27.4, 27.1, 26.4 and 26.3 kg; $P < 0.01$). Rack weights (1.98, 2.09, 2.25, 2.23 and 2.13 kg) and loin weights (2.38, 2.65, 2.79, 2.84 and 2.72 kg) increased linearly ($P < 0.01$) as percent WD increased. There were no differences in leg weights. Carcasses from 7/8 WD were fattest while carcasses from PP lambs were leanest (Quadratic, $P < 0.01$). Longissimus muscle area was largest for WD and smallest for PP lambs (Linear, $P < 0.01$). Yield grades were lowest for PP and WD lambs (1.8, 2.3, 2.6, 2.9 and 1.8; Cubic, $P < 0.01$). Percent closely trimmed boneless retail cuts increased as percent WD increased (48.3, 48.1, 47.9, 48 and 49.1%; Linear, $P < 0.01$). Results from this project indicate carcasses of percentage WD lambs compare favorably to those of PP lambs for most traits.

Key words: White Dorper, Polypay, carcass characteristics

Alpharma Beef Cattle Nutrition Symposium: Enhancing Beef Production Efficiency with New Knowledge and Technologies: Building the Bridges for Future Collaboration

691 Implications of nutritional management for beef cow/calf systems. R. N. Funston*, *University of Nebraska, West Central Research and Extension Center, North Platte.*

The beef cattle industry relies on the utilization of high forage diets to maintain the cow herd, develop replacement females, and stocker operations. Forage quantity and quality fluctuate with season and environmental conditions. Depending on the class and physiological state of the animal, a grazed forage diet may not always meet nutritional requirements resulting in low ADG or weight loss if supplemental nutrients are not provided. It is important to understand the consequences of such weight loss and the economics of providing supplementation to the beef production system. Periods of nutrient restriction can actually result in compensatory gain once dietary conditions improve and may be of less impact in breeding animals where actual weight is not as important as animals destined for the feedlot provided reproductive efficiency is not compromised. A rapidly evolving body of literature is also demonstrating effects on subsequent offspring developing in a restricted environment in utero. Maternal stimuli or an insult during a critical period of fetal development having long-term implications for the offspring is the concept of fetal programming. In recent studies at the University of Nebraska, calf birth weights were unaffected while calf weaning weights were greater from cows gestated on dormant winter range receiving protein supplementation during late gestation compared with non-supplemented cows. Subsequent steer carcass weights and quality grades were also improved in calves born to supplemented dams and more heifers from supplemented dams were pubertal before breeding and had greater pregnancy rates. This body of research provides compelling evidence of a fetal programming response to maternal nutrition in beef cattle. Future competitiveness of the beef industry will continue to be dependent on the utilization of high forage diets to meet the majority of nutrient requirements. Consequences of nutrient restriction must be considered not only on individual animal performance but also the developing fetus.

Key words: beef cattle, fetal programming, nutrition

692 Altering the ruminal microbiome and its potential impact on animal nutrition and performance. S. L. Lodge-Ivey*, *New Mexico State University, Las Cruces.*

This presentation will address current advancements in rumen biochemistry and how these advancements may need to be dealt with in current paradigms. How these interactions within rumen microbiology, nutrition or metabolism may be understood and how future research may account for this additional source of variation. Characterization of the rumen microbial communities may eventually lead to enhanced production efficiency of grazing animals. Conventional culture-base methods of enumerating rumen microorganism are being replaced by culture independent methods that rely on analysis of nucleic acids extracted from ruminal samples. For example, sampling location within the rumen, liquid versus particulate faction and handling techniques are all areas of consideration when collecting ruminal samples for analysis with DNA- and RNA-based techniques. Application of modern tools has modified and altered how rumen microbial diversity is measured. The rumen microbiome represents a huge resource with great potential. The future of rumen microbiology research is dependent upon the application of molecular research technologies. There is a need to apply modern technologies to improve production efficiency of ruminants. The goal of this presentation is to identify areas of current research within the field of rumen microbiology and how research nutritionists, consultants and other disciplines can develop partnerships for interactions of multidisciplinary, integrated research approaches to address large novel projects being requested currently by granting agencies.

Key words: rumen microbiology, modern techniques, multidisciplinary interactions

693 Nutrition and the genome. H. L. Neibergs*, *Washington State University, Pullman.*

It has long been appreciated that animals fed the same diet may perform differently. This is due to the ability of nutrients to interact with and affect molecular pathways that result in differences in weight gain, production performance or disease resistance. To understand these effects, studies are being undertaken to discover how the differential expression and function of genes occurs with different diets. These studies are exploiting new technologies, genomic resources and analyses that have recently become available for domestic animals. Nutrigenomics and nutrigenetics incorporate these research approaches to optimize health by looking beyond the diet to understand the effects of food at the genetic and epigenetic levels. Nutrigenomics is focused on the effects of diet on health through an understanding of how bioactive chemicals in foods and supplements alter gene expression or the structure of an animal's genome. Nutrigenetics focuses on how the genetic composition (genetic variation) of an animal influences their response to a given diet. Results from these studies will aid in formulating nutritious efficient diets that may be optimized for animals based on their genomic underpinnings. Nutrigenomics and nutrigenetics unite many fields: nutrition, bioinformatics, molecular biology, genomics, functional genomics, epidemiology and epigenomics. The use of multi-disciplinary tools from these fields promises new opportunities to investigate the complex interactions of the genome and an animals diet. Through these new approaches, the partnerships of the genome and nutrition will be revealed resulting in improved efficiency of diets, enhanced sustainability of animals as a protein source and improved methods for preventing illnesses.

694 Impacts of health status and disease prevention with nutrition and performance of beef cattle. B. P. Holland*[1] and L. O. Burciaga-Robles[2], [1]*Department of Animal and Range Sciences, South Dakota State University, Brookings,* [2]*Feedlot Health Management Services Ltd., Okotoks, Alberta, Canada.*

Research in the health of growing and finishing cattle by nutritionists has focused primarily on the interaction of diet, management, and incidence of BRD, and the effects of clinical BRD on subsequent animal performance. Veterinary research has provided a wide array of vaccines, combined with antimicrobials and health management protocols for disease prevention and intervention. While some strategies have

been shown to reduce morbidity and improve performance on an individual lot basis, overall incidence of BRD has increased over time. Management strategies can be employed to minimize the effects of disease on carcass characteristics and profitability. However, diagnosis of disease is subjective and inconsistent, requiring that these strategies be applied to diverse populations with limited discrimination. Recent advances in technology can help researchers understand the metabolic status of animals in healthy and diseased states and the impact of disease and the immune response on nutrient requirements. Results from proteomic methods have cast doubts on traditional experimental models of stress-induced immunosuppression. Data such as these can be used to more accurately create experimental models for studying animal health. In addition, definitions of illness based on biochemical measures can be created so that health responses to treatment can be assessed more accurately and more targeted management can be imposed. Ongoing research is being conducted to determine impacts of prenatal nutrition and lifetime management strategies on animal reproduction, growth, and carcass traits. Measures of health and immune responses should be included in such research to better understand nutrition and epigenetic effects on disease susceptibility and create more inclusive lifetime management systems. Discoveries made using biochemical methods should be incorporated into practical tools so that illness can be prevented, reducing the use of antimicrobials and the subsequent impacts of the immune response on beef production. This paper will review interactions of health and nutrition in beef cattle and propose considerations for future research.

Key words: beef cattle, health, growth

695 Interactions with beef cattle nutrition and metabolism: Developing an integrated across discipline approach to research; building the bridges for future collaboration, summary. D. L. Boss*, *Montana State University, Bozeman.*

As animal science disciplines embark on future research, each discipline is finding and understanding interactions that affect more than one traditional area of training and research. Alpharma Beef Cattle Nutrition symposium proposes to address reviews of current and potentially new interactions between beef cattle nutrition and other major animal science disciplines. Grant opportunities are becoming larger and need to include multidisciplinary approaches to solve intricate systems biology research questions. Granting agencies are requesting applications that address an integrated approach. Synergistic collaboration of interdisciplinary team approach to research and outreach allows new collaborative teams to address issues or questions that are vital to stakeholder interests. As research and industry beef cattle nutritionists develop programs for the next 10 to 20 years, these interactions will need to be addressed in design and implementation of new novel nutrition research. In this symposium, experts in several areas discuss and identify future areas for multidisciplinary interaction and development of integrated research programs to address complex and novel areas of investigation to help in the process of building the bridges for future collaboration. By crossing disciplines to integrate research programs, an increased allocation of resources can be achieved and integrated approaches can assist with large scale biological questions. Current advancements in ruminal biochemistry need to be placed in context within existing paradigms of conventional nutritional research. Genomics and endocrinology as influenced by nutrition will address interactions as well as emerging technologies and techniques to beef cattle nutrition. Past, present and future management decisions and their impacts upon beef cattle nutrition such as fetal programming and disease prevention and intervention will be investigated through across discipline research discussions.

Key words: beef cattle nutrition, integrated across discipline

696 Effect of a micronutrient supplement on the functional capacity of neutrophils harvested from the blood of dairy cows during the periparturient period. X. S. Revelo*, A. L. Kenny, N. M. Barkley, and M. R. Waldron, *University of Missouri, Columbia.*

The objective of this study was to investigate the effect of a micronutrient supplement on the functional capacity of neutrophils (PMNL) isolated from the blood of dairy cows during the periparturient period. Cows received 56 g/day of either OmniGen-AF (n = 8) or sham control (soybean hulls; n = 12) mixed into total-mixed rations from d 46 ± 1 before calving until d 31 after parturition. PMNL were collected from cows on d 49 ± 2, 28 ± 1, 19 ± 1, and 9 ± 1 prepartum and 1, 7, 14, and 30 postpartum to determine their luminol-dependent generation of reactive oxygen species (ROS), formation of extracellular traps (NETs), chemotaxis toward interleukin-8 (IL-8) and antimicrobial capacity against Staphylococcus aureus. There was no effect of dietary OmniGen-AF on any of the parameters used to assess PMNL function ($P \geq 0.20$). In contrast, ROS production and NET release by phorbol 12-myristate 13-acetate (PMA)-activated PMNL changed between days relative to parturition (time effect, $P \leq 0.01$). ROS production increased by 40% between 49 and 19 d prepartum ($P \leq 0.05$) and then declined 63% to reach a lowest level on d 1 postpartum ($P \leq 0.05$). ROS generation by PMA-activated PMNL did not differ and persisted low on d 1, 7 and 14 ($P \geq 0.20$), however, it recovered to a level similar to that found prepartum by d 30 postpartum. NET release by PMA-stimulated PMNL collected from all cows was highest on d 49 prepartum but decreased 26% and 40% by d 28 and 19 prepartum, respectively ($P \leq 0.05$). The expression of NETs by PMNL remained low until d 14 relative to parturition, but slightly increased on d 30 postpartum (25% higher compared with d 19 prepartum, $P \leq 0.05$). There was no effect of day relative to parturition on PMNL chemotaxis toward IL-8 or killing ability against S. aureus ($P \geq 0.05$). These results suggest that impairment of ROS production and release of NETs contribute to the altered PMNL function in periparturient dairy cows.

Key words: neutrophil, immunosuppression, micronutrient supplement

697 Multiple *Mycoplasma* spp. detected in bulk tank milk samples using real-time PCR and conventional culture, and agreement between test methods. D. J. Wilson*[1], A. Justice-Allen[2], J. D. Trujillo[3], and G. Goodell[4], *[1]Utah State University, Logan, [2]Arizona Game and Fish Department, Phoenix, [3]Iowa State University, Ames, [4]The Dairy Authority, Greeley, CO.*

A PCR method and standard culture were both used to test for Mycoplasma spp. in bulk tank milk samples, and results were compared. Bulk tank milk samples (n = 165) from 16 dairy farms that had been found mycoplasma-positive were tested as were 15 samples from a farm previously negative. All samples were cultured on modified Hayflick medium and incubated at 37°C in 10% CO_2. DNA extraction, PCR reaction using SYBR green, and dissociation curve analysis to determine the melt curve and Tm were also performed in triplicate. For selected samples, and samples with Tm different than the M. bovis positive control, bp length was determined by capillary electrophoresis, and DNA sequence of amplicons was compared to known sequences using BLAST to detect multiple *Mycoplasma* spp. A true mycoplasma-positive sample was defined as having at least 1 positive test, whether culture or at least 1 SYBR PCR; specificity was 100% by definition. Test sensitivity was calculated as the number of positive cultures or PCR tests divided by the number of tests performed on true positive samples. The confidence interval for sensitivity of the 2 tests was calculated and evaluated for overlap, and test method agreement was also assessed with a kappa statistic. Results are in the table. Ninety samples were mycoplasma-negative and 90 were positive. Forty-eight samples were positive on all 4 tests (1 culture, 3 PCR). Culture sensitivity = 62/90 = 68.9%; PCR sensitivity (3 tests/sample) = 207/270 = 76.7%; Agreement = 141/180 = 78.3% ($\kappa = 0.54$, moderate agreement); 95% CI overlap indicated comparable sensitivity. Of 52 speciated samples there were 39 *M. bovis* (75%) isolates, 13 *M. alkalescens* (25%), 4 *M. arginini* (8%), 2 *M. gateae* (4%), 1 *M. bovigenitalium* (2%). All 7 double-positive samples included *M. bovis*. The *M. bovigenitalium* was found in 1 tank sample from the herd previously mycoplasma-negative. Both test methods demonstrated useful and comparable sensitivity for detection of mycoplasma in bulk milk.

Table 1. Comparison of mycoplasma culture and PCR results on bulk tank milk

	PCR positive	PCR negative	Total
Culture positive	51	11	62
Culture negative	28	90	118
Total	79	101	180

Key words: mastitis, mycoplasma, PCR

698 Multiple tests based estimates of *Mycobacterium avium* ssp. *paratuberculosis* prevalence in domestic ruminant population suspected for Johne's disease. S. V. Singh*[1], P. K. Singh[1], A.V. Singh[1], B. Singh[1], A. Kumar[1], A. Srivastav[2], S. Gupta[1], H. Singh[1], A. Mittal[1], S. Yadav[2], and J. S. Sohal[1], *[1]Central Institute for Research on Goats, Mathura, Uttar Pradesh, India, [2]College of Veterinary Sciences, Mathura, Uttar Pradesh, India.*

Mycobacterium avium subspecies *paratuberculosis* (MAP), the cause of Johne's disease (JD) is a major animal pathogen worldwide and is endemic in the animal population wherever investigated. Despite low per animal productivity, JD received low priority outside developed countries. JD is endemic in the domestic ruminant population of the country. Planning major initiative on the control knowledge of epidemiology of MAP is essential. Due to lack of "true estimates" on the prevalence of MAP, disease is not a priority for the control in the domestic livestock in the country. In 2010, 3007 samples were submitted to Animal Health Division (Central Institute of Research on Goats, Mathura) for screening against MAP. Samples originated from cattle, buffaloes, sheep and goats suspected for JD from 9 states (Uttar Pradesh, Tamil Nadu, Himanchal Pradesh, Gujarat, Assam, Kerala, Madhya Pradesh, Rajasthan and Punjab). Samples (3007) were screened by microscopy (716 feces), IS900 PCR (183 feces and 510 blood) and "indigenous ELISA kit" (1598 serum). Using microscopy, fecal PCR, blood PCR and indigenous ELISA kit, 51.0, 27.3, 19.6 and 68.4% samples were positive, respectively. With respect to the 4 tests, study showed moderate to high levels of prevalence in the suspected livestock population. Study revealed value of microscopy and indigenous ELISA kit as screening tests, whereas IS900 PCR (blood and feces) was at best confirmatory. Higher presence of MAP in the test samples showed the need for wider study to estimate sero and molecular prevalence of MAP in domestic ruminants population of the country.

Key words: paratuberculosis, epidemiology

699 Evaluation of a BVD milk ELISA test detecting anti-p80 antibody and comparison with ear notch testing for PI cattle. D. J. Wilson*[1], K. A. Rood[1], and G. Goodell[2], [1]*Utah State University, Logan,* [2]*The Dairy Authority, Greeley, CO.*

A milk ELISA test for antibody (Ab) against Bovine Viral Diarrhea (BVD) was studied and compared with standard ear notch testing for Persistently Infected (PI) cows. Milk metered samples were tested from a dairy herd with past diagnoses of BVD abortions and PI cows. BVD MLV vaccine was given to calves 3 mo and 4 mo old, to all cows at dryoff and 15-21 DIM post calving. 247 and 258 cows were tested 1 mo apart using a competitive ELISA for milk antibody (Ab) binding to p80 BVD protein. Results are reported as % binding by a second test kit Ab; higher second Ab binding means the milk had less anti-BVD p80 Ab. Interpretation: 90-100%, little Ab - PI or vaccine failure if consistent; 60-89%, moderately low Ab; 30-59%, moderate Ab; 10-29%, high Ab; 0-9%, very high anti-BVD Ab. Four samples from each cow were handled differently: fresh milk, fresh with preservative pill, frozen 7 days, room temp 7 days with preservative. Ear notches were sampled concurrently from all cows for BVD antigen (Ag) testing. No PI cows were found from ear notch Ag tests of 345 cows. Milk handling method was significant; fresh milk mean 49% second Ab binding was higher than other methods, 7 days preserved was especially lower at 42% ($P \leq 0.01$, ANOVA, Tukey's). All further results here are from fresh milk. Binding ranged from 3%-98%, quartiles 29%, 47%, 62% 1st mo, 35%, 56%, 71% 2nd mo. 15 cows had 90-98% binding on one test, but 14 were milking each mo and were below 90% on the other test; 60% mean binding the other mo. For cows >90%, DIM was 41-188, 305ME mean 12,935 kg, daily milk mean 44 kg. No PI or vaccine failures (consistently >90%) were found by milk ELISA. DIM significantly affected Ab binding: 1-9 DIM, 16%*; 10-30 DIM, 34%*; 31-60 DIM, 46%; 61-150 DIM, 60%*; 151-300 DIM, 47%; 301-360 DIM, 40%; >360 DIM, 46%. * = $P \leq 0.025$, ANOVA, Tukey's. Lactation number did not affect binding. The milk ELISA agreed with ear notch testing in finding no PI cows. Anti-BVD Ab was high in early lactation and then decreased. The ELISA warrants further study.

Key words: BVD, antibody, ELISA

700 Biophotonic imaging as a method to evaluate efficacy of intramammary antibiotics against *Staphylococcus aureus* in vitro. J. Curbelo*, J. Brett, C. Steadman, H. L. Sanchez, T. Rowlison, K. S. Seo, P. L. Ryan, and S. T. Willard, *Mississippi State University, Mississippi State.*

In this study we evaluated whether biophotonic imaging (BI) could be adapted to evaluate antimicrobial efficacies of intramammary antibiotic preparations (IAP) against bioluminescent *Staphylococcus aureus* (S. aureus-Xen8.1) in bovine milk in vitro. Whole bovine milk (500 mL; n = 4) were inoculated with S. aureus-Xen8.1 and treated with commercial IAP (cephapirin sodium (CEP), hetacillin potassium (HET) and/or pirlimycin hydrochloride (PIR)), and a control (CON) containing no antibiotics. Aliquots were collected from each inoculated sample (100µL; n = 5) over a 9 h period, placed in a 96-well plate, imaged and plated to correlate the number of cfu with photonic emissions (PE). An ANOVA and Fisher LSD test were performed to determine significant differences in PE and cfu between treatments. Photonic emissions from S. aureus-Xen8.1 increased in CON, HET and CEP treatments in a parallel manner with no differences in PE and cfu ($P > 0.05$) from 0 to 2 h post antibiotic addition. PE in the PIR treatment decreased during the same period ($P < 0.05$), but remained stable for the remaining 7 h. However cfu did not correspond with these results, remaining unchanged during the first 4 h. Differences in PE between HET and CEP were first observed at 2 h post antibiotic addition (243.3 ± 4.5 and 236.9 ± 1.4, respectively; $P < 0.0001$), which corresponded to the differences first observed in cfu between these 2 treatments after 2 h ($3.4 \times 10^7 \pm 4.4 \times 10^6$ and $2.2 \times 10^7 \pm 1.1 \times 10^6$, respectively; $P < 0.0001$). In summary, the discrepancies found between PE and cfu in the PIR treatment could be attributable to its mode of action. Pirlimycin is a bacteriostatic antibiotic and interferes with protein synthesis, therefore suppressing the production of light at the ribosomal level. In contrast, CEP and HET are bactericides and target cell wall synthesis. Therefore, the degree of impairment caused by these 2 antibiotics against S. aureus-Xen8.1 corresponded to the changes in PE detected, which allows for the quantification in real time of bacterial progress during in vitro and/or in vivo antimicrobial studies.

Key words: biophotonic, *Staphylococcus aureus*, mastitis

701 Experimental induction of *Streptococcus uberis* mastitis in bred dairy heifers: A challenge model. K. A. Jackson*, D. J. Hurley, F. M. Kautz, L. O. Ely, and S. C. Nickerson, *University of Georgia, Athens.*

A challenge model for experimentally inducing *Streptococcus uberis* mastitis in 7 bred dairy heifers from a university herd was developed. Heifers were randomly assigned 2 contralateral quarters to receive an infusion of the *S. uberis* challenge strain NIRD-0140J. To challenge the heifers, a bacterial suspension was created to achieve a concentration of 1000–2000 cfu/mL in 1 mL of physiological saline. For a successful challenge, 3 of 4 consecutive microbiological cultures had to be positive for *S. uberis* based on the API 20 Strep miniaturized identification kit. Once infection was confirmed, the challenged quarter was treated with SPECTRAMAST DC. Preliminary analysis showed that 6 of the 7 heifers (85%) were challenged successfully with the dose used. The average concentration used to challenge the 7 heifers was 1,080 cfu/mL, which fell within the goal range of 1000–2000 cfu/mL. Data showed that before challenge, SCC averaged 11.5×10^6/ml across control and challenge quarters. At 24 h post challenge, SCC increased to 23.8×10^6/ml in challenged quarters and remained elevated. In contrast, unchallenged quarters resulted in no change in SCC and the concentration remained at or below 10.1×10^6/mL. Differential leukocyte data showed that before challenge, macrophages predominated in secretions followed by lymphocytes and neutrophils. By 24 h after challenge, there was a marked spike in neutrophils, which lasted for the duration of the trial. Results suggest that the challenge model developed was successful in routinely establishing experimental S. uberis mastitis in dairy heifers, which was controlled (100% cure) by the administration of nonlactating cow therapy.

Key words: experimental challenge, mastitis, *Streptococcus uberis*

702 Effects of OmniGen-AF on enhancing immunity in dairy heifers vaccinated with a *Staphylococcus aureus* bacterin. V. J. Eubanks*[1], N. E. Forsberg[2], Y. Q. Wang[2], K. Zanzalari[3], J. Chapman[3], D. J. Hurley[1], F. M. Kautz[1], L. O. Ely[1], and S. C. Nickerson[1], [1]*University of Georgia, Athens,* [2]*Oregon State University, Corvallis,* [3]*Prince Agri Products Inc., Quincy, IL.*

The purpose of this study was to evaluate the effect of a commercial feed additive on amplifying heifers' immune response to *Staphylococcus aureus* vaccination, with the goal of calving heifers free of infection with low somatic cell counts (SCC) to meet the proposed

legal limit of 400,000/mL. Overall animal health was monitored by measuring blood immune parameters, body growth, health incidents, and prevalence of mastitis. Bacterial culture of teat canal swabs and mammary secretions to determine presence of mastitis revealed that 40% and 55.1%, respectively, were infected with *S. aureus* and other *Staphylococcus* and *Streptococcus* spp. along with elevated SCC $\geq 1 \times 10^6$/ml. S. aureus was found to be the most prevalent pathogen in both the teat canal swabs (11.4%) and mammary secretions (20.5%). Heifers fed the commercial feed additive did not show a significant advantage or disadvantage in growth based on weight and height measurements. However, L-selectin and IL-8 receptor mRNA analyses on blood leukocytes showed that post-treatment L-selectin (3.6) and Il-8 (2.38) receptor mRNA levels were higher for heifers fed the commercial feed additive than control heifers (1.53 and 1.19, respectively), suggesting greater antibacterial leukocyte activity and elevated immune status in treated animals. S. aureus antibody titers across both treatment groups before vaccination averaged 1:400. By 1 mo post-vaccination, titers increased 2–10 fold, and the titers of several heifers continued to increase through the 3rd mo post-vaccination; however, no differences have been detected between treatments.

Key words: mammary immunity, mastitis, *Staphylococcus aureus*

703 Genetic parameters of adaptive immune response traits in Canadian Holsteins and implications for health. K. Thompson-Crispi*[1], A. Sewalem[2,3], F. Miglior[2,3], and B. Mallard[1], *[1]Dept. Pathobiology, Ontario Veterinary College, University of Guelph, Guelph, Ontario, Canada, [2]Guelph Food Research Center, Agriculture and Agri-Food Canada, Guelph, Ontario, Canada, [3]Canadian Dairy Network, Guelph, Ontario, Canada.*

Infectious diseases contribute to substantial economic loss in the dairy industry with human and animal health implications. The immune system is a tightly genetically regulated system that largely controls response to infectious disease. Including estimated breeding values (EBV) of immune response (IR) traits in a selection index has the potential to improve inherent animal health. Previously, cows classified as High Immune Responders in dairy herds in Ontario and the US were found to have improved response to vaccine, increased milk and colostrum quality and decreased incidence of diseases like mastitis, metritis, ketosis and retained placenta. The objectives of this study were to evaluate antibody-mediated (AMIR) and cell-mediated IR (CMIR) traits in Holstein cattle on a national scale and estimate genetic parameters of these traits. In collaboration with the Canadian Bovine Mastitis Network, 690 Holsteins from 58 herds across Canada were immunized to measure delayed-type hypersensitivity as an indicator of CMIR and serum antibody (AMIR) to putative type 1 and type 2 test antigens. The statistical procedure included the fixed effects of parity and stage of lactation and the random effects of herd-technician, animal and residual. A linear animal model was used to estimate genetic parameters and breeding values using a DMU software package. Heritability of CMIR was 0.18 and for AMIR between 0.14 – 0.41 depending on time and antibody. The genetic correlations between CMIR and AMIR were negative and ranged from −0.13 to −0.45. EBV were used to classify cows as High (H), Average or Low (L) for IR. Health and production records are available for correlation with these diverse immune response profiles. Preliminary results show no difference in 305 d production between IR categories, indicating selection for IR would not impact production. Selective genotyping of H and L immune responders using the Bovine SNP50 BeadChip is underway. Identifying H and L immune responders and determining genetic profiles of these phenotypes may make it feasible to include IR in breeding indices to improve health of dairy cows.

704 The relationship between measured optical density of uterine lavage samples and clinical endometritis. V. S. Machado*, M. L. S. Bicalho, and R. C. Bicalho, *Cornell University, Ithaca, NY.*

The objective of this study was to evaluate a novel clinical endometritis diagnosis technique using optical density of uterine lavage samples. Clinical endometritis is the inflammation of the endometrium diagnosed by the detection of purulent or mucupurulent uterine exudates after 21 d postpartum, not accompanied by systemic signs. In the present study, the diagnosis of clinical endometritis was evaluated using low-volume uterine lavage technique at 35 ± 3 DIM, examining the presence of purulent or mucupurulent content only in the uterine secretion. The study enrolled 554 cows from a dairy farm located near Ithaca NY from May 4th 2010 until January 17th 2011. After they were cultured for *A. pyogenes*, the uterine lavage samples were frozen in −80°C until they were processed for the assessment of optical density (OD), as follows: hypertonic saline solution (10%) was added to the uterine lavage in a 1:1 proportion, followed by incubation at room temperature for 30 min and centrifugation for 30 min at 3,000 x g at 4°C. The supernatant was collected and an aliquot of 0.2 mL was added to microplate wells. The OD200, OD352, OD620, OD790, OD860 and OD960 were assessed. The prevalence of clinical endometritis in the present study was 16.8% (93 cows). The ROC analysis of the accuracy of ODs in the detection of clinical endometritis was done for several OD wavelengths. The OD620 (optical density at 620 nm) presented the highest area under the curve in the ROC analyzes and was selected for further analysis. The ROC analyzes indicated an optimal cut-off point of 0.049 (OD620); sensitivity was 88.17% and sensitivity was 70.93%. The positive predictive value and negative predictive value for the test were 37.96% and 96.75%, respectively. The mean OD620 for endometritis negative cows was 0.07 (±0.005), which was significantly lower than for cows diagnosed with endometritis 0.24 (±0.03). The OD620 mean for *A. pyogenes* culture negative cows was significantly lower (0.9 ± 0.007) than for *A. pyogenes* culture positive cows (0.17 ± 0.03).

Key words: endometritis, uterine health, dairy cows

705 Survey of individual cow records to identify factors associated with lameness in dairy cattle in New Zealand. C. M. Lira-Diaz[1], J. K. Margerison*[1], and N. Lopez-Villalobos[2], *[1]Massey University, IFNHH, Palmerston North, New Zealand, [2]Massey University, IVABS, Palmerston North, New Zealand.*

This study aimed to assess the main factors associated with the occurrence of lameness of dairy cattle, using 1969 individual cow records from 3 dairy farms in the North Island of New Zealand and monitored cows for locomotion score (LS) using a 5 point scale (1 not lame, 3 tender footed, 4 lame, 5 very lame (not weight bearing on a limb/ limbs)) on a daily basis for a 12 mo period. A total of 9.34% of cows were diagnosed as lame at least once during the year (LS > 3) and assessment of individual claws was recorded using the international foot map (IFM) (0 = inter-digital, 1+2 = white line, 3 = axial lateral sole, 4+5 = sole area, 6 = heel, 10 = inter-digital heel, 11 = other cause of lameness). The incidence of lameness was significantly higher in hind claws 3.73 times more frequently (78.88% of cases) than fore claws (21.12% of cases), with no significant difference (*P*

< 0.8498) between right (Rt) and left (Lt) claws (Lt: 49.40%, O.R.1, C.I.95%; Rt: 50.60%; O.R.1.024, 95% C.I.). Lateral claws had the highest incidence of lameness (55.38%, O.R. 1.24, C.I 95%; $P < 0.05$) from medial claws. Results indicate a significantly ($P < 0.001$) higher percentage of LS 4 (59.20%, O.R. 7.05, C.I.95%), followed by LS 3 (32.40%, O.R.1.83, C.I. 95%), while LS 5 was lowest (8.40%, O.R. 1.00, C.I.95%). Highest incidence related to areas of the sole (IFM 4+5: 23.11%) followed by abaxial (IFM 3: 22.71%) and while line (WL) (IFM 1+2: 16.33%) areas, followed by inter-digital (IFM 0+10: 15.54%) and heel (IMF 6: 10.76%), while in 11.55% of cases the exact area affected was not identified. Claw examination showed the type of lameness most frequently diagnosed was WL disease (26.29%), followed by sole penetration (23.11%), inter-digital necrosis (16.33%), sole ulcer (11.16%), medial claw overgrowth (4.78%), thick hock (3.19%) and 15.14% was other causes. In conclusion, the main claws affected were the hind (88.45% of cases) and the main types of lameness were WL disease and foreign body penetration of the sole.

Key words: lameness, dairy cattle

706 Claw horn disease and claw horn anatomy: A meta-analysis in UK and New Zealand first-lactation dairy cattle. L. A. Lethbridge and J. K. Margersion*, *IFNHH Massey University, Palmerston North, New Zealand.*

In dairy cattle lameness is one of the main economic and welfare issues and claw horn related issues are the main pathogenesis. There is considerable amounts of data exist in many countries, there have been few similarly detailed studies assessing claw horn disease (CHD) and anatomical characteristics in the first lactation completed in New Zealand (NZ). This research used meta analysis to compare studies of CHD in the UK and NZ by the same research methods over a 3 year period. Days postpartum (dpp) significantly affected the number, percentage and total lesion score for both sole and white line, and peak hemorrhaging in NZ occurred at 110 dpp and had declined by 160, a similar pattern where peak lesions were seen at 100 dpp and levels had reduced by 150 dpp (UK). The median locomotion score of 1 with a peak score of 2 occurred between 71 and 98 dpp (NZ), which was a little sooner than the 110 to 120 dpp found in many other studies. A similar pattern for claw lesion score (CLS) to peak approx 110 to 120 d occurs irrespective of location. However the UK based research had far lower CLS (0.3) for both sole and white line lesions than in NZ. Overall, there were no significant relationships found between claw horn growth and wear rates, CLS dpp and PR (growth = Average growth = 5.98 - 0.386 Sole PR + 0.0324 d + 0.0033 CLS Sole R-Sq(adj) = 15.4% $P = 0.402$ and average wear = 9.52 - 0.458 Sole PR + 0.0173 d - 0.0112 CLS Sole R-Sq(adj) = 3.4% $P = 0.600$, and net change Net = - 11.2 + 0.244 Sole PR + 0.0396 d + 0.0303 CLS Sole R-Sq(adj) = 12.6% $P = 0.573$). Monthly growth rates were generally higher in the NZ compared with the UK, while claw horn wear rates were higher in NZ compared with the UK at 100 dpp. NZ heifers maintained a shallower claw angle, shorter dorsal border and higher heel height than UK heifer resulting in a smaller more compact foot and smaller wearing surface. The dorsal borders and heel depth in UK heifers were longer and shallower than those in NZ heifers, but UK foot angle was steeper than NZ.

Key words: claw horn disease, dairy cattle

707 Methods for the assessment of milk coagulation properties: A genetic analysis. A. Cecchinato*, M. Penasa, M. De Marchi, C. Cipolat Gotet, I. Bazzoli, N. Cologna, and G. Bittante, *Department of Animal Science, University of Padova, Viale dell'Università, Legnaro, Padova, Italy.*

Milk coagulation properties (MCP: clotting time, curd firmness) are of great importance because they influence cheese processing, yield and quality. Assessment of MCP can be performed through Formagraph (FMG), which is an instrument based on the tiny forces exerted by pendulums when samples of coagulating milk are exposed to linear oscillations, or Optigraph (OPT), which is based on an optical signal in the near-infrared reflectance spectroscopy. The FMG provides measures of milk clotting time (RCT, min), defined as the time from the addition of rennet to milk until the beginning of coagulation (within a 90-min testing time), and curd firmness (in mm) measured at different time: 30 (a30), 60 (a60), 75 (a75) and 90 (a90) min from the beginning of the test. The OPT provides same measures of MCP by means of particular feature points extracted from optical information acquired in real time. The aim of this study was to estimate heritabilities of and genetic correlations between MCP obtained from FMG and OPT. A total of 1,014 Brown Swiss cows were sampled once in 68 herds from January 2010 to February 2011. Individual milk samples were collected during the evening milking and analyzed for MCP by using FMG and OPT. A Bayesian standard linear model was implemented via Gibbs Sampling. The model included the non genetic effects of days in milk, parity, herd and the additive genetic effect of animals. For RCT measured by FMG, marginal posterior mean (SD) of heritability was 0.30 (0.09). Estimates of heritability for a30, a60, a75 and a90 averaged 0.14 (0.06) and ranged from 0.13 (0.06) to 0.16 (0.07). For OPT, corresponding estimates were slightly lower. Genetic correlations between MCP from FMG and OPT approached 0.90 (0.06). On the basis of the genetic parameters obtained in this study, the improvement of MCP through selection is possible, regardless the method used.

Key words: milk coagulation properties, near-infrared spectroscopy, genetic parameters

708 Genetic relationships between fertility and content of major fatty acids in milk for first-parity Walloon Holstein cows. C. Bastin*[1], N. Gengler[1,2], and H. Soyeurt[1,2], *[1]University of Liège, Gembloux Agro-Bio Tech, Animal Science Unit, Gembloux, Belgium, [2]National Fund for Scientific Research, Brussels, Belgium.*

Fertility traits are difficult to measure and have low heritabilities. Consequently, indicators traits are of interest for breeding value estimation for fertility especially if these traits are easier to measure, have higher heritabilities and are well correlated with fertility. Furthermore, some traits of the milk fatty acid (FA) profile could be considered because they can be related to the energy balance status. Therefore the objective of this study was to estimate genetic correlations between days open (DO) and the contents of 19 individual and groups of milk FA. Fatty acids contents (in g/dl of milk) were estimated by MIR and were: saturated, unsaturated, monounsaturated, polyunsaturated, long chain, short chain, medium chain, C4:0, C6:0, C8:0, C10:0, C12:0, C14:0, C16:0, C17:0, C18:0, C18:1, C18:1 cis, and C18:1 cis-9. Data included 143,332 FA and 29,792 DO records collected from 29,792 Holstein cows in first parity. Co(variances) were estimated using 19 2-trait models that included random regression for FA traits. Overall, genetic correlations between DO and FA contents in milk changed significantly over the lactation. For unsaturated, monounsaturated, long chain, C18:0, C18:1, C18:1 cis, and C18:1 cis-9, genetic correlations with DO were positive in early lactation and became negative after 100 d in milk. For the other fatty acids, genetic correlations with DO were negative along the whole lactation. At 5 d in milk, genetic correlation between DO and C18:1 cis-9 was 0.40 and genetic correlations between DO and C6:0 to C16:0 ranged between −0.55 and −0.20. These results emphasized the relationship between fertility and energy balance status and could be explained by the release of long chain fatty acids in early lactation due to the mobilization of body fat reserves and the consequent inhibition of de novo FA synthesis in the mammary gland. At 200 d in milk, correlations between DO and fatty acid contents ranged between −0.40 for C18:1 cis-9 to −0.10 for C6:0. This research suggested the interest of using FA contents in milk in indirect selection for better fertility in dairy cows.

Key words: fatty acid, fertility, genetic correlation

709 Relationships between mortality and 305-d milk yield of Holstein cows in three regions in US. K. Tokuhisa*, S. Tsuruta, and I. Misztal, *University of Georgia, Athens.*

Several recent research reports have indicated increasing dairy cow mortality over the years; however, the reasons for the increase are unclear. This study aimed to investigate the relationship between mortality and 305-d milk yield. DHI data contained 3 regions: Southeast (SE), Southwest (SW), and Northeast (NE). A total of 3,522,824 records for 3 parities were used: 732,009 (SE), 656,768 (SW), 2,134,047 (NE) from 1999 to 2008. Termination code "6" was regarded as "death" and used for mortality calculation. A 2-trait (305-d milk yield, mortality) animal model fitting fixed effects of herd year, age, DIM, month-of-termination, and random animal genetic effect was used to compute correlations and heritability, separately for each region and parity. Mortality was the highest in August for any parity, and the lowest in spring (i.e., the largest difference between the highest and the lowest mortality in SE was 0.63% in 3rd parity). The highest mortality was observed in SE, and mortality in NE and SW were similar. Mortality increased with parity in all regions. Mortalities in first 3 parities across regions were 3.3%, 4.8%, 7.2% (SE), 2.4%, 3.3%, 5.0% (SW), and 2.2%, 3.7%, 5.4% (NE). The span of mortality between 1st and 3rd parity was the largest in SE (3.9%) and the smallest in SW (2.6%). Genetic correlations between the 2 traits were 0.09, 0.09, 0.17 (SE), −0.03, −0.05, 0.17 (SW), and 0.19, 0.19, 0.00 (NE). The environmental correlations were 0.03, 0.05, 0.06 (SE), 0.03, 0.05, 0.05 (SW), and 0.01, 0.05, 0.06 (NE). Heritability estimates of milk yields were 0.28, 0.19, 0.13 (SE), 0.32, 0.19, 0.16 (SW), and 0.35, 0.24, 0.19 (NE). Heritability estimates of mortality were 0.01 for all 3 parities and all 3 regions. The mortality is the highest in SE and is influenced by season and by parity. Environmentally, high milk producing cows tend to have high mortality. Genetically, effects of high milk production on mortality are less clear. Results may have been influenced by special veterinary care to superior cows.

Key words: US Holsteins, cow mortality, regions

710 Genetic parameters of body condition score and other type traits in Canadian Holsteins. S. Loker*[1], C. Bastin[2], F. Miglior[3,4], A. Sewalem[3,4], L. R. Schaeffer[1], J. Jamrozik[1], and V. Osborne[5], *[1]CGIL, Dept. of Animal and Poultry Science, University of Guelph, Guelph,*

ON, Canada, [2]University of Liège, Gembloux Agro-Bio Tech, Gembloux, Belgium, [3]Guelph Food Research Centre, Agriculture and Agri-Food Canada, Guelph, ON, Canada, [4]Canadian Dairy Network, Guelph, ON, Canada, [5]Centre for Nutrition Modelling, Dept. of Animal and Poultry Science, University of Guelph, Guelph, ON, Canada.

The objective of this research was to estimate the genetic parameters of body condition score (BCS) and other type traits. The data analyzed in this study was from Holstein Canada's new classification system and included BCS, angularity (ANG), chest width (CW), height at front end (HFE), body depth (BD), pin width (PW), and stature (STA), recorded between rounds 72 to 79 (year 2006 to 2010). The model included the fixed effects age of calving × stage of lactation, and herd × round × classifier, and a random additive genetic animal effect. All 7 traits were analyzed together. In general, it was found that larger cows (taller, wider, less angular cows) were genetically inclined to have higher than average BCS, which other studies have linked to better health and fertility. The 2 traits with the strongest genetic correlation with BCS were ANG (−0.70) and CW (0.72). Heritabilities were 0.21, 0.18, and 0.19 for BCS, ANG, and CW, respectively. Genetically, ANG was strongly negatively correlated with BCS (−0.70), whereas CW was strongly positively correlated with BCS (0.72), but ANG and CW were not strongly correlated with each other (−0.16), and so both could be useful as additional information in a genetic evaluation of body condition score. All 3 traits would be useful in conjunction with Valacta's BCS (Sainte-Anne-de-Bellevue, QC, Canada) (collected several times per cow throughout lactation for Québec herds) for a first lactation longitudinal genetic analysis of BCS. A genetic evaluation of BCS would inevitably lead to selection for cattle with improved health and fertility.

Key words: body condition score, type traits, genetic correlation

711 Relationship between body condition score, locomotion and dairy strength with functional longevity in Canadian Holsteins. A. Sewalem*[1,2], F. Miglior[1,2], and G. Kistemaker[2], *[1]Agriculture and Agri-Food Canada, Guelph, Ontario, Canada, [2]Canadian Dairy Network, Guelph, Ontario, Canada.*

The aim of this study was to explore the impact of body condition score (BCS), locomotion and dairy strength on the functional survival of Canadian Holstein cows using a Weibull proportional hazard model. The data set consisted of 490,791 cows from 13,786 herds sired by 8,126 sires. Functional survival was defined as the number of days from first calving to culling, death, or censoring. The statistical model included the effects of stage of lactation, season of production, the annual change in herd size, type of milk recording supervision, age at first calving, effects of milk, fat and protein yields calculated within herd-year-parity deviations, herd-year-season of calving, each type trait and the sire. Analysis was done one at a time for each of 3 type traits. The relative culling rate was calculated for animals in each class after accounting for the above-mentioned effects. BCS showed a curvilinear relationship with longevity. Cows with score of 1 (classified as lean) were 35% more likely to be culled compared with the reference class (score = 5). Similarly, cows with score of 9 (classified as fat) were less likely to stay longer in the herd compared with the reference group. This indicates that neither too lean nor fat cows are desired for breeding purposes. The result also showed that lameness and dairy strength had a clear linear relationship with longevity. Cows classified with score 1(namely cows considered as lame) were more than 34% more likely to be culled than cows classified as intermediate group (score = 5). Additionally, cows with higher score than average were less likely to be culled than cows from the average group (score = 5). Similarly, for dairy strength cows with poor score were nearly 50% more likely to be culled than the reference group (Good Plus). However, cows with excellent score were found to have longer longevity than the other groups.

Key words: functional survival, body condition score, locomotion

712 Modeling of residual feed intake for primiparous dairy cow using orthogonal polynomial random regression. G. Manafiazar*, T. McFadden, E. Okine, L. Goonewardene, and Z. Wang, *Department of Agricultural, Food and Nutritional Science, University of Alberta, Edmonton, Alberta, Canada.*

Residual feed intake (RFI) is defined as the difference between an animal′s actual energy intake (AEI) and its expected energy intake (EEI) based on its maintenance and various production requirements. Due to the complexities of multifunctional (maintenance, growth, pregnancy, and lactation) energy requirements, there is no method available for evaluating individual RFI in dairy cows currently. The objective of this study is developing a statistical model to evaluate individual RFI for first lactation dairy cow. Two hundred first lactation cows were used in an experiment at the Dairy Research and Technology Center of the University of Alberta. Individual feed intake was measured daily while individual body weight and body condition score of each animal were assessed at the times of calving and each of DHI milk sampling days. Individual milk yield and composition data were obtained from the official DHI data set. The net energy required for maintenance (NE_M), lactation (NE_L), pregnancy (NE_P); energy balance (EB) and 4% fat corrected milk (FCM) traits for each animal were derived from the data. Twenty 5 alternative Legendre polynomial (LP) models were fitted for each trait with fixed (FP) and random (RP) polynomial regressions of orders from 1 to 5. The best model for each trait was selected using multiple statistical criterion. The selected model for NE_M, NE_L, EB and FCM was FP_1RP_4, FP_2RP_2, FP_1LP_4 and FP_2RP_2, respectively, where the subscript numbers stand for order of LP. An individual conversion coefficient of gained or lost energy for each animal was estimated with a simple linear regression of predicted daily FCM on predicted daily EB in the negative period while AEI on predicted daily EB in the positive period. The individual EEI is calculated as a summation of predicted NE_M, NE_L, NE_P and net gained or lost energy from that individual. The model made it feasible to evaluate dairy RFI while accounting for multi-functional energy requirements.

Key words: dairy, feed efficiency, Legendre polynomial

713 Genetic association of days open with feed intake and efficiency. J. E. Vallimont[1], C. D. Dechow*[1], J.M. Daubert[1], M. W. Dekleva[1], and J. W. Blum[2], *[1]Pennsylvania State University, University Park, [2]University of Bern, Bern, Switzerland.*

The objective of this study was to determine the genetic relationship between feed efficiency and days open in dairy cows. Dry matter intake, body weight (BW), and body condition score (BCS) were collected monthly on 970 cows in 11 tie-stall herds for 6 consecutive months and merged with test-day records. Two methods of feed efficiency were considered. Dry matter efficiency (DME) was the ratio of 305-d fat-corrected milk (FCM) to 305-d dry matter intake (DMI). Residual feed intake (RFI) was the difference between DMI and feed intake predicted from National Research Council equations. High values of RFI represent cows with lower feed efficiency. Associations of DMI, DME and RFI with days open were estimated with 5-trait

animal models that included days open, FCM, BW, BCS and either DMI, DME or RFI. Fixed effects were herd-calving-cluster, age at calving and lactation number. Random effects were animal, permanent environment and error. Analyses of DME and RFI were conducted with and without covariables for BCS and change in BCS from day in milk 5 to 60. Heritability estimates were 0.18 for DMI and DME, 0.05 for RFI, and 0.07 for days open. The genetic correlation of DMI with days open was slightly favorable (−0.15), whereas genetic correlations of days open with DME (0.68) and RFI (−1.0) were more unfavorable than the genetic correlation between days open and FCM (0.49). RFI was genetically correlated with higher BCS (0.41), whereas higher DME was genetically correlated with lower BCS (−0.68). Adjustment of RFI and DME for BCS traits had a modest effect on genetic correlation estimates with days open (−0.85 and 0.58, respectively). Genetic differences among cows for the RFI measure used in this study were small and appeared to partly reflect BCS differences among cows that were not considered in the predicted DMI equations. There were genetic differences among cows in DME, but cows that were more feed efficient were less efficient reproductively.

Key words: feed efficiency, heritability

714 A comparison of six protocols for isolation of high quality and quantity ovine genomic DNA suitable for microarray analysis. A. Psifidi[1], C. I. Dovas[2], G. Bramis[1], G. Arsenos[1], and G. Banos*[1], *[1]Department of Animal Production, Faculty of Veterinary Medicine, Aristotle University of Thessaloniki, Thessaloniki, Greece, [2]Laboratory of Microbiology and Infectious Diseases, Faculty of Veterinary Medicine, Aristotle University of Thessaloniki, Thessaloniki, Greece.*

Isolation of high quality and quantity genomic DNA is a crucial step in large-scale SNP discovery projects using microarrays. Few of the current DNA extraction procedures can be easily adapted to high-throughput operation for microarray genotyping at low cost. In this study, 6 different DNA extraction protocols were evaluated and compared for the isolation of ovine genomic DNA. Blood samples used were taken from 16 ewes of the Chios dairy breed, in 9mL K_2EDTA Vacutainer blood collection tubes. Protocols 1 and 6 were direct applications of commercial kits Nucleospin Blood and Nucleospin Blood L (Macherey-Nagel), respectively. Protocols 2 and 3 were direct applications of extraction kits Nucleospin Blood and Nucleospin Tissue (Macherey-Nagel), respectively, with a buffy coat of 9mL blood being used instead of 200µl whole blood. Protocols 4 and 5 were based on modified protocols of 2 and 3, respectively, aiming at increasing DNA recovery and purity. The key modification was the incorporation of a chloroform extraction step. Spectrophotometer measurements were used as criteria for evaluating quantity and quality (OD260/280 and OD260/230) of the extracted DNA. All samples were subjected to real-time PCR to amplify part of the PRNP gene and test the efficiency of amplification as a measure of DNA sample purity and quality. Processing time and cost were also evaluated. Extraction methods were compared using a model that included the effects of protocol and sample. The model applied separately to DNA concentration, final DNA concentration accounting for volume, OD260/280 and OD260/230. Protocol had a significant ($P < 0.05$) effect on all parameters. Protocols 4, 5 and 6 yielded the highest DNA concentration even after accounting for volume. Method 6 had the lowest values for OD260/280 and OD260/230 suggesting less pure DNA. All samples were amplified with real-time PCR. Incubation time was greater for protocols 2, 3, 4 and 5. Protocol 6 was the most expensive. Based on results, protocols 4 and 5 were selected for further application.

Key words: ovine, DNA extraction, microarrays

715 Association between the ghrelin gene with milk production traits in Murrah buffaloes (*Bubalus bubalis*). F. M. M. Gil, F. R. P. Souza, G. M. F. de Camargo*, P. D. S. Fonseca, D. F. Cardoso, R. R. Aspilcueta-Borquis, G. Stefani, and H. Tonhati, *São Paulo State University, Jaboticabal, São Paulo, Brazil.*

Ghrelin is a gastrointestinal hormone and a potent release stimulator of growth hormone (GH) in the somatotropic cells of the hypophysis and hypothalamus. It also influences the general metabolism of the body. Polymorphisms in the ghrelin gene in dairy cows were associated with milk yield, fat and protein percentage. The characterization of the ghrelin gene (GHRL) in buffaloes is important because it is a gene related to growth, carcass and milk production traits. The aim of this study was to associate a SNP in intron 2 of the GHRL gene in Murrah buffaloes with milk production traits. The SNP is a T/C substitution at position 1456 bp of GHRL. The DNA was extracted from hair of 206 dairy buffaloes from one farm in São Paulo state, Brazil. The animals were genotyped by PCR-RFLP using the restriction enzyme NcoI. For the analysis, the GLM procedure of SAS was used, the model included as fixed effects birth season, birth year and genotype and as a covariable the age of the buffalo. The possible association of the polymorphism with the phenotypic values of milk yield, protein yield, fat yield, protein percentage and fat percentage at a statistical significance of 5% was tested. Three genotypes were obtained. The genotypes CC, CT and TT have the frequencies 0.29, 0.56 and 0.19, respectively. The allelic frequencies of C and T were 0.57 and 0.43, respectively. The results indicate that there is association of the SNP with milk yield ($P = 0.0104$), fat yield ($P = 0.0045$), protein yield ($P = 0.0031$), fat percentage ($P = 0.0403$) and protein percentage ($P = 0.0368$). It indicates that the SNP may be used as a molecular marker for the traits analyzed in dairy Murrah buffaloes. However, further analyses with a bigger number of animals are necessary to confirm the results obtained.

Key words: molecular marker, SNP, PCR-RFLP

716 Relationship between horn fly infestation and polymorphisms in cytochrome P450 and prolactin promoter genes in beef cows. A. R. Boyer*[1], M. A. Brown[2], M. L. Looper[3], A. H. Brown, Jr.[1], C. D. Steelman[1], and C. F. Rosenkrans Jr.[1], *[1]University of Arkansas, Fayetteville, [2]USDA-ARS, Grazinglands Research Laboratory, El Reno, OK, [3]USDA-ARS, Dale Bumpers Small Farms Research Center, Booneville, AR.*

Individual animal variation occurs regarding external parasite infestation in beef cattle. Our objective was to determine if horn fly infestations present on beef cattle are associated with the single nucleotide polymorphism (SNP; T318C) in the cytochrome P450 gene (CYP3A28) and the prolactin (PRL) promoter gene (C1286T). Unrelated beef cows of Angus (A), Brahman (B), and crossbred (BA and AB) breed types were used, and genotyped for the T318C SNP (n = 64) and the C1286T SNP (n = 43). Cattle were on either common bermudagrass (BG) or endophyte-infected tall fescue (E+) throughout the study. Individual horn fly counts on cows were recorded for 21 wks beginning in May. Horn flies were counted by walking around each cow at a set distance of 5 to 10 m. Horn fly numbers ≤25 were counted individually, while numbers >25 were counted in groups of 5. Chemical fly control containing coumaphos was used wk 9 and 16 of the study. Genomic DNA was prepared from buffy coat, and 3 genotypes for the CYP3A28 gene and PRL promoter gene were identified. Results found an effect of week occurred for both the T318C ($P < 0.0001$) and the C1286T ($P < 0.0001$) SNP. Homozygous thymine cows (TT) for T318C SNP had greater ($P < 0.0001$) numbers of horn flies (180.1 ± 10.9 flies) than heterozygous thymine-cystine (TC; 96.7 ± 12.4 flies) and homozygous cystine (CC; 53.5 ± 35.0 flies) cows. Cows homozygous CC for the C1286T SNP had greater ($P = 0.0025$) numbers of horn flies (207.7 ± 21.6 flies) than heterozygous CT (127.9 ± 14.6 flies) and homozygous TT (87.6 ± 27.3 flies) cows. A genotype x week interaction occurred for both the T318C ($P < 0.0001$) and C1286T ($P = 0.0018$) SNP. Cattle grazing E+ tall fescue tended to have fewer horn flies than those grazing BG for both the T318C (86.2 ± 22.4 vs. 134.0 ± 12.8 flies; $P = 0.06$) and C1286T (120.0 ± 18.5 vs. 162.1 ± 17.1 flies; $P = 0.10$) SNP. Different genotypes appear to have an effect on external parasite infestation observed on beef cows, and genetic selection of cows with these SNP could improve external parasite resistance in beef cattle.

