Postmaster: Send address changes to *Journal of Dairy Science*, Elsevier Health Sciences Division, Subscription Customer Service, 3251 Riverport Lane, Maryland Heights, MO 63043.

Customer Service (orders, claims, back volumes, online access, change of address): Elsevier Health Sciences Division, Subscription Customer Service, 3251 Riverport Lane, Maryland Heights, MO 63043. Telephone: 800.654.2452 (US and Canada), 314.447.8871 (outside US and Canada); fax: 314.447.8029; e-mail: journalscustomerservice-usa@elsevier.com (for print support) or journalsonlinesupport-usa@elsevier.com (for online support). Allow 4 to 6 weeks for the change of address to be implemented.

Institutional Subscription Rates: For institutions in the United States and possessions: $949 for print. For institutions in all other countries (prices include airspeed delivery): $1070 for print. Current prices are in effect for back volumes and back issues. Electronic access is additional. Please contact customer service for pricing.

ADSA Membership Rates: For individual membership, contact the ADSA office (adsa@assochq.org) to pay dues and obtain access to the journal. For professional members: $110 per year, graduate student membership: $10, undergraduate student affiliate membership: $5. Membership includes electronic version of the journal; additional $61.50 for paper copy in US, and additional $91.50 for paper copy in all other countries). Membership in the ADSA is on a calendar year basis from January through December.

Advertising Information: To advertise a position announcement in the News and Announcements section of the journal, please use the FASS Job Resource Center (http://www.fass.org/job.asp); e-mail jrc@assochq.org if you have questions.

For display advertising orders and inquiries please contact Ken Senerth at 609.577.0916; by fax at 212.633.3980; or by e-mail at kensenerth@gmail.com. For non-recruitment classified advertising orders and inquiries please contact John Marmero at 212.633.3657; by fax at 212.633.3820; or by e-mail at j.marmero@elsevier.com.

Author Inquiries: For inquiries relating to the submission of articles, complete Instructions for Authors can be found online at http://www.journalofdairyscience.org. Manuscripts submitted for consideration should be submitted electronically at http://mc.manuscriptcentral.com/jds in accordance with the Instructions for Authors. Need help? Contact shaunam@assochq.org.

Offprints. Authors may place orders for offprints when proof corrections are sent to the editorial office (before the journal is sent for printing). For queries about offprints or order status, e-mail vickip@assochq.org; fax 217.378.4083.

Reprints. To order author reprints after the issue has been printed, e-mail authorsupport@elsevier.com. To order 100 or more reprints for educational, commercial, or promotional use, contact the Commercial Reprints Department, Elsevier Inc., 360 Park Avenue South, New York, NY 10010-1710; fax: 212.633.3820; e-mail: reprints@elsevier.com. Access to single articles available online may be obtained by purchasing Pay-Per-View access on the journal website (http://www.journalofdairyscience.org).

Application for membership in the American Society of Animal Science (ASAS) is invited from persons with interest in animal science and livestock production. In 2014, annual dues including access to the electronic version of the Journal of Animal Science are $135 in the United States, Canada, and Mexico and in other countries. For those in the United States, Canada, or Mexico who wish to receive a paper copy of the journal, the additional fee is $200; for those in other countries, the additional fee is $300. Student affiliate membership is granted to those who are certified by a professional member as a regularly enrolled college student who does not hold a full-time position at the time of application for, or annual renewal of, membership. Graduate student memberships ($20 annually) and undergraduate student memberships (free) include access to the electronic version of the Journal of Animal Science. Postdoctoral fellows' membership dues are $65. An institutional subscription ($599 annually) entitles an institution Internet access to e-JAS within appropriate IP addresses. For an additional $125 fee, institutions within the United States, Canada, and Mexico will receive a paper copy of the journal (an additional $150 fee for all other countries). For corporate subscriptions, please contact the ASAS office for pricing. Individual sustaining membership, $375 per year. Applications for membership with remittance should be mailed to the ASAS Business Office.

ASAS Business Office, PO Box 7410, Champaign, IL 61826
Telephone: 217-356-9050; Fax: 217-689-2436; E-mail: asas@asas.org Office hours: 8:00 a.m.–5:00 p.m.

Calendar of American Society of Animal Science Upcoming Meetings

Midwestern Section (with ADSA)	March 16–18, 2014	Des Moines, IA
Western Section	June 24–26, 2014	San Angelo, TX
Northeast Section	July 20–24, 2014	Kansas City, MO
National Annual Meeting (with ADSA)	July 20–24, 2014	Kansas City, MO

Manuscript Submission. Information about manuscript submission is given in *Style and Form* published on the journal website (http://jas.fass.org). All manuscripts submitted to the *Journal of Animal Science* must be accompanied by the JAS manuscript submission form certifying that any research that involves animals has followed established standards for the humane care and use of animals. Manuscripts should be submitted online via http://mc.manuscriptcentral.com/jas.

Address Change and Missing Copies. Notice of change in address should be received by the ASAS Business Office 60 days in advance of change. A claim for a missing copy of the *Journal of Animal Science* should be received within 30 days (90 days foreign) after publication date to ensure replacement at no additional charge. The current policy is one replacement per monthly issue of the *Journal of Animal Science*. If additional replacements are requested beyond that, a single-issue price of $60 per issue domestic and $65 per issue foreign shall be charged. These prices reflect the current single issue pricing structure.

Journal of Animal Science (ISSN 0021-8812) is published 12 times per year (monthly) by the American Society of Animal Science. Periodicals postage paid at 201 W. Springfield, Ste 1202, Champaign, IL 61820 and at additional mailing offices. Form 3579 to be returned to the ASAS Business Office. Postmaster: Send change of address to American Society of Animal Science, PO Box 7410, Champaign, IL 61826.

ADSA FOUNDATION SYMPOSIUM: MEETING THE PRESENT AND FUTURE DEMAND FOR EMPLOYEES WITH A PhD IN DAIRY SCIENCE

0001 Current problems with funding PhD programs.

L. H. Baumgard* and M. G. Hogberg, *Iowa State University, Ames.*

The dairy industry's need for scientifically trained personnel is increasing, whereas academic output of PhD graduates with a dairy emphasis is decreasing. This enhanced requirement for industry scientists is the obvious result of a maturing, evolving, and increasingly educated global dairy industry. Reasons for the reduction in the number of PhD candidates are less apparent and multifaceted. First, the field of dairy science is becoming more geographically regionalized and thus many U.S. land grant institutions have either de-emphasized or eliminated their dairy curriculum and dairy research capabilities. Second, the means by which graduate students are funded has markedly changed over the last 30 yr. In the past, most faculty members were "allocated" state-appropriated monies that were used to pay graduate student stipends and fund research projects. At most universities, these state "lines" have either experienced severe attrition or, in most cases, have completely been eliminated. Although variable among universities, current graduate student stipends (direct and indirect costs) range between $25,000 and $40,000 annually. Consequently, faculty are required to generate approximately $70,000 or $140,000 in stipend funds for a M.S. or PhD student, respectively, to graduate students in a timely manner. Funds to support research are necessary in addition to the stipend, raising total training costs for a PhD to < $300,000. Federal grants (USDA, NSF, NIH, etc.) are often monetarily large (i.e., $300,000 to $1 million), typically run for 3 to 5 yr, and are generally "focused" on a specific area of biology. However, the likelihood that a PI can continuously fund a research program based on competitive funding is low, as success rates on federal grants are commonly < 10%. This is especially true for applied researchers. Alternate sources of research funding are commodity groups and allied industry. However, relying on industry funding to train a PhD student requires successfully obtaining at least 4 yr' worth of industry grants large enough to complete a student's degree. Further, research revenue from different aspects of the industry will undoubtedly create inconsistencies in the area and type of research that the student conducts. Consequently, the experiments are less likely to "build on each other" and lack biological continuity; circumstances that compromise critical thinking and jeopardize scientific independence. Therefore, untraditional and creative funding strategies are urgently needed to meet the global demand for technically trained dairy scientists. Potential strategies will be provided in the presentation.

Key Words: funding

0002 Current situation for finding qualified people with a PhD; an industry perspective, dairy production.

W. C. Weldon*, *Elanco Animal Health, Greenfield, IN.*

A population growing to 9 billion people and 3 billion people moving to the middle class is projected by 2050. These global trends are increasing milk demand globally. Milk demand is projected to exceed supply, as people drink milk and eat dairy products to improve their nutrition, as their economic status improves. The increased need for milk will drive a significant demand for individuals with a PhD in dairy science. Industry roles for PhD graduates span a significant spectrum, including leading research, providing nutrition, reproduction, health, and management consulting services. There is also significant advancement in the underlying technology being used to produce milk and dairy products, requiring a continual investigation and learning over the course of an entire career. The demand for milk globally is significantly increasing the demand for qualified PhD graduates across the globe, in an effort to develop products, practices, and genetics that can rapidly improve productivity. In our experience, the most successful PhD scientists have a broad view of the industry, coupled with deep technical training. Including real life experiences through industry cooperation can help students develop key industry knowledge that will be critical for their future. These experiences will enhance their career. Our industry is becoming more complex with multiple partnerships. This requires students that are not only good in the lab but are very effective at collaboration and transferring knowledge. Finding PhD scientists with these qualities is difficult. In many cases, it can take a year or more to fill a position with a qualified candidate. The long searches can negatively impact the hiring companies. Significant opportunities exist to increase global milk production by increasing the population of PhD dairy science graduates to help meet the global demand for the nutrition from milk and dairy products. These scientists will be most effective if PhD programs focus on sound scientific training but also expose and train students in interpersonal skills, economics, and dairy industry fundamentals.

Key Words: dairy, PhD

0003 Current situation for finding qualified people with a PhD; an industry perspective, dairy foods. C. Allen*, *Kraft Foods, Glenview, IL*.

The current situation for finding qualified PhD graduates with dairy foods experience is bleak. There are limited experienced people in the industry and an even smaller amount coming out of the universities. The trends in dairy that are continuing to influence the dynamic evolution of employee requirements are: economic shift to the extremes and decline of the middle, continual push to drive for sustainable products, and global shifts in the commodity market. Dairy foods are complex matrices and span a wide range of food systems. The need for dairy talent with deep and varied expertise is urgent, but academic institutions shouldn't lose sight of the need to produce talent with a strong base in fundamental sciences and strong technical rigor. Companies are often recruiting, developing, and retaining their specific talent, but this approach is minimally successful and often leaves gaps in expertise. Suggestions to close this gap are: applied internships within strong fundamental programs or joint university programs (degreed or specialty) that combine strong fundamentals with application.

Key Words: dairy foods, internships

0004 Current situation for finding qualified people with PhDs; an academic perspective. V. V. Mistry*, *South Dakota State University, Brookings.*

The tripartite mission of teaching, research, and extension established 150 yr ago remains at the core of land grant universities today, but numerous structural differences today have an impact on programs. The PhD-holding candidates at universities may find positions, such as post-doctoral research associates, faculty members, and later in their careers, administrative positions, such as department head, associate dean, and dean, that help define academic programs. University programs that were typically funded by state and federal funds in the form of teaching, Hatch, and extension funds have seen a substantial reduction in dependency on these funds due to competition from other local (state) and national needs. Therefore, dependency on other non-appropriated funds has become essential (e.g., competitive grants, tuition and fees, and discretionary funds). Expectations of research output from faculty members have also increased. Thus, dependency on competitive grants for supporting research programs, graduate students, and portions of faculty salaries has become imperative. Simultaneously, non-university research programs, as in industry, have also become more sophisticated and, in many cases, targeted at long-term research efforts. Consequently, only those high quality PhD graduates that have a strong desire to develop a career in academia become candidates for faculty positions. Salaries in industry are usually higher than academic faculty positions. It is essential for universities to fill faculty positions with highly competitive individuals that in today's climate are not just excellent researchers that have an interest in teaching but are also competitive entrepreneurs. Such individuals if provided the right resources through start-up funds, grant writing training, and research resources will be well positioned to develop research programs that will train graduate students. Opportunities provided in a university environment are sometimes not known by prospective faculty members, such as the ability to consult, ability to share royalties from patents and licensed intellectual property they develop, and the general fulfilling nature of training students. It is therefore imperative that industry, universities and state and federal governments jointly develop efforts to help make the academic career attractive for PhD-holding candidates. Further, university graduate programs should be encouraged to design curricula that will help students position themselves for a successful academic career. Examples include courses or training in teaching, grant writing, and publications. Also important is the ability for students and faculty to develop relationships with industry.

Key Words: faculty, recruitment, university

0005 Short-term employment opportunities in industry for people pursuing graduate degrees. C. Johnson*, *Land O'Lakes, Inc., Arden Hills, MN.*

Short-term employment opportunities offer companies seeking to employ people with graduate degrees and people seeking graduate degrees several key benefits. First, short-term employment opportunities allow potential employers to determine what the graduate degree candidate can bring to the table before extending an employment offer. Graduate degree candidates can acquire valuable skills and training in practical, "real world" work settings. Acquired skills and training can complement the candidate's academic education and increase the candidate's market value when pursuing employment. These short-term employment opportunities also allow the graduate candidate to determine if a position and/or company are a right fit for the candidate's career goals, further solidifying career direction and understanding broader applicability of one's education. Another benefit of short-term employment opportunities for graduate degree candidates is the ability to expand their business network, which is not only beneficial in the short term when seeking employment but also throughout one's career. Finally, short-term employment opportunities allow graduate candidates to add depth and breadth to their curriculum vitae, setting themselves apart from other candidates.

ADSA SOUTHERN SECTION SYMPOSIUM: STRATEGIES FOR HOUSING DAIRY ANIMALS IN THE SOUTHEAST

0006 Photoperiod management of dairy cattle: considerations and applications. G. E. Dahl*, *University of Florida, Gainesville.*

Photoperiod, the duration of light exposure relative to darkness in a day, has significant impact on productivity and health of dairy cattle and other farmed species. A light:dark cycle of 16 h light and 8 h dark (16L:8D) is termed a long day photoperiod, whereas a 8L:16D cycle is termed a short day photoperiod. The physiological basis for the response begins with light perception at the eye and signaling to the hypothalamus and pineal gland to alter secretion of melatonin. Circulating melatonin increases during exposure to darkness from concentrations that are typically undetectable and thus the lighting schedule drives a pattern of melatonin release that allows the animal to track daylength. The most consistent endocrine effects of variable photoperiod are the responses of circulating prolactin and insulin-like growth factor-1, both of which impact growth and mammary gland function throughout the life cycle. Specifically, long day photoperiod increases lean growth in heifers and increases milk yield in lactating cows. In contrast, cows maintained on short days during the dry period subsequently produce more milk than those on long days when dry. Cows on short days when dry and those on long days in lactation have increased dry matter intakes relative to herdmates on the respective opposite treatments. Managing lighting in barns is easily implemented with commonly available fixtures and lamps. Indeed, the choice of light installed is made by combining the highest efficiency lamp available for the effective mounting height of the barn. Typically, with lower ceilings, a compact fluorescent lamp is the most appropriate selection, whereas the higher mounting heights available in freestall barns are better suited to metal halide or similar high efficiency lamps. Recently, LED lamps have been recommended due to their superior energy efficiency, but direct, robust testing of LED lamps has not been reported. Low intensity red lighting can be used in facilities during darkness, as it is not perceived as light by many species, including cattle. Target light intensity is in the range of 150 lux at a level 1 m above the barn's floor and that intensity should be maintained throughout the facility. Photoperiod manipulation is a low cost, high return method to increase a dairy herd's productivity throughout the cow's life cycle.

Key Words: dairy cow, housing, photoperiod

0007 Impacts of heat stress on cow and calf. S. Tao*[1], G. E. Dahl[2], and J. K. Bernard, *[1]University of Georgia, Tifton, [2]University of Florida, Gainesville.*

Heat stress has negative impacts on dairy cattle at different stages of their life cycle. Compared with the lactating dairy cow, the dry cow and neonatal calf have lower upper critical temperature, but their performance is still negatively impacted by heat stress. During the dry period, heat stress elevates cow body temperature and also disrupts several normal physiological functions during late gestation, such as impaired mammary growth and fetal development, which compromise future performance of the cow and calf. Compared with cooled cows, heat-stressed dry cows have lower milk production in the subsequent lactation and altered metabolic and immune function during the transition period. Maternal heat stress of dams during the dry period also has negative effects on their offspring. For example, calves born to heat-stressed cows have lower birth weight and impaired ability to absorb immunoglobulin from colostrum relative to calves from cooled dams. Emerging evidence also suggests that heat stress in utero may have long-term impact on a heifer's future performance, including milk production in the first lactation. Heat stress has direct negative impact on neonatal calf performance, as well. When exposed to heat stress, calves have impaired passive immunity and high mortality rate in the first month of life. Additionally, heat stress lowers a calf's average daily gain, feed efficiency, and overall growth during early life. Thus, proper management tools need to be implemented to cool the dry cow and neonatal calf as a way to alleviate the negative impacts of heat stress on these animals.

Key Words: dairy calves, dry period, heat stress

0008 Implications of overstocking on the behavior, health, and productivity of dairy cows in the Southeast. P. D. Krawczel*, *The University of Tennessee, Knoxville.*

The survivability of dairy farms across the Southeastern United States is being challenged by a variety of factors, such as high costs of production and aging housing and milking facilities. One common response to this is to attempt to increase revenue by increasing herd size, yet keep costs low by not investing in related infrastructure. This approach may be counterproductive to the overall performance of the farm, as there is a growing body of evidence that suggests there are negative consequences on lactating dairy cows that are required to compete for resting and feeding resources. This presentation reviews the current understanding of: 1) the relationships among overstocking, behavior, health, and productivity; 2) the behavioral strategies that dairy cows use to mitigate the effects of overcrowding and potential consequences of these strategies on health and productivity; 3) factors that are spe-

cific to the Southeast that may impact the relationship among stocking density and other considerations of housing management; and 4) current gaps in our knowledge that should be addressed with future research. Overall, the behavioral changes that were evident in overstocked freestall-based housing facilities included a decrease in the number of hours spent lying per day, an alteration of the feeding times and overall time spent feeding, and increased antagonistic behaviors occurring at the freestalls and feed barriers. From a performance perspective, there were indications that both milk production and reproductive success might be altered by overstocking either the freestalls or feed barriers of a housing facility. The hot, humid summers, which typify the region, and the age, design, and management of freestall facilities represent 2 factors with the potential to compound the overall impact of overcrowding in the Southeast. On the other hand, the commonality of pasture access in the overall housing strategy across the region might mitigate some of the negative effects of overstocking on lactating cows. The extent to which these interactions are detrimental or successful when associated with overstocking reflects a major gap in our current understanding of managing dairy housing systems in the Southeast. Beyond freestall-based housing facilities, there is a growing interest in the use of composted bedding pack housing in the region. However, there is little empirical data to support recommendations for the space required per cow within these housing systems.

Key Words: behavior, dairy cow, housing, overstocking

0009 Managing heat stress in dairy calves and heifers: Housing considerations. S. H. Ward*, *Mississippi State University, Mississippi State.*

Dairy calves and heifers are often overlooked when considering not only cooling strategies but housing in general. Providing housing with cooling in the summer for both young calves and older heifers could improve growth, subsequent lactation performance, and profitability for the dairy operation. While hutches for dairy calves have become fairly standard throughout the industry, providing a source of shade over the hutches has been shown to improve respiration rates and reduce skin temperature of calves (Spain and Spiers, 1996). Coleman et al. (1995) found a tendency for improved feed efficiency when calves were housed in shaded hutches, along with lower rectal temperatures. Calves that were housed under metal roofing, with and without cooling, had lower temperatures, increased IgG, and lower mortality rates compared with those housed in hutches (with metal covers). Providing a source of shade over hutches during prolonged heat stress can improve calf performance, but cooling the shaded area may not result in further improvements. Similar trends have been noted in older heifers housed on pasture with different shade sources. Twenty-one yearling, Holstein heifers (n = 7) were assigned to 1 of 3 paddocks, each with a different type of shade: 1) natural shade from trees (T); 2) hutches (H); and 3) shade cloth (SC). All heifers were fed a commercial grain mix and ryegrass hay, and grazed a grass-legume mix pasture. Body weight, frame measures, rectal temperatures, and blood samples were collected once per week. Heifer behavior was observed twice weekly for a total of 24 h. There was a tendency for decreased body weights in heifers housed under SC, but ADG, wither height, or hip height were not affected by shade type. Blood parameters were not affected by shade type. Time spent in the shade vs. not was also not different with shade type, but time spent lying was greater in both T and SC when compared with H ($P < 0.05$). Temperature was also lower in T and SC compared with H, which may have contributed to decreased time lying down.

Key Words: dairy heifers, heat stress, housing

0010 Compost bedded pack barns as a lactating cow housing system for the Southeast. J. M. Bewley*[1], R. A. Black[2], F. A. Damasceno[3], E. A. Eckelkamp[1], G. B. Day[1], and J. L. Taraba[1], *[1]University of Kentucky, Lexington, [2]University of Tennessee, Knoxville, Federal University of Mato Grosso, Campus Rondonópolis, Brazil.*

A compost bedded pack barn is a lactating dairy cow housing system consisting of a large, open resting area, usually bedded with sawdust or dry, fine wood shavings. Bedding material is composted in place, along with manure, when mechanically stirred on a regular basis. Recently, the popularity of compost bedded pack barns has unquestionably increased in the Southeast (at least 80 compost bedded pack barns have been constructed in Kentucky). Because of warm climates, the compost bedded pack barn fits the Southeast particularly well. Galama (2011) suggested that compost bedded pack barns fit within goals of sustainable agriculture because of benefits to the cow (space, rest, exercise, and social interaction), farmer (low investment, labor extensive, reduced manure storage costs), and environment (reduced ammonia and greenhouse gas emissions, odor and dust emissions, reduced energy consumption). Producers report reduced incidence of lameness and improved hoof health, resulting from greater lying times and a softer, drier surface for standing. Cows may be more likely to exhibit signs of estrus because of improved footing on a softer surface, leading to improved heat detection rates. Compost bedded pack barns reduce the need for liquid-based manure storage systems and provide producers with the option to economically transport nutrients in a dry, concentrated form to areas where there is an off-farm demand for nutrients. The initial investment costs of a compost bedded pack barn are lower than for traditional freestall or tiestall barns, because less concrete and fewer internal structures (stall loops, mattresses) are needed. This system represents a viable entry option for smaller, start-up dairies. Proper composting increases the bedding temperature and decreases the bedding moisture by increasing the drying rate. Keeping the top layer of bedding material dry is the most important part of

managing a compost bedded pack barn. The pack should be stirred at least twice daily. Stirring is typically accomplished while the cows are being milked, using various types of cultivators or roto-tillers. Poor management may lead to undesirable compost bed conditions, dirty cows, elevated SCC, and increased clinical mastitis incidence. Proper management of compost bedded pack barns includes facility design, ventilation, timely addition of fresh, dry bedding, frequent and deep stirring, and avoidance of overcrowding.