Key words: horn fly, genotype, single nucleotide polymorphism

717 Gene expression analysis and fatty acid profiling in concentrate and pasture based beef finishing systems. J. W. Buchanan*[1], A. J. Garmyn[1], G. G. Hilton[1], D. L. VanOverbeke[1], Q. Duan[2], D. C. Beitz[2], and R. G. Mateescu[1], [1]*Oklahoma State University, Stillwater,* [2]*Iowa State University, Ames.*

Expression analysis of genes involved in lipogenesis and lipid desaturation provides understanding about the genetic component controlling intramuscular fatty acid profile in different finishing systems. The health advantages of grass finished beef compared with concentrate finished beef include increased monounsaturated fatty acids (MUFA), polyunsaturated fatty acids (PUFA), conjugated linoleic acid (CLA), and an improved omega-3 to omega-6 fatty acid ratio. Intramuscular (IM) samples were taken at slaughter from 100 heifers finished on a concentrate (CO) diet and 60 heifers finished on pasture (PA). Across treatments, CO heifers had a higher hot carcass weight and higher marbling score ($P < 0.05$) than PA heifers, but no significant differences were found in frame size and fatness due to hot carcass weight, rib eye area, marbling score, and yield grade within treatment. IM fatty acid profiles were characterized using gas chromatography fatty acid methyl ester analysis and data were analyzed using the PROC GLM procedure in SAS (SAS Institute Inc., Cary, NC). IM samples were sorted into healthy and unhealthy groups based on the atheroindex (AI) ($P < 0.001$), and 10 samples from each treatment (n = 20) were selected for gene expression analysis. Differences in fatty acid profile across treatments included a higher AI, and a lower omega-3 to omega-6 ratio, lower percent PUFA, and lower percent omega-3 fatty acids in CO compared with PA ($P < 0.05$). Total RNA was extracted from each sample and gene expression was quantified in real-time using SYBR Green RT-PCR detection. Data were normalized against the geometric mean of the most stable housekeeping genes β actin and RPS15A as determined by the BESTKEEPER software. The transcriptional regulator PPAR gamma was upregulated in PA vs. CO heifers ($P < 0.05$) by 5- and 6-fold in healthy and unhealthy AI groups, respectively. Significant upregulation in PA vs. CO heifers was also detected across AI groups ($P < 0.05$), where DGAT2, ADIPOQ, and FABP4 were upregulated 3-, 7-, and 26-fold in unhealthy vs. 1-, 2-, and 7-fold in healthy samples.

Key words: fatty acid profile, gene expression, grass finished beef

718 Expression analysis of key genes of bovine fat metabolism indicated correlated trans regulatory mechanisms in a bovine resource population segregating for two major genes affecting growth and lipid deposition. Ch. Kuehn*, C. Kalbe, R. Brunner, T. Goldammer, and R. Weikard, *Leibniz Institute for Farm Animal Biology (FBN), Dummerstorf, Germany.*

Recently, the mutations NCAPG I442M and GDF8 Q204X were identified as major loci affecting growth and lipid deposition in an F2 resource population from Charolais and German Holstein. Therefore, the effects of both mutations on the expression of key genes in lipid deposition (ADIPOR1, FABP4, SCD and DGAT2) could be comparatively investigated on an identical genetic background. Additionally, genome-wide linkage studies were performed to identify further genomic loci with impact on the expression of those 4 genes involved in regulation of lipid metabolism, fatty acid transport and desaturation and triglyceride synthesis. Our study comprised 150 bulls, which had been generated by consistent application of embryo transfer during generation of the resource population and had been fed a semi ad libitum feed ration of concentrates and chaffed hay until slaughter at 18 mo of age. Tissue samples of skeletal muscle (M. longissimus) were taken immediately after slaughter and snap frozen for further gene expression analysis by quantitative real-time PCR analysis. All F2 bulls and all P0 and F1 ancestors were genotyped for the NCAPG I442M and GDF8 Q204X mutation as well as for 565 further genetic markers (SNPs, microsatellites) distributed across the entire genome. Association studies revealed a significant effect ($P < 0.05$) of the GDF8 Q204X mutation on the expression of the ADIPOR1, SCD, and DGAT2 gene. For the NCAPG I442M mutation, a significant effect was restricted to the SCD gene. This fits the previous observation that the GDF8 Q204X mutation had a larger effect on intramuscular fat deposition compared with NCAPG I442M. Further genome-wide linkage analyses searching for other QTL affecting the expression of the 4 investigated key genes of fat metabolism indicated a trans regulation of their transcription, because none of the QTL detected (most significant QTL for ADIPOR1: BTA12, FABP4: BTA22, SCD: BTA6, DGAT2: BTA1) was located on the chromosome harboring the respective target gene.

Key words: lipid deposition, eQTL, NCAPG

719 Sound and efficient designs and models for RNA-seq experiments with application in animal genomics. J. P. Steibel* and P. Reeb, *Michigan State University, East Lansing.*

Next generation RNA sequencing (RNA-seq) will become the method of choice for high throughput quantification of transcriptomes. In order for an RNA-seq experiment to produce meaningful results, a sound experimental design has to be matched with the corresponding analysis model. Consequently, the objective of this work is to introduce experimental designs and models of RNA-seq experiments with application in animal functional genomics. We separate the experimental design into 2 parts: a) the sampling scheme and b) the sequencing scheme and we show how to efficiently combine the 2 parts. Following features common across RNA-seq platforms, we consider lane effects and barcode effects as blocking factors. We show general design rules that result in efficient designs, but illustrate their use with 3 sampling schemes widely used in animal functional genomics. 1) Tissue differential expression, where RNA is extracted from T tissues in each of N animals, 2) Complete block design where K treatment are applied to N animals, but they are blocked in groups of size K and 3) Repeated measurement experiments, where K treatments are applied to each of N animals and RNA is extracted at S subsequent time points. We show sequencing schemes for the 3 experiments with or without resorting to bar coding. We present the appropriate analysis model using overdispersed Poisson likelihoods. When using a single level sampling scheme (experiments 1 and 2), publicly available R packages (e.g., edgeR, DGEseq) can be used to fit the required models. But in case of multilevel sampling designs (example 3), there is currently no software package available that would produce the required fit. We discuss alternatives (e.g., using SAS or R functions) and their main advantages and disadvantages to perform the analysis. While this technology is still novel and there are not many experimental data sets available, this paper addresses basic issues that should be considered before such data sets are generated to ensure that experimental and nuisance factors can be appropriately accounted for and disentangled to produce meaningful conclusions.

Key words: RNA-seq, experimental design, gene expression

720 Microbial and sensory evaluation of fresh Mozzarella cheese. B. Ganesan*, D. Irish, C. Brothersen, and D. J. McMahon, *Western Dairy Center, Department of Nutrition, Dietetics and Food Sciences, Utah State University, Logan.*

Commercial fresh Mozzarella cheese is made by direct acidification and stored dry or in water without salting. The cheese has a shelf life of ~6 wk, but usually develops off flavor and looses textural integrity by 4 wk, potentially due to the lack of salt that allows outgrowth of undesirable bacteria. We hypothesized that low salt promotes unwanted bacterial survival in fresh Mozzarella cheese thereby altering its quality and safety. To study the impact of salt on the microbial and sensory quality and the ability of pathogen-related bacteria to survive during refrigerated storage, we made fresh mozzarella cheese with high (2%) and low (0.5%) salt. Both cheeses were stored dry and the low salt cheese also in 0.5% brine of which one part was used for sensory evaluation and the rest for microbial studies. Consumers preferred the 1% salt dry cheese to the other cheeses ($P < 0.05$), but found no off flavors at 14 d storage in any cheese and also preferred a salad-style serving (cheese served with a cherry tomato marinated in balsamic vinegar) to fresh cheese. Descriptive panelists perceived higher levels ($P < 0.05$) of bitter, umami, brothy, and salty attributes in 1% salt dry cheese. Coliforms and psychrophiles were not detected in cheeses or brine over 9 wks. Standard plate counts remained at 100–300 cfu/gm up to 2 wks, but increased by 1,000–10,000-fold ($P < 0.05$) between 4 and 6 wks in all cheeses independent of salting, and coincides with the observed reduction in cheese quality. This showed that 2% salt was insufficient to control bacterial growth, and that slow-growing, cold- and salt-tolerant bacteria may survive and spoil fresh mozzarella cheese. *E. coli* and *Enterococcus faecalis* added to the 3 cheeses also increased by 100-fold ($P < 0.05$) over 90 d of storage. Interestingly, *E. coli* added to the cheese brine first grew in the brine by 100-fold ($P < 0.05$) before attaching to the cubes, whereas *Ent. faecalis* attached to the curd within 24 h and grew only in the cubes. These observations suggest that incident bacteria may survive and attach to curd by different mechanisms in fresh mozzarella cheese that need to be collectively addressed to reduce pathogen survival and spoilage.

Key words: fresh Mozzarella, safety

721 CheddarCyc: A database of Cheddar cheese flavor reactions and pathways. B. Ganesan* and K. Brown, *Western Dairy Center, Department of Nutrition, Dietetics and Food Sciences, Utah State University, Logan.*

Cheese flavor is a summation of all microbial enzymatic and chemically spontaneous reactions that sugars, proteins, and lipids and their degradation products undergo during cheese aging. To understand cheese flavor development mechanisms attributable to bacteria we currently host and actively maintain metabolic pathway databases for LAB involved in cheese flavor generation at the ProCyc webserver (www.usu.edu/westcent/procyc). However the flavor-related pathways are scattered among the individual bacterial databases, which also contain metabolic routes that do not generate flavor compounds. Alternately, a large number of chemical reactions that are not captured in bacterial metabolic databases, either spontaneous or yet unattributed to enzymes, also participate in flavor compound production. In the current format, metabolic databases do not unify the diverse routes of cheese flavor compound generation. To that end, we created a cheese flavor enzymatic and chemical reaction database that links uncharacterized compounds and their reactions to flavor development and microbial metabolism and additionally contains selected flavor compound-generating metabolic pathways of bacteria. The database called "CheddarCyc" contains information on ~100 known Cheddar cheese flavor compounds based on current knowledge from literature. Key mechanisms of flavor generation such as carbohydrate metabolism, amino acid metabolism related to Arg, aromatic, sulfur, and branched chain amino acids, mechanisms of free fatty acid generation, and individual reactions demonstrated in literature are connected together. The database provides a chemical context in our ongoing effort to define flavor profiles of Cheddar cheese. Similar databases that are specific to flavor compounds found in other cheeses can be reconstructed relatively quickly using this mechanism. This provides us a resource to comprehensively tackle flavor generation routes and discover solutions to preexisting issues on Cheddar cheese flavor chemistry and enzymology. CheddarCyc will be publicly available at ProCyc and will eventually house the vast majority of Cheddar cheese flavor compound reactions proposed to date.

Key words: Cheddar cheese, flavor, metabolism

722 New approaches to understand cheese ripening. S. Lortal*[1,2], V. Gagnaire[1,2], S. Jeanson[1,2], J. Floury[1,2], and M.-N. Madec[1,2], *[1]INRA, UMR1253, STLO, Rennes, France, [2]Agrocampus-Ouest, UMR1253, STLO, Rennes, France.*

Cheese ripening is usually described in terms of kinetics of proteolysis, lipolysis and aroma compound production, which provides an averaged view of ripening. However, after milk inoculation and rennet action, bacteria are immobilized as colonies into the curd and grow as such. This colonial distribution is a reality in all kind of cheeses. The efficiency of bacteria within these colonies to act on dairy matrices (gene expression and activity of the enzymes produced) will thus depend on local physico-chemical conditions, matrix structure, diffusion limitations and inter-colony distance. The ambition of our team is to understand the ripening mechanisms in situ at a microscopic scale level, considering the colonial distribution. For that purpose, the following fields were explored: i) to characterize the spatial distribution of bacterial colonies according to the level of inoculation by mathematical modelization and by in situ validation using confocal laser microscopy (Jeanson et al., 2011 Appl. Environ. Microbiol. doi:10.1128/AEM.02233-10); ii) to estimate the diffusion rate of small solutes in dairy matrices differing in composition and microstructure. Indeed diffusion of water and salt were extensively characterized (Floury et al., 2010 Dairy Sci. Technol. 90:477–508) but not the diffusion of small solutes which are crucial for the bacterial metabolic activity and the ripening reactions. Moreover, the impact of cheese composition and microstructure on this diffusion is far from being well understood. The diffusion coefficient of a small solute was estimated for the first time by a noninvasive way within a cheese matrix using new imaging approaches, the Fluorescence Recovery After Photobleaching and using fluorescent 4 and 20 kDa dextran molecules. iii) to reveal in situ bacterial enzymes within and around the colonies immobilised in cheese. Cell wall protease and intracellular peptidases were first detected in situ by immunofluorescent antibodies and confocal microscopy.

Key words: cheese ripening, bacterial colony, diffusion of solutes and enzymes

723 In situ proteolytic activity of *Lactobacillus helveticus* and stretchability of Swiss-type cheese. L. Sadat-Mekmene[1,2], R. Richoux[3], L. Aubert-Frogerais[3], M.-N. Madec[1,2], C. Corre[1,2], M. Piot[1,2], J. Jardin[1,2], S. Lortal*[1,2], and V. Gagnaire[1,2], *[1]INRA, UMR1253, STLO, Rennes, France, [2]Agrocampus Ouest, UMR1253, STLO, Rennes, France, [3]Actilait, Rennes, France.*

In contrast to other lactic acid bacteria, *Lactobacillus helveticus* can possess 2 cell-envelope proteinases (CEPs) called PrtH2 and PrtH (Genay et al. 2009, Appl. Environ. Microbiol.. 75:3238–3249; Sadat et al. 2011a, in press Int. J. Food Microbiol.). These CEPs exhibit different cleavage specificity on pure αs1-casein (Sadat-Mekmene et al., 2011b, Appl. Environ. Microbiol. 77(1) 179–186). The aim of this work was to investigate the proteolytic activity of *L. helveticus* strains in cheese matrix according to the number of their CEPs and the cheese stretchability. Two strains were selected, ITGLH77 and ITGLH1 which possess one CEP, PrtH2, and 2 CEPs, PrtH and PrtH2, respectively. The proteolysis was monitored during ripening: i) casein hydrolysis by urea-PAGE; ii) peptide pattern of the cheese aqueous extracts first by SDS-PAGE and second by RP-HPLC. Three chromatographic fractions were collected and peptides identified by RP-HPLC coupled on-line with tandem mass spectrometry. In parallel, the dynamic of stretchability of Emmental cheese was measured to determine the contribution of CEPs in its generation, since *L. helveticus* is known to enhance stretching properties in contrast to other lactobacilli, such as *L. delbrueckii* ssp. *lactis*. The microstructure of the strands of Emmental cheeses was observed by confocal laser scanning microscopy. The stretchability of Emmental was significantly higher in cheese manufactured with strain ITGLH77. By using Principal Component Analyses, the stretching properties were found to be correlated with the presence of peculiar peptides derived from primary proteolysis, hydrophobic peptides, containing more than 20 amino acid residues and derived from αs1-casein, which were accumulated in cheese manufactured using strain ITGLH77. The presence of these peptides suggest their less hydrolysis by this strain, in agreement with results observed in vitro (Sadat-Mekmene et al., 2011b), namely different cleavage specificity of CEPs PrtH et PrtH2 on pure αs1-casein.

Key words: cell envelope proteinase, *Lactobacillus helveticus*, Swiss-type cheese stretchability

724 Influence of Hofmeister salts on the textural and rheological properties of nonfat process cheese. J. A. Stankey* and J. A. Lucey, *University of Wisconsin, Department of Food Science, Madison.*

Hofmeister salts (HS) weaken or strengthen hydrophobic interactions of proteins resulting in salting in or salting out, respectively. Hydrophobic interactions also play a key role in casein particles and gels. In process cheese manufacture emulsifying salts (ES) are used to chelate Ca and disperse the insoluble casein matrix while heating. Since HS modify hydrophobic interactions we investigated the impact of HS on textural and rheological properties of nonfat process cheese (NFPC) made without ES. A directly acidified nonfat cheese base was made with citric acid (pH 5.6) and ripened for 7 d. Cheese was shredded and frozen until use. Two levels (0.1 or 0.3 M) of chaotropic (NaSCN) or kosmotropic (Na_2SO_4, NaCl) types of HS were blended with thawed, nonfat cheese. Cheese and HS were heated in a waterbath to 85°C and mixed using an overhead stirrer (6 min). Molten cheese was poured into plastic molds, sealed and stored (4°C) for 7 d before analysis. Small amplitude oscillatory rheological properties were measured while heating from 5 to 85°C. Moisture contents and pH of NFPC were ~55% and ~5.8, respectively. Calcium concentrations (475 mg/100 g) were similar in all NFPC. Sulfur content increased in NFPC made with increasing concentrations of NaSCN or Na_2SO_4. The NFPC made with 0.3 M NaSCN were shiny, stickier, had lower hardness, higher LT values (indicating higher meltability) and melt occurred at lower temperatures than other treatments. The NFPC made with 0.3 M Na_2SO_4 were tough, very viscous, had increased hardness values and lower LT values (less meltable). At 0.3 M concentrations, hardness increased in cheeses in the following order: NaSCN < NaCl < Na_2SO_4. Cheeses made with 0.3 M NaCl or Na_2SO_4 lost water during processing. Hydrophobic interactions increase with temperature during manufacture; the addition of kosmotropic HS strengthened these interactions resulting in "salting out" (water loss) and a firmer (less meltable) NFPC. Addition of chaotopic HS reduced hydrophobic interactions and resulted in weakened protein-protein bonds and thus created a softer (more meltable) NFPC network.

Key words: rheology, Hofmeister series, nonfat process cheese

725 Impact of reforming on low-fat cheese texture as influenced by pH. C. Akbulut* and J. A. Lucey, *Department of Food Science, University of Wisconsin, Madison.*

Grating of cheese and repressing it to "reform" its shape is an approach that could be used to improve the texture of excessively firm low-fat cheese. Our objective was to study the impact of pH on the properties of low-fat cheese that was reformed after grinding. Low-fat cheese bases having 4 different pH values were produced by direct acidification of milk to pH 6.2 with citric acid and altering the final pH by the addition of glucono-δ-lactone (0, 0.1, 0.3 and 0.4%) to curd, to obtain cheeses with pH values 6.2, 5.8, 5.5 and 5.3, respectively. Cheeses were stored for 2 wk at 4°C, and then ground and reformed by pressing ground cheese into plastic cups using a laboratory hydraulic press for 1 h at 20°C. They were kept at 4°C overnight and then removed from plastic cups, vacuum-sealed and stored for 1 wk before analysis. Hardness was determined at 80% compression. Dynamic moduli and loss tangent was measured during heating from 5 to 85°C. Melt profiles were obtained by the UW-Melt Profiler. Acid-base titrations were used to determine the amount of residual insoluble Ca in cheese. Reforming low-fat cheese reduced its hardness at all pH levels, however the decrease in hardness of high pH cheese was much greater than the decrease obtained when low pH cheese was reformed. As a result, the relatively harder texture of high pH low-fat cheese was softened to a level that could also be accomplished by pH reduction. Meltability increased slightly as a result of reforming. Fluorescence microscopy was used to observe the fusion in the contact region between 2 cheese slices that were held together at 4°C for 1 wk. The pH 6.2 cheese slices remained intact (little fusion). Reducing the cheese pH resulted in a greater fusion between slices. With a decrease in cheese pH, there was a decrease in the insoluble Ca content; cheese became more meltable and softer making it easier to reform. These results showed that reforming cheese with a lower pH didn't alter the texture as much as at high pH since most bonds appeared to reform on storage at low pH. The rubbery and firm texture of the low-fat cheese made at high pH was improved by reforming as the texture became shorter and softer.

Key words: low-fat cheese, texture, pH

726 Recovery of ω-3 fatty acids in Cheddar cheese curd and long-term stability of ω-3 fatty acids in whey powder. B. Ganesan*, C. Brothersen, and D. J. McMahon, *Western Dairy Center, Depart-*

ment of Nutrition, Dietetics and Food Sciences, Utah State University, Logan.

Full-fat Cheddar cheese was made with milk fortified with ω-3 fatty acids and the partitioning of ω-3 fatty acids into curd and whey was determined, along with flavor attributes of ω-3 fatty acid-containing whey powder over storage. ω-3 fatty acids from both animal and plant sources were incorporated into the milk. The encapsulated powder was added to cheese milk or the milled curd during dry salting. The oil form of ω-3 fatty acids was either mixed or homogenized oil in milk or cream, wherein the homogenized milk and cream constituted 10% of fat in cheese milk. The recovery of ω-3 fatty acids from the animal source was 90.5%, significantly higher ($P < 0.05$) than that of the plant source (80.3%). Homogenization provided similar recoveries of ω-3 fatty acids (90–93%, $P > 0.05$) for the 2 sources, whereas homogenized treatments were significantly different from non-homogenized treatments (79–83%, $P < 0.05$). Addition of encapsulated ω-3 fatty acids to the cheese curd during salting provided higher recovery (91–99%, $P < 0.05$) for both animal and plant sources and was the most efficient method of fortifying Cheddar cheese with ω-3 fatty acids. Whey collected during cheese making from the various fortification treatments was further dried into powder using a drum dryer and stored for 9 mo at 4°C or room temperature (18–22°C) to study changes in attributes perceived by a descriptive panel. Sweet taste was perceived higher ($P < 0.05$) at 3, 6, and 9 mo than at 0 mo and perceived at varying levels across the different cheese milk treatments. Bitter, salty, sour, brothy, cooked, and lactone/fatty acid flavor attributes were only perceived higher at 0 and 3 mo; whereas fishy flavor was discerned only at 6 and 9 mo, with all ω-3 fatty acid-incorporated whey powders scoring higher than the unincorporated control ($P < 0.05$). Notably, panelists scored the whey powders similarly for other attributes despite the whey powders containing different levels of ω-3 fatty acids. Commercial preparations of ω-3 fatty acids appear to be prone to develop off flavors in whey powder and lose acceptability during long-term storage.

Key words: Cheddar cheese, omega-3 fatty acids, whey powder

727 Rheology, microstructure and quality of curd made from buffalo milk: A comparison with ultrafiltered cows' milk. I. Hussain*, A. S. Grandison, and A. E. Bell, *Department of Food and Nutritional Sciences, University of Reading, Reading, Berkshire, UK.*

Rennet induced curds were made from buffalo, cows' and ultrafiltered cows' milk (UF cows' was concentrated such that it has chemical composition approximately equivalent to buffalo milk). These milk samples were compared on the basis of rheology, physicochemical characteristics and curd quality. The ionic and soluble calcium contents were similar in all milk samples. The total and casein bound calcium were higher in UF cows' milk than untreated cows' milk, and found to be lower than in buffalo milk. This is due to concentration of colloidal part of milk (casein) during the ultrafiltration process. The rennet coagulation time was almost the same in UF cows' and buffalo milk while it was higher in cows' milk. The dynamic moduli (G', G") values were higher in buffalo and UF cows' milk than cows' milk 90 min after chymosin addition. The loss tangent was the same in UF cows' and buffalo milks and has a lower value as compared with cows' milk. The frequency profile (0.1–10Hz) was recorded 90 min after the enzyme addition; all of treated samples found to be weak viscoelastic frequency dependent gel. The cows' curd was weaker (dynamic moduli) than buffalo and UF cows' curds. The yield stress was measured 95 min after the enzyme addition, and attained a higher value in buffalo milk as compared with other milk samples. The curd yield, curd moisture and curd fat retention were found to be higher in UF cows' milk than for buffalo and cows' milk. The minimum whey fat losses occurred in UF cows' milk. The total mineral contents were also higher in UF cows' milk than in the buffalo and cows' milk. The electron micrographs showed that sizes of casein micelles and fat globule were different in the 2 types of milk. The curd structure appeared to be more "dense" in buffalo milk than cows' milk.

Key words: rheology, curd, ultrafiltration

728 Effect of milk processing on the MFGM proteins and phospholipids. X. ElÍas-Argote* and R. Jiménez-Flores, *California Polytechnic State University, San Luis Obispo.*

MFGM phospholipids (PLs) and proteins have been ascribed antimicrobial and antiviral properties, as well as anticancer and antihypercholesterolemic activities. However, few studies have highlighted the effects of processing on the MFGM constituents and the repercussion it may have on their functionality. In this study, we have applied analytical and proteomic techniques to analyze the protein and lipid profile in the MFGM throughout milk processing. Milk was collected/treated at 6 different points: before reaching the storage unit (35°C), storage temperature (4°C), batch, high temperature short time (HTST), and ultra high temperature (UHT) pasteurizations, and by pulsed light treatment. MFGM proteins were analyzed using 1D and 2D-PAGE and LC-MS. Over 117 proteins were identified using HPLC-MS, and their relative quantities at different motilities in the SDS gel were analyzed using Scaffold 3 and Delta2D_4. As the heat treatment increased, more protein aggregates were observed, especially in the UHT milk, where caseins, lactoferrin, and guanine nucleotide-binding proteins were detected in the high molecular weight region (>150 kDa). Also, low heat at a prolonged time (63°C, 30min) resulted in more MFGM proteins being released into the skim milk. In addition, the protein profile for the light pulse treatment was similar to the 4°C and HTST samples. In contrast, variation in the phospholipid composition of the membrane throughout milk processing was not statistically significant ($P > 0.05$). From this study, the best method to preserve milk bioactivity might be HTST, which reduces pathogenic microorganisms and still preserves most of the MFGM proteins. In regard to functionality, formation of aggregates might reduce the full potential of a nutraceutical MFGM protein, thus more studies are needed to create processing methods that retain the proteins' native state, including the consideration of pulsed light treatment as a new pasteurization method.

Key words: MFGM, proteomics, phospholipids

729 Focus on milk fat globule membrane proteins from goat milk. C. Cebo*[1], C. Henry[2], S. Truchet[3], F. Bouvier[4], H. Caillat[5], and P. Martin[1], *[1]INRA, UMR1313 Unité Génétique Animale et Biologie Intégrative, Jouy-en-Josas, France, [2]INRA, Plateforme PAPSSO (Plateforme d'Analyse Protéomique Paris Sud Ouest), F-Jouy-en-Josas, France, [3]INRA, Unité Génomique et Physiologie de la Lactation, Jouy-en-Josas, France, [4]UE332 Domaine de Bourges, Osmoy, France, [5]INRA, UR631 Station d'Amélioration Génétique des Animaux, Castanet-Tolosan, France.*

Fat is present in milk as droplets of triglycerides surrounded by a complex membrane deriving from the mammary epithelial cell and called the Milk Fat Globule Membrane (MFGM). In-depth proteomic studies have been published for bovine MFGM proteins. However, to date, only sparse studies exist on MFGM proteins from non-cow milks. The objective of this study was thus to investigate the protein composition of the goat Milk Fat Globule Membrane. MFGM proteins from goat milk were separated by 6% and 10% SDS-PAGE and Coomassie or Periodic Acid / Schiff (PAS) stained. Most of MFGM proteins (mucin-1, fatty acid synthase, xanthine oxidase, butyrophilin, lactadherin and adipophilin) already described in cow milk were identified in goat milk using peptide mass fingerprinting. A prominent difference between the cow and the goat species was demonstrated for lactadherin. Indeed, we have shown that lactadherin from goat milk appears as a single polypeptide chain in 6% SDS PAGE whereas 2 polypeptide chains are easily identified in cattle. In addition, goat MFGM proteins were subjected to 1D-LC-MS/MS (one dimensional gel coupled to tandem mass spectrometry) analysis. Twenty-five µg MFGM proteins were separated in 10% SDS-PAGE and Coomassie stained. The lane was divided in 20 slices and each slice was digested by trypsin and subjected to LC/MS/MS analysis. This approach led us to identify - with at least 2 unique peptides (Bos Taurus Database)- more than 160 proteins associated with the goat Milk Fat Globule Membrane. Interestingly, integrative analysis of MFGM-associated proteins using DAVID Bioinformatics Resources demonstrated that identified biological processes are not only connected with lipid metabolic processes or exocytosis-related biological processes, but also with G-protein receptor signaling pathway, translation, or regulation of apoptosis, as previously demonstrated for MFGM proteins from bovine milk. These findings may help in the understanding of lipid droplet formation in the goat species, where an apocrine mechanism for milk secretion is hypothesized.

Key words: milk fat globule membrane, goat, lactadherin

730 Identification of major milk fat globule membrane proteins from pony mare′s milk highlights the molecular diversity of lactadherin across species. C. Cebo*[1], E. Rebours[1], C. Henry[2], S. Makhzami[1], P. Cosette[3], and P. Martin[1], *[1]UMR1313 Unité Génétique Animale et Biologie Intégrative, Jouy-en-Josas, France, [2]INRA, Plateforme PAPSSO (Plateforme d'Analyse Protéomique Paris Sud Ouest), Jouy-en-Josas, France, [3]UMR6270 CNRS, Université de Rouen, Plateforme Protéomique de l'IFRMP23, Mont-Saint-Aignan Cedex, France.*

Although numerous studies have been devoted to the soluble fraction, namely caseins and whey proteins, to date, little is known about the milk fat globule membrane (MFGM) fraction from mare′s milk. Using mass spectrometry, most of MFGM already described in cow or goat milks were identified in mare′s milk. Prominent differences through species were highlighted for lactadherin. Indeed, whereas one or 2 polypeptide chains are respectively identified by peptide mass fingerprinting matrix-assisted laser desorption/ionization-time of flight (PMF MALDI-TOF) analysis for caprine and bovine lactadherin, lactadherin from mare′s milk appears as 3 polypeptide chains in 6% SDS PAGE. Digestion of MFGM proteins from mare′s milk with Peptide N-glycosidase F (PNGase F) revealed that the existence of 3 distinct polypeptide chains for equine lactadherin could not be solely explained by differential N-glycosylation of a single polypeptide chain. On the other hand, polymerase chain reaction (PCR) experiments on lactadherin transcripts isolated from milk fat globules revealed that splicing events occur on lactadherin from mammary gland with the existence of 2 distinct lactadherin transcripts in the horse species. Cloning and sequencing of both lactadherin transcripts revealed the existence of a cryptic splicing site usage located at the end of exon 5 of equine lactadherin and liquid chromatography coupled to tandem mass spectrometry (LC-MS/MS) analyses confirmed the existence of 2 lactadherin variants in the MFGM from mare′s milk. Interestingly, this cryptic splicing event led to the suppression of a putative N-glycosylation site in the protein. Whatever, we demonstrate here that expression of lactadherin is species-dependent, therefore questioning about of the precise function of these different isoforms in mammary gland biology across species.

Key words: milk fat globule membrane, lactadherin, cryptic splicing site

731 Effect of methane emission reducing diet on coagulation properties of bovine milk. A. Aprianita*[1], O. N. Donkor[1], P. J. Moate[2], M. J. Auldist[2], J. S. Greenwood[2], W. J. Wales[2], and T. Vasiljevic[1], *[1]School of Biomedical and Health Sciences, Faculty of Health, Engineering and Science, Victoria University, Melbourne, Victoria, Australia, [2]Department of Primary Industries, Ellinbank, Victoria, Australia.*

The effects of methane emission reducing diets on coagulation properties of bovine milk were investigated. The treatment diets included supplementation with fat, tannin or combination of fat and tannin to a normal diet which also served as a control. The obtained milk samples were skimmed, standardized (C/*F* = 0.7), homogenized (25 MPa), and heat treated (60°C; 30 min). Subsequently, glucono-delta-lactone (GDL) (2.2%) or commercially available rennet (0.2 mL/L) was added to induce gel formation. For rennet-gel, calcium chloride (0.02%) was added before rennet addition. Both types of gel were analyzed for rheological parameters (small amplitude oscillatory and large deformation), syneresis, permeability, and microstructural characteristics. This study indicated that fat or tannin supplementation could improve gelatinization characteristics of acid milk gel by increasing storage modulus (G'), gel hardness and reducing time of gelatinization. Addition of tannin enhanced the elastic property of gel greater in comparison to that of fat; while combination of fat-tannin did not alter G' value. Supplementation of fat, tannin, or combination of fat and tannin slightly increased syneresis of acid milk gel. This was confirmed by shift angle and permeability values. The presence of fat during rennet induced coagulation had a substantial impact on the properties of the gel. Addition of fat alone or in combination with tannin increased G' and reduced gelation time. In contrast, tannin supplementation impaired gelatinization by reducing G' and increasing gelation time. All types of diet also slightly increased syneresis of milk gel, with tannin giving the highest impact. This study showed that milk obtained from cows fed a methane emission reducing diet had altered coagulation properties that were apparently dependent on the supplement.

Key words: methane emission reducing diet, milk properties, coagulation

732 Development of a method to determine the susceptibility of raw milk to oxidation. J. K. Amamcharla* and L. E. Metzger, *Midwest Dairy Foods Research Center, Dairy Science Department, South Dakota State University, Brookings.*

The initial quality of raw milk plays a critical role in the consumer acceptability of pasteurized milk. In recent years especially in the Midwest region, numerous cases have been reported where pasteurized milk is susceptible to spontaneous oxidation. The objective of the present work was to investigate the applicability of Ferric Reducing Antioxidant Power (FRAP) assay for identification of raw milk that are susceptible to oxidation. In this study, the FRAP assay was modified for analysis of raw milk. A FRAP working reagent consisting of 300 mmol/L of acetate buffer (pH 3.6), 20 mmol/L of ferric chloride, and 10 mmol/L of 2, 4, 6-tripyridyl-s-triazine made up in 40 mmol/L of hydrochloric acid was used. All 3 solutions were mixed in the ratio 10:1:1. To measure the FRAP value, 0.3 mL of milk was mixed with 4.5 mL of FRAP reagent and incubated at 37°C for 4 min. After the incubation, the sample was filtered using a 0.45µm syringe filter to remove precipitated protein. Absorbance at 593 nm was measured on the filtrate relative to the FRAP reagent as a blank. The FRAP value was calculated using ferrous sulfate calibration standards (50–600µ mol/L). Raw milk samples were collected from 6 individual cows. Each of the 6 samples was divided into 4 sub-samples. Three of the sub-samples were spiked with either 0.1 ppm of copper, 7.5 IU/quart of vitamin E, or both. The remaining fourth sub-sample served as a control. Each of the sub-samples was again divided into 3 equal parts and kept refrigerated. On each experimental day, one sub-sample was withdrawn and analyzed using the FRAP assay. The data was analyzed as repeated measures design using the GLM procedure in SAS. The treatment (presence or absence of copper or vitamin E), time and their interaction significantly ($P \ll 0.05$) influenced the FRAP value of raw milk. Moreover, the average percent reduction in FRAP value by the end of 48 h was found to be 27, 54, 28, and 47% for control, copper, vitamin E, and copper + vitamin E spiked samples, respectively. Overall the FRAP assay shows potential in the identification of milks susceptible to oxidation.

Key words: milk oxidation, ferric reducing antioxidant power (FRAP)

733 Measurement of a milk gelation time constant using laser-scanning fluorescence confocal microscopy and image processing techniques. R. Hennessy*[1] and R. Jimenez-Flores[2], *[1]Cal Poly Biomedical Engineering, San Luis Obispo, [2]Cal Poly, DPTC, San Luis Obispo.*

The gelation kinetics of milk can dictate how nutrients are absorbed after ingestion and are therefore important when determining the nutritional benefit of a dairy product. Current methods to measure gelation kinetics, such as near-infrared spectroscopy and rheology, are destructive and only provide one-dimensional data, while other methods, such as the Berridge clotting time method, are subjective because they depend on an operator's skill. A 2-dimensional, non-destructive, objective measurement technique is needed to accurately quantify the gelation kinetics of milk. The purpose of the present study was to investigate the ability of laser-scanning fluorescence confocal microscopy (LSFCM) to measure gelation kinetics. In this study, a mixture of raw milk and chymosin was imaged using LSFCM. The milk was stained with the fluorescent markers Nile red, which stains lipids, and fast green FCF, which stains proteins. Once chymosin was added to the raw milk, images were captured every 5 seconds for 30 minutes. Because gelation causes the milk to change from a liquid to a solid, the instantaneous gelation rate could be estimated by calculating the mean difference between successive images (R). As the milk begins to gel, the movement of the lipids and proteins eventually ceases, and the mean difference between successive frames eventually reaches zero. R was plotted versus time and fit to the curve B=e exp-kT[Ch]t, where B is the initial value of R, T is the temperature of the milk at the time the images were acquired, [Ch] is the concentration of chymosin, t is the time, and k is the gelation time constant of the milk. The gelation time constant, k, was then used to characterize the gelation kinetics. Because this method is able to account for the initial rate of the gelation process, the chymosin concentration, and the temperature when calculating the gelation time constant, it shows promise as a technique to measure and compare the intrinsic gelation characteristics for different milk varieties.

734 Mid-infrared predictions of lactoferrin content in bovine milk. H. Soyeurt*[1,2], C. Bastin[1], F. Colinet[1], V. Arnould[1,3], D. Berry[4],

E. Wall[5], N. Gengler[1,2], P. Dardenne[6], and S. McParland[4], *[1]University of Liège, Gembloux Agro-Bio Tech, Animal Science Unit, Gembloux, Namur, Belgium, [2]National Fund for Scientific Research, Brussels, Brussels, Belgium, [3]CONVIS Herdbuch, Ettelbruck, Luxembourg, [4]Animal and Grassland Research and Innovation Centre, Teagasc, Fermoy, Cork, Ireland, [5]Animal and Grassland Research and Innovation Centre, Teagasc, Penicuik, Midlothian, UK, [6]Agricultural Walloon Research Centre, Quality Department, Gembloux, Namur, Gembloux.*

Lactoferrin (LF) is a glycoprotein present in milk and active in the immune system of cows and humans. Therefore, an inexpensive and rapid analysis to quantify this protein is desirable. A previous study reported the potential to quantify LF from the mid-infrared (MIR) spectrometry from 69 milk samples. Through the European Robust-Milk project (www.robustmilk.eu), 3,606 milk samples were collected in Belgium, Ireland, and Scotland from individual cows and analyzed using a MIR MilkoScanFT6000 spectrometer. Milk LF content was quantified using ELISA in duplicate. Average ELISA data with a CV lower than 5% were used. After the detection of spectral and ELISA outliers, the calibration set contained 2,499 samples. An equation to predict LF content from MIR was developed using partial least squared regression. A first derivative pre-treatment of spectra was used to correct the baseline drift. To improve the repeatability of the spectral data, a file which contained the spectra of samples analyzed on 5 spectrometers was used during the calibration. The lactoferrin mean was 159.28 mg/l of milk with a SD of 97.21 mg/l of milk. The calibration (C) coefficient of determination (R^2) was equal to 0.73 with a standard error (SE) of calibration of 50.54 mg/l of milk. A cross-validation (CV) was used to assess the robustness of the equation. R^2 CV was 0.72 with a SE-CV of 51.16 mg/l of milk. An external validation (V) was conducted on 150 milk samples collected in Belgium. The SE of prediction (SEP) was 59.17 mg/L of milk. The similarity between R^2 C and R^2CV as well as between SE-C and SE-CV and between SE-CV and SEP confirms the equations developed are robust. The correlation between predicted and measured LF values was 0.71. This lower value compared with the one obtained from the calibration set (0.85) could be explained by the low ELISA reproducibility (16.24% ± 25.51%). If the developed equation is used to clean the validation data set, a total of 16 samples can be deleted. The validation coefficient for these 134 samples increased to 0.82. From these results, the developed equation could be used for screening the dairy cow population for breeding purposes.

Key words: milk, lactoferrin, infrared

735 First assessment of diffusion coefficients in model cheese by fluorescence recovery after photobleaching (FRAP) analysis. J. Floury*[1,2], M. N. Madec[2], M. H. F. Famelart[2], S. Jeanson[2], and S. Lortal[2], *[1]Agrocampus Ouest, UMR1253, Rennes, France, [2]INRA, UMR1253, Rennes, France.*

In cheese technology, mass transfer of solutes like salt, moisture and metabolites, is very important for the final quality of cheese, through the control of the brining and ripening processes. Numerous studies have reported salt and water transfer in cheese, but very few have dealt with the mass transfer properties of other solutes in cheese. Most of the reported diffusion coefficients have been obtained by macroscopic and destructive methods. The objective of the study was to develop, for the first time, the FRAP technique that allows in situ measurements of diffusion properties at the microscopic scale inside cheese. The effect of the matrix microstructure on mass transfer properties of small solutes was also studied. A model matrix based on ultrafiltrated milk, mimicking soft-type cheese, was used. Its structure was modified by adding gelatine and analyzed by confocal microscopy and rheological measurements. Two different sizes of FITC-dextran molecules (4 and 20 kDa) were chosen as models of small migrant solutes. Diffusion coefficients were estimated with a new modeling approach which allows to take into account diffusion of the molecules during the bleach phase. The two FITC-dextrans were able to migrate in the model cheese network, but their mobility is reduced compared to water: diffusion coefficient values were equal to 68 ±9 $\mu m^2/s$ for the 4kDa and 23±3 $\mu m^2/s$ for the 20kDa dextran. The composition of the matrix has a great influence on the mass transfer properties. The diffusion coefficients of the dextrans were reduced by a factor 3 in the model cheese with gelatin. This result was explained by structural measurements: gelatin led to a more heterogeneous microstructure than the UF model cheese that increased the global length path of the migrating solutes. This study shows the power and the potentiality of the FRAP technique to study mass transfer properties of fluorescent solutes in complex food matrices such as cheeses.

Key words: mass transfer, FRAP, modeling

736 Repeated transport influences feed intake, but not feed efficiency in Holstein calves. A. L. Adams*, G. A. Holub, T. H. Friend, A. J. Krenek, S. M. Garey, C. L. Terrill, and M. J. Carter, *Texas A&M University, College Station.*

Previous studies have determined that stress causes decreases in feed intake and efficiency in cattle, but the effect of repeated transport on these parameters has not been well studied. This study determined how repeated transport affected feed intake and growth in calves. Thirty-six 4-mo-old Holstein steer calves were housed in groups of 6 with each group randomly assigned to either transport (T) or control (C) treatments. Each calf was assigned to an individual feed bunk and feed intake was recorded daily. Transported and control calves did not have access to feed during treatment. Calves were transported for 6 h in their group of 6 in a 7.3 m x 2.4 m goose-neck trailer divided into 3 compartments, at an average density of 0.87 m^2/calf, every 7 d for 5 consecutive wk. Feed intake was analyzed as a repeated measure in an autoregressive covariance mixed model ANOVA. Average daily gain (ADG) and feed efficiency were analyzed using a diagonal mixed model ANOVA. Control calves had a higher feed intake than transported calves overall (C: 7.29 ± 0.23 kg, T: 6.91 ± 0.23 kg, P = 0.012), on the day of treatment (C: 6.78 ± 0.43 kg, T: 6.01 ± 0.43 kg, P = 0.0074), and the day after treatment (C: 7.83 ± 0.45 kg, T: 7.08 ± 0.45 kg, P = 0.015). On days of treatment, feed intake for transported calves significantly decreased during wk 2, but increased with each successive transport (P < 0.0001). Overall, control calves had higher ADG than transported calves (C: 1.53 ± 0.12 kg/day, T: 1.36 ± 0.12 kg/day, P = 0.024). The largest difference in ADG occurred during wk 2 (C: 1.69 ± 0.41 kg/day, T: 1.10 ± 0.41 kg/day, P = 0.031). Transported calves tended to have decreased feed efficiency during wk 2 and 3, but increased feed efficiency during wk 4 and 5 (P = 0.072). These results suggest that calves exposed to repeated transport may decrease feed intake as an initial response to stress, however, overall feed efficiency is not affected and calves may quickly acclimate to repeated transport.

Key words: calf, feed intake, transport

737 Effects of serum protein-based arrival formula and serum protein supplement (Gammulin) on plasma metabolites in transported dairy calves. A. Pineda*[1], J. K. Drackley[1], J. M. Campbell[2], and M. A. Ballou[3], *[1]University of Illinois, Urbana, [2]APC Inc., Ankeny, IA, [3]Texas Tech University, Lubbock.*

Adequate nutrition is important to provide all nutrients for proper health and growth of young calves, especially in the presence of stressors like cold and transport. Serum protein products have been proposed to improve health and diminish effects of stress in dairy calves. Previously we reported that a commercial serum protein supplement (G; Gammulin, APC Inc.) in milk replacer decreased mortality (P = 0.007) in transported male calves. The aim of this portion of the study was to assess the effects of a serum protein-based arrival formula (AF) and use of G in milk replacer on plasma indicators of nutritional adequacy and acute-phase response. Nine-3 male Holstein calves were stratified by arrival BW and plasma protein, and then randomly assigned to 1 of 4 treatment groups. Treatments were 1 = control electrolyte, milk replacer with G (n = 24); 2 = control electrolyte, milk replacer without G (n = 25); 3 = AF, milk replacer with G (n = 22); and treatment 4 = AF, milk replacer without G (n = 22). At first feeding, calves were fed either AF or a control electrolyte solution. Six h later, all calves received either a commercial calf milk replacer (20% CP, and 20% fat; no G supplementation) or the same milk replacer supplemented with G (50 g/d during the first 14 d only). Blood samples were taken at d 0 (before treatments), 2, 7, 14, and wk 4. Calves remained in the experiment until d 56, below the low critical temperature. Data were analyzed using the MIXED procedure of SAS. IgG concentrations at d 0 were not different (P > 0.17) among treatments. Cortisol tended to be greater (P = 0.06) for calves that received AF. Concentrations of haptoglobin, acid-soluble protein, albumin, and zinc did not differ among treatments. Supplementation with G resulted in greater total protein (P = 0.04) and urea N (P = 0.01) in plasma at wk 4 (2 wk after G supplementation ended). Despite the marked reduction in mortality of transported cold-stressed male calves fed the serum protein product, indicators of acute-phase response were not affected; however, protein status of calves may have been improved.

Key words: calf, acute phase response, serum protein

738 Digestive function and plasma oxidative status of intra–uterine growth retarded fully weaned piglets. J. Michiels*[1,3], M. De Vos[2], J. Missotten[3], A. Ovyn[3], S. De Smet[3], and C. Van Ginneken[2], *[1]Faculty of Biosciences and Landscape Architecture, University College Ghent, Ghent, Belgium, [2]Laboratory for Veterinary Anatomy, Embryology and Pathology, Department of Veterinary Sciences, University of Antwerp, Wilrijk, Belgium, [3]Laboratory for Animal Nutrition and Animal Product Quality, Department of Animal Production, Ghent University, Melle, Belgium.*

Intra–uterine growth retarded (IUGR) pigs, relative to normal birth weight (NBW) littermates, have lower birth weights and vitality scores, both of which are associated with a higher incidence of postnatal mortality and a lower growth rate in surviving IUGR pigs. To better understand developmental differences, digestive function and plasma oxidative status of fully weaned IUGR and NBW pigs were studied. Newborns from 13 hyper–prolific sows were weighed. At weaning (26.3 ± 1.2 d after parturition) pairs (n = 21) of IUGR and NBW littermates were selected and fed a commercial starter diet until sampling day (22.3 ± 4.3 d post-weaning). An IUGR piglet was defined as having a birth weight <1 kg and < mean litter birth weight – 1.5 SD. For each piglet 97 variables were determined including anatomy of digestive organs, digesta characteristics, small intestinal morphology, secretory and absorptive capacity, barrier function, brush–border enzyme activities, cytokines and density of growth-factor receptors, serum IGF-I, and plasma oxidative status. Data were analyzed using the paired Student′s T-test (continuous variables) or the Wilcoxon rank test (categorical). Few parameters showed significant differences. However, in the IUGR pig, the structural and functional maturation of the digestive tract post–weaning was delayed: lower small intestinal weight to length ratio (P < 0.001) due to a thinner Tela submucosa and Tunica muscularis (both P < 0.001) and a higher numerical secretory capacity in the distal jejunum. These observations might be a consequence of lower circulating IGF–I concentrations (126 ± 43.7 vs. 152 ± 44.9 ng/mL, P = 0.034 for IUGR and NBW, respectively) and a lower density of IGF–I receptors in proximal jejunal tissues (P < 0.05). Additionally, the plasma antioxidant capacity was lower for the IUGR pigs (ferric reducing ability, 106 ± 14.4 and 114 ± 9.7 μmol Fe^{2+}/L, P = 0.042 and glutathione-peroxidase enzyme activity, 0.29 ± 0.054 and 0.33 ± 0.047 U, P = 0.001 for IUGR and NBW, respectively). The

described changes in fully weaned IUGR pigs resemble those reported for IUGR neonates.

Key words: intra-uterine growth retardation, gastrointestinal tract, pig

739 Effect of dietary energy manipulation on mares and their foals: Glucose and insulin dynamics. K. N. Winsco*[1], J. L. Lucia[1], C. J. Hammer[2,3], and J. A. Coverdale[1], *[1]Department of Animal Science, Texas A&M University, College Station, [2]Department of Animal Sciences, North Dakota State University, Fargo, [3]Center for Nutrition and Pregnancy, North Dakota State University, Fargo.*

To investigate the effect of dietary DE manipulation of mares in the last third of pregnancy on mare and foal glucose and insulin dynamics, 30 Quarter Horse mares (538 to 695 kg BW and 4 to 19 yr) were blocked by expected foaling date. All mares were allowed ad libitum access to bermudagrass (*Cynodon dactylon*) hay and randomly assigned within block to dietary treatment: forage (F), or forage + grain (FG; grain fed at 0.75% BW as-fed). Treatments began 110 d before expected foaling date and terminated at parturition. A modified frequent sampling i.v. glucose tolerance test (FSIGT) was performed on mares 20 d before expected foaling date and on foals at 80 and 160 d of age. Jugular catheters were placed 1 h before FSIGT, and horses were allowed ad libitum access to bermudagrass hay and water throughout. A baseline plasma sample was harvested, then glucose bolus of 0.3 g/kg BW administered. An insulin bolus of 30 mU/kg BW was given 20 min after the glucose bolus. Blood samples were harvested at 1, 2, 3, 4, 5, 6, 7, 8, 10, 12, 14, 16, 19, 22, 23, 24, 25, 27, 30, 35, 40, 50, 60, 70, 80, 90, 100, 120, 150, and 180 min into tubes containing sodium heparin, immediately placed on ice, and centrifuged within 20 min. Glucose concentrations were analyzed using a colorimetric assay and insulin concentrations determined using a commercial RIA kit. All data were analyzed using the PROC MIXED procedures of SAS. Mare glucose area under the curve (AUC) was greater for FG compared with F ($P < 0.01$). Mare insulin AUC and peak insulin were also greater for FG compared with F ($P \leq 0.05$). Foal glucose AUC and peak glucose were not influenced by maternal treatment ($P \geq 0.82$), but both increased with age ($P \leq 0.05$). Foal insulin AUC and peak insulin were influenced by maternal treatment with foals from FG mares having greater peak insulin compared with foals from F mares ($P \leq 0.10$ and $P \leq 0.05$, respectively). An influence of age was observed on foal insulin AUC ($P \leq 0.05$), with all foals decreasing from d 80 to d 160. In summary, dietary treatments affected both mare and foal glucose and insulin dynamics.

Key words: glucose, insulin, maternal nutrition

740 Expression of key transcription factors during differentiation of equine bone marrow mesenchymal stem cells into osteoblast cells. E. R. Ackell*[1], A. Sanchez[2], C. Mora[1], S. A. Zinn[1], T. A. Hoagland[1], and K. E. Govoni[1], *[1]Department of Animal Science, University of Connecticut, Storrs, [2]Cummings School of Veterinary Medicine, Tufts University, North Grafton, MA.*

A novel method to improve fracture healing in horses is the use of equine bone marrow mesenchymal stem cells (eBMSC). Additional research is needed to identify optimal culture conditions and determine the mechanisms involved in regulating eBMSC differentiation into osteoblasts. We hypothesize that eBMSC have greater proliferation potential in allogenic serum and expression of key transcription factors is required for optimal differentiation. The eBMSC were isolated from the sternum of 3 Morgan horses (3.4 ± 0.3 yr of age). Cells were treated with fetal bovine serum (FBS) or horse serum (HS) and cell proliferation was determined by alamarBlue assay and bromodeoxyuridine (BrdU) incorporation. To induce osteoblast differentiation, cells were incubated with L-ascorbic acid-2-phosphate and glycerol-2-phosphate in the presence or absence of human bone morphogenetic protein 2 (hBMP-2), dexamethasone (DEX), or both. Alkaline phosphatase (ALP) activity, an indicator of osteoblast differentiation, was determined by ELISA in these cultures. Total RNA was isolated from cells at d 0, 3, 6, 9, 12, 15, and 18 of culture to determine expression of RUNX2 and Tbx3 using real-time RT-PCR. Data were analyzed by ANOVA using SAS and expressed as mean ± SE. Relative to control (CON) (serum-free media), FBS and HS increased cell number (133 ± 5 and 116 ± 5%, respectively; $P < 0.001$) and BrdU incorporation (173 ± 16 and 172 ± 16%, respectively; $P < 0.001$). Treatment with DEX (1,638 ± 38%; $P < 0.001$), but not hBMP-2 ($P > 0.05$) increased ALP activity compared with CON. Osteocalcin expression increased 260-fold by d 18 of culture ($P < 0.001$) demonstrating differentiation into osteoblasts. By d 6 of culture RUNX2 expression increased 3-fold ($P < 0.001$). Tbx3, a gene involved in regulating osteoblast function, increased 1.8-fold at d 3 ($P < 0.01$), however expression was 4-fold less at d 18 ($P < 0.01$). In summary, FBS induced greater proliferation of eBMSC, DEX is essential for differentiation into osteoblast cells, and inhibition of Tbx3 may be required for optimal differentiation of eBMSC.

Key words: bone marrow mesenchymal stem cell, osteoblast, transcription factor

741 Inter-relationship of BW with linear body measurements in Hissardale sheep at different stages of the life cycle. M. Abdullah*, U. Younas, J. A. Bhatti, T. N. Pasha, M. Nasir, and M. A. Jabbar, *University of Veterinary & Animal Sciences, Lahore, Punjab, Pakistan.*

Determining animal live BW, linear body measurements, and their inter-relationship and correlation is imperative for determining genetic potential, breed standards, and improved breeding programs for greater meat production. Hissardale is the only fine wool sheep breed maintained in Pakistan and developed by crossing exotic Merino with a local carpet wool sheep Bikaneri. Monthly BW data from 314 Hissardale sheep and linear body measurements including heart girth (HG), height at wither (HAW), body length (BL), ear length (EL), ear width (EW), neck length (NL), neck width (NW), tail length (TL), and tail width (TW) were analyzed after random selection at the Livestock Experiment Station, Jahangirabad, Khanewal, Pakistan to determine the appropriate model for estimating BW at different ages of life cycle including pre-weaned and post-weaned sheep. Animals were categorized according to their age (≤6, 7 to 12, 13 to 18, 19 to 24, and > 24 mo). The BW (mean ± SD) of animals was found to be 10.87 ± 1.82, 16.40 ± 1.40, 21.04 ± 1.44, 25.57 ± 2.94 and 47.10 ± 4.41 kg in all age groups (≤6, 7 to 12, 13 to 18, 19 to 24, and > 24 mo, respectively). Body weight was found to be significantly ($P < 0.001$) and positively correlated with HAW for all 5 age groups (0.79, 0.85, 0.67, 0.73, and 0.54, respectively), BL (0.69, 0.83, 0.53, 0.82, and 0.46, respectively) and HG (0.58, 0.85, 0.70, 0.76, and 0.42, respectively). However, the relationship between BW and other linear body measurement like EL, EW, NL, NW, TL, and TW were found significant ($P < 0.05$) but comparatively less correlated except for neck width in 0 to 6- and 7 to 12-mo age groups; neck length, neck width, tail length, tail width in 13 to 18- and 19 to 24-mo age groups. The recorded body measurements had a strong positive correlation with BW, indicating that they can be

used to estimate BW in Hissardale sheep of varying ages under field conditions.

Key words: Hissardale sheep, live body weight, linear body measurements

742 Gene expression of Red Angus sired steers and heifers evaluated for residual feed intake. C. M. Welch*[1], G. K. Murdoch[1], C. S. Schneider[1], K. C. Chapalamadugu[1], K. J. Thornton[1], J. K. Ahola[2], J. B. Hall[1], and R. A. Hill[1], *[1]University of Idaho, Moscow, [2]Colorado State University, Fort Collins.*

To improve our mechanistic understanding of variation in residual feed intake (RFI), gene expression studies have been suggested. In the present study, 42 progeny (25 steers, 17 heifers) of Red Angus sires divergent for maintenance energy (ME) EPD were RFI–tested during an 84-d post-weaning period. Subsequently, biopsy samples were collected from the biceps femoris muscle and mRNA expression of key genes in various regulatory pathways was evaluated through quantitative real-time PCR. A 2-sample t-test at a 2-tailed $P < 0.05$ was used to identify differentially expressed genes in the 2 extreme RFI quartile groups. Fatty acid synthase (FASN) was expressed in greater abundance in inefficient (high RFI) compared with efficient (low RFI) animals ($P = 0.03$). Gene expression of C/EBPα ($P = 0.06$) and PPARγ ($P = 0.13$) also tended toward greater abundance in inefficient animals. When these data were analyzed by sex, inefficient heifers showed a similar expression pattern for C/EBPα ($P = 0.003$) and PPARγ ($P = 0.08$), while FASN tended to be up-regulated in inefficient steers ($P = 0.11$). These patterns of gene expression in skeletal muscle suggest that lipogenesis was up-regulated in inefficient heifers, while fatty acid synthesis was up–regulated in inefficient steers. In addition, IGFBP5 ($P = 0.06$) tended to be up-regulated in inefficient animals although there was no difference ($P > 0.05$) in expression of the type 1 IGF receptor, IGFBP2, IGFBP3 or growth hormone receptor (GHR). When analyzed by sex, inefficient heifers tended to show higher expression of IGFBP2 ($P = 0.12$), IGFBP3 ($P = 0.15$), IGFBP5 ($P = 0.08$), and GHR ($P = 0.13$), thus muscle anabolic processes may be altered. No differences in expression of these genes were detected in steers. Thus, differential gene expression provides a tool to suggest metabolic pathways that may be involved in RFI variation of beef cattle.

Key words: IGF, C/EBPα, PPARγ

743 Effects of timing of an initial implant on performance of feedlot heifers. M. R. McDaniel*[1], W. C. Murdock[1], K. M. Taylor[1], N. P. Miller[1], B. H. Carter[1], F. Castillo[1], N. A. Elam[3], D. U. Thomson[2], and C. A. Loest[1], *[1]New Mexico State University, Las Cruces, [2]Kansas State University, Manhattan, [3]Nutrition Services Associates, Hereford, TX.*

Calves affected by disease repartition nutrients to support immune function, which could interact with anabolic implant modulation of growth. This study evaluated effects of timing of an initial implant on performance of 408 Angus-cross heifers (200 ± 0.8 kg BW). Heifers were assigned to 24 pens and 3 treatments in a completely randomized design. Treatments were: 1) no implant (CON); 2) an implant (Revalor-H; 140 mg trenbolone acetate and 14 mg estradiol; Intervet/Schering-Plough Animal Health) at initial processing (IMP0); and 3) an implant (Revalor-H) 21 d after initial processing (IMP21). Heifers were fed once daily a 68% concentrate diet from d 0 to 21, a 75% concentrate diet from d 22 to 63, and an 82% concentrate diet from d 64 to 126. Statistical analysis used the mixed procedure of SAS and differences of least squares means. From d 0 to 21, DMI of heifers was not affected ($P = 0.34$), and ADG was greater ($P < 0.05$) for IMP0 (1.03 kg/d) than CON (0.86 kg/d) and lesser ($P < 0.05$) for IMP21 (0.65 kg/d) than CON. Also, G:F was greater ($P < 0.05$) for IMP0 (0.299) than CON (0.247) and lesser ($P < 0.05$) for IMP21 (0.196) than CON from d 0 to 21. From d 0 to 42, DMI of heifers was not different among treatments ($P = 0.31$), ADG was greater ($P < 0.05$) for IMP0 (1.23 kg/d) than CON (1.04 kg/d) and intermediate for IMP21 (1.15 kg/d), and G:F was greater ($P < 0.05$) for IMP0 (0.245) and IMP21 (0.238) than for CON (0.211). From d 0 to 63, DMI was not different among treatments ($P = 0.38$), ADG was greater ($P < 0.05$) for IMP0 (1.39 kg/d) and IMP21 (1.36 kg/d) than for CON (1.21 kg/d), and G:F was greater ($P < 0.05$) for IMP0 (0.238) and IMP21 (0.236) than for CON (0.212). From d 0 to 126, DMI was greater ($P < 0.05$) for IMP0 (7.01 kg/d) and IMP21 (7.00 kg/d) than for CON (6.75 kg/d), ADG was greater ($P < 0.05$) for IMP0 (1.31 kg/d) and IMP21 (1.33 kg/d) than for CON (1.24 kg/d), and G:F was not different ($P = 0.28$) among treatments. In summary, heifers that received IMP0 and IMP21 had similar performance by d 42, which implies that delaying the initial implant for 21 d does not affect overall feedlot performance. Authors acknowledge Texas Cattle Feeders Association funding.

Key words: implant, performance, heifer

744 Effect of feeding 25-hydroxycholecalciferol on porcine fetal myoblast proliferation and differentiation. E. A. Hines[1], J. D. Coffey[1], M. A. Vaughn[1], C. W. Starkey[1], T. K. Chung[2], and J. D. Starkey*[1], *[1]Texas Tech University, Lubbock, [2]DSM Nutritional Products Asia Pacific Pte. Ltd., Singapore.*

Little is known regarding the effects of maternal supplementation of different vitamin D sources on fetal muscle development. To determine the effects of feeding the circulating metabolite of vitamin D, 25-hydroxycholecalciferol (25OHD3, Hy•D, DSM Nutritional Products), on fetal myoblast proliferation and differentiation, 38 PIC C22 gilts in 4 replicates were randomly assigned to 1 of 2 corn-soybean meal-based diets. The control diet (CTL) was formulated to contain 2,500 IU D3/kg diet, while the experimental diet (25OHD3) contained 500 IU D3/kg diet + 50 µg 25OHD3/kg diet. Gilts were fed 2.7 kg of their assigned diet once daily beginning 42 d before breeding. Gilts were artificially inseminated with PIC 337-G semen 12 and 24 h after exhibiting estrus. At gestational d 90 (±1), pregnant gilts were harvested (CTL n = 12; 25OHD3 n = 13), fetuses were extracted, and the right semitendinosus muscles of all fetuses from each litter were pooled and used for myoblast isolation. Myoblasts were cultured and proliferation index was measured at 24, 48, 72, and 96 h post plating using bromodeoxyuridine labeling and fluorescence microscopy. Myoblast differentiation capacity was determined by enumerating nuclei fused into myotubes 12 d post plating. Data were analyzed using the GLIMMIX procedure of SAS. The percentage of proliferating myogenic cells observed at 48 h was not different ($P > 0.05$) among treatments. However, at 24 ($P = 0.08$), 72 ($P = 0.07$), and 96 ($P < 0.05$) h post plating the percentage of proliferating myogenic cells was greater in the 25OHD3 cultures compared with CTL. Additionally, the differentiation capacity of myoblasts (percentage of nuclei fused into myotubes after 12 d in culture) was not different among treatments ($P > 0.05$). These results indicate that the proliferation phase of myoblasts derived from fetuses from 25OHD3 gilts may be extended. Extension of the proliferative phase of myoblasts in fetal muscle at gestational d 90, when muscle fiber hyperplasia is complete, could result in greater

capacity for muscle fiber hypertrophy and ultimate meat yield in the offspring of gilts fed 25OHD3.

Key words: myoblast, cell proliferation, vitamin D

745 Early postnatal myofiber increase in pig muscle results from myofiber elongation and tertiary myofiber formation. J. Bérard*[1,3], D. Loesel[1], A. Tuchscherer[2], C. Rehfeldt[1], and C. Kalbe[1], *[1]Leibniz Institute for Farm Animal Biology (FBN), Research Unit Muscle Biology and Growth, Dummerstorf, Germany, [2]Leibniz Institute for Farm Animal Biology (FBN), Research Unit Genetics and Biometry, Dummerstorf, Germany, [3]Institut Agricole Régional, Aosta, Italy.*

Myogenesis in pigs is commonly considered a biphasic phenomenon with the formation of primary and secondary fibers. Hyperplasia is accomplished around 90 d of gestation. However, some studies suggest a substantial increase in the total fiber number (TFN) from birth to 4 to 5 wk of age, but the origin is uncertain. Few studies indicate that early after birth tertiary myofibers of very small diameter expressing embryonic/fetal isoforms of myosin heavy chains (MyHC) appear. On the other hand, maturation and elongation of existing myotubes may contribute to muscle growth after birth. The aim of this study was to establish in which way TFN increases after birth and whether this increase is imputable to tertiary myofibers and(or) fiber elongation. The semitendinosus muscle of 128 German Landrace piglets was examined by histological and (immuno-)histochemical techniques at d 1 (n = 63), 7 (n = 12), 21 (n = 12), and 28 (n = 41) of age. Birth weight groups (BWG) were established on the basis of the 25 and 75% quartiles of birth weight frequency distribution of all piglets; low (L-BW ≤1.16 kg), medium (M-BW >1.16 to 1.52 kg), and heavy (H-BW ≥1.52 kg). Data were analyzed by ANOVA using PROC MIXED of SAS including the fixed effects age, BWG and age x BWG. Least squares means were pair-wise tested by Tukey Kramer or Dunnett test. Eosin-stained muscle cross sections allowed determining muscle cross-sectional area and TFN. TFN was increased at d 7, 21, and 28 of age compared with d 1 of age ($P < 0.01$). From d 1 to 28 of age TFN increased from 463×10^3 to 825×10^3 on average and amounted 85% in L-BW, 91% in M-BW, and 61% in H-BW piglets ($P < 0.001$). Microscopy of longitudinal and consecutive (every 110 μm) transversal sections revealed that at d 7 of age very small fibers expressing the embryonic MyHC isoform were apparent all over the muscle. In addition, intrafascicular endings of normal-sized fibers expressed embryonic MyHC. These results suggest that the TFN is not fixed at birth and its postnatal increase may be related both to the elongation of existing muscle fibers and to the genesis of tertiary myofibers.

Key words: skeletal muscle, myogenesis, total fiber number

Meat Science and Muscle Biology: Lamb and Pork Quality and Muscle Biology and Meat Products

746 Carcass and meat attributes of Red Sokoto buck goats as influenced by post-slaughter processing methods. A. B. Omojola*[1], E. S. Apata[1], and O. O. Olusola[1], *[1]University of Ibadan, Ibadan, Oyo State, Nigeria, [2]Olabisi Onabanjo University, Ago Iwoye, Ogun State, Nigeria, [3]University of Ibadan, Ibadan, Oyo State, Nigeria.*

A total of 27 good grade Red Sokoto buck goats weighing between 18.25 and 19.50kg were purchased from a specialized goat market, quarantined and stabilized on a standard diet for 20 one days. The goats were sacrificed to evaluate the effects of scalding, singeing and skinning on their yield, carcass and meat attributes in a completely randomized design. The animals were well rested, starved of feed for 16 h, weighed, stunned mechanically and slaughtered in batches of 3 under commercial conditions. The samples for shear force, cooking loss and water holding capacity (WHC) were taken from the loin. The result showed that the dressing percentage was highest ($P < 0.05$) in scalded carcasses (58.29%) and least in skinned carcasses (46.27%). The carcass length was least ($P < 0.05$) in singed carcass (34.35cm) and highest (44.76cm) in skinned carcasses. Singeing imposed a higher degree ($P < 0.05$) of toughness (6.61 kg/cm^3) on the meat as against 5.20 and 4.12 kg/cm for meat from scalded and skinned carcasses respectively, while the cooking loss was highest ($P < 0.05$) in singed carcasses. WHC was highest ($P < 0.05$) in meat from skinned carcasses (68.76%) followed by skinned (62.70%) and least in meat from singed carcasses (53.80%). The visual color score was highest ($P < 0.05$) for singed carcasses (7.45), followed by scalding (6.16) and least in skinned (5.30). The rib eye area and the depth of chest were not significantly ($P > 0.05$) affected by the post slaughter processing methods however, width and length of leg were highest ($P < 0.05$) in skinned carcasses and least in singed carcasses. Skinning elicited higher ($P < 0.05$) meat quality attributes and the leather industry will benefit immensely as the skin of Red Sokoto goats are highly priced. Post slaughter processing methods (dressing) were found to affect the quality of meat from Red Sokoto goats.

Key words: skinning, scalding, singeing

747 Yield of West African dwarf buck goats slaughtered at different weights. A. B. Omojola*[1], S. Attah[2], and O. O. Olusola[1], *[1]University Of Ibadan, Ibadan, Nigeria, [2]University of Agriculture, Markurdi, Nigeria, Markurdi, Nigeria, [3]University of Ibadan, Ibadan, Nigeria.*

Goat meat is highly relished and forms a major item of food in Nigeria and other developing African countries however there is no proper documentation on its yield as affected by different slaughter weights. A total of 36 male West Africa Dwarf goats with initial live weight between 5.47 and 8.82 kg were reared on a 16.8% crude protein concentrate diet until they reached the pre-determined slaughter weight (SW) of 10, 15 and 20 kg. Each carcass was split into two halves along the back bone. The right side of each carcass was separated into wholesale cuts and weighed while the left half was split into trunk, pelvic and pectoral limbs. Each part was subsequently dissected into lean, fat and bones. The result obtained showed that the hot carcass weight (HCW), chilled carcass weight (CCW) and the dressing percentage (DP) increased ($P < 0.05$) as the SW increased while there was an inverse relationship between the SW and the percent chilling loss. The percent external offal (head, skin and feet) reached maximum weight at 15 kg SW. The liver and the empty stomach gave highest values for goats slaughter at 15 kg, while the relative weight of organs such as lung, heart, kidney, pancreas and spleen were not significantly ($P > 0.05$) affected by the SW. The leg cut gave the highest percentage (25.53-28.18%), followed by shoulder (21.43-23.24%), rack (11.11-12.34%) and loin (10.07-40.7%). The percentage weight of the leg and shoulder were highest ($P < 0.05$) at 15 kg SW while that of rack was highest ($P > 0.05$) at 10 kg SW. Goats slaughtered at 15 kg SW has the highest proportion of lean, external and internal offal.

Key words: slaughter weight, offal, carcass

748 Fatty acid composition of muscles from Sarda suckling lamb reared indoor and outdoor. A. Nudda*, M. G. Manca, G. Battacone, R. Boe, M. Sini, N. Castanares, and G. Pulina, *University of Sassari, Dipartimento di Scienze Zootecniche.*

In dairy sheep farms the production of meat by milking lamb is an relevant source of income. The knowledge of the fatty acid composition of lamb meat is important for its economic value. The aim of this work was to study the effect of rearing system on the fatty acid composition of 2 muscles from suckling lambs of Sarda breed. Forty-eight suckling lambs were divided into 2 groups subjected to different rearing system: 24 lambs raised indoor (Group IN) and fed only dam's milk during the night when they were kept together; while 24 lambs followed their mothers also in outdoor pasture (Group OUT). Lambs were weighed weekly and finally slaughtered at 28 d of age. After 24 h of refrigeration, at 4°C, the tight muscles (TM) and longissimus dorsi (LD) were dissected from each right half-carcass. Intramuscular fatty acid composition (FA) of each sample was determined by gas-chromatography. Data were analyzed by 2 ways ANOVA with rearing system, muscle type and their interaction as fixed factors. The weight gains of lambs were not affected by rearing system. The intramuscular fat content was significantly higher in TM than in LD muscle, while this variable was not affected by rearing system. The type of muscle influenced significantly almost all FA concentration, except the C18:1 c9 content.The PUFA n3 were higher in LD, because of the highest content of C18:3 n3 and very long chain FA (EPA, DPA and DHA), compared to TM. The content of PUFA n6 was also higher in LD than in TM sample, due to the highest content of C18:2 c12,c15 and C20:4 n6. Concentrations of C16:0, C18:1 t11, and CLA c9,t11 were higher in TM than in LD samples. The rearing system of lambs does not seem to affect significantly the FA composition of intramuscular fat, except for C18:0 content. The comparison between two rearing system performed in this trial did not show effect on FA composition of intramuscular fat of suckling lambs. Moreover, results suggest that muscle type should be take in to account when examining FA profile in meat.

Key words: lamb muscles, fatty acid, rearing system

749 Nutritive and organoleptic characteristics of kilishi as affected by meat type and ingredient formulation. O. O. Olusola*, A. B. Omojola, and A. O. Okubanjo, *University of Ibadan, Ibadan, Oyo, Nigeria.*

Kilishi is a ready-to eat-intermediate moisture meat which is highly relished. The product is traditionally prepared from beef infused with spices and defatted groundnut paste. It contains about 46% meat and

54% non meat ingredients. This study tried to appraise the eating quality of kilishi as affected by meat types and ingredient formulation. Three different kilishi recipes viz fresh, frozen and oven dried groundnut paste representing recipes 1, 2 and 3 respectively were formulated and used for the preparation of pork and beef kilishi in a completely randomized design. The nutrient composition and eating qualities of each kilishi type were evaluated. The results obtained showed that kilishi from the recipes were similar in crude protein content with a value ranging from 55.47 – 62.33%. These differed significantly from the crude protein content of the dried raw pork (46.1%) and the dried raw beef (35.85%) which were not infused in the mixture of spices and groundnut paste. The ash content was highest ($P > 0.05$) in beef kilishi from recipe 1 with a value of 10.31 percent and least (6.96%) in pork kilishi from recipe 2. The color rating was highest in all pork kilishi irrespective of the recipe. The panelist also rated pork kilishi higher in juiciness with a value range of 3.50 – 4.30 as against values of 1.80 – 4.40 for beef kilishi. Beef kilishi from recipe 1 had the highest flavour rating while the overall acceptability was highest in both products from recipe 1 with values of 6.30 and 5.20 for beef and pork kilishi respectively. The plant ingredients in the recipes highly contributed to the crude fiber values of 2.96 – 4.42% obtained in products across the recipes. The results obtained in this study showed that the non meat ingredients contributed substantially to the nutritive value of kilishi produced from the three recipes, however the use of recipe 1 with fresh groundnut paste was better in product qualities than frozen or oven dried groundnut paste.

Key words: groundnut paste, kilishi, pork/beef

750 Over-nutrition during pregnancy increases collagen content in the skeletal muscle of mature male offspring. Y. Huang*, M. J. Zhu, R. J. McCormick, N. M. Nathan, S. P. Ford, and M. Du, *Department of Animal Science, University of Wyoming, Laramie.*

Collagen and its crosslinking in meat contribute to the background toughness. However, mechanisms regulating collagen accumulation has not been well studied. We hypothesized that the fetal stage of development would have dramatic effects on the muscle collagen content of offspring meat. To test, ewes were fed a control diet (CON, fed 100% of NRC, n = 7) or an over-nourished diet (OB, fed 150% of NRC, n = 7) from 60 d before conception to lambing. After weaning, male offspring were penned together and fed to requirements to 2 −3 years old when the Longissimus dorsi (LD) muscle was sampled. An increase of 37.8 ± 19.0% ($P < 0.05$) was observed in collagen content in OB offspring LD muscle compared with Con offspring. The mRNA expression of Collagen I and Collagen III, the major types of fibrillar collagen in muscle, also tended to elevated ($P < 0.10$) in OB offspring (80.7 ± 49.8 and 42.2 ± 21.6%, respectively) when compared with CON offspring. Matrix metalloproteinases (MMPs) and tissue inhibitors of metalloproteinases (TIMPs) are involved in collagen remodeling. There was an increase in MMP1 expression in OB offspring LD muscle compared with CON offspring (52.6 ± 25.0%, $P < 0.05$), but CON offspring expressed more MMP13 (91.7 ± 35.4%, $P < 0.05$) than OB offspring. The mRNA expression of TIMP1 and TIMP3 in LD muscle tended to increase ($P < 0.10$) in OB offspring compared with CON offspring (49.7 ± 21.1 and 94.6 ± 45.8%, respectively). Lysyl oxidase is a key enzyme catalyzing collagen cross-linking; the expression of lysyl oxidase was higher in OB offspring compared with the CON offspring LD muscle (74.0 ± 32.3%, $P < 0.05$). In summary, our data demonstrate that over-nutrition during pregnancy increased collagen content in the muscle of mature male offspring. This increase is associated with both enhanced collagen synthesis and decreased connective tissue remodeling (Supported by USDA-2008–35206–18826, NIH 1R01HD067449, and INBRE #P20RR016474).

Key words: collagen, offspring, muscle

751 Intrauterine crowding impairs formation as well as growth of secondary myofibers. C. E. Pardo[1,2], A. Koller-Bähler[1], M. Kreuzer[2], and G. Bee*[1], *[1]Agroscope Liebefeld Posieux, Posieux, Switzerland, [2]Department of Agricultural and Food Science, Zurich, Switzerland.*

There is evidence that intrauterine crowding is linked to intrauterine growth retardation and impaired myofiber hyperplasia. The aim of the study was to determine the impact of differences in uterine space using unilateral hysterectomized-ovariectomized (UHO) and unilateral oviduct ligated (OL) sows on reproduction performance, organ and muscle development of selected progeny at birth. In the study 8 UHO and 10 OL Swiss Large White third parity sows were used. At farrowing litter size and litter birth weight (BtW) were determined. Subsequently, within each litter 2 male and 2 female progeny with the lowest (L) and highest (H) BtW were sacrificed and internal organs and the LM were collected and weighed. To determine the number and diameter of primary (Prim) and secondary (Sec) myofibers and to calculate the Sec:Prim ratio, histological analyses were performed on the LM using mATPase staining after pre-incubation at pH 4.3 and 10.2. The litter size was similar (8.0 vs. 7.6; $P > 0.75$) for the 2 sow groups. However, as expected progeny born from UHO sows were lighter (1.43 vs. 1.85 kg; $P \leq 0.01$) than those from OL sows. When expressed per 100 g BtW, the heart, liver, kidney and spleen of UHO and OL progeny were of similar ($P \geq 0.36$) weight whereas the brain was heavier (2.52 vs. 1.92%; $P < 0.01$) and the brain:liver ratio was greater (1.03 vs. 0.75; $P < 0.01$) in UHO than OL piglets. Due to a numerically higher ($P = 0.13$) number of Prim but not ($P = 0.92$) Sec myofibers, the Sec:Prim myofiber ratio was lower (27.1 vs. 29.6; $P = 0.05$) in the LM of UHO than OL progeny. The Sec but not the Prim myofibers were smaller (8.1 vs. 9.1 μm; $P < 0.01$) in diameter in the LM of UHO than OL piglets. In L piglets a brain sparing effect was observed as their relative brain weight (2.4 vs. 2.0%) and brain:liver ratio (0.99 vs. 0.79) was higher ($P < 0.01$) than in H piglets. Only Prim myofiber number, which tended ($P = 0.06$) to be higher in L than H piglets, was affected by BtW. The current data suggest that regardless of BtW and gender, in individuals born from a crowded environment, formation as well as growth of Sec myofibers in the LM was impaired.

Key words: intrauterine crowding, muscle development, pig

752 Microarray analysis of the differentially expressed genes in adipose tissues between Jinhua pigs and Landrace pigs. T. Wu*, Z. Yuan, Y. Wang, and T. Shan, *Institute of Feed Science, Zhejiang University, Hangzhou, Zhejiang province, China.*

This study was conducted to detect the gene transcriptional expression profiles and further screen out the differentially expressed genes in subcutaneous fat between Jinhua pigs (at age of 90 d) and landrace (at age of 90 d) by Microarray. A total of 458 genes at least 2.0-fold significant difference were screened out including 223 higher expressed genes (77 genes with annotation available) and 235 lower expressed genes (58 genes with annotation available) in subcutaneous fat tissues of Jinhua pig compared with that of landrace. Furthermore, semiquantitative PCR and real-time quantitative PCR were used to confirm the 9 differentially expressed genes (Leptin, salivary lipocalin, heat shock 27kDa protein 8, Cyclin B2, Carboxylesterase 1, phosphoglycerate

mutase 2, Short/branched chain specific acyl-CoA dehydrogenase, apolipoprotein D, Cellular retinoic acid binding protein 1). The PCR depicting results showed great consistency with the microarray. Six categories including fat metabolism, energy metabolism, transcription, splicing factor, protein synthesis, protein degradation were classified through bioinformatics analysis. Taken together, this research demonstrates previously unrecognized changes in gene transcription of subcutaneous fat between Jinhua pigs and landrace pigs, and some potential candidate cascades identified in the study merit further investigation.

Key words: adipose tissue, differential expressed gene, microarray

753 SIFT-MS identifies unique volatile masses in 24 h postmortem loins from Berkshire- and Landrace-influenced swine. S. Taylor*, C. A. Wick, J. Harper, M. Wick, K. Shircliff, and S. J. Moeller, *The Ohio State University, Columbus.*

The objective of this preliminary study was to test the efficacy of using Selected Ion Flow-Tube Mass Spectrometry (SIFT-MS) as a novel device for the discrimination of swine of different maternal genetic composition that have previously been observed in our laboratory to differ in pork quality. Berkshire-sired market pigs, derived from matings to one purebred Berkshire (BB, n = 5), one purebred Landrace (BL, n = 5), and one Berkshire-Saddleback crossbred (BS, n = 5) dam were raised on straw with access to outdoor concrete from 30 kg through harvest (~5 mo of age, ~100 kg). A 3 phase feeding program was followed, providing ad libitum access to feed and water. Pigs were harvested following a 15-h fast. Pork loin quality was assessed at 24 h postmortem and a 2.54 cm diameter core removed from carcass and placed in LN2 for subsequent analysis. Warner-Bratzler Shear Force (WBSF) was assessed on one chop after a 7 d aging period. Loin 24 h pH was greater (0.14 units, $P < 0.05$) in BB and BS pig when compared with BL pigs, and chops from BB (3.01 kg) and BS (2.84 kg) exhibited less WBSF when compared with chops from BL pigs (4.67 kg). Each sample was divided into 3 equal parts, pulverized in LN2 and analyzed by SIFT-MS analysis. Sixty-one masses were identified and the relationships of the masses to maternal background determined by SIMCA. The BB and BS were not different from each other ($P > 0.05$); however, the BL loins were different from both the BB and BS loins ($P < 0.05$). These data support our hypothesis that rapid analysis by SIFT-MS is able to discriminate Berkshire from Landrace genetic influences in the present study. Future analysis by SIFT-MS will allow for the identification of the primary components unique to the different genetic lines and assess implementation as a tool for product characterization.

Key words: swine, pork quality, SIFT-MS

754 A partial replacement of soybean meal by whole or defatted algal meal in diet for weanling pigs does not affect their plasma biochemical indicators. E. Isaacs*[1], K. Roneker[1], M. Huntley[2], and X. G. Lei[1], *[1]Cornell University, Ithaca, NY, [2]Cellana, Kailua-Kona, HI.*

Marine algae have recently emerged as a new exciting source of biofuel. Our objective was to determine effect of supplemental defatted algal biomass from biofuel production on biochemical indicators of protein metabolism in plasma of weanling pigs. A total of 27 weanling pigs (BW = 10.69 ± 0.22 kg) were divided into 3 groups (n = 9/group), and fed a corn-soybean meal basal diet (BD), the BD plus 6.6% whole algal meal, or the BD plus 7.2% defatted algal meal (provided by Cellana, Kailua-Kona, HI) for 6 wk. Plasma urea nitrogen concentration, an indicator of dietary protein utilization efficiency, was not affected by the treatments as the 3 groups of pigs had similar values (mg/L) at Wk 3 (112.4 ± 9.4, 93.3 ± 11.0, and 102.1 ± 9.1) and Wk 6 (163.0 ± 22.1, 170.8 ± 14.7, and 155.9 ± 16.9). There was no group difference in plasma alanine aminotransferase or alkaline phosphatase activity at either time point. Ultrasound scan of vertebral fat and muscle depth of individual pigs at Wk 3 and Wk 6 predicted similar body lean yield (%) among all the 3 groups (Wk 3: 50.7 ± 0.2, 50.8 ± 0.2, and 50.7 ± 0.1; Wk 6: 52.2 ± 0.2, 52.1 ± 0.4, and 52.4 ± 0.1). In conclusion, adding 6.6% of whole algal meal or 7.2% of defatted algal meal into a corn-soy basal diet for weanling pigs effectively replaced the same amount of soybean meal without adverse effect on the biochemical indicators of protein metabolism or health.

Key words: algae, biofuel, pigs, protein, ultrasound

755 Effects of soybean meal of different origins and micronization of high protein soybean meal on nutrient digestibility and productive performance of weanling pigs. J. D. Berrocoso, E. A. Monteserín, L. Cámara, M. P. Serrano, R. P. Lázaro, and G. G. Mateos*, *Universidad Politécnica de Madrid, Madrid, Spain.*

The effects of the inclusion in the diet of a regular soybean meal (R-SBM, 44% CP) or a high protein SBM (HP-SBM, 49% CP), and the degree of grinding of the HP-SBM, on apparent total tract digestibility and growth performance of piglets from 27 to 56 d of age were studied. There were 6 diets in pellet form with similar nutrient content based on 6 different sources of SBM that supplied in all cases, 6.5% of dietary CP. There was a diet that included 15.8% R-SBM, a diet that included 10% soy protein concentrate (SPC) in substitution of the R-SBM, and 4 additional diets arranged factorially with 2 sources of HP-SBM (USA or Argentinean origin) ground or micronized (geometric mean diameter of 881 or 60 μm). Each treatment was replicated 8 times (6 pigs per pen). Adequate orthogonal comparisons were performed to test the effects of SPC, type of SBM, and the micronization of the HP-SBM on the traits studied. From 28 to 56 d of age, diet did not affect growth performance, but piglets fed the micronized HP-SBM had better G:F ($P \leq 0.05$) from 28 to 35 d of age and ADFI ($P = 0.06$) from 35 to 42 d of age than piglets fed the ground HP-SBM. In general, nutrient digestibility was higher for the SPC than for the R-SBM with the HP-SBM being intermediate. In fact, N digestibility was higher (84.1 vs. 81.4%; $P \leq 0.01$) for the SPC than for the R-SBM containing diets and that of DM (82.2 vs. 81.1%; $P \leq 0.05$) and OM (86.0 vs. 84.9%; $P \leq 0.05$) was higher for the HP-SBM than for the R-SBM. However, micronization of the SBM did not affect nutrient digestibility. It is concluded that the inclusion of SPC in the diet in substitution of R-SBM improved N digestibility but did not affect growth performance. Micronization of SBM did not affect nutrient digestibility but improved G:F during the first wk post-weaning but not thereafter. Under the conditions of the present experiment, the inclusion of added value soy products in piglet diets presents slights advantages over the use of R-SBM but further economical studies are required.

Key words: nutrient digestibility, soy products, piglet performance

756 Effects of adding cracked corn to a pelleted supplement for nursery and finishing pigs. C. B. Paulk*[1], A. C. Fahrenholz[1], J. M. Wilson[1], L. J. McKinney[1], J. D. Hancock[1], K. C. Benhke[1], J. C. Ebert[2], and J. J. Ohlde[2], *[1]Kansas State University, Manhattan, [2]Key Feeds, Clay Center, KS.*

Two experiments were completed to determine the effects of feeding ground and cracked corn with a pelleted supplement to nursery and finishing pigs. For both experiments, treatments were corn-soybean meal-based and fed as mash, pellets, and pellets with 50% of the corn (ground or cracked) blended into the diet after the rest of the formulation (the supplement) had been pelleted. In Exp. 1, a total of 224 nursery pigs (avg BW of 7.4 kg) were used with 7 pigs/pen and 8 pens/treatment. For the 28-d experiment, pigs fed mash had greater ($P < 0.03$) ADG and G:F compared with pigs fed the other treatments. However, this resulted from adding ground or cracked corn outside the pellets (complete pellets vs corn and pelleted supplement, $P < 0.001$). In Exp. 2, a total of 252 finishing pigs (avg BW of 40 kg) were used with 7 pigs/pen and 9 pen/treatment. For the 80-d experiment, pigs fed mash had lower ($P < 0.03$) ADG compared with pigs fed diets with pellets. Pigs fed complete pellets had greater ($P < 0.03$) ADG and G:F compared with pigs fed corn and the pelleted supplement and pigs fed the supplement blended with cracked corn had greater ($P < 0.02$) ADG than pigs fed the supplement blended with ground corn. With hot carcass weight used as a covariate, dressing percentage of pigs fed mash was greater than for pigs fed the other treatments with no differences for fat thickness or percentage fat free lean index among pigs (FFLI) fed the various treatments ($P > 0.13$). In conclusion, adding ground or cracked corn to a pelleted supplement had negative effects on growth performance compared with feeding a complete pellet.

Table 1.

Item	Mash	Pellet	Ground Corn	Cracked Corn	SE
Nursery (d 0 to 28)					
ADG, g	510	498	487	473	12

757 Inulin, alfalfa and citrus pulp in diets for piglets: Effects on digestibility and metabolism of N. S. Brambillasca*[1], E. Menezes[1], P. Zunino[2], and C. Cajarville[1], *[1]Departamento de Nutrición Animal, Facultad de Veterinaria, UdelaR, Montevideo, Montevideo, Uruguay, [2]Departamento de Microbiología, Instituto de Investigaciones Biológicas Clemente Estable, MEC, Montevideo, Montevideo, Uruguay.*

The addition of fibrous components in the diet of pigs may reduce the N output in feces and urine. So, the aim of this work was to evaluate the effect of the inclusion of inulin, alfalfa, and citrus pulp in diets for piglets on N digestibility and metabolism. Twenty 4 cross-breed piglets (12.1 ± 1.7kg BW) in a randomized complete block design were housed in metabolic cages and assigned to one of 4 treatments: corn and soybean meal based diet (CO; 3.56% N), 97% CO+3% inulin (IN; 3.08% N), 95.5% CO+4.5% fresh alfalfa (AL; 3.06% N) and 95.5% CO+4.5% fresh citrus pulp (CP; 2.94% N) in DM basis. The experiment consisted of an 11 d adaptation period followed by 5 d of feces and urine collection. Diets, feces and urine were analyzed for N, and digestibility, fecal and urinary output, retention, excretion and utilization of N were calculated. Data were analyzed by PROC MIXED considering treatment effect and means were separated by orthogonal contrasts. Pigs fed CO presented the highest intake, digestibility, retention and utilization of N; these parameters were reduced when aditives were included to diets. Urinary N output and total N excretion was higher for animals consuming AL. The low N utilization when animal received AL could be related to a higher N urinary output. Lower N digestibilities could be associated to the inclusion of fibrous components in AL and CP diets. Acknowledgments: ANII for scholarship of the first author.

Table 1. Effect of diets on N digestibility and balance

	Treatment					*P*-value		
	CO	IN	AL	CP	SEM	CO vs ADDIT	IN vs AL+CI	AL vs CI

758 *Nannochloropsis oculata* meal did not alter nutrient usage and had no adverse health effects when fed to rabbits as a protein source. B. A. Howe*[1], I. N. Roman-Muniz[1], B. D. Willson[2], and S. L. Archibeque[1], *[1]Colorado State University, Department of Animal Sciences, Fort Collins, [2]Colorado State University, Department of Mechanical Engineering, Fort Collins.*

Twenty-four adolescent male New Zealand White rabbits were used (n = 12/treatment) to evaluate the safety and potential animal feed use of *Nannochloropsis oculata* algae meal that remained after oil extraction for biodiesel production. Algae meal was included at 10% (DM basis) to a test diet that was isocaloric and isonitrogenous to the control diet (with no algae meal). Rabbits had ad-libitum access to feed for 45 d, including a 7 d. transition period to the Control and Algae diets. Body weights were recorded every 7 d. Blood was drawn via an ear puncture on d 0 and 28 of the study and analyzed for metabolites. A nutrient balance trial was conducted from d 28 through 35. On d 45 of the study, the rabbits were euthanized, blood was collected via a heart puncture, organs were weighed, and histological samples were collected. Intake of DM (194.9 v. 180.3 g/d), N (6.21 v. 5.68 g/d) and NDF (83.6 v. 76.8 g/d) were similar ($P > 0.05$) across treatments. Intake of ADF (53.41 vs. 42.72 g/d) was greater ($P < 0.01$) for the rabbits fed the Control diet than those fed the Algae diet. Subsequently, apparent ADF digestibility was decreased ($P = 0.03$) for rabbits consuming the Algae diet compared with the Control. Total N excretion (4.41 v. 3.95 g/d) was not different ($P > 0.05$) between the diets, however total P excretion (0.99 v. 0.78 g/d) was greater ($P < 0.01$) for rabbits fed the Control diet. There were no differences ($P > 0.10$) in final BW, blood glucose ($P > 0.10$), or serum urea N ($P > 0.10$). No differences ($P > 0.10$) were observed in kidney, liver or spleen histology of animals fed either the control or diet with algae meal. These data indicate that the algae meal of *Nannochloropsis oculata* may be a safe alternative protein source for herbivorous animals, yet the digestibility may be limited by the increased fiber content of the algae meal.

Key words: algae, biodiesel, digestibility

759 Comparative efficacy of meal and extracts of *Aspilia africana* leaf in laying quails. O. O. K. Oko*, *University of Calabar, Calabar, Cross River State, Nigeria.*

The study evaluated the mode of action of *Aspilia africana* leaf meal and extracts as potential phytogenic feed additives compared with an antibiotic growth promoter. Three forms of *Aspilia africana* leaf; meal, aqueous and ethanolic extracts were tested against a negative control and a standard antibiotic growth promoter (oxytetracycline) in a 70 d study employing 540 (7 wk-old) growing quails. Each *Aspilia africana* leaf form was supplemented at 2.5%, 5.0%, 7.5% or 10.0% into the basal diet, while oxytetracycline (positive control) was supplemented at 0.002%. Fourteen dietary treatments of 30 birds per treatment with 10 birds per replicate of 3 were studied in a RCB design. Traits measured included; production performance, egg composition, internal and external egg qualities. A 2-way ANOVA at $P < 0.05$ was conducted. Results showed that the impact of dietary supplementation with *Aspilia africana* leaf were similar to or better than ($P < 0.05$) those of the antibiotic growth promoter. Egg production characteristics were form and dose-dependent. While hen-day production increased up to 86.24% in birds on *Aspilia africana* leaf compared with those on oxytetracycline (69.20%) and basal (61.38%) diets; their egg shell thickened up to 0.35 mm, yolk color intensified ($P < 0.05$) from 3.03 to 6.25 whereas, percentage crack comparatively decreased. Crude extracts of *Aspilia africana* leaf exhibited higher ($P < 0.05$) phytogenic effects than the meal at supplementation levels of 5–7.5%. The aqueous extract further demonstrated higher egg boosting potentials. Therefore, an inclusion level of 5% aqueous extract of *Aspilia africana* leaf in layer diet is recommended as an alternative growth promoter.

Key words: phytobiotic, egg booster, plant extract

760 Effect of mycotoxin inhibitor (sim wall) on mold colonized feed in broiler chicken. S. Aikore[1], D. Eruvbetine*[1], R. Bandyopadhyay[2], J. Atehnkeng[2], M. A. Oyekunle[1], and A. M. Bamgbose[1], *[1]University of Agriculture, Abeokuta, Ogun State, Nigeria, [2]International Institute of Tropical Agriculture, Ibadan, Oyo State, Nigeria.*

To determine the effect of mycotoxin inhibitor (Sim wall) on mold colonized feed, broiler chickens were divided into 9 treatment groups in a factorial arrangement. Maize grains were colonized with either *A. flavus* 3228 strain (aflatoxin producer) or *A. flavus* 3229 strain (non afalatoxin producer). Non treated maize was used as a control. Sim wall was included at 3 levels (0, 1000 and 2000 ppm). Standard broiler starter followed by broiler finisher diets composed of the treated and untreated maize with and without Sim wall were fed to the birds for 8 wk. Records of BW, feed intake and mortality were kept. Blood samples were collected for determination of blood parameters and enzyme levels. After slaughtering, liver samples were examined for histopathological changes. Data was analyzed using ANOVA (SAS2009). Results revealed that the birds fed atoxigenic maize treated diets had BW, feed intake and feed conversion values similar to that of the control diet ($P \geq 0.05$). However, the birds fed diets containing aflatoxigenic maize had lower BW and less efficient feed conversion and the highest level of mortality ($P \leq 0.05$). Inclusion of 2000 ppm Sim wall had the best result in terms of BW. Among the blood parameters measured, serum total protein, albumin, globulin and enzymes alanine amino transferase and aspartate amino transferase the best results were obtained in the control group, the atoxigenic treated group and the group fed 2000ppm Sim wall ($P \leq 0.05$). Lesions of the liver were pronounced in the birds fed aflatoxigenic treated diets showing severe fatty changes, necrosis and fibrosis. However, inclusion of 2000 ppm Sim wall recorded mild lesions of the liver. It can be concluded that the deleterious effects of aflatoxin contaminated maize in diets for broilers can be ameliorated by the inclusion of 2000 ppm Sim wall.

Key words: aflatoxin, mycotoxin inhibitor, broilers

761 Impact of tylosin phosphate and ractopamine hydrochloride alone or in combination on growth performance, feed efficiency and water intake in finishing pigs. C. M. Pilcher*[1], R. Arentson[2], and J. F. Patience[1], *[1]Iowa State University, Ames, [2]Elanco Animal Health, Greenfield, IN.*

Ractopamine hydrochloride (RAC) is a nutrient repartitioning agent added to diets in late finishing to increase weight gain, feed efficiency and carcass leanness. Tylosin phosphate (TP) is used in swine diets to control diseases such as ileitis and swine dysentery and to improve growth performance. There is very limited information on the impact of these 2 products when used in combination. The objective of this study was to evaluate the impact of TP and RAC alone or in combination on growth performance, feed efficiency and water intake in finishing pigs fed corn-soybean meal or corn-soybean meal-dried distillers grains with solubles (DDGS) based diets. A total of 72 PIC gilts (start BW = 107.4 ± 0.50 kg) were blocked by weight and randomly assigned to a 2 × 2 × 2 factorial arrangement of treatments: TP (0 or 44 ppm), RAC (0 or 5 ppm), and DDGS (0 or 30%). Pigs were housed individually and fed treatment diets for 17 d. TP treated pigs were administered 66 mg tylosin per liter of water for 3 d before receiving treatment diets. Feed was provided twice daily, as much as the pigs could consume within 1 h per meal (ADFI = 2.98 ± 0.045 kg/d). Water was provided to the pigs between feeding periods, ad libitum (ADWI = 7.76 ± 0.23 kg/d). Data were analyzed with the MIXED procedure of SAS. There were no significant interactions ($P > 0.10$) among any of the treatments. RAC improved ADG (1.31 vs. 1.11 kg/d; $P < 0.0001$) and G:F (0.446 vs. 0.368; $P < 0.0001$) and had no effect on ADFI. TP had no effect on ADG, ADFI or G:F. DDGS inclusion reduced ADFI (2.80 vs. 3.18; $P < 0.0001$) and ADG (1.15 vs. 1.27 kg/d; $P = 0.001$) and had no effect on G:F. There was no significant effect of dietary treatment on water intake ($P > 0.10$); however, pigs fed RAC or DDGS increased water to feed ratio (2.77 vs. 2.47; $P = 0.03$ and 2.79 vs. 2.49; $P = 0.02$, respectively). In conclusion, under the conditions of this experiment, TP did not affect growth performance, RAC enhanced growth performance, and there were no interactions between the response to TP and RAC. The inclusion of DDGS did not affect the responses to either TP or RAC.

Key words: ractopamine, tylosin phosphate, swine

762 Dietary nucleotides as an alternative to antibiotic growth promoters (AGP) for nursery pigs. R. Patterson*[1], E. McMillan[2], O. Jones[1], and B. A. Slominski[3], *[1]Canadian Bio-Systems Inc., Calgary, Alberta, Canada, [2]Nutreco Canada Agresearch, Burford, Ontario, Canada, [3]University of Manitoba, Winnipeg, Manitoba, Canada.*

The potential of dietary nucleotides to replace AGP in nursery pig diets was evaluated using 168 mixed-sex pigs weaned at 17 ± 2 d of age in a completely randomized design. The test article, Maxi-Gen Plus, is a nucleotide-rich yeast product (NP) containing a mixture of mononucleotides. Pigs were randomly assigned to the following dietary treatments: Positive control (PC; containing 110 ppm chlortetracycline HCl and 31.2 ppm tiamulin per kg of feed); Negative control (NC; no antibiotics); NC + 0.1% NP; NC + 0.2% NP. Diets were fed ad libitum for 28 d. On d 14, 0.2% NP pigs had greater BW than NC pigs (9.32 vs 8.76 kg, $P = 0.005$) but did not differ ($P > 0.1$) compared with PC (9.32 kg) or 0.1% pigs (9.11 kg). On d 28, pigs fed the 0.1% NP diet were heavier than NC pigs (16.52 vs 15.40 kg, $P = 0.028$) and weighed the same as PC (16.31 kg) and 0.2% pigs (16.30 kg). FCR was not affected by dietary treatments during the study. From d 7–14, pigs fed the 0.2% NP diet had greater ADG (332 vs 284 g/d, $P = 0.048$) and ADFI (406 vs 349 g/d, $P = 0.034$) than NC pigs but did not differ compared with PC or 0.1% pigs. ADG was not affected by dietary treatments from d 14–21, however during this period, pigs fed a diet supplemented with 0.1% NP had an ADFI of 641 g/d, which tended ($P = 0.09$) to be greater than that of NC pigs (569 g/d). Although ADFI was not affected by dietary treatments from d 21–28, pigs given the 0.1% NP diet had an ADG of 623 g/d which was the same as that of PC (572 g/d) and 0.2% (565 g/d) pigs and greater than that of NC pigs (537 g/d, $P = 0.041$). Overall, no differences were observed for ADFI between either NP treatment. However, pigs fed the 0.1% NP diet had greater ADG than NC pigs (379 vs 335 g/d, $P = 0.05$) and the same ADG as 0.2% (379 g/d) and PC pigs (379 g/d). This study indicates that AGP can be withdrawn from nursery pig diets without a loss of performance when diets are supplemented with 0.2% nucleotides from d 0–14 and with 0.1% nucleotides from d 15–28. It thus appears that dietary nucleotides have the potential to replace AGP in nursery pig diets as pigs receiving dietary nucleotides performed the same as pigs receiving AGP.

763 In vitro fermentative characteristics of citrus pulp, apple pomace and inulin combined in increasing levels with a predigested dog food. S. Brambillasca*, C. Deluca, A. Britos, L. Reyes, and C. Cajarville, *Departamento de Nutrición Animal, Facultad de Veterinaria, UdelaR, Montevideo, Montevideo, Uruguay.*

The fermentation characteristics of citrus pulp (CP), apple pomace (AP) and inulin (IN) mixed with a pre-digested dog food was studied. A commercial dog food was predigested (pepsin+pancreatin) and mixed with AP, CP or IN to obtain 3 different mixtures: 3, 5 and 7% in DM basis. 0% level consisted in the pre-digested food incubated as sole substrate. In vitro gas production was performed using diluted feces from 3 dogs fed the same dog food and gas volume was recorded at 2, 4, 6, 8, 10, 12, 18, 24, 48, 67 h after inoculation. Organic matter disappearance (OMD) was determined by ashing the fermentation residues. Asymptotic gas production (A, mL/g OM), time to reach 50% of the asymptote (B, h), maximal rate of gas production (Rmax, mL/h) and time of occurrence of Rmax (Tmax, h) were determined. Data were analyzed by PROC MIXED considering fiber source, inclusion level and its interaction, and means were separated by Tukey test. No source x level interaction was detected. IN produced more gas with a faster rate than the other 2 fiber sources. A and Rmax were the highest for the 5 and 7% levels, whereas Tmax for the 0% level was the lowest. OMD was affected by inclusion level and highest for 0 and 7% levels. The fermentative parameters of CP and AP were similar to those produced when IN was included in the mixtures. This suggests that these by-products can be included at 5 to 7% levels in diets for dogs and enhance the fermentative activity of the colonic microbiota as a recognized commercial prebiotic do. Acknowledgments: CIDEC–Fvet for the financial support of this work.

Table 1. In vitro fermentation parameters according to fiber source and inclusion level

	A (mL/g OM)	B (h)	Rmax (mL/h)	Tmax (h)	OMD (%)

Nonruminant Nutrition Symposium: Nutrition and Gut Microbiome

764 Whole-body systems approaches for gut microbiota-targeted, preventive healthcare. L. Zhao*, *Shanghai Jiao Tong University, Shanghai, China.*

Humans are superorganisms whose phenotypes are dictated by 2 integrated genomes, the genetically inherited human genome (23,000 genes) and the environmentally acquired human microbiome (over 1 million genes). The 2 genomes must work in harmonious integration to maintain health. Gut microbiota constitutes the majority of the human microbiome. Bioactive substances (antioxidants, vitamins or various toxins) produced by particular members of gut microbiota may get into bloodstream via enterohepatic circulation or impaired gut barrier to affect host immunity and metabolism. Undigested nutrients from the diet or drugs that arrive in the colon play a dominating role in shaping the structure of the gut microbiome. For example, accumulating evidence supports the new hypothesis that obesity and related metabolic diseases develop because of low-grade, systemic and chronic inflammation provoked by increased antigen load from a diet-disrupted gut microbiota. On the other hand, changes of host health induced by biotic or abiotic perturbations may also disrupt gut microbiota which in return can further deteriorate host health. Due to the tight integration of gut microbiota into human global metabolism, molecular profiling of urine metabolites and gut microbiome can provide an ideal window for reflecting physiological functions of the host. Variations in gut microbiota and urine metabolites can thus be employed as emergent functions for quantitative assessment and monitoring of health at the whole-body level with the advantage of measuring human health based on the results of interactions between the 2 genomes and the environment rather than just host genomic sequences. Large-scale, longitudinal cohort studies in conjunction with these whole-body systems approaches will generate pre-disease biomarkers with predictive power, thus making preventive health management of populations with rapidly changing disease spectrums possible through re-engineering of the imbalanced gut microbiome with specially designed drugs/diets.

Key words: gut microbiome, host health, additives

765 Dietary modulation of the gut microbiota by prebiotics and probiotics. G. R. Gibson*, *University of Reading, Reading, UK.*

The human large intestine is an intensively colonized area containing bacteria that are health promoting, as well as pathogenic. This has led to functional food developments that fortify the former at the expense of the latter. Probiotics have a long history of use in humans as live microbial feed additions. In contrast, a prebiotic is a non digestible food ingredient that beneficially affects the host by targeting indigenous components thought to be positive. Dietary carbohydrates, such as fibers are candidate prebiotics but most promise has been realized with oligosaccharides. As prebiotics exploit non-viable food ingredients, their applicability in diets is wide ranging. Main prebiotic targets at the moment are bifidobacteria and lactobacilli (although this may change as our knowledge of the flora diversity and functionality expands). Any dietary component that reaches the colon intact is a potential prebiotic, however much of the interest in the development of prebiotics is aimed at non-digestible oligosaccharides such as inulin type fructooligosaccharides (FOS) and trans-galactooligosaccharides (TOS). Other prebiotics are emerging. Some prebiotics occur naturally in several foods such as leek, asparagus, chicory, Jerusalem artichoke, garlic, artichoke, onion, wheat, banana and oats. However, these foods contain only trace levels, so developments have taken the approach of removing the active ingredients from such sources and adding them to more frequently consumed products to attain levels whereby a prebiotic effect may occur, e.g., cereals, confectionery, biscuits, infant feeds, yogurts, table spreads, bread, sauces, drinks, etc. The rationale for using probiotics and prebiotics to reduce risk will be reviewed. On the contrary, the role of the gut flora in various clinical states will be briefly discussed. Building upon this information, research will be presented on the generation and testing of a novel prebiotic (TOS) which has led to the development of products designed to improve immune health in the elderly, reduce the symptoms of Irritable Bowel Syndrome and help prevent traveler's diarrhea.

Key words: gut microbiome, host health, pro pre biotic

766 Effect of dietary change on equine and swine gut microbiota. K. Daly*[1], A. Darby[2], N. Hall[2], C. Proudman[3], D. Bravo[4], and S. P. Shirazy-Beechey[1], *[1]Department of Molecular and Cellular Physiology, University of Liverpool, Liverpool, UK, [2]Department of Functional and Comparative Genomics, University of Liverpool, Liverpool, UK, [3]Equine Division, Department of Veterinary Clinical Sciences, University of Liverpool, Liverpool, UK, [4]Pancosma, Geneva, Switzerland.*

The large intestinal tracts of mammalian species contain vast populations of microorganisms that interact with each other and co-exist with their host in a mutually beneficial relationship. The total number of these microorganisms (~10^{14}) exceeds the number of cells in the body by 10-fold. It is becoming increasingly evident that intestinal microbiota play an important role in maintaining the health and well being of the host. Several environmental factors such as age, disease, antibiotics and diet are known to influence the composition of the microbiota, and subsequent microbial metabolites produced. By far the biggest influence on the composition and activity of the gut microbiota is diet. Domesticated animals, such as the horse, are often fed diets that differ significantly to their natural forage. Indeed, dietary change and the amount of grain fed to horses are two important variables that have emerged from a number of studies as risk factors for acute intestinal disease. Our studies, using molecular biological strategies, have indicated that there are significant modifications in microbiota and fermentation products when horses were maintained on grain based diets, compared to horses maintained on traditional forage; these changes became much more exaggerated in horses affected by a form of dietary-induced intestinal disease. To determine any alterations in gut microbiota that occur during development in piglets, from suckling to weaning, and in response to changes in diet, from hydrolysable to fermentable carbohydrates and addition of nutritional supplements, we have employed a combination of 454 pyrosequencing and 16S rRNA-oligonucleotide hybridization using samples of colonic contents taken from piglets weaned onto various controlled diets. We shall report on the characteristics of microbial transformations that occur.

Key words: gut microbiome, host health, pyrosequencing

767 Dietary manipulation of canine and feline microbiota. K. S. Swanson*, *Department of Animal Sciences and Division of Nutritional Sciences, University of Illinois, Urbana.*

The canine and feline colon is inhabited by a complex and dense community of bacteria, archaea, fungi, protozoa, and viruses. A signifi-

cant hindrance to the field has been the inability to effectively identify and quantify microbial species, their metabolic end products, and mechanisms by which they affect host health. Molecular tools, including qPCR, FISH, DGGE, RFLP, and DNA sequencing, have overcome many of the limitations of culture-based techniques. Recently developed high-throughput techniques (e.g., 16S rRNA microarrays; next-generation sequencing) have dramatically changed the research landscape in regards to gastrointestinal microbiology. These techniques are now being used to characterize canine and feline gastrointestinal microbiota and identify the effects of diet, age, and disease on these communities. Continued use of DNA-based techniques to characterize microbial phylogeny and metabolic capacity, along with other technologies to analyze microbial RNA (gene expression), protein, and metabolite profiles, will increase our understanding of host-microbe relationships in pets. Composition of the commensal microbiota is dependent on several factors, including host genotype, age, and diet. The main energy source of colonocytes (i.e., SCFA) is derived primarily from microbial fermentation of carbohydrate-based energy substrates reaching the large bowel. Dietary proteins may also serve as fermentable materials, but result in the production of putrefactive compounds such as ammonia, biogenic amines, and phenols that are implicated as the major odor components of feces and may have negative influences on gut health. The supplementation of dietary fibers, prebiotics, or probiotics has become a popular strategy for improving gut health in humans and pets. In the past couple decades, over 50 peer-reviewed publications have reported the effects of these dietary ingredients in dogs and cats, with many demonstrating beneficial changes in gastrointestinal microbiota, fecal fermentative end products, and stool characteristics. Our current understanding and future research opportunities in this field will be reviewed.