Key Words: cow comfort, compost bedded pack, housing,

ADSA-ASAS NORTHEAST SECTION SYMPOSIUM: **OPPORTUNITIES TO MEET CHANGING CONSUMER PREFERENCES FOR ANIMAL PRODUCTS**

0011 The science and art of cheesemaking.
K. E. Kaylegian*, *Pennsylvania State University, University Park.*

Without a doubt, the interest in cheese is growing. From a total volume perspective, the increase in the use of cheese in foodservice and fast food is good for the dairy industry. However, the more interesting story is the explosive growth in specialty and artisanal cheeses. The American public is becoming more focused on connecting with the manufacturers of their foods. This is illustrated by the increase in popularity of local farmers' markets and the Buy Fresh Buy Local organization that now has chapters in 24 states. Consumers are adventurous and always looking for new flavors, shapes, and varieties of cheese. The dairy industry is quite responsive to this opportunity, seeing these value-added products as a way to stay viable in an industry that is relatively saturated in the fluid milk market. Artisanal cheeses are produced on levels from large, multi-plant operations to 1-person farmstead operations, making cheese only using their farm's milk. Artisanal cheeses are marketed in many different outlets. Some cheesemakers choose to sell more common types of cheese, like plain and flavored varieties of Cheddar, Colby and Jack for their local markets, whereas others choose to make unique cheeses destined for restaurants or high-end cheese shops. There are legal constraints regarding standards of identity and raw milk cheese aging requirements that must be followed. Beyond these, the world of cheese offers an empty canvas for the cheesemaker's creativity. Cheesemakers have an amazing palette of bacteria, yeasts, and molds to choose from to develop unique cheeses that complement their milk, the seasons, their geographical location, their values, and their passions. Milk from cow, goats, sheep, and water buffalo are used to make cheese, further expanding the varieties of cheese that can be created. Understanding how to combine these variables to make a high quality, consistent cheese requires an understanding of the science behind the cheesemaking process. The growth in cheese varieties is measured by the number of entries in cheese competitions. The first American Cheese Society Competition in 1985 had 89 cheeses in 7 categories; in 2003 there were 762 cheeses; and in 2013 there were > 1700 cheeses entered in ~80 categories. The interest in cheese is definitely growing.

Key Words: artisan cheese, value-added

0012 The 'Greek yogurt effect:' Impact on milk production and the dairy industry in New York.
A. Novakovic*, *Cornell University, Ithaca, NY.*

The production of Greek yogurt has nearly quadrupled from 2008 to 2013 in New York. In the last decade, Greek yogurt has gone from being a relatively obscure product imported from Greece to New York City to an exciting new product that is transforming the retail dairy case, spinning off a host of new products and capturing the imaginations of consumers around the country. Long a significant player in the yogurt category, New York rapidly moved to become the dominant player in the Greek yogurt segment and is now the leading manufacturer of yogurt in the United States. The large farm milk production sector in New York is an important factor in the development of this product segment, but the proximity of this large production area relative to the demographically large, rich, and diverse population centers of the northern Atlantic Coast is even more important. The new Greek yogurt category has strong appeal and should be a durable feature in U.S. dairy markets, but this is not without challenges. New York's role in this burgeoning sector is likely to be durable as well, but it will surely see increased competition as processors expand product lines and develop markets. The development of this new product category has had a positive impact on dairy sector sales and revenue, but the impact is small when measured against the total dairy sector. There are significant impacts for local communities in which new plants are located and meaningful benefits to nearby farmers who are able to supply those plants instead of more distant customers.

Key Words: dairy demand, dairy products, Greek yogurt, milk markets, milk prices, milk production, New York, yogurt

0013 New approaches to low-fat meat products to better meet consumer demands.
E. W. Mills*, *Penn State University, University Park.*

Reduced fat meat products have received a great deal of consumer interest for several years. Livestock producers and meat processors work together to provide products that satisfy consumers' desire for products with low fat, low saturated fat, and low trans-fat, among others. The techniques for fat reduction in meat products are more important now than ever. The biggest challenge has always been maintaining desirable texture, flavor, and juiciness in reduced fat meat products. Options available for ensuring palatability of reduced fat products focus mostly on replacement of fat with 1 or more ingredients that mimic the actions of fat. Water is commonly utilized for fat replacement because it imparts juiciness at a very low cost. Various ingredients may be included to bind water in the product or provide a more oil-like mouth feel. Whole muscle cuts pose different challenges than comminuted products when fat is reduced. In whole muscle cuts, water containing

a small amount of salt, water binding agent, and flavorings is often injected to improve juiciness of the cooked product. In this context, the ingredients should be fully soluble or easily suspended, and generally must not impart detectable color to the product. Processors and suppliers are constantly trying new label-friendly ingredients that may provide the functions of water binding, texture modification, or flavoring. Natural plant extracts, including hydrocolloids, carbohydrates, and proteins, may be used. Comminuted products offer a different set of challenges and opportunities. Ingredients utilized in these products need not be soluble because they will be incorporated by mixing. Also, their visible presence may make a desirable contribution to the product's appearance. This is especially true in situations where products are made to suit a particular ethnic or regional consumer preference. A coarse texture or distinctive particles of seasoning are often used to establish the character of a niche product. One of the biggest challenges in formulating reduced fat meat products is flavor delivery. In conventional products, fat serves as a carrier for hydrophobic flavor compounds. In low fat products, the absence of a hydrophobic delivery system means that some flavor compounds are not detected. It may be necessary to use different forms of seasonings to improve seasoning flavor. With continued consumer interest in lower fat foods, it is imperative that meat producers and processors use the best technology available to provide those products.

Key Words: fat replacer, low fat, meat

014 Dairy Fats: The good, the bad, and the ugly. H. Potts*, B. A. Corl, and D. R. Winston, *Virginia Tech, Blacksburg.*

Consumers have a misinformed, negative perspective of dairy products because of their fat content, specifically the "bad" saturated fats and "ugly" trans fatty acids. However, dairy fats also contain a valuable "good" fat that does not show up on a nutrient label: conjugated linoleic acids (CLA). Conjugated linoleic acids are biologically active isomers of linoleic acids, a type of trans fatty acid, which have been studied for their possible health benefits. The 2 most abundant CLA isomers are the cis-9, trans-11 isomer and trans-10, cis-12 isomer, and are found in significant concentrations in high fat dairy products, such as full-fat milk, cheese, and butter. Research began when the anti-carcinogenic properties of CLA were discovered. Then, it was looked at as a possible weight loss mechanism and more recently the research has focused on CLA's possible effects in preventing cardiovascular disease. Animal and human studies on CLA's effects related to major components of cardiovascular health, including heart disease, cholesterol levels, and high blood pressure, have shown that consumption of high levels of CLA can lead to a decrease in many cardiovascular risk factors. Pintus et al. showed that a dietary intervention of CLA-enriched cheese lowered LDL cholesterol by 7% in 42 adult volunteers. Further studies demonstrated that CLA consumption was nearly as effective in humans as taking certain hypertension drugs. However, current CLA intake in different countries shows that consumers are only eating minor amounts of CLA. Current negative consumer perspectives on dairy fats need to be changed so consumers will include these beneficial dairy fats in their diets at levels high enough to receive cardiovascular health benefits. The main way to accomplish this is through educating the American consumer on where to find these "good" dairy fats and how to get their associated health benefits. The best consumer education will be accomplished through media advertisements and including information regarding CLA on dairy product labels and packaging.

Key Words: cardiovascular health, conjugated linoleic acid, fats

0015 Differences in bovine and caprine cheese production. K. Wolf* and J. M. Bewley, *University of Kentucky, Lexington.*

The dairy goat cheese market is the primary milk-based income source for dairy goat producers. Efficient cheese production is more challenging with goat milk than cow milk. These challenges arise from structural and molecular characteristics unique to goat milk. Goat milk has a lower pH than cow milk, which results in differences in the acidification process for initializing curd formation. Another factor is the smaller fat globules of goat milk, which result in a natural homogenization effect and greater difficulty in separating smaller particles. Less particle separation results in lower cheese yields. Possibly the most significant difference is seen in the α S1-casein frequencies across the goat population when compared with the cow population. Casein is the major protein in milk and is essential for cheese production. The primary casein subclasses are α and β caseins. In cow milk, the α caseins are more prevalent than any others, whereas in goat milk β caseins are more typically observed. Alpha S1-casein, in particular, is associated with higher solids non-fat content than any other casein class, but it is among the least common goat milk proteins. This means lower cheese yield because the most important cheese protein is not the most prevalent in goat milk. Presence and frequency of α S1-casein is primarily genetic with 17 alleles identified. Further variation in α S1-casein expression exists among dairy goat breeds, with the Swiss breeds expressing the weakest α S1-casein alleles compared with African and American breeds, which have a higher α S1-casein frequency. The breed relationships to cheese proteins suggest that the first step in achieving good cheese yields is selecting goats of the correct breeds. Additional problems to be combatted are the higher SCC seen in goats compared with cows, reducing curd formation ability, and a greater variation in diet with most goat herds compared with cow herds, which can cause inconsistent yields, textures, and flavors. Cheese recipes can be modified to optimize yield from goat milk by adding more rennet, using less starter, and maintaining a lower temperature during the cheesemaking process.

Key Words: α S1-casein, cheese, goat

0016 Do current regulations for raw milk cheeses ensure consumer safety? C. T. Redding*, K. H. Ingawa, and S. P. Washburn, *North Carolina State University, Raleigh.*

Raw milk cheeses are made from milk that is not pasteurized nor homogenized, and it is currently legal in the United States to sell raw milk cheeses that have been aged for at least 60 d. In some studies, raw milk cheeses have been documented to have more intense flavor than pasteurized cheeses and variations in diets with various pasture species can also affect flavor. In a preference study, 890 consumers sampled Cheddar and Gouda cheeses made from either raw milk or pasteurized milk. A majority of the consumers preferred raw milk cheese, even though many of them either were not sure or had considered raw milk cheeses to be less safe. However, there can be situations in which pathogenic organisms or resulting toxins could survive the aging process. One study investigated 8

pathogens that were intentionally injected into raw milk that was then used to make Swiss hard or semi-hard cheeses. The study showed hard cheeses to be free of inoculated pathogens 1 wk after production. The semi-hard cheeses were free of most pathogens and toxic metabolites, except for *Listeria monocytogenes*, which had survived the manufacturing and ripening processes. A recent study that used milk spiked with various strains of *E. coli* resulted in detection of *E. coli* in almost all cheeses at the end of the 16-wk ripening period, which could be a food safety issue. In contrast to studies in which pathogens were injected into milk, most raw milk produced for small scale artisan cheesemaking in Vermont was of high microbiological quality with no detectable target pathogens in the cheese. Aging for 60 d seems effective for eliminating or reducing most pathogens, but frequent testing to ensure milk is pathogen free before making cheese is recommended.

Key Words: food safety, pathogens, raw milk cheese

0017 Applications for functional dairy starter cultures.

G. G. FitzPatrick* and D. R. Olver, *Pennsylvania State University, University Park.*

Bacteria starter cultures are large numbers of cells of microorganisms that are used to initiate a fermentation process in certain foods, such as cheese, yogurt, butter, sourdough, and fermented meats. Certain bacterial strains can be selected or genetically modified to exhibit functional properties that enhance the foods they help produce. For instance, specific strains of bacteria can be used to combat the growth of *Listeria monocytogenes* and other pathogenic microbes. Maisnier-Patin et al. demonstrated that starter cultures containing nisin-producing subspecies of *Lactococcus lactis* were able to control growth of *Listeria monocytogenes* while maintaining suitable pH for Camembert cheese development. This may have importance in raw milk cheese production. Consumers often prefer the interesting flavors offered by these cheeses but have concerns about the health risks of consuming raw milk products. Additional types of functional bacteria starters have the potential to improve the sensory qualities of cheese. Guldfeldt et al. used genetically modified strains of *Lactococcus lactis* to improve flavor and reduce bitterness in Cheddar cheese. Other functional starters have been used to speed up the maturation process of cheese aging and prevent over acidification in yogurt. Functional starter cultures offer the opportunity to produce wholesome, safe products with enhanced sensory properties and probiotic qualities desired by consumers.

Key Words: cheese, functional starter culture

0018 Dairy cow welfare: Bridging the gap.
E. A. Morabito* and J. M. Bewley, *University of Kentucky, Lexington.*

Most consumers are unaware of dairy production practices and generally rely on information from print, television, and social media to obtain information. Animal welfare is 1 consumer concern that often creates a gap between consumers and dairy producers. Differing values and ethics increase the complexity of animal welfare as an ethical issue. Current dairy welfare research includes objective physiological, behavioral, preference, and motivational research. Objective research observes measureable variables to determine whether the welfare of a dairy cow is compromised. These measures may not be useful indicators of psychology or natural behaviors, but are helpful in other types of welfare research. Cow comfort research examines cow behavior with different facilities and management practices. This research demonstrates how cow comfort is beneficial for welfare and production. Preference research includes observing dairy cow choices among alternative situations. This indicates cow inclinations and helps redefine natural behaviors. Motivational research is similar to preference research where an obstacle is used to get to 1 of the situations. An obstacle could include a physical barrier or longer walk to get to the destination. This demonstrates how motivated a cow is to choose 1 situation over another. All of these current research areas are allowing scientists to understand more about animal behavior and psychology. Knowledge of dairy cow emotions is still lacking and difficult to measure. Animal welfare models have been created to understand the broader definition of welfare. These models go beyond the traditional measures of welfare and include less measureable traits, such as emotions and an animal's need for a natural environment. Before applying these models to improve the definition of animal welfare, research must be conducted to understand more about emotion, psychology, physiology, and natural behavior. Some studies on both lab and livestock species have been conducted to measure emotions. Translating these studies into dairy research may be beneficial in the future. Publicizing information about current and future research is important for public education. Education, along with the implementation of welfare models, may help bridge the gap between consumers and dairy producers. Improving animal welfare will improve dairy cow well-being, public perception, and overall dairy production.

Key Words: dairy, ethics, welfare

0019 The effects of overcrowding on the behavior of lactating dairy cows in freestall housing systems.
S. F. Templeton*, R. A. Black, and P. D. Krawczel, *University of Tennessee, Knoxville.*

Overcrowding is commonly seen among freestall dairy operations to increase herd size without altering facilities. Overcrowding occurs at stocking densities > 100%. Overcrowding at the feedbunk is defined as > 1 cow per headlock or < 0.6 m of linear feedbunk space per cow. Overcrowding at the resting space is defined as providing < 1 stall per cow. At maximum capacity, 48.5% of freestall farms in the United States provided < 1 stall and 67.9% provided < 0.6 m of feedbunk space per animal (USDA, 2010). These crowded environments interfere with time budgets of cows by disrupting lying and feeding behaviors. A normal behavior time budget for a lactating dairy cow includes 3 to 5 h of eating per day (Grant & Albright, 2001). As stocking density increased, time cows spent feeding decreased, whereas feeding rate increased. This may alter intake during these feeding bouts. Increased feeding rate may increase the risk for ruminal acidosis and displaced abomasums after calving. Aggressive interactions among animals resulting in displacements from the feedbunk also occur more frequently in overcrowded pens (DeVries et al., 2004). Providing 0.5 m of feeding space as opposed to 0.1 m of feeding space resulted in 60% less space between animals and 57% more aggressive interactions while feeding. Subordinate animals are most affected, as they will often be displaced from the bunk by a dominant animal. Feed quality tends to decline throughout the day as TMR is sorted and submissive cows will ultimately consume a poorer quality diet after waiting for feedbunk access. A typical lactating dairy cow will rest for 12 to 14 h/d to meet her daily time budget (Grant & Albright, 2001). Cows prioritize rest and will choose to rest rather than eat when both lying time and feeding time are limited (Munksgaard et al., 2005). At stocking densities of 150%, cows spent 1.7 h/d less lying relative to those housed at 100% (Fregonosi et al., 2007). These data may help explain the positive relationship between milk production and freestall availability described by Bach et al. (2008). Krawczel et al. (2008) reported average time standing idly in the alley also increases at stocking densities > 110%, which is associated with an increased risk for lameness.

Key Words: freestalls, overcrowding, stocking density

0020 A Polled Future.
M. Richard*[1] and C. C. Williams[2], *[1]Louisiana State University, Baton Rouge, [2]Louisiana State University AgCenter, Baton Rouge.*

The horn is an adaptation of the skin, characterized by hardened keratin in the epidermis. Dairy cattle have used their horns as a defense mechanism since the beginning of their existence. However, since dairy cattle no longer need to ward off predators in the wild, their horns do not serve a purpose. Addi-

tionally, horns can cause injury to handlers and other cows in the herd. Thus, disbudding or dehorning is necessary to lower risk associated with the horns of dairy cattle. Disbudding and dehorning techniques differ; however, they both have disadvantages associated with the procedure relating to cost, health, and animal welfare. The solution presents itself in polled genetics. Animals born without horns carry 1 or 2 polled alleles. German researchers found that this genetic marker was associated with certain mutations, such as a hairy eyelid. Since the polled gene is dominant, genetic selection can improve rapidly. An animal with 2 polled alleles will produce 100% polled offspring, whereas an animal with only 1 polled allele will still have 50% of its offspring polled. Polled genetics are also more cost efficient than dehorning, as a farmer can spend an additional $7.50 for polled genetics. Other advantages of polled genetics include eliminating the risk of infection and reduced labor required. However, limited genetic selection is a major reason dairy farmers are hesitant to embrace polled genetics. Although still a minority, polled dairy cattle are increasing in generic merit and polled bulls are beginning to rank in the top of genetic evaluations. In conclusion, using polled genetics provided a more cost efficient and less labor intensive alternative to traditional dehorning methods.

Key Words: dairy cattle, polled genetics

0021 The future role of metabolomics in dairy science.
A. E. Kraus*, K. J. Harvatine, and D. R. Olver, *Pennsylvania State University, University Park.*

Metabolomics is an emerging field used to investigate chemical fingerprints left behind by biological and pathological processes. Although research in this discipline far predates its modern name, metabolomics studies are now conducted in a more global, non-targeted manner because of technological advancements. Metabolites in tissues and biofluids are identified using chromatography coupled with mass spectrometry platforms. Metabolites can then be identified by matching their unique masses and fragmentation patterns with standards in metabolome databases. Changes in metabolite fingerprints can differentiate between healthy cows and those with subacute diseases. For example, the metabolites in rumen fluid and milk can be used to gain insight into the mechanisms behind subacute diseases such as acidosis, ketosis, and mastitis. By examining these global changes in metabolite expression, researchers can investigate perturbations to biochemical pathways and eventually use these novel biomarkers to develop metabolite monitoring systems. An increasing number of metabolomics studies are being conducted to better understand the health-disease continuum in humans and model organisms. However, the potential for this tool in dairy science research remains largely unrealized as endogenous and exogenous metabolites continue to be characterized. Recent investigations published in the *Journal of Dairy Science* demonstrate the potential for metabolomics to help increase feed efficiency and reduce production losses in the dairy industry. In the future, metabolomics will be influential in revealing the complex mechanisms behind costly subacute metabolic disorders and pathogen-induced diseases in dairy cattle.

Key Words: mass spectrometry, metabolomics, subacute disease

0022 Polled genetics: Benefits, detriments, and identification of polled dairy cattle.
A. L. Patch*, R. R. Cockrum, and D. R. Winston, *Virginia Polytechnic Institute, State University, Blacksburg.*

The polled trait demonstrates autosomal complete dominance that results in horn growth suppression. Selection for polled cattle has become increasingly popular and can be identified phenotypically by observation and/or genotypically through genomic testing. Dairy cattle are classified with 3 identifiers: observed polled (PO), heterozygous polled (P), and homozygous polled (PP). Observed polled cattle are visually identified by the producer, whereas genomic testing requires analysis of the DNA. Animals identified through genotyping can be determined with a high density SNP chip. A genome-wide association analysis in beef and dairy cattle revealed a 1 Mb region within chromosome 1 associated ($P \leq 0.002$) with P and PP. Further analyses determined a SNP (AC000158:G1390292G > A) located within intron 3 of Interferon γ receptor 2 gene (IFNGR2) and an immune gene was co-segregated with polled in Holsteins. The SNP, AC000158:G1390292G > A, can be used as a genetic marker when testing for polled in dairy cattle. The benefits of polled cattle include: increased docility, decreased labor requirements, improved public perception, and eliminating the necessity of dehorning the animal. Polled genetics allow the producer to realize a profit of $7.50/animal. Conversely, the disadvantages of selecting for polled genetics include: decreased genomic total production index (GTPI), reduced net merit value (NM$), and an increased risk of inbreeding, due to a smaller available gene pool. One possible solution to incorporate polled genetics into the herd is to breed for heterozygous polled cattle by crossing genetically superior cows with polled bulls or breeding polled cows with superior bulls.

Key Words: dairy cattle, polled, single nucleotide polymorphism

---

0023 Crossbreeding—Is it a good option?
R. J. Yarbrough* and S. Washburn, *North Carolina State University, Raleigh.*

Long-term selection of dairy cattle for increased production has resulted in a decline in various functional traits, including reduced fertility, as well as concerns about soundness of feet and legs, resistance to disease, and overall shorter productive life. Some of those effects may be related to increased inbreeding and others due to unfavorable correlations of production traits to fitness traits. Crossbreeding is 1 way to

eliminate inbreeding and bring heterosis into a herd, which could result in improved functional traits in that herd. There has been renewed interest in crossbreeding worldwide with use of both traditional and non-traditional dairy breeds. Some studies have documented up to a 10% economic gain in the F_1 crosses. Holstein and Jersey crosses are popular, due to the commonality of these 2 breeds. Those crosses generally have advantages in fertility, calving ease, neonatal survival, maintenance of body condition score, and are still competitive for milk yield and milk components. Holsteins have a higher milk yield, but Holstein × Jersey crosses produce milk with higher fat and protein content. Across time, 2-breed crosses maintain 67% of the heterosis of the original F_1, whereas 3-breed crosses maintain ~86% of the initial heterosis. Cows that have lower fertility or lack functionality otherwise lead to lost revenue, greater cow turnover, and simply do not last long term on a farm. Selection for improved fitness within breed is a good approach, but crossbreeding may also be a strategy to improve the bottom line in some herds.

Key Words: functionality, heterosis, inbreeding

ADSA-SAD UNDERGRADUATE STUDENT PAPER COMPETITION: ADSA-SAD UNDERGRADUATE PRESENTATIONS—ORIGINAL RESEARCH

0024 Weaning age impacts growth, feed intake, and behavioral indicators of stress in Holstein calves fed a high plane of nutrition. H. E. Brown*[1], E. C. Eckert[1], K. E. Leslie[1], T. J. DeVries[1], and M. A. Steele[2], [1]*University of Guelph, ON, Canada,* [2]*Nutreco Canada, Guelph, ON.*

Recent research has revealed the short- and long-term advantages of feeding more nutrients preweaning. Unfortunately, calves that are fed more nutrients preweaning may be more susceptible to depressed growth and weaning stress during the transition from liquid to solid feed. The objective of this study was to investigate the relationship between age of weaning and feed intake, growth, and behavioral indicators in dairy calves fed higher planes of nutrition. To meet this objective, 20 Holstein female calves were randomly assigned at birth to be weaned at 6 or 8 wk. Milk replacer (mixed at 150 g/L) was offered at 1.2kg/calf/d in 2 meals until a 1-wk stepdown, where meals were reduced by 50% 1 wk before weaning. Measurements included daily starter, chopped straw, and water intake, as well as weekly body weight until d 70 of life. Behavioral indicators, including ruminating, lying/standing, vocalizing and non-nutritive oral behavior, were measured by visual observation each minute for 3 h/wk before the second feeding of the day. Data were analyzed using a repeated measures general linear mixed model; comparisons were made by week relative to weaning and week of life. The calves weaned at 8 wk compared with 6 wk had higher ($P < 0.01$) ADG for the week preweaning (0.79 ± 0.09 vs. 0.34 ± 0.10 kg/d) and post weaning (1.05 ± 0.09 vs. 0.35 ± 0.11 kg/day), and were heavier ($P < 0.01$) at the end of the experiment (99.92 ± 1.81 vs. 91.01 ± 2.26 kg). Starter, straw, and water intake were delayed in calves weaned at 8 wk of age. However, their overall starter intakes and growth rates were not different during the last week of the experiment. Furthermore, calves weaned at 8 wk compared with 6 wk had higher ($P < 0.01$) starter intake for the week preweaning (1.36 ± 0.13 vs. 0.40 ± 0.08 kg/d) and post weaning (2.51 ± 0.20 vs. 1.16 ± 0.15 kg/day). Treatment × week relative to weaning interactions indicated that several behaviors varied between early- and later-weaned calves during the week before weaning; 6-wk calves tended ($P = 0.07$) to exhibit 75% more non-nutritive oral behavior, spent 55% less ($P < 0.01$) time ruminating, and 36% less ($P = 0.01$) time lying than 8-wk calves. These results suggest that calves fed higher planes of nutrition preweaning benefit from extending weaning age from 6 to 8 wk of age.