Key words: gut microbiome, feline, canine

768 Rumen microbiota, assessed by evolving techniques. R. J. Wallace*, *Rowett Institute of Nutrition and Health, University of Aberdeen, Aberdeen, UK.*

Our present understanding of ruminal microbiology was built initially upon a few epoch-changing advances made many years ago: Gruby and Delafond's (1843) microscopic observations of protozoa; Hungate's (1947) appreciation of the anaerobic nature of the rumen that led to novel culture techniques for the bacteria; Orpin's (1975) realization that some flagellate protozoa were in fact zoospores of anaerobic fungi, until then a contradiction in terms. Isolation and study of pure cultures was invaluable in understanding the likely role of different species of bacteria, protozoa or fungi in the overall fermentation. Cultivation techniques could not deal with more than a very small number of samples, however, in attempting to assess the effects of diet or manipulation on rumen ecology. Even then, it was known that such analyses were flawed by cultivation bias. We have since passed through a period of evolving molecular techniques, based mainly on ss-rRNA gene analyses. Cloning and sequencing provided community analyses that were free from the biases imposed by cultivation techniques. Related techniques for microbiome analysis quickly followed (DGGE, TGGE, RFLP, ARISA). qPCR and FISH enabled groups or species to be quantified. Now, next-generation sequencing has exploded onto to the scene. A bacterial genome can be sequenced in an afternoon, and sequencing of the entire community's DNA – the metagenome - is about to become routine. Are these seismic increases in information that we can generate about the rumen microbiota as epoch-changing as the historic discoveries? And can they be used to improve the efficiency of animal production, animal welfare and environmental impact? Very recent genomic and metagenomic results confirm that there is a huge amount that we do not understand about genes and organisms that break down plant fiber. Other studies on fatty acid biohydrogenation have come to a similar kind of conclusion, reaching almost an impasse in identifying key genes and species. We now need equally innovative thinking and technology to ensure that the answer to both questions will be yes.

Key words: rumen microbiome, host health

769 Effect of short-term supplementation and temporary weaning in hepatic gene expression in Hereford cows grazing native pasture. A.L. Astessiano*[1], F. Bialade[1], M.P. Grignola[1], J. Laporta[1], C. Viñoles[2], and M. Carriquiry[1], *[1]School of Agronomy, UDELAR, Montevideo, Uruguay, [2]National Research Institute for Agriculture, Tacuarembo, Uruguay.*

Short-periods of improved nutrition associated with temporary weaning increased early pregnancy rates in grazing conditions, but the underlying mechanisms involved in this response remain unknown. Primiparous beef cows (n = 25; 388 ± 7 kg BW and 3.6 ± 0.2 units BCS) in anestrus were used in a randomized block design with a 2x2 factorial arrangement of short-term supplementation, with 2.5 kg/cow of whole rice middlings (90.3%DM, 10%CP, 9%EE, 14%NDF; SUP, n = 12 vs. CON, n = 13) for 23 d, and temporary weaning, by applying nose plates to calves for 14 d (with, n = 13 vs. without, n = 12), before initiation of the breeding period (103 ± 1 d postpartum) to study hepatic expression of GH-IGF axis genes. Liver biopsies were obtained at the initiation and end of the treatment period. The abundance of mRNA of growth hormone receptor (GHR), GHR-1A, insulin-like growth factor-I (IGF-I), IGF binding proteins-2 (BP2),-3 (BP3), and insulin receptor (INSR) were measured by real time RT-PCR normalized by hypoxanthine phosphoribosyltransferase and β-actin as endogenous control genes. Means from a mixed model analysis were considered to differ when $P < 0.05$. Neither short-term supplementation nor temporary weaning affected cow BCS. Expression of GHR and IGFI mRNA were not affected by any of the factors evaluated in this study while the expression of INSR mRNA tended be greater ($P = 0.11$, 2.96 vs. 1.83 ± 0.55) in temporary weaned than suckled cows. Expression of BP3 and BP2 mRNA was greater in SUP than CON cows (1.38 vs. 0.85 ± 0.003 and 18.50 vs. 12.63 ± 0.04, respectively). In addition, BP2 mRNA was less in temporary weaned than suckled cows (12.60 vs. 18.53 ± 0.04). The BP3/BP2 ration was not affected by short-term supplementation but was greater in temporary weaned than suckled cows. Short-term supplementation and temporary weaning before initiation of the breeding season could affect IGF availability through changes in hepatic IGFBP synthesis.

Key words: mRNA, suckling management, nutritional treatment

770 Feeding distillers grains as an energy source to gestating and lactating heifers: Impact on ovarian function and reproductive efficiency. P. J. Gunn*[1], J. P. Schoonmaker[1], R. P. Lemenager[1], and G. A. Bridges[2], *[1]Purdue University, West Lafayette, IN, [2]University of Minnesota, Grand Rapids.*

Angus-cross beef heifers pregnant to a single sire (n = 80; BCS = 5.1 ± 0.03; BW = 518 ± 6 kg) were used to assess the effects of feeding dried distillers grains with solubles (DDGS) as an energy source during late gestation and early lactation on follicular development, cyclicity and fertility. At 192 d in gestation, heifers were stratified and allotted by BW and BCS to receive one of 2 isocaloric dietary treatments: a control diet of corn silage and haylage (CON; 10% CP prepartum; 11.8% CP postpartum) or corn residue and DDGS (DG; DDGS at 1.2% BW per d; 15.7% CP). Treatments concluded and cattle were commingled 30 d after synchronization with the 5 d CO-Synch + CIDR timed-AI protocol (118 ± 0.1 d postpartum; DPP). BW and BCS were assessed every 28 d during treatment. At 32 ± 0.2 DPP, 1 follicular wave was mapped via ultrasonography in 10 anestrous heifers per treatment. Starting 40 DPP, blood samples were taken every 10 d until synchronization to determine return to cyclicity via progesterone. Plasma urea nitrogen (PUN) was assessed in blood samples taken at AI. Categorical and continuous data were analyzed with the GLIMMIX and MIXED procedures of SAS, respectively. Dominant (15 ± 0.7 vs. 13 ± 0.6 mm) and secondary (11 ± 0.5 vs. 9.0 ± 0.4 mm) follicle diameter was greater ($P \leq 0.05$) and wavelength (8.9 ± 0.6 vs. 7.5 ± 0.5 d) tended ($P = 0.08$) to be greater in DG than CON, respectively. Percentage of cyclic heifers at estrous synchronization did not differ (89%), but DG (58 ± 2 d) tended ($P = 0.10$) to resume estrous activity at fewer DPP than CON (63 ± 2 d). PUN concentrations at AI were greater ($P < 0.01$) in DG (17.1 ± 0.6 mg/dL) than CON (6.6 ± 0.3 mg/dL). Timed-AI pregnancy rates were numerically ($P = 0.30$) greater in DG (28/36, 78%) than CON (22/33, 67%). Breeding season pregnancy rates did not differ between treatments (99%). In summary, feeding DDGS at 1.2% of BW per d to first-parity heifers resulted in greater dominant follicle growth during the postpartum anestrous period, marginally hastened resumption of estrous cycles, and did not detrimentally impact AI pregnancy rates.

Key words: beef heifer, DDGS, fertility

771 Comparison of Brahman females evaluated for residual feed intake (RFI) as heifers and reevaluated for RFI as gestating cows. B. L. Bradbury*[1,2], S. L. Morgan[1,2], A. N. Loyd[1,2], D. A. Neuendorff[1], A. W. Lewis[1], J. P. Banta[1], D. G. Riley[2], T. D. A. Forbes[3], T. H. Welsh Jr.[2], and R. D. Randel[1], *[1]Texas AgriLife Research, Overton, [2]Texas AgriLife Research, College Station, [3]Texas AgriLife Research, Uvalde.*

Use of residual feed intake (RFI) as a tool to identify feed efficient beef cattle is increasing. This study was designed to examine the relationship between postweaning RFI and mature RFI in Bos indicus females. Mature cow RFI data was collected over 2 years on 2 different cohorts of cows that were previously evaluated for RFI postweaning. In 2009 and 2010, 37 (3–7 yr of age) and 41(2–3 yr of age) cows, respectively, in their first trimester of gestation (affirmed by palpation) were retrained to eat from Calan gates system and evaluated for RFI. Cows were fed twice daily (0800 h and 1600 h) at 2.6% BW for 70 d with BW recorded weekly. Body condition scores were recorded weekly in 2009 and at d 0 and d 70 in 2010. Females were classified according to their RFI values, with a negative RFI = efficient and a positive RFI = inefficient. Residuals for average daily feed intake (ADFI) by heifer and cow (n = 78) were generated using a mixed model. Sire (n = 16) was included as a random effect in both models. Fixed effects included year of record for heifers (2004–2009: $P < 0.001$) and for cow (2009 and 2010; $P < 0.001$). Heifer pen (n = 11: $P = 0.0008$) was nested within year. Cow age (2, 3, 4, 5, 6, or 7 yr; $P < 0.001$), lactation status (lactating or not; $P = 0.07$), and pen (n = 11; $P < 0.001$) were included as nested within year. Regression coefficients of ADFI on ADG and mid-test weight (MTW) for heifers were −0.15 ± 0.03 kg ($P = 0.0002$) and 0.13 ± 0.002 kg ($P < 0.0001$), respectively. Regression coefficients of ADFI on MTW, ADG, and days pregnant were 0.09 ± 0.02 kg ($P < 0.001$), 0.76 ± 0.29 kg ($P = 0.01$), 0.01 ± 0.003 kg ($P = 0.007$), respectively for cows. The Pearson correlation coefficient (r = −0.24, $P = 0.0348$) indicates that heifer RFI may not be an accurate predictor of RFI as a mature cow in the first trimester of gestation.

Key words: RFI, cow, repeatability

772 Effect of temperament on response to cannulation and glucose challenge in Brahman heifers. B. L. Bradbury*[1,2], L. C. Caldwell[2], A. W. Lewis[1], D. A. Neuendorff[1], R. C. Vann[3], T. H. Welsh Jr.[2], and R. D. Randel[1], *[1]Texas AgriLife Research, Overton, [2]Texas AgriLife Research, College Station, [3]MAFES-Brown Loam Experiment Station, Raymond, MS.*

Temperamental cattle have greater serum concentrations of cortisol (CS) which mediates glucose (GLU) metabolism. The objective was to determine the effects of temperament on blood GLU and insulin (INS) following a stressor and a subsequent infusion of dextrose. Brahman heifers (200–300 kg) were evaluated for temperament and 6 calm (C) and 6 temperamental (T) heifers were fitted with jugular catheters and placed in individual stalls. Blood samples were collected at cannulation and then at 0, 30, 60, and 90 min. At 90 min after cannulation dextrose was infused via the cannula at 0.5 mg/kg BW. Blood samples were collected at −5, 0, 10, 15, 20, 30, 40, 60, 80, 100, 120, 140, 160, 180 min relative to the time of dextrose infusion. CS and INS were assayed by RIA and GLU by colorimetry. CS, GLU, INS, insulinogenic index and their interactions with time and temperament were analyzed by GLM for repeated measures. Peak INS concentration, time to peak, GLU disappearance and time to half life were analyzed using GLM procedures. Following cannulation T heifers had elevated GLU (P = 0.0005) and CS (P = 0.0238). There was a significant temperament by time interaction (P = 0.0434) influencing INS following cannulation. During the challenge a temperament by time interaction affected CS (P = 0.0041), GLU (P = 0.0428), and INS (P = < 0.0001). Glucose concentrations were significantly higher in T heifers (P = 0.0011) at half life (P = 0.0092), and time to half life was significant (P = < 0.0001) between temperaments. Peak INS concentrations (mIU/mL) for the C and T heifers were 54.5 ± 7.6 and 27.2 ± 7.6, respectively. Insulinogenic index was affected by temperament (P = 0.0173) and there was a temperament by time interaction (P = 0.0003). These data indicate that temperament (P = 0.0282) has an impact on CS secretion following cannulation stress which subsequently results in elevated GLU and INS concentrations. Temperament modifies metabolic regulatory responses in heifers and this altered metabolism of temperamental cattle may partially explain their decreased productivity.

Key words: cattle, temperament, glucose

773 The role of parathyroid hormone and calcitonin in the prevention of hypocalcemia under induced metabolic acidosis in cattle. E. M. Rodríguez*[1], A. Bach[1,2], and A. Arís[1], *[1]Department of Ruminant Production, IRTA, Caldes de Montbui, Spain, [2]ICREA, Barcelona, Spain.*

Metabolic acidosis ameliorates parturient hypocalcemia by increasing plasma concentrations of 1,25-dihydroxyvitamin D (1,25-D) in cows. Under acidosis, it has been reported in other mammals that parathyroid hormone (PTH) function is enhanced through an upregulation of PTH receptor (PTHR) and increasing 1,25-D levels. The objective of this study was to evaluate the PTH/PTHR concentrations under an acidic state in cattle and to assess changes in calcitonin (CALC), also involved in calcium homeostasis with opposite effects to PTH. Twenty-four Holstein bulls (497 ± 69 kg of BW and 341.5 ± 10.5 d of age) were randomly assigned to 2 treatments [acidosis (ACI), or control (CON)]. Acidosis was induced by oral administration of ammonium chloride (2.5 Eq/day) during 10 d and animals were then slaughtered following commercial practices. Blood samples were taken before slaughter, and samples of urine, kidney, and thyroid gland were harvested immediately after sacrifice. Blood and urine pH were measured immediately after collection. Expression of CALC, CALC receptor (CALCR), PTH and PTHR from kidney and thyroid gland was measured by qRT-PCR. CALC activity under acidotic conditions was tested in vitro using human breast T47D cultures expressing CALCR. Data was analyzed with an ANOVA using the treatment as the main effect. As expected, blood pH was lower (P<0.001) in ACI than CON bulls (7.57 vs. 7.64 ± 0.02). Urine pH was lower (P<0.01) in ACI than CON bulls (5.95 vs. 7.38 ± 0.13). No differences were detected on CALC and PTH expression or on PTH serum concentrations. Expression of PTHR in kidney was greater (P<0.05) in ACI than CON bulls. Furthermore, CALC activity in vitro at pH 7.4 was greater (P<0.01) than that found at more acidic or alkaline pHs. In conclusion, PTH function is enhanced in metabolic acidosis by an increased expression of PTHR in kidney, and whereas CALC/CALCR expression is not affected, its binding activity may be hampered. These findings demonstrate that, in an acidic state, PTH and CALC are complementary hormones promoting increased blood calcium levels.

Key words: hypocalcemia, calcitonin, parathyroid hormone

774 Molecular control of puberty as affected by nutrition and leptin infusion in zebu heifers. J. Diniz-Magalhães*, M. V. Carvalho, A. B. S. Machado, M. A. V. Silva Júnior, and L. F. P. Silva, *Universidade de São Paulo, Pirassununga, São Paulo, Brazil.*

Leptin has been proposed to affect several genes in the hypothalamus to modulate the effect of nutrition on sexual maturation. The objective was to evaluate the effect of oLeptin infusion, and of high or low energy intake, on the expression of oxytocin (OXT), β-arrestin 1 (ARRB1), and insulin-like growth factor binding protein-2 (IGFPB2). Thirty 6 prepubertal Nelore heifers, 18 to 20 mo-old, 275.8 ± 17.2kg BW and BCS of 5 ± 0.5 (1 to 9 scale) were randomly assigned to each of 3 treatments: H (high-energy diet), L (low-energy diet), and LL (low-energy diet + oLeptin). Diets were formulated to promote weight gains of 0.4kg/day (groups L and LL) or 1.2kg/day (H group). Heifers were fed ad libitum once a day, they were weighed and had their BCS evaluated twice weekly. After 21 d of adjustment, heifers in LL group received subcutaneous injections of oLeptin at 4.8µg/kg BW twice a day, for 56 d. Groups H and L received similar injections of 2mL saline solution. Age at puberty was considered to be the age on first detection of a corpus luteum by twice weekly transrectal ultrasonography, confirmed by plasma concentrations of progesterone of >1ng/ml. Twenty 4 heifers were slaughtered at the time of puberty for harvesting of the hypothalamus. Expression of transcripts of OXT, ARRB1 and IGFBP2 was quantified by real-time PCR. Changes in gene expression were calculated by relative quantification with the ΔΔCt method, using the gene 18S ribosomal RNA as the reference gene. ANOVA used the MIXED procedure of SAS considering the fixed effects of treatment, gene and trt × gene, and the random effects of heifer(trt), and heifer × trt(gene). There was no effect of leptin, or of nutrition on expression of OXT and IGFBP2 (P > 0.10) at the time of puberty. Also, leptin infusion did not alter ARRB1 expression. However, high energy intake reduced expression of ARRB1 by 1.5 folds (P = 0.02). ARRB1 acts inhibiting protein-G receptors, such as the neuropeptide Y receptors. Therefore, downregulation of ARRB1 could be associated with lower sensibility of the hypothalamus to NPY action, and consequently with hastening of puberty.

775 Energy balance alters leptin but not adiponectin mRNA in Holstein cows. D. A. Koltes* and D. M. Spurlock, *Iowa State University, Ames.*

Adipokines are recognized as important signaling molecules secreted by adipose tissue that alter metabolic activity in multiple target tissues. Thus, adipokines likely play a critical role in homeorhetic adaptations that occur throughout the transition period and lactation cycle in dairy cows. Currently, the regulation of adipokines in response to changing energy balance is not well characterized. Therefore, the objective of this research was to determine if changes in energy balance status alter the mRNA abundance of 2 important adipokines, leptin and adiponectin, in lactating Holstein cows. Three models of altered energy balance were investigated, including transition from pregnancy to lactation, feed restriction, and administration of recombinant growth hormone (GH), Posilac. Adipose tissue was collected from 26 cows before calving, and at 5, 21, and 150 d in milk. In different experiments, adipose tissue was collected before treatment, and on d 1 and 4 of feed restriction (n = 19) and d 3 and 7 following administration of GH (n = 20). For all experiments, net energy balance was calculated from daily individual feed intake and milk production, and weekly body weight and milk component analysis. Cows in early lactation and under feed restriction experienced a similar decline in net energy balance with a nadir of –7.38 and –8.09 MCal, respectively ($P < 0.01$). Net energy balance also declined with GH administration ($P < 0.01$), but to a lesser degree (0.23 MCal on d 7). Leptin mRNA abundance decreased with the onset of lactation and with feed restriction ($P < 0.05$), and there was a trend for its decrease with GH administration ($P = 0.08$). In contrast, a significant change in adiponectin mRNA abundance was observed only with GH administration, where adiponectin mRNA increased on d 3, but not d 7 relative to pre-treatment ($P < 0.05$). These results show that leptin mRNA consistently decreased with declining energy balance, while changes in adiponectin mRNA were not associated with energy balance status. Thus, altered leptin, but not adiponectin, may represent a mechanism by which adipose tissue signals a need for physiological change during times of negative energy balance.

Key words: growth hormone, feed restricted

776 Effect of a high-energy diet after weaning on luteinizing hormone secretion in Holstein bulls. M. Maquivar*[1], L. A. Helser[2], M. D. Utt[1], L. H. Cruppe[1], F. M. Abreu[1], G. E. Fogle[1], J. M. DeJarnette[2], and M. L. Day[1], *[1]The Ohio State University, Columbus, [2]Select Sires Inc., Plain City, OH.*

Feeding a high energy diet to beef heifers weaned at 2 to 3 mo of age prematurely activates the reproductive axis and results in precocious puberty. The objective of the present study was to evaluate the impact of a high energy diet, initiated approximately 2 mo of age, on secretion of LH in Holstein bull calves. Male calves received 1 of 2 diets beginning at 58 ± 0.7 d of age. Diets were designed to contain the same amount of protein (14.1% CP) but different amount of energy: high energy diet (n = 9, HIGH, 2.2 Mcal/kg NEm and 1.37 Mcal/kg NEg) targeting for ADG of 1.5 kg/d and control diet (n = 10, CONT, 1.70 Mcal/kg NEm and 1.09 Mcal/kg NEg) targeting for ADG of 0.75 kg/d. Monthly serial blood samples (10 min intervals for 8 h) were collected via jugular catheters from 6 bulls in each treatment, to assess patterns of LH secretion at 69, 97, 125, 156, 181 and 210 d of age. The ADG differed among treatments (1.47 ± 0.05 HIGH vs. 0.95 ± 0.04 kg/d CONT, $P < 0.01$). Body weight tended ($P < 0.1$) to differ at 118 and 134 d of age and differed ($P < 0.05$) from 146 to 218 d. At 125 d of age, concentration of LH was greater in the HIGH (1.83 ± 0.05 ng/ml) than CONT (1.50 ± 0.07 ng/ml) treatment and was lesser ($P < 0.01$) at 181 (1.07 ± 0.04 vs. 1.43 ± 0.08, respectively) and at 210 (1.00 ± 0.03 vs. 1.34 ± 0.06, respectively) days of age (trt x age, $P < 0.01$). Number of LH pulses did not differ between treatments at 69, 97, 156 and 181 d of age but was greater ($P < 0.01$) in the HIGH than CONT treatment at 125 d (8.33 ± 0.95 vs. 3.00 ± 0.44, respectively) and tended ($P = 0.07$) to be greater at 210 d of age (trt x age, $P < 0.01$). The amplitude of LH pulses was greater ($P < 0.05$) in the CONT than HIGH treatment at 125, 181 and 210 d of age and a tended ($P < 0.1$) to be greater at 97 and 156 d of age. These data suggest that a high energy diet initiated at 2 mo of age induces a rapid activation of the gonadotropic axis in Holstein bulls expressed as increased frequency of LH pulses of a lesser amplitude which results in a greater mean concentration of LH. This alteration in LH secretion may accelerate maturation of the reproductive axis in bulls.

Key words: reproductive axis, LH, male calves

777 Effects of volatile fatty acid infusions on angiopoietin-like protein 4 concentration in plasma and ruminal papillae of cattle. S. H. Li*, B. J. Bradford, and L. K. Mamedova, *Kansas State University, Manhattan.*

Angiopoietin-like protein 4 (ANGPTL4), a plasma regulator of energy and lipid metabolism, may be influenced by microbial populations. Microbes could influence ANGPTL4 production via changes in volatile fatty acid (VFA) production. The objective of this study was to evaluate the effects of VFA on plasma and papillae ANGPTL4 concentrations. Six ruminally cannulated lactating Holstein cows were randomly assigned to treatment sequence in replicated 3x3 Latin squares and fed a standard lactation diet ad libitum. Cows were initially infused with 10 mol/d acetate, propionate, or butyrate for 2d, provided as bolus infusions every 4 h. However, during period (P) 1, both DMI and calculated ME intake were decreased by infusions ($P < 0.001$) relative to pre-treatment. Therefore, in P2 and P3, infusion rates were decreased to 5 mol/d. Blood and ruminal fluid samples were collected immediately before and after infusions. Ruminal papillae samples were collected after infusions and ruminal pH data were collected every 5 min during treatment with an indwelling pH probe. Five d were allowed between treatment periods. Period 1 results were analyzed independently from P2 and P3 data using mixed model analysis. There were no treatment effects on DMI, ME intake, or ruminal pH at either infusion rate ($P > 0.12$). Plasma ANGPTL4 concentration was determined by ELISA, which revealed no treatment effects at either infusion rate ($P > 0.14$). Papillae ANGPTL4 concentration was determined by Western blot, and no effects of treatment were observed at either infusion rate ($P > 0.51$). Furthermore, no correlations were observed between ANGPTL4 and ruminal VFA concentration. However, papillae ANGPTL4 was positively correlated with both ruminal pH ($P = 0.02$) and ME intake ($P = 0.03$). Conversely, plasma ANGPTL4 had an inverse relationship with ruminal pH ($P < 0.01$), with regression estimates ranging from 5.6 to 1.9 ng/mL as mean ruminal pH increased from 6.0 to 6.2. Consistent with previous findings, ruminal ANGPTL4 abundance is positively associated with ruminal pH, but is not associated with plasma ANGPTL4 concentrations.

Key words: ANGPTL4, cattle, volatile fatty acids

778 Incorporation of essential and non-essential fatty acid into distinct lipid classes in cultured bovine and porcine small intestine and muscle explants. C. Caldari-Torres* and B. A. Corl, *Virginia Polytechnic Institute and State University, Blacksburg.*

In foregut fermenters, microbial biohydrogenation leads to saturation of essential fatty acids (EFA) and a loss in their biological function. Despite no literature reporting EFA-deficiency in ruminants, EFA conservation mechanisms in these animals are not well understood. The aim of this study was to examine fatty acid (FA) esterification patterns in ruminant and non-ruminant small intestine (SI) and muscle explants. We performed in vitro culture of bovine and porcine SI and muscle explants with radiolabeled FA to track esterification of EFA and non-EFA into lipid classes. Tissue explants were incubated in media containing radiolabeled non-EFA ([1-^{14}C]16:0 or [1-^{14}C]C18:1), or EFA ([1-^{14}C]C18:2 or [1-^{14}C]C18:3). Porcine SI explants incorporated more non-EFA than EFA (17.9 vs 12.4 ± 2.0 nmol•2 h^{-1}•150 mg $tissue^{-1}$, $P = 0.002$). Bovine muscle explants incorporated more EFA than non-EFA (8.73 vs 6.32 ± 0.86 nmol•2 h^{-1}•150 mg $tissue^{-1}$, $P < 0.001$). Pig muscle explants and cattle SI explants did not exhibit preferential esterification of non-EFA compared with EFA. Cattle SI explants esterified more FA into triglycerides (TG) compared with phospholipids (PL) (3.54 vs 2.42 ± 0.35 nmol•2 h^{-1}•150 mg $tissue^{-1}$, $P = 0.01$). Muscle explants from both species incorporated EFA into PL more readily than non-EFA (Cow: 1.98 vs 1.27 ± 0.39 nmol•2 h^{-1}•150 mg $tissue^{-1}$, $P = 0.02$, Pig: 0.98 vs 0.77 ± 0.13 nmol•2 h^{-1}•150 mg $tissue^{-1}$, $P = 0.004$). An increase in PL/TG ratio was observed when measuring incorporation of EFA compared with non-EFA in bovine muscle explants (1.71 vs 0.61 ± 0.19 nmol•2 h^{-1}•150 mg $tissue^{-1}$, $P < 0.001$). There was no difference in PL/TG ratio in porcine muscle explants or bovine or porcine SI explants when quantifying incorporation of EFA compared with non-EFA. Results suggest that muscle esterification patterns of cattle facilitate greater EFA incorporation into PL, while SI esterification patterns of FA seem to have no preference for EFA in ruminants. Support provided by NSF grant IOS-0920491.

Key words: fatty acid, muscle, small intestine

779 Hepatokine, growth hormone, and PPARα-regulated gene network expression in liver of peripartal cows fed two levels of dietary energy prepartum. J. Khan*[1], D. Graugnard[1], D. H. Keisler[2], B. J. Bradford[3], L. K. Mamedova[3], J. K. Drackley[1], and J. J. Loor[1], *[1]University of Illinois, Urbana, [2]University of Missouri, Columbia, [3]Kansas State University, Manhattan.*

Fibroblast growth factor 21 (FGF21) and angiopoietin-like 4 (ANGPTL4) are hepatokines under control of PPARα. During starvation or fasting, liver FGF21 increases leading to inhibition of STAT5ab and impaired growth hormone (GH) action. We examined the expression of 40 genes associated with the network encompassing FGF21, GH, long-chain fatty (LCFA) oxidation, and PPARα in cows (n = 6/diet) assigned to a control (CON; NEL = 1.34 Mcal/kg DM) or moderate-energy (OVER; NEL = 1.62 Mcal/kg DM) diet during the entire dry period. All cows were fed a common lactation diet (NEL = 1.69 Mcal/kg DM) postcalving. A percutaneous liver biopsy was collected at −14, 7, 14, and 30 d relative to parturition (DIM) for transcript profiling via quantitative PCR. Estimated prepartal energy balance (EBAL) was greater (~159% vs. 102%, $P < 0.05$) in OVER vs. CON, but during the first wk postpartum cows fed OVER prepartum were in more negative EBAL. Prior to calving, CON cows had greater ($P < 0.05$) serum FGF21 which corresponded with greater ($P < 0.05$) liver FGF21 expression. Concentration of FGF21 decreased ($P < 0.05$) gradually postpartum regardless of diet. Along with more severe negative EBAL, cows fed OVER vs. CON prepartum had greater ($P < 0.05$) postpartal serum NEFA, BHBA, and GH, and greater liver triglyceride concentrations. Those data agreed with greater expression of ACOX1, CPT1A, ACADVL, HMGCS2, FGF21, and ANGPTL4 in OVER vs. CON at 7–14 DIM. Serum ANGPTL4 concentration was not affected by diet or time. Despite the gradual increase in serum GH after calving, at 7–14 DIM liver from cows fed OVER prepartum had greater ($P < 0.05$) IGFALS potentially to counteract the temporal decrease in hepatic GHR, STAT5ab, and IGF-1. Our results revealed a link between prepartal energy overfeeding and postpartal negative EBAL leading to greater serum NEFA coupled with transcriptional adaptations in liver. Those encompassed not only LCFA oxidation and GH signaling but also hepatokine production. The apparent lack of relationship between liver mRNA of FGF21 and ANGPTL4 with blood concentrations merits further study.

Key words: transition cow, metabolism, growth factors

Production, Management and the Environment: Dairy Facilities

780 Herd turnover and mortality in low profile cross-ventilated and naturally ventilated dairy barns in the Upper Midwest. K. M. Lobeck*, M. I. Endres, S. M. Godden, and J. Fetrow, *University of Minnesota, St. Paul.*

The objective of this study was to describe herd turnover and mortality rates in low profile cross-ventilated barns (CV) compared with conventional naturally ventilated (NV) freestall barns. The study was conducted in 12 commercial dairy farms in Minnesota and eastern South Dakota. All farms had deep sand freestalls and had been in operation for at least 1 year before the beginning of the study. Farm records were collected from January to December 2008. Herd size was stable except 1 CV herd expanded from 1300 to 1600 cows in the summer. One NV and 1 CV barn were excluded at the end of the study because of substandard records. Sold and died events were examined. Herd turnover rate was calculated as the number of animals that were sold or died during the year, divided by the average herd size. Mortality rate was calculated as the number of animals that died divided by average herd size. Seventeen categories were created for sold and died reasons: abortion, udder conformation, Johne's positive, mastitis, low milk production, reproduction, lame, metabolic problems, metritis, animals that were unable to rise, calving problems, injury, sick, miscellaneous, unknown, and no reason stated. Overall herd turnover rate was 26.8 ± 3.2 and mortality was 5.4 ± 0.8. Herd turnover rates (LSMeans ± SE) were 24.6 ± 4.6 and 29.0 ± 4.6, and mortality rates were 5.8 ± 1.2 and 5.0 ± 1.2 in CV and NV barns, respectively. There were no differences between the 2 systems. Top 3 reasons for cattle to die on farm were sickness (33.6 ± 0.4), metabolic disease (9.5 ± 0.03), and injuries (8.6 ± 0.02) with no differences between CV and NV barns. Top reasons to be sold from the herd were low production (10.3 ± 0.1), mastitis (9.6 ± 0.1) and reproduction (8.6 ± 0.1). Cows housed in NV barns were more likely to be sold due to low milk production (21.9 ± 0.1 vs. 12.9 ± 0.1; $P < 0.001$) than cows housed in CV barns. The CV barns reported selling more animals due to reproductive problems (16.0 ± 0.1 vs. 7.6 ± 0.1; $P < 0.001$) and mastitis (10.2 ± 0.1 vs. 6.0 ± 0.1; $P = 0.02$) than NV barns, respectively. Based on these results, CV and NV barns appeared similar for mortality and turnover rates.

Key words: dairy cattle, mortality, turnover

781 Mortality and herd turnover rates in dairy herds utilizing recycled manure solids for bedding freestalls. A. W. Husfeldt*, M. I. Endres, J. A. Salfer, and J. K. Reneau, *University of Minnesota, St. Paul.*

The objective of this study was to evaluate mortality and herd turnover rates in Midwest dairy herds utilizing recycled manure solids in deep bedded or mattress based freestalls. The study included 34 commercial dairy operations with herd sizes ranging from 100 to 3700 lactating cows. Forty 5 percent of the herds had mattresses and 55% had deep bedded stalls. Sold and died events were examined. Herd turnover rate was calculated as the number of animals that were sold or died during the year, divided by the average herd size. Mortality rate was calculated as the number of animals that died divided by average herd size. Overall mortality rate (mean ± SD) was 8.2 ± 3.1%. Deaths were categorized as mastitis, injury, lameness, euthanasia, pneumonia, and miscellaneous or unknown reasons. Main causes of death were miscellaneous or unknown reasons (63.6 ± 15.5), injuries (15 ± 8.9), and mastitis (12 ± 6.9). Overall herd turnover rate was 38.2 ± 6.9%. Reasons for turnover were categorized as injury, low production, mastitis, reproduction, udder conformation, feet and legs, sick, aborted, dairy, and miscellaneous or unknown reasons. Main reasons for turnover were mastitis (19.5 ± 10.9), reproduction (15.8 ± 10.2), and low production (14.3 ± 14.8). Turnover rate during the first 60 DIM was 9.9 ± 3.4%. There was no association between stall surface and mortality. Mortality rates (LSmeans ± SE) were 8.2 ± 0.7 and 8.6 ± 0.9 for deep bedded and mattress herds, respectively. Herd turnover rates were 37.2 ± 1.7 and 38.6 ± 1.9 for deep bedded and mattress herds, respectively. No association was found between turnover rates and stall surface. There was a trend for stall surface to be associated with voluntary (dairy) and involuntary (other) reasons for removal ($P = 0.054$). Voluntary turnover was 16.7 ± 2.5 and 8.8 ± 3.1 for deep bedded and mattress, respectively. Sixty DIM turnover rates were 10.4 ± 0.09 for deep bedded herds and 9.5 ± 1.0 for mattress herds. Stall surface was not associated with 60 DIM turnover rates. Results indicate stall surface had a relatively minor association with mortality and turnover rates in dairy herds utilizing recycled manure solids as bedding.

Key words: mortality, herd turnover, manure solids

782 Effectiveness of fly traps and baits at three primary fly sites on Florida dairy farms. M. E. Sowerby*[1] and J. A. Hogsette[2], [1]*University of Florida, Gainesville,* [2]*USDA-ARS-CMAVE, Gainesville.*

The house fly, *Musca domestica* L., is a ubiquitous pest on dairies. They can cause production losses from fly worry, disperse from farms to nearby towns, transmit diseases like pinkeye, and carry pathogens like *E. coli* O157:H7. The calf raising, commodity barn/feed storage, and feeding barn areas tend to attract and support large house fly aggregations on dairies. If flies could be successfully managed in these areas, farm-wide populations might be significantly reduced. Traps or toxic baits would be the best management tools because house flies are resistant to most pesticides applied as space and residual sprays. Our objective was to evaluate the relative effectiveness of a trap, a toxic scatter bait and a toxic bait strip for house fly managment in high-density fly congregation areas. Three dairies having the aforementioned fly aggregation areas were selected. Treatments were the Farnam Captivator trap (baited with Terminator Fly Attractant), the QuickStrike Bait Strip (nithiazine 1% AI) and QuikStrike Scatter Bait (dinotefuran 0.5% AI). Treatments were placed, one at each area, on all 3 dairies according to a pre-arranged random rotational schedule. After 24 h, flies were counted and devices were rotated to the next area. A complete rotation constituted one replication in a 3 × 3 Latin square design and a test was composed of 6 replications. Data were normalized with $\log_{10} + 1$, subjected to ANOVA, and means separated with the Ryan-Einot-Gabriel-Welsch Multiple Range Test ($P < 0.05$). The mean numbers of flies captured by treatment were: Captivator trap (1624)>QuikStrike Scatter Bait (138)>QuikStrike Strip (95). The mean numbers of flies captured at each area, treatment overlooked, were: commodity barn/feed storage area (1050)>the calf pens (558)>the feeding barn (249). The Captivator trap captured significantly more flies than the bait strip and the scatter bait at all areas. Thus the Captivator trap is recommended for management of flies at the three fly aggregation areas, and the most attractive area, based on our research, is the commodity barn/feed storage area.

Key words: house flies, bait strips, dairy farms

783 Chemical and bacteriological characteristics of digested, composted, and separated raw manure solids prior to use as freestall bedding. A. W. Husfeldt*, M. I. Endres, K. A. Janni, J. A. Salfer, and J. K. Reneau, *University of Minnesota, St. Paul.*

The objective of this study was to investigate the chemical and bacteriological characteristics of digested, composted, and separated raw manure solids. The study included samples of recycled manure solids from 38 Midwest dairy herds collected before use as freestall bedding. Twenty-five composite samples of digested solids, 9 samples of separated raw solids, and 4 samples of composted solids were collected once and analyzed for chemical and bacteriological characteristics. Chemical analyses included moisture, pH, fiber, fat, non-fiber carbohydrates (NFC), ash, nitrogen, phosphorous, potassium, carbon, and C:N ratio. Bacterial counts (colony forming units per mL) of bacillus, coliforms, environmental streptococci, staph species, and yeasts were performed. Moisture content (LSmeans ± SE) was different ($P <$ 0.001) between composted (60.3 ± 1.6)and both digested (72.9 ± 0.7) and raw (72.6 ± 1.1) solids. The pH, nitrogen, phosphorous, NFC, and total ash content were different ($P < 0.001$) between digested and separated raw solids. The pH was 9.3 ± 1.0 for digested solids and 8.9 ± 1.0 for raw manure solids. Nitrogen (%) was 1.50 ± 0.03 and 1.17 ± 0.05% for digested and raw solids, respectively. Phosphorus (ppm) was 5,451 ± 240 for digested and 2,321 ± 415 for raw solids. The NFC (%) was 3.8 ± 0.26 for digested and 6.2 ± 0.45 for raw solids. Ash (%) was 10.2 ± 0.32 and 8.1 ± 0.56 for digested and raw solids, respectively. Differences in coliform ($P < 0.001$) and environmental streptococci ($P =$ 0.002) populations were also found between digested and raw manure solids. Log-transformed coliform bacterial counts in digested and raw solids were 4.0 ± 0.4 and 9.4 ± 0.7, respectively. Coliforms were not found in composted solids. Environmental streptococci counts were 9.4 ± 0.7 in digested solids and 14.8 ± 1.2 in raw solids. Other minor differences between digested and composted manure solids as well as composted and separated raw manure solids were also observed. These results indicate that anaerobic digestion of manure may affect the characteristics of recycled solids before use as bedding for freestalls.

Key words: recycled manure solids, freestall bedding, bacterial counts

784 Chemical and bacteriological characteristics of digested, composted, and separated raw manure solids used as freestall bedding. A. W. Husfeldt*, M. I. Endres, K. A. Janni, J. A. Salfer, and J. K. Reneau, *University of Minnesota, St. Paul.*

The objective of this study was to investigate the chemical and bacteriological characteristics of digested, composted, and separated raw manure solids used as freestall bedding. The study was conducted on 38 dairy farms in the Midwest. Composite bedding samples from each lactating pen and one dry pen collected at one visit were analyzed for bacterial counts of bacillus, coliforms, environmental streptococci, staphyloccocus species and yeasts. Total number of samples for bacterial analysis included 199 digested, 38 composted, and 71 separated raw solids. Subsamples from high and low production groups as well as first parity and dry cow groups were analyzed for moisture, pH, NDF, non-fiber carbohydrates (NFC), ash, N, C, and C:N ratio. Total number of samples for chemical analysis included 85 digested, 14 composted, and 29 separated raw solids. Bedding moisture adjusted for bedding frequency (LSmeans, % ± SE) of composted solids was 40.0 ± 1.1. Composted solids moisture was different ($P < 0.001$) than digested (54.3 ± 1.0) and raw (56.5 ± 1.1) solids. The NDF (%) in digested solids (70.6 ± 0.55) was different than composted (75.0 ± 1.1, $P < 0.001$) and raw solids (73.1 ± 0.9, $P = 0.012$). The NDF content was not different between composted and raw solids. Ash (%) in composted solids was 7.7 ± 1.1 and was different than digested (12.3 ± 1.0, $P < 0.001$) and raw solids (9.7 ± 1.1, $P = 0.024$). In addition, ash content was different between digested and raw solids ($P < 0.001$). Nitrogen (%) was different between raw and digested solids (1.7 ± 1.1 and 2.0 ± 1.0, respectively; $P = 0.001$). There were no differences among the bedding types for coliform counts. Environmental streptococci counts were different ($P < 0.001$) between digested and raw, and digested and composted solids; however, this was a minor biological difference. Environmental streptococci counts (log-transformed colony forming units per mL) were 14.1 ± 0.11, 15.2 ± 0.18, and 15.4 ± 0.24 for digested, raw, and composted solids, respectively. In conclusion, we found only minor differences among digested, composted, and separated raw manure solids when used as bedding in freestalls.

Key words: bacterial counts, freestall bedding, manure solids

785 Temperature and humidity in cross-ventilated and naturally ventilated dairy barns in the upper Midwest. K. M. Lobeck*, M. I. Endres, S. M. Godden, and J. Fetrow, *University of Minnesota, St. Paul.*

The objective of this study was to describe barn temperature, humidity, and some measurements of cow comfort in low profile cross-ventilated barns (CV) compared with conventional naturally ventilated freestall barns (NV). The study was conducted on 12 commercial dairy farms in Minnesota and eastern South Dakota from January to December 2008. Herd sizes ranged from 400 to 1600 lactating cows. All herds had stalls bedded with sand. All NV barns used fans and soakers and all CV barns used evaporative cooling pads for heat abatement. Cow respiration rates were measured on 75 cows from the high production pen on each farm twice during the summer visit. Morning observation was the baseline respiration rate with the second observation taken a minimum of 3 h later in the afternoon. Temperature and humidity were collected hourly inside the facility with data loggers and from the nearest weather station for the entire year. Cow comfort index (CCI) was calculated as the number of animals lying down in the stalls divided by total number of animals touching a stall (lying, 2 feet in a stall, or standing with all 4 feet in the stall) and it was measured 3 times during each visit. The CV barns were warmer in the winter than the NV barns (3.9 vs. −1.7°C; $P < 0.001$). There were no differences in temperature between CV and NV barns in spring, summer, or winter. However, summer temperature-humidity index (THI) was lower in CV than NV barns (65.9 vs. 68.5; $P < 0.001$). Respiration rates were not different between CV and NV barns (55.6 vs. 56.6 breaths/min, respectively). Outside THI was similar for CV and NV barns during respiration rate measurement (73.8 vs. 73.6). Each 1 unit increase in outside THI increased respiration rates by 0.26 ± 0.09. Overall CCI were 84.2, 85.2, 79.7, and 84.6 for winter, spring, summer, and fall, respectively. The CV barns had higher CCI than NV barns (84.2 vs. 75.3; $P = 0.047$) during the summer, with no differences in the other seasons. In conclusion, CV barns had greater CCI and lower THI during the summer than NV barns (possible indicators of improved cow comfort) although respiration rates did not differ.

Key words: temperature, cross-ventilated barn, humidity

786 A one-year comparison of house fly and stable fly populations at three different types of dairy facilities in the Texas Panhandle. S. L. Swiger*[1], K. J. Lager[2], T. R. Bilby[1], B. R. Henderson[2], R. G. S. Bruno[2], and E. R. Jordan[3], *[1]Texas AgriLife Extension and*

Research, Stephenville, [2]Texas AgriLife Extension, Canyon, [3]Texas AgriLife Extension and Research, Dallas.

Throughout the years work has been done to construct the most efficient and economical dairy facility that increases production, eliminates health issues and disease risks. Three main types of dairy facilities are currently utilized in the United States; open dry-lot, free-stall and cross ventilation. Each style of facility has a unique impact on the fly populations on and around a dairy. The objective of this study was to determine the effect of 3 different dairy facility types on number of house flies and stable flies present during summer. House flies were collected with 4 dinotefran baited scatter bait traps and stable flies were collected with 4 Olson sticky traps within each of the 3 dairy facility types. The fly traps were placed throughout each facility and flies were collected weekly for 12 wks from May until August 2010. The 3 facilities were found to contain both house flies and stable flies. The open dry-lot barn had more ($P < 0.05$) stable flies (n = 18,067) than either the free-stall (n = 5,423) or cross ventilation barns (n = 1,130) and the free-stall barn had more ($P < 0.01$) stable flies than the cross ventilation barn. There were more ($P < 0.05$) house flies in the free-stall barn (n = 5,270) than the open dry-lot (n = 418) or cross ventilation barn (n = 2,438) and the cross ventilated barn had more ($P < 0.01$) than the open dry-lot. In conclusion, results show that using a cross ventilated barn reduced stable but not house fly populations compared with a free-stall or open dry-lot facility. Further studies are needed to assess the ability of different facility types to reduce the negative effects of different fly populations on dairy cattle.

Ruminant Nutrition: Dairy: Minerals, Vitamins, and Other Stuff

787 Effect of sodium chloride intake on urea concentration in milk from dairy cows. J. W. Spek*[1], J. Dijkstra[1], J. J. G. C. van den Borne[1], and A. Bannink[2], *[1]Wageningen University, Wageningen, the Netherlands, [2]Wageningen UR Livestock Research, Lelystad, the Netherlands.*

A reliable indicator of nitrogen (N) excretion by dairy cattle is required to easily estimate N excretion on farm and to evaluate N excretion mitigation strategies. Milk urea nitrogen (MUN, mg/dl) has been shown to be positively correlated to excretion of urea and total N in urine in dairy cows. However, a significant proportion of variation in urine N-excretion (UN) remains unexplained by MUN content. In the present experiment, it was hypothesized that urine volume is affected by dietary salt intake and affects MUN content and the relationship between MUN and UN. Twelve lactating Holstein Friesian cows (milk production 25.4 ± 2.53 kg/d and 207 ± 41.3 DIM), of which 4 were fitted with catheters in the urine bladder, were randomly assigned to 4 dietary levels of salt (3, 9, 13, and 18 g Na/kg DM) in a 4 × 4 Latin square design. Cows were fed at 95% of ad libitum feed intake to ensure equal N-intake across dietary levels of Na. During the last 2 d of each one-week treatment period, milk was sampled and analyzed for MUN. Urine and feces of catheterized cows were collected quantitatively during the last 2 d of each treatment week. Urine was analyzed for total N and urea, and feces for total N and DM. Data were analyzed with the PROC MIXED procedure of SAS in which the blocking factors cow and period were included as random and fixed effects, respectively. Dry matter and N intake were 21.4 ± 1.24 kg/d and 522 ± 32.0 g/d, respectively, and equal across treatments. A significant negative linear correlation was found between intake of Na and level of MUN: MUN = 12.8 ± 0.44 - 0.70 ± 0.075 × 100 g Na/d. Based on the 4 catheterized cows, for every 100 g increase in Na consumption, a significant linear increase was found for urine production (13.7 ± 0.87 L/d), UN (5.3 ± 2.07 g/d) and urinary non-urea N excretion (4.2 ± 0.57 g/d). However, excretion of urinary urea N was unaffected (1.2 ± 1.62 g/d) by Na intake level. It is concluded that salt intake level affects MUN without an effect on urinary urea excretion. Level of salt intake should hence be considered when using MUN as an indicator of urinary urea excretion or UN.

Key words: milk urea nitrogen, urinary nitrogen excretion, sodium chloride

788 2010 National survey of barriers related to precision phosphorus feeding. J. H. Harrison*[1], R. James[2], C. Stallings[2], E. Whitefield[1], M. Hanigan[2], and K. Knowlton[2], *[1]Washington State University, Puyallup, [2]Virginia Tech, Blacksburg.*

A national survey was conducted in cooperation with ARPAS to document barriers related to phosphorus feeding. The electronic survey link was sent to all ARPAS members with a dairy emphasis. Approximately 130 respondents replied to 8 questions. 53% of respondents indicated that balancing for ration P was a priority (rank of 7–10 out of 1–10 rank). 75.2% of respondents indicated that they perceived current NRC recommendations for P as adequate, while 8.5% indicated that they are too low, and 16.3% indicated they are too high. When asked to identify the most challenging aspect of reducing P in the diet, 54.8% indicated uncertainty of P content of feedstuffs, 36.8% indicated cost, and 9.6% indicated uncertainty of ration ingredients. 52 of approximately 130 respondents replied when asked if their recommendations were above those of NRC. They indicated: concern about negative impact on metabolic diseases (46.2%), mastitis (9.6%), foot problems (7.7%), heat detection efficiency (55.8%), conception rate (63.5%), and retained placenta (23.1%). Most respondents (99%) indicated that they had reduced their recommendations for dietary P content over the last 3 to 5 years. When asked what information is needed to assist them in ration formulation for P, 69.7% indicated availability of P from different sources; 56.3% indicated updated requirements for maintenance, production and reproduction; and 45.4% indicated that more documentation was needed that current NRC recommendations for P are adequate. Additional questions were asked about target level of P in the key production groups, and what sources of P were included in diets. Information collected from the survey indicate that more progress needs to be made to assure the P availability from feedstuffs and assure that no impairment of reproduction would be expected from feeding NRC recommended levels of P.

Key words: phosphorus, feed management, nutrition

789 Evaluation of ruminally protected niacin on thermal regulation and productivity of high-producing dairy cows during summer heat stress. S. R. Wrinkle*[1], P. H. Robinson[1], and J. E. Garrett[2], *[1]Department of Animal Science, University of California, Davis, [2]Quali Tech Inc., Chaska, MN.*

Heat stress resulting in animal production losses costs the dairy industry hundreds of millions of dollars annually in the USA, especially in southern areas such as California. Niacin as a dietary supplement typically induces "flushing," or increased blood flow to the skin, causing a decrease in core body temperature which has been shown to reduce heat stress in dairy cows. Our objective was to determine if feeding ruminally protected niacin (RPNi) is effective in alleviating heat stress in dairy cows. Two 2x2 factorial experiments, each with 28 d periods, were conducted in the summer of 2010. In Expt. 1, 2 pens, each ~180 early lactation multiparity cows were used, and in Expt. 2, 2 pens of ~180 mid-lactation mixed parity cows were used. The basal total mixed ration, of 17% CP, 33% aNDF and 15% starch, was the same for all cows with the exception of RPNi added to RPNi diets. Treatment cows received 19 g RPNi/cow/d, estimated to deliver ~7 g of intestinally absorbable niacin/cow/d as determined by ruminal in sacco incubation. In Expt. 1, respiration rate (RR) and panting score (PS) were measured 4 times/d. RR was lower ($P = 0.02$) at 09:00 h, but not impacted at other times, while PS was lower ($P \leq 0.01$) at 04:30, 09:00 and 20:30, but not impacted at 16:30 h, in cows fed RPNi. Side udder (SU) and back udder (BU) temperatures did not differ at 14:15 or 22:15, but BU was lower ($P = 0.03$) at 06:00 h in cows fed RPNi. There was no difference in DM intake or milk and milk component yields, but milk fat % for RPNi cows was lower ($P < 0.01$). In Expt. 2, where PS, RR, SU and BU were not measured, DM intake and milk yield did not differ between treatments, and there were no differences in milk yield, or milk protein or lactose %. However, fat % was higher in RPNi cows ($P = 0.01$). While symptoms of heat stress were reduced for cows fed RPNi, the increase in cow comfort did not result in increased productivity. Differences in the milk fat % response between stages of lactation suggests that niacin affects metabolism differently if cows are in negative (early lactation) or positive (mid-lactation) energy balance.

Key words: niacin, heat stress, milk fat

790 Effects of feeding a rumen protected lysine (AjiPro-L) from calving to the fourth week of lactation on production of high-producing dairy cows. J. E. Nocek*[1], T. Takagi[2], and I. Shinzato[2], *[1]Spruce Haven Farm and Research Center, Auburn, NY, [2]Ajinomoto Co., Inc., Tokyo, Japan.*

Sixty-five multiparous Holstein cows were used to examine the effects of feeding a rumen protected lysine (AjiPro-L, Ajinomoto Co., Inc., Japan) from calving to the 4th week of lactation on production of dairy cows. Cows were balanced across treatments based on the previous ME305 and body condition score at 21 d pre-partum and assigned to 3 dietary treatments. The experimental diets contained either 0 (Control), 100 or 200g/d of AjiPro. Cows were individually housed in tie-stalls and were fed the experimental diets for 4 weeks from calving, and all cows were moved to free-stall barns and fed a common lactation TMR from 5th to 12th week of lactation to see the carry-over effects. Individual milk yield was measured daily, and milk component contents were measured weekly throughout the study. Individual dry matter intake (DMI) was measured daily during the first 4 weeks of lactation. During the supplementation period, mean yields of milk, FCM and fat were significantly higher ($P < 0.01$) for cows receiving 100 or 200g AjiPro than Control, but neither DMI nor milk protein yield differed between treatments. Milk production efficiency was significantly higher for cows receiving 200g AjiPro than the other 2 treatments. In the post-supplementation period, 100g AjiPro resulted in significantly higher yields of FCM and fat than 200g AjiPro with Control being intermediate. Protein yield was higher ($P < 0.01$) for Control and 100g AjiPro than 200g AjiPro. MUN was higher for 200g AjiPro ($P < 0.05$) than Control. In this study, 100g AjiPro supplementation resulted in increased milk production during the supplementation period and showed a numerical tendency for positive carry-over effects in the post-supplementation period compared with Control, whereas an over-feeding (200g AjiPro) had slight adverse effects in the post-supplementation even if it resulted in the best performance during the supplementation period. These results suggest that optimal lysine supplementation maybe involved with triggering nutrient (both energy and protein) partitioning in early lactation cows.

Key words: rumen protected lysine, milk production, early lactation

791 Feeding a C16:0-enriched fat supplement increased the yield of milk fat and improved feed efficiency. A. L. Lock*, C. L. Preseault, K. E. DeLand, and M. S. Allen, *Michigan State University, East Lansing.*

Previous work has indicated that dietary palmitic acid (C16:0) may increase milk fat yield over and above expected values either without additional fat supplementation or compared with other dietary fatty acids. The effect of dietary C16:0 on feed intake, yield of milk and milk components, and feed efficiency was evaluated in an experiment with a crossover arrangement of treatments with 25 d periods. A fermentable starch challenge (FSC) on the last 4 d of each period was utilized as a split-plot within period. Sixteen midlactation Holstein cows (249 ± 33 DIM) were assigned randomly to treatment sequence. Treatments were either a C16:0-enriched (~85% C16:0) fat supplement (FAT, 2% DM) or a control diet (CON) containing no supplemental fat. Diets containing dry ground corn grain were fed from d 1 through 21 of each period. On the last 4 d of each period, dry ground corn was replaced by high-moisture corn grain on an equivalent DM basis. Response variables were averaged for d 18 to 21 for the dry corn diet and d 22 to 25 for the FSC. There were no treatment effects on milk yield (32.0 kg/d) or milk protein yield (1.1 kg/d). FAT increased milk fat concentration from 3.88 to 4.18% and fat yield from 1.23 to 1.33 kg/d compared with CON ($P < 0.001$). Consequently FAT increased 3.5% fat-corrected milk yield by 1.7 kg/d ($P < 0.05$). FAT decreased DMI by 0.7 kg/d ($P < 0.05$) and increased feed efficiency (3.5% fat-corrected milk yield/DMI) 7.5% ($P < 0.001$) compared with CON. The FSC did not affect milk fat, DMI or feed efficiency. The increase in milk fat yield by FAT was entirely accounted for by an increase in C16:0 output into milk. Data demonstrates the potential for a dietary C16:0-enriched fat supplement to improve milk fat concentration and yield as well as efficiency of feed conversion into milk. Further studies are required to verify and extend these results and to determine whether responses are similar across different diets and levels of milk production.

Key words: palmitic acid, milk fat, feed efficiency

792 Characterizing the effect of Amaferm on forage NDF digestibility. J. E. Nocek*[1] and H. Jensen[2], *[1]Spruce Haven Farm and Res. Ctr, Auburn, NY, [2]Biozyme Inc., St Joseph, MO.*

Amaferm is a fermentation extract shown to stimulate ruminal bacterial and anaerobic fungal growth and enzymatic activity. Our aim was to evaluate the effect of Amaferm on extent and rate of ruminal NDF digestion from a random samplings of corn silage, haylage and hay . Samples (~75 each) of corn silage, haylage and hay of various NDF concentrations and digestibilities were subjected to in situ digestion. Limited sample size restricted cow numbers and rumen residence times used. Two lactating, ruminally cannulated cows (40–120 DIM) were used to determine rumen digestibility: one received control diet only with no Amaferm, the other received the same diet with Amaferm. A standardization procedure with grass hay was used to evaluate cow variation before and after Amaferm supplementation. Rumen polyester bag residence times were 12, 24 and 36 h which allowed time point calculation of rumen NDF disappearance and linear digestion rate determination. Grass hay DM digestibility was not ($P > 0.10$) affected by cow in time. Twelve and 24 h of ruminal incubation of corn silage demonstrated no difference in residual NDF between Control and Amaferm. However at 36 h, Amaferm supplementation resulted in a 8.2% increase ($P < 0.01$) in NDF disappearance, which translated into an increased (15.2%, $P < 0.01$) rate of corn silage NDF digestion. Amaferm supplementation had little effect on Hay NDF digestion at 12 h, however, at 24 h of ruminal exposure, NDF disappearance was higher (11.5%, $P < 0.05$) with Amaferm supplementation. Haylage NDF disappearance at 12, 24 and 36 h was increased by 13.3, 12.6 and 10.0% respectively with Amaferm supplementation. Linear NDF rate of haylage digestion was 16.6% higher ($P < 0.01$) with Amaferm supplementation compared with Control. In summary, Amaferm affected NDF digestibility differently for each forage type evaluated. All forage types tested experienced a significant enhancement in extent of NDF digestibility at some point through 36 h of ruminal exposure when supplemented with Amaferm.

Key words: forage, fermentation extract, NDF digestibility

793 Methionine availability to dairy cows when added to mechanically extracted soybean meal with soy gums. D. W. Brake*[1], E. C. Titgemeyer[1], B. J. Bradford[1], J. F. Smith[1], and C. A. Macgregor[2], *[1]Kansas State University, Manhattan, KS, [2]Grain States Soya Inc., West Point, NE.*

We investigated availability of supplemental DL-Met fed to dairy cows when added to soy gums before application to a mechanically extracted soybean meal (meSBM) at the time of manufacture. Holstein

cows (25) were assigned to treatment sequences in 5 replicated 5 × 5 Latin squares with 14-d periods. Cows were fed 1 of 5 treatment diets as TMR supplemented with 0, 2.5, or 5 g/d metabolizable Met provided as a commercially available ruminally protected (RP) Met (MetiPEARL brand, Kemin Industries, Des Moines, IA) or with 4.2 or 8.4 g/d DL-Met added as part of a meSBM product. For the diets providing added Met from meSBM, a product containing 0.3% Met replaced one-half or all of a meSBM product containing no added Met (Soy Best®, Grain States Soya, Inc., West Point, NE). Diets were designed to be first-limiting in metabolizable Met and contained (DM) 14.3% CP. The diet without added Met was estimated to deliver 6.53% of MP as Lys and 1.76% of MP as Met. Diets contained (DM): 35% ground sorghum grain, 25% corn silage, 15% alfalfa hay, 10% soybean hulls, 9% meSBM, and RP-Lys (LysiPEARL brand, Kemin Industries) to provide 0.055% of diet DM as metabolizable Lys. Plasma Met and Ser concentrations increased with supplemental RP-Met ($P < 0.05$), but were not affected by Met supplied in meSBM. Yields of milk (45 kg/d), protein, fat, and lactose were not different among treatments. Concentrations of milk protein were increased ($P \leq 0.05$) by RP-Met, and concentration of SNF tended to increase with RP-Met. Intakes of DM (25.4 kg/d) and N were not different among treatments nor were apparent digestibilities of DM or N. Milk N:N intake was not different among treatments. Increases in BCS were greater ($P < 0.05$) and N retention was numerically greater when Met was supplied by meSBM. Milk protein yield was not responsive to metabolizable Met supply, but based on concentrations of plasma Met and of milk protein there was little evidence to suggest that supplemental Met provided as meSBM markedly increased supply of metabolizable Met to dairy cattle. The unresponsiveness of milk protein yield may suggest our model was not optimal for assessing Met supply.

Key words: methionine, dairy, soybean meal

794 Effects of chromium propionate fed through the periparturient period and starch source fed postpartum on productive performance and dry matter intake of Holstein cows. R. J. Rockwell* and M. S. Allen, *Michigan State University, East Lansing.*

Holstein cows (n = 48) entering second or later lactation were used in a randomized block design experiment with a 2 × 2 factorial arrangement of treatments to determine production and dry matter intake (DMI) responses to chromium propionate supplementation throughout the periparturient period and starch source in the postpartum (PP) diet. Treatments were chromium propionate (KemTRACE Chromium Propionate, Kemin Industries, Cr–Pr, 8 mg Cr/cow/d) or control (CONT, ground corn) top–dressed (20 g/d) daily at feeding from 28 ± 3 d before expected parturition until 28 ± 3 d PP, and dry corn (DC) or high moisture corn (HMC) in diets fed from parturition until 28 ± 3 d PP. Cows were fed a common diet from 28 ± 3 to 84 ± 3 d PP. Data was analyzed using a mixed model with repeated measures. No treatment effects were detected for daily DMI from parturition until 28 ± 3 d PP, but an interaction of chromium, corn and days PP was detected ($P = 0.06$) when cows were fed a common diet. An interaction among chromium, starch source, and week was detected for 3.5% fat–corrected milk (FCM, $P = 0.07$) from parturition until 28 ± 3 d PP. The Cr–Pr/HMC and CONT/DC treatments resulted in consistent and higher (54.9 kg/d) and lower (49.3 kg/d) FCM, respectively throughout the period compared with the other treatments in which FCM decreased over time. After treatment ceased, Cr–Pr tended to increase milk yield (55.4 vs. 51.9 kg/d, $P = 0.09$) and FCM (52.0 vs. 48.3 kg/d, $P = 0.108$) from 28 ± 3 to 84 ± 3 d PP. There was also an interaction of starch source by week for FCM ($P < 0.001$) with FCM increasing throughout the period for DC, but decreasing for HMC; yield of FCM was greater for HMC compared with DC at 42 ± 3 d PP (57.0 vs. 48.0 kg/d), but lower at 84 ± 3 d PP (48.3 vs. 49.3 kg/d). No main effects of treatment or interactions with time relative to parturition were observed for body weight or body condition score. Cr–Pr interacted with starch source throughout the periparturient period in PP diets and days PP to affect production responses that were also affected after treatment application ceased.

Key words: peripartum, starch, chromium propionate

Small Ruminant Symposium: Advancements in Genetic Selection of Small Ruminants for Performance and Parasite Resistance

795 Advancements in genetic selection of small ruminants for performance and parasite resistance: Introduction and purpose. K. Andries*, *Kentucky State University, Frankfort.*

Small ruminant production has steadily increased over the past 10 to 15 years. Most of this increase has been in the area of meat goat production and started with the introduction of the Boer breed in the 1990 ′s. This growth has led to an increased need for basic and applied research into meat goat production. There has been an increasing need for information on genetics and breed differences in meat goats and re-evaluation of many sheep breeds due to changes in selection focus and breed types being used. There is a vast amount of genetic information available on cattle; however, little information is available for sheep and little to no information is currently available for goats, especially meat goats. The cattle industry has been able to utilize research in genetics to make tremendous advancements in productivity in the past 30 years. The Sheep Improvement Program has also moved forward using similar information through the calculation of flock expected progeny differences. Dairy goats also have genetic selection information available through the national dairy improvement program. However, meat goats do not have these types of programs readily available today. The use of molecular genetics as seen in the beef industry demonstrates the potential for small ruminants to find major genes for economically important traits. The sheep industry has implemented some of this research already but research in the goat industry is lagging behind. The one trait that seems to be achieving more research than others is parasite resistance. These efforts will play a major role in the future of small ruminant production. The purpose of this symposium is to show some of the history of genetic research and use of the information in other species and in small ruminants today. The hope is that this will help inspire future research and extension efforts in small ruminants to move both sheep and meat goats into more use advanced animal breeding methodology to improve production in these industries.

Key words: small ruminant, genetic

796 Genetic evaluation: Lessons learned in the beef industry. J. K. Bertrand*, *University of Georgia, Athens.*

The goal of the presentation is to provide a history of US beef cattle genetic evaluation programs and the lessons learned from their implementation. Initially, visual appraisal was to sole criteria for selection of beef cattle. In the 1950s and 60s, State Beef Cattle Improvement Associations and Performance Registry International were formed for the collection of objective phenotypic information. In 1968, The Beef Improvement Federation was formed to provide a framework for standardized record collection and systematic genetic evaluation procedures. During the late 1960s, beef breed associations became the "keepers" of phenotypic and pedigree information in the US During the 1970s and 80s, the beef breed associations began partnerships with Land Grant Universities, where the universities supplied the research and development and also conducted the genetic evaluations for the breed associations in return for grant dollars. In the end, this model was not sustainable due to insufficient funding to cover personnel and equipment. The National Beef Cattle Evaluation Consortium was formed in 2001 with a federal special grant that provided funds to the universities involved in servicing beef genetic evaluation programs to help supplement costs over and above those provided by the breed associations. Beginning in 2007, there was movement toward universities divesting themselves from the servicing of genetic evaluations to allow them to concentrate solely on research. Entities have formed or are still forming, usually at a breed association, to conduct genetic evaluations using the software/methodology provided by universities. Based on the experience of the beef industry, a sustainable industry-wide genetic evaluation program is dependent on 1) use of common sires across herds to provided the proper data infrastructure, 2) a system that allows for the collection of on-farm performance records, 3) a centralized system that maintains both phenotypic and pedigree information, and now genomic information, 4)) a national organization that provides leadership for record and procedure standardization, 5) a well funded group of research scientists and servicing personnel.

Key words: genetic evaluation, beef cattle

797 National Sheep Improvement Program's current impact and future potential. D. F. Waldron*, *Texas AgriLife Research, San Angelo.*

Since implementation in 1987 the US National Sheep Improvement Program (NSIP) has evolved to take advantage of developments in technology. The methods used in NSIP make use of all available performance records along with pedigree information to predict genetic merit for economically important traits. Statistical methods employed in NSIP were first developed for, and applied to, dairy cattle and later to beef cattle and other meat-producing livestock. Beef cattle breeders in the US increased adoption rates of the technology through the 1980s and 1990s. The US sheep industry's use of NSIP is expanding. Although NSIP is available to all breeds of sheep, many of the NSIP participants are from a small number of breeds. Targhee, Suffolk, and Polypay are the breeds that have had the most NSIP participation. Estimates of genetic trends are indicators of the impact of using NSIP for selection decisions. The impact of NSIP in the US sheep industry has been limited by low adoption rates. Costs of performance recording, perceived value of genetic evaluation, and lack of a consensus, within a breed, on breeding objectives are all factors that have limited the use of NSIP in the US sheep industry. Adoption of a national genetic improvement program by US sheep breeders has lagged behind that of US beef breeders. An adaptation of NSIP was developed first for Boer goats (Boer Goat Improvement Network) and then for Kiko goats. Participation in NSIP by breeders of meat-producing goats is lower than it is for sheep. As the impact from use of NSIP becomes more evident, participation is expected to increase. Recently implemented NSIP evaluations for fecal egg count as an indicator trait for resistance to parasites may lead to increased participation. Advances in genomic evaluation, as implemented in dairy cattle genetic evaluation, may be feasible to use for small ruminants in the future. However, the substantial numbers of recorded animals required to develop effective genomic evaluations are not currently available. If breeders of small ruminants will realize the potential of genomic evaluation, increased participation in NSIP is necessary, so that the records are available.

Key words: sheep, goats, genetic improvement

798 Advancements in genomics: Application and potential for small ruminant research. P. K. Riggs*, *Texas A&M University, College Station.*

Genome science and genomic tools have led to revolutionary biological breakthroughs that dramatically affect and continue to advance animal agriculture. In a short period of time, costs have fallen while technology has improved to make possible the reality that assembled genome sequences can be produced for any species of interest, particularly agricultural species. Research focused on small ruminant genomes will be able to make rapid progress by leveraging resources, tools, and knowledge gained from bovine and other species' genome projects. The cattle and sheep genome research consortia have recently completed high density gene maps, genome assemblies, haplotype maps, and related analyses. Research in goat genomics can take advantage of comparative genome similarity, as well as lessons learned from bovine and ovine studies, to make progress toward development of caprine-specific genome tools. Currently, several efforts are underway for construction of radiation-hybrid gene maps, SNP discovery, and genome sequence assembly. All of these projects present challenges for production of high quality data, storage and management of data, and bioinformatic analyses, but goat genome research can potentially move quickly as a result of previous findings. The future availability of genomic resources for goat provides great opportunity for application in the goat industry.

Key words: genomics, goat, molecular genetics

799 Sheep and goat genetic resources: Recent findings and potential for future development. H. Blackburn*, *National Animal Germplasm Program, National Center for Genetic Resources Preservation, Agricultural Research Service, Ft. Collins, CO.*

Genetic variability underpins the ability to manipulate sheep and goat populations for increased productivity and profitability. An assessment of the genetic variability of 28 sheep and 5 goat breeds using microsatellite marker panels has been made. The sheep analysis was extended to determine genetic distance and variation for US vs 5 Kazakhstan (KAZ) breeds. For US sheep the average number of alleles per locus and heterozgousity varied (3.7 to 8.2 and 0.42 to 0.65, respectively) suggesting some breeds (Rambouillet, Suffolk, Polypay, Dorper) possess substantial genetic variability for utilization. Nei′s genetic distances (GD) for US and KAZ breeds generally showed small genetic distances among KAZ breeds and moderate to large GD when compared with US breeds. The greatest GD was among US breeds. Analysis of Angora (AG), Spanish (SP), Myotonic, Boer, and LaMancha goat breeds showed high levels of heterozygousity (0.58 – 0.73) and large GD (0.21 – 0.57). The SP and AG breeds have undergone contractions in population sizes but ranked highest for genetic diversity measures. For sheep and goats these results suggest US breeds have substantial neutral genetic variability which might translate into important variability for traits of interest. But, to fully utilize genetic diversity at the genomic level or via quantitative methodology, development of substantial phenotypic databases that contain economically relevant data in addition to pedigree information must be initiated and utilized. Employing such databases will facilitate combining phenotypic and genomic information; which in turn will provide producers across breeds with an opportunity to improve sheep and goat performance and profitability.

Key words: sheep, goats, genetic resources

Teaching/Undergraduate and Graduate Education Symposium: Adapting Our Teaching to Meet Current and Emerging Societal Needs

800 Effecting change in teaching and learning in the agricultural sciences. R. Kirby Barrick*, *University of Florida.*

Two recent reports provide insight regarding how teaching and learning in the agricultural sciences should and must keep pace with changes in society. The National Research Council (NRC) report (2009) on Transforming Agricultural Education for a Changing World and the Academic Programs Section (APS), Board on Agriculture Assembly of APLU report on Human Capacity Development (May 2009) serve as a call to action to meet the challenges of global competitiveness. The NRC report outlines 9 recommendations for change, and the APS publication offers recommendations to achieve 4 strategic goals for preparing the next generation of scientists and the agricultural workforce. Implications for action center on the following major areas: strategic planning, introductory courses, broadening the undergraduate student experience, faculty development, rewarding teaching, partnerships with other colleges and universities, connecting with K-12 education, partnerships with stakeholders, integration of teaching, research and outreach, doctoral education, recruitment and retention of students, and the utilization of technology. This session will attempt to place in context the recommendations of 2 major national studies with the initiatives of agencies such as USDA/NIFA and the National Science Foundation. Implications to consider in reviewing and updating teaching and learning in both undergraduate and graduate education will be shared with participants for further discussion and potential action in departments and colleges throughout the country.

Key words: teaching and learning, undergraduate education, graduate education

801 Perspectives on using values-based communications as a tool for preparing animal science students to address consumer trust issues challenging the animal industry. J. L. Garrett*, *JG Consulting Services LLC, Dowling, MI.*

Consumer choices and perceptions have a profound impact on global food production, supply and policy. Yet, criticism of animal agricultural practices by national and social media continues to erode consumer trust in the animal industry. Preparing Animal Science students to communicate facts, skills and competence is important in minimizing this decline in trust. However, research shows that communications demonstrating values are 5 times more important in building consumer trust than competence alone. The objectives of this presentation are to: 1) discuss current consumer attitudes and trust research specific to food and agriculture, 2) compare values-based communications with traditional approaches, 3) review and discuss values-based communications learning outcomes with dairy and crop farmers over the last 2 years, and 4) share literature and experiential based best practice considerations for incorporating values-based communications into the animal science curricula for better preparing graduates for success in a consumer-driven economy.

Key words: teaching, values-based communications, consumer trust

802 Course and activities based learning teams: A method of enhancing the first-year university experience. M. D. Kenealy*, *Iowa State University.*

In 1995, under the direction of the Center for Excellence in Learning and Teaching (CELT), Iowa State University (ISU) began testing the concept of course-based learning teams (LTM) with the goal of enhancing the first year experience of students, improving academic performance, and increasing retention rate. The Department of Animal Science (AnS) joined the university effort and placed approximately one-third of freshman students in course-linked LTM's. Students were grouped in teams based upon species interest and level of academic achievement during high school. A typical AnS LTM included linking AnS orientation, introductory AnS, introductory biology, and English composition for a group of 13 students. Faculty in the courses exchanged texts and syllabus materials with the linked English lecturer so that students could write about science topics and see the connections in their learning activities, thereby avoiding the silo concept of education. Additionally, each AnS LTM was assigned an upper-class student mentor and an academic advisor to guide additional team activities, such as study sessions, industry visits, and participation in club activities. As a program incentive, competitive grant monies were available from CELT to compensate student mentors and support LTM programming. Animal Science faculty used the programming grant monies to sponsor field trips to industries and organizations to introduce LTM members to potential internships and careers. Over 15 years, average first year to second year retention rate for ISU was 8 percent higher (89 vs 81 percent) for LTM students versus control groups of non-LTM students. Average 6 year graduation rate was 12 percent higher (74 vs 62 percent) for the LTM students. For FY2010, AnS freshman average cumulative grade-points were: linked-course LTM's: 2.96 (4.0 scale); non-course-linked LTM's: 2.91; non-LTM students: 2.52. Comparison group surveys validated that LTM students had higher satisfaction and engagement with their department and ISU at the end of their first year at the university.

Key words: learning teams, graduation rate, student retention

803 Innovative and effective practices for student development—What are the difference makers? D. Mulvaney*, *Auburn University, Auburn, AL.*

Our animal and allied industries are confronted by a complex array of contemporary issues and problems and need a well-prepared workforce ready to address them. Educational programs in tertiary institutions need to persist in preparing students for life after graduation that: 1) enables them to innovatively solve problems that do not yet exist, and 2) present skills that are most highly demanded or coveted by employers. Are we utilizing available student development theory and data to intentionally prepare students for productive adaptive futures in a constantly changing, flat world? Development of the whole, well-rounded student is a complex process. While multiple theories surround evidence-based practices contributing to student development, the academy may not always incorporate programming insights found in a rapidly growing body of literature focused on growth and development of students. Learning and experiential outcomes for Animal Science curricula often transcend the classroom alone and include opportunities for development of life success skills, work experience, project-based experiential learning, leadership development, emotional intelligence, and social skills to name but a few. The National Summit on Higher Education in Agriculture combined with a National Academies Report on: The New Biology for the 21st Century: Ensur-

ing the United States Leads the Coming Biology Revolution, reinforce the importance of reexamining our approaches to student development and clearly identifying the difference makers. Of benefit to faculty, students and decision makers, this careful examination of theory and application of best practices for development of contemporary Animal Science students should lead to recommendations for strengthening learning environments which foster development of leaders and professionals essential for addressing emerging challenges of the day.

Key words: animal sciences, student development, best practices

804 Best practices in designing undergraduate research experiences in animal science curricula. C. Rosenkrans Jr.*, *University of Arkansas, Fayetteville.*

Experiential learning is an excellent method of facilitating student learning and includes a variety of techniques for student discovery of knowledge. Undergraduate research is an experiential learning technique that is well suited for motivated students who are interested in applying or extending a classroom concept. Identifying students that are a good "fit" in the mentor's research program is essential for successful undergraduate research programs. I have found that a personal interview is the most efficient method of determining if mutual research interests exist and if the student and mentor have compatible personalities, i.e., "fit." However, others prefer to assess "fit" by asking the student to write a brief research proposal before accepting the mentee. After a mentor-mentee match has been established it is incumbent on the mentor to: explain the ethics and importance of quality data collection; establish the learning experience and work expectations; design a challenging research project that can be completed by the student in a timely manner; ensure that supervision is encouraging and occurs in a timely manner; and complete the process by assisting the student in disseminating their results. Students at UofA have the opportunity for oral presentations at professional society meetings (ASAS, etc.), and local events sponsored by Gamma Sigma Delta. Publication opportunities include local undergraduate research publications (Discovery and Inquiry), departmental publications, and peer-reviewed journals. Undergraduates who successfully complete research projects have a more thorough understanding of Animal Science, and enhanced skills related to analysis, interpretation, and communication. In addition, students typically graduate with a greater connection to the department. Undergraduate research is an experiential learning technique that enhances the collegiate experience for our students, and integrates the teaching and research missions for a faculty member.

Key words: scholarship, student learning, integrated projects

805 Casting a line—Creating a national Scholarship of Teaching and Learning (SoTL) for animal sciences: Adapting to the gaps through SoTL and networking. M. A. Wattiaux*, *University of Wisconsin-Madison, Madison.*

In college classrooms both teaching and learning are inextricably linked, yet for the most part each continues to reside in different domains. The gap between what students actually learn and what they should learn was addressed when Schillo (1997; J. Anim. Sci. 75:950–953) drew a sharp contrast between indoctrination (claiming knowledge of scientific fact without critical evaluation) and education (ability to think analytically and make independent judgments about scientific claims). Arguably, the gap between what –and how– instructors actually teach and what –and how– they should teach, remains a professional challenge if not an emotionally charged issue that few are willing to raise. Given the realities of academia (funding, time constraints, reward system), the prospect for instructors to engage in scholarly teaching as an integral part of their professional identity remains an elusive proposition because of: a) lack of graduate training, b) departmental, college or university cultural norms, c) expertise and effort involved in pedagogical research, d) lack of reward, or e) unawareness. Studies have revealed that in order not to jeopardize professional progress, a choice is often made not to oppose traditional ways of teaching. However, the lack of negative correlation between research outcomes and teaching effectiveness should serve as a guide to allow for part of the open space that comes with academic freedom to be committed to high impact teaching practices. Although SoTL (the systematic inquiry into the learning environment for the purpose of advancing the practice of teaching within a discipline in making research findings public) is the most demanding form of commitment, small but significant networks are also effective tools to channel creativity and innovation that cultivate continuous improvement of teaching and student learning. At any point in one's career path, documenting the impact either may have on student learning could serve to alleviate some the aforementioned barriers. There is a need to lay the foundation of an integrated framework that aligns clearly opportunities with expectations and rewards for scholarly teaching efforts in the animal sciences.

Key words: SoTL, pedagogy

806 Casting a line—Multi-institutional collaborations to enhance animal science education. D. L. Boggs*, *Kansas State University, Manhattan.*

Comprehensive undergraduate curricula in animal sciences have traditionally consisted of relevant disciplinary courses and courses that applied these disciplines to management of all relevant species within a state or region. Consolidation of many animal industries has decreased the number of students entering animal sciences programs with background in these industries and interest in exploring them as career options. Thus the enrollment in many species based courses has decreased below the threshold of viability. At the same time, budgetary restrictions have decreased the ability of colleges and universities to maintain a critical mass of faculty within some disciplines and species. Therefore, many departments have eliminated faculty positions as well as animal facilities for experiential learning and are no longer able to offer comprehensive curricula. This first manifested itself in poultry, where budget redirections eliminated many departments, farm units and faculty positions. Recognition of the need to still develop professionals for the industry led to the development of the Midwest Poultry Consortium, a collaborative program to educate students for this industry. Collaborations need to expand if we are to comprehensively educate professionals and leaders for animal industries. Distance education technologies provide numerous opportunities for faculty to work across institutional and physical boundaries to provide innovative educational programs. The Institute for Academic Alliances at Kansas State University identifies the following keys to successful collaboration: commitment of faculty and administration to quality programs and e-learning, work with similar organizations, and combine complementary areas of expertise. AG*IDEA is an affiliate of the Great Plains Interactive Distance Education Alliance and provides an infrastructure for faculty and students to participate in educational collaborations. The AG*IDEA Swine Science Online Certificate is an example of a collaboration among several universities and industry. Opportunities exist to enhance educational opportunities via multi-institution collaborations.

Key words: collaboration, AG*IDEA, distance learning

ADSA Production Division Symposium: Current and Future Determinants of Dairy Product Pricing

807 Factors that are important in determining US milk prices. D. S. Brown*, *Food and Agricultural Policy Research Institute, University of Missouri, Columbia.*

The US dairy industry has experienced extreme volatility in milk prices over the past several years. The milk pricing system is often described as one of the most complicated pricing mechanisms in agriculture. In the past few years, the industry has seen milk prices go from record highs to record lows in very short periods of time. This research will provide some answers and insight into the reasons milk prices have become so volatile. Analysis of retail markets for the major dairy products will be included in this research. Retail pricing of all cheeses, butter, nonfat dry milk and whey are important in understanding how the US dairy industry operates. One longstanding component of federal dairy policy is the federal milk marketing order system. Milk orders provide a mechanism to set minimum prices to be paid for milk used in different manufacturing processes based on dairy product prices. Federal orders only provide for minimum pricing and over-order premiums can also be an important component in determining farm-level milk prices in some areas of the United States. The move to end product pricing with the last round of federal order reform has made for some challenges between processors and producers. There are currently four classes of milk in the federal order system. State milk pricing can also be important in determining milk prices with California's milk pricing system being just one example of other pricing methods in use today. Other federal dairy policy can play a role in US milk prices as well. Currently, the industry has a price support program in place for some manufactured dairy products. In periods of low prices, the government stands ready to purchase all products offered at the set purchase prices. This program has had a smaller effect in the past few years given the rise in feed prices. The Milk Income Loss Contract (MILC) program also operates in the dairy industry as a direct payment program in periods of low milk prices and/or high feed costs. This program can also affect the outlook for milk prices. A brief look at potential new dairy policy will be addressed as it relates to milk prices.

808 Issues facing US dairy exports: Regulatory coherence and trade barriers. J. Castaneda*, *U.S. Dairy Export Council, Arlington, VA.*

Lack of regulatory coherence and trade barriers limit the US dairy industry's access to export markets. The crux of the problem is the unjustified use of technical barriers, particularly sanitary and phytosanitary (SPS) measures that US exports face. This issue is one that threatens to grow even larger and more problematic in the future if not immediately addressed. We, collectively as an association and individually as members, are spending more and more time on these issues. In too many cases the problems faced by the dairy industry are growing and trade is being negatively affected. This presentation will focus on some of the problems we and other sectors have encountered with SPS measures, including lack of regulatory coherence among the various US agencies working on SPS issues. I will address (1) promotion of approaches that could improve the situation, including increased transparency, notification, harmonization between nations; (2) how the Administration can use past, current and future trade agreements to provide a vehicle for strengthening international rules and practices, which will help facilitate trade. It is important to note that the World Trade Organization's SPS agreement is essentially the only tool we have to deal effectively with countries that create SPS barriers to block trade. It provides a set of rules and an institutional setting to pressure countries that clearly stray from science-based standards to stop imports. However, as a set of principles agreed to 15 years ago, the SPS agreement is currently insufficient. In many cases there is a need for stronger and more specific rules to address trade barriers. This will be the focus of our attention in the coming years, so that the U.S. Dairy Export Council can assist in keeping international markets open for our products.

809 Producing for a global export market. M. Piper*, *Fonterra (USA) Inc., Rosemont, IL.*

After more than 18 years in the New Zealand dairy industry, with roles ranging from technical and commercial to marketing; living in 3 countries (New Zealand, Japan and now the USA), I have developed a good understanding of the world dairy environment. During my involvement in the global dairy market, there has been an evolution in the way people view quality: from product quality and consistency to supply chain quality. Traditional concerns about price still exist, but they have now been overtaken by concerns about food safety, and attention to issues encompassed by new phrases like "application focus" and "value added." To succeed in today's global environment we need to understand our future customers. The historic dairy markets of Europe and North America still remain the leading consumers of dairy products, but Asia is fast emerging as the new market for growth. Standard dairy products are still required along with development of additional products for these "new" markets, but the focus on application know-how and food safety concerns in Asia differ from what we consider the "norm" in Europe and North America. This presentation will focus on identifying new customers and touching on some of the areas that need to be front-of-mind when supplying these new global customers.

Thursday, July 14, 2011

SYMPOSIA AND ORAL SESSIONS

Animal Health: Dairy II

810 I. Dairy calving management: Dystocia and timing for intervention. G. M. Schuenemann*, I. Nieto, S. Bas, K. N. Galvao, and J. Workman, *Department of Veterinary Preventive Medicine, The Ohio State University, Columbus.*

Dystocia is defined as an abnormal or difficult birth at any stage of labor. The objective of this study was to determine the timing for intervention in dairy cattle [primiparous (PRIM) and multiparous (MULT)] that need assistance during calving. Cows (85) from 1 commercial dairy operation were used in this study. Periparturient dairy cows (PRIM, n = 54; MULT, n = 31) were placed in calving pens and constantly monitored until birth. The calving ease (CE) of cows (1–2 scale; 1 = unassisted or 2 = assistance required), timing from amniotic sac (AS) appearance to birth, and stillbirth (born dead or within 24 h after birth) were recorded. According to farm protocol, assistance was provided to cows without calving progress 80 min after the AS appearance. Data were analyzed using PROC MIXED of SAS. Least squares means (LSM) and 95% CI were reported. For unassisted calving (CE1), the time from AS appearance to birth was not different ($P > 0.05$) for PRIM (51 min; CI: 38.9–63.2) and MULT (46.7 min; CI: 31.4–61.9) cows. For cows that received assistance (CE2), the time from AS appearance to birth was not different ($P > 0.05$) for PRIM (83.6 min; CI: 66.4–100.8) and MULT (79.4 min; CI: 53.5–105.2) cows. However, the overall time from AS appearance to birth differed ($P < 0.05$) for CE1 cows (48.9 min; CI: 39.1–58.6) compared with CE2 cows (81.5 min; CI: 65.9–97). Cows with CE2 had greater incidence of stillbirth (23.2%) compared with CE1 cows (0.8%; $P < 0.05$). Cows with assisted births (dystocia) had longer time period from the AS appearance to birth and increased incidence of stillbirth as opposed to cows with unassisted calving. This study suggested that calving personnel should start assisting cows 60 min after the AS appearance. Recognizing the signs of normal calving such as appearance of the AS and timing to birth is critical to know when to intervene. These findings have important implications for dairy personnel executing the calving tasks.

Key words: calving management, education, dystocia

811 II. Dairy calving management: Effect of perineal hygiene scores on metritis. G. M. Schuenemann*, I. Nieto, S. Bas, K. N. Galvao, and J. Workman, *Department of Veterinary Preventive Medicine, The Ohio State University, Columbus.*

The objective of the present study was to assess the impact of hygiene scores of the perineal region (HSPR; surface around the birth canal) of dairy cows [primiparous (PRIM) and multiparous (MULT)] at the time of calving on the risk of metritis. Cows housed in free-stalls from 2 commercial Ohio dairies were used in this study. Periparturient cows (n = 562) were placed in individual calving pens and monitored until birth. Wheat straw bedding was changed every 2 d. Immediately before calving, the HSPR of cows was recorded using a 1–3 scale (1 = free of dirt-manure and completely dry; 2 = slightly wet dirt-manure in 1–10% of the surface; 3 = moderately covered with wet dirt-manure in 11–30% or greater of the surface) by 1 calving personnel in each farm. Both calving personnel received calving training at the beginning of the study. The average length of stay per cow in the calving pen was 1.9 h. Immediately after calving, cows were moved to a fresh pen. The calving ease (CE; 1–2 scale; 1 = unassisted or 2 = assistance required), stillbirth (born dead or within 24 h after birth), and retained fetal membranes (RFM) were recorded. Lactating cows were screened for metritis within 14 DIM by farm personnel. Metritis was defined as a foul-smelling red-brown watery uterine discharge. Data were analyzed using PROC GLIMMIX of SAS, accounting for the effects of CE, parity, stillbirth, herd, and RFM. Cows with a HSPR of 3 (n = 84) or 2 (n = 177) had greater incidence of metritis (22.4 ± 6% and 18.9 ± 4%, respectively) compared with cows (n = 301) with a HSPR of 1 (10.8 ± 3%; $P < 0.05$). These findings indicate that cleanliness of the perineal region at the time of calving is significantly associated with metritis.

Key words: calving hygiene, education, metritis

812 Dam heat load affects neonatal calves' bacterial levels and innate immunity. D. Pan*[1,2], C. N. Lee[3], M. H. Rostagno[2], and S. D. Eicher[2], *[1]Purdue University, W Lafayette, IN, [2]USDA- ARS, W Lafayette, IN, [3]University of Hawaii, Honolulu.*

Heat stress is known to suppress animal's immunity, making them more susceptible to bacterial infections. Field observations have shown that calves have greater morbidity and mortality when they are born after a heat event. Objectives of this study were to determine effects of heat load on bacterial levels in the calves' environment and on calves' innate immunity. The study was undertaken in March and August, 2010 on 2 commercial dairies (dairy 1 and dairy 2) located in Hawaii. Fifty-three neonatal Holstein calves were used, 27 born in spring (SP) and 26 born in summer (SU). Hide and udder swabs (100 cm^2) from the dams on dairy 1 were taken shortly after calving. Rectal and nasal swabs from calves on the same farm (n = 15 for each SP an SU) were taken 1, 2, and 3 wk after birth. Colony forming units of total aerobes and total coliforms were determined for all samples. Jugular blood samples from calves on dairy 2 (n = 12 and 11 for SP and SU, respectively) were collected wk 1, 2, 3, and 4 after birth to determine blood leukocyte RNA expression of toll-like receptor 4 (TLR4) and tumor necrosis factor-α (TNF-α). All data were transformed and analyzed using the MIXED procedure of SAS with season and time as fixed effects. Hide and udder total coliform counts did not differ between SP and SU cows. However, compared with the SP cows, SU cows had greater hide ($P = 0.0003$) and udder ($P = 0.0002$) total aerobe counts. Rectal coliform counts in SP calves were greater ($P < 0.0001$) than in SU calves throughout the 3-wk study. SP calves also had greater ($P < 0.0001$) nasal coliform counts at wk 2. No difference was found in rectal aerobe counts between SP and SU calves. SU calves had greater ($P < 0.0001$) nasal aerobe counts than SP calves at wk 1 and 3. No difference in TLR4 expression was detected between SP and SU calves. However, TNF-α expression in SU calves was less ($P < 0.01$) at wk 2 compared with SP calves. Our results showed that heat load increased the total aerobes in the calving environment and

decreased TNF-α expression of neonatal calves, thus may increase calf morbidity and mortality.

Key words: heat stress, innate immunity, microbial populations

813 Antisecretory factor counteracts calf diarrhea and increases daily weight gain. B. E. O. Johansson*[1], E. Johansson[2], and S. Lange[2,3], *[1]Lantmännen Lantbruk, Lidköping, Västra Götaland, Sweden, [2]Bacteriological Laboratory, Sahlgrenska University Hospital, Gothenburg, Västra Götaland, Sweden, [3]Institute of Biomedicine, Department of Infectious Diseases, Section of Clinical Bacteriology, University of Gothenburg, Gothenburg, Västra Götaland, Sweden.*

Antisecretory factor (AF) is a protein with potent antisecretory and anti-inflammatory actions and part of the natural, innate defense system. This study investigated whether the AF level in calf blood were correlated with diarrhea. The study was performed in 101 dairy calves raised according to standard Swedish procedures: colostrums/whole milk for 3 d, milk replacer d 4 to 55 with ad lib access to forages and concentrates. No experimental diet was given. Live weight and incidents of diseases were documented during the study period. Blood plasma samples were taken at d 3 after birth and AF activity in the samples was tested by an in house developed enzyme-linked immunosorbent assay (ELISA). The AF activity was compared for calves who either got diarrhea before 55 d or who did not. Live weight at d 55 was compared between calves with or without diarrhea before this age. Both comparisons were made with one-way ANOVA in Minitab 15 and sample means were tested with Student′s *t*-test. Differences were judged significant when the p-value was lower than 0.05. Standard error means are reported directly after the group means. Live weight was recorded for 83 of the 101 calves. Plasma was analyzed from 17 of the 83 calves with live weight records, and from 18 without weight records. In total were 35 plasma samples analyzed and live weight compared on 83 calves. The mean AF activity (net absorbance at 405 nm) in calves suffering from diarrhea was significantly lower than in the healthy calves (0.520 ± 0.049 vs. 1.287 ± 0.164, $P < 0.05$). On d 55, calves who had experienced diarrhea weighed 75 ± 2.15 kg compared with the 81 ± 0.94 kg of healthy calves ($P < 0.05$). The natural level of AF activity in calves has a positive and significant correlation to diarrhea. Thus, calves with low AF activity are subjected to an increased risk of catching a diarrheal disease, which is commonly followed by a diminished growth rate.

Key words: antisecretory factor, calf diarrhea, innate defense system

814 Innate immune function of Holstein calves after commingling. L. E. Hulbert*[1,2], C. J. Cobb[1], L. R. Schwertner[1], and M. A. Ballou[1], *[1]Department of Animal and Food Sciences, Texas Tech University, Lubbock, [2]Department of Animal Sciences, University of California-Davis, Davis.*

Sixty-four Holstein dairy calves were all reared in individual polyethylene calf-hutches (Agri-Plastics) until they were randomly assigned to treatments of Grouped (3 calves/pen, n = 36 calves) or Control (remained in hutch, n = 28 calves). The individual calf hutch design (5.98 m^2 of free space) allowed visual, olfactory and auditory contact but no physical contact with other calves. Grouped calves were moved at 68 ± 2.3 d of age to pens of 3 calves (5.97 m^2/calf of free space). Whole blood was collected via venapuncture from all calves at 68, 71, 75, and 87 d of age. Cortisol and haptoglobin concentrations, total leukocyte and differential counts, neutrophil L-selectin and β_2-integrin expressions, neutrophil phagocytosis and oxidative burst, and tumor necrosis factor-α (TNF-α) secretion from lipopolysaccharide (LPS)-stimulated whole blood were measured. Grouped calves had reduced ADG, DMI, and gain:feed for the 21 d period, and weighed less than Control calves at 87 d of age ($P < 0.01$). Seven d after commingling, Grouped calves had greater cortisol concentrations than Control calves ($P < 0.01$). In addition, Grouped calves tended ($P = 0.06$) to have more total leukocytes than Control calves for the entire period. Grouped calves also had decreased oxidative burst response 3 d after commingling ($P < 0.05$); however, the phagocytic responses were increased on d 3, but were decreased 7 d after Group calves were commingled ($P < 0.01$). On d 87 of age, all calves had increased haptoglobin concentrations and TNF-α secretion ($P < 0.05$), and Grouped calves had increased neutrophil:lymphocyte ratio and neutrophil β_2-integrin expression with a concomitant decreased neutrophil L-selectin expression ($P < 0.05$) compared with Control calves at d 87 of age. Commingling calves decreased innate immune responses and performance during the 21 d observation period.

Key words: calf, grouping, immunity

815 Risk factors and impact of postpartum anovulation in dairy cows. J. Dubuc*[1], T. F. Duffield[2], K. E. Leslie[2], J. S. Walton[3], and S. J. LeBlanc[2], *[1]Faculté de médecine vétérinaire, Université de Montréal, St-Hyacinthe, Québec, Canada, [2]Department of Population Medicine, University of Guelph, Guelph, Ontario, Canada, [3]Department of Animal and Poultry Science, University of Guelph, Guelph, Ontario, Canada.*

The objective of this study was to identify risk factors for and to quantify the impact of postpartum anovulation on reproductive performance in dairy cows. Data from 2178 Holstein cows (6 herds) enrolled in a randomized clinical trial were used. Data on periparturient disease, calving history, and body condition score at calving were collected. Cytological endometritis (CYTO) was defined as ≥6% polymorphonuclear cells in endometrial cytology at wk 5 postpartum. Purulent vaginal discharge was defined as the presence of mucopurulent or purulent vaginal discharge at wk 5 postpartum. Serum BHBA, NEFA, and haptoglobin were measured at wk 1, 2, and 3 postpartum. Serum progesterone (P4) was measured at wk 3, 5, 7, and 9 postpartum. The end of postpartum anovulation period was defined as the first sampling time at which P4 was >1ng/mL. Statistical analyses were performed using logistic regression models and Cox proportional hazard models in SAS, accounting for the effects of treatments in the clinical trial and herd clustering. The prevalence of anovulation was 72, 44, 26, and 17% at wk 3, 5, 7, and 9, respectively. Risk factors for prolonged anovulation (ANOV; no P4 > 1 ng/ml through wk 9) were CYTO (OR = 1.5; $P = 0.02$), and elevated NEFA concentration (≥0.9 mmol/L; OR = 1.5; $P = 0.02$), hyperketonemia (≥1.2 mmol/L; OR = 1.4; $P = 0.03$), and hyperhaptoglobinemia (≥0.8 g/L; OR = 1.6; $P < 0.01$) at wk 1. Parity group (≥3; OR = 1.5; $P < 0.01$) and season (summer and spring; OR = 1.6; $P < 0.01$) were also associated with ANOV. Cows with ANOV had an increased median time to first breeding (ANOV = 77 d; cyclic = 72 d; HR = 0.88; $P < 0.01$) but no difference in first service conception risk (ANOV = 28.9%; cyclic = 30.1%; $P = 0.73$). The impact of ANOV on median time to pregnancy was conditional on parity group; a detrimental impact was present in cows of parity ≥3 (ANOV = 196 d; cyclic = 135 d; HR = 0.56; $P < 0.01$) but there was no impact in cows of parity ≤2 (ANOV = 137 d; cyclic = 128 d; HR = 0.91; $P = 0.54$). Overall, these findings suggest that ANOV was associated with indicators of energy balance and uterine inflammation, and with detrimental impacts on reproductive performance.

Key words: dairy cow, anovulation, risk factor

816 Inflammation and infection of the reproductive tract in dairy cows. T. Osawa*[2], R. C. Neves[1], and S. J. LeBlanc[1], [1]*University of Guelph, Guelph, ON, Canada,* [2]*Iwate University, Morioka, Japan.*

Purulent vaginal discharge (PVD), cytological endometritis (>6% neutrophils; CYTO_U), and cytological cervicitis (>5% neutrophils; CYTO_C) are associated with impaired reproductive performance. Weak agreement between PVD and CYTO_U led to the question of the source of PVD. The objective was to describe relationships among inflammation and bacterial infection in various parts of the reproductive tract of postpartum dairy cows. 102 cows were examined by vaginoscopy, ultrasound (US), and cytobrush cytology of the vagina (V), cervix (C), and uterine body (U) at 3 and 5 weeks postpartum. In a subset of 78 cows, aerobic and anaerobic bacterial cultures were performed from each site. At wk 3 and 5 postpartum the prevalence of PVD was 17 and 13%, of CYTO_U 32 and 18%, of CYTO_C 37 and 14%, and of bacterial contamination of V 65 and 59%, C 68 and 54%, and U 69 and 49%, respectively. There was no association of CYTO_U or CYTO_V or of prior or concurrent gross vaginitis or cervicitis with PVD at wk 5. However, 43% of cows with CYTO_C had PVD vs. 8% among cows without CYTO_C ($P = 0.003$). Infection of V, C, or U with A. pyogenes (prevalence = 8–11%) and fluid in the uterus visible by US (sensitivity = 85%; specificity = 51%) were associated with PVD at wk 5. In a logistic regression model, CYTO_C and uterine A. pyogenes infection were significantly ($P = 0.002$) associated with increased odds of PVD. CYTO_U was associated with gross and cytological cervicitis but not with bacterial infection of any segment of the tract. There was strong association ($P < 0.0001$) and good agreement (Kappa = 0.4) between CYTO_C and CYTO_U, yet 43 to 55% of cows with inflammation in one location did not have it in the other. In a logistic regression model, CYTO_C and swollen cervical folds seen by vaginoscopy were associated with cytological endometritis at wk 5. Leukocyte esterase test strips on uterine swabs provided good to high (85–93%) negative predictive value but moderate to low (66–33%) positive predictive value for cowside diagnosis of CYTO_U using test scores of 3 to 1, respectively. Cervicitis and endometritis are distinct, sometimes overlapping conditions.

Key words: reproductive health, endometritis, cervicitis

817 Physiological and behavioral characteristics related to vitality of newborn dairy calves and the efficiency of absorption of immunoglobulins. C. Murray*[1], D. Viera[2], A. Nadalin[2], V. Bielmann[1], and K. Leslie[1], [1]*Department of Population Medicine, University of Guelph, Guelph, Ontario, Canada,* [2]*Agriculture and Agri-Food Canada, Agassiz, British Columbia, Canada.*

Calving difficulty and stillbirth are formidable issues for the dairy industry. Recent research has identified associations between assisted calving and failure of passive transfer of immunoglobulins. The objective of this research was to examine physiological and behavioral characteristics of newborn Holstein calves with the aim of developing a newborn calf vitality scoring system that would be strongly associated with absorption of colostral immunoglobulins, general health and performance. A total of 48 calving events (n = 51calves) were continuously monitored from the first sight of fetal membranes. All calves were assessed for measures of vitality at the time of first sternal recumbency (SR), and at 2 and 24h, 7 and 14 d of age. Measurements included time to SR and standing, blood gases, oxygen saturation, lactate, glucose, rectal temperature, respiration and heart rates, suckling response, IgG absorption and growth. At 2 h, all calves were separated from their dam and fed 180 g of IgG from a commercial colostrum replacer by esophageal tube feeder. Calves born from a hard pull (n = 10) were more acidotic (mean pH ± SD: 7.20 ± 0.12 vs. 7.28 ± 0.05) and took twice as long to attain SR than those born unassisted (n = 18) (SR ± SD: 5.2 ± 3.0 vs. 10.3 ± 4.4 min). All calves achieved a normal pH (7.4 ± 0.04) within 24 h of birth. A higher proportion of calves born from a hard pull had a weak suckling response at SR and at 2 h compared with unassisted calves (86 vs. 43% and 50 vs. 6%, respectively). No correlation was found between SR, first attempt to stand, to stand for 2.5 and 5 min when compared with IgG concentration at 24 h of age. There was no trend between level of calving difficulty and average apparent efficiency of absorption of IgG. Overall, calves born from a hard pull are weaker and less responsive in the first few hours than calves born unassisted or from an easy pull. Yet, objective and easy to measure physiological or behavioral outcomes that are highly correlated to calf vitality and success of passive transfer remain unclear.

Key words: newborn, calf, vitality

818 The effect of omega-3 supplementation on the immune response of Holstein calves. E. L. Karcher*[1], T. M. Hill[2], N. Vito[1], L. M. Sordillo[1], H. G. Bateman[2], R. L. Schlotterbeck[1], and M. J. VandeHaar[1], [1]*Michigan State University, East Lansing,* [2]*Nurture Research Center, Provimi North America, Lewisburg, OH.*

The ability to reduce incidence of disease in calves and improve early vaccination strategies is of particular interest for dairy producers. Omega-3 fatty acids (FA) were shown to reduce inflammation in human diseases, such as diabetes and cardiovascular disease, but there is limited research in calves. Therefore, the objective of this study was to determine if supplementation with omega-3 FA from fish and flax oils improves immune function in calves. Forty-eight Holstein bull calves from a commercial dairy were randomly assigned to 1 of 3 diets beginning at 4 d old: 1) control milk replacer (MR) with all pork fat, 2) MR with 2% flax oil, and 3) MR with 2% fish oil. All diets were 27% CP, 17% fat on DM basis with all protein from whey sources. Calves were each fed 654 g DM of MR daily for the first 25 d and then 327 g/d for d 26, 27, and 28. On d 28, calves were challenged with a *Pasteurella* vaccine (Presponse HM) and the temperature response to the vaccine was recorded. Milk and feed intake and fecal scores were recorded daily and BW and skeletal measures were recorded weekly. Blood was collected on d 25. One tube of collected blood was incubated with endotoxin (LPS, 2 μg/mL) for 2 h. Quantitative RT-PCR was used to assess the effects of LPS stimulation on TNFα and IL-4 gene expression in leukocytes isolated from whole blood. During the 28 d, calves supplemented with flax oil had a greater gain to feed efficiency than calves supplemented with fish oil (0.522 ± 0.02 vs. 0.477 ± 0.02 g gain/g feed; $P < 0.03$). Both flax and fish oils tended to decrease the expression of TNFα following a 2 h in vitro stimulation with LPS compared with the control ($P < 0.08$). Flax oil, but not fish oil, decreased the expression of the IL-4 ($P < 0.05$). Calves receiving the flax oil treatment tended to have a decreased rise in rectal temperature in response to a *Pasteurella* vaccine ($P < 0.08$). In conclusion, supplementation with omega-3 FA tended to decrease the expression of the pro-inflammatory cytokine TNFα and reduce the temperature increase in response to a *Pasteurella* vaccine. Results indicate that supplementation may affect the ability of the calves to respond to a disease challenge.

Key words: calves, omega-3

819 Impact of intrauterine dextrose therapy on conception of lactating dairy cows with clinical endometritis. T. A. Brick*, S. Bas, J. B. Daniels, C. Pinto, D. M. Rings, and G. M. Schuenemann, *The Ohio State University, Columbus.*

The objective of this study was to determine if lactating dairy cows with clinical endometritis (CE) treated with an intrauterine infusion of 50% dextrose in water (DEX) have similar pregnancy per AI (PAI) compared with parental ceftiofur crystalline free acid (CEF) and untreated cows (CON). Cows (n = 760) from 2 herds were screened using vaginoscopy for CE at 26 ± 3 DIM and scored using a 0–3 scale. Cows scored as 2 or 3 were stratified by parity and randomly allocated into 1 of 3 treatment groups: 1) CON (n = 83), 2) 6.6 mg/kg CEF sq (n = 75), or 3) 200 mL DEX (n = 79). Fourteen days post-therapy (at 40 ± 3 DIM), treated cows were re-examined to assess treatment responses. All cows were presynchronized with 2 injections of PGF given 14 d apart (starting at 26 ± 3 DIM) followed by Ovsynch (OV; GnRH-7 d-PGF-56 h-GnRH 16 h-timed-AI; TAI) 12 d later. Cows displaying standing estrous any time during the protocol received AI, while the remaining cows were subjected to TAI-16 h after second GnRH of OV. Body condition scores (BCS) were recorded at calving, 26 ± 3 and 40 ± 3 DIM. Pregnancy diagnosis was performed via ultrasonography at 39 ± 3 d post-AI. DIM to first service (DIMFS) and pregnancy per AI (PAI) were evaluated. DIMFS, milk yield at first service, BCS at treatment, rectal temperature at treatment were not different among the treatment groups. Mortality within 10 d post-treatment and culling rate at 250 DIM were not different for cows with or without CE. Cows with CE had greater cervical diameters at the time of treatment compared with cows without CE. Mean vaginoscopy scores were reduced for DEX cows compared with CON and CEF cows ($P = 0.05$). PAI in DEX (29.8 ± 4%) tended to differ from cows in CON (21.1 ± 4%) and CEF groups (19.7 ± 4%; $P = 0.1$). However, PAI in DEX cows was not different from cows without CE (39.1 ± 2%). Based on these findings, the use of intrauterine DEX alone or as an adjunct of antibiotic therapy for the treatment of cows diagnosed with CE needs further investigation.

Key words: dairy cow, dextrose, endometritis

820 Effect of propylene glycol in fresh cows diagnosed with subclinical ketosis on milk yield and resolution of ketosis. J. A. A. McArt*[1], D. V. Nydam[1], P. A. Ospina[2], and G. R. Oetzel[3], *[1]Cornell University, Department of Population Medicine and Diagnostic Science, Ithaca, NY, [2]Cornell University, Department of Animal Science, Ithaca, NY, [3]School of Veterinary Medicine, University of Wisconsin, Madison.*

The purpose of this study was to determine the effect of oral propylene glycol (PG) administration on ketosis resolution and milk yield in cows diagnosed with subclinical ketosis (SCK) using the Precision Xtra meter (Abbott Laboratories, Abbott Park, IL). Cows from 4 freestall dairy herds in NY and WI were each tested 6 times for SCK from 3 to 16 d in milk. SCK was defined as a β-hydroxybutyrate (BHBA) reading of 1.2–2.9 m*M*; clinical ketosis was defined as ≥ 3.0 m*M*. Cows with SCK were randomized to treatment group (oral PG) or control group (no PG); treatment cows were drenched with 300 mL PG once daily from the day they tested 1.2–2.9 m*M* until the day they tested < 1.2 m*M*. Outcomes evaluated for all farms included time from SCK until BHBA test < 1.2 m*M* or until BHBA test ≥ 3.0 m*M*; individual milk weights for the first 30 d in milk were evaluated for 3 farms. Semiparametric proportional hazards models were used to evaluate time to event outcomes; repeated measures ANOVA was used to assess milk weights which were stratified by herd after a significant treatment by herd interaction was found. A total of 741 of 1,777 (41.7%) eligible enrolled cows had at least one BHBA test of 1.2–2.9 m*M*. Of these, 372 were assigned to the treatment group and 369 to the control group. Based on hazard ratios, PG treated cows were 1.50 (95% confidence interval (CI) = 1.26 to 1.79) times more likely ($P < 0.0001$) to resolve their SCK and 0.56 (95% CI = 0.35 to 0.88) times less likely ($P = 0.013$) to develop clinical ketosis than control cows. Treated cows produced more milk per milking on Farm A (0.98 kg, $P = 0.0002$) and Farm B (1.16 kg, $P < 0.0001$) in the first 30 d of lactation than control cows, for a total difference of 2.94 kg and 3.49 kg per day, respectively; there was no difference in milk (0.055 kg, $P = 0.70$) between the 2 groups on Farm D. These results show the positive effects of oral PG administration in fresh cows with SCK by both helping resolve SCK as well as prevent clinical ketosis. In addition, oral PG significantly improves milk yield during early lactation in some herds.