Key Words: age, calves, weaning

0025 Effects of AICAR, rapamycin, and non-essential amino acids on cell signaling in bovine mammary tissue. A. Felock*, S. I. Arriola Apelo, R. L. Garnett, and M. D. Hanigan, *Virginia Polytechnic Institute and State University, Blacksburg.*

Studies in animal and cell culture models have revealed that essential amino acids play a role in regulating protein synthesis not only as substrates but also through direct signaling to the protein synthetic machinery. Essential AA affect the mammalian target of rapamycin- (mTOR) signaling pathway in bovine mammary cells, which is associated with increased milk protein synthesis. Three experiments were conducted to study the effect of AICAR, an activator of AMP kinase, rapamycin, a mTOR complex 1 inhibitor, and non-essential AA on mTOR signaling in mammary tissue. Three Holstein cows in late lactation were slaughtered and mammary tissue was collected from uninfected rear quarters. Tissue slices (120 ± 30 mg) were incubated for 4 h in the respective treatment medium. In the first experiment, treatments consisted of complete Dulbeco Modified Eagle Medium (DMEM) or DMEM with essential AA (EAA) at 5% of regular concentrations, and AICAR at 0, 0.4, or 4.0 mM. The second experiment consisted of the same EAA treatments supplemented with rapamycin at 0, 0.5, and 10 μM. In the third experiment, tissue slices from 2 cows were incubated in minimum essential medium supplemented with 4.5 g glucose,10 μg insulin, and per liter of media. The AA examined were Ala, Asx, Glx, Gly, Pro, and Ser, where Asx represented Asn plus Asp, and Glx represented Glu plus Gln. Phosphorylated and total forms of mTOR, eukaryotic elongation factor 2, and ribosomal protein S6 were determined by Western blotting and the ratio of phosphorylated to total ratio was calculated. Essential AA had no effect on signaling proteins in either experiment. The AICAR significantly reduced mTOR phosphorylation but had no effect on phosphorylation of eEF2 or rpS6. Rapamycin did not affect phosphorylation of mTOR or eEF2. However, rapamycin significantly reduced rpS6 phosphorylation. Non-essential AA had no effect on phosphorylation of signaling proteins in the mTOR pathway. There was no effect of EAA on protein synthesis rates, implying that there are other causes regulating synthesis rates besides cell signaling.

Key Words: AICAR, mTOR, rapamycin

0026 Within day alteration of ration starch fermentability had no effect on feed intake, total tract NDF digestibility, and milk fat concentration of cows in late lactation. B. C. Oglesby* and M. S. Allen, *Michigan State University, East Lansing.*

The objective of this experiment was to evaluate the effects of feeding lactating cows diets differing in starch fermentability twice per day on DMI, total tract NDF digestibility, and milk fat concentration. Feeding highly fermentable starch sources

to ruminants is expected to increase short-chain fatty acid production by rumen microbes, increase the flux of propionate to the liver during meals, and potentially decrease ruminal pH, NDF digestibility, and milk fat concentration. Diurnal variation in feeding results in lower digesta mass and rumen buffering, and increased plasma NEFA and hepatic acetyl CoA concentrations before the morning feeding. We previously reported that propionic acid is more hypophagic when hepatic acetyl CoA concentration is elevated. Therefore, we hypothesized that the negative effects of greater starch fermentability would be more pronounced following the morning feeding compared with the evening feeding. Sixteen multiparous cows (291 ± 68 DIM; mean ± SD) were used in a crossover design experiment with 14-d periods, including 10 d for diet adjustment and 4 d for sample collection. Cows were offered diets containing either dry corn grain (DC, less fermentable) or high (33%) moisture corn grain (HM, more fermentable), at 0900 h and 1700 h each day in opposite sequences: 1) HM at 0900 h, DC at 1700 h, and 2) DC at 0900 h, HM at 1700 h. Sequence DC:HM tended to increase the amount of DMI following the morning feeding (10.6 vs. 9.7 kg, $P = 0.07$) and decrease DMI following the afternoon feeding (14.4 vs. 15.4 kg, $P = 0.08$), compared with HM:DC, resulting in no overall effect of treatment ($P > 0.15$). Treatment did not affect digestibility of NDF or DM, or yields of milk, fat, protein, lactose, or milk composition. Sequence DC:HM tended to decrease BW (776 vs. 771 kg, $P < 0.10$) but not BCS compared with HM:DC. Lack of treatment effects on digestibility of NDF and concentration of milk fat indicate that the buffering capacity of rumen contents was likely adequate to maintain ruminal pH during the morning when digesta mass is normally lowest. Opposite effects of treatment on DMI following the morning and afternoon feedings suggest that HM tended to decrease DMI compared with DC similarly at each feeding. These results indicate that potential advantages to altering ruminal starch fermentability within a day are minimal for late lactation cows.

Key Words: diurnal variation, feeding management, starch fermentability

---

0027 Growth of periruminant Holstein bull calves fed a fermentation extract of *Aspergillus oryzae*.

E. M. Dudash*, T. T. Yohe, R. M. Townsley, Y. Roman Garcia, A. R. Gibson, K. M. O'Diam, and K. M. Daniels, *Department of Animal Sciences, The Ohio State University, Wooster.*

A fermentation extract of the fungus *Aspergillus oryzae* can be used as a direct fed microbial. The objective was to determine if dietary inclusion of an extract of *A. oryzae* would improve the growth of Holstein bull calves from birth through 1 wk postweaning; it was hypothesized that it would. Bull calves ($n = 52$) were used in this experiment. Calves were randomly assigned to a slaughter age, 4 wk ($n = 16$) or 8 wk ($n = 36$), and treatment, control (CON; $n = 27$) or direct fed microbial (DFM; $n = 25$). Calves averaged 43.2 ± 1.0 kg BW and 2.8 ± 0.3 d of age at the beginning of the experiment. Calves were housed and fed individually; no bedding was used. Calves assigned to DFM were fed 2 g of DFM daily. Liquid DFM was delivered in milk replacer for the first 4 wk of the trial; solid DFM was top dressed on texturized grain thereafter. Calves were fed non-medicated milk replacer twice daily (22.0% CP, 20.0% fat DM basis; 680 g/d) and were weaned on consumption of 0.91 kg of grain (20% CP, 2.0% fat; medicated with decoquinate) for 3 consecutive days or on d 45 of the study, whichever came first. Calves had ad libitum access to grain and water throughout the trial. Feed intake was recorded daily. Body weight was recorded weekly. There was no effect of treatment on BW; 8 wk BW was 74.5 ± 1.9 kg for CON and 74.6 ± 1.9 kg for DFM. Total DMI per calf did not differ: from 0 through 4 wk (19.48 ± 0.67 kg of DM), 5 through 8 wk (39.44 ± 2.05 kg of DM), or for the whole trial (58.70 ± 3.30 kg of DM). Lastly, the gain to feed ratio did not differ by treatment: from 0 through 4 wk (0.59 ± 0.05), 5 through 8 wk (0.53 ± 0.03), or for the whole trial (0.56 ± 0.04). Here, dietary inclusion (2 g/d) of an extract of *A. oryzae* did not result in improved calf growth when supplemented animals were compared with cohorts not fed the direct fed microbial. It is possible that the dose used here was not high enough to elicit treatment effects. Given that effects have been noted in other species, a follow-up dose titration study with similar diets as used here seems warranted.

Key Words: dairy calf, direct fed microbial, growth, nutrition

0028 [Withdrawn]

0029 Case study: Effect of alley floor scraping frequency on environmental mastitis-causing pathogen counts.

J. L. Lowe*, K. A. Akers, A. E. Sterrett, J. D. Clark, and J. M. Bewley, *University of Kentucky, Lexington.*

The objective of this case study, conducted at the University of Kentucky Coldstream Dairy from 21 August 2013 to 29 September 2013, was to determine if increased alley scraping frequency decreased teat end and milk environmental mastitis-causing pathogen counts (EMC). Sixteen Holstein cows were monitored during two, 3-wk treatments; removing manure from the alley floors once (1X) or twice (2X) daily. Milk and teat end swab samples were collected twice weekly to observe changes in EMC and somatic cell score (SCS). The GLM procedure of SAS (SAS Institute, Inc., Cary, NC) was used to evaluate fixed effects of treatment, parity group (1 or ≥ 2), and days in milk group (≤ 150 or > 150), and their interactions on teat end and milk *Escherichia coli*, total coliform, *Klebsiella* spp., and streptococci counts, with cow as subject. Stepwise backward elimination was used to remove

nonsignificant interactions ($P \geq 0.05$) and all main effects were kept in each model, regardless of significance level. The CORR procedure of SAS was used to evaluate the correlations between all study variables. The least squares means (± SE) indicated increased scraping frequency decreased milk sample total coliform count from 0.30 to 0.05 ± 0.09 $\log_{10}$ cfu/g ($P < 0.05$). Likewise, teat end total coliform, *E. coli*, and streptococci counts decreased between 1X and 2X; 2.11 to 1.56 ± 0.14 $\log_{10}$ cfu/g, 1.86 to 1.30 ± 0.14 $\log_{10}$ cfu/g, and 5.06 to 4.10 ± 0.19 $\log_{10}$ cfu/g, respectively ($P < 0.01$). Increased scraping frequency did not significantly affect SCS, milk *E. coli,* streptococci, and *Klebsiella* spp. counts, or teat end *Klebsiella* spp. counts ($P > 0.05$). Teat end total coliform and streptococci counts were moderately correlated with the same bacteria counts within the milk ($r = 0.53$, $P < 0.01$ for both species). Milk streptococci counts were moderately correlated with SCS ($r = 0.40$, $P < 0.05$). Because increased scraping frequency decreased EMC, which could reduce intramammary infection risk, this practice could reduce mastitis caused by environmental mastitis-causing pathogens.

Key Words: environmental mastitis, pathogen counts, scraping frequency

0030 Dry matter intake and efficiency in lactating Holstein cows grouped by direct genomic values for feed utilization.

I. W. Haagen* and C. D. Dechow, *Pennsylvania State University, University Park.*

Feed costs represent the largest expense for lactating dairy cows, yet the dairy industry does not currently select directly for feed efficiency. The purpose of this study was to observe how accurately genomic predictions of feed utilization developed from a small reference population could predict feed utilization in lactating Holsteins. Feed intake data were collected from 970 Holstein cows across 11 commercial Pennsylvania herds. Genetic evaluations of 4 feed utilization traits were conducted: DMI, dry matter efficiency (DME; energy corrected milk/DMI), crude protein efficiency (CPE; protein yield protein intake), and residual feed intake (RFI). A genome-wide association study was performed using 45,138 SNP genotypes from 340 cows with the e-BIGS program (http://bigs.ansci.iastate.edu) and SNP associations were used to generate direct genomic values (DGV) of feed utilization. Cows were subsequently separated into feed utilization groups, with pen milk yield and feed intake monitored for 2 wk. High and low DGV groups of 20 cows for each of the 4 feed utilization traits were observed at Penn State, whereas cows from a commercial dairy farm were divided into high, medium, and low DGV groups of 51 cows for DMI and 68 cows for DME. Mixed models were used to evaluate differences in feed utilization between high, medium (commercial herd only), and low DGV groups, and included DGV group, a random effect for date, and random error. The high DMI group consumed 10.8 kg more dry matter per day ($P < 0.01$) than the low DMI group at Penn State. Likewise, the high CPE group produced 0.04 kg more protein per kilogram of protein intake ($P < 0.05$). The high DME group tended ($P < 0.10$) to produce more milk (+0.17 kg) per kilogram of intake than the low group. Differences among high and low RFI groups were opposite of expectations, with the low group consuming significantly more dry matter than predicted ($P < 0.01$), based on milk yield and body weight, compared with the high group. Differences in DMI ($P = 0.36$) and DME ($P = 0.14$) were not significant among groups on the commercial dairy farm. This research demonstrated that it is feasible to apply genomic predictions of feed utilization developed from a reference population to select for improved efficiency in commercial dairy herds. However, not all the predictions were as expected and a larger reference population is required to increase prediction accuracy.

Key Words: feed efficiency, genomics

0031 Can prior subjection to pre-heating enhance the heat tolerance of mesophilic bacterial cultures?

R. E. Brown*[1] and K. J. Aryana[2], [1]*Louisiana State University, Baton Rouge,* [2]*Louisiana State University Agricultural Center, Baton Rouge.*

The enhancement of heat tolerance of mesophilic bacterial cultures is important for withstanding the elevated temperatures in the development of probiotic processed cheeses. The objective was to determine whether prior subjection to preheating would enhance heat tolerance of mesophilic cultures. *Lactococcus lactis* ssp. *lactis* and *Lactococcus lactis* ssp. *cremoris* were suspended in a 0.1% peptone and exposed to the preheat temperatures of 30°C, 40°C, 50°C, 60°C, 70°C, or 80°C for 1, 5, or 10 min. The cultures were then grown in M17 broth at 32°C for 72 h. After the first generation of growth, the cultures were then subjected to the same preheat temperature and time, and then grown in M17 broth at 32°C for 72 h. The second generation was also subjected to the same preheat temperature and time, and grown in M17 broth at 32°C for 72 h. After 3 generations of growth, the cultures were then subjected to the challenge conditions of 95°C for 5 min. The control cultures were exposed to the challenge conditions without the subjection to any of the preheat temperatures and times. The cultures were plated in M17 agar and allowed to incubate aerobically at 32°C for 72 h. Three replications were conducted. No growth was obtained when any of the pre heat treated cultures were subjected to the challenge temperature and time conditions. Heat tolerances of mesophilic cultures studied were not enhanced under these conditions.

Key Words: cheese, heat tolerance, mesophilic cultures

ANIMAL BEHAVIOR AND WELL-BEING I

0032 Associations between bovine respiratory disease complex and the probability and latency of group-reared neonatal dairy calves to approach a novel object or stationary person. M. C. Cramer* and A. L. Stanton, *University of Wisconsin-Madison, Madison.*

Bovine respiratory disease complex (BRD) is an important disease that impacts the welfare and performance of dairy calves. With group housing of calves becoming more common, it is imperative to identify behaviors indicative of illness in a socially competitive environment. The objective of this study was to determine associations between BRD status of group-housed dairy calves and their latency to approach a novel object or stationary person. On a commercial dairy in Wisconsin, 75 Holstein preweaned, group-housed heifer calves were tested once a week for 6 wk. The average age of calves on enrollment was 4.1 ± 1.9 d. Calves were housed in 8 pens with an average of 9 ± 1 calves per pen. Each week, all calves in the study were tested for their willingness to approach a novel object (OBJ) and a stationary person (SP) within 60 s. Approach was defined as 1 step in the direction of SP. or OBJ. Pen and test order were randomized. After both OBJ and SP. tests were complete, a standardized health assessment was conducted. The behaviors of calves with clinical signs of BRD were compared with calves with no clinical signs of BRD. All models were controlled for week, pen, pen order, and test order. Associations between probability of approach and BRD status were analyzed, using a linear mixed model with a logit transform (PROC GLIMMIX), controlling for calf as a random effect. Calves without BRD were 2.5 (95% CL: 1.4 to 4.6) and 2.6 times (95% CL: 1.4 to 4.8) as likely to approach than calves without BRD for the SP. ($P < 0.005$) and OBJ tests ($P < 0.005$), respectively. The latency of calves that approached the SP. or OBJ was analyzed using a Cox proportional hazards regression (PROC PHREG). The BRD status did not significantly impact the latency to approach in either test. The median latency to approach was 18 and 9 s for SP. and OBJ tests, respectively. Clinical signs of BRD impacted the probability of approach but did not impact the latency to approach, which indicates that BRD influences the willingness to approach but not the rapidity at which a calf approaches. These findings suggest that approach tests may be used to identify calves with BRD in group housing.

Key Words: behavior, BRD, calves

0033 Effect of concentrate feeder design on feeding behavior in Holstein bulls fed high-concentrate diets. M. Verdu*[1], A. Bach[2], and M. Devant[1], *[1]IRTA-Department Ruminant Production, Caldes Montbui-Barcelona, Spain, [2]Department of Ruminant Production, IRTA, Caldes de Montbui, Spain*

A total of 240 Holstein bulls (121 ± 2.0 kg BW and 99 ± 1.0 d of age), in a replicated factorial study, were randomly allocated in 1 of 6 pens and assigned to 1 of the 3 treatments, according to the feeder design: conventional feeder with 4 feeding spaces (CF), conventional feeder with less concentrate capacity (CFL), and a single-space feeder with lateral protections (SF). Also, each pen had 1 straw feeder and 1 drinker. Each feeder was suspended on 4 load cells that registered continuously contained concentrate weight. Feeding pattern was video recorded for 24 h on d 7, 119 to 120, and 215 to 216 of the study, and was analyzed by continuous scan sampling. Only 12 h (from 0600 to 0018 h) were analyzed as the greatest activity was observed during that time window. Data were analyzed using a mixed-effects model with repeated measures. The percentage of concentrate bunk attendance was greater ($P < 0.01$) in SF (79.3% ± 0.75%) compared with CF and CFL (70.2% ± 0.75%). The number of visits in SF (44.3 ± 17.36) was less ($P < 0.05$) compared with CF and CFL (118.6 ± 17.36). Obviously, the number of bulls at the SF feeder was ($P < 0.01$) 1 and constant throughout the study in contrast with CF and CFL (1.7 ± 0.02), where the number of bulls at the feeder was > 1.5 and decreased with age. No displacements at SF were observed ($P < 0.01$), whereas in the other feeders some displacements at feeder were registered (CF: 2.3 ± 0.51, CFL: 3.4 ± 0.51 displacements/1 h). The percentage of waiting time at the feeder was greater ($P < 0.01$) in SF (13.3 ± 2.18%) than CF and CFL (0.53 ± 2.18%). However, the waiting time at the feeder in SF was reduced ($P < 0.05$) with age. The eating rate increased ($P < 0.05$) with age in all treatments, being greater in CF (205.7 ± 7.84 g/min) than CFL (177.4 ± 7.84 g/min) and SF (151.2 ± 7.84 g/min). In conclusion, the design of the SF, 1 feeding space with lateral barriers, distributes feeder visits throughout the day, decreases displacements at the feeder, and decreases eating rate compared with the conventional feeders. The reduction of concentrate capacity at the feeder increases displacements and decreases concentrate eating rate at the feeder.

Key Words: beef, feeder, feeding behavior

0034 The effect of respiratory disease on lying behavior in Holstein dairy calves. T. L. Ollivett[1], K. E. Leslie[*1], D. V. Nydam[2], T. F. Duffield[1], G. Zobel[3], J. Hewson[1], and D. F. Kelton[4], *[1]University of Guelph, ON, Canada, [2] Department of Population Medicine and Diagnostic Sciences, Cornell University, Ithaca, NY, [3]University of British Columbia, Vancouver, Canada, [4]Department of Population Medicine, Ontario Veterinary College, University of Guelph, Canada.*

The objective of this cohort study was to determine the effect of naturally occurring bovine respiratory disease (BRD) on lying behavior in preweaned Holstein dairy calves. This study was performed on 1 commercial dairy in southwestern Ontario, Canada, during November and December 2012. Calves were enrolled at 10 d of age and were grouped according to vaccination status ($n = 19$ vaccinated and $n = 20$ unvaccinated). Each calf was examined at weekly intervals for signs of BRD before and during the peak 4-wk period when calves are at risk for developing disease. Respiratory scoring (RS) and thoracic ultrasonography (US) were performed at each of the 5 visits. Individual electronic accelerometers recorded lying behavior throughout the 4-wk period. Descriptive statistics and repeated measures linear models were developed using commercially available software. Fever, sickness, and lung consolidation increased from 11%, 3%, and 0%, respectively, at the first examination to 33%, 33%, and 58%, respectively, at the last examination ($P < 0.05$). Overall, calves spent 20.6 ± 0.7 h/d (mean ± SE) or 86% of the day lying down when all variables were set to the referent. Lying time (LT) decreased by 4 ± 1 min/d for each successive day of age. Fever was associated with 44 ± 14 min/d additional LT. Calves housed in group pens had lower but not statistically significant LT than those housed in single pens. Also, housing type confounded the LT estimate for age. Ultrasonographic lung consolidation and health status (RS > 4) were not significantly associated with LT. Lying bout duration (BD) was 72 (61 to 85) min/d (median; IQR) and lying bout frequency (BF) was 16 (13 to 18) bouts per day (median; IQR). Health status and lung consolidation were not significantly associated with BD or BF. Fever numerically increased BD but was not associated with BF. Monitoring LT in preweaned dairy calves might have a place in identifying febrile animals requiring individual examination and possible intervention. Further studies are needed to determine if early identification and treatment of animals experiencing fever improves future health and performance, as compared with traditional methods of disease detection. Lastly, researchers should consider monitoring rectal temperature during behavioral studies to assess for bias due to undetected fevers.

Key Words: accelerometer, dairy calf pneumonia, ultrasonography

0035 Freestall housing during the dry period altered lying time but did not affect milk quality or energy balance compared with pasture. R. A. Black[*1], H. M. Dann[2], and P. D. Krawczel[1], *[1]University of Tennessee, Knoxville, [2]William H. Miner Agricultural Research Institute, Chazy, NY.*

The objective was to determine changes in behavior and performance of cows housed in freestalls or pasture during a 60-d dry period. Non-lactating Holstein cows were assigned to either deep-bedded, sand freestalls ($n = 14$) and grassy pasture ($n = 14$) at stocking densities below industry recommendations using rolling enrollment. At dry off, cows were equipped with an accelerometer to determine daily lying time (h/d), lying bouts (bouts/d), and steps (steps/d). Data were divided into 4 periods relative to calving: FO (d −60 to -15), CU (d -14 to -1), CA (d 0), and PP (d 1 to 14). Cows were scored for BCS (1 = thin, 5 = obese), hygiene (1 = clean, 5 = dirty), locomotion (1 = normal, 5 = severely lame), and weighed 1 wk before dry off, at dry off, at calving, and on d 7 and 14 postpartum. All cows commingled following calving in a pen identical to the freestall housing treatment. Blood samples were analyzed cow side for β-hydroxybutyrate (BHBA) on d 0, 2, 5, 8, 11, and 14. Milk samples collected at the morning milking on d 0, 1, 2, 7, and 14 were analyzed for somatic cell count (SCC), fat, and protein. On d 0, colostrum volume and quality were assessed. Data were analyzed with the MIXED procedure of SAS with model effects for day, treatment, and the interaction of day and treatment. Cows housed in freestalls lay down longer during FO (11.9 ± 0.3 vs. 10.2 ± 0.3 h/d; $P < 0.01$) and CU (12.6 ± 0.3 vs. 10.3 ± 0.3 h/d; $P < 0.01$) periods. Freestall cows had fewer lying bouts during the CA (11.6 ± 0.8 vs. 15.8 ± 0.8 bouts/d; $P < 0.01$) period with no other periods differing. Freestall cows took fewer steps during FO (1844.5 ± 165.1 vs. 2909.4 ± 202.0 steps/d; $P < 0.01$), CU (1714.6 ± 177.0 vs. 2648.8 ± 214.9 steps/d; $P < 0.01$), and CA (2015.8 ± 204.2 vs. 2874.3 ± 245.6 steps/d; $P < 0.01$) periods. Overall, milk fat was greater for freestall cows (4.9% ± 0.2 vs. 4.1% ± 0.2, respectively; $P < 0.01$). Lower locomotion scores tended to be associated with freestall housing compared with pasture (1.4 ± 0.1 vs. 1.8 ± 0.1, respectively; $P = 0.06$). No differences in BHBA, colostrum amount and quality, hygiene, SCC, milk protein, BCS, or weight existed between housing treatments ($P > 0.22$). Freestall-housed cows were less active (fewer steps and greater lying times) throughout the dry period; however, this did not affect colostrum or energy balance postpartum. The more important factor (lying time vs. moderate exercise) needs to be established for improved management of dry cows.