Key words: ketosis, propylene glycol, milk yield

821 Association between serum metabolite concentrations in the transition period and milk production in dairy cows. N. Chapinal*[1,2], M. E. Carson[1], S. L. Leblanc[1], K. E. Leslie[1], S. Godden[3], M. Capel[4], J. E. P. Santos[5], M. W. Overton[6], and T. F. Duffield[1], *[1]Department of Population Medicine, University of Guelph, Guelph, ON, Canada, [2]Animal Welfare Program, University of British Columbia, Vancouver, BC, Canada, [3]Department of Veterinary Population Medicine, University of Minnesota, St. Paul, [4]Perry Veterinary Clinic, Perry, NY, [5]Department of Animal Science, University of Florida, Gainesville, [6]Department of Population Health, University of Georgia, Athens.*

The objective was to study the association of the serum concentrations of nonesterified fatty acids (NEFA), β-hydroxybutyrate (BHBA) and calcium with milk yield across the first 4 Dairy Herd Improvement (DHI) tests. Serum from 1919 Holstein cows in 45 herds was collected weekly from 1 wk before through 2 wk after calving. The herds were located in California, southeast (Georgia, Florida, Virginia, South and North Carolina), northeast (New York and Ontario, Canada) and Midwest (Wisconsin and Minnesota) North America. Repeated measures ANOVA was conducted including parity, clinical disease, precalving body condition score, and region as covariates, and the random effect of herd. Serum concentrations were dichotomized at various cut-points to identify the thresholds of metabolites with the strongest associations with milk loss. Precalving NEFA ≥ 0.5 mEq/L (in multiparous cows only; 25% of the cows), BHBA ≥ 600 μmol/L (26% of the cows) and calcium ≤ 2.1 (5% of the cows) were associated with milk loss of 1.6 ± 0.5, 1.7 ± 0.4, and 3.3 ± 0.8 kg/d, respectively, across the first 4 DHI tests. In wk 1 after calving, NEFA ≥ 0.7 mEq/L (in multiparous cows only; 41% of the cows), BHBA ≥ 1,400 μmol/L (12% of the cows) and calcium ≤ 2.1 (23% of the cows) were associated with milk loss of 1.9 ± 0.6, 2.5 ± 0.6, and 2.6 ± 0.5 kg/d, respectively, at the first DHI test. In wk 2 after calving, NEFA ≥ 1.0 mEq/L (12% of the cows), BHBA ≥ 1,200 μmol/L (20% of the cows) and calcium ≤ 2.1 (8% of the cows) were associated with milk loss of 1.7 ± 0.8, 1.4 ± 0.6, and 4.8 ± 1.0 kg/d, respectively, at the first DHI test. Increased serum concentrations of NEFA and BHBA and decreased concentrations of calcium around calving are associated with milk loss in early lactation.

822 Whey protein nanoparticles prepared by desolvation: Encapsulation capacity and interfacial activity. I. Gülseren* and M. Corredig, *University of Guelph, Dept. of Food Science, Guelph, Ontario, Canada.*

Whey protein nanoparticles were prepared using a desolvation method, using ethanol as solvent. Physical characterization including particle size characteristics, encapsulation capacity for a model hydrophilic molecule (Brilliant Blue FCF), and interfacial activity at the oil-water interface were carried out, after diluting the samples in acidic conditions (pH 3). The particle size distribution was determined using dynamic light scattering technique, and particle diameter was between a few nm up to about 100 nm. Solvent composition was highly influential on the average particle size and its distribution. The release of the Brilliant Blue from the nanoparticles with storage was quantified using UV-Visible spectrophotometry, after separation of the whey protein particles by centrifugation. Both unloaded and loaded nanoparticles were stable at room temperature after one month of storage, and little release of the encapsulated dye molecules was observed. The interfacial properties of the unloaded nanoparticles were also tested using drop tensiometry, and it was shown that nanoparticle formation only slightly affected the interfacial activity.

Key words: whey protein nanoparticles, desolvation, encapsulation

823 Comparative proteomic analysis of whey proteins between healthy and subclinical mastitic cows. J. Bian, Q.-Z. Li*, and X.-J. Gao, *Key Laboratory of Dairy Science of Ministry of Education, Northeast Agricultural University, P.R. China.*

This study was to investigate different whey protein contents between healthy dairy cows and subclinical mastitical dairy cows, and to explore the mechanism of pathogenesis. This study presented changes of the whey proteins from healthy dairy cows and subclinical mastitical dairy cows by using 2-DE. After the protein stained with coomassie blue G-250, 21 differential expression protein spots were detected by ImageMaster 2D Platinum 6.0 software, then 10 protein spots were analyzed by using the MALDI-TOF/MS. Meanwhile. Proteins were identified by using the Mascot software to search the NCBInr database and the swiss-port database.8 proteins were identified successfully. In cows with subclinical mastitis, 3 proteins were downregulated: Alpha-S1 casein precursor, Chain D of bovine β-Lactoglobulin A and Chain B of the bovine β 1,4 galactosyltransferase catalytic domain ; 5 proteins were upregulated:Serotransferrin precursor, α-1-acid glycoprotein, β 2- microglobulin, Complement C3 precursor and Cytokeratin 9, these proteins were involved in signal transduction, binding and transportion and immune defense activity. The α-1-acid glycoprotein expression in whey of cows with subclinical mastitis was 2.55-fold higher than the healthy dairy cows confirmed by ELISA protocol. The results provided valuable information for the investigation on mechanism of the subclinical mammitis of dairy cows and potential protein targets for treatment.

Key words: subclinical mastitis, whey protein, comparative proteome

824 Controlling whey proteins spontaneous self assembly. T. Croguennec*[1], D. Salvatore[2], T. Nicolai[3], V. Forge[2], and S. Bouhallab[1], *[1]UMR 1253, INRA- Agrocampus Ouest, Science et Technologie du Lait et de l'Oeuf, Rennes, France, [2]Laboratoire de Chimie et Biologie des Métaux, CEA-Grenoble, Grenoble, France, [3]UMR CNRS-Université du Maine, Polymères, Colloides, Interfaces, Le Mans, France.*

Sustainability in food manufacture involves a profound reasoning of the way food are produced. Reducing energy input during food processing and optimizing ingredient formulation to meet both sensorial acceptance and nutritional benefit through a controlled release of macro- and micro-nutriments constitute great challenges for food industries. Controlled self-assembly of molecules into biomaterials throughout bottom-up approach is a promising way to achieve these goals. Because of their omnipresence in food systems, whey proteins are the focus of many attempts for their use as building blocks for such biomaterials. For instance, the apo form of α-lactalbumin (α-LA) and β-lactoglobulin are able to self-assemble into well-defined microspheres in the presence of an oppositely charged protein such as lysozyme (LYS). Formation and destabilization of microspheres are inducible by changing the physicochemical conditions. Because of this reversibility, such microspheres could be used to trap, protect during processing and storage, carry and deliver bioactives. However, to complete this challenge, a perfect understanding of protein assembly and disassembly mechanisms are necessary. In this communication we address the mechanism of formation of microspheres of α-LA and LYS from the molecular scale to the microspheres. One of the first events in the mechanism of formation of microspheres is a specific interaction between α-LA and LYS leading to a heterodimer. Probably throughout charge screening, α-LA/LYS heterodimers rapidly self-assembled into nanometer-sized aggregates. These small entities further aggregate into clusters following a diffusion limited mechanism (DLCA) and fuse upon physical contact into spherical microspheres. The driving force for the reorganization of the clusters into microspheres is suggested to be the decrease of the total surface free energy. However, the reorganization of the clusters was only inducible when the temperature was increased above 30°C, temperature above which α-LA adopt a molten globule structure. We put forward that the higher flexibility of α-LA above 30°C may facilitate clusters–microspheres transition.

Key words: self assembly, α-lactalbumin, microsphere

825 Study of the combined acidification and rennet gelation behavior of casein micelles using single *Streptococcus thermophilus* strains, with high or very low exopolysaccharide production. Z. Miao*, E. Kristo, and M. Corredig, *University of Guelph, Guelph, Ontario, Canada.*

The effect of the presence of exopolysaccharide (EPS) produced by lactic acid bacteria on the gelation properties of caseins is still largely unknown. Objective of this work was to study the gelation behavior of caseins during renneting, after controlled fermentation with high-EPS producing or very low-EPS producing *S. thermophilus* cultures. Fresh skim milk was fermented with either a high ropy exopolysaccharide-producing strain (CHCC-5086, Chr. Hansen); or a very low EPS producing strain (CHCC-742, Chr. Hansen), as control. The inoculated skim milk was incubated at 40°C and rennet was added when a pH of 6.2 was reached. The gelation behavior was followed using rheology, diffusing wave spectroscopy (DWS) and confocal microscopy. Milk containing the high-EPS producing strain showed a significantly higher viscosity than the control during fermentation up to pH 6.2. After addition of rennet, the gelation point occurred earlier (at significantly higher pH values) in milk fermented with high-EPS producing strain compared with milk fermented with control strain. Confocal

microscopy also showed differences in the microstructure between the gels, with larger pores in the presence of EPS. These results further our fundamental understanding of the effect of EPS on the beginning stages of the rennet-induced gelation.

826 In situ structural investigations of the milk fat globule membrane revealing heterogeneities and sphingomyelin-rich domains. C. Lopez*, *INRA-STLO, Rennes, France.*

In recent years, the milk fat globule membrane (MFGM) has attracted the attention of scientists and industrials because of its interesting functional, nutritional and health properties. These properties of the MFGM result from its chemical composition, but they may also be influenced by the capacity of the MFGM components to be specifically structured. Various models of the MFGM have been proposed, all of them presenting polar lipids as a homogenous 2D solvent for membrane proteins (Singer & Nicholson fluid mosaic model). However, the structure of the MFGM still remains the least understood aspect of milk. The objective of this work was to investigate the organization of the MFGM in situ in milk, using confocal laser scanning microscopy and adapted fluorescent dyes (exogenous polar lipid, lectins). For the first time, our work revealed i) the lateral segregation of sphingomyelin (SM; 20 to 25% of milk polar lipids) in rigid liquid-ordered domains surrounded by the fluid matrix of the glycerophospholipids (PC, PE, PI, PS), ii) that the SM-rich domains are of micronic size with a circular shape for bovine milk, iii) that the SM-rich domains diffuse in the plane of the outer bilayer of the MFGM as a function of time, iv) that the SM-rich domains are devoid of proteins. These SM-rich domains have been characterized whatever the size of milk fat globules and in milks from various species. As a conclusion, we showed that the MFGM is a heterogeneous and highly dynamic biophysical system. Moreover, on the basis of our experimental results, we proposed a new model for the organization of the MFGM. These original results raised the question of the role played by these SM-rich domains on the functional and nutritional properties of milk fat globules. Directions for future research studies will be discussed.

Key words: milk fat globule membrane, sphingomyelin, confocal microscopy

827 Fractionation of glycomacropeptide and beta lactoglobulin using positively charged ultrafiltration membranes in staged configurations. S. Gemili* and M. R. Etzel, *University of Wisconsin-Madison, Madison.*

Membrane ultrafiltration is a commonly used method for the concentration and diafiltration of protein solutions. For fractionation of proteins, ultrafiltration is not commonly used, because it lacks the separation capability of chromatographic methods. The selectivity of membrane ultrafiltration is increased dramatically when a charge is added to the membrane surface. Configuring the membranes in stages also increases the selectivity of the separation. Using membrane ultrafiltration instead of chromatography for protein fractionation has advantages for the dairy industry of a lower cost of manufacture resulting from decreased buffer consumption and the use of existing installed membrane equipment. In this study, positively charged cross-flow ultrafiltration membranes having a 300 or 30 kDa molecular weight cut off were used to fractionate glycomacropeptide (GMP) and β lactoglobulin (BLG). Sieving coefficients of GMP and BLG were determined experimentally by ultrafiltration of binary protein mixtures. These sieving coefficients were used to calculate purity and yield of GMP products from one-stage and 2-stage membrane configurations using mass balance models. Flow configurations that allowed for recycle of by-product streams were compared with cases without recycle. Different volume concentration factors (ratio of permeate to feed solution) ranging from 0.01% to 80% were also included in the evaluation. A ratio of 80% gave the highest GMP purity (97%) using a 300 kDa membrane in the first stage and a 30 kDa membrane in the second. However, this configuration gave the lowest GMP yield (21%) in the permeate stream. In contrast, a one-stage configuration using a 300 kDa membrane gave a 60% yield of GMP in the permeate stream at a purity of 74%. In conclusion, GMP fractionation can be accomplished using positively charged ultrafiltration membranes. Different flow configurations and membranes having different molecular weight cut offs can be used to balance yield and purity.

Key words: ultrafiltration, fractionation, glycomacropeptide

828 Antimicrobial role of serum amyloid A3 in goat milk. A. Domènech*[1], J. G. Raynes[2], A. Arís[1], A. Bach[1,3], and A. Serrano[1], *[1]Department of Ruminant Production, IRTA, Caldes de Montbui, Spain, [2]Immunology Unit, Department of Infectious and Tropical Diseases, London School of Hygiene and Tropical Medicine, London, United Kingdom, [3]ICREA, Barcelona, Spain.*

Milk is an important source of antimicrobial compounds. Serum Amyloid A3 (SAA3) is an acute phase protein which level is particularly high in colostrum and milk during mastitis, suggesting a potential protective role against infections. The aim of this study was the recombinant production of the milk goat SAA3 (gM-SAA3) and to evaluate 2 possible mechanisms of antimicrobial activity, directly preventing bacterial gastrointestinal adhesion and indirectly participating in macrophage-phagocytosis activation. Previous studies have explored some of these roles using either just fragments of the bovine milk-derived protein or the human plasma circulating form (SAA1). The recombinant gM-SAA3 was cloned from goat milk through RNA isolation, retrotranscription and specific amplification. Recombinant expression was achieved using the pET101 TOPO-cloning. For gastrointestinal assays, differentiated intestinal Caco-2 cells were incubated in 6-duplicates during 1h with 30 µg/mL of gM-SAA3 prior 2 h infection with 10^6 cfu/well of enteropathogenic *Escherichia coli* (EPEC). Phosphate buffer saline (PBS) and 10^8 cfu/well of *Lactobacillus rhamnosus* were used as negative and positive controls. Bacterial adhesion was quantified by viable cell counts. Human blood and goat milk macrophages were isolated using histopaque gradient density or conventional centrifugation. Macrophages were incubated for 1 h with 3 and 30 µg/mL gM-SAA3, PBS or human serum along with fluorescent labeled *E. coli* BL21-GFP+. Phagocytosis was evaluated using confocal microscopy and quantified as the association index (AI): number of fluorescent bacteria per 100 macrophages. Soluble gM-SAA3 was successfully expressed at 0.5 mg/ml. In gastrointestinal assays, a 70% decrease ($P < 0.001$) in EPEC binding was observed after incubation with gM-SAA3. Also, gM-SAA3 increased ($P < 0.05$) the AI in both human (62 ± 11%) and goat (72 ± 17%) macrophages, compared with PBS (9.8 ± 8% and 18 ± 15% respectively). These results confirm that the whole gM-SAA3 protein may play an active role in the newborn's defense via milk intake and it could participate in the clearance of bacteria through macrophage activation.

Key words: SAA, antibacterial, phagocytosis

Lactation Biology 2

829 Effects of short- and long-chain fatty acids on expression of lipogenic genes in bovine mammary epithelial cells. A. A. A. Jacobs*[1], J. S. Liesman[2], M. J. VandeHaar[2], J. Dijkstra[1], A. M. van Vuuren[1], and J. van Baal[1], *[1]Wageningen University, Wageningen, the Netherlands, [2]Michigan State University, East Lansing.*

Several long-chain polyunsaturated fatty acids can exert an inhibitory effect on the expression of lipogenic genes, including acetyl-CoA carboxylase (ACC), fatty acid synthase (FAS) and stearoyl-CoA desaturase 1 (SCD1), in the bovine mammary gland. Nevertheless, the effect of the short-chain fatty acids acetate (Ac) and β-hydroxybutyrate (BHBA), which are the main precursors for de novo fatty acid synthesis, on expression of these lipogenic genes remains unclear. To examine these effects, we used a bovine mammary epithelial cell line (MAC-T) incubated in fatty acid-free media (CON) and added either 5 m*M* Ac, 5 m*M* BHBA or a combination of 5 m*M* Ac + 5 m*M* BHBA. Furthermore, MAC-T cells were treated with either 100 μ*M* palmitic acid (PA), 100 μ*M* stearic acid (SA), 100 μ*M* oleic acid (OA), 100 μ*M* trans-vaccenic acid (TVA), 100 μ*M* linoleic acid (LA) or 100 μ*M* α-linolenic acid (ALA), which were complexed with BSA. Cells were grown to confluence in DMEM-F12 with 10% serum and all treatments were performed in triplicate. Fatty acids were added to the cells in serum-free DMEM-F12 including the hormones insulin, prolactin, apo-transferrin, progesterone and hydrocortisone. After 12 h of incubation, total RNA was extracted from the cells and mRNA expression of ACC, FAS and SCD1 was analyzed by real-time PCR. In comparison with CON, expression of ACC was increased by Ac (+44%) and was reduced by LA (−48%) and ALA (−49%). Expression of SCD1 was increased by Ac (+61%) and was reduced by OA (−61%), LA (−84%) and ALA (−88%). The treatments did not significantly affect expression of FAS compared with CON. Our results demonstrate that Ac upregulates the expression of ACC and SCD1 in MAC-T cells, which indicates that Ac may increase de novo synthesis and desaturation of fatty acids in the bovine mammary gland.

830 Effect of timing of feed intake on circadian pattern of milk synthesis. L. W. Rottman*, Y. Ying, and K. J. Harvatine, *The Pennsylvania State University, University Park.*

The rate of feed intake varies over the day and is expected to create a daily rhythm of nutrient absorption. The objective of this study was to characterize the effect of timing of feed intake on the pattern of milk synthesis. Twenty Holstein cows were used in a crossover design with 21d periods. Cows were milked every 6 h on d 14 to 21 of each period. Milk samples were collected at each milking on d 18 through 21, and 6 blood samples were collected on d 20 to 21. Treatments were feeding a TMR once daily (1x fed) or in 4 equal meals every 6 h (4x fed). All cows were fed ad libitum at 110% of daily DMI. Data were analyzed as a repeated measures design, and the model included the random effect of period, sequence, and cow nested within sequence, and the fixed effect of treatment, time, and the interaction of treatment and time. Treatment did not affect daily milk yield, and there was no treatment by time interaction. Milk yield was different by time ($P < 0.001$) with peak yield at 0200 h and 2000 h and a nadir at 1400 h. There was a treatment by time interaction for milk fat percent, but 4x fed resulted in higher milk fat percent at all time points compared with 1x fed (0.22 to 0.45% higher; $P < 0.05$). Daily milk fat yield was increased 0.13 kg/d by 4x feeding ($P < 0.001$). However, milk protein percent and daily yield were higher in 1x fed (0.1% and 0.05kg/d; $P < 0.001$). Plasma nonesterified fatty acids had a daily pattern with a predominant peak at 0700 h and a second, smaller peak at 1800 h (Time, $P < 0.0001$). Interactions were detected between treatment and time for plasma glucose, insulin, and blood urea nitrogen. Plasma glucose nadirs occurred at 0200 h, 1400 h, and 2200 h for 4x fed whereas 1x fed showed a single, higher nadir at 1000 h ($P < 0.01$). More peaks were observed, and the daily range of plasma insulin was greater in 1x fed (21.56 vs. 11.43 μIU/mg). Blood urea nitrogen peaked at 1400 h in 4x fed compared with 1000 h in 1x fed, but had similar daily ranges and nadirs. In conclusion, dairy cows have a circadian pattern of milk synthesis that is responsive to the timing of feed intake.

Key words: circadian, dairy cow

831 Long term effect of feeding rumen protected fish oil or microalgae on mammary gene expression in Holstein cows managed under pasture or confinement systems. P. Vahmani*[1], K. Glover[2], L. A. MacLaren[2], J. Green-Johnson[3], and A. Fredeen[2], *[1]Dalhousie University, Halifax, NS, Canada, [2]Nova Scotia Agricultural College, Truro, NS, Canada, [3]University of Ontario Institute of Technology, Oshawa, ON, Canada.*

The objective of this study was to examine how milk fat percent and yield, and the expression of mammary lipogenic genes were affected by the source of dietary marine oil (fish oil vs. microalgae) in grazing or confined dairy cows. Forty 8 Holstein cows were deployed across 2 feeding systems: either grazing pasture (n = 23) from Apr08 to Sep08, or receiving a TMR in confinement (n = 25) from Oct 08 to Feb09. Cows within each feeding system were blocked by calving date and assigned randomly within block to a control (no supplement) or one of 2 isolipidic supplements: rumen protected fish oil (RPF) or rumen protected microalgae (RPM) for 125 ± 5 d beginning 30 d pre-calving. The RPM supplement provided ~50 g/d of DHA, whereas the RPF supplement provided ~25 g/d each of EPA and DHA. Milk samples were taken at 90 ± 5 DIM for compositional analysis. Four cows from each treatment within each feeding system were slaughtered at 95 ± 5 DIM and mammary parenchymal tissue was sampled. Expressions of mammary genes involved in de novo fatty acid synthesis (ACACA, FASN), desaturation (delta5-, delta6- and delta-9 desaturases), fatty acid uptake (LPL), transcriptional regulation (SREBP1, ChREBP, INSIG1, SCAP, THRSP) and nuclear receptor signaling (PPARα, PPARγ) were determined using qPCR. Milk fat percent was higher ($P = 0.02$) for control (3.52 ± 0.18) compared with RPM (3.02 ± 0.19), but was not different ($P = 0.23$) from RPF (3.28 ± 0.19). However, milk fat yield was not affected ($P = 0.25$) by the lipid supplements (1.34 ± 0.07, 1.25 ± 0.08 and 1.22 ± 0.09 kg/d for control, RPF and RPM, respectively). Expression of SREBP1, the main transcriptional regulator of milk fat synthesis, was reduced ($P < 0.05$) by 26% with RPM or RPF compared with the control, but the rest of measured genes were not altered by the treatments. The lipid supplements did not affect the regulation of the mammary lipogenic complex except for a reduced expression of SREBP1. This effect was apparently insufficient to alter the expression of lipogenic genes and milk fat yield.

Key words: fish oil, microalgae, mammary gene expression

832 Reduced milking frequency increases the concentration of host-defense proteins in milk. K. Stelwagen*[1], M. K. Broadhurst[2], K. Kim[2], A. J. Molenaar[2], D. P. Harris[2], and T. T. Wheeler[2], *[1]Agri-Search Ltd., Hamilton, New Zealand, [2]AgResearch Ltd., Hamilton, New Zealand.*

Milk is a very complex fluid and while its main components, fat, lactose, caseins and major whey proteins, have been reasonably well studied, increasingly its minor components are being elucidated. Many of these minor components have known bioactive properties, including those related to innate immune function, and may have potential to add economic value to the dairy industry. We have previously shown that once-daily milking (ODM), compared with twice daily (TDM), can be used as an on-farm tool to increases the content and yield of the host-defense protein lactoferrin in milk. In the present study we show the effect of ODM on the level of several additional host-defense proteins in milk. Lactating (128 ± 15 DIM) New Zealand Friesian dairy cows (n = 10), grazed on pasture, were continued on normal TDM for the first 3 d of the experiment and then switched to ODM for a further 9 d. At each milking samples were collected for analysis of gross milk composition, SCC, and the abundance of the host-defense proteins lactoferrin, serum amyloid A3 (SAA3), angiogenin/RNase5 and RNase4. The level (μg/mL) of all 4 proteins was increased ($P < 0.05$) during ODM (TDM vs. ODM: lactoferrin, 81%, 110.1 vs. 199.8 ± 38.7 ; SAA3, 82%, 0.09 vs. 0.16 ± 0.02; angiogenin/RNase5, 12%, 8.63 vs. 9.63 ± 0.27; RNase4, 38%, 1.77 vs. 2.39 ± 0.11). The moderate increase of angiogenin/RNase5 is likely to be a consequence of the corresponding decrease in milk yield of 8% due to ODM, as the total yield of angiogenin/RNas5 did not differ significantly between TDM and ODM. Based on indirect indicators of mammary tight junction permeability and a small but significant increase in SCC (TDM vs. ODM: 30 vs. 42 ± × 1000/mL; $P < 0.05$), the increase in milk of host-defense proteins is likely to be due to a mild sterile intramammary inflammatory response accompanying the transition from TDM to ODM. This study shows that ODM may be used as a management tool to increase the level of valuable immune-related minor proteins in milk.

Key words: milk bioactive, milking frequency, host-defense

833 Effect of milking frequency early post-partum on energy metabolism in grazing dairy cows. C. V. C. Phyn[1], T. M. Grala[2], J. K. Kay[1], A. G. Rius[1], S. R. Morgan[1], and J. R. Roche*[1], *[1]DairyNZ Ltd., Hamilton, New Zealand, [2]DairyNZ Ltd., C/- ViaLactia Biosciences (NZ) Ltd., Auckland, New Zealand.*

In grazing dairy cows, short-term once-daily (1X) milking immediately post-calving results in long-term decreases in milk, fat and protein yields, and improves BCS, whereas thrice-daily (3X) milking does not increase energy-corrected milk yields. This study investigates the immediate and long-term effects of post-calving milking frequency (MF) on energy metabolism. Multiparous Holstein-Friesians (n = 150) were randomly assigned to one of 5 groups following calving: milked 1X for 3 or 6 wks and twice daily (2X) thereafter; milked 2X for the entire lactation (control); or milked 3X for 3 or 6 wks and 2X thereafter. Weekly blood samples (wks 1 to 12 post-calving) were analyzed for plasma NEFA, glucose, and aspartate aminotransferase (AST). Liver and adipose tissue was collected at 3, 6 and 9 wks post-calving (n = 12 cows/trt), and gene expression measured using RT-qPCR. Data were analyzed using mixed models fitted with REML in GenStat including: treatment and contrasts to test MF, duration and their interaction as fixed effects, and cow as a random effect. Gene expression of growth hormone receptor (GHR)-total and GHR1A was reduced ($P < 0.05$) and insulin receptor-B increased ($P < 0.01$) at 3 wks post-calving in the liver of cows milked 3X. Cows milked 1X had greater insulin-like growth factor (IGF)-I expression at 3 wks compared with cows milked 2X or 3X. Expression of lipogenic genes (SCD, LPL, THRSP) in adipose tissue was greater ($P < 0.05$) in cows milked 1X at 3 and 6 wks. In contrast, at 9 wks post-calving, cows milked 3X for 6 wks had decreased lipogenic (SCD, THRSP), lipolytic (hormone sensitive lipase) and GHR-total expression. Plasma glucose was greater ($P < 0.001$) and NEFA was lower ($P < 0.001$) during wks 1 to 6 in cows milked 1X. Cows milked 1X for 6 wks also had greater glucose post-treatment (wks 7 to 12). During wks 1 to 3, cows milked 3X had lower glucose and greater NEFA, while AST was greater ($P < 0.05$) throughout (wks 1 to 12). Results indicate that grazing cows milked 1X post-calving maintained a better energy balance and greater lipogenesis than cows milked 2X, whereas 3X milking induced a more severe negative energy balance.

Key words: milking frequency, dairy cow, energy metabolism

834 Regulation of STAT and IGF signaling during reversible and irreversible involution of the bovine mammary gland. K. Singh*[1], J. Dobson[1], K. Oden[1], A. Molenaar[1], R. Murney[1], K. Swanson[1], and K. Stelwagen[2], *[1]AgResearch Ltd., Ruakura Research Centre, Hamilton, New Zealand, [2]Agri-Search Ltd., Hamilton, New Zealand.*

STAT and IGF signaling play a major role at the onset of rodent mammary involution. The aim of this study was to investigate the reversibility of mammary STAT5/3 and IGF signaling following involution induced by not milking, and subsequent re-milking in dairy cows. Mammary alveolar tissue was obtained from non-pregnant cows (n = 5/group) slaughtered at mid-lactation 6h post-milking (control), cows not milked for either 7 or 28d, and cows that were re-milked for 7d following both non-milked periods. Western blot analyses showed that pSTAT5 (activated) protein levels following 7 and 28d involution were lower ($P < 0.001$; 8.5- and 9.5-fold, respectively), compared with lactating controls and cows returned to lactating levels when re-milked following both non-milked periods. In contrast, apoptosis marker pSTAT3 levels were much greater ($P < 0.001$; 40- and 16-fold, respectively) following both 7 and 28d of involution, compared with lactating controls and remained greater ($P < 0.01$; 5-fold) following re-milking after a 28d involution. Similar results were observed for other indicators of apoptosis, lactoferrin and αBax. In contrast to rodent involution, IGF-I was increased in 7 ($P < 0.1$; 2-fold) and 28d ($P < 0.01$; 3.5-fold) non-milked cows and only returned to lactation levels when cows were re-milked after the 7d non-milked period. IGF-II and IGF-BP5 mRNA levels were similar between all groups ($P < 0.1$). Average expression of the major milk proteins αS1-, β-, and κ-CN, α-LA and β-LG declined (RT-PCR; $P < 0.05$) following 7 and 28d of involution (3.5 to over 200-fold) compared with lactating controls. Levels returned to those of lactating controls re-milked after 7d of involution. When re-milked after 28d non-milking, all but κ-CN returned to lactating levels. The variability in milk protein gene expression in response to involution and re-milking between animals was supported by histological analyses demonstrating differences in response rates between cows. These data suggest that STAT3 and IGF-I play a role in the irreversible phase of involution.

Key words: STAT5/3, IGF, bovine mammary involution

835 Variations in the mammary uptake of nutrients throughout an extended milking interval in dairy cows. J. Guinard-Fla-

ment*, C. Hurtaud, and S. Lemosquet, *UMR Production du Lait, INRA/Agrocampus Ouest, Saint-Gilles, France.*

The rate of milk secretion remains steady until 16 h after milking. However, little is known about milk synthesis and the way the udder adapts its nutrient uptake in relation to variations in arterial nutrient flow to sustain its metabolic activity. A trial was carried out to describe variations in mammary blood flow, and in arterial concentrations, mammary arteriovenous differences (AVD), extraction rates (ER), and uptake of nutrients in the course of milk accumulation in the udder over a 36-h period. The trial was performed twice on 2 consecutive wk with 3 dairy cows (34 kg/d of milk). Cows were fed and milked twice daily at the same time, except over the 2 36-h intervals. During milk accumulation, 20 blood samples were collected using 1- to 3-h intervals between samplings. Uptakes of glucose, acetate, BHBA, glycerol, O2, and release of CO2 were reduced by 27–38% on the last 12 h compared with the first 12 h of milk accumulation ($P < 0.05$). But patterns of variations in the course of time between feed distributions were preserved. The mammary uptake of glucose and glycerol did not vary or only slightly between feed distributions (1.4-fold variation; $P < 0.05$). In contrast, acetate and BHBA showed larger variations to a maximum of 50 to 100% ($P < 0.05$ except for BHBA on the last 12 h of milk accumulation). Uptakes of acetate and BHBA were maximal 3 h after feed distribution and were correlated to their arterial concentrations and AVD (r = 0.73 and 0.88 for acetate and r = 0.63 and 0.83 for BHBA, respectively) whereas those of glucose and glycerol were correlated to ER (r = 0.80 and 0.90, respectively). Maximal uptakes of acetate and BHBA were also associated with greater uptakes of glucose, glycerol, O2 and maximal releases of NEFA and CO2 ($P < 0.05$). These results suggest that the de novo synthesis of milk fatty acids could vary throughout the day according to the arterial concentration of acetate or BHBA or both. In contrast, the uptake of glucose and glycerol would depend on the metabolic activity of the mammary gland, the udder modifying its efficiency of extraction from blood according to its metabolic needs.

Key words: milk synthesis, udder uptake, dairy cow

836 Effect of heat stress during the dry period on insulin sensitivity of multiparous dairy cows. S. Tao*, I. M. Thompson, A. P. Monteiro, M. J. Hayen, and G. E. Dahl, *University of Florida, Gainesville.*

Heat stress during the dry period affects hepatic gene expression and adipose tissue mobilization during the transition period. One of the possible outcomes may be altered insulin action on peripheral tissues. Our objective was to evaluate the effect of heat stress during the dry period on insulin sensitivity in the transition period. Cows were dried off 46 d before expected calving and assigned to 1 of 2 treatments: heat stress (HT, n = 16) or cooling (CL, n = 16). During the dry period, the average THI was 78, but CL cows were cooled with sprinklers and fans and HT cows were not. After calving, all the cows were housed together in the same barn and cooled. Rectal temperatures (RT) were measured twice daily (0730 and 1430h) and respiration rate (RR) recorded thrice weekly during the dry period. DMI was recorded daily from dry-off to 42 d relative to calving (RTC). BW and BCS were measured weekly from dry-off to 42 DIM. Milk yield and composition were recorded daily to 126 DIM. Glucose and insulin tolerance tests were performed at dry-off, −14, 7 and 28 d RTC from a subset of cows (HT, n = 8; CL, n = 8). Relative to HT, CL cows had lower RT in the afternoon (39.3 vs. 39.0 0C; $P < 0.01$) and lower RR (69 vs. 48 breaths/min; $P < 0.01$). CL cows consumed more feed than HT cows prepartum (11.4 vs. 10.2 kg/d; $P = 0.05$), but not postpartum ($P = 0.25$). Compared with HT, CL cows gained more weight before calving ($P = 0.01$) but lost more weight in the early lactation ($P = 0.02$). Treatment did not affect BCS. CL cows produced more milk than HT cows (40.4 vs. 32.7 kg/d; $P < 0.01$), but prepartum cooling did not affect milk composition. Preliminary data from the glucose tolerance test indicate that CL cows had similar glucose disposal rates ($P = 0.3$) relative to HT cows 2 weeks before calving. Regardless of treatment, cows had increased glucose disposal rate at −14 d RTC compared with dry-off. We conclude that heat stress during the dry period compromises lactation performance but does not affect insulin sensitivity late in the dry period.

Key words: heat stress, insulin sensitivity, dairy cow

837 Dry period seasonal effects on the subsequent lactation. I. M. Thompson*, A. P. Monteiro, and G. E. Dahl, *University of Florida, Gainesville.*

Photoperiod and heat stress during the dry period influence subsequent lactational performance, and health. To determine the effects of heat stress abatement during the dry period on subsequent lactation under commercial conditions in north central Florida, cows were dried off approximately 45d before expected calving and randomly assigned to 2 treatments, heat stress (HT; n = 77) and cooling (CL; n = 56). Cool cows were kept outside and provided with sprinklers, fans and shade, whereas HT cows were outside under shade. Relative to HT, CL cows had greater milk production (45.62 vs. 43.21; $P = 0.02$) through 120 DIM. Having confirmed significant production effects of heat stress during the dry period, we analyzed records of 2,614 multiparous cows under commercial conditions in Florida over 3 years to determine seasonal effects during the dry period on subsequent lactation performance, reproduction and occurrence of health disorders during the first 60 DIM. Seasons were Cool (Dec, Jan and Feb) and HOT (June, July and Aug). Traits analyzed were lactation number, 305d milk production, calving interval, number of breedings, days open and occurrence of postpartum health disorders such as digestive problems, mastitis, metritis, retained fetal membranes, and respiratory problems. Cows dried during HOT months had lower milk yield in the subsequent lactation relative to COOL cows (10,351 vs. 10,902 kg; $P < 0.01$). Additionally, HOT cows had a higher incidence of mastitis ($P < 0.01$) and respiratory problems ($P < 0.01$) compared with COOL cows. Moreover, cows exposed to heat tended to have a higher incidence of retained fetal membrane ($P < 0.07$) compared with cows cooled while dry. Of interest, COOL cows had a higher incidence of postpartum digestive problems ($P < 0.01$). Therefore, environmental management strategies during the dry period may be needed to attain optimal lactation performance.

Key words: dry period, season, milk production

Meat Science and Muscle Biology: Extracellular Matrix in Skeletal Muscle Development and Meat Quality

838 Stem cell niche and postnatal muscle growth. S. Kuang*, *Purdue University, West Lafayette, IN.*

Stem cell niche plays critical roles in regulating the function of adult stem cells that underlie tissue growth, maintenance and regeneration. In the skeletal muscle, stem cells called satellite cells contribute to postnatal muscle growth and hypertrophy, thus meat production in animal agriculture. Satellite cells are located adjacent to mature muscle fibers underneath a basal lamina sheath. Microenvironmental signals from extracellular matrix mediated by the basal lamina and from the adjacent muscle fiber both impinging on satellite cells to regulate their activity. This talk focuses on how such signals acting together to affect stem cell fate in the niche, and use Dlk1 as an example to elucidate how extracellular cues dynamically regulate satellite cell function during muscle growth and regeneration. Ongoing research in my lab takes advantage of this knowledge to engineer bioactive scaffolds that mimic the key physical and chemical properties of satellite cell niche, and explore the potential of using engineered stem cell niche to enhance tissue regeneration in vivo.

Key words: stem cell niche, skeletal muscle, satellite cell

839 Extracellular matrix regulation of skeletal muscle formation and growth. S. Velleman*, *The Ohio State University/OARDC, Wooster.*

Skeletal muscle growth and development is a highly organized process regulated by interactions between muscle cells and their extracellular environment. Communication between the extracellular matrix (ECM) and cells plays a pivotal role in the regulation of muscle cell proliferation and differentiation. The ECM is a dynamic network of molecules secreted by the cells and includes collagens, proteoglycans, and noncollagenous glycoproteins. The ECM was viewed to be merely a component that the cells were embedded in and provided a structural framework for the cells. In skeletal muscle, the ECM is a major component of the intramuscular connective tissue. In recent years, the ECM has been shown to be an integral part of the cellular communication network regulating cell shape and gene expression. Proteoglycans are a diverse family containing a central core protein and at least one covalently attached glycosaminoglycan (GAG) chain. Proteoglycans are involved in tissue hydration, regulation of gene expression, cell proliferation and differentiation, migration, and adhesion which are all essential for the muscle development process. Two major groups of membrane-associated heparan sulfate proteoglycans, the syndecans and glypicans, are found in skeletal muscle. Both are capable of regulating fibroblast growth factor 2 (FGF2) signal transduction. Syndecan-4 and glypican-1 differentially affect muscle cell proliferation and differentiation and the cellular response to FGF2. Differential regulation of muscle growth by these proteoglycans results, in part, from different signal transduction pathways, such as mitogen activated protein kinase and protein kinase C α, being activated. Understanding the effect of these proteoglycans on these pathways is necessary to develop a comprehensive insight into the mechanisms of proteoglycan-mediated modulation of muscle development and growth. Recent research findings on syndecan-4 and glypican-1 regulation of muscle development will be discussed.

840 The influence of extracellular matrix on intramuscular and extramuscular adipogenesis. G. J. Hausman*, *USDA ARS, Athens, GA.*

The extracellular matrix (ECM) and specific ECM components can have a major influence on cell growth, development and phenotype. The influence of the ECM and ECM components on adipogenesis in vivo and in vitro will be reviewed. Engelbreth-Holm-Swarm (EHS) substratum and laminin per se markedly increased attachment, spreading, and hypertrophy of preadipocytes in serum free primary cultures of adipose tissue stromal-vascular (SV) cells while antagonizing spreading of non-preadipocytes. In addition, adipocyte number increased on these substrata resulting in a greater proportion of preadipocytes. Furthermore, immunocytochemistry in primary cultures of adipose tissue S-V cells showed that preadipocytes express ECM components after preadipocyte recruitment and the ECM may be critical for morphological development of adipocytes. Preadipocytes on ECM substrata accumulated lipid but were "flat" and did not express ECM components, regardless of insulin or DEX treatment. The influence of ECM was examined in "marbling" adipocytes by developing a protocol to culture semitendinosus muscle stromal-vascular (SV) cells. The co-development of myotubes and preadipocytes was evident only on laminin substrata when compared with other ECM components following seeding and plating with fetal bovine serum (FBS) with or without DEX. In vivo studies of fetal adipose tissue staining for galactose binding lectins, type IV collagen and laminin will also be reviewed. Adipocyte reactivity for laminin was strong throughout development and was similar for developing adipocytes and vasculature. Staining for lectins and type IV collagen was greater for blood vessels than for adipocytes. The differentiation of the extracellular matrix of blood vessels and adipocytes is clearly distinct throughout development. Therefore, these studies indicated that the ECM and in particular laminin may play a critical role in morphological aspects of preadipocyte development.

Key words: adipogenesis, extracellular matrix, differentiation

841 Connective tissue turnover and meat quality. P. P. Purslow*, *Department of Food Science, University of Guelph, Guelph, ON, Canada.*

Intramuscular connective tissue (IM-ECM) is necessary for patterning muscle development and its turnover is also necessary during muscle growth. The amount and state of maturity of IM-ECM are strong contributors to cooked meat toughness. Amounts of IM-ECM in each muscle appear to be dictated by functional requirements, but its maturity may be reduced by increasing its turnover, as newly deposited IM-ECM has immature crosslinks. IM-ECM degradation is principally by the matrix metalloproteinases (MMPs), and synthesis is by intramuscular fibroblasts. Studies in our laboratory have shown: (1) Fibroblasts from 3 bovine muscles have different proliferation rates and different levels of MMP expression, with fibroblasts in the Semitendinosus being most active. (2) Reactive oxidative species depress new collagen synthesis and increase MMPs expression by intramuscular fibroblasts moderately. When vitamins E or C (or both) are added, both MMP expression and collagen synthesis are elevated. (3) IM-ECM degradative activity is located at the periphery of muscle fibers and fascicles in adult skeletal muscle, and is mostly MMP-related. The major-

ity of MMP expression is in fact from muscle cells, and the levels may vary with muscle fiber size or type. (4) The activity of collagenases expressed by myoblasts is comparable to fibroblasts in cell culture, and responds more to mechanical stimulation. Mechanical stimuli (exercise) are known factors for muscle adaptation and hypertrophy. (5) The stress hormone epinephrine increases the extracellular activity of MMP-2 from fibroblasts, but more so from myoblasts at physiological levels. The β-agonist ractopamine increases both MMP but especially the MMP inhibitor TIMP-1 expressed by myoblasts. These studies suggest that there is good capacity to manipulate IM-ECM turnover by several pathways, including dietary manipulations, by altering the rates of degradation by MMPs and synthesis of new collagen, with less heat-stable crosslinks. However, phenotypic differences between muscles may mean that different muscles may react quite differently to a given treatment applied to the whole animal.

Key words: extracellular matrix, meat quality, proteolysis

Nonruminant Nutrition: Energy and Dietary Fat

842 Determining the energy digestibility of mold-damaged corn selected for low mycotoxin content in finishing pigs. C. M. Pilcher*, A. Greco, C. R. Hurburgh, G. P. Munkvold, C. K. Jones, and J. F. Patience, *Iowa State University, Ames.*

There is very limited information on the impact of mold damage on the digestibility of nutrients in corn. The objective of this study was to determine the DE content of mold damaged corn samples selected for low mycotoxin content. Corn samples with visible mold damage were collected from 14 Midwestern sites and corn samples with no visible mold damage were selected from 4 Midwestern sites. All samples were screened for mycotoxin content and only samples with low mycotoxin content (i.e., < 1.0 ppm deoxynivalenol; < 20 ppb aflatoxin; < 10 ppm fumonisin; < 3 ppm zearalenone) were selected for use in the trial. A single control sample was created by blending 3 samples with no visible mold damage, and 7 mold damaged samples were selected. Corn samples were inspected by an official US grain inspection agency. Mold damaged samples varied in test weight (58 to 72 kg/hL; mean = 67 ± 5.2 kg/hL), total damaged kernels (9.4 to 65.8%; mean = 33.8 ± 21.70%) and moisture (13.9 to 16.5; mean = 14.9 ± 0.84%). Experimental diets were comprised of 96.9% corn from the control or one of the 7 mold damaged sources supplemented with vitamins and minerals. Barrows (initial BW = 99.0 ± 4.98 kg, n = 16) were allotted to an 8 × 3 Youden square design with the 8 diets and 3 replicate periods. Periods included 6 d of adaptation to treatment diets followed by a 2 d fecal collection period. Pigs received a fully balanced finishing diet for 4 d between replicates. Gross energy of diets and feces was determined by bomb calorimetry. There was a considerable range among the mold damaged corn samples for DM digestibility (85.2 to 87.3%; $P < 0.01$), energy digestibility (83.2 to 85.7%; $P < 0.01$) and DE (3,436 to 3,611 kcal/kg DM; $P < 0.0001$). DM digestibility (86.8 vs. 89.2%; $P < 0.01$), energy digestibility (85.0 vs. 87.8%; $P < 0.01$), and DE (3,558 vs. 3,714 kcal/kg DM; $P < 0.001$) were lower for mold damaged corn compared with the control corn. The current practice of blending mold damaged corn with good quality corn presents risks of lowering nutrient availability.

Key words: corn, mold, swine

843 Effects of dietary energy density on performance and lean deposition of growing-finishing pigs raised in a commercial environment. L. C. Chu*, C. J. Cai, G. J. Zhang, S. Y. Qiao, and D. F. Li, *China Agricultural University, Beijing, China.*

Three experiments were conducted to determine the effects of digestible energy (DE) density on performance and lean deposition in growing-finishing pigs (Yorkshire × Landrace × Duroc) during 3 separate phases when housed in a commercial environment. A completely randomized block design within sex was used involving 480 pigs (20.8 to 55.9 kg) in Exp. 1, 420 pigs in Exp. 2 (57.0 to 76.6 kg) and 240 pigs (78.6 to 105.8 kg) in Exp. 3. Pigs were allotted to one of 5 treatments containing 13.62, 13.87, 14.12, 14.37 and 14.62 MJ DE/kg. Pig body weight and feed consumption were determined every 2 weeks and carcass composition was evaluated at the start and end of the experiments to evaluate lean deposition. ANOVA, linear and quadratic contrasts and the broken-line regression model was used to analyze the experimental data. In Exp. 1, energy density had no significant effect ($P > 0.05$) on weight gain or feed efficiency. Meanwhile, carcass fat-free lean gain decreased (linear, $P = 0.02$; quadratic, $P = 0.02$) and fat-free lean index decreased quadratically (quadratic, $P = 0.05$) with increasing dietary energy density. The optimum level of dietary DE to maximize lean deposition was 13.81 MJ DE/kg. In Exp. 2, both weight gain ($P = 0.01$) and feed efficiency ($P = 0.06$) increased linearly with increasing DE density, while carcass fat-free lean gain ($P = 0.05$) and fat-free lean index decreased significantly ($P < 0.01$). The optimum level of dietary DE to maximize lean deposition was 13.76 MJ DE/kg. In Exp. 3, weight gain ($P = 0.09$) and feed efficiency ($P = 0.05$) also showed an increasing trend. The decreasing trend of carcass fat-free lean gain ($P = 0.05$) and fat-free lean index ($P < 0.01$) suggest the optimum level of dietary DE to maximize lean deposition was 13.82 MJ DE/kg. The results of the present study demonstrate that pigs reared in a commercial environment require different dietary energy levels for lean deposition compared with performance. Therefore, diets may be formulated with different energy levels depending on the overall goal of a swine producer.

Key words: digestible energy, growing-finishing pigs, lean deposition

844 Effect of feeding soy and sunflower based reconstituted fat or monoestearate as fat sources in piglet diets. J. J. Mallo[1], J. Alcañiz*[1], M. I. Gracia[2], and C. Millán[2], *[1]Norel, S.A., Madrid, Spain, [2]Imasde Agroalimentaria, S.L., Madrid, Spain.*

A total of 216 weaned piglets (Large White x Landrace*Large White) were allocated at random to 4 experimental treatments (T1: basal diet, 4% soy oil; T2: 4% Soy+Sunflower oil fatty acids esterified with glycerol (reconstituted fat, RE); T3: 4% Soy+Sunflower oil monoestearate (ME); and T4: 2% soy oil + 2% ME), including 6 replicates of 9 piglets per treatment (half male and half female). Mash feeds and water were offered ad libitum with no added growth promoter or veterinary antibiotics. A common prestarter diet was offered from weaning at 26 d during a week. Experimental treatments were applied in the starter diets from 33 to 63 d of age. After consuming the experimental diets for 9 d, fecal samples were taken to calculate nutrient digestibility. Observations included body weight (BW), growth (ADG), feed intake (ADFI), feed conversion ratio (FCR) and apparent fecal digestibility of dry matter, organic matter, ether extract and gross energy of the diets. Data were analyzed as a completely randomized design by GLM of SAS. No significant differences were observed between fat sources in any of the performance parameters studied (374, 368, 375, 357 g/d and 1.28, 1.34, 1.32, 1.35 g feed/g gain for growth and feed conversion at 33–63 d of age, for T1 to T4, respectively; $P > 0.10$). Significant differences were observed in digestibility between the 4 treatments. Apparent fecal digestibility of dry matter was improved with RE, ME and the combination when compared with the basal diet (68.8^{b}, 75.0^{a}, 78.1^{a}, 76.6^{a} %, $P = 0.0288$, for T1-T4, respectively). Apparent fecal digestibility of gross energy (DCGE) and organic matter (DCOM) were improved when ME or the combination were used, presenting RE intermediate results (DCGE: 68.7^{b}, 73.5^{ab}, 77.8^{a}, 76.3^{a} %, $P = 0.0334$; and DCOM: 73.8^{b}, 78.2^{ab}, 81.5^{a}, 80.9^{a} %, $P = 0.0246$, for T1-T4, respectively). It is concluded that soy and sunflower oil reconstituted fat or monoestearate improve digestibility of piglet diets and can be used as an alternative to soya oil for weaned piglets.

Key words: monoestearate, vegetable reconstituted fat, piglets

845 Impact of fat source on nutrient digestibility and performance in nursery pigs. S. M. Mendoza* and E. van Heugten, *North Carolina State University, Raleigh.*

This study was designed to evaluate the impact of fat saturation (iodine value, IV) and FFA concentration of fat on nursery pig performance and digestibility of fat and gross energy. Pigs (n = 189; BW = 9.32 ± 0.11 kg) were weaned at 21 d and fed a common diet for 14 d. Pigs were housed 3 pigs per pen using a total of 63 pens and assigned within weight blocks to one of 7 dietary treatments. Diets were corn-soybean meal based (3.76% SID lysine/Mcal ME) and consisted of a negative control diet without added fat and a basal diet with 6% added fat from a combination of 4 fat sources to create 6 diets with 2 levels of FFA (0.4 or 54.0%) and 3 degrees of fat saturation (IV = 77, 100, or 123) in a 2 × 3 factorial arrangement. Fat sources were: soybean oil (SO, 0.3% FFA, IV = 129.4), soybean-refined cottonseed acid oil (SAO, 70.5% FFA, IV = 112.9), choice white grease (CWG, 0.6% FFA, IV = 74.8), and choice white acid grease (CWAG, 56.0% FFA, IV = 79.0). Fat sources were included in diets at the following proportions: diet 1, 100% CWG; diet 2, 95% CWAG and 5% CWG; diet 3, 50% SO and50% CWG; diet 4, 38% SAO, 12% SO, 48% CWAG, and 2% CWG; diet 5, 100% SO; and diet 6, 76% SOA and 24% SO. Fat supplementation decreased ADFI (812 vs. 873 g/d; $P = 0.02$) and improved G:F (715 vs. 646 g/kg; $P < 0.001$) compared with the negative control diet. Diets with high FFA tended ($P = 0.08$) to improve BW (21.69 vs. 21.13 kg) and ADG (592 vs. 566 g/d). Apparent digestibility of fat was higher in fat supplemented diets than control diets (63.3 vs. 28.1%, $P < 0.001$). Fat digestibility was higher in diets with low FFA (65.6% vs. 60.9%, $P < 0.001$) and decreased linearly with increasing IV (72.6, 65.5, and 58.9%) when FFA concentration was low, but was unaffected by IV when FFA concentration was high (60.6, 61.3, and 60.9%). Digestibility of GE was higher in diets with low FFA (83.1% vs. 80.9%; $P < 0.001$). In conclusion, G:F was improved when fat was supplemented to pigs. Digestibility of fat and GE was reduced for fats high in FFA. However, nursery pig performance tended to be improved with high FFA, indicating that SAO and CWAG could be economic alternatives to more expensive fats.

Key words: pigs, fat, digestibility

846 Effect of altering the dietary omega-6 to omega-3 fatty acid profile of sow diets on the immune responses of their offspring when challenged with *E. coli* lipopolysaccharide. L. Eastwood*[1,2], A. D. Beaulieu[1,2], and P. Leterme[3], *[1]Prairie Swine Centre Inc, Saskatoon, SK, Canada, [2]Animal and Poultry Science, University of Saskatchewan, Saskatoon, SK, Canada, [3]Cargill - R & D Centre Europe, Havenstraat, Vilvoorde, Belgium.*

The objective of this experiment was to determine the effects of altering the omega-6 (n6) to omega-3 (n3) fatty acid (FA) ratio in sow diets on the immune responses of their offspring. Sows consumed one of 5 treatment diets for 2 reproductive cycles. Treatments were a control (tallow based) or plant based diets with n6:n3 ratios of 10:1, 5:1, 1:1, or a fish based 5:1 ratio. Piglets weaned from the 2nd cycle (d28 of lactation) were used in the immune challenge study. On d 6 post-weaning, weanling pigs (n = 100), 20 from each diet group, were randomized to a challenge control group (saline) or to an *E. coli* lipopolysaccharide (15 µg/kg BW; LPS) injected group (n = 10/challenge/diet). Rectal temperatures were recorded at 0, 1, 2, 3, 4, 5, 6, 12 and 24 h post injection and blood samples were collected at 0, 2, 6 and 12 h post injection for cytokine analysis (IL-1β, IL-6, IL-8, TNFα). Treatments were arranged as a 5 × 2 factorial (diet x immune challenge) and analyzed with time of sampling as a repeated measure. The sow′s milk had n6:n3 ratios of 7.5:1, 4.5:1, 1.5:1 and 3:1 for the 10:1, 5:1, 1:1 and 5:1 fish diets respectively. For all parameters except IL-6, an effect of challenge, time and the challenge by time interaction were observed ($P < 0.05$), indicating the LPS elicited an immune response. Piglets from the 1:1 dietary treatment group had the highest body temperature ($P = 0.0004$). The diet by immune challenge interaction tended to be different for body temperature ($P = 0.12$) and IL-8 ($P = 0.18$). Piglets from the 1:1 and 5:1 fish groups had a greater IL-8 response to the immune challenge relative to piglets from the other diets. A greater febrile response to the LPS challenge was seen in piglets originating from sows consuming the 1:1 diet. Weanling pigs produced from sows consuming different n6:n3 FA ratios respond differently to a LPS induced immune response. This implies that the fatty acid profile of a sow′s diet may affect the response of her offspring to immune challenges that occur regularly at the time of weaning.