Key Words: behavior, dairy cattle, dry cow housing

0036 Health of dairy calves when using automated feeders in the Midwest United States.
M. Jorgensen*[1], A. Adams Progar[1], S. Godden[1], H. Chester-Jones[2], J. Rushen[3], A. M. de Passille[3], and M. I. Endres[1], *[1]University of Minnesota, St. Paul, [2]University of Minnesota Southern Research and Outreach Center, Waseca, [3]University of British Columbia, Agassiz, Canada.*

Research is limited regarding best housing and management practices for automated calf feeding systems, particularly in terms of how these factors influence animal health and welfare. This ongoing study is characterizing health scores, morbidity, and mortality of group-housed calves on U.S. farms and relating these to housing and management practices. Thirty-eight dairy farms in the Midwest United States were visited every 60 d. During each visit, calves (n = 7779) were scored for health using 4 categories: attitude (0 to 4), ears (0 to 4), nose (0 to 3), eyes (0 to3), and cleanliness (an indicator of diarrhea, 0 to 2), with 0 representing a normal, healthy calf. In addition, blood was drawn from any calves 1- to 5-d old (n = 711) and serum protein concentration was used to assess passive immunity transfer. During each season, milk samples were collected from the mixing container inside the feeder and the tube leading to the nipple for measurement of standard plate count (SPC) and coliform count. Pearson's correlation coefficient was used to analyze the relationship between mean SPC and health scores. There was a large variation among farms in calf health. On the 10 farms with the best health scores, a mean of 9.7% (range of 2.9 to 12.9) of animals displayed abnormal scores for attitude, 3.7% (1.7 to 5.1) for ears, 12.2% (7.8 to 14.8) for nose, 7.2% (2.0 to 11.9) for eyes, and 26.4% (20.1 to 32.6) for cleanliness. On the 10 farms with the worst health scores, a mean of 22.8% (15.7 to 30.3) of animals displayed abnormal scores for attitude, 14.4% (10.0 to 22.5) for ears, 27.2% (22.8 to 30.6) for nose, 30.3% (22.5 to 36.4) for eyes, and 54.9% (50.6 to 60.3) for cleanliness. Mean serum protein across all samples was 5.40 ± 0.74 mg/dl. Mean serum protein by farm was 5.34 mg/dl (minimum = 4.27, maximum = 6.5). The highest overall bacterial counts were recorded in feeder tube samples (median, coliform = 2550 CFU/ml; SPC = 330,000 CFU/ml; Q3 = 3350,000). No relationship was observed between tube SPC and attitude, ears, nose, or eyes scores; however, SPC was correlated with calf cleanliness scores (r = 0.26, P = 0.002). The variation in health scores among farms shows that welfare in automated feeder systems can be improved. In addition, results indicate that the cleanliness of automated feeder equipment may influence calf health; however, further data collection and analyses of calf morbidity and mortality should provide a more complete understanding of risk factors. This project is supported by Agriculture and Food Research Initiative competitive grant no. 2012–67021–19280 from the USDA National Institute of Food and Agriculture.

Key Words: automated calf feeders, calf health

0037 Effect of heat retaining covers on calf hutch temperature during cold weather.
J. A. Haberman*, T. H. Friend, and W. Binion, *Texas A&M University, College Station.*

Previous studies have demonstrated that reflective hutch covers reduce temperatures inside calf hutches, but the efficacy of reflective covers during cold weather has yet to be determined. This study determined the effect of heat-retaining covers on the internal air temperature of polyethylene calf hutches. Treatments on farm 1 included an aluminized 3.0-ml, black, low-density polyethylene (LDPE; reflective) and a 4.0-ml, LDPE (non-reflective) cover. Farm 2 included only the reflective cover. The covers fit over the top of the hutch, overlaying the top, sides, and back, leaving the front of the hutch exposed. The study was conducted for a 29-d period from December to January at 2 dairy farms located near Plainview, TX. At both farms, 5 uncovered (control) hutches and 5 hutches from each treatment were fitted with duplicate temperature loggers that recorded temperature every 30 min for the duration of the study. At the start of the study, hutches housed calves 2 to 4 d of age. The coldest 2-h period was identified and treatment effects were determined with ANOVA and LSD. At farm 1, the reflective covers were warmer than control hutches by 1.5°C (P < 0.01) and the non-reflective covers were warmer than the control by 1.2°C (P < 0.01). At farm 2, the reflective covers were warmer than the control by 1.5°C (P < 0.05). This period was also characterized by very little wind. When the coldest ambient temperature each day throughout the study was identified, covers were not significantly different than the control (P > 0.05) on both farms. This emphasizes the importance of wind influencing air temperature in the hutch. However, there was still a consistent trend on both farms in which the reflective cover was warmer by 1.16°C on farm 1 and 1.5°C on farm 2. In conclusion, the reflective cover was more effective and the hutch covers had the greatest effect on internal air temperature in low wind. The heat-retaining covers in this study can be expected to improve the comfort of calves in cold temperatures; however, the biological significance of these covers is currently being investigated.

Key Words: cold stress, dairy calf, hutch

0038 Modeling the effect of reflective film calf hutch covers on reducing heat loss.
W. Binion* and T. H. Friend, *Texas A&M University, College Station.*

Many dairy operations are located in environments subject to periods of cold weather and calf hutches are a popular method of protecting calves from environmental extremes. This study determined if a reflective film could be useful in moderating the rate of heat loss from calves housed in polyethylene hutches during cold weather. An engineering approach was

used in which rate of heat loss was modeled, using 38-l, water-filled, steel drums covered by a yearling cow hide. Hides were collected the day before and cut to fit the drums so no metal was exposed. Duplicate loggers mounted in the center of each drum recorded temperature at 5-min intervals during each experiment. Two agitators circulated the water inside each drum. The reflective film (cover) consisted of aluminized 2.5-ml, low-density polyethylene, full metal on olive color, with flat black spray paint covering the olive. The covers were 1.8- × 3-m finished size with the aluminized side facing the hutch and paint facing outward. Two of 4 hutches were either uncovered or had covers across the top and sides of the hutch, leaving the front and back exposed. Water temperature ranged from 43.3°C to 32.2°C and there was an average 24 data points per experiment. Data loggers in each drum were averaged at each 5-min interval and averaged within treatments, and quadratic regression was used to predict rate of heat loss. During the cold night experiment, when ambient temperature was declining (mean temperature -13.6°C), the mean rate of temperature loss was -0.21°C per 5-min interval in the covered and -0.25°C in the uncovered ($R^2 = 0.99$). During the daytime trial when the sun was shining and ambient temperature was rising (mean 14.3°C), mean rate of heat loss was -0.15°C per 5-min interval in the covered and -0.11°C in the uncovered ($r^2 = 0.99$). Reflective film does appear to have potential to reduce the rate of heat loss when calves would be most at risk, cold nights. When the sun was shining on the hutches during mid-day, the uncovered warmed up more and hence, reduced the rate of heat loss when compared with the covered. Even with a black surface toward the sun, the covers did inhibit heating of the hutches, but calves would be able to move into the sun during those periods. Improved materials and designs for hutch covers are presently being developed.

Key Words: cold stress, dairy calf, hutch

ANIMAL BEHAVIOR AND WELL-BEING II

0039 Evaluation of hair cortisol as a biomarker of chronic stress in beef cattle. D. Moya*, M. He, Y. Wang, T. A. McAllister, and K. S. Schwartzkopf-Genswein, *Agriculture and Agri-Food Canada, Lethbridge, AB.*

Three experiments were conducted to assess hair cortisol concentration as a biomarker of chronic stress in beef cattle. In Exp. 1, 24 calves (230.4 ± 13.0 kg BW) were randomly split into 2 groups immediately after weaning. Half of them remained at the ranch of origin (OR), whereas the other half were transported to a feedlot (TF). Weight and hair samples were collected from all calves at the time of weaning and for a period of 30 d postweaning to determine performance and cortisol concentration. In Exp. 2, 24 calves (299.1 ± 28.2 kg BW) were randomly split in 2 treatments: no castration (CT) or band castration (BA). Weight and hair samples were collected from all calves at d 0, 35, and 63 after castration to determine performance and cortisol concentration. In Exp. 3, 160 crossbred steers (538 ± 36 kg BW) were used in a 84-d experiment, with a randomized block design, to study the effects of wheat- (WH; 88.4% DM) or barley- (BA; 89% DM) based diets, or processing index (PI) of either 75% (PI75) or 85% (PI85) of their original volume-weight, on growth performance, stress, and behavior of finishing beef cattle. Cattle were allocated to 16 feedlot pens (10 animals per pen, 4 pens per treatment), 8 of which were equipped with an automatic feed monitoring system. Flight speed and hair and saliva samples were collected on d 1, 28, 56, and 84 to determine behavior and acute and chronic stress. The TF group had a greater ADG ($P < 0.01$) and hair cortisol concentration ($P = 0.05$) than OR. There was a castration × time interaction ($P < 0.05$), where BA calves had greater hair cortisol and lower ADG than CT only at d 35 after castration. The PI75 treatment reduced ($P = 0.05$) DMI and increased ($P = 0.04$) feed efficiency. Cattle fed WH had greater hair cortisol ($P = 0.01$) and flight speed ($P < 0.01$) than those fed BA. There was a trend ($P = 0.07$) for a grain × PI interaction, where heifers fed WH-PI85 had lower salivary cortisol than those fed other treatments. Results indicate that hair cortisol can be used to assess chronic stress in beef cattle related to conditions associated with calf management at weaning, band castration, or feeding management.

Key Words: feedlot, stress, welfare

0040 Maternal behavior in sheep production: Effects on lamb performance and economic indicators. C. Raineri[*1,2], B. C. Nunes[3], T. B. Bovo[4], E. A. Titto[4], E. R. Afonso[1], and A. H. Gameiro[1], *[1]Department of Animal Nutrition and Production, University of São Paulo School of Veterinary Science and Animal Science, Pirassununga, Brazil, [2]Federal University of Uberlândia. School of Veterinary Medicine, Uberlândia, Brazil, [3]Ministry of Science, Technology and Innovation, Brasilia, Brazil, [4]University of São Paulo. School of Animal Science and Food Engineering, Pirassununga, Brazil.*

This study assessed the economic impact of inadequate maternal behavior of sheep between birth and first suckle of lambs in a commercial flock of meat sheep. We observed 222 pregnant Santa Ines ewes and their 327 lambs. Behavioral observations were performed, by direct method with focal samplings every 5 min. Maternal activities considered negative were preventing suckling, withdrawing, and butting. Statistical analyses were conducted by multiple linear and logistic regression models, using functions PROC REG and PROG LOGISTIC of the software SAS 9.3. In economic analysis, we simulated the ratios for production costs and revenues in case of manifestation or not of negative maternal activities. We investigated connections between maternal behavior, incidence of dystocia, need for artificial rearing, birth weight, preweaning mortality, prolificacy rate, and weaning weight. Negative maternal behaviors were displayed by 19.37% of the ewes. Lamb weaning weight was influenced by birth weight ($P < 0.001$) and litter size ($P < 0.01$), but not by maternal behavior, artificial rearing, or dystocia. Preweaning mortality was probably affected by maternal behavior ($P = 0.10$) and litter size ($P < 0.05$), but not by artificial rearing. Lambs from dams that did not display negative behavior had 82% higher chances of surviving until weaning. Probability of surviving until weaning fell 50% with the increase of each additional lamb in the litter. Maternal behavior was significantly influenced by birth weight ($P < 0.01$) and dystocia ($P < 0.05$), but not by litter size. The chance of ewes not displaying negative maternal behavior increased 105% for each 1-kg increase on birth weight of lambs. On the other hand, dystocia incidence increased in 79% the chances of negative behavior to occur. In the studied flock, dystocia incidence was not related to lamb birth weight. Economic analysis demonstrated that production cost would be higher for lambs whose mothers displayed negative behaviors, mainly due to greater need for artificial rearing, whereas sale income would be similar between groups. Negative maternal behavior was related to increases in preweaning mortality rate and need of artificial rearing. Thus, negative maternal behavior resulted in economic impact, represented by the increase of production cost and the decrease in 7% of revenues. These results are important to guide viability evaluation of investments that aim to improve maternal-offspring relation in

sheep. Reasons for displays of negative behavior by important portions of that flock are not clearly elucidated, although data suggest relations with higher prolificacy and dystocia.

Key Words: economic evaluation, ewe, production cost

0041 Effect of rest-stop duration during long-distance transport on indicators of animal welfare in weaned beef calves. S. Marti* and K. S. Schwartzkopf-Genswein, *Agriculture and Agri-Food Canada, Lethbridge, AB.*

Forty newly weaned Angus beef calves (260 ± 32.6 kg) were transported 15 h in a livestock trailer (7.3 × 2.1 m) on 2 separate days (20 calves per day) to evaluate the effect of rest-stop duration on indicators of calf welfare. Immediately following the 15-h journey, all calves were unloaded at a feedlot and randomly assigned to 1 of the 4 treatments. Treatments included: 0- (Control; C), 5- (RS5), 10- (RS10), or 15- (RS15) h rest periods in pens containing ad libitum access to water and long-stem hay. Following each rest period, calves were reloaded onto the same trailer and taken on another 5-h journey for a total transport event lasting 20 h. Control calves did not have access to feed or water until the end of the 20-h transit event. Behavioral measurements included: loading and unloading scores (fall, aggression, mount, slip, trip, balk and walk, trot, or run), animal condition (non-ambulatory, lame, injured, fatigued, wet coat, and dirty), number of steps (steps per day), feeding behavior (minutes per day), standing and lying frequency (number per day), and duration (minutes per day) during rest periods and at the end of the 20-h transport event. Physiological measurements included: saliva and hair cortisol, total blood cell count, and substance P concentrations. All measurements were taken immediately before loading and after unloading at the rest stop and the end of the 20-h event. Salivary cortisol was greater ($P < 0.01$) in C and RS15 than in RS5 and RS10 calves at the end of each rest stop period and the 20-h event. The RS15 calves had greater ($P = 0.02$) salivary cortisol concentrations before and after the last 5 h of transport compared with RS5 and RS10 calves. The RS10 calves spent more ($P < 0.01$) time lying than any other treatment. No treatment differences ($P = 0.14$) were observed for feeding duration, although it was numerically less in RS10 calves. Meal duration following 20 h of transport was less ($P = 0.05$) in C calves than all other treatments. The results of this study indicate that provision of a rest stop < 10 h reduces stress in weaned calves as witnessed by reduced salivary cortisol concentration and less time spent lying.

Key Words: calves, resting stop, transport, welfare

0042 Monitoring stress behavior in grazing beef cows with a long range pedometric system. R. Gabrieli*, *Ministry of Agriculture and Rural Development, Extension Service, Beit Dagan, Israel, Beit Dagan.*

Beef breeding is an extensive operation performed in vast pastures. Hierarchy within the herd is an important factor that determines priority of access to limited resources and level of feed intake, resulting in stress to the subordinate animals. Hierarchy is mainly passive, thus difficult to detect in conventional breeding systems. Most of the cows that are culled due to low production are subordinate cows. Identifying subordinate cows may enable the breeder to improve grouping management and thereby minimize stress. This will lead to improved production and lower replacement costs. A newly developed long range pedometric system, based on RF transmission, providing online activity monitoring, was installed in a crossbred Simmental beef herd of 250 cows, grazing in a 300-ha pasture in the Upper Galilee, Israel. The hypothesis was that the average cow will maintain a daily activity routine, whereas stress will result in deviations of activity expressed in the graph. Thirty transmitting tags were mounted on front legs of randomly selected cows. Analysis of data showed 17 cows with regular activity graphs (i.e., lower than average values of activity with lower values of standard deviation, 161 + 105 steps per hour) and 13 expressed irregular activity graphs (higher than average values of activity with higher values of standard deviation, 209 + 128 steps per hour). Observations near the food trough were conducted during feeding time to rank cows according to their social status. A cow that reached the trough and wasn't rejected was ranked "dominant." Order was established thereafter by number of rejections from the trough each cow received. The lowest ranking cows did not approach the trough during feeding at all. Comparison between activity graphs and observations showed that dominant cows expressed regular activity graphs and subordinate cows expressed irregular activity graphs. Cortisol levels in hair samples were taken to validate activity results (0.1975 + 0.039 and 0.2862 + 0.0423 μg/dL for dominant and subordinate, respectively; $P = 0.018$). Cortisol level in hair reflects the stress status over a fortnight, thus the effect of sampling-related stress is minimal. The activity pattern expressed while measuring hourly activity online, we believe, reflects the measure of freedom each cow has to choose for her ongoing activity within the herd. Assuming that establishing an individual routine is beneficial for cows, detecting those that are unable to do so and grouping them by social order will minimize stress and improve production.

Key Words: beef breeding, stress

0043 Effect of 4 different reflective barriers on black-globe temperatures in calf hutches and on calf ADG. T. H. Friend*, W. Binion, and J. Haberman, *Texas A&M University, College Station.*

Polyethylene hutches are a popular method of housing dairy calves from birth to ± 60 d of age, although these hutches get hot when in full sun. Shading the hutches and yard has been effective, but shade increases concerns about increased pathogens and moisture from the lack of sunlight. This study characterized the relative differences in the ability of 4 different types of radiant barriers to reduce black globe (BG) temperature within these hutches during hot weather and reports the results from some field trials. Treatments for the BG trials included 3 different types of covers [2 types of reflective laminates (Cadpak P and Cadpak ESD) and an aluminized 3.0-mL white low-density polyethylene (LDPE)], and a reflective paint (LO/MIT-1). The reflective covers were 1.8- × 3-m finished size and covered the top and sides of the hutch down to 0.15 m above the ground, leaving the front and back exposed. The LO/MIT-1 paint covered the entire sides and roof of the hutch. Two 24-h trials, 1 wk apart, were conducted during relatively hot and clear days in early August. Black globe temperatures were recorded at 20-min intervals in duplicate, using blackened table tennis balls mounted 0.3 m above the floor in the center of each hutch. Ambient temperature (shade) during the hottest 2-h period for both trials averaged 39.9°C, whereas the uncovered control averaged 41.1°C and LO/MIT-1 39.9°C, both of which were significantly higher (ANOVA followed by LSD, $P < 0.01$) than the Cadpak P (38.9), Cadpak ESD (38.6), and aluminized LDPE (38.7°C). Twelve to 24 of the covers were field tested on 3 collaborating dairy farms in the Panhandle Region of Texas from June to September 2013. Despite having a relatively cool summer, the farms reported increased ADG ranging from 0.018 to 0.045 kg/d. A statistical analysis was not possible because the calves in each treatment were weighed as a group on the farms ($n = 3$). Both the Cadpak P and Cadpak ESD were starting to delaminate at the end of the trails. The reflective covers evaluated in this study can be expected to improve calf comfort and most likely gain, but additional field testing is needed to refine the design and determine cost effectiveness of the covers.

Key Words: calf, hutch heat stress

0044 Effects of 3 tail painting formulations on behavior of dairy heifers. C. S. Skenandore* and F. C. Cardoso, *University of Illinois, Urbana.*

Studies have shown that the correct use of tail paint can identify almost 90% of cows in standing heat. To investigate the potential relationship among the use of different formulations of commercially available tail paint and their effectiveness in heifers, 18 Holstein heifers at breeding age were selected, balanced by age (13.7 ± 1.2 mo), body weight (394 ± 32 kg), and BCS (3.43 ± 0.1 on a 1 to 5 scale), and randomly assigned to 1 of 3 treatment groups. Experimental treatments were: Control (CON), orange color, tail chalk, commercial formulation; Treatment A (TRTA), orange color, tail chalk, new formulation; and Treatment B (SPRAY), orange color, spray formulation. Experimental design was a replicated 3 × 3 Latin square design with 6 total squares, 3 animals per square. Each period was 14 d. Visual observations were performed for tail paint licking (LICK; being licked at the tail paint), social licking (SOCLICK; being licked at the head, neck, or leg areas), rump licking (RUMPLICK; being licked at the rump area), and product disappearance (TPREMOVED; score from 0 to 2, according to the degree of tail paint removal) in 30-min segments every 2 h from 0600 to 1800 h. Video recordings were used to confirm observations. The outcome variables of interest, LICK, SOCLICK, and RUMPLICK, were summarized to daily counts of interactions. Assessment of TPREMOVED was done once daily before subsequent treatment application. A synchronization protocol (Ovsynch: 100 mg GnRH, then 25 mg $PGF2_{\alpha}$ 7d later, and 100 mg GnRH 2d after $PGF2_{\alpha}$) was used to stimulate high and low social interactions. Statistical analyses were performed using the GLIMMIX procedure of SAS (SAS v9.3 Institute Inc., Cary, NC, USA). Half of the heifers (51.4%) received at least 1 SOCLICK, but only 10.1% of the heifers received a RUMPLICK. There were no treatment differences for SOCLICK ($P > 0.88$) or RUMPLICK ($P > 0.42$). The majority (75.3%) of heifers did not receive LICK and < 2% of the heifers received < 1 LICK. Heifers receiving SPRAY had a lower number of LICK per day ($P = 0.005$) when compared with CON or TRTA. Heifers that received SPRAY had less TPREMOVED ($P = 0.0001$) when compared with CON or TRTA, and TRTA heifers had less TPREMOVED ($P = 0.01$) when compared with CON. In conclusion, SPRAY had a lower number of LICK and lower TPREMOVED. Licking behavior seen on commercial dairy farms may be primarily from social licking rather than tail paint licking.

Key Words: dairy heifers, licking behavior, tail paint

0045 Balking behavior incidence in cattle at the processing plant and carcass implications. M. L. Thomas*[1], Y. V. Thaxton[2], A. H. Brown, Jr.[1], K. E. Pfalzgraf[1], K. D. Christensen[3], K. Anschutz[1], and C. F. Rosenkrans[4], *[1]Department of Animal Science, University of Arkansas Division of Agriculture, Fayetteville, [2]Center for Food Animal Wellbeing, University of Arkansas, Fayetteville, [3]Center of Excellence for Poultry Science, University of Arkansas, Fayetteville, [4]University of Arkansas, Fayetteville.*

Balking behavior in the cattle processing line can pose welfare issues as electric prod use to coerce forward movement is implemented. Temperament differences have been shown among breed-type categories, within breed-type categories,

among crossbreds, and between genders. Objectives in this study were to determine if breed-type predominance, based on coat color or gender, had an effect on balking behavior and if that behavior affects carcass economics. A total of 6510 balking observations over 7 random dates in 1 yr were recorded at the entrance to the restrainer in a high-capacity processing plant. Balking scores were assigned on a scale of 1 to 5 by a trained, consistent observer. Thirteen color combinations and 16 feedlot sources were represented at random collection dates and times. Holstein cattle balked more ($P < 0.0001$) than all other colors, which were similar. Gender differed in balking incidence with heifers balking more ($P = 0.05$) than steers and pens containing both steers and heifers balked intermediately. The feedlot source affected ($P < 0.0001$) balking behavior, with balking score means ranging from the lowest at 1.1 to 2.3 as the highest mean. Balking behavior was negatively correlated (r = -0.18, $P < 0.0001$) with dressing percentage. Mean pen weight and dressing percentage were also affected ($P < 0.0001$) by feedlot source. Mean pen weight was affected by color. Holstein cattle had greater ($P < 0.0001$) pen weights than all other colors, which were similar. Steers had heavier ($P < 0.0001$) pen weights than mixed pens, with heifers having the lowest pen weight (602.8 ± 15.4, 546.1 ± 0.59, and 541.1 ± 0.36kg, respectively). Dressing percentage was affected ($P < 0.0001$) by coat color and gender ($P = 0.01$). Steers had the greatest ($P = 0.01$) dressing percentage at 64.8 ± 0.1 vs. heifers at 64.3 ± 0.3, with mixed pens being intermediate at 63.4 ± 0.5. Our results suggest an association with dressing percentage and balking behavior, and dressing percentage is affected by coat color and gender.