Key words: cytokine, omega-3, swine

847 Impact of dietary fat on milk composition, milk output and apparent digestibility is fat source dependent in lactating sows. D. S. Rosero*[1], E. van Heughten[1], J. Odle[1], V. Fellner[1], and R. D. Boyd[2], *[1]Department of Animal Sciences, North Carolina State University, Raleigh, [2]Hanor Company Inc., Franklin, KY.*

This study investigated the impact of 2 sources of supplemental fat on milk composition and apparent digestibility of fat during lactation. In Exp. 1, milk samples were collected from 30 sows (PIC Camborough) during d 4, 11 and 18 of lactation. Sows were assigned to a control diet without added fat and 2 diets supplemented with 6% fat consisting of either animal-vegetable blend (AV; 14.5% FFA, IV = 89) or choice white grease (CWG; 3.7% FFA, IV = 62). In Exp. 2, fecal samples were collected from 56 sows to calculate fat digestibility using TiO2 as a marker. Sows were assigned to a 2 × 3 factorial arrangement and a control diet without fat. Factors included: 1) fat sources (AV and CWG); and 2) fat level (2, 4 and 6%). For the 2 studies, sows were balanced for parity 1, and 3 to 5 (P3+). Diets were corn-soybean meal based with 8% DDGS and 6% wheat middlings, and contained 3.56 g standardized ileal digestible Lys/Mcal ME. Piglet growth rate in Exp. 1 was improved by CWG ($P < 0.05$; 197.7 g/d) but not with AV (169.9) compared with the control (169.2). Calculated milk production (2.5 x ADG + 80 x initial BW + 7) was greater for CWG ($P < 0.01$; 646 $g \bullet pig^{-1} \bullet d^{-1}$) than AV and the control diet (564 and 569, respectively). CWG, but not AV increased ($P < 0.05$; 7.35%) fat content in the milk (6.30, 6.70, for control and AV, respectively). Milk protein decreased ($P < 0.001$; 5.2, 4.6 and 4.7% for d 4, 11 and 18, respectively), lactose increased ($P < 0.001$; 5.2, 5.7 and 5.7) and Ca increased ($P = 0.003$; 0.16, 0.17 and 0.18) during lactation. Linoleic (C18:2) and linolenic acid (C18:3) were higher ($P < 0.001$) in milk fat from sows fed AV (23.2 and 1.4%, respectively) than CWG (18.9 and 1.0) and control (17.4 and 0.7). Milk fat IV was higher ($P < 0.001$) for AV (75.9) than CWG (72.5) and control (68.4). Apparent digestibility of fat increased with each increment (Linear, $P < 0.001$), but CWG was more digestible than A-V (Fat x Level, $P < 0.05$). In conclusion, digestibility of fat was improved with increasing levels of fat and was higher for CWG than AV, affecting positively composition and production of milk, consequently improving piglet growth rate.

Key words: sow, fat, milk

Production, Management and the Environment: Environmental Quality

848 Ammonia emissions from a commercial feedyard measured using passive samplers and a box model. N. A. Cole*[1], R. W. Todd[1], D. B. Parker[2], M. Rhoades[3], and A. Mason[1], *[1]USDA-ARS, Conservation & Production Research Lab, Bushland, TX, [2]USDA-ARS-MARC, Clay Center, NE, [3]West Texas A&M University, Canyon.*

Animal feeding operations are a major source of ammonia gas emitted to the atmosphere. Ammonia emissions can potentially affect air quality and sensitive ecosystems, but because measuring ammonia emissions from open lots is difficult, few studies have investigated ammonia losses from beef cattle feedyards. Our objective was to measure ammonia emissions from a 77-ha, 45,000-head beef cattle feedyard on the southern High Plains. Profiles of ammonia concentration, wind speed, and air temperature were measured downwind (5 d in summer) or in the middle (6 d in winter) of the feedyard. In addition, ammonia concentrations were measured at 7 locations downwind (summer) or in the middle (winter) of the yard using a combination of active and passive samplers. Ammonia flux was estimated using a box model. Samples of rations, fresh feces, pen manure, and compost were obtained for chemical analyses (DM, N, P). Dietary N concentrations averaged 2.14% during the summer and 2.51% during the winter. Hourly ammonia-N flux averaged 365 ± 49 mg/m^2 in the summer and 212 ± 92 mg/m^2 in the winter. Ammonia-N emission rates averaged 5,453 ± 741 kg/d in the summer (63% of N intake), and 3,170 ± 1,383 kg/d in the winter (31% of N intake), with an annualized average of 4,311 ± 1,612 kg/d (47% of N intake). Nitrogen volatilization losses, estimated from the changes in the N:P ratio of rations and dry pen manure, averaged 42% of N intake. The annualized emission factor was 15.4 ± 2.2 kg ammonia-N/head fed. Nitrogen volatilization losses from the compost windrows, estimated from changes in the N:P ratio of manure and compost, averaged 3.4 ± 1.4% of N placed in the windrows during winter and 13.3 ± 1.3% in summer. Ammonia-N volatilization losses from the retention pond, estimated using an empirical model, averaged 5.5 ± 4.4 kg/ha daily or 166 ± 130 kg/d. These values agree well with emissions estimated using an inverse dispersion model and demonstrate that the pen surface is the primary source of feedlot ammonia, and that emissions are greater in summer than winter. This research was partially supported by grant #TS2006–06009 from the USDA-CSREES.

Key words: beef cattle, ammonia, emissions

849 Effects of feeding birdsfoot-trefoil on greenhouse gases emissions from fresh and land incorporated dairy manure. Q. Wang*, R. Franco, Y. Zhao, Y. Pan, and F. Mitloehner, *University of California, Davis, Davis.*

Birdsfoot-trefoil, a legume containing condensed tannins, may improve N utilization efficiency and shift urine N to fecal N. This shift might affect greenhouse gas (GHG) emissions because fecal N versus urine N is less utilizable by denitrifying bacteria that produce GHG from manure. The present study investigated the effects of feeding birdsfoot-trefoil (BFT) on GHG emissions from fresh and land-incorporated dairy manure (LIDM). Eighteen lactating Holstein cows were randomly assigned to 1 of the 2 treatments: 1) alfalfa (ALF) based ration, and 2) BFT based ration. Within each treatment, 9 cows were randomly assigned to 3 groups (n = 3). Animals were fed the respective diets for 8 d and then moved into an environmentally controlled chamber for 12 h to allow for GHG monitoring. Blood samples for blood urea N analysis were collected before cows left the chamber. The fresh manure was left on the chamber floor for 12 h to measure GHG emissions with INNOVA 1412 gas analyzer. CO_2, CH_4 and N_2O emissions from the fresh manure of ALF and BFT fed cows are 5.29, 0.05, 0.01 ppm and 4.71, 0.10, 0.01 ppm, respectively. Then the aged manure was collected and incorporated into loamy soil to simulate LIDM. Flux chambers were connected to the INNOVA 1412 gas analyzer to measure GHG emissions from LIDM over a 10 d period. CO_2 and N_2O emissions from the LIDM of ALF and BFT fed cows are 102.70, 0.02 ppm and 78.15, 0.02 ppm, respectively. Blood urea N was lower in BFT versus ALF fed animals ($P < 0.05$). However, GHG emissions were similar between BFT and ALF fed cow manure. In the present study, BFT did not affect the GHG emissions from dairy manure. A follow-up study, will investigate the effects of BFT on N partitioning over time.

Key words: alfalfa, birdsfoot-trefoil, greenhouse gas

850 Prediction of individual methane emission by dairy cattle from milk mid-infrared spectra. A. Vanlierde*[1], C. Delfosse[1], F. Dehareng[1], E. Froidmont[2], H. Soyeurt[3,4], M. Hammida[1], J.-M. Romnee[1], and P. Dardenne[1], *[1]Walloon Agricultural Research Centre, Quality Department, Gembloux, Belgium, [2]Walloon Agricultural Research Centre, Department of Production and Sectors, Gembloux, Belgium, [3]University of Liège Gembloux Agro-Bio Tech, Animal Science Unit, Gembloux, Belgium, [4]National Fund for Scientific Research, Brussels, Belgium.*

Methane produced by ruminants contributes to global warming. Different experiments were conducted on Holstein cows to predict their individual methane production. The objective was to obtain a wide variation in methane emissions to establish predictive equations. For this, the cows were selected according to their stage and number of lactation and received different types of diet known to promote or not the production of methane during rumen fermentation. Individual methane emission was daily measured by a sulfur hexafluoride tracer during a week. In the same time, a sample of individual milk was analyzed by mid-infrared (MIR) spectrometry. The daily methane data was then related to an average of daily milk spectrum (AMS). Five different calculations were used because of the delay between the generation of fermentation products and their use in the milk components. The methane emissions were compared with AMS at d 0, 0.5, 1, 1.5, and 2. Equations were built with partial last square regression and showed that the AMS at d 1.5 gave the best prediction of the CH4 emission with a cross validation R^2 of 0.79. It indicates that there is more than one day between the formation of feed fermentation products and their "detection" in milk analysis. There is also a close correlation between fatty acid (FA) profile and methane emission at d 1.5. However, results show that applying directly the developed methane equation gives a better prediction than the use of correlation between FA and methane. These observations suggest the feasibility of methane prediction from MIR spectra. Now, it is important to increase the reliability of prediction and make a validation to predict continuously the individual methane emissions in small and large scales and also to identify low methane emitted cows.

Key words: methane, mid–infrared, milk

851 Effects of biotechnology on greenhouse gases, volatile organic compounds, and ammonia from feedlot cattle. K. R. Stack-

house*, M. S. Calvo, S. E. Place, T. L. Armitage, Y. Pan, Y. Zhao, and F. M. Mitloehner, *University of California, Davis.*

The feedlot industry uses biotechnologies such as antibiotics, growth implants, and β_2-adrenergic agonists to improve health and growth performance of cattle. These biotechnologies alter microbes in the rumen and nitrogen retention in the animal, which may lead to changes in greenhouse gas (GHG), volatile organic compound (VOC), and ammonia emissions from feedlots. The present study investigated GHG, VOC, and ammonia emissions from 160 Black Angus steers. Steers were blocked by weight and randomly assigned to 16 pens of 10 animals each. Treatments applied were: (1) control (no biotechnology application, CON), (2) Rumensin and Tylosin (RUM), (3) Rumensin, Tylosin, and Revalor-s (IMP), and (4) Rumensin, Tylosin, Revalor-s, and Zilpaterol hydrochloride (BAA). Cattle were on feed for an average of 107 d and performance and blood urea nitrogen (BUN) measured. Gaseous emissions were measured during the last 10 d of the feeding period when animals were housed in 4 totally enclosed identical cattle pen enclosures. The control was compared with 3 treatment groups using a 4 by 4 Latin square design (n = 4). Nitrous oxide, carbon dioxide, methanol, ethanol, and ammonia were measured using the INNOVA 1412 gas analyzer. Methane was measured using the TEI 55C analyzer. Emissions are reported in g^{-1} kg HCW^{-1} d. All measurements were analyzed using Proc Mixed in SAS. Treatment with IMP and BAA increased ($P < 0.05$) ADG and final BW. BAA vs. other treatments increased HCW ($P < 0.05$) and reduced ($P < 0.05$) methane and ammonia emissions as well as BUN. The present study will provide a better understanding of how antibiotics and growth enhancement application used in feedlot cattle affect atmospheric emissions of GHGs, VOCs, and ammonia per kg of product.

Key words: beef cattle, greenhouse gas, ammonia

852 Life cycle assessment of greenhouse gas emissions from beef production systems in California. K. R. Stackhouse*[1], C. A. Rotz[2], and F. M. Mitloehner[1], *[1]University of California, Davis, [2]USDA/Agriculture Research Service, Pasture Systems and Watershed Management Research Unit, University Park, PA.*

Beef production is recognized as a source of GHG emissions; however, little information exists on the net emission from production systems. A life cycle assessment (LCA) was conducted using the Integrated Farm System Model (IFSM) to estimate whole-farm GHG emissions from representative beef production systems in California. The IFSM is a process-level farm model that simulates crop production, feed production and use, animal production, and the return of manure nutrients back to the land to predict the environmental impacts and economics of production systems. The carbon footprint of major production systems was determined as the net exchange of all GHG in carbon dioxide (CO_2) equivalent units per unit of HCW produced. The calculation of net emissions determined the relative contributions of the cow-calf, stocker, and feedlot phases of beef production to the overall carbon footprint of the consumable product. The IFSM was used to predict all important sources and sinks of methane, nitrous oxide, and carbon dioxide from primary and secondary sources. Primary emission sources included enteric fermentation, manure, cropland used in feed production, and fuel combustion in handling manure and producing feed. Secondary emissions were those produced during the production of resources used on the farm, which included fuel, electricity, machinery, fertilizer, pesticides, and replacement animals. Simulated beef production systems included the cow-calf, stocker, and feedlot phases for the traditional British beef breeds and calf ranch and feedlot phases for Holstein steers. An evaluation of differing production management strategies produced carbon footprint values ranging from 5.4 to 19.3 kg CO_2 equivalent / kg of HCW produced. Within the British beef production cycle, the cow-calf phase was responsible for approximately 70% of total GHG emissions with 12% from feedlot sources. Holstein steers that entered the beef production system as a by-product of milk production had the lowest carbon footprint because the emissions associated with their mothers were attributed to milk rather than meat production.

Key words: beef cattle, carbon footprint, greenhouse gas

853 Effects of calf hutch flooring on air quality and exposure. M. S. Calvo*[1], M. van der Voort[2], J. A. McGarvey[3], J. P. Reynolds[4], T. L. Armitage[1], E. A. M. Bokkers[2], and F. M. Mitloehner[1], *[1]Department of Animal Science, University of California, Davis, [2]Department of Animal Sciences, Wageningen University, Wageningen, the Netherlands, [3]USDA Agriculture Research Service, Plant Mycotoxin Research Unit, Albany, CA, [4]Veterinary Medicine Teaching & Research Center, University of California, Davis, Tulare.*

Respiratory diseases in calves are associated with the exposure of airborne pathogenic microorganisms and dust, as well as gases that can compromise the defense mechanisms of the respiratory system. Calf bedding provided inside hutches may increase the exposure of animals to ammonia, particulate matter (PM), and airborne microorganisms. The present study quantified concentrations of these compounds in calf hutches supplied with or without bedding. In addition, the effectiveness of applying sodium bisulfate (SBS), an acidifier, to calf bedding was tested to determine if a reduction in pH could reduce these air compounds. Holstein bull calves (n = 63) were randomly assigned to one of the 3 treatments at 1 d of age: 1) elevated hutches with conventional wooden slatted floor and no bedding (CON); 2) hutches with dirt floor and bedding provided (BED); 3) hutches with dirt floor and bedding treated with SBS provided (SBED). Ammonia, PM, and airborne bacteria were measured weekly inside calf hutches using an INNOVA 1412 multigas analyzer, cyclone and open-face cassette samplers, and Andersen biological cascade impactors, respectively. Ammonia differed ($P < 0.001$) across treatments, with CON yielding the highest (0.57 ± 0.03 ppm) and SBED the lowest (0.35 ± 0.03 ppm) concentrations. The PM concentrations were similar ($P > 0.05$) across treatments for both fine (diameter ≤ 2.5 μm) and coarse (diameter ≥ 2.5 μm) particles. Bacteria concentrations were lower ($P < 0.0001$) for CON ($1{,}163 \pm 696$ cfu/m^3) versus BED ($3{,}233 \pm 731$ cfu/m^3) and SBED ($2{,}705 \pm 919$ cfu/m^3), which were similar ($P > 0.05$). Overall, the results improve the understanding of air quality inside wooden hutches housing newborn calves. The management of calf bedding may affect certain air compounds known to affect respiratory health.

Key words: ammonia, bacteria, calf

854 Feeding saponins to reduce air emissions from steers. W. Li* and W. J. Powers, *Department of Animal Science, Michigan State University, East Lansing.*

A series of experiments (Exp) were conducted to quantify the effect of saponin extracts from *Quillaja saponaria* (Q), *Yucca schidigera* (Y) and *Camellia sinensis* (T) on gaseous emissions from steers. Exp1 compared a control diet (C; corn-corn silage basal diet), Y (0.64% DM) and Q (1.5% DM); 4 replicates per treatment. Exp 2 evaluated the effect of T (0.25% DM) and C. Products inclusion level was established to provide the same saponin concentration across Exp. Exp 3

compared C, Q (1.5% DM), Y (1.5% DM) and T (0.5% DM). Holstein steers (n = 12) at initial BW of 353 ± 18 kg (Exp1), 428 ± 23 kg (Exp 2) and 391 ± 22kg (Exp 3) were housed, individually, in environmental rooms for 22 d per study. Emissions of methane (CH_4), ammonia (NH_3), hydrogen sulfide (H_2S), nitrous oxide (N_2O) and non-methane total hydrocarbons (NMTHC) were monitored in room exhaust air. In Exp 1, DMI (7.54 ± 0.09 kg) and ADG (1.11 ± 0.18 kg) were not affected by diet ($P > 0.05$). DMI was improved in Exp 2 by adding TS into the diet (8.94 kg in TS vs. 8.53 in C; $P < 0.05$), while ADG was not affected by diet. During Exp 3 steers fed the T diet ate less (6.43 kg/d) and gained less (0.39 kg/d) compared with the average DMI (8.69 kg) and ADG (1.37 kg) of the other 3 treatments ($P < 0.05$). Across Exp, saponin inclusion did not alter daily CH_4 emission when reported on a DMI basis (13.25, 11.08 and 12.65 g/kg DMI, for Exp 1, 2, and 3, respectively). Daily NH_3 emission was not affected by diet in Exp 1 (17.3 g/d). Feeding TS in Exp 2 reduced NH_3 emissions per unit of N intake (131.0 vs. 186.5 mg/g N intake; $P < 0.05$). Feeding Q in Exp 3 resulted in greater mass of NH_3 emitted compared with the other treatments (18.9 g/d vs. 14.1 g/d; $P > 0.05$). Average daily H_2S, N_2O and NMTHC emissions were 84.59, 2963.78 and 1436.06 mg, respectively, across all Exp with no diet effects observed within Exp ($P > 0.05$). Results show that 0.5% DM of T in diet reduced CH_4 emission at the expense of DMI and ADG. Inclusion of Q and Y demonstrated the potential to increase NH_3 emissions.

Key words: *Quillaja saponaria*, *Yucca schidigera*, *Camellia sinensis*

855 Supplementary concentrate type affects nitrogen balance in early lactation dairy cows offered grazed pasture. S. J. Whelan*, K. M. Pierce, J. J. Callan, B. Flynn, and F. J. Mulligan, *School of Agriculture, Food Science and Veterinary Medicine, University College Dublin, Belfield, Dublin 4, Ireland.*

Nitrogen (N) losses from dairy cow production systems have a detrimental effect on the environment. Dietary strategies to improve N balance in dairy cows may help alleviate these effects. This experiment evaluates the effect of supplementary concentrate type on N balance in early lactation dairy cows offered a perennial ryegrass pasture. A total of 48 were assigned to 1 of 4 dietary treatments in a randomized block design (n = 12). All cows received a perennial ryegrass pasture plus one of the following concentrate types: Hi-Pro (18% CP), Lo-Pro (14% CP), Lo-Pro Meth (14% CP, with added methionine) and Lo-Pro Maize (14% CP). Hi-Pro, Lo-Pro and Lo-Pro Meth contained rolled barley, whereas Lo-Pro Maize contained stone ground maize as the starch source. Concentrates were isoenergetic (1.11UFL/kg DM) and offered at 3kg twice daily. On wk 6 and 10 post calving N balance studies were conducted. Data was analyzed using Proc Mixed of the SAS institute. Feed N intake was greater ($P < 0.05$) for Hi-Pro vs. all other dietary treatments; Lo-Pro, Lo-Pro Meth and Lo-Pro Maize were not different ($P > 0.05$). Feces N recovery (N out ÷ N in) was lower ($P < 0.05$) for Hi-Pro vs. all other dietary treatments; Lo-Pro, Lo-Pro Meth and Lo-Pro Maize were not different ($P > 0.05$). Recovery of N in the urine was greater ($P < 0.05$) for Hi-Pro vs. Lo-Pro Meth and Lo-Pro Maize; Lo-Pro was not different ($P > 0.05$) from other treatments. Recovery of N in the milk was lower ($P < 0.05$) for Hi-Pro vs. Lo-Pro Meth and Lo-Pro Maize; Lo-Pro was lower ($P < 0.05$) vs. Lo-Pro Maize but not Hi-Pro or Lo-Pro Meth. Improved milk N recovery with Lo-Pro Maize and Lo-Pro Meth allows for a reduction in urinary N portion.

Table 1. Effect of supplementary concentrate type on nitrogen (N) balance

Concentrate Type	Hi-Pro	Lo-Pro	Lo-Pro Meth	Lo-Pro Maize	SEM
Feed N ($kg \cdot d^{-1}$)	0.511^{a}	0.462^{b}	0.456^{b}	0.445^{b}	0.0160
Proportion of ingested N excreted in feces, urine and milk					
Feces	0.376^{b}	0.440^{a}	0.432^{a}	0.418^{a}	0.0107
Urine	0.374^{a}	0.320^{ab}	0.277^{b}	0.291^{b}	0.0257
Milk	0.250^{c}	0.251^{bc}	0.284^{ab}	0.298^{a}	0.0166

856 Development of a user-friendly online system to quantitatively measure metabolic gas fluxes from ruminants. P. Zimmerman*[1], S. Zimmerman[1], S. Utsumi[2], and D. Beede[2], *[1]C-Lock Inc., Rapid City, SD, [2]Michigan State University, East Lansing.*

We developed and tested a new internet-interfaced system to quantitatively measure methane, carbon dioxide and other metabolic emissions from individual animals and to track changes in emissions over time. Methane is not only a powerful greenhouse gas, but emissions also represent significant losses of energy and feed efficiency. Changes in fluxes are also sensitive indicators of changes in diet, behavior, and health. The system has been tested in robotic dairies, tie-stalls, and pastures. The system includes the following elements: a headstall unit to restrict and control atmospheric mixing; a radio-frequency identification (RFID) of each animal; a feed or water dispenser so that the animal voluntarily keeps its head in the correct position to obtain quantitative, representative metabolic gas measurements; sensors to detect animal head position; a gas intake manifold with mixing and flow conditioning elements; a fan unit to capture expired and eructated gases along with a sensor to measure air flow-rate through the headstall manifold; a tracer gas sampling system; a controlled tracer gas release to calibrate the capture rate of metabolic gases and to corroborate air flow rates; sensors, including methane, carbon dioxide, water vapor, molecular hydrogen, hydrogen sulfide, and air flow rate; a data acquisition and control system; a remote data link to transmit data to a specified secure location; and, a centralized computer for automated data processing. To date, millions of data points have been collected from many individual animals. For beef cattle on pasture, methane emissions averaged 200 g/animal per d; for a herd of lactating dairy cows average methane emissions were 408 g/animal per d over a 7-mo period. A 2-fold difference in methane emissions between high and low emitting animals also was measured. Changes in feeding patterns and health conditions also were reflected in metabolic gas fluxes. For example, carbon dioxide emissions increased significantly with little change in methane fluxes when dairy cattle were moved to a fresh pasture. The system is user-friendly and relatively easy to maintain and operate.

Key words: methane, ruminant, measurement

857 Effects of oxygenated drinking water on gaseous emissions, rumen microorganisms and milk production in dairy cattle. C. J. Neumeier*[1], J. A. McGarvey[2], Y. Pan[1], Y. Zhao[1], and F. M. Mit-

loehner[1], [1]*Department of Animal Science, University of California-Davis, Davis,* [2]*United States Department of Agriculture, Agricultural Research Service, Albany, CA.*

Dairy cattle production systems contribute to greenhouse gas emissions, predominantly in the form of methane. Enteric methane is formed by methanogenic archaea (methanogens) that require anaerobic conditions to thrive. A water treatment system (Oxion, Hugoton, KS) increases the dissolved oxygen concentration in drinking water. We hypothesize that by increasing the dissolved oxygen concentration of the rumen through intake of oxygenated drinking water, one creates an environment detrimental to the proliferation of methanogens. The present study evaluated carbonaceous and nitrogenous gaseous emissions in addition to performance parameters. A total of 36 lactating Holstein dairy cows were used in a completely randomized design. The cows were assigned to 2 treatment groups: control water and oxygenated drinking water (CON and OXI, respectively). The cows were housed in 3 groups of 6 animals within each treatment (n = 3). Dry matter intake (DMI), water intake and milk yield were recorded daily. Rumen fluid samples were extracted via an orogastric tube and quantified for bacteria, methanogens and protozoa. Cows were placed inside an environmental chamber to measure carbon dioxide, nitrous oxide and ammonia using the Innova 1412 photoacoustic field gas monitor (California Analytical Instruments, Orange, CA) and methane using the TEI 55C direct methane analyzer (Thermo Environmental Instruments, Franklin, MA). All measurements were analyzed using Proc Mixed in SAS. The DMI, water intake and energy corrected milk yield were similar but OXI vs. CON treated cattle showed decreased milk yield ($P < 0.01$). Bacteria, methanogen and protozoa quantification yielded no significant differences. While methane production was similar ammonia emission increased for OXI vs. CON treated cattle ($P < 0.05$). Introduction of excess oxygen to the rumen via drinking water did not produce the anticipated effect on methane reduction but instead seems to cause changes in nitrogen cycling of the animal which deserves further investigation.

Key words: greenhouse gas, methane, water treatment

Ruminant Nutrition: Beef: Supplements

858 Effects of residual feed intake classification and breed type on carcass characteristics, tenderness and value in feedlot heifers. J. W. Behrens*[1], R. K. Miller[1], J. C. Bailey[1], J. T. Walter[1], A. N. Hafla[1], E. D. Mendes[1], D. S. Hale[1], T. Machado[2], L. O. Tedeschi[1], and G. E. Carstens[1], *[1]Texas A&M University, College Station, [2]Texas A&M University at Kingsville, Kingsville.*

The objectives were to determine the effects of residual feed intake (RFI) classification and breed type on carcass characteristics, tenderness and value in Angus (AN; n = 184), Brangus (BN; n = 266), Simbrah (SI; n = 196), and Braford (BO; n = 241) heifers obtained over 3 years from Deseret Ranch. Each year, heifers were received in 2 groups; fall and spring (initial age and BW of heifers = 337 vs. 501 ± 86 d and 278 vs. 324 ± 48 kg, respectively). Heifers were fed a high-grain diet (ME = 3.08 Mcal/kg DM), and feed intakes measured using a GrowSafe system for 70 d. Thereafter, heifers were fed in group pens and harvested at an average backfat thickness of 1.2 cm in 2 groups. Within trial, RFI was computed as the difference between actual and expected DMI from the linear regression of DMI on mid-test BW $^{0.75}$ and ADG. Heifers were categorized into low, medium and high RFI groups based on ± 0.50 SD from the mean. Heifers were commercially harvested and USDA Yield and Quality grade characteristics obtained. Warner-Bratzler (WBSF) and Slice shear force (SSF) values were measured on top loin steaks after 1, 7 and 14 d of vacuum-packaged storage at 2°C. The model included fixed effects of RFI, breed, age and interaction terms and random effects of trial and pen. Low and medium RFI carcasses had lower adjusted fat thickness (AFT; $P = 0.001$) and lower yield grades (YG; $P = 0.004$) than high RFI heifers (1.19 and 1.22 vs. 1.30 ± 0.51 cm, respectively; 2.77 and 2.77 vs. 2.89 ± 0.10, respectively). RFI classification did not affect ($P > 0.05$) HCW, KPH, REA, marbling score or WBSF and SSF values. BO heifers had lighter HCW, smaller REA and higher ($P < 0.001$) YG than SI heifers, with AN and BN heifers being intermediate. Marbling scores were lower ($P < 0.001$) and d 1 WBSF was higher ($P < 0.001$) for BO and SI heifers compared with AN and BN heifers. In this study, breed type had more influence on carcass-quality traits than RFI classification. Heifers with low and medium RFI had lower YG than high RFI heifers, but RFI classification did not affect carcass marbling or tenderness traits.

Key words: breed, residual feed intake, tenderness

859 Effects of residual feed intake classification and breed type on feed efficiency and feeding behavior traits in heifers fed a high-grain diet. J. C. Bailey*, G. E. Carstens, J. T. Walter, A. N. Hafla, E. D. Mendes, L. O. Tedeschi, and R. K. Miller, *Texas A&M University, College Station.*

Objectives of this study were to evaluate the effects of residual feed intake (RFI) classification and breed on feed efficiency and feeding behavior traits in heifers fed a high-grain diet (ME = 3.08 Mcal/kg DM). Six trials were conducted over 3 yr with Angus (AN; n = 185), Braford (BO; n = 241), Brangus (BN; n = 266) and Simbrah (SI; n = 196) heifers from the Deseret Ranch; with 2 trials conducted each yr during the fall (n = 415) and spring (n = 473). Initial ages were 337 vs. 501 ± 86 d for heifers used in the fall (younger) and spring (older) trials. DMI and feeding behavior traits were measured for 70 d using a GrowSafe system. Within trial, RFI was calculated as the difference between actual and expected DMI from linear regression of DMI on ADG and mid-test BW$^{0.75}$, and heifers classified into RFI groups based on ± 0.5 SD from the mean. Low RFI heifers consumed less ($P < 0.0001$) DM (8.91 vs. 10.97 ± 1.04 kg/d), had lower ($P < 0.0001$) F:G (6.71 vs. 8.47 ± 1.81), but had similar initial BW (315.2 ± 48 kg) and ADG (1.38 ± 0.34 kg/d) compared with high-RFI heifers. Younger heifers with low RFI consumed 18.2% less DM than high-RFI heifers, whereas, older low-RFI heifers consumed 19.3% less DM than high-RFI heifers (RFI x age interaction; $P < 0.05$). Bunk visit frequency (48.5 vs. 63.4 ± 4.2 events/d) and duration (55.1 vs. 64.0 ± 3.6 min/d) were less ($P < 0.0001$) in heifers with low compared with high RFI. Likewise, low-RFI heifers had lower ($P < 0.005$) meal frequency (6.27 vs. 6.81 ± 0.80 events/d) and duration (139 vs. 157 ± 8.6 min/d) than high-RFI heifers. BO heifers had lower ($P < 0.001$) ADG (1.26, 1.45, 1.40 and 1.41 ± 0.07 kg/d) and DMI (9.50, 10.36, 10.13, 9.83 ± 0.43 kg/d) than AN, BN and SI heifers, respectively. F:G tended ($P < 0.13$) to be lower in SI compared with BO heifers (7.37 vs. 7.78), with AN and BN heifers (7.65 and 7.62 ± 1.8) being intermediate. In contrast, breed type did not affect RFI. Independent of breed, heifers with low RFI consumed 18.8% less DM and had fewer feeding behavioral activities than high-RFI heifers.

Key words: feeding behavior, residual feed intake

860 Analysis of the ruminant microbial ecosystem in cattle divergent for residual feed intake using next generation sequencing technology. C. A. Carberry*[1,2], D. A. Kenny[1], C. J. Creevey[1], and S. M. Waters[1], *[1]Animal and Bioscience Department, Animal and Grassland Research and Innovation Centre, Teagasc, Grange, Dunsany, Co. Meath, Ireland, [2]School of Agriculture, Food Science and Veterinary Medicine, University College Dublin, Belfield, Dublin 4, Ireland.*

As feed is one of the main input costs in beef production, improvements in feed efficiency are paramount to maintaining and increasing the profitability of the enterprise. There is now general agreement that the concept of residual feed intake (RFI) is the most appropriate approach for the selection of more energetically efficient beef cattle without compromising animal growth or performance. However, although suggested as having a putative role in determining the feed efficiency phenotype of an animal, little is known on whether the rumen microbial ecosystem differs between animals of different RFI phenotypes. The objective of this research was to analyze the rumen microflora in cattle divergent for RFI using 454 pyrosequencing technology. Beef heifers (n = 86), initially selected on the basis of sire EBV for RFI, were ranked on the basis of phenotypic RFI over an 80 d finishing period while consuming a 30:70 maize silage to concentrate diet. The 7 highest (HRFI; least efficient) and 7 lowest (LRFI; most efficient) ranking animals were selected for use in this study. Both groups had similar mean bodyweight and ADG at ranking but HRFI had, on average, 20% higher DMI. Following ranking on RFI all animals were offered a grass silage diet ad libitum for a 6 week period. Ruminal fluid was sampled at the end of this period using a specialized trans-esophageal sampling device. Total microbial DNA was isolated from the ruminal fluid and amplified using fusion primers including adaptors for titanium 454 sequencing and a region complementary to the bacterial 16s V3 region. Analysis of this data revealed many shared bacterial populations between the HRFI and LRFI animals, predominantly from the bacteriodales and clostridia clades. Most interestingly however, a significantly higher number of bacterial clusters were found to be unique to the rumen of HRFI compared with the LRFI animals. This suggests a correlation between microbial diversity and

feed efficiency in cattle and a mechanism through which differences in inherent ruminal microbial populations may influence feed efficiency in cattle.

Key words: residual feed intake, rumen bacteria, pyrosequencing

861 Association of myostatin with weight and carcass traits in crossbred heifers adjusted to different endpoints. S. K. Pruitt*, K. M. Rolfe, B. L. Nuttelman, W. A. Griffin, G. E. Erickson, and M. L. Spangler, *University of Nebraska-Lincoln, Lincoln.*

The objective of this study was to investigate a potential association of an inactive myostatin allele with performance and carcass traits using 60 individually fed crossbred heifers (395 ± 27 kg) genotyped for 0, 1, or 2 copies of the inactive myostatin (IM) (n = 25 homozygous active myostatin, n = 26 heterozygous, and n = 9 homozygous inactive myostatin, respectively). Heifers were fed a finishing diet that consisted of 52% corn, 35% wet distillers grains plus solubles, 8% hay and 5% supplement (DM basis) for 114 d. Ultrasound measurements of rump fat (RUMF), rib fat (RIBF), LM area (uLMA) and intramuscular fat percentage (IMF) were taken at 28 d intervals over the feeding period. Initial BW, final BW, DMI, and ADG decreased linearly ($P < 0.01$) with increasing copy number of IM. A linear decrease ($P = 0.03$) in G:F was observed as IM copy number increased. A quadratic decrease ($P < 0.05$) was observed in HCW, LM area, and marbling as well as a linear decrease ($P < 0.01$) in fat depth as IM copy number increased. Final ultrasonically measured traits, BW, and age were adjusted to common endpoints (BW, age, RIBF and RUMF) using regression estimates pooled within genotype class. Common endpoints were determined by the average value of each endpoint across genotype classes. Best-fit endpoints were determined by comparing Akaike′s Information Criterion (AIC) values. Given the strong correlation between RIBF and RUMF, BW was chosen for adjustment and was ranked second for AIC. Adjusted data were 4.69, 4.06, 2.35% for IMF (adjusted for RIBF); 90.3, 94.8, 110.3 cm^2 for uLMA (adjusted for age); 506, 485, and 453 kg for BW (adjusted for age); and 1.04, 0.74, and 0.46 cm for RIBF (adjusted to BW) for homozygous active, heterozygous, and homozygous inactive animals, respectively. Age adjusted to a constant BW and RIBF suggests that homozygous IM animals would require 26 and 84 more d on feed as compared with homozygous active animals to reach the same harvest BW and RIBF, respectively. This suggests that inactive myostatin genotype decreases IMF, G:F, RIBF, and final BW, while increasing uLMA.

Key words: beef cattle, compositional endpoints, myostatin

862 Effects of varying forage levels in diets containing whole flint corn and benefits of steam flaking the corn on finishing Nellore bulls performance, carcass characteristics, and liver abscesses. R. S. Marques[1], J. R. R. Dórea[1], A. M. Pedroso[2], A. W. Bispo[1], C. G. Martins[1], W. F. Angolini[1], and F. A. P. Santos*[1], *[1]University of Sao Paulo, Piracicaba, SP, Brazil, [2]Embrapa Cattle Southeast, Sao Carlos SP, Brazil.*

The objective of the present study was to determine the effect of increasing levels of sugar cane bagasse (0, 3, and 6% of diet DM) in finishing diets with whole flint corn and also the effect of processing flint corn as steam flaking on performance and carcass characteristics of zebu cattle. One hundred sixteen Nellore bulls with an initial BW of 373 kg were used in an 86-d randomized complete block design feeding trial. Animals were blocked by initial BW and randomly assigned to 20 pens. Animals were raised on pasture and were adapted to the feedlot diets during a 21 d pre-trial period. The final diets contained sugar cane bagasse, corn, urea, vegetable protein (soybean meal) and mineral and vitamin mix with monensin. Treatments were: 1) W0 (whole corn and no forage); 2) WC3 (whole corn with 3% sugar cane bagasse); 3) WC6 (whole corn with 6% sugar cane bagasse); 4) WC6-Opt (W6 with extra nitrogen from slow release urea - Optigen); 5) SFC6 (steam flaked corn with 6% sugar cane bagasse). Data were analyzed using the Mixed procedure of SAS (1999) with pen as experimental unit. There was a quadratic effect ($P < 0.01$) of forage level in whole corn diets for DMI, ADG, final BW and hot carcass weight. Compared with whole corn, steam flaked corn decreased DMI ($P < 0.01$), had no effect on ADG ($P > 0.05$) and improved feed efficiency (ADG/DMI) ($P < 0.01$). Carcass characteristics were not affected by treatments ($P > 0.05$) and liver abscesses incidence was negligible.

863 Evaluation of two complete-feed receiving diets. C. J. Schneider*[1], B. L. Nuttelman[1], K. M. Rolfe[1], W. A. Griffin[1], T. J. Klopfenstein[1], R. A. Stock[2], and G. E. Erickson[1], *[1]University of Nebraska, Lincoln, [2]Cargill Inc., Blair, NE.*

A receiving trial was conducted to evaluate effects of feeding 2 complete feeds on cattle performance during the receiving period. Crossbred steers (n = 965; BW = 261.1 ± 6.6 kg) were received over a 2-d period and processed within 12 h of arrival. Steers were blocked by arrival date and randomly allocated to pens within block based on processing order, resulting in 15 and 20 cattle per pen for blocks 1 and 2, respectively, with 17 pens per treatment. Treatments included a control receiving diet (35% alfalfa hay, 30% Sweet Bran, 30% dry rolled corn, and 5% supplement; 16.7% CP, 36.7% NDF) and 2 complete feeds. RAMP (21.9% CP, 41.9% NDF) and Test Starter (23.4% CP, 43.5% NDF) contained a high level of Sweet Bran with a minimal amount of forage and were formulated and provided by Cargill Inc., Blair, NE. All diets contained 27.6 mg/kg monensin and 26.5 mg/kg thiamine. Cattle were offered ad libitum access to treatment diets for 30 or 31 d and limit-fed a common diet (47.5% Sweet Bran, 23.75% grass hay, 23.75 alfalfa hay, and 5% supplement) for 5 d before collecting final BW to minimize variation in gut fill. Initial and final BW were averages of 2-d weights and a 4% pencil shrink was subtracted from final BW. Feeding RAMP increased ($P = 0.03$; Table 1) ADG when compared with the control diet. ADG for cattle fed Test Starter was not different ($P > 0.11$) from cattle fed control or RAMP. Final BW, DMI, and G:F were similar ($P > 0.14$) for all treatments. Starting cattle on RAMP is a viable alternative to starting cattle on a mixture of grain and forage.

Table 1. Performance of cattle fed RAMP, Test Starter, or a control receiving diet

Item	Treatment			SEM	*P*-value
	Control	RAMP	Test Starter		
Initial BW, kg	261	262	260	6.6	0.89
Final BW, kg	293	298	293	9.2	0.36
DMI, kg/d	6.08	6.30	6.26	0.11	0.14
ADG, kg	0.90[a]	1.03[b]	0.93[ab]	0.10	0.08
G:F	0.148	0.165	0.148	0.019	0.18

[a,b]Means within a row without a common superscript are different, $P = 0.03$.

864 Rumen degradable protein supply effects microbial efficiency in continuous culture and growth in crossbred Angus steers. M. A. Brooks*[1,2], R. M. Harvey[2], N. F. Johnson[2], and M. S. Kerley[2], *[1]North Carolina State University, Raleigh, [2]University of Missouri - Columbia, Columbia.*

We hypothesized microbial efficiency (MOEFF) and output from ruminal fermentation was optimized when rumen degradable peptide (RDPep) supply was balanced with RDPep requirement. This study was conducted to measure response of varying RDPep supply on ruminal fermentation characteristics and steer growth. A continuous culture experiment was conducted with diets formulated to achieve a predicted RDPep balance (RDPep supplied/ RDPep required) of 0.0, 0.6, 1.8, and 3.0% DM and rumen degradable nitrogen (RDN) balance (RDN supplied/ RDN required) of −0.2% DM. Two additional treatments had RDPep balances of 0.0 and 1.8% CP with −0.5% DM RDN balance. Twenty-four single-flow fermenters (n = 6) were inoculated with rumen fluid and maintained anaerobically at 39°C with a 0.06 h^{-1} dilution rate. Inadequate RDN (0.5% RDN balance) decreased OM digestion and microbial N and increased rumen undegradable nitrogen ($P < 0.01$). MOEFF was also poorer in diets with 0.5% RDN balance and greatest when RDPep balance ranged from 0 to 1.83% ($P < 0.01$). Total VFA concentration decreased with 0.5% RDN balance while increasing levels of lactate were measured ($P < 0.01$). The second experiment was a growth study consisting of 4 diets varying in RDPep balance (0.52, −0.13, −0.48, −0.97% DM) but with similar and adequate RDN (~−0.7% RDN balance). Forty-nine yearling crossbred Angus steers (initial body weight ~370 kg) were assigned by weight into treatment groups (n = 12, with an extra steer in −0.48% RDPep treatment). Each treatment was divided into 3 pens with 4 animals per pen. Animals were maintained on treatment for 70 d with pen intake recorded daily and animal weights taken on d 0, 1, 21, 42, 70 and 71. Final body weight (average of d 70 and 71 weight) decreased linearly with decreasing RDPep ($P = 0.05$). DM intake did not differ among treatments (7.77 to 8.51 kg/hd/d; $P = 0.09$). Gain efficiency (G:F) and ADG displayed a quadratic effect with greater values occurring at the higher RDPep level ($P = 0.02$). We concluded balancing RDPep supply to requirement improved fermentation efficiency and output, which in turn improved animal performance.

Key words: peptide, microbial efficiency, nitrogen

865 Beef cow performance when fed cotton co-product and distillers grain blocks as a hay replacement. G. M. Hill*, A. N. Franklin, G. W. Stone, and B. G. Mullinix, *University of Georgia, Tifton.*

A compressed 250 kg block product (CPM; A. G. Daniel Co., Eastman, GA) containing cotton gin trash (59%), distillers dried grains with solubles (15%), wheat middlings (15%), a molasses product and minerals (11%), was evaluated as a hay replacement for cows. Angus cows (n = 52; AOD 5.9 ± 1.9 yr; initial BW 667.0 ± 53.67 kg) were ranked by BW, and randomly assigned to replicated treatments for 42 d. Initial and final cow BW were 2-d full BW means. A preliminary steer CPM intake study suggested that cow CPM intake might be elevated. Therefore, treatments included: free-choice Hay (HFC); 1 CPM block/6 cows every 4 d with hay (CPM4D); 1 CPM block/6 cows every 3 d with hay (CPM3D); free-choice CPM (CPMFC). The DM, CP, ADF, NDF (% DM basis) of 10 bermudagrass hay samples, were: 89.3, 9.4, 37.3, 77.2; and of 10 CPM samples, were: 89.8, 17.5, 37.3, 46.3. The TDN, K, S (% DM basis), NE_m and NE_g (Mcal/kg), in CPM were: 49.4, 2.4, 0.46, 0.91, 0.36. Cows were fed CPM blocks in bunks in a barn, and round-baled hay was weighed and fed free-choice in hay rings. The experiment began October 26, 2010, and the days pregnant at palpation on July 13, 2010, respectively, by treatment, were: 78.8, 87.7, 81.9, 78.7, SE 3.47, ($P < 0.27$). Cow ADG was greatest for CPM4D and CPMFC, intermediate for CPM3D, and lowest for HFC cows (Table; $P < 0.01$). Cow BCS tended to increase ($P < 0.97$) for cows fed CPM compared with HFC. The DMI of CPM in CPMFC was increased compared with CPM4D and CPM3D, and total DMI of CPMFC was 65% greater than HFC. All CPM treatments substantially increased cow BW gain in late pregnancy, while cost of providing CPM free-choice may be prohibitive.

Table 1

Item	HFC	CPM4D	CPM3D	CPMFC	SE
No. Cows	14	12	12	14	
Initial BW, kg	674.4	659.9	662.1	669.8	14.87
42-d ADG, kg[d]	0.39[c]	1.15[a]	0.88[b]	0.99[ab]	0.08
Initial BCS (Scale 1 to 9) [d]	5.34	5.51	5.39	5.46	0.18
42-d BCS Change[d]	0.13	0.18	0.26	0.24	0.22
CPM DMI, kg/d	0.00	9.52	11.91	22.31	
Hay DMI, kg/d	13.49	8.29	7.22	0.00	
Total DMI, kg/d	13.49	17.80	19.13	22.31

866 Effects of energy supplementation frequency and forage quality on performance of replacement beef heifers. P. Moriel*[2], R. F. Cooke[1], F. N. T. Cooke[1], E. Alves[2], L. Custodio[2], D. W. Bohnert[1], J. M. B. Vendramini[2], and J. D. Arthington[2], *[1]Oregon State University–Eastern Oregon Agricultural Research Center, Burns, [2]University of Florida–Range Cattle Research and Education Center, Ona.*

The objective was to compare performance of beef heifers consuming forages differing in nutritional quality and offered an energy-based supplement at 2 different frequencies. Forty-eight Brahman × British heifers were ranked by initial BW and age and allocated to 16 drylot pens (3 heifers/pen). Pens were assigned to receive, in a 2 × 2 factorial arrangement, 1 of the 4 treatment combinations: 1) low-quality hay (LF; *Cynodon nlemfuensis* with 8% CP, DM basis) and daily supplementation (S7), 2) LF and supplementation 3x/wk (S3), 3) medium-quality hay (MF; *C. dactylon* with 12% CP, DM basis) and S7, 4) MF

and S3. Forages were offered ad libitum to heifers throughout the experimental period (d 0 to 120). Supplement was based on soybean hulls and offered at a daily rate of 2.2 (1.0% of initial BW) and 1.1 (0.5% of initial BW) kg of DM to LF and MF heifers, respectively. Heifer shrunk BW was obtained at the beginning and end of the experiment. Forage and total DMI were evaluated daily, from d 20 to 26, d 33 to 39, and d 46 to 52. Mean BW gain was greater ($P < 0.01$) for LF vs. MF heifers (0.34 vs. 0.19 kg/d, respectively). Mean forage DMI was greater ($P < 0.01$) for MF vs. LF heifers (3.6 vs. 2.6 kg/heifer/d) and for S7 vs. S3 heifers (3.4 vs. 2.9 kg/heifer/d). Total DMI was greater ($P < 0.01$) for S7 vs. S3 heifers (5.1 vs. 4.6 kg/heifer/d). Mean NE_m and NE_g intakes were greater ($P < 0.01$) for LF vs. MF heifers (5.8 vs. 5.0 and 3.0 vs. 2.4 Mcal/heifer/d of NE_m and NE_g, respectively) and for S7 vs. S3 heifers (5.6 vs. 5.2 and 2.8 vs. 2.6 Mcal/heifer/d of NE_m and NE_g, respectively). Mean CP intake was greater ($P < 0.01$) for MF vs. LF heifers (0.64 vs. 0.59 kg/heifer/d) and for S7 vs. S3 heifers (0.64 vs. 0.59 kg/heifer/d). In summary, independently of forage quality, replacement beef heifers offered an energy-based supplement daily had greater nutrient intake but similar BW gain compared with cohorts supplemented 3x/wk. Heifers consuming low-quality forage and supplemented at 1.0% of BW had similar DMI, reduced CP intake, but greater energy intake and BW gain compared with cohorts consuming medium-quality forage and supplemented at 0.5% of BW.

Key words: supplementation, forage, heifer

867 Impact of rumen digesta inoculation on feeding value of urea-molasses treated wheat straw. M. Sarwar*, M. A. Shahzad, and M. Nisa, *Institute of Animal Nutrition and Feed Technology, University of Agriculture, Faisalabad, Punjab, Pakistan.*

The study was conducted to examine the chemical composition of urea–molasses treated wheat straw (WS) fermented with bovine rumen digesta (RD). The WS treated with varying levels of urea (0, 2 and 4%) and molasses (0, 2 and 4%) was ensiled with 10% rumen digesta (on dry matter basis) for different fermentation periods (20, 30 and 40 d). Data were analyzed using completely randomized design with 3 × 3 × 3 factorial arrangement of levels of urea, molasses and fermentation time, respectively and means were separated by Duncan's multiple range test using general linear model procedure of SPSS. Fermented wheat straw (FWS), after each fermentation period, was analyzed for pH, dry matter (DM), crude protein (CP), true protein (TP), ammonia nitrogen (NH3-N), neutral detergent fiber (NDF) and acid detergent fiber (ADF). High ($P < 0.05$) pH, CP, TP, NH3-N and low ($P < 0.05$) NDF contents were observed with increase in urea level, however, DM and ADF contents remained unaltered. Increasing molasses level resulted in high ($P < 0.05$) CP, TP, NH3-N and low ($P < 0.05$) NDF contents were observed while increase in fermentation period resulted in high ($P < 0.05$) CP, TP and minimum ($P < 0.05$) NH3-N, NDF contents. The pH, DM, CP, TP, NH3-N and NDF contents were affected ($P < 0.05$) by urea × molasses interaction and urea × fermentation days interaction. The CP, TP, NH3-N and NDF contents were also influenced ($P < 0.05$) by molasses × fermentation days interaction, however, pH, DM and ADF contents remained unaffected. Similar trend was observed in urea × molasses × fermentation days interaction. The 4% urea and 4% molasses after 40 d of fermentation period indicated increase in CP and TP contents and decrease in NDF content of WS. The study found 4% urea and 4% molasses for 40 d fermentation period best combination for large-scale production of FWS to evaluate its feeding value for ruminants.

Key words: nutritive value, rumen digesta, wheat straw

868 Effect of sorghum grain supplementation on glucose metabolism 1: Bovine. M. Aguerre*[1], M. Carriquiry[2], A. L. Astessiano[2], C. Cajarville[3], and J. L. Repetto[1], *[1]Departamento de Bovinos, Facultad de Veterinaria, Universidad de la República, Montevideo, Uruguay, [2]Departamento de Producción Animal y Pasturas, Facultad de Agronomía, Universidad de la República, Montevideo, Uruguay, [3]Departamento de Nutrición Animal, Facultad de Veterinaria, Universidad de la República, Montevideo, Uruguay.*

Crossbred heifers (n = 12; 210 ± 42.5 kg), blocked by BW, were used to evaluate the effects of sorghum grain supplementation (0 vs. 1.5% BW, S0 vs. S1.5, respectively) on plasma glucose, insulin and glucagon concentrations and on hepatic expression of genes related to glucose metabolism. Heifers were fed ad libitum fresh *Lotus corniculatus* (31.8% DM, 12.4% CP, 41.8% NDF). At the end of treatments (31 d) blood samples were taken every 2 h from 0 to 6 h post-supplementation, to determine glucose by colorimetry and insulin and glucagon by RIA. Liver biopsies were collected to quantify abundance of pyruvate carboxylase (PC), phosphoenolpyruvate carboxykinase (PCK-1) and insulin receptor (IR) mRNA by SYBR-Green real-time PCR, using hypoxanthine-guanidine phosphoribosyltransferase as endogenous control. Data were analyzed with MIXED procedure (SAS). Glucose were greater in S1.5 than S0 (74.3 vs. 63.5 ± 9.88 mg/dL, $P = 0.004$) and the shape of the curves was similar over the 6 h post-supplementation. Insulin levels tended to be greater in S1.5 than S0 (12.2 vs. 8.33 ± 2.18 μUI/mL; $P = 0.084$), recording a 2-fold increase from 0 to 2h only in S1.5 group (6.96 vs. 15.0 ± 2.70 μUI/mL, $P = 0.050$). Glucagon concentrations were lower in S1.5 than S0 (58.0 vs. 66.9 ± 4.52, $P = 0.020$) but while glucagon decreased 4 h post-supplementation (77.6 vs. 56.9 ± 5.75 μUI/mL, $P = 0.002$) in the S0 group, glucagon increased in the first 2 h post-supplementation in the S1.5 (48.5 vs. 61.8 ± 6.16 μUI/mL, $P = 0.057$). The insulin/glucagon ratio tended to be greater in S1.5 than S0 (0.20 vs. 0.13 ± 0.03, $P = 0.084$). Plasma insulin and glucagon were correlated with each other (r = 0.60, $P = 0.032$) and insulin was correlated with OM intake (r = 0.67, $P = 0.013$). The IR and PC mRNA did not differ between treatments (14.2 vs. 12.1 ± 1.86 and 60.2 vs. 40.7 ± 7.44, for S0 and S1.5 respectively), but PCK-1 mRNA was lower in S.15 than S0 (15.4 vs. 28.4 ± 3.42, $P = 0.020$). The expression of PCK-1 was negatively correlated with plasma insulin (r = –0.86, $P = 0.001$). Sorghum supplementation increased glucose and insulin concentration and reduced glucagon and PCK-1 mRNA abundance. This would indicate an increased anabolism in supplemented animals.

Key words: hormones, liver mRNA, grazing cattle

869 Response to increased sorghum grain supplementation levels: Comparison between cattle and sheep. M. Aguerre*[1], C. Cajarville[2], and J. L. Repetto[1], *[1]Departamento de Bovinos, Facultad de Veterinaria, Universidad de la República, Montevideo, Uruguay, [2]Departamento de Nutrición Animal, Facultad de Veterinaria, Universidad de la República, Montevideo, Uruguay.*

Crossbreed heifers (n = 24; 210 ± 42.5 kg), and lambs (n = 24; 45.6 ± 6.2 kg), blocked by BW, were used to compare the response on OM intake and digestibility (OMI and OMD), ruminal pH, N–NH_3 and microbial protein synthesis (MPS) to increased levels of sorghum grain supplementation (0, 0.5, 1.0 and 1.5% BW). Heifers and lambs were fed ad libitum fresh *Lotus corniculatus* (31.8% DM, 12.4% CP, 41.8% NDF). After 21d, OMI was measured for 10d and all feces and urine were collected for 5d. The MPS was calculated from total urinary excretion of purine derivatives. Ruminal liquor samples were taken every 1h from 0 to 6h post-supplementation, to determine pH

and N-NH_3. Mean data values and linear regressions were compared among species with the MIXED procedure (SAS). Mean OMD did not differ between cattle and sheep (71.4 vs. 72.1 ± 0.98%; $P = 0.635$), but mean ruminal pH, N-NH_3 and MPSE were different between species (6.38 vs. 6.05 ± 0.10, $P = 0.056$; 21.8 vs. 37.1 ± 1.58 mg/dL, $P < 0.01$; 16.5 vs. 11.8 ± 0.68 g of MN/kg of DOMI, $P < 0.01$, for cattle and sheep respectively). No differences were detected on OMD, ruminal pH, N-NH_3 and MPS efficiency (MPSE) response to the increasing sorghum supplementation levels between species (Table 1). In contrast, OMI and MPS were differently affected in both species ($P < 0.01$). While in heifers OMI and MPS increased as sorghum supplementation increased, in lambs OMI and MPS decreased as the level of supplementation increased. Increasing levels of supplementation affected differently cattle and sheep. Therefore, both species should not be used as similar models for ruminant nutrition research.