Key Words: balking, behavior, welfare

0046 Effects of ractopamine or zilpaterol on physiologic and metabolic parameters in feedlot steers.

A. L. Fuller*[1,2], T. L. Covey[2], T. E. Lawrence[1], and J. T. Richeson[1], *[1]West Texas A&M University, Canyon, [2]OT Feedyard and Research Center, Hereford, TX.*

The feeding of β adrenergic agonists has recently been implicated as a potential animal welfare concern. The objective of this study was to determine the effects of ractopamine hydrochloride or zilpaterol hydrochloride on physiologic and metabolic blood parameters indicative of stress. Thirty crossbred steers (BW = 573 ± 27.4 kg) were used in a randomized complete block design. Steers were grouped into 2 blocks based on harvest date, stratified by BW within block, assigned randomly to treatment, and then placed into individual pens. A basal finishing ration was delivered to each steer twice daily. Treatments were applied via premix containing 20 g ground corn at each feeding and consisted of: 1) no β agonist (CON), 2) 300 mg/d ractopamine hydrochloride (RH), or 3) 90 mg/d zilpaterol hydrochloride (ZH). Blood samples were collected via jugular venipuncture on d −7, -1, 0, 0.25, 0.5, 1, 3, 7, 14, and 21, relative to initial delivery of treatment. Whole blood (excluding d 21) was analyzed for complete blood count using an automated hemocytometer. Serum was analyzed for cortisol and haptoglobin via ELISA, and an array of blood metabolites were evaluated using an automated analyzer. Overall, the total leukocyte concentration was greater ($P = 0.01$) in steers that received RH compared with CON; whereas ZH did not differ ($P \geq 0.43$). On d 1, total leukocytes were greater for both RH and ZH vs. CON (treatment × d; $P \leq 0.046$). Overall, neutrophil concentration was greater in RH ($P = 0.01$) and ZH ($P < 0.01$) compared with CON. Neutrophils were greater for ZH on d 1 and 3, and RH on d 7 compared with CON (treatment × d; $P \leq 0.045$). Although RH did not alter ($P = 0.36$) the neutrophil to lymphocyte ratio (NLR), NLR was greater ($P = 0.03$) in steers fed ZH vs. CON. Treatment did not affect any other complete blood count variables ($P \geq 0.10$) and cortisol and haptoglobin were not different ($P \geq 0.19$). Serum urea nitrogen was decreased ($P < 0.02$) and potassium and chloride were increased ($P < 0.01$) for both RH and ZH. Creatine kinase was increased for ZH on d 14 and 21 ($P \leq 0.017$). Serum albumin, globulins, NEFA, creatinine, calcium, phosphorus, and magnesium were not different ($P \geq 0.57$). Under conditions of this study, feeding of either β-agonist did not clearly affect blood parameters indicative of physiological stress.

Key Words: β-agonists, stress

ANIMAL BEHAVIOR AND WELL-BEING III

0047 Breeding may simultaneously reduce pig aggressiveness at regrouping and in stable social groups, but management may not.
S. P. Turner*[1], S. Desire[1], R. B. D'Eath[1], L. Canario[2], and R. Roehe[1], *[1]SRUC, Edinburgh, United Kingdom, [2]INRA UMR1388, F-31326 Castanet-Tolosan, France.*

Aggression between pigs compromises welfare and productivity. Individual sow stalls are now banned in the European Union after wk 4 of gestation and are being phased out in some parts of North America. Better control of both acute regrouping aggression and chronic aggression in stable social groups is required at all ages. This paper examines whether efforts to control these 2 forms of aggression may be complementary or antagonistic, and whether optimal aggression phenotypes can be identified to target in management or breeding. Acute regrouping and subsequent chronic aggressiveness are stable traits of the individual but highly variable among animals and groups. Delivery of aggressive behavior at regrouping is heritable (h^2 > 0.31 SE 0.04) as is the number of skin lesions from regrouping or chronic aggression (h^2 = 0.19 SE 0.02 to 0.43 SE 0.04). The lesion count is genetically correlated to reciprocal fighting or receipt of non-reciprocal bullying, and is therefore an indicator of aggressive propensity (e.g., r_g between reciprocal fighting duration at regrouping and lesions to the anterior of the body = 0.67 SE 0.04). The lesion count shows a low but positive genetic correlation between 24-h and 3-wk post-regrouping (r_g 0.28 SE 0.07 to 0.50 SE 0.09), suggesting that breeding to reduce regrouping lesions would also reduce lesions from chronic aggression. However, at the phenotypic level, individual pigs or entire social groups that fight greatly at regrouping, even if this is often unsuccessful, show few injuries from chronic aggression (group level, r = -0.28 to -0.38, $P < 0.05$). Furthermore, pigs with a beneficial effect on the growth of penmates can be more aggressive at regrouping but receive fewer lesions 3 wk later. Acute aggression may therefore reduce the costs of chronic aggression at the phenotypic level. Fight quantity appears to primarily drive this association as fight outcome at regrouping had less impact on later lesions. However, some pigs show few injuries from both acute and chronic aggression. The behavior of these pigs will be discussed to highlight whether optimal phenotypes can be targeted in management or breeding. Currently, breeding for reduced regrouping aggressiveness is likely to simultaneously reduce subsequent chronic aggression, but phenotypically reducing regrouping aggression through management change may lead to long-term increases in aggression unless controlled.

Key Words: aggression, breeding, pig

0048 Effect of concentrate feeder design on performance, animal behavior, and ruminal health in Holstein bulls fed high-concentrate diets.
M. Verdu*, A. Bach, and M. Devant, *IRTA-Department Ruminant Production, Caldes Montbui-Barcelona, Spain*

A total of 240 Holstein bulls (121 ± 2.0 kg BW and 99 ± 1.0 d of age), in a replicated factorial study, were randomly allocated in 1 of 6 pens and assigned to 1 of 3 treatments, according to the feeder design: conventional feeder with 4 feeding spaces (CF), conventional feeder with less concentrate capacity (CFL), and a single space feeder with lateral protections (SF) forming a chute (1.4 × 0.8 m). Also, each pen had 1 straw feeder and 1 drinker. Concentrate intake was recorded daily, straw consumption weekly, and BW every 14 d. On d 7, 119 to 120, and 215 to 216, rumen fluid and blood samples were collected to determine rumen pH and VFA, and serum NEFA. Animal behavior was registered on d 1, 3, 5, 8, 14 and every 28 d by scan sampling. Animals were slaughtered after 221 d and HCW, rumen wall, and liver lesions were recorded. Data were analyzed using a mixed-effects model with repeated measures. Bulls on CF tended (P = 0.07) to have greater ADG than CFL and SF bulls (1.54, 1.50, and 1.49 ± 0.017 kg/d, respectively). However, no differences among treatments were observed in concentrate intake (7.6 ± 0.16 kg/d), straw intake (0.8 ± 0.03 kg/d), FE (0.2 ± 0.01 kg/kg), HCW (247.2 ± 2.09 kg), dressing percentage (53.6 ± 0.23%), and rumen and liver lesions. Mean rumen pH was always > 5.6; at 7 and 215 to 216 d, SF bulls had greater ($P < 0.05$) rumen pH compared with CF and CFL bulls. Acetate to propionate ratio was greater ($P < 0.05$) in SF compared with CFL and CF. At d7, NEFA of SF was greater ($P < 0.05$) compared with CF and CFL, although at 119 to 120 d in SF bulls serum NEFA concentration was less ($P < 0.01$) than in CF and CFL bulls. Bulls on SF spent more time ($P < 0.05$) eating straw, exhibited fewer ($P < 0.05$) displacements at feeders and drinker, and expressed more oral behaviors ($P < 0.05$) than CF and CFL bulls. The CFL bulls tended (P = 0.10) to perform more mounts than SF and CF. In conclusion, the different feeder designs evaluated did not affect overall performance, although some behavior traits differed among them. Serum NEFA concentrations at the beginning suggest that animals at the SF may have adaptation problems and SF does not negatively affect rumen wall health and pH.

Key Words: beef, feeder, performance

0049 Impact of using an electrified crowd gate on milk yield and milk flow. I. Guasch[1], A. Pinto[2], and A. Bach[*3,4], *[1]Blanca, Hostalets de Tost, Spain, [2]Department of Ruminant Production, IRTA, Barcelona, Spain, [3]Department of Ruminant Production, IRTA, Caldes de Montbui, Spain, [4]ICREA, Barcelona, Spain.*

Many dairy enterprises use automatic crowd gates in the milking parlor's waiting area to assist and expedite the entrance of cows into the parlor. Some of these systems include electrified gates. We hypothesized that the use of an electrified crowd gate may impose an alert response in the cows, which in turn may negatively affect milk let down and production. One hundred fifty dairy cows (71 primiparous, 79 multiparous; days in milk = 225 ± 109 d) were split into 2 groups and milked in a 32-stall rotary parlor, using a crowd gate that was either not electrified (NEG) or electrified (EG). The experiment followed a 2 × 2 Latin square design with 2 periods of 9 d each. The waiting area was 200 m^2 and equipped with rubber flooring. The crowd gate was 13 m long. Cows were milked at 0600 and 1800 h. At each milking, milk production, milk fat content, milk protein content, average milk flow, maximum milk flow, and time to peak milk flow were recorded on an individual basis. The first 4 d of each period were discarded and data from the last 5 d were averaged by cow and analyzed using a 2-level mixed-effects model that accounted for the random effect of cow and period, and the fixed effects of type of crowd gate, parity, their 2-way interaction, and days in milk as a covariate. Time elapsed between the initiation of milking and peak milk flow (1.61 ± 0.05 min). Peak milk flow did not differ ($P = 0.67$) between treatments. However, peak milk flow tended to be greater ($P = 0.10$) in NEG (5.8 ± 0.16 kg/min) than in EG (5.6 ± 0.16 kg/min) cows. Similarly, average milk flow tended to be greater ($P = 0.06$) in NEG (3.00 ± 0.07 kg/min) than in EG (2.96 ± 0.07 kg/min) cows. Milk yield was greater ($P < 0.01$) when cows were milked with NEG (14.0 ± 0.25 kg/milking) than when milked with EG (13.6 ± 0.25 kg/milking). Treatment had no effect on milk protein ($P = 0.33$) or fat ($P = 0.77$) content. It is concluded that using an electrified crowd gate may compromise milk flow and results in decreased milk yield.

Key Words: let down, parlor, stress

0050 Using designer diets to reduce aggression in pregnant sows. A. Sapkota[*1], J. N. Marchant-Forde[2], B. T. Richert[1], and D. C. Lay Jr.[2], *[1]Purdue University, West Lafayette, IN, [2]USDA-ARS, West Lafayette, IN.*

The U.S. Swine industry is under pressure to switch from individual to group housing for pregnant sows. The study objective was to evaluate effects of increased dietary fibrous ingredients to reduce aggression during mixing by increasing satiety. Five isocaloric (NE basis) treatment diets (CONTROL, Resistant-STARCH, BEET pulp, soy hulls INCREASED INTAKE, and SOY Hulls + FAT diets) were fed to 5 sows (parity 1 to 6) per treatment per replicate. One hundred fifty sows (25 sows/replication × 6 replications) were used for the study. Sows were bred and moved into individual crates (0.61 × 2.13 m) on d 7 to 14 post-breeding. Sows remained in crates for 21 d while fed assigned diets. Data on weight, backfat, and BCS for each sow were collected on first and last days in crates. On d 22, sows were moved into mixing pens (2.13 × 3.05 m mixing area and five 0.61 × 2.13 m crates). As a measure of aggressiveness, lesions on left and right in front, mid, and rear parts of each sow were counted before mixing, and on d 1, 2, and 3 of mixing. After 72 h of mixing, sows were switched to regular diets and management. Production data (piglets born, percent alive, average birth weight, average wean weight, percent weaned, farrowing rate) were collected from 75 sows (3 replications). The effects of diets on skin lesions, backfat, weight, BCS, and production data were compared using PROC GLM and least squares means in SAS 9.3. Chi-square test was performed to compare farrowing rates. Skin lesions in the front left portion of sows were 6.7 ± 0.9^{ab}, 6.8 ± 0.9^{a}, 7.4 ± 1.0^{ac}, 4.0 ± 1.0^{b} and 9.9 ± 1.0^{c} for CONTROL, Resistant-STARCH, BEET, INCREASED INTAKE, and SOY Hulls + FAT diets, respectively, on d 1 ($P = 0.002$). Skin lesions in the front left portion of sows were 11.2 ± 1.6^{a}, 11.5 ± 1.6^{a}, 10.3 ± 1.6^{a}, 9.7 ± 1.6^{a}, and 16.5 ± 1.7^{b} for CONTROL, Resistant-STARCH, BEET, INCREASED INTAKE and SOY + FAT diets, respectively, on d 3 ($P = 0.038$). Diets did not affect ($P > 0.05$) other skin lesion scores, number of piglets born, percent alive, average birth weight, average wean weight, percent weaned, and farrowing rate. Change in weight, backfat, and BCS did not differ with treatments ($P > 0.05$). There were fewer skin lesions in INCREASED INTAKE treatment on d 1 indicating less aggression and higher skin lesions in left front parts of the sows fed SOY Hulls + FAT diet, indicating more aggression compared with other diets.

Key Words: aggression, group housing, sow

0051 Selection and breeding for improved feed efficiency alter gilt behavioral responsiveness to a novel object. J. D. Colpoys[*1], N. K. Gabler[1], C. E. Abell[2], A. F. Keating[1], S. T. Millman[1], J. M. Siegford[3], and A. K. Johnson[1], *[1]Iowa State University, Ames, [2]DNA Genetics, Columbus, NE, [3]Michigan State University, East Lansing.*

As feed efficiency is becoming more of a priority, our objective was to determine if divergent selection for residual feed intake (RFI) altered gilt approach and fear behavior. Twenty low-RFI (more feed efficient) and 20 high-RFI (less feed efficient) gilts (36 ± 5.7 kg BW) from the ninth generation Iowa State University Yorkshire RFI selection lines were randomly selected. Gilts were evaluated once over a 2-wk period, using a

novel object test (NOT). Individual gilts were moved from the home pen into a weigh scale for 1 min. Gilts then entered the NOT arena (4.9 long × 2.4 m wide with black corrugated plastic walls 1.2 m high) and their behavior was video recorded for 10 min. All testing occurred between 1300 and 1900 h. The video was watched continuously by 1 trained observer for latency, frequency, and duration of novel object touches (defined as oral, nasal, and/or facial interaction with the novel object, an orange traffic cone), frequency of escape attempts (defined as 2 front legs off the ground, possibly including a jump), and frequency and duration of freezing postures (defined as the whole body remaining still for $\geq$ 3 sec). Data were analyzed using the GLIMMIX procedure of SAS and the model included the fixed effect of genetic line, covariate of gilt age, and pig as the experimental unit. Compared with high-RFI gilts, low-RFI gilts tended to take longer to first touch the object ($P = 0.06$) and touched the object fewer times ($P = 0.0001$); however, there was no observed differences between lines in duration of time spent touching the object ($P = 0.14$). Low-RFI gilts attempted to escape fewer total times compared with high-RFI gilts ($P = 0.001$). No difference was observed in frequency or duration of freezing ($P \geq 0.14$). In conclusion, low-RFI gilts interacted with the novel object fewer times but engaged in fewer total escape attempts compared with high-RFI gilts. These data suggest that while there are differences in approach behaviors to a novel object between low- and high-RFI selection lines, selecting for improved feed efficiency (low-RFI) may have resulted in calmer, less fearful gilts.

Key Words: approach, fear, residual feed intake

ANIMAL BEHAVIOR AND WELL-BEING IV

0052 Sprinkler flow rate affects dairy cattle physiological and behavioral responses.
J. M. Chen*[1], K. E. Schütz[2], and C. B. Tucker[1], [1]*University of California, Davis,* [2]*AgResearch, Hamilton, New Zealand.*

The accumulation of heat load can be problematic for dairy cow welfare and productivity. Sprinklers effectively reduce heat load, but little is known about the optimal amount of water needed for cooling or about cattle behavioral responses to this resource. Two studies assessed how flow rate affected: 1) the effectiveness of sprinklers and 2) cattle preferences. In Exp. 1, 19 lactating cows were restrained at the feedbunk for 1 h/d and received 1 of 4 treatments in a crossover design: Control (0 L/min; 3X total) or sprinkler (0.4, 1.3, and ≥ 4.5 L/min, 6X each). Spray was delivered in 4 cycles (3 min on 12 min off). Cooling effectiveness was evaluated using body temperature (BT) and respiratory rate (RR), by taking the differences between measurements recorded before the first spray cycle (-2 min) and after the final cycle (49 min). In Exp. 2, 18 lactating cows were tested in a shaded Y-maze, with 3 pairwise comparisons between either the Control (0 L/min) and/or 0.4 or 4.5 L/min sprinklers. For each pairing, cows chose once daily (12 min/d) for 8 consecutive days. In Exp. 1, BT and RR differed among all 4 treatments: as flow rate increased, so did cooling effectiveness ($P < 0.01$, GLMM). However, for BT, there was an interaction with weather [volume × air temperature (AirT), $P < 0.004$]. At AirT < 28°C, both sprinklers ≥ 1.3 L/min kept BT from rising ($P \leq 0.003$), whereas at AirT ≥ 32°C, only the ≥ 4.5 L/min sprinkler did ($P \leq 0.001$). In Exp. 2, cows choose 0.4 L/min over Control 69% of the time (SE: 9.3%, $P = 0.096$, Wilcoxon signed-rank test) and showed no preferences in the other comparisons (4.5 L/min: 58% vs. Control, SE: 9.4%; 42% vs. 0.4 L/min, SE: 9.6%; $P \geq 0.552$). However, preferences for 4.5 L/min over Control tended to depend on weather ($P = 0.065$, GLMM): at AirT ≤ 24.9°C, the probability of choosing 4.5 L/min was 0.40, whereas at AirT ≥ 30.0°C, this increased to 0.74. In conclusion, sprinkler flow rate influenced both cooling effectiveness and cattle preferences. In warmer weather, sprinklers ≥ 4.5 L/min were most effective and were preferred over shade alone. However, more work is needed to fully understand how cattle choose to use cooling resources throughout the day.

Key Words: heat load, preference, sprinklers

0053 Short-term increases in stocking density did not alter feeding behavior of lactating Holstein dairy cattle.
R. A. Black*[1], R. J. Grant[2], and P. D. Krawczel[1], [1]*University of Tennessee, Knoxville,* [2]*William H. Miner Agricultural Research Institute, Chazy, NY.*

Increasing stocking density at key resources may have negative effects on the feeding pattern of dairy cattle. The objective of this study was to determine the impact of short-term increases in stocking density on meal duration and frequency of lactating Holstein dairy cattle. Cows ($n = 136$) were allocated to 1 of 4 groups ($n = 34$), balanced for parity, days in milk (DIM), and milk production. Four stocking density treatments of 100% (1 cow per freestall and headlock), 113%, 131%, and 142% were assigned using a 4 × 4 Latin Square, with treatments imposed for 14-d periods. Twelve cows from each pen were selected to form focal groups, balanced by milk production (50.2 ± 1.1 kg), parity (2.2 ± 0.2), DIM (162.2 ± 7.0 d), BW (700.1 ± 11.0 kg), and BCS (3.09 ± 0.05). On d 11 of each period, feeding behavior was recorded at 10-min intervals for 24 h. Meals were defined as repeated observations of eating with a maximum 20 min of not eating between observations. To evaluate diurnal effects, 24 h of data was divided into BLOCK1 (0400 to 1200 h), BLOCK2 (1200 to 2000 h), and BLOCK3 (2000 to 0400 h), based on milking time. The MIXED procedure of SAS (SAS 9.3, SAS Inst., Cary, NC) was used to determine the effect of stocking density on meals per day, meals per hour, meal duration, time between meals, and meal duration 2 h before and after milking. Stocking density did not affect the number of meals per day ($P = 0.25$), time between meals ($P = 0.93$), number of meals per hour ($P = 0.71$), or meal duration ($P = 0.33$). However, meals were longer during BLOCK1 (38.8 ± 1.2 min) and BLOCK2 (39.7 ± 1.2 min), compared with BLOCK3 (33.8 ± 1.3 min; $P < 0.01$). Feed delivery occurred daily at 0430 h, with feed pushed up throughout the day. This suggests meal length decreases relative to time of feed delivery. However, meal duration increased after milking compared with before milking (29.5 ± 1.0 vs. 21.0 ± 1.0 min, respectively; $P < 0.01$), regardless of stocking density ($P = 0.98$). Short-term increases in stocking density did not impact the feeding pattern of lactating dairy cows. Future studies should investigate ways cattle compensate for increased stocking density while avoiding changes in feeding pattern.

Key Words: dairy cattle, feeding behavior, stocking density

0054 Evaluation of prepartum lying behavior as an indicator of health disorders in transition dairy cows. K. Lobeck-Luchterhand*[1], P. Basso Silva[1], R. C. Chebel[2], and M. I. Endres[1], [1]*University of Minnesota, St. Paul,* [2]*Department of Veterinary Population Medicine, University of Minnesota, St. Paul.*

The objective of this study was to determine if prepartum lying behavior (lying time, lying bouts, or lying bout duration) could be used as an indicator of health disorders in transition dairy cows. Lying behavior of 281 prepartum Jersey cows enrolled 4 wk before expected calving date was recorded using HOBO Pendant G data loggers attached to the cow's rear leg 1 d after entrance into the close-up pen, left on for 12 d, removed for 7 d, and reattached for 12 d or until the cow calved. Blood samples were taken on days in milk (DIM) 3, 10, 17, and 24 for determination of BHBA concentrations. All cows were examined on DIM 1, 4, 7, 10, and 13 for metritis and retained fetal membrane. Locomotion (1 to 5 scale) was evaluated on DIM -28, 0, and 35; cows with locomotion score $\geq$ 3 were considered lame. Data were analyzed using PROC MIXED of SAS. Increased daily lying time was associated with displaced abomasum (Difference, LSMEANS ± SE, min/d; 54.0 ± 13.2; $P < 0.01$), retained fetal membrane (20.4 ± 6.6; $P < 0.01$), twin pregnancies (59.4 ± 14.4; $P < 0.01$), and lameness at DIM 0 (163.2 ± 21.0; $P < 0.01$). Decreased daily lying time was associated with subclinical ketosis (50.4 ± 13.8; $P < 0.01$) and mastitis (34.2 ± 8.4; $P < 0.01$). An increase in the number of daily lying bouts was associated with lameness at DIM 0 (2.28 ± 0.61; $P < 0.01$) and first AI pregnancy (0.24 ± 0.12; $P = 0.04$). A decrease in the number of lying bouts was associated with displaced abomasum (1.45 ± 0.36; $P < 0.01$), retained fetal membrane (0.68 ± 0.22; $P < 0.01$), mastitis (1.21 ± 0.26; $P < 0.01$), and pregnancy loss from first AI (1.46 ± 0.27; $P < 0.01$). Decreases in lying bout duration (min) were associated with subclinical ketosis (14.4 ± 3.0; $P < 0.01$) and first AI pregnancy (2.4 ± 0.6; $P = 0.01$). Displaced abomasum (18.0 ± 3.0; $P < 0.01$) and pregnancy loss from first AI (7.8 ± 2.4; $P < 0.01$) were associated with increased lying bout duration. In conclusion, changes in lying behavior may be an indicator of cows at risk for transition disorders; however, the behavioral relationships were not consistent among the health disorders evaluated in this study.