Table 1

Item	Cattle	Sheep	P^1
OMI (% $BW^{0.75}$)	Y = 10.3 + 2.00X; $R^2 = 0.50$, $P < 0.01$	Y = 9.65 – 1.32X; $R^2 = 0.23$, $P = 0.02$	<0.01
OMD (%)	Y = 68.7 + 3.64X; $R^2 = 0.21$, $P = 0.03$	Y = 68.7 + 4.65X; $R^2 = 0.23$, $P = 0.02$	0.674
Ruminal pH	Y = 6.73 – 0.46X; $R^2 = 0.22$, $P < 0.01$	Y = 6.46 – 0.55X; $R^2 = 0.34$, $P < 0.01$	0.477

870 A ring test of in vitro neutral detergent fiber digestibility: analytical variability and sample ranking. M. B. Hall* and D. R. Mertens, *U. S. Dairy Forage Research Center, USDA-ARS, Madison, WI.*

In vitro neutral detergent fiber (NDF) digestibility (NDFD) is an empirical measurement used to describe fermentability of NDF by rumen microbes. Variability is inherent in assays and affects the precision that can be expected for replicated samples. The study objective was to evaluate variability within and among laboratories (labs) of 30 h NDFD values measured in repeated runs. Subsamples of alfalfa (n = 4), corn silage (n = 5), and grass (n = 5) ground to pass a 6 mm screen were sent to 10 labs on 3 occasions over a 12 mo period. Subsamples passed a test for homogeneity. Labs ground the samples and ran 2 or 3 replicates of each sample within run, and analyzed 2 or 3 sets of samples. A lab that did not provide in-run replicate data was not included in evaluation of standard deviations (SD). Mean and SD for sample within run within lab were calculated. Factors in the statistical model were lab, run within lab, sample, and lab by sample. All factors affected NDFD ($P < 0.01$ for all) and within-run SD of NDFD ($P < 0.03$ for all). The lab by sample effect suggests against a simple lab bias. Labs used 2 NDFD procedures: 8 labs used a procedure similar to Goering and Van Soest, 1970 (GVS) using fermentation vessels or filter bags, and 2 used a procedure with pre-incubated inoculum (PInc.). Among GVS labs, NDFD results were affected by all factors ($P < 0.01$ for all; mean 48.5%, range 42.7 to 53.2%, SED = 0.98). For PInc., mean NDFD was 30.7% (range: 31.8 to 29.6%); GVS and PInc. NDFD differed ($P < 0.01$, SED = 0.95). Mean within-run SD were 1.9% (range: 0.5 to 3.4%) for GVS and 2.6% (range 1.8 to 3.4%) for PInc. The mean SD for all labs of 2.0% indicates that 95% of results for a sample within a run would be within a range of 8.0% NDFD. Labs ranked samples similarly within forage type. Spearman correlation coefficients between average rankings and those reported by labs were 0.83 for alfalfa, 0.70 for corn silage, and 0.90 for grass ($P < 0.01$ for all). It is concluded that across all labs an average precision of 8% NDFD can be expected for a single analysis within run. Differences between GVS and PInc. suggest using results in contexts appropriate to each procedure.

Key words: NDF, digestibility

871 Effects of supplemental Smartamine or MetaSmart in moderate-energy close-up diets on peripartal liver tissue composition and blood metabolites. J. S. Osorio*, P. Ji, J. K. Drackley, and J. J. Loor, *University of Illinois, Urbana.*

Twenty-eight multiparous Holstein cows were fed a control diet (ME, n = 11; 1.49 Mcal/kg DM prepartum and 1.67 Mcal/kg DM postpartum), ME plus MetaSmart (MS, n = 9; Adisseo France S.A.S.), or ME plus Smartamine (SA, n = 8; Adisseo France S.A.S.). All cows received a common diet (1.30 Mcal/kg DM) during the far-off period [-50 to −21 d in milk (DIM)]. Treatments started at −21 DIM and continued through 30 DIM. MetaSmart (0.19% of DM prepartum and 0.18% of DM postpartum) and SA (0.07% of DM prepartum and postpartum) were top-dressed on the ME diet. Blood samples were collected at −17, −10, 7, 14, and 21 DIM. Whole blood phagocytosis (Phagotest) was assessed at d −10, 3, and 21. Total liver lipid and triglyceride content (Biopsy) were evaluated at −10, 7, and 21 DIM. Data were analyzed using the MIXED procedure of SAS with the preplanned contrasts ME vs. SA+MS and SA vs. MS. Treatments did not affect total lipid and triglyceride concentrations in liver. In contrast to MS and SA, however, the slope of total lipid % between d 7 and 21 for ME was significant ($P = 0.04$) suggesting that supplemental Met prevented increased lipid accumulation during that time-frame. Serum NEFA (0.511 mEq/L) and glucose (54.0 mg/dL) concentrations did not differ due to treatment. Although slopes of NEFA concentrations were negative for all treatments between 7 and 21 DIM, only those of Met-supplemented cows were significant ($P = 0.02$) suggesting that Met decreased NEFA more rapidly after calving. Analysis of whole blood phagocytosis after calving revealed an increase (treatment × time $P = 0.005$) due to MS and SA vs. ME. Energy corrected milk (ECM) was greater ($P = 0.05$) for MS+SA vs. ME (46.4 vs. 42.8 kg/d). Close-up and postpartal DMI did not differ. Enhanced ECM due to MS or SA was associated with a faster decline in serum NEFA and lack of additional lipid accumulation between 7 and 21 DIM. The overall effect of Met supplementation to peripartal cows is encouraging but more conclusive evidence would require increased sample size.

Key words: transition cows, methionine, immune function

872 Effect of supplemental Smartamine or MetaSmart in moderate-energy close-up diets on peripartal cow performance. J. S. Osorio*, P. Ji, J. K. Drackley, and J. J. Loor, *University of Illinois, Urbana.*

Peripartal cows are in negative methionine (M) balance due to increased requirements of tissues for methylated compounds and M for milk protein production. Decreased dry matter intake (DMI) during early lactation aggravates the supply of nutrients such as M. Therefore, supplementation of rumen-protected M during the peripartal period may improve yield of milk and protein. Forty multiparous Holstein cows were fed a controlled-energy diet (1.30 Mcal/kg DM) during the far-off dry period [-50 to −21 d in milk (DIM)]. During the close-up dry period (−21 to 0 DIM), cows were fed a higher-energy diet (1.49 Mcal/kg DM) without (ME, n = 14) or with 0.07% of DM Smartamine (SA, Adisseo France S.A.S.; n = 15) or 0.19% of DM MetaSmart (MS, Adisseo France S.A.S.; n = 11). Supplementation of M continued until 30 DIM. Body weight (BW), body condition score (BCS), DMI, milk yield and composition, and energy corrected milk (ECM) were recorded during the study. Data were analyzed using the MIXED procedure of SAS with the preplanned contrasts ME vs. SA+MS and SA vs. MS. No differences in close-up DMI were observed (average of 12 kg/d). When comparing SA+MS vs. ME, DMI through the first 30 DIM was significantly greater ($P = 0.04$) for M-supplemented cows (14.7 kg/d vs. 12.2 kg/d). Milk yield with SA+MS (41.5 kg/d) was greater ($P = 0.06$) compared with ME (37.7 kg/d). Although milk protein % during wk 2 through 4 did not differ between SA+MS vs. ME, supplemental MS resulted in greater ($P = 0.05$) milk fat % than SA (4.68% vs. 4.09%). There was a tendency ($P = 0.11$) for greater ECM when feeding SA+MS vs. ME (46.0 kg/d vs. 42.8 kg/d). The positive response to MS or SA on milk production seemed to be associated with greater (treatment × time $P = 0.02$) ECM/DMI, at least during the first wk postpartum. The present results suggest that increasing the availability of Methionine in moderate-energy close-up feeding systems may improve lactational performance and DMI.

Key words: methionine, transition cow, amino acid

873 Determining the effectiveness of proteases on production variables in lactating Holstein cows. E. Sucu*[1,2], A. Nayeri[1], M. V. Sanz-Fernandez[1], N. C. Upah[1], S. C. Pearce[1], and L. H. Baumgard[1], *[1]Department of Animal Science, Iowa State University, Ames, [2]Department of Animal Science, Uludag University, Bursa, Turkey.*

Ninety-six multiparous lactating Holstein dairy cows (2.7 ± 1.6 parity, 153.8 ± 103.7 DIM, 40.3 ± 5.9 kg milk/d, 624 ± 62 kg BW) housed in a free stall barn were blocked by parity, days in milk and previous milk production and randomly assigned to a control TMR or a TMR containing a blend of supplemental protease enzymes (4 g/cow/d; Rumagentin, Feed Sources LLC, Alta Loma CA). The TMR consisted primarily of corn silage, alfalfa hay, dried distiller grains, and concentrate and did not contain supplemental by-pass protein. Cows were housed 24 to a pen (4 pens total) and thus pen was the experimental unit in a crossover design with 2 21 d experimental periods. Two pens received the supplement during period 1 and the other 2 pens received the control. Pens then switched treatments during period 2 and there was a 7 d washout between periods. The 7 d immediately before period 1 were used as a covariate in the statistical analysis (repeated measures in the Proc Mixed procedure of SAS). Daily pen milk yield and DMI were recorded and milk composition from all cows was determined on d 15, 17, 19 and 21 of each period. All data was condensed into weekly means. There was no treatment effect on milk yield (37.6 kg/d), but supplemental enzyme-fed cows had less DMI (0.93 kg/d; $P < 0.05$) compared with controls and therefore tended ($P = 0.08$) to have improved (13%) feed efficiency (solids corrected milk/DMI). Protease treatment had no effect on milk fat (3.53%) or milk protein (3.24%), but tended ($P = 0.08$) to increase milk lactose (4.73 vs. 4.76%). Feeding supplemental enzymes tended ($P = 0.10$) to decrease milk urea nitrogen levels (15.1 vs. 14.6 mg/dl) but had no effect on milk SCC. In conclusion, supplementing a proprietary blend of protease enzymes improves feed efficiency and may enhance feed nitrogen utilization in lactating dairy cows.

Key words: protease enzymes, feed efficiency, feed intake

874 Effects of supplementing a mixture of plant extracts to lactating dairy cows on milk and methane production. G. F. Schroeder*[1], D. Bravo[2], M. Jerred[1], and B. D. Strang[1], *[1]Cargill Animal Nutrition, Innovation Campus, Elk River, MN, [2]Pancosma S.A., Geneva, Switzerland.*

The goal of this study was to determine the effects of supplementing a mixture of plant extracts containing cinnamaldehyde, eugenol, and garlic on milk production and composition, DMI, and methane production in lactating dairy cows. Six rumen-cannulated Holstein cows (100 DIM) were used in a replicated 3 × 3 Latin square design with 3 25-d periods (18 d for adaptation and 7 for data collection). Cows were housed in individual tie-stalls and received the same diet (46.2% DM, 18.7% CP, 31.1% NDF, 3.8% EE, and 37.3% NFC) twice daily. Treatments consisted in the supplementation (top-dress) with: none (Control), 300 mg/d monensin (MON), or 300 mg/d of plant extract mixture (PEM). Milk production and DMI was measured daily and milk composition was determined twice during the last 7 d of each period. Methane production was measured using the SF6 tracer technique during the last 4 d of each period. Although milk yield and DMI were not statistically different among treatments, supplementing with PEM increased feed efficiency respect to the Control. Both monensin and PEM reduced milk fat concentration and PEM also reduced milk protein concentration, but total production of those components was not affected. Methane production was not significantly affected but either additive. Total VFA concentration (99.4 mM), acetate to propionate ratio (2.43) and rumen pH (5.9) were similar among treatments. Results of this study indicate that the mixture of plant extracts evaluated can be a valid alternative to increase feed efficiency in lactating dairy cows. Further research is needed to better determine the optimal dose of PEM.

Table 1

	Control	Mon	PEM	SEM	*P* =
Milk, kg/d	37.7	39.0	39.6	2.34	0.57
DMI, kg/d	25.0	24.9	24.1	0.79	0.37
Efficiency, kg/kg	1.50[b]	1.57[ab]	1.65 [a]	0.06	0.06
Milk fat, %	3.29[a]	3.09[b]	3.06 [b]	0.15	0.10
Milk fat, kg/d	1.22	1.19	1.21	0.10	0.84
Milk protein, %	2.89[a]	2.86 [a]	2.72 [b]	0.07	0.08
Milk protein, kg/d	1.07	1.11	1.07	0.06	0.58
CH4, g/d	411.1	408.6	382.3	25.6	0.72
CH4, g/kg milk	10.9	10.5	9.67	0.42	0.95

875 Effects of feeding hay and baleage on growth and rumen parameters in prepubertal Holstein heifers. T. S. Dennis*, J. E. Tower, and T. D. Nennich, *Purdue University, West Lafayette, IN.*

Although ensiled forages are commonly included in diets of growing dairy heifers, little research has been conducted to evaluate feeding baleage as a primary forage source. The objectives of this study were to evaluate the effects of feeding dry hay or baleage to prepubertal dairy heifers on growth, feed efficiency, and rumen parameters. Thirty-six Holstein heifers (age = 189.3 ± 9.3 d; BW = 185.3 ± 1.3 kg) were randomly assigned to 1 of 12 pens and fed a 60:40 forage-to-concentrate diet (DM basis) containing either dry hay (H) or baleage (B) as the only forage source. Heifers were weighed biweekly and hip and withers heights, heart girth circumference (HGC), and body condition scores (BCS) were measured monthly. Blood was collected monthly for plasma urea nitrogen and glucose analysis. Rumen fluid was collected from 24 heifers at the start and end of the study via esophageal tube and measured for pH and rumen ammonia. Rumen fluid was also collected to evaluate in vitro cellulose digestion and total gas production. Data were analyzed as repeated measures using the MIXED procedure of SAS with pen as the experimental unit. Heifers fed H were 6.7 kg heavier ($P < 0.01$) than heifers fed B at the conclusion of the study. Heifers fed H also gained 0.63 kg/d compared with 0.56 kg/d for heifers fed B ($P < 0.05$). Overall, heifers fed H consumed 0.30 kg more DM/d than B ($P < 0.01$), resulting in a tendency ($P < 0.10$) for a 5.4% improvement in gain to feed ratios for H compared with B. Hip and withers heights, HGC, and BCS were similar ($P > 0.10$) between treatments. Plasma urea nitrogen and glucose concentrations were similar between treatments ($P > 0.10$), as was rumen pH ($P > 0.10$). Cellulose disappearance tended to be 9.4% greater for H compared with B ($P < 0.10$); however, total in vitro gas production was similar between treatments. Rumen ammonia concentrations were similar between H and B ($P > 0.10$), though ammonia concentrations declined significantly from 16.3 to 13.2 mg/dL over the entire study ($P < 0.05$). In summary, feeding baleage decreased BW gain, but did not alter skeletal growth or rumen parameters in prepubertal dairy heifers.

Key words: dairy heifer, baleage, hay

876 Direct enumeration of metabolically active yeast from the rumens of lactating dairy cows. H. C. Bruns*[1], A. R. Hippen[1], M. Witt[2], and J. M. Tricarico[2], *[1]South Dakota State University, Brookings, [2]Alltech, Lexington, KY.*

Four ruminally cannulated Holstein cows were used to evaluate the potential for direct enumeration of metabolically active yeast from rumens. A diet devoid of supplemental yeast was individually fed once daily at 1000 h. The diet contained 54% forage and 46% concentrate mix. All ruminal liquid samples were collected directly under the fibrous mat, strained into a thermos and immediately transported to the laboratory. Samples were diluted in 1% Bacto Peptone NaCl solution ranging from 10^{-2} to 10^{-4} and plated onto Dichloran Rose Bengal Chloramphenicol agar. Yeast colonies were enumerated after incubation at 30°C for 48 h. A logarithmic transformation (base 10) was applied on yeast counts before analysis. No yeast was recovered from cows consuming the basal diet or 24 h after dosing with supplemental yeast. A second study examined if the daily pattern of yeast recovery varied between cows. All cows were dosed intraruminally with 25×10^9 colony forming units (cfu) of *Saccharomyces cerevisiae* (Yea-Sacc, Alltech Inc., Nicholasville, KY). Samples were collected at 0.5, 1, 2, 4, and 6 h after dosing on 3 d. Average yeast counts were: 5.17, 5.33, 4.85, 4.34, and 3.95 log cfu per g of rumen contents at 0.5, 1, 2, 4, and 6 h after dosing, respectively. The fractional rate of yeast disappearance from the rumen was similar between cows and averaged 0.052^{h-1}. Lastly, a 4 × 4 Latin square was used to examine the quantitative recovery 1 h after dosing with increasing supplemental yeast (0, 5, 25, or 125×10^9 cfu). Polynomial contrasts were used to examine linear and nonlinear trends. Yeast counts from rumen fluid increased linearly with dose (0, 4.22, 4.89, and 5.83 log cfu per g, respectively; $P < 0.01$). Percent yeast recovery also increased linearly with dose (43.5, 47.0, and 52.6%, for 5, 25, and 125×10^9 cfu, respectively). Assuming metabolically active yeast can be enumerated with this culture-based procedure, we estimate that 25×10^9 cfu of supplemental metabolically active yeast will no longer be detectable 12 h after dosing (limit of detection 10^2 cfu/g) and will no longer be present in rumen fluid of lactating dairy cows 19 h after dosing.

Key words: dairy cows, enumeration, yeast

877 Evaluation of dry hay and baleage for transitioning post-weaned, prepubertal dairy heifers to higher forage diets. L. N. Pereira*, T. S. Dennis, J. E. Tower, and T. D. Nennich, *Purdue University, West Lafayette, IN.*

Dairy heifers often undergo rapid diet changes as they transition from the post-weaned phase to the growing period. Feeding strategies during this transition period have the potential to improve feed efficiency and growth performance of dairy heifers. The objective of this study was to determine whether feeding dry or ensiled forages during the transition period improved heifer performance and rumen parameters. Sixty Holstein heifers (141.9 ± 1.2 kg BW) were randomly assigned to 1 of 12 pens for a 4 wk period. Individual pens were assigned to 1 of 2 treatments: dry hay (H) or baleage (B) and were fed diets containing 40% hay or baleage (on a DM basis). Heifers were weighed weekly, with hip heights, withers heights, heart girth circumference (HGC), and body condition score (BCS) measured every 2 wk. Blood was collected every 2 wk and analyzed for plasma urea nitrogen (PUN), amylase and glucose. During this same collection time, rumen fluid was collected via an esophageal tube from 2 heifers in each pen and analyzed for pH, rumen ammonia, and cellulose disappearance. Data were analyzed as repeated measures using the Proc Mixed procedure of SAS. Average daily gain (ADG) was greater ($P = 0.04$) for H than for B (1.01 and 0.89 kg/d, respectively), though final BW were similar ($P = 0.26$). Heifers fed H had gain to feed ratios of 0.071 compared with 0.037 kg/kg for B during wk 4 ($P = 0.03$), and DMI were similar between treatments over the study ($P = 0.44$). Hip height, withers height, HGC, and BCS were similar between treatments. Rumen pH was greater for B than for H at wk 2 (6.85 and 6.58, respectively; $P = 0.01$), and rumen ammonia ($P < 0.01$) levels were greater for H at wk 2 with levels of 15.5 and 11.7 mg/dl for H and B, respectively. Cellulose disappearance was similar between treatments ($P = 0.25$). Plasma urea nitrogen was greater for H at both wk 2 and 4 ($P = 0.02$). Blood amylase was similar between treatments, but there was a trend ($P < 0.10$) for blood glucose levels to be greater in H at wk 2. Diets containing dry hay resulted in greater ADG than heifers fed ensiled forage during the transition period.

Key words: baleage, dairy heifer, transition

878 Rumen fill score was not related to feed intake response of fresh cows to a less filling diet. K. A. Kurtz, S. E. Stocks*, and M. S. Allen, *Michigan State University, East Lansing.*

Feed intake is likely controlled by mechanisms unrelated to ruminal distention for cows immediately postpartum but as lactation advances, control of feed intake likely begins to be dominated by ruminal distention. We conducted a switchback design experiment with 31 multiparous lactating cows to determine if a visual scoring system for rumen distention (1 = least, 5 = greatest) can be used to predict response in DMI to a less filling diet. We hypothesized that DMI of cows with a higher rumen fill score when fed a higher fill diet (HF, 34% NDF) would respond more positively to a lower fill diet (LF, 29% NDF). Cows ranged between 7 and 27 d postpartum and were blocked by calving date. Treatment diets were fed for 3 d each in the sequence HF-LF-HF for a total of 9 d per block. Cows were fed once and milked twice per day. Feed intake, milk yield, and milk components were measured daily throughout the experiment. Rumen fill score was observed 30 min before feeding (RS-BF) and 8 h later (RS-AF) each day in period 1. Rumen fill score ranged from 1.3 to 3.5 for RS-BF and from 1.6 to 4.3 for RS-AF among cows, was 0.73 units higher after feeding compared with before feeding, and RS-BF and RS-AF were highly correlated ($r = 0.8$, $P < 0.0001$). Response to diet was determined as the response for LF (period 2) minus the mean response for HF (periods 1 and 3) and ranged from −4.9 to 5.1 kg/d for DMI and −11.6 to 9.1 kg/d for milk yield. Response was greatest for the first day following the diet switch with 1.8 kg higher DMI for LF compared with HF, which decreased to 0.20 kg/d for d 2 and −0.30 kg/d for d 3. DMI response was not related to RS-BF, RS-AF, or their difference ($P > 0.71$) nor was it related to days in milk, BW, BCS, or DMI in period 1 ($P > 0.33$). Although response to diet was highly variable among cows for both DMI and milk yield, responses for DMI and milk yield were not related ($P = 0.73$). Further research is needed to assess the usefulness of rumen fill score for moving cows from the fresh diet to the high-group diet.

Key words: intake control, grouping cows, transition period

879 Effects of abomasal dosing of ferrous or ferric sulfate on short-term iron status of lactating dairy cows. O. N. Genther*, J. A. Zyskowski, T. H. Herdt, and D. K. Beede, *Michigan State University, East Lansing.*

The majority of Fe in feeds is in the ferric (Fe^{3+}) state, and poorly absorbed by ruminants. We hypothesize that the majority of Fe naturally occurring in drinking water is in the more bioavailable ferrous (Fe^{2+}) state. Therefore, Fe from drinking water, though present in lower concentrations, could have a greater impact on Fe status and potential toxicity than feed Fe. Our objective was to evaluate the difference in short-term effects of Fe^{2+} and Fe^{3+} when administered at concentrations to simulate total daily Fe intake from high-Fe drinking water. Six mid-lactation Holstein cows were assigned in a replicated 3 × 3 Latin Square balanced for treatment sequences. There were 7 d between experimental periods. Treatments were: 1) 0 mg Fe; 2) 1.5 mg Fe from ferrous sulfate/kg BW; and, 3) 1.5 mg Fe from ferric sulfate/kg BW. Treatments were iso-sulfate. The Fe^{2+} treatment approximated total Fe intake from water containing 9 ppm Fe, and the Fe^{3+} treatment provided the same Fe concentration. Treatments were infused in ~1 min directly into the abomasum via the ruminal fistula in 1.5 L of deionized water to avoid ruminal effects on Fe valence. Six hourly blood samples were taken before dosing; and, post-dosing hourly for 12 h each period. Liver biopsies were 0 (before dosing), 18 and 36 h of each period. Mean of pre-dosing blood samples was used as a covariate for each dependent variable in statistical analysis. There were no treatment by time interactions ($P > 0.10$) for serum Fe, unsaturated iron-binding capacity (UIBC), total iron-binding capacity (TIBC), percent Fe saturation, Zn, and for liver Fe, Cu and Zn. There was no main effect of treatment for any response variables. There was an effect of hour pooled across all treatments for serum Fe ($P = 0.014$), TIBC ($P = 0.043$), Fe saturation ($P < 0.0001$) and Cu ($P = 0.033$). There was a treatment by time interaction for serum α-tocopherol ($P = 0.016$) and Cu concentration ($P = 0.091$). Results indicate that dosing of amounts of Fe used in this study do not impact short-term Fe status of lactating dairy cows.

Key words: iron, lactating dairy cows, iron status

880 Evaluation of total mixed rations fractions retained on the Penn State Particle Separator as additional variables to influence milk production and composition. A meta-analysis. I. Schadt*[1], M. Caccamo[1], G. Azzaro[1], and G. Licitra[1,2], *[1]CoRFiLaC, Regione Siciliana, Ragusa, Italy, [2]DISPA, Catania University, Catania, Italy.*

Determination of forage and total mixed ration (TMR) fractions retained on the Penn State Particle Separator (PSPS) has become a widely used application on dairy farms and in research. The objective of this study was to evaluate the following variables on milk yield and percentage fat and protein: PSPS TMR fractions (% of total); chemical composition of TMR, [dry matter (DM % of as-fed), crude protein, neutral detergent fiber], and forage content (all as % of DM); average days in milk and average dry matter intake. A data file containing 109 treatment means was generated from 28 published research papers and one unpublished study conducted at the CoRFiLaC dairy research center. The variables, squared variables and possible interactions were tested, using the backward-forward elimination, stepwise selection option in PROC REG, multi-regression procedure using SAS statistical software. Models were calculated both ways, excluding and including PSPS fractions as variables and interactions where PSPS fractions were involved. A total of 150 or 108 variables were allowed to determine either predicting models including or excluding PSPS variables. Corrected R^2 values for the prediction models of milk yield were 0.95 and 0.91 when PSPS fractions were either admitted or not, involving 34 and 32 model terms, respectively. The models for milk fat prediction contained 32 and 26 possible terms, and corrected R^2s were 0.86 and 0.75 when PSPS variables were either included or not. Models to predict milk protein selected 18 and 17 terms either including or excluding PSPS variables, and respective R^2s were 0.79 and 0.58. These results suggest that for adequate formulation of dairy rations we might be able to eliminate some of the chemical analysis of feeds, which are currently recommended by some nutrition models. The consistent improvement in R^2 of predictive models suggests that physical measurements such as particle TMR fractions retained on the PSPS would provide additional information for dairy ration formulation, especially for milk composition.

Key words: TMR, feed evaluation, particle size

881 Effect of supplementary concentrate type on energy balance and blood metabolites in early lactation dairy cows offered grazed pasture. K. M. Pierce*, S. J. Whelan, J. J. Callan, and F. M. Mulligan, *School of Agriculture, Food Science and Veterinary Medicine, University College Dublin, Belfield, Dublin 4, Ireland.*

This experiment evaluates the effect of supplementary concentrate type on energy balance and blood metabolites in early lactation dairy cows offered a perennial ryegrass pasture. Forty 8 cows of mixed parity were assigned to 1 of 4 concentrate types in a randomized block design. Cows received perennial ryegrass plus 3 kg twice daily of the following concentrate types: Hi-Pro (18% CP), Lo-Pro (14% CP), Lo-Pro+ Meth (14% CP, with added methionine) and Lo-Pro Maize (14% CP). Hi-Pro, Lo-Pro and Lo-Pro+ Meth contained rolled barley, whereas Lo-Pro Maize contained stone ground maize as the main starch source. Blood was collected on d 14, 21, 28 and 35 post-calving for analysis of urea, non esterified fatty acids (NEFA), β-hydroxy butyric acid (BHBA) and glucose (GL). Pasture DMI was determined on wk 6 and 10 post calving. Data was analyzed using PROC MIXED of SAS. Dietary energy intake (18.23 ± 0.054 UFL/d) was not affected ($P > 0.05$) by treatment. A greater ($P < 0.05$) portion of dietary energy was recovered in the milk for Lo-Pro+ Meth (0.638 ± 0.034 of UFL intake) vs. Hi-Pro (0.535 ± 0.034 of UFL intake); Lo-Pro and Lo-Pro Maize were not different ($P > 0.05$) from other treatments. BHBA was higher ($P < 0.05$) for Hi-Pro (0.73 ± 0.045 mmol/L) vs. Lo-Pro Maize (0.58 ± 0.045 mmol/L); Lo-Pro and Lo-Pro+ Meth were not different from other treatments. NEFA were lower ($P < 0.05$) for Lo-Pro Maize (0.39 ± 0.058 mmol/L) vs. other treatments (0.59 ± 0.058 mmol/L). GL was higher for Lo-Pro Maize (3.34 ± 0.051 mmol/L) vs. Hi-Pro (3.14 ± 0.051 mmol/L); Lo-Pro and Lo-Pro+ Meth were not different from other treatments. Blood urea (1.39 ± 0.108 mmol/L) was not affected by treatment. Reducing concentrate CP and offering supplementary methionine improved energy efficiency. Reduced concentrations of GL, NEFA and BHBA in Hi-Pro vs. Lo-Pro Maize may be due to better energy balance.

Key words: supplementary concentrates, blood metabolites, dairy cows

882 Effect of total mixed rations particle fractions retained on the Penn State Particle Separator on milk yield lactation curves using a random regression animal model. M. Caccamo*[1], J. D. Ferguson[2], R. F. Veerkamp[3], I. Schadt[1], R. Petriglieri[1], G. Azzaro[1], A. Pozzebon[1], and G. Licitra[1,4], *[1]CoRFiLaC, Regione Siciliana, Ragusa, Italy, [2]University of Pennsylvania, PA, [3]WageningenUR Livestock Research, Animal Breeding and Genomics Centre, Lelystad, the Netherlands, [4]DISPA, Catania University, Catania, Italy.*

Several studies reported influence of diet on milk production. As part of a larger project aiming to develop management evaluation tools

based on results from test-day (TD) models, the objective of this study was to estimate the effect of total mixed rations (TMR) particle fractions estimated using the Penn State Particle Separator (PSPS) on milk, fat, and protein yield curves. A random regression TD animal model was fitted to a full data set (134,579 test-day records) to obtain variance components. The model included parity, days in milk (DIM), age at calving, year and season at calving, days dry, calving interval and stage of pregnancy as fixed effects. The term DIM was modeled using 9-order Legendre polynomial. Animal, sire and maternal grand sire effects were modeled using 3-order Legendre polynomials. Model fitting was carried out using ASREML. Then, the same model with fixed variance components was used on a subset containing 46,531 TD milk yield records from 2006 through 2008 from 3,554 cows in 27 herds in southeastern Sicily where TMRs were sampled immediately before or right after the TD. In these herds, TMR samples were collected every 3 mo, sieved using a PSPS including 19 (upper), 8 (middle), and 1 (lower) mm sieves and an additional bottom pan and proportions were measured. All sieve proportions and their interaction with DIM were included in the model as fixed effects. Conditional Wald F statistic on fixed effects revealed significant effects ($P < 0.001$) for all sieves on milk, fat, and protein yield, except upper sieve on fat and lower sieve on protein production. In particular, pan and lower sieve proportions were negatively related whereas those retained on the middle sieve were positively related to fat production at the beginning of the lactation. Furthermore, the correlations between milk curve shape and middle and lower sieve proportions were positive and negative, respectively, throughout the whole lactation, suggesting that PSPS sieve fractions could represent an additional important parameter for the formulation of dairy rations.

Key words: particle size, test-day model, total mixed ration

Ruminant Nutrition: Mycotoxins – Prevalence, Impact, and Control Strategies in Ruminant Diets

883 Major mycotoxins in ruminant diets. D. E. Diaz*, *Novus International Inc., St. Charles, MO.*

Mycotoxins are undesirable, but mostly unavoidable, mold produced feed contaminants. The level of mycotoxins in foods and feed can fluctuate widely and vary significantly from year to year. These fluctuations depend on many factors, including adverse conditions that favor fungal invasion and growth either in the field or during storage. Apart from their threat to public health, mycotoxins are also associated with significant economic losses for both crops and animals. Although several hundred mycotoxins have been described in the scientific literature, less than 10 have been extensively studied since the discovery of aflatoxin in the early 1960s. Mycotoxins can increase disease incidence and reduce production efficiency in livestock. They can cause dermal toxicity, reproductive effects, carcinogenicity, neurotoxicity, teratogenicity, nephotoxicity and hepatoxicity. Additionally, mycotoxins may affect immune function and cause lipid peroxidation. In spite of current research advances, applied aspects of mycotoxicology are either limiting or difficult to extrapolate into the real world. This review will attempt to discuss some of the most common problems related to presence of mycotoxin in ruminant diets.

Key words: mycotoxins, ruminant

884 Impact of mycotoxins on the immune system. T. K. Smith*, *University of Guelph, Guelph, ON, Canada.*

Ruminant animals are generally considered to be more resistant to feed borne mycotoxins than monogastric animals because of the potential for rumen microorganisms to inactivate mycotoxins before they enter the blood stream. One symptom of mycotoxicoses that is sometimes observed in ruminants and monogastrics is immunosuppression. Lingering health problems in the herd, animals that do not respond to medications and failure of vaccination programs can be seen. Positive identification of mycotoxins as the causative factor is difficult because many conventional analytical techniques underestimate the degree of mycotoxin contamination of feedstuffs. This is further complicated by the fact that symptoms and lesions noted are not the classical lesions characteristic of mycotoxicoses. They are lesions caused by infections resulting from a mycotoxin-induced compromised immune system. The severity of immunosuppression can be further influenced by management systems. Environmental stresses arising from some management practices will also impart a degree of immunosuppression which may, therefore, appear to exaggerate mycotoxin-induced immunosuppression. The feeding of aflatoxin contaminated feeds to ruminants has been shown to lower disease resistance and to compromise vaccine-induced immunity. Several mechanisms of bovine immunosuppression by aflatoxin have been demonstrated in vitro including mitogen-induced stimulation of peripheral lymphocytes and inhibition of bovine lymphocyte blastogenesis. Recent studies in dairy cows demonstrated that feed naturally contaminated with *Fusarium* mycotoxins (mainly deoxynivalenol) can also affect immune function. Decreased serum IgA concentrations, depressed neutrophil phagocytosis and stimulated primary antibody response to ovalbumin immunization were seen. It can be concluded that ruminant animals can be subject to immunosuppression and decreased disease resistance when exposed to feed borne mycotoxins.

Key words: ruminants, mycotoxins, immunity

885 Prevalence of mycotoxins in feedstuffs. D. Taysom*, *Dairyland Laboratories Inc., Arcadia, WI.*

Each year molds and mycotoxins have a major economic impact on the feed industry and despite advances in analysis of the toxic metabolites produced by molds, they still prove to be difficult to measure and quantify. There are hundreds of unique mycotoxins in the environment; however, there are good analytical methods for approximately 15 – 25 toxins and depending on the sample matrix, most labs are proficient at testing 5 to 8 toxins. A variety of methods; ELISA, TLC, HPLC, HPLC/MS, HPLC/MS/MS are available with verifiable low detection limits on grains and meal product. However products that have undergone fermentation (corn silage) or are mixtures, (grain mixes, TMRs) are limited in number of methods available and must utilize higher detection limits. While complete "panels" of mycotoxin analysis are often recommended when trouble shooting mycotoxin contamination, there is a lack of evidence that this approach is more successful in determining the presence of mycotoxins when compared with analyzing for toxins commonly referred to as "markers." New research indicates that having samples identified for mycotoxin producing molds may also be an effective diagnostic tool. The most common approach for monitoring the prevalence of mycotoxins across a broad geographic region is to summarize data from laboratories performing mycotoxin analysis. While this is useful information, one should consider that most samples submitted for laboratory analysis are suspect in nature and laboratory summaries are not random sampling of products for mycotoxin contamination. There would be a great benefit to the feed industry for a mycotoxin monitoring program that included random sampling of products, accounted for seasonal differences and was implemented consistently over several years.

Key words: mycotoxins, prevalence, laboratory summary

886 Evaluation of feed additives for reducing mycotoxins. I. P. Oswald*, *INRA, ToxAlim Reseach Center, 31027 Toulouse Cedex 03, France.*

Mycotoxins are secondary metabolites elaborated by filamentous fungi and the contamination of food and feed with mycotoxins is a worldwide problem. These toxins have significant human and animal health, economic and international trade implications. The major mycotoxins of concern are aflatoxins, trichothecenes, ochratoxin, ergot alkaloids, zearalenone and fumonisins, most of which are highly toxic and some are carcinogenic in humans. With global warming, the threat from fungal invasion of crops is likely to increase. Every effort must be made to reduce the occurrence of mycotoxins. This is a complex task that require an integrated understanding of crop biology, agronomy, fungal ecology, harvesting methods, storage conditions, food or feed processing and detoxification strategies. The use of feed additives to alleviate nutrient deficiencies, increase product pigmentation, improve pellet quality and adsorb toxicants and toxins is a well established practice in the animal feed industry. A diverse variety of substances have also been investigated as potential mycotoxin-detoxyfying agents. Depending on their mode of action, these feed additives may act by reducing the bioavailability of the mycotoxins or by degrading them or transforming them into less toxic metabolites. We can define at least 2 main categories: (1) One of the strategies for reducing the exposure to mycotoxins is to decrease their bioavailability by including various

mycotoxin adsorbing agents in the compound feed, which leads to a reduction of mycotoxin uptake as well as distribution to the blood and target organs. (2) Another strategy is the degradation of mycotoxins into non-toxic metabolites by using biotransforming agents such as bacteria/fungi or enzymes. Substances that do not directly interact with mycotoxins, i.e., antioxidant agents, immunostimulatory agents, are not considered sensu stricto as mycotoxin-detoxifying agents. However, such compounds may be very efficient for reducing the toxicity of mycotoxins.

Key words: feed additive, mycotoxin, ruminants

Teaching/Undergraduate and Graduate Education

887 Perceptions of livestock practices by students entering introductory animal science courses. G. A. Holub*[1], C. T. Boleman[2], and S. W. Ramsey[1], *[1]Texas A&M University, College Station, [2]Texas AgriLife Extension, College Station.*

The purpose of this study is to determine attitudes of introductory animal science course students about common livestock management practices to alter teaching methods of the course based on the results. The IRB approved, anonymous survey was conducted for 3 Introductory Animal Science classes at Texas A&M University over the course of 2008 (n = 847). The study used an ex post facto approach and a correlational design. Quantitative data were analyzed using SPSS 15.0 for Windows software. Descriptive statistics were used to summarize data. Frequencies, percentages, central tendency measures, and variability measures were used to describe these data. The majority of respondents by category were male (63.0%), freshman (53.9%), less than 20 years of age (79.0%), and college of agriculture science students (50.7%). To determine the background of the students, they were asked to define where they were raised. The most frequent response was for "major city (over 100,000)" - 24.8%. This was followed closely by respondents from a "town (between 2,500 and 25,000)" – 22.2%, "rural" – 20.6%, "city (between 25,000 and 100,000)" – 18.9%, and "rural community (<2,500 population)" - 13.8%. Fourteen production practices were evaluated for acceptance by respondents The Likert scale used for acceptance was defined as 1 = Very Acceptable to 5 = Very Unacceptable. Seven of the 14 statements yielded mean values of less than 2.0. Six production practices yielded mean values between 2.0 and 3.0. Only one production practice yielded a mean value of greater than 3.0. The summary table shows the results of these analysis in order of acceptance by the students. Conclusions of the survey include half of the production practices are considered acceptable by the students before any teaching about the practices and half needed more emphasis by the instructor to enable students to have a more positive perception of the practice.

Table 1. Likert scale means for the acceptance of livestock production practices by introductory animal science students

Practices	N	Mean	SD
Vaccinate	845	1.21	0.54
Shearing	846	1.27	0.55
A.I.	846	1.61	0.85
Castration	842	1.83	1.03
Squeeze chutes	842	1.88	0.99
Ear notching	846	1.93	0.95
Dehorning	846	1.94	1.01
Feedlots	839	2.08	0.97
Auction market handling	840	2.09	0.93
Hot iron branding	846	2.13	1.09
Farrowing crates	839	2.54	0.90
Battery cages for laying hens	844	2.74	0.98
Separating calves/mothers	843	2.85	1.17
Debeaking	846	3.15	1.15

Key words: animal science, undergraduate, perceptions

888 Demographics and eating habits of students entering introductory animal science courses. G. A. Holub*[1], C. T. Boleman[2], and S. W. Ramsey[1], *[1]Texas A&M University, College Station, [2]Texas AgriLife Extension, College Station.*

The objectives were to determine the background and demographics and eating habits by protein sources (red meat, eggs, poultry and dairy) of students in introductory animal science classes to alter instruction for the semester based on the results. The study was conducted with 3 introductory Animal Science level classes at Texas A&M University in 2008 (n = 847). Frequencies, percentages, central tendency measures, and variability measures were used to describe these data. The majority of respondents by category were male (63.0%), freshman (53.9%), less than 20 years of age (79.0%), and college of agriculture science students (50.7%). Students were asked to define where they lived. The most frequent response was "major city (over 100,000)" - 24.8%, followed by "town (between 2,500 and 25,000)" – 22.2%, "rural" – 20.6%, "city (between 25,000 and 100,000)" – 18.9%, and "rural community (<2,500 population)" - 13.8%. Respondents were asked about their farming background, pet ownership, and eating habits. A total of 496 respondents (59.2%) were presently associated with farming and 93.1% had a family pet. With regard to eating habits, 96.7% classified themselves as meat eaters, while 3.3% classified themselves as either a vegetarian or vegan, but 757 respondents (89.7%) said there were no family members who were considered vegetarians. Respondents were asked to provide their consumption of animal food products by determining the number of servings they eat per week. The products included eggs, red meat, poultry, and dairy. For egg consumption, 455 (53.8%) respondents said they consume 1–2 servings per week, followed by 3–4 servings at 19.8%, and zero servings at 14.5%. Similar to egg consumption, dairy had a majority response where > 56% indicated they consume milk daily. Red meat and poultry were more evenly distributed as compared with eggs or dairy. A total of 268 (31.8%) respondents said they eat 3–4 servings of red meat per week and 222 respondents (26.2%) 5–6 servings per week. The leading category for poultry was 3–4 servings, 365 respondents (43.2%), followed by 253 respondents (30.0%) at 5–6 servings per week.

889 Incorporating an issues survey assignment into an introductory animal science course. J. A. Sterle*, *Texas A&M University, College Station.*

Eighteen undergraduates enrolled in General Animal Science Honors course were required to develop, administer and interpret a survey about livestock industry issues. Objectives of the project were to 1) expose the students to scientific process, 2) investigate livestock issues in society, 3) increase understanding of interpretation of survey data, and 4) expose students to advocacy and agriculture education. Public perception of agriculture was discussed in-depth. Students responded as participants to a livestock production perception study, followed by discussion of each question's wording, possible misinterpretation, and overall bias. Students were allowed to choose survey topic, although exact duplicates were discouraged. Topics included livestock terminology, food safety, horse harvest, organic food, government grazing lands, gestation stalls, growth implants, and the general use of animals (pets and livestock) in society. Surveys varied in length and type of questions, although all had at least 10 questions. Students submitted several drafts before final printing. "Fact cards" was also developed

for each survey, consisting of 3–8 bullet points, educating respondents about the topic once survey was taken. One hundred copies of each survey were distributed. Students were allowed to determine audience and place of distribution. Students collected, recorded and analyzed data, and presented findings. They were also asked to present possible misinterpretations of results (i.e., by media or groups opposing livestock production). When surveyed about the project, students noted peer apathy about completing the survey. All students responded "a significant amount" when asked how much they learned by completing this project. Most students (75%) indicated a higher level of understanding of survey research, and 15/18 (83.33%) declared a preference to conduct the survey via internet. Students indicated that participants were concerned with answering the questions "correctly," even though they were asked opinions. Every student specified a "greatly improved" understanding of public perception of animal agriculture by completing the project.

890 Improving learning through integration of an upper division class with an introductory class in companion animals. J. P. McNamara*, *Washington State University, Pullman.*

To increase the depth and breadth of science understanding and application to animal nutrition and management, 2 courses at WSU: AS 205, Companion Animal Nutrition (General University Biology Course) taught to all classes and majors; and AS 464, Companion Animal Management, a primarily major course for seniors, have been used for the last 4 years in a project to integrate several levels of learning and application skills. The learning outcomes of the project were to increase scientific knowledge, media and information literacy, critical thinking across a wide spectrum, quantitative reasoning, working with groups to solve problems; and learning how to communicate to others. Lessons in the biology class investigated connections between nutritional chemistry, animal diversity, and practical decision making (use of pet food labels); or the biology behind the interaction of nutritional states and disease and their impacts on society. In the advanced class, students researched topics from the canine genome project and mechanisms of genetic diseases; to the human animal bond and how it affects economic and political decisions. Each advanced student then individually developed a teaching module on a broad topic to be used by the students in the introductory class. The course objectives in part read: To help you identify media and science concepts displayed in select videos and other media to relate media messages about scientific topics, or animals, to your own life and to society in general. To think critically about how media provides various messages, how they relate to animals and science, and how such messages and ads could influence others. Surveys (Likert Scale) from both classes over the last 3 years (60 students in advanced class; 450 students in introductory class; over 80% response rate) were approximately 78 to 85% positive on thinking critically, working on a team, improving information literacy and understanding interdisciplinary importance; and 90+ % on improving ability to "answer my own questions." Other faculty may be able to use such approaches to expand the role of Animal Sciences in overall university instruction and improve student learning.

Key words: companion animal, teaching, course integration

891 Internships and international collaboration in beef cattle reproductive management. K. G. Pohler*[1], D. A. Mallory[1], D. J. Patterson[1], M. F. Smith[1], J. L. M. Vasconcelos[2], R. F. G. Peres[3], and E. R. Vilela[4], *[1]University of Missouri, Columbia, [2]FMVZ - UNESP, Botucatu, SP, Brazil, [3]Agropecuária Fazenda Brasil, Barra do Garças, MT, Brazil, [4]Lageado Agricultural Consulting LTD, Mineiros, GO, Brazil.*

Recent advances in reproductive technologies in cattle (e.g., fixed-time artificial insemination [AI]) have created demand for qualified individuals capable of implementing these technologies. The University of Missouri developed a reproductive management internship in conjunction with Select Sires, Inc. (F. B. Miller Internship in Reproductive Management) to address this issue. Objectives of this internship include the following: 1) Provide undergraduate and graduate students with extensive practical training in the implementation of estrus synchronization (ES) and AI programs in beef and dairy herds, and 2) Provide students with the ability to solve "real world" reproductive management problems, both individually and as a team. Over the past 15 years, the internship provided opportunities for 156 students to work with over 190,000 heifers and cows in production settings in 12 states. Outcomes include the following: 1) Increased competency of students' reproductive management skills, 2) A deeper understanding of the US beef and dairy industries, and 3) A network of allied industry contacts, that expand career opportunities beyond the classroom. The internship was expanded in 2011 to provide graduate students with international experience in reproductive management. Objectives of this program include the following: 1) Gain extensive practical experience in implementing ES and AI protocols in large Brazilian herds, and 2) Provide students with knowledge of the Brazilian beef industry. Recently, 2 graduate students worked with over 20,000 beef heifers and cows located on more than 15 farms and ranches in 3 states in Brazil. A goal of the program is to promote future collaborations with Brazilian researchers and allied industry. Based on the placement of students into careers that involve implementation of reproductive management technologies (e.g., AI employees, veterinarians, extension specialists in reproduction, etc) the internship program has been successful. Supported by National Research Initiative Competitive Grant no. 2005–55203–15750 from the USDA Cooperative State Research, Education, and Extension Service

892 Predictors of performance in an Animal Nutrition classroom. M. A. Soberon*, D. J. R. Cherney, and R. C. Kiely, *Cornell University, Ithaca, NY.*

Accurately identifying predictors of classroom performance better equips advisors to make course recommendations to undergraduate advisees as well as instructors striving to meet the needs of a diverse classroom. This research endeavors to discover predictive relationships between SAT scores, residency, transfer status, major, gender, grade in a recommended chemistry prerequisite (Chem) and performance in an animal nutrition course (Nutr; Cornell University). Data from a total of 443 students, representing 4 semesters (Fall 2007–2010) of Nutr students was collected from the CALS Registrar and analyzed using SAS 9.2. The instructor was the same and the class material was essentially unaltered during this time. All of the analyzed predictors were significant with the exception of major; this was affected by the low number of non-majors in the class. Final cumulative GPA was highly correlated with Nutr grade, indicating students with high grades in the course tend to also have a high cumulative GPA. The highest correlation for an analyzed predictor was Chem grade, with a significant Nutr grade difference for students who completed the Chem prerequisite (86.3 vs. 80.6). Twenty-nine percent of the students were transfer students. This research identified areas where predictors could be better

utilized for transfers. Although SAT scores are correlated with performance, they were not on record with CALS Registrar for 86.8% of transfer students. Moreover, transfers rarely take Cornell Chem. In a survey conducted for the fall 2010 class, students identified the following as influencing their grade in Nutr: study habits (81.2%), test taking (70.6%), transfer status (48% of transfers), animal experience level (27.1%), personal problems (24.7%) and class prerequisites (22.4%).

Table 1. Predictors of student performance in Animal Nutrition

Item		n	Grade	SE	*P*-value	r^2
GPA[1]		174	83.5	6.85	<0.001	0.450
SAT Math		299	84.4	7.83	<0.001	0.144
SAT Verbal		299	84.4	7.79	<0.001	0.152
Chemistry		227	86.3	5.90	<0.001	0.409
Residency	Resident	251	82.5	8.73	0.007	0.017
	Non-resident	192	84.8			
Transfer status	Four year	314	84.4	8.69	0.001	0.025
	Transfer	129	81.3			
Major	Animal Sci	403	83.5	8.80	0.854	0.00
	Non-major	40	83.8

893 Attitudes and knowledge of high school students about the department of animal industry of the University of Puerto Rico at Mayagüez. G. Ortiz-Colón*, J. M. Huerta-Jiménez, E. Jiménez-Cabán, and M. Pagán-Morales, *University of Puerto Rico at Mayagüez, Mayagüez, PR.*

The student enrollment in the College of Agricultural Sciences of the University of Puerto Rico at Mayagüez has been stagnant for at least the last 6 years. Within the College of Agricultural Sciences, the situation of the Department of Animal Industry (DAI) is not different. The DAI enrollment has declined in 7% over the last 6 academic years. The reasons for this phenomenon have not been previously investigated. We hypothesized that high school students of Puerto Rico did not understand the professional options a bachelor in Animal Industry has to offer. Surveys were developed to evaluate what knowledge high school students possessed about the DAI. Surveys (2,700) were distributed to 135 professionals (20 surveys /professional) of the Cooperative and Agricultural Extension Service who were assigned to visit at least one school in each of the 78 counties of Puerto Rico. A total of 726 surveys were returned representing students in 31 high schools representing 26 counties of Puerto Rico. Of the surveyed individuals, 75.8% were 15 to 16 years old and 57.6% were females. Most students (89%) were in 10th and 11th grade. The majority of the surveyed individuals (72.2%) had no experience in agriculture. Only 49.9% of the studied population could correctly define "animal industry." However, when students were asked to define the term "animal science," 78% did it correctly. Although only 7.4% of the surveyed population was interested in an animal industry academic program, 19.4% was interested in an animal science academic program. These data suggest that students do not understand the term animal industry and this could be limiting their interest in enrollment at the DAI. The data suggests that if the name of the DAI is changed to the Department of Animal Science more high school students might applied to this academic program.

Key words: Hispanic serving institutions, animal science, student recruitment

894 Mentoring underrepresented students through agricultural related research projects. J. S. Pendergraft*[1], R. M. Legere[1], and A. RodrÍguez[2], *[1]Sul Ross State University, Alpine, TX, [2]University of Puerto Rico, Mayaguez, PR.*

Sul Ross State University (SRSU) was awarded a Hispanic-Serving Institutional grant of $290,000 over a 4-year period to increase the number of underrepresented students entering and completing graduate school through developing a science-based mentoring program. To facilitate cross-cultural and cross-institutional collaboration, SRSU partnered with key personnel at the University of Puerto Rico at Mayaguez (UPRM). The research mentoring model allowed faculty to work with top graduate students to select a team of undergraduates that would work together on sustainable agricultural and biological research projects. Three projects were designed in the fall of 2010 to begin comparing student participation in the new research mentoring model with the successful managerial mentoring model at SRSU. These research projects were conducted utilizing 30 students, 3 faculty members, and 3 universities which included Eastern New Mexico University. Of the 30 participating students in the research projects 10 of them were underrepresented animal science students. This was a 50% increase in total participation and a 30% increase in minority participation compared with the projects conducted over 2 years in the managerial mentoring program. Notably, 2 of the 7 graduate mentors were Hispanic students. Thirty percent of the undergraduate participants were either freshmen or sophomores in classification and half of them were minority students. Undergraduate student participants represented 5 different Animal Science concentrations and Natural Resource Management degree programs. One of the mentors has been invited to attend veterinarian school at Kansas State University. The science-based research mentoring model developed at SRSU from the Hispanic Serving Institute grant will increase the quality of its postsecondary instruction while enhancing the educational equity for underrepresented students in agricultural programs. Acknowledgments: Dr. D. Smith, Eastern New Mexico University

Key words: Hispanic, experiential, mentoring

895 Graduate student course curriculum in animal science departments. R. F. Leuer*[1] and H. M. White[2], *[1]University of Minnesota, St. Paul, [2]Indiana University, Indianapolis.*

Graduate education in animal science is at a crossroads at many colleges and universities. As faculty numbers have dropped and research areas have become increasingly specialized, meeting all graduate student course needs has become increasingly difficult. An online survey was conducted during the summer of 2010 to assess the quality of graduate courses available within animal science departments. One-hundred respondents representing 34% MS and 66% PhD students studying nutrition, animal breeding and genetics, physiology, management and production systems, reproduction, and other areas, completed the survey. Only 50% of students were satisfied with the course curriculum offered within their department. Satisfaction was not affected ($P > 0.05$) by degree currently being pursued. Basic graduate courses were reportedly available to 72% of students and advanced courses were available to 61% of students. Dissatisfaction with the

basic course offerings tended ($P = 0.06$) to influence and dissatisfaction with advance course offerings influenced ($P < 0.05$) overall satisfaction. Students working with swine and equine species were less satisfied ($P < 0.05$) with overall course offerings than students working with beef, dairy, or poultry. The possibility of participation in internet-based courses to augment current classes appealed to 87% of students and PhD students were more supportive ($P < 0.05$) of this option. Support for online course options was higher ($P < 0.05$) among students who worked with beef, dairy, and swine compared with students working with equine, companion animals and small ruminants. Of 2 format options presented for online courses, more students indicated that they would prefer ($P < 0.05$) broadcasted live lectures compared with self-paced online tutorials (65 vs. 35%). These survey results indicate that graduate student course needs are not always being met and that gaps in course offerings in advanced subject areas influences overall course curriculum satisfaction. These results also suggest that future development of online courses, offered across universities, may augment current course curriculums.

896 Increasing awareness of the Multimedia Educational Resource for Learning and Online Teaching (MERLOT) website.
J. Bertrand*[1] and M. Rieger[2], *[1]University of Georgia, Athens, [2]University of Florida, Gainesville.*

The objective of this abstract is to increase awareness of the Multimedia Educational Resource for Learning and Online Teaching (MERLOT) Web site and solicit materials for inclusion in the Animal Science section of the Agricultural and Environmental Sciences Community (www.merlot.org). MERLOT is a well-established reservoir of peer-reviewed free on-line teaching resources targeted for use in higher education. Its strategic goal is to increase the availability of quality online learning material and thereby improve the effectiveness of teaching. Materials found in MERLOT can be used for online course development as well as in web-enhanced face-to-face courses. Types of materials include animations, case studies, collections, drill and practice activities, learning objects, lectures, online courses, open textbooks, exams, reference material, simulations, tutorials, and training materials. Some ideas for using material found in Merlot include assigning supplemental readings, developing an assignment around a site, incorporating materials into presentations, and using online tools to complete assignments. The Agricultural and Environmental Sciences Editorial Board and online Community was established in 2010 and currently contains sections for the disciplines of Agriculture Education, Agriculture and Bio Engineering, Agriculture, Environment & Development Economics, Animal Sciences, Environment and Natural Resources, Food Science, and Plant Science. Online material is being solicited for all sections, including Animal Sciences. Submission of material for peer-review is open to all persons and easily accessed. Publishing materials on MERLOT offers the opportunity for faculty to contribute to the scholarship of teaching and learning.