Key Words: lying behavior, transition cow

0055 Effect of stocking density on social and feeding behavior of prepartum dairy cows. K. Lobeck-Luchterhand*[1], P. Basso Silva[1], R. C. Chebel[2], and M. I. Endres[1], [1]*University of Minnesota, St. Paul,* [2]*Department of Veterinary Population Medicine, University of Minnesota, St. Paul.*

The objective of this study was to investigate the effect of 2 feedbunk stocking densities on prepartum social and feeding behavior of dairy cows. Seven hundred fifty-seven Jersey cows at 4 wk before expected calving date were assigned randomly to 1 of 2 treatments. Treatments were 80% (38 cows/48 headlocks; 80D) or 100% (48 cows/48 headlocks; 100D) feedbunk stocking density. Four pens with sand-bedded freestalls were used: 2 nulliparous and 2 mixed primiparous and multiparous, referred to as "parous" pens over 4 repetitions (total of 350 nulliparous and 407 parous cows were used). Cows were balanced for BCS and cows with a locomotion score > 2 were excluded from the study. Pens were stocked twice a week to maintain the desired stocking density. Displacements from the feedbunk were measured using video recordings during 3 h following fresh feed delivery on d 2, 5, and 7 of each week of the 5-wk rep. Feeding times were measured using 10-min video scan sampling on d 2, 5, and 7 of the first week of the rep and d 2 and 5 for the final 4 wk of the rep. Displacements and feeding behavior data were analyzed using PROC MIXED of SAS with observation day (rep) as repeated measures. The random statement cow ID (pen) was included for the feeding behavior model. The 80D cows had fewer displacements from the feedbunk than 100D cows (15.2 ± 0.7 and 21.3 ± 0.7, respectively; $P < 0.001$). There was a treatment × parity interaction for daily feeding time ($P = 0.014$). Parous 80D cows had a tendency for longer feeding times than parous 100D cows (296.9 ± 3.3 and 289.3 ± 2.9 min, respectively; $P = 0.081$), whereas there was a tendency for longer feeding times for nulliparous 100D than nulliparous 80D cows (251.2 ± 3.2 and 242.8 ± 3.6, respectively; $P = 0.079$). In conclusion, stocking cows at 80% of headlocks reduced displacements from the feedbunk and had a tendency to increase daily feeding time for parous cows but not nulliparous cows.

Key Words: stocking density, transition cows

0056 Using prepartum feeding behavior to identify dairy cows at risk for transition health disorders. K. Lobeck-Luchterhand*[1], P. Basso Silva[1], R. C. Chebel[2], and M. I. Endres[1], [1]*University of Minnesota, St. Paul,* [2]*Department of Veterinary Population Medicine, University of Minnesota, St Paul.*

The objective of this study was to investigate whether changes in prepartum feeding behavior could be used as an indicator of health disorders in postpartum transition cows. Retrospective daily feeding times for 925 Jersey dairy cows within 21 d prepartum were used. Data were from 2 studies: study 1, 209 prepartum cows enrolled in either a stable group of 44 cows moved to a pen with no new cows added during a 5-wk rep or conventional group with cows added once weekly to maintain a desired pen stocking density of 44 cows; or study 2, 716 prepartum cows housed at either 80% (38 cow/48 headlocks) or 100% (48 cows/48 headlocks) feedbunk stocking density with twice weekly entrance of new animals. Prepartum feeding behavior was measured using 10-min video scan sampling for

24-h periods (4 d/wk for study 1 and 2d/wk for study 2). Blood samples were taken on days in milk (DIM) 3, 10, 17, and 24 for measuring BHBA concentrations. Cows were classified with subclinical ketosis when BHBA levels were $\geq$ 1400 μmol/L. All cows were examined on DIM 1, 4, 7, 10, and 13 for metritis and retained fetal membrane. Lameness was evaluated on DIM -28, 0, and 35; cows with locomotion score $\geq$ 3 (1 to 5 scale) were classified as lame. Cows with a health disorder were excluded from the lameness analysis. Other health events were obtained from on-farm records. The MIXED procedure of SAS was used to determine if feeding times were associated with transition health disorders. There was a reduction in daily prepartum feeding time for cows with metritis (Difference, LSMEANS ± SE min/d; 7.4 ± 2.7; $P < 0.01$), ketosis (15.4 ± 7.2; $P = 0.03$), retained fetal membrane (8.8 ± 3.9; $P = 0.02$), mastitis (9.2 ± 4.3; $P = 0.03$), lameness at DIM 0 (56.2 ± 10.0; $P < 0.01$), and lameness at DIM 35 (25.0 ± 6.2; $P < 0.01$), compared with cows without the respective disorder. There was a tendency for a reduction in feeding time for cows with displaced abomasum ($P = 0.09$) and cows carrying twins ($P = 0.08$). In conclusion, prepartum feeding behavior appears to be a useful indicator of cows at risk for transition disorders.

Key Words: feeding behavior, prepartum behavior, transition cows

0057 Eating and drinking behavior prediction by use of Tri-axial accelerometers in dairy cattle.
K. J. Haerr* and F. C. Cardoso, *University of Illinois, Urbana.*

Tri-axial accelerometers are often used to measure behavior in cows (e.g., estrus, standing, and lying). However, there may be other practical uses for accelerometers on dairy farms. Our objective was to determine if accelerometers placed on a collar around the cow's neck can be used to monitor feeding and drinking behaviors. For this study, 12 lactating Holsteins (DIM 76 ± 35) were housed in stanchion stalls and continuously recorded for 6 d (Swann Pro-530 night/day cameras, DVR). Cows were fitted with Onset Pendant G accelerometers on the collar and sampling intervals set at 6 s. Video data were watched and evaluated by the same person. Daily video duration (Video) of each behavior was summarized and compared with daily duration predicted by accelerometers. Three methods were created to evaluate behavior prediction by accelerometers. For method 1 (MET1), data set was constructed based on the mean for the 3 axes recorded. For method 2 (MET2), data set was constructed based on the mean plus the standard error for the 3 axes recorded. For method 3 (MET3), data set was constructed based on the mean minus the standard error for the 3 axes recorded. Four behaviors analyzed were standing and eating with head up (SEHU), standing and eating with head down (SEHD), standing and eating (EAT = SEHU + SEHD), and drinking (DRK). Statistical analysis was performed using the MIXED procedure in SAS. For SEHU, there was difference ($P < 0.001$) between Video (119.0 min) and MET1, MET2, and MET3, and tendency ($P > 0.06$) for differences among MET1, MET2, and MET3. For SEHD, there was a difference ($P < 0.001$) between Video (141.7) and MET1, MET2, and MET3, and tendency ($P > 0.09$) for differences among MET1, MET2, and MET3. For EAT, there was a difference ($P < 0.001$) between Video (260.7 min) and MET1, MET2, and MET3, however, there was no difference ($P > 0.48$) among MET1, MET2, MET3, and EAT. For DRK, there was no difference ($P = 0.89$) between Video (315.3 min) and MET1, MET2, and MET3. The accelerometer under predicted SEHU by 42.6%, 35.4%, and 49.2%; SEHD by 72.0%, 65.3%, and 71.8%; EAT by 57.6%, 51.6%, and 61.05% for MET1, MET2, and MET3, respectively. The accelerometer accurately predicted DRK by 100%, 103%, and 99% for MET1, MET2, and MET3, respectively. In conclusion, accelerometers were successful in predicting drinking behavior.

Key Words: accelerometer, intake, prediction

0058 Herding cows with a robot: The behavioral response of dairy cows to an unmanned ground vehicle.
C. E. Clark, S. C. Garcia*, K. L. Kerrisk, J. P. Underwood, J. I. Nieto, M. S. Calleija, S. Sukkarieh, and G. M. Cronin, *University of Sydney, Australia.*

Advances in technology could reduce time farmers spend on repetitive tasks. In pasture-based systems, herding cows from grazing areas to the milking parlor is a repetitive task ideally suited to automation. We conducted a field study at Sydney University's dairy farm to determine the behavioral response of dairy cows to a remotely operated unmanned ground vehicle (UGV) across time. Twenty milking cows were separated from the main herd at 0830 h and offered 0.5 ha of an ad libitum kikuyu pasture allocation (50 kg DM/cow to ground level). A pre-defined Fig. 8 route was determined for the UGV within this area. The UGV entered the pasture allocation at 0900 h and traversed this route at a target speed of 2.5 km/h, with the whole procedure repeated 6 times at 15-min intervals. The 0.5 ha was virtually split into 4 sectors. Four observers monitored cows exiting or entering each sector. Data were analyzed by REML, where Cows out = Fixed [Robot (presence/absence) × Traverse number] + Random (Cow). Alongside human observations, 3D LiDAR data from the UGV determined the velocity of cow movement for each traverse. There was a significant effect of Robot ($P = 0.02$) and Traverse ($P < 0.01$) on the number of cows (% of total cows) exiting a sector; however, there was no interaction between these fixed effects. Twice as many cows exited a sector when the robot was present (8%) as compared with absent (4%). More cows exited a sector in traverse 1 (14%) as compared with all other traverses (mean = 4%). The 3D LiDAR data showed a reduction in cow velocity moving away from the UGV for the first 3 traverses (Table 0058). These results show that dairy cows

habituated quickly to an UGV. The greater number of cows exiting a sector in the first traverse was likely associated with an initial period of increased cow movement as cows foraged. Future work will aim to fully automate the process of herding and integrate this process with the monitoring of animal health, ground cover, and soil moisture levels.

Key Words: cow behavior, herding, unmanned ground vehicle

Table 0058. Average (SD) velocity of cows away from the unmanned ground vehicle (UGV; m/s) for traverse 1 to 5

Traverse	Average (SD) velocity of cows moving away from UGV (m/s)
1	0.06 (0.27)
2	0.04 (0.27)
3	0.02 (0.21)
4	0.01 (0.17)
5	0.01 (0.19)

0059 Responses to rectal and uterine palpation for assessment of visceral pain associated with metritis in dairy cows.

J. Stojkov[*1], D. M. Weary[1], and M. A. G. von Keyserlingk[2], *[1]Animal Welfare Program, Faculty of Land and Food Systems, The University of British Columbia, Vancouver, Canada, [2]University of British Columbia, Vancouver, Canada.*

Metritis is a common disease in dairy cattle following calving, but to our knowledge no work has assessed the associated pain. A common method of assessing pain in human and veterinary medicine is through responses during tissue palpation. The objective of this study was to evaluate visceral pain responses in cows with clinical signs of metritis during rectal and uterine palpation. A total of 62 Holstein dairy cows (mean ± SD parity 3 ± 1.5) were subjected to systematic health checks starting d 3 after parturition and continuing every third day for 21 d. Cows were scored for vaginal discharge (0 to 4); 13 cows showed a discharge score ≥ 2 during at least 1 health check; these cows were classified as metritic. A matched (by parity and days in milk at diagnosis) sample of 13 cows was classified as "healthy." Cows showing any other signs of disease (including mastitis, ketosis, and lameness) were not included in the study. Behavioral and physiological responses during palpation were recorded using video and heart rate monitors. The effects of health status (healthy vs. metritic) and exam method (rectal vs. uterine palpation) were tested using the MIXED model. Back arch (cm^2) on the day of diagnosis was higher for metritic cows than healthy cows ($P < 0.01$), with no significant effect of palpation method or interaction. During rectal palpation, back arch averaged (± SE) 28 ± 2.3cm^2 for metritic vs. 18 ± 2.3cm^2 for healthy cows. During uterine palpation, back arch averaged 31 ± 2.3 vs. 19 ± 2.3cm^2, respectively. Standard deviation between normal to normal inter beat intervals (SDNN) and root of the mean square of successive differences (RMSSD) were log transformed before analysis. Both measures varied in response to exam method ($P < 0.05$) but not health status or interaction. The SDNN during rectal palpation averaged (± SE) 2.7 ± 0.16 compared with the uterine palpation 2.1 ± 0.16. Similarly, RMSSD was 1.8 ± 0.14 during the rectal palpation but decreased in the uterine palpation to 1.4 ± 0.14. The heart rate variation measures indicate that both healthy and metritic cows found uterine palpation more stressful than rectal palpation. The back arch results indicate that metritic cows are more sensitive to palpation (both methods) than healthy cows. These results also suggest that these types of veterinary exams may be used to identify cows that are experiencing pain associated with metritis and thus may be useful in deciding which animals will benefit from treatment with analgesics.

Key Words: metritis, pain response, visceral pain

ANIMAL HEALTH SYMPOSIUM I: ANIMAL HEALTH RESEARCH FROM THE PERSPECTIVE OF INFORMATION GAPS

0060 Animal health—From systems biology to translational research. C. Gay*, *USDA-ARS Office of National Programs, Beltsville, MD.*

Genome-enabled technologies are driving fundamental changes in the approaches used to understand mechanisms of disease, selection of animals for beneficial health traits, and discovery of tools to control and mitigate animal diseases. New research strategies using high-throughput gene expression analysis are providing novel platforms for more comprehensive understanding of host–pathogen interactions. In particular regard to application of the findings that result from these new technical capabilities, a systems biology approach has begun, is evolving in focus, and rapidly revolutionizing the analysis of whole genome responses of host and pathogens, which will ultimately lead to a better understanding of disease processes in affected animals. Concurrently, the capabilities facilitate new insights into the mechanisms through which pathogens evade host immunity, the genetic basis of host–pathogen interactions, and ultimately the discovery of novel and highly effective vaccines, drugs, biotherapeutics, and integrated management strategies that ensure the abundance and safety of the food supply while maintaining its economic affordability to all.

Key Words: animal, disease, intervention

0061 Respiratory disease management in livestock—New challenges and knowledge gaps. What is critical on the horizon? A. W. Confer*, *Oklahoma State University, Stillwater.*

Despite availability and use of numerous bovine respiratory pathogen vaccines and new antimicrobial drugs as well as a greater understanding of the pathogenesis of bovine respiratory disease (BRD), pneumonia ranging from subclinical to fatal remains a major cause of morbidity, mortality, and economic loss to the beef and dairy cattle industries. Gaps in our BRD knowledge that could greatly enhance our clinical management schemes mainly fall into 4 general questions. The objective of this presentation is to address briefly each question from the standpoint of general current knowledge and what we need to know to improve management and control of BRD. First, various environmental factors and stressors stimulate potential pathogens that are quiescent in the nasopharynx to replicate and be inhaled, resulting in disease. Can a better understanding of this process translate into improved disease management? Second, currently published studies indicate low heritability for BRD resistance. Can BRD morbidity and mortality be reduced through genomic studies and breeding for genetic resistance. Third, numerous antibiotics are currently available and in use to control and treat BRD. Does in vitro antibiotic resistance and susceptibility of BRD pathogens correctly predict in vivo antimicrobial efficacy? Fourth, in the last 20 yr, we have greatly increased our knowledge base about immunity against BRD pathogens. What has been and can be translated from the research laboratory into improved commercial vaccines?

Key Words: cattle, disease, management

0062 Metabolic and health consequences of heat stress: Knowledge gaps and opportunities. L. H. Baumgard*[1], J. W. Ross[1], N. K. Gabler[1], S. M. Lonergan[1], A. F. Keating[1], J. T. Selsby[1], and R. P. Rhoads[2], [1]*Iowa State University, Ames,* [2]*Virginia Tech, Blacksburg.*

Environmental-induced hyperthermia compromises efficient animal production and jeopardizes animal welfare. Reduced animal agriculture productive output during heat stress was traditionally thought to result from decreased nutrient intake. Our results in ruminants and monogastrics challenge this dogma and indicate heat-stressed animals use homeorhetic strategies to modify metabolic and fuel selection priorities independently of nutrient and energy intake. Systemic shifts in bioenergetics are characterized by increased basal and stimulated circulating insulin. Hepatocyte and myocyte metabolism also show clear differences in glucose production and oxidation during heat stress. Perhaps most intriguing given the energetic shortfall of the heat-stressed animal is the apparent lack of basal adipose tissue mobilization coupled with reduced responsiveness to lipolytic stimuli. The origin of the aforementioned metabolic changes may lie at the gastrointestinal track. For a variety of reasons, heat stress compromises intestinal integrity. Increased permeability to luminal contents results in local and systemic inflammatory responses. Bacterial components might be additional signals influencing insulin secretion during heat stress. For example, in vivo lipopolysaccharide (LPS) IV infusion acutely increases circulating insulin in pigs and cattle, which is paradoxical as endotoxemia is a potent catabolic condition accompanied by severe pyrexia and marked hypophagia. Understanding how and why LPS induces hyperinsulinemia remains to be elucidated, but the practical implications of this phenomenon to animal agriculture are numerous. Consequently, heat-stressed animals are simultaneously confronted with life-threatening hyperthermia and endotoxemia. However, the fields of both environmental metabolism and intestinal integrity are essentially in their infancies (especially in animal agriculture). As a result, there are numerous knowledge gaps that exist and need attention before mitigation strategies can be developed. Of particular relevance to animal agriculture are the tissue- and organ-specific consequences of heat stress. For example, how the liver, muscle, adipose, mammary, and

ovarian systems respond to elevated temperatures, endotoxemia, and LPS-induced inflammation is of obvious interest. Further, determining how these systems are homeostatically and homeorhetically coordinated to prioritize acclimation and survival vs. agriculturally productive purposes would presumably enlighten mechanisms amenable to manipulation. In summary, heat stress is 1 of the primary hurdles to efficient animal production. Defining the physiology and mechanisms that underlie how heat stress jeopardizes animal performance is critical for developing approaches to ameliorate current production issues and a prerequisite for generating future strategies (genetic, managerial, nutritional, and pharmaceutical) to improve animal well-being and performance.

Key Words: heat stress, insulin, intestinal integrity

0063 Ensuring good health and well-being in the aging equine population. K. Malinowski*, R. C. Avenatti, and K. H. McKeever, *Rutgers Equine Science Center, New Brunswick, NJ.*

One of the largest industries in the United States involves horses, a $39.2 billion business associated with 9.2 million animals. The horse industry's contribution to the U.S. gross domestic product is $102 billion, generating more than 1.4 million full-time equivalent jobs across the country. More than 15% of the equine population is > 20 yr old and many of these animals continue to participate in athletic activities. Partly responsible for the increased lifespan of horses is the fact that equine nutritionists have advanced the development of "senior feeds," and that the animal pharmaceutical industry has developed effective anthelmentics for parasite control. However, advancing age in horses is often associated with declining body condition, muscle tone, aerobic capacity, thermoregulatory ability in response to acute exercise, and general well-being. While aging and obesity-related loss of function and diseases have many factors, understanding the underlying imbalance of molecular signaling mediators in metabolically important tissues, such as muscle, to preserve functionality of physiological systems, needs to be addressed. Advanced age in horses is associated with a decline in immune response and is characterized by increased production of pro-inflammatory cytokines, termed inflammageing, which has been linked to obesity. Horses > 20 yr old can improve aerobic performance, reduce body fat, and partially restore changes that occur in the hypothalamic-pituitary-adrenal axis, in response to acute exercise and insulin sensitivity with regular exercise training. Physiological similarities between humans and horses allow for broad implications of equine exercise physiology research in relation to aging and performance. Understanding the molecular mechanisms behind the adaptive response to exercise will aid in the development of exercise conditioning and nutritional strategies meant to preserve the health and well-being of this socioeconomically important species.

Key Words: aging, exercise, horses

ANIMAL HEALTH I: **MODELS OF DISEASE AND STRESS**

0064 Heat stress as a model to study the effect of a gut health concept (Presan-Fx) on the intestinal barrier function of weanling piglets. P. J. Roubos* and Y. M. Han, *Nutreco Research and Development, Boxmeer, Netherlands.*

An acute heat stress model is used to study effects on the intestinal barrier function. During heat stress, the animal redistributes the blood supply to the periphery, leading to increased gut permeability. To mitigate the impairment on barrier function, a mixture of Presan-Fx (synergistic blend of organic acids, medium chain fatty acids, butyrates, and a phenolic compound) was used in this model with weanling piglets. The objective of this study was to evaluate the effect of a heat stress challenge on intestinal barrier function and the role of gut health concept in it. Twenty-four piglets were distributed over 4 treatments in a 2 × 2 factorial design, with a control diet with or without Presan-Fx (2 kg/ton), under the condition with or without heat challenge. After a 6-d adaptation period, animals in the heat stress groups were given an acute heat stress of 40°C for 10 h followed by 28°C for 24 h. Animals were monitored for growth performance and the barrier function was evaluated by morphological assessment, tight junction proteins, and cytokine production. Heat stress decreased ADG, but the impact was reversed significantly in animals fed Presan-Fx (see Table 0064). For the animals fed Presan-Fx, villus height was higher and the crypt depth was lower after heat stress compared with the control, suggesting that enterocytes had fewer damaged villi and higher cell production. Heat stress decreased the overall expression of the tight junction proteins Claudin-4, Claudin-7, and Occludin had no effect on E-cadherin. The dietary treatments did not influence the expression of tight junction proteins. However, the expression of 5 inflammatory cytokines (Il-1α, IL-8, IL-10, IL-17, and IL-23) was decreased by the Presan-Fx as measured by Q-PCR. In conclusion, an acute heat stress impaired intestinal barrier function. Adding Presan-Fx supported the animals with a better resistance to a heat stress challenge.

Key Words: gut health, heat stress, intestinal barrier function

Table 0064. Average daily growth and histology data

	No stress		Heat stress		
	Control	Presan-Fx	Control	Presan-Fx	P-value
ADG 0 to 6, g	411.0	455.5	456.6	416.7	0.98
ADG 6 to 8, g			90.0[a]	341.7[b]	0.05
ADG 6 to 11, g	550.0	503.3

0065 A dual challenge of corticotropin-releasing hormone and vasopressin alters immune cell profiles in beef heifers. J. A. Carroll*[1], N. C. Burdick Sanchez[1], J. O. Buntyn[2], S. E. Sieren[3], S. J. Jones[3], and T. B. Schmidt[3], *[1]USDA-ARS, Livestock Issues Research Unit, Lubbock, TX, [2] Department of Animal Science, University of Nebraska, Lincoln, [3]University of Nebraska, Lincoln.*

The duration and magnitude of cortisol release can have different effects on the immune response. Over the last decade, studies have suggested that acute stress, when cortisol is elevated for a short duration of time, can be immuno-stimulatory rather than immuno-suppressive. This study was designed to determine the effect of an induced cortisol release, via a dual corticotropin-releasing hormone (CRH) and vasopressin (VP) challenge, on changes in immune cell profiles of beef heifers. Four days before the challenge, 10 heifers (605 ± 13 kg) were fitted with indwelling jugular cannulas and indwelling vaginal temperature (VT) recording devices that measured VT continuously at 5-min intervals. On d 0, heifers were challenged IV with 0.3 µg/kg BW bovine CRH and 1.0 µg/kg BW bovine VP concurrently. Two whole blood samples were collected at 30-min intervals from -2 to 8 h relative to the challenge at 0 h. One vacutainer containing EDTA was collected for complete blood cell count (CBC) analysis and the second was collected in a 9-mL monovette serum tube. After collection, serum was isolated and stored at −80°C until analyzed for cortisol concentrations by ELISA. There was a time effect ($P < 0.001$) for VT, cortisol, and CBC variables. A multiphasic response was observed for VT, with VT initially increasing ($P = 0.05$; relative to 0 h) within 15 min post challenge. Serum cortisol concentrations increased ($P < 0.001$) immediately after the challenge, reaching maximum concentrations between 0.5 and 2 h post challenge, and then continuously decreasing until reaching baseline concentrations at 6 h post challenge ($P = 0.17$; 0 vs. 6 h). Total white blood cell and lymphocyte concentrations increased ($P < 0.001$) 2 h after CRH/VP challenge and remained elevated for the duration of the blood collection period. Monocyte concentrations initially decreased 1 h post challenge ($P < 0.001$), and returned to baseline concentrations by 2 h post challenge ($P = 0.08$; 0 vs. 2 h). In contrast, neutrophil concentrations decreased ($P = 0.02$) 3 h post challenge and remained decreased throughout the duration of the blood collection period. These data demonstrate that immune cell populations are influenced by an acute activation of the hypothalamic-pituitary-adrenal axis. Additionally, the increase in circulating concentrations of lymphocytes and decrease in circulating concentrations of neutrophils observed in this study are indicative of an immunological priming event that could be beneficial to the animal.

Key Words: acute stress, cortisol, immune response

0066 Investigating innate immune response differences between Angus and Holstein cattle with the dermal fibroblast model. A. L. Benjamin[*1], W. J. Weber[2], S. D. McKay[1], B. A. Crooker[2], and D. E. Kerr[1], *[1]University of Vermont, Burlington, [2]University of Minnesota, St. Paul.*

Individual immune responses to pathogens can be variable, depending on environmental, genetic, and possibly epigenetic influences. Holstein and Angus cattle are selectively bred and managed for different traits, which could impact disease susceptibility between these breeds. A dermal fibroblast model was used to investigate potential genetic and epigenetic influences on the innate immune response in each breed. Skin biopsies were collected from the shoulder area of 5 Holstein and 12 Angus 19-mo-old heifers. Fibroblasts were isolated by collagenase digestion and cryopreserved. Revived cells were challenged with LPS (100ng/ml; 24h) and levels of secreted IL-8 were determined. The Holstein cultures produced ~3 times more ($P < 0.01$; unpaired t test) IL-8 then the Angus cultures (2190 ± 600 vs. 650 ± 370 pg/ml, respectively). Total RNA was collected from 4 Angus and 4 Holstein cultures that were cultured in parallel and challenged with LPS for 0, 2, and 8 h. Whole transcriptome analysis was performed by RNA-seq with an average of 46 million reads per sample aligned to the UMD 3.1 reference genome by NextGENe software. Breed differences in gene expression were determined with the edgeR statistical package. Between breeds, there were 849, 1014, and 751 genes differentially expressed genes (FDR < 0.05, fold change > 2) at h 0, 2, and 8 post-LPS, respectively. Immune response genes, such as TNF-a at 2,h and IL-8 and CCL20 at 8 h, were induced 6.9-, 4.5-, and 8.6-fold more in Holsteins compared with Angus, whereas expression at 2 h of CXCL12 and TRAIP, an inhibitor of TRAF2-mediated NF-kB activation, were 7.4- and 2.7-fold higher in Angus. Additionally, a semi-quantitative assessment of global DNA methylation was performed by methylated CpG island recovery assay (MIRA-seq) on genomic DNA extracted from these cultures. Read alignment (44 million reads per sample) and differential methylation region (DMR) analysis were performed similarly to RNA-seq. The genome was analyzed in consecutive 3 kb regions and revealed 51 DMR (FDR < 0.1, fold change > 2). Of these, 35 were more methylated in Angus and 16 were more methylated in Holsteins. Relationships among these DMR and the differential gene expression are not readily apparent, but are being further investigated. Our results reveal breed differences in the LPS response of dermal fibroblasts isolated from Angus and Holstein heifers. Given that the cells were cultured side by side in controlled environmental conditions, the observed differences are likely due to a combination of genetic and epigenetic factors.

Key Words: epigenetics, variation

0067 Predictive models of lameness in dairy cows achieve high sensitivity and specificity with force measurements in 3 dimensions. J. T. Dunthorn[*1], R. M. Dyer[2], U. Tasch[3], N. Neerchal[3], P. Rajkondawar[4], and G. Steingraber[4], *[1]Step Analysis, Baltimore, MD, [2]University of Delaware, Newark, [3]University of Maryland, Baltimore County, Baltimore, [4]BouMatic, Madison, WI.*

Lameness remains a significant cause of production losses and a growing welfare concern across the dairy industry. Metabolic, nutritional, and housing factors interact to sustain a steady increase in the prevalence of lameness, driving a growing need for automated and continuous methods of lameness detection. A force-plate system restricted to the vertical (z) dimension yielded a high specificity but low sensitivity of detection. The objective of this study was to determine the effect of supplementing the vertical dimension with the transverse (x) and longitudinal (y) dimensions on detection accuracy. We used a parallel, force-plate system to measure the ground reaction forces (GRF) across 3 orthogonal directions (3D). The GRF for randomly selected cows ($n = 83$) were recorded and a clinical diagnosis of lameness was generated using locomotion score, lesion diagnosis, lesion score, and claw and interdigital integument pain score. Logistic regression was used to characterize the relationship between the clinical characteristics and GRF across all 3 orthogonal dimensions to generate a statistical algorithm for the probability of lameness. Misclassification error was estimated using a modification of the Leave-One-Out (LOO) method of cross validation. The LOO

Table 0067. Model performance using various combinations of measurement directions (1-degree, 4-knot spline transformation). Results have been ordered by increasing AUC

Measurement direction (including stance time)	TN	FP	FN	TP	Sensitivity	Specificity	AUC
x	213	44	94	45	0.32	0.83	0.59
z	212	45	87	52	0.37	0.82	0.62
x, z	210	47	61	78	0.56	0.82	0.73
y	218	39	77	62	0.45	0.85	0.75
y, z	222	35	53	86	0.62	0.86	0.79
x, y	221	36	50	89	0.64	0.86	0.83
x, y, z	239	18	14	125	0.90	0.93	0.98

x = transverse (medial-lateral) direction; y = longitudinal (cranial-caudal) direction; z = vertical (weight) direction.

cross validation trains the model using all but a single run. We modified LOO to leave out all runs except for those from a single cow, Leave-One-Cow-Out (LOCO), to use as the training data and tested the resulting model using the runs of the cow not used in model development. This preliminary study determined that 76 variables across all 3 dimensions resulted in a model with 90% sensitivity, 93% specificity, and 98% area under the receiver operating curve (AUC). Furthermore, all 3 dimensions were both necessary and sufficient to accurately establish the probability of lameness (Table 0067).

Key Words: animal welfare, lameness, 3-dimensional ground reaction forces

0068 Performance trends in commercial livestock populations in the United States before and subsequent to the inclusion of genetically modified feed in livestock diets. A. L. Van Eenennaam*, *University of California-Davis, Davis.*

The first genetically modified (GM) crops were planted in the United S in 1996; by 2000, GM soy and cotton comprised > 50% of U.S. land devoted to these crops. Adoption increased steadily thereafter and in 2013 a total of 93% of soy, 90% of cotton, and 90% of all corn grown in the United States were GM varieties. It is estimated that 70 to 90% of harvested GM biomass is fed to food-producing animals, making the world's livestock populations the largest consumers of the current generation of GM crops. It has been purported by some that GM feed has deleterious effects on underlying animal health. The United States feeds billions of livestock each year, providing a very large uncontrolled GM feeding field data set. Considering that animal health is critical to optimizing production performance and animal production systems are managed to minimize disease, it would be reasonable to hypothesize that if animal feed derived from GM crops had deleterious effects on the billions of animals that have been fed on diets containing predominantly GM feed, then animal performance and health attributes in these large populations would have been negatively impacted. To test this hypothesis, data on livestock productivity and health (somatic cell count, percent mortality, percent postmortem carcass condemnation) were collated from publicly available sources for 2 time periods: 1983–1994, before the introduction of GM crops in 1996, and 2000–2011, a period with high levels of GM feed based on high rates of U.S. adoption and international trade of GM crops. These data on broilers, dairy and beef cattle, and swine revealed improving productivity and animal health trends. Productivity improvements in all livestock species continued in the positive direction they were trending before the introduction of GE feed, often at an accelerated rate ($P < 0.05$), and health parameters also improved over time. Available mortality and carcass condemnation data suggest that these rates actually decreased during the 2000–2011 time period when high levels of GM ingredients would be expected to be present in livestock feed. Field data sets representing billions of observations do not reveal disturbing trends in U.S. livestock health and productivity data. These data are in agreement with the many peer-reviewed, controlled animal feeding studies that have reported no biologically relevant difference between the nutritional attributes and safety of feed from GM plants, as compared with feed derived from conventional crop varieties.

Key Words: animal health, feed, genetically modified, GMO

0069 Evaluation of a Brix refractometer to estimate serum immunoglobulin G concentration in neonatal dairy calves. S. M. Deelen[1], T. L. Ollivett[1], D. M. Haines[2], and K. E. Leslie*[1], *[1]University of Guelph, ON, Canada, [2]University of Saskatchewan, Saskatoon, Canada.*

The objective of this study was to evaluate the utility of a digital Brix refractometer for the assessment of success of passive transfer of maternal immunoglobulin, as compared with the measurement of serum total protein (STP) by refractometry. Blood samples (n = 400) were collected from calves 3 to 6 d of age. Serum IgG concentration was determined by radial immune-diffusion (RID) and STP and percent Brix (%Brix) using a digital refractometer. The mean (± SD) IgG concentration was 24.1 ± 10.0 g/L, with a range from 2.1 to 59.1 g/L. The mean STP concentration was 6.0 ± 0.8 g/dL, with a range from 4.4 to 8.8 g/dL. The mean %Brix concentration was 9.2 ± 0.9%, with a range of 7.3 to 12.4%. Brix percentage was highly correlated with IgG [correlation coefficient (r) = 0.93]. Test characteristics were calculated for the assessment of failure of passive transfer (FPT; serum IgG < 10 g/L). The sensitivity and specificity of STP at 5.5 g/dL were 76.3% and 94.4%, respectively. However, it is noteworthy that relatively few samples had IgG levels < 10 g/L. As such, further evaluations of different populations are warranted. A receiver operating characteristic curve was created to plot the true positive rate against the false positive rate for consecutive %Brix values. The optimal combination of sensitivity (88.9%) and specificity (88.9%) was at 8.4% Brix. Serum total protein was also positively correlated with %Brix (r = 1.00) and IgG (r = 0.93). The results of the current project suggest that dairy producers can successfully monitor their colostrum management and the overall success of passive transfer using a digital Brix refractometer to estimate IgG concentration of colostrum and calf serum.

Key Words: calf, passive transfer, refractometer

0070 Associations of serum haptoglobin in newborn dairy calves with future health, growth, and mortality up to 4 mo old. C. F. Murray[1], C. Windeyer[2], T. F. Duffield[1], K. M. Waalderbos[1], and K. E. Leslie[*1], *[1]University of Guelph, ON, Canada, [2]University of Calgary, AB, Canada.*

The objective of this research was to investigate factors associated with serum haptoglobin (Hp) levels in newborn calves. In addition, the associations between serum Hp levels in newborn calves with future growth, morbidity, and mortality in calves up to 4 mo of age were investigated. A total of 1365 Holstein heifer calves from 15 dairy farms were enrolled in this study during 2008. Following calving, a birth record was completed, including information on the calving event, colostrum administration, and other details. During weekly farm visits, each calf was assessed at 1 to 8, 15 to 21, 36 to 42, and 90 to 120 d of age. At these times, each calf was assessed using a standardized clinical score for general health and height and weight were measured. At the first sampling event, a blood sample was collected for the determination of serum total protein and Hp. Treatment events and death loss were recorded by the farm staff throughout the study. Data analysis was conducted using a multivariable linear regression model to evaluate associations of explanatory variables with serum Hp. Separate multivariable logistic models were used to determine associations of various factors with treatment for disease and mortality. Serum Hp concentration in the first week of life was not significantly associated with the degree of calving difficulty. However, serum Hp was higher in calves with a higher rectal temperature and depressed attitude at the first sampling event. Calves with higher Hp in their first week of life had a significantly higher total health score throughout the entire sampling period. Haptoglobin was not significantly associated with ADG or treatment for bovine respiratory disease. Yet, for every 1 g/L increase in serum Hp in the first week of life, the odds of being treated for any other disease during the study period increased by 7.6 times. In addition, Hp concentration in the first week of life was associated with mortality in calves up to 4 mo of age. The optimal cut point for Hp was determined to be 0.13 g/L for the prediction of disease and death, although the sensitivity of Hp concentration as a diagnostic test for individual calves was low. Monitoring serum Hp in the first week of life shows considerable promise at the group level for overall assessment of calving management and the impact of calving events on future health and mortality.

Key Words: haptoglobin, health, mortality

0071 Dynamics of culling for Jersey, Holstein, and crossbred cows in large multi-breed herds. P. J. Pinedo[*1], A. Daniels[2], J. Shumaker[3], and A. De Vries[4], *[1]Texas A&M AgriLife Research, Amarillo, [2]Circle H Headquarters LLC, Dalhart, TX, [3]Magnolia Veterinary Services, Amarillo, TX, [4]University of Florida, Gainesville.*

The objective of this observational study was to describe and compare the dynamics of reason-specific culling risk for the genetic groups Jerseys (JE), Holsteins (HO), and Jersey × Holstein crossbreds (JH), considering parity, stage of lactation, and milk yield, among other variables, in large multi-breed dairy herds in Texas. The secondary objective was to analyze the association between survival and management factors, such as breeding and replacement policies, type of facilities, and use of cooling systems. After edits, available data included 202,384 lactations in 16 herds, ranging from 407 to 8773 cows calving per year during the study period from 2007 to 2011. The distribution of lactation records by genetic group was 58%, 36%, and 6% for HO, JE, and JH, respectively. Overall culling rates across breeds were 30.1%, 32.1%, and 35.0% for JH, JE, and HO, respectively. The dynamics of reason-specific culling were dependent on genetic group, parity, stage of lactation, milk yield, and herd characteristics. Early lactation was a critical period for "died," and "injury-sick" culling. The risk increased with days after calving for "breeding" and, in the case of HO, "low production" culling. Open cows had a 3.5 to 4.6 times greater risk for overall culling compared with pregnant cows ($P < 0.01$). The odds of culling with reason "died" within the first 60 d in milk (DIM) were not significantly associated with genetic group. However, both JE and JH had lower odds of live culling within the first 60 DIM compared with HO cows [OR = 0.72 ($P < 0.001$) and 0.82 ($P = 0.002$), respectively]. Other cow variables significantly associated with the risk of dying within the first 60 DIM were cow relative 305 mature equivalent (MEQ) milk yield, parity, and season of calving. Significant herd-related variables for death included herd size and origin of replacements. In addition to genetic group, the risk of live culling within 60 DIM was associated with cow relative 305 MEQ milk yield, parity, and season of calving. Significant herd-related variables for live culling included herd relative 305 MEQ milk yield, herd size, type of facility, origin of replacement, and type of maternity. Overall, reason-specific culling followed similar patterns across DIM in the 3 genetic groups.

Key Words: culling, death, Holstein, Jersey

0072 Relationship of ocular and rectal temperatures to indicators of stress in mature horses.

M. J. Anderson*, J. L. Lucia, K. J. Stutts, M. M. Beverly, and S. F. Kelley, *Sam Houston State University, Huntsville, TX.*

Rectal temperature has commonly been used as an indicator of health in many species of livestock, including horses. However, collection of a rectal temperature can be difficult and stressful on the animal. New technology, such as thermal imaging cameras, have recently become more prevalent and have been used to collect the body temperature of animals at other, less-invasive sites, including the ocular globe. The objective of this research was to determine the relationship between rectal temperature and ocular temperature, and to evaluate the efficacy of these measurements as indicators of the stress level of horses. To accomplish this, ocular temperature (OT), rectal temperature (RT), neutrophil count, lymphocyte count, heart rate (HR), and respiration rate (RR) were recorded before and during an immune challenge, using a novel vaccination of 30 mature horses (413 to 551 kg and 5 to 10 yr). Neutrophil to lymphocyte ratio (N:L) has been shown to be a good indicator of systemic inflammation and overall stress in an animal, and was used as the primary indicator of stress in this study. To determine the relationship between temperatures and among indicators of stress, the PROC CORR procedure of SAS was used. The relationship between OT and RT was found to have a weak correlation ($r = 0.37$; $P < 0.01$), illustrating that OT is not a good substitute for traditional RT measurements. Additionally, OT had very little relationship with N:L ($r = -0.01$; $P = 0.94$), HR ($r = 0.19$; $P = 0.31$), or RR ($r = 0.17$; $P = 0.38$). While still very weak, RT had stronger relationships than OT with N:L ($r = -0.11$; $P = 0.40$) and RR ($r = 0.26$; $P = 0.17$) and a similar correlation to HR ($r = 0.19$; $P = 0.31$). Of all the non-invasive measurements (OT, HR, and RR), RR had the strongest correlation to N:L as an indicator of systemic stress, ($r = -0.24$; $P = 0.21$). While OT is less invasive than RT, a direct measurement of OT is not a reliable predictor of RT in an animal. Still, it may hold some value to livestock and wildlife producers due to its ease of measurement, but without further investigation into the relationship of OT and indicators of stress, its utility remains limited.

Key Words: ocular temperature, rectal temperature, stress

0073 Enhancement of the acute phase response to lipopolysaccharide in feedlot steers supplemented with OmniGen-AF.

N. C. Burdick Sanchez*[1], J. O. Buntyn[2], J. A. Carroll[1], T. Wistuba[3], K. DeHaan[3], S. E. Sieren[4], S. J. Jones[4], and T. B. Schmidt[4], *[1]USDA-ARS, Livestock Issues Research Unit, Lubbock, TX, [2]Department of Animal Science, University of Nebraska, Lincoln, [3]Prince AgriProducts Inc., Quincy, IL, [4]University of Nebraska, Lincoln.*

This study was designed to determine the effect of supplementing feedlot steers with OmniGen-AF on the acute phase response to a lipopolysaccharide (LPS) challenge. Steers ($n = 18$; 270 ± 5 kg BW) were separated into 2 treatment groups ($n = 9$/treatment): 1 group was fed a standard receiving diet (Control, Cont) and the other group was fed the same receiving diet supplemented with OmniGen-AF at 4 g/45.4 kg BW for 29 d (OmniGen-AF). On d 27, steers were fitted with indwelling jugular cannulas and rectal temperature (RT) monitoring devices, and placed in individual stalls. On d 28, steers were challenged IV with LPS (0.5 μg/kg BW at 0 h). Sickness behavior scores (SBS) and 2 whole blood samples were collected at 30-min intervals from -2 to 8 h relative to the challenge at 0 h. One vacutainer containing EDTA was collected for complete blood cell count (CBC) analysis and the second was collected in a 9-mL monovette serum tube; after collection, serum was isolated and stored at −80°C until analyzed for cortisol and cytokine concentrations. Rectal temperature, SBS, and cortisol were affected by time ($P < 0.001$). Before the challenge, RT was greater ($P < 0.001$) in Cont steers (39.31 ± 0.03°C) than OmniGen-AF steers (39.14 ± 0.03°C). Therefore, post-challenge RT was analyzed as the change in response from baseline values. The change in RT relative to baseline values increased ($P < 0.001$) in both groups in response to LPS challenge but was not affected by treatment ($P = 0.49$). Sickness behavior scores increased ($P < 0.001$) after LPS challenge and tended ($P = 0.09$) to be greater in Control (1.57 ± 0.02) than OmniGen-AF steers (1.51 ± 0.02). Cortisol concentrations were affected by treatment ($P = 0.005$) and time ($P < 0.001$). For both groups, cortisol increased ($P < 0.001$) in response to LPS challenge. Cortisol was greater in Cont (29.2 ± 0.9 ng/mL) than OmniGen-AF steers (25.5 ± 0.9 ng/mL). White blood cell and lymphocyte concentrations were greater ($P \leq 0.004$) in Cont than OmniGen-AF steers throughout the study. Neutrophils were decreased ($P = 0.04$) in Cont steers (0.7 ± 0.2 K/uL) compared with OmniGen-AF steers (1.3 ± 0.2 K/uL) before the LPS challenge. There was a treatment ($P \leq 0.02$) and time ($P < 0.001$) effect for tumor necrosis factor-α (TNFα) and interferon-γ (IFNγ). Specifically, TNFα and IFNγ concentrations increased ($P < 0.001$) in response to LPS challenge. Furthermore, concentrations of TNFα and IFNγ were decreased in ($P \leq 0.02$) in Cont steers compared with OmniGen-AF steers. These data suggest that OmniGen-AF supplementation served to prime the immune

system before the LPS challenge, allowing for an enhanced response to LPS challenge.

Key Words: cattle, immune response, OmniGen-AF

0074 Age-dependent changes in heifer fibroblast DNA methylation and LPS-induced gene expression.

B. B. Green*, S. D. McKay, and D. E. Kerr, *University of Vermont, Burlington.*

To determine how the innate immune response develops in dairy calves, dermal fibroblasts were isolated from 15 heifers at 3 stages of development (5, 11, and 16 mo of age) and challenged with 100 ng/ml of lipopolysaccharide (LPS) for 36 h. The secretion of interleukin- (IL) 8 protein into media in response to LPS increased significantly ($P < 0.01$) at each age as measured by a paired 1-way ANOVA with average IL-8 levels of 300 ± 220, 1340 ± 530, and 1750 ± 560 pg/ml at 5, 11, and 16 mo, respectively. To investigate a potential involvement of DNA methylation in this differential responsiveness, cultures from 3 of these animals obtained when they were young (5 mo) and older (16 mo), underwent DNA de-methylation through exposure to 10mM 5-aza-2'-deoxycytidine (AZA) for 4 d before 24-h LPS exposure ($n = 3$/group). The AZA treatment abolished the differential IL-8 response to LPS seen under control conditions ($P < 0.01$), primarily due to an increase in production by the young cultures (control young vs. old 240 ± 20 vs. 1350 ± 290 pg/ml, respectively; AZA Young vs. Old 1580 ± 50 vs. 1690 ± 70 pg/ml, respectively). The role of DNA-methylation in the gene expression response to LPS was further investigated by comparing the findings of methylated -CpG island recovery assay (MIRA-seq) on DNA from 3 pairs of young and older cultures to RNA-seq findings on the same cultures at 0, 2, and 8 h post-LPS exposure. The resulting libraries averaged 71 and 49 million reads per sample for RNA-seq and MIRA-seq, respectively. Sequence reads were aligned to the UMD3.1 reference genome using NextGENe software and expression and methylation analysis were performed with EdgeR. The overall response to LPS was robust with 617 and 414 genes displaying differential expression (> twofold difference; FDR < 0.05) at h 2 and 8, respectively, as compared with h 0. Older cultures had greater expression than younger cultures of many immune-associated genes, such as IL-8, IL-6, TNF-a, and CCL20 at 2 h post-LPS exposure (5.8-, 10.5-, 10.4-, and 18.1-fold, respectively). In addition, whole genome MIRA-seq analysis of consecutive 3 kb regions identified 20 differentially methylated regions between young and older cultures (> twofold difference; FDR < 0.1). Further analysis of these candidate regions is being conducted to determine how DNA methylation changes within animals over time and its potential role in development of the innate immune response.

Key Words: epigenetics, innate immunity, methylation

0075 Effect of trace mineral supplementation on clinical signs, immune response variables, and mineral balance of calves following exposure to bovine viral diarrhea virus and subsequent *Mannheima haemolytica* infection.

B. K. Wilson*[1], G. I. Zanton[2], D. L. Step[1], R. W. Fulton[1], A. W. Confer[1], C. L. Maxwell[1], C. A. Gifford[1], C. R. Krehbiel[1], and C. J. Richards[1], *[1]Oklahoma State University, Stillwater, [2]Novus International, Inc., St. Charles, MO.*

The objective was to determine the influence of copper, manganese, and zinc supplementation on the clinical signs, immune response variables, and mineral balance of calves, following a bovine viral diarrhea virus (BVDV) and *Mannheima haemolytica* (MH) immune challenge. Steers ($n = 16$; BW = 225 ± 20 kg) from a single ranch were processed, weaned, and randomly pairwise assigned to either the mineral supplemented (MIN) or control (CON) experimental treatments. The MIN calves received 150 mg of Cu, 130 mg of Mn, and 360 mg of Zn daily, whereas CON calves received the basal diet with no additional Cu, Mn, or Zn supplementation. The basal diet contained sufficient Mn and Zn, but inadequate Cu based on published nutrient requirements. After 46 d on the experimental treatments, all calves were naturally exposed to BVDV type 1b for 4 d and subsequently infected with *MH*. Data were analyzed using the GLM procedure of SAS with sampling time serving as a repeated measure. Calf served as the experimental unit. The immune challenge was validated via increased ($P < 0.001$) BVDV antibody titers, MH whole cell (WC) and leukotoxin (LKT) antibody titers, rectal temperatures (TEMP), and subjective clinical scores (CS). A time by treatment interaction was observed for BVDV and MHWC antibody titers ($P \leq 0.04$). Calves receiving MIN had reduced ($P = 0.03$) BVDV antibody titers but increased ($P = 0.02$) MHWC antibody titers compared with CON calves. Mineral supplementation did not impact CS, TEMP, or MHLKT antibody titers ($P \geq 0.48$). There was a significant ($P < 0.001$) time by treatment interaction observed for liver Cu levels. Time significantly impacted the concentrations of Cu, Mn, Fe, and Zn within the liver and Cu, Zn, and Fe within the muscle and serum ($P \leq 0.03$). Calves receiving MIN had greater liver Cu ($P < 0.001$) and Mn ($P = 0.04$) concentrations compared with CON calves. In contrast, serum Cu concentrations were increased ($P = 0.02$) in CON calves compared with MIN calves. Mineral supplementation did not impact mineral levels within the muscle samples ($P \geq 0.20$). The supplementation of Cu, Mn, and Zn may potentially impact the antibody response to a BVDV and MH immune challenge in calves. When Cu is supplemented to calves receiving a marginally Cu deficient diet, Cu status within the body can be altered.

Key Words: bovine respiratory disease, mineral supplementation, immune challenge

ANIMAL HEALTH SYMPOSIUM II: OPTIMIZING DISEASE RESPONSE MODELING

0076 Understanding animal-to-animal variation in disease management. D. E. Kerr*, *University of Vermont, Burlington.*

A long-term goal of animal health research is to understand causes of animal-to animal variation in innate immune function, such that this knowledge can be applied to breeding, selection, management, or other strategies to generate animals with enhanced disease resistance. Key to this research is an accurate determination of phenotype. However, variation in expression of the phenotype due to differing environmental conditions, including differing physiological states of the animal, confound the ability to accurately compare animal-to animal responses, except under well-defined experimental conditions. The range of infection responsive phenotypes is quite likely dependent on underlying genetic variation that gives much promise to finding genetic markers for use in breeding programs. However, the evolving field of epigenetics suggests that in utero and early life environments can have significant effects on gene expression. Model systems to evaluate variation in the innate immune response may assist in more accurate determination of phenotype to enable detection of genetic or epigenetic biomarkers. These model systems may also be of use in testing immature animals for a prediction of adult performance. An example of a model system is the in vivo endotoxin (LPS) challenge that has been used to identify hyper responder animals. Another approach is the dermal fibroblast model in which substantial animal-to-animal variation has been revealed by how their fibroblasts respond to an in vitro LPS challenge. In this model, the cells are cultured under controlled conditions for several passages to limit environmental effects in an attempt to reveal underlying genetic or epigenetic causes for animal variation. Future studies using these and other model systems, combined with well-controlled disease challenges of extreme phenotypes, will lead to a greater understanding of factors contributing to variation in disease resistance.

Key Words: epigenetics, innate immunity, LPS

0077 Can the genetic selection for improved immune response be tailored to expand the efficacy of disease management interventions. B. Mallard*, *Department of Pathobiology, OVC, University of Guelph, ON, Canada.*

Infectious diseases are costly to all aspects of domestic animal management, care, and well-being across all aspects of husbandry, including companion, food, and sport animals. One aspect of animal health, however, serves as both an intriguing puzzle and an opportunity to exploit the basis for the puzzle. That aspect encompasses the underlying cause for some animals to be devastated by an infecting organism that another might only be minimally affected by. Observations of cattle resistant to natural infections have implied the feasibility of breeding livestock for disease resistance. Studies of pigs selected for antibody- (AMIR) and cell- (CMIR) mediated immune responses have demonstrated increased immune responsiveness, suggesting enhanced protection by both type 2 and type 1 responses, respectively. Additionally, natural or artificial infections of cattle suggest that the production of particular IgM, IgG1, and IgG2 isotypes are important for protecting against pathogens. In fact, IgG1/IgG2 ratios are often used to establish whether type 1 (CMIR) or type 2 (AMIR) responses predominate following immunization or infection. With this in mind, this presentation will address novel aspects of animal-to-animal variability in adaptive immune response, as well as some newer findings in the rapidly expanding area of epigenetics and chromatin modifications, and present both new findings, as well as suggestions for promising areas of research out of which may result better strategies toward maintaining animal health.

Key Words: cattle, immunity, phenotype

0078 Selecting pharmacological interventions through rapid screening motifs and proper cell models. E. Zudaire*, *NIH-NCI, Bethesda, MD.*

There is no doubt that the magnitude and complexity of challenges to pharmacological intervention in disease processes are increasing exponentially. These challenges span all facets of intervention from countering antimicrobial resistance to expanding the pharmacogenomic capacity toward individualizing therapy and prevention. While the drug development landscape is rapidly evolving, current pipelines to approval and applied medicine often rely on well-established compartmentalized research models. In this rubric, targets are first identified in laboratories, frequently on the basis of the now discredited philosophy of "disease-causing" targets. More appropriately, target-specific therapeutics are capable of being designed with the goal of increasing efficacy while better managing undesirable toxicities. However, it has recently been proposed that target-based approaches often fail under clinical trials due in part to the robust nature of networks that control biological processes. The issue is 1 of having the needed target specificity as screenable with high throughput cell-based assessment models, where those models accurately reflect the complexity of in vivo cell-cell interactions and associated gene expression patterns, largely now in evidence in traditional 2D monoculture conditions. The goal is then to connect diseases with underlying pharmacologically tractable targets and drugs that can be translated for their clinical management. To this aim, I will present the case for increasing research into novel technological approaches based on the hypothesis that the most effective therapies for a given disease

would target a complex set of interactions among different components of the system, rather than the activity of a single component. I will expand on how the discovery of effective disease therapeutic modulators requires the development of novel kinds of in vitro assays, which recapitulate the complexity of disease-specific tissue microenvironments.

Key Words: disease, intervention, pharmacogenomics

0079 Managing animal health from an aquaculture perspective. C. A. Shoemaker*, B. R. LaFrentz, D. Xu, and D. Zhang, *USDA-ARS, Aquatic Animal Health Research Unit, Auburn, AL.*

Aquaculture is the production of aquatic animals for food. The aquaculture industry is a rapidly expanding segment of U. S. agriculture and NOAA estimated the industry was worth $1.2 billion in 2011. Disease-related losses in aquaculture either by decreased performance and/or mortality is estimated by the World Bank to be around $3 billion globally. In 1974, Snieszko proposed the host-pathogen-environment relationship theory as applied to fish with regard to development of disease. Age, species, strain(s), nutritional, and immunological status of the host are relevant to disease induction. The pathogen, including exposing dose, virulence, and genetic type (strain), is also pertinent to disease in aquatic animals. For aquatic animals, the environment is probably the most important factor in relation to disease development. Fish are produced in all types of water (i.e., fresh, brackish, and salt water) and fish must rely on water for temperature regulation, oxygen, waste removal, etc., for optimal performance and health. Aquatic animal health management is unique due to the fact that animals are reared in water. Disease can be difficult to discover in water. Once disease is identified, treatment can be problematic because of the size of ponds and/or volume of water. Also, limited treatment options are available due to the fact that few medicines are FDA approved. In some aquaculture operations (e.g., catfish production), all sizes of fish may be raised together in a multi-batch culture. Therefore, separation of healthy and sick animals is challenging. Prevention is the key to successful health management of fish and should include good husbandry practices to limit stress, providing adequate balanced nutrition, use of vaccines, and prudent use of medicines. This presentation will highlight the unique aspects of aquatic animal health management and outline areas where further work may improve our understanding of animal health.

Key Words: aquaculture, fish, health management

ANIMAL HEALTH II: HOST–MICROBIAL INTERACTIONS: DETECTION AND INTERVENTION

0080 Alterations in the response of pigs to *Salmonella typhimurium* when provided *Enterobacter cloacae*. J. R. Donaldson*[1], J. A. Carroll[2], N. C. Burdick Sanchez[2], J. W. Dailey[2], T. B. Schmidt[3], T. R. Callaway[4], and J. G. Wilson[1], *[1]Mississippi State University, Mississippi State, [2]USDA-ARS, Livestock Issues Research Unit, Lubbock, TX, [3]University of Nebraska, Lincoln, [4]USDA-ARS, College Station, TX.*

Weanling pigs are at risk of succumbing to illness due to an immature immune system and insufficient supply of available energy at the time of weaning. Recent evidence has suggested that providing pigs with *Enterobacter cloacae* can increase the concentration of circulating triglycerides (TAG) and thus available energy. To determine if this increase in TAG improved the response of pigs to an infection, 36 weaned pigs 30 d of age (6.7 ± 0.1 kg BW) were individually housed and randomly assigned to 3 treatment groups: 1) *Enterobacter cloacae* (JD6301; 1×10^{10} CFU); 2) an alternate form of this bacterium (JD8715; 1×10^{10} CFU) that secretes TAG into the surrounding environment; or a control of PBS. For each treatment, bacteria were supplemented to the water daily using a medicator water system (~1×10^6 CFU/mL). Pigs were provided water supplemented with *E. cloacae* for 5 d before and 3 d after in relation to being challenged with lipopolysaccharide (LPS) from *Escherichia coli* (25 ug/kg BW, time 0 h) and *Salmonella typhimurium* (1×10^9 CFU, time 6 h). Serum samples were collected every 6 h for a period of 72 h and analyzed for NEFA, TAG, and whole blood cell counts. At 24, 48, and 72 h post-challenge, gastrointestinal contents were collected and analyzed for the presence of *E. cloacae* and *S. typhimurium*. Circulating TAG increased ($P = 0.05$) in pigs provided JD6301 in comparison with PBS controls within 5 d of supplementation but did not increase ($P = 0.33$) in pigs provided JD8715. Within 18 h post-challenge with LPS (and 12 h post-challenge with *S. typhimurium*), an increase in NEFA ($P < 0.05$) and TAG ($P < 0.04$) was observed in pigs provided PBS in comparison with pigs provided either form of *E. cloacae*. Pigs provided JD6301 had a reduction ($P = 0.05$) in *S. typhimurium* populations between 24 and 72 h post-challenge. However, *S. typhimurium* populations in pigs provided either JD8715 or PBS did not decrease ($P = 0.18$) during this time period. Pigs provided JD8715 did have an increase ($P = 0.05$) in neutrophil concentrations within 6 h post-exposure to the endoxotin. These data suggest that the oleaginous bacteria JD6301 may improve clearance of *S. typhimurium* from the gastrointestinal tract. Further research is needed to determine whether this decrease is due to an improved immune response or competitive inhibition.

Key Words: pigs, probiotics, triglycerides

0081 Adhesion of *Escherichia coli* in piglets and association of phenotypes to known candidate genes in South African breeds. N. S. Chaora*, *Agricultural Research Council, Pretoria, South Africa.*

Enterotoxigenic *Escherichia coli* is a major pathogenic bacterium that causes diarrhea in preweaned and postweaned piglets. The adhesion of *E. coli* to the brush borders of the epithelial cells of piglets is a prerequisite for effective colonization leading to diarrhea. Successful adhesion occurs in the presence of *E. coli* receptors that are found on the brush borders of epithelial cells. The study's objective was to compare the susceptibility of South African breeds to enterotoxigenic *E. coli* strains. An in vitro adhesion experiment was performed for F4, PAA, and EAST-1 *E. coli* strains, using intestinal brush borders from 109 pigs of 3 South African pig breeds. Large White, indigenous, and crossbred pigs that were 3- to 12-wk old were used. The results showed significant differences ($P < 0.05$) in adhesion frequencies of receptors among the 3 breeds. Adhesion phenotypes, adhesive, weakly adhesive, and non-adhesive were found in all breeds. The F4 and PAA strains adhered in all 3 breeds. The indigenous pigs had the highest frequency of non-adhesive intestines and > 70% of the Large White pigs were adhesive to all strains. Indigenous and crossbred pigs' adhesion was higher in suckling piglets than weaners. The *TFRC*, *MUC13*, *MUC4*, and *MUC20* genotypes were not associated with adhesion phenotypes. The South African population studied carried receptors for all strains measured. If there is an outbreak of *E. coli* carrying the above strains, the South African population is most likely to be affected. The indigenous pigs of the South African population studied were more resistant to F4, PAA, and EAST-1 *E. coli* strains, compared with Large White and crossbred pigs.

Key Words: adhesion, *E. coli* strains, piglets, susceptibility

0082 Effect of metaphylaxis on production responses and antimicrobial usage in high-risk steers. A. B. Word*[1], T. A. Wickersham[1], G. Mays[1], L. A. Trubenbach[1], and J. E. Sawyer[2], *[1]Texas A&M University, College Station, [2]Texas AgriLife Research, College Station.*

A trial was conducted to determine the effects of on-arrival metaphylaxis in beef cattle for controlling bovine respiratory disease (BRD) and determining subsequent effects on health and performance. Male calves in a randomized complete block design ($n = 198$, arrival weight = 231 kg ± 2.43) received either 3.3 mL/100 kg (6.6 mg/kg) ceftiofur crystal-

line free acid (EXC), 4.4 mL/100 kg (13.2 mg/kg) tilmicosin phosphate (MIC), or were not treated (CON). These products are commonly used in production settings. Cattle receiving metaphylaxis had 25.2% lower morbidity rates than CON (P = 0.01; 51.5% vs. 76.7%). Significant differences were not observed in morbidity rates (P = 0.14) between cattle on the MIC (46.4% ± 4.32%) or EXC treatments (56.5% ± 4.32%). Of cattle requiring BRD therapy, the CON group displayed symptoms ~5 d earlier than cattle in the metaphylaxis group (P = 0.01). Cattle displaying BRD symptoms in the MIC group required treatment 3 d earlier than those in the EXC group (P = 0.02, 8 vs. 11 d, respectively). Metaphylaxis improved ADG (1.63 vs. 1.28 kg/d; P = 0.06) and G:F (0.29 vs. 0.22, P = 0.01) during the first 14 d compared with CON, but differences between EXC and MIC were not significant (P > 0.40) during the first 14 d. Despite differences at 14 d, no differences were observed in ADG (P = 0.20) or G:F (P = 0.18) between CON and treatment groups across the 42-d trial. Total antimicrobial usage was 6.03 vs. 6.16 g active ingredient per animal for CON vs. metaphylaxis (P = 0.88), and 5.99 vs. 6.33 for MIC vs. EXC (P = 0.74). These results suggest that both tilmicosin phosphate and ceftiofur crystalline free acid effectively reduce overall morbidity and delay onset of clinical illness in newly received beef cattle. Furthermore, this reduction in overall morbidity was achieved with minimal increase in total antimicrobial use. While overall performance outcomes were not different, animal health was improved with metaphylaxis.

Key Words: bovine respiratory disease, metaphylaxis

0083 PR-39 ameliorates *Salmonella typhimurium*-induced intestinal epithelial barrier dysfunction.

X. Xi*, *Institute of Feed Science, Zhejiang University, Hangzhou, China.*

Salmonella enterica Serovar typhimurium infection is a primary enteric pathogenic disease affecting both human and animals. PR-39 is a porcine antimicrobial peptide that shows strong antibacterial effects toward *Salmonella typhimurium* in vitro and multiple immunomodulation functions. Here we investigated the potential mechanisms of PR-39 in preventing *Salmonella typhimurium*-induced gut barrier dysfunction in mouse infection model and in polarized intestinal porcine epithelial cell line IPEC-J2. The intestinal permeability, the expression of tight junction proteins, and biodistribution of PR-39 were determined by using chamber, immunofluorescence, qRT-PCR, and in vivo fluorescence imaging technology, respectively. One-way ANOVAs were performed using a 95% confidence interval. The results revealed that PR-39 attenuated the altered ileum architecture and reduced the increased intestinal permeability in *Salmonella*-infected mice. These protective effects were not attributed to the antibacterial activity of PR-39 because PR-39 showed no antimicrobial activity against *Salmonella typhimurium* in simulated intestinal liquids or serum. Moreover, pre-treatment with PR-39 significantly reduced the adhesion and invasion of *Salmonella typhimurium* toward polarized IPEC-J2 monolayer, and attenuated the decreased ZO-1 and claudin-1 expression caused by *Salmonella* infection. Collectively, these findings provide evidence that PR-39 could prevent *Salmonella typhimurium*-induced intestinal epithelial barrier dysfunction through an antimicrobial-independent mechanism.

Key Words: intestinal epithelial barrier function, PR-39, *Salmonella typhimurium*

0084 Quantification of microbial populations in organic and inorganic dairy cattle bedding materials.

R. F. Rowbotham*[1,2], T. L. Peters[2], T. M. Walker[2], and P. L. Ruegg[2], *[1]Grande Cheese Company, Brownsville, WI, [2]Department of Dairy Science, University of Wisconsin-Madison, Madison.*

The objective of this study was to quantify differences in microbial populations of 4 different bedding types used in dairy barns: 1) deep-bedded, new sand (NS), 2) deep-bedded, recycled sand (RS), 3) deep-bedded organic solids (DBOS), and 4) shallow-bedded organic solids on top of mattresses with foam cores (SBOS). Weekly composite bedding samples were systematically collected from selected locations within randomly selected stalls in each of 4 identical pens containing 32 freestalls and ~28 lactating cows during the 49-wk study period. Microbial populations were determined by plating 10-µL inoculations of duplicate sets of serial dilutions (10^{-1} to 10^{-5}) on 3 selective media. Bacterial groups were quantified as: Gram-negative (total growth on MacConkey's agar), coliforms (lactose-positive colonies on MacConkey's agar), *Klebsiella* (red to pink colonies on MacConkey inositol-carbenicillin agar), and Streptococci spp. (total growth on Edward's modified medium agar). The relationship between bacterial populations and bedding type was analyzed in a repeated measures model using PROC MIXED (SAS 9.3). The model included effects of bedding type with sampling date repeated. $Y_i = \alpha + \beta_1 X_{i1} + \beta_2 X_{i2} + e_i$ where Y_i is the $\log_{10}$ CFU count for bedding sample i from pen X_{i1} and date X_{i2}. Bacterial counts differed among bedding materials. Fewer bacteria were isolated from NS as compared with other bedding materials, with the exception of *Klebsiella* in SBOS and Streptococci spp. in DBOS. More bacteria were isolated from DBOS compared with other bedding materials, except for Streptococci spp. in sand bedding. Distribution of bacteria varied among bedding types. In general, NS had the fewest bacteria, whereas DBOS contained the most bacteria.

Key Words: bacteria, bedding, dairy

Table 0084. Bacteria isolated from different dairy cattle bedding types (Log_{10}CFU/g)

Bedding material	Gram-negative	Coliform	*Klebsiella*	Streptococci spp.
NS	4.72[a]	3.59[a]	2.41[a]	6.88[a]
RS	5.25[b]	4.10[b]	3.19[b]	7.21[b]
SBOS	5.81[c]	4.08[b]	2.74[ab]	8.16[c]

0085 Prevalence of bovine mastitis pathogens in bulk tank milk. Y.-L. Bi[*1], Z. J. Cao[1], W. Sun[2], Y. Qin[2], and S. L. Li[1], *[1]State Key Laboratory of Animal Nutrition, College of Animal Science and Technology, China Agricultural University, Beijing, [2]Laboratorios Hipra, Gerona, Spain.*

Bovine mastitis is the most significant disease of dairy herds that can cause huge economic losses in the world. The objective of this study was to assess the bacteriological quality of bulk tank milk at herd level. Bulk tank milk samples collected from 894 dairy herds in Inner Mongolia (375), Heilongjiang (242), and Hebei Province (277) of China were examined for the presence of mastitis pathogens from March 2012 to May 2013. Each sample was tested using a previously validated Multiplex PCR assay for the detection of 12 pathogens at a time. In addition, a maximum of 21 samples were examined simultaneously using the Multiplex PCR assay. Contagious pathogens, including *Streptococcus agalactiae* (90.16%), Coagulase negative staphylococci (89.17%), *Streptococcus dysgalactiae* (71.14%), *Arcanobacterium pyogenes* (60.51%), *Staphylococcus aureus* (44.85%), and environmental pathogens, consisting of Coliforms (63.26%) and *Escherichia coli* (31.66%), were detected in the milk samples. Of the 894 bulk tank milk samples, 743 (83.11%) contained 4 or more species of bacterial pathogens. It was also observed that an increase in the frequency of isolation of bacterial pathogens was significantly associated with an increased bulk tank bacterial and somatic cell counts. Bulk tank milk with lower bulk tank bacterial and somatic cell counts had fewer species of bacteria. Herd size and farm management practices had considerable influence on the species of bacteria and bacterial and somatic cell counts in bulk tank milk. The percentage of small herds (< 50 cows) with 4 or more types of bacterial pathogens detected in milk samples was higher than that of big herds (> 500 cows), which was 86.45% and 71.79%, respectively. Of the bulk tank milk samples, 85.20% (501/588) had 4 or more types of bacterial pathogens in winter, whereas the percentage was 88.89% (272/306) in winter. There were no differences in the species of bacteria in bulk tank milk between summer and winter. In conclusion, species of bacteria and bacterial and somatic cell counts could serve as indicators of bulk tank milk quality and we should formulate strategies to improve milk quality and reduce the incidence of mastitis in dairy herds.

Key Words: bulk tank milk, bovine, mastitis pathogens

0086 Modulation of the acute phase response in feedlot steers supplemented with *Saccharomyces cerevisiae*. J. O. Buntyn[*1], N. C. Burdick Sanchez[2], J. A. Carroll[2], E. Chevaux[3], K. Barling[4], S. E. Sieren[5], S. J. Jones[5], and T. B. Schmidt[5], *[1]Department of Animal Science, University of Nebraska, Lincoln, [2]USDA-ARS, Livestock Issues Research Unit, Lubbock, TX, [3]Lallemand Animal Nutrition, Milwaukee, WI, [4]Lallemand Animal Nutrition, Iola, TX, [5]University of Nebraska, Lincoln.*

This study was designed to determine the effect of supplementing feedlot steers with *Saccharomyces cerevisiae* CNCM I-1079 (SC) on the acute phase response to a lipopolysaccharide (LPS) challenge. Steers (n = 18; 266 ± 4 kg BW) were separated into 3 treatment groups (n = 6/treatment). One group was fed a standard receiving diet (Control, Cont); 1 group was fed the standard receiving diet supplemented with SC (Lallemand, Inc.) at 0.5 g/steer/d (SC-0.5), and the final group was fed the standard receiving diet supplemented with SC at 5.0 g per steer day (SC-5.0) for 29 d. On d 27, steers were fitted with indwelling jugular cannulas and rectal temperature (RT) probes that measured RT continuously at 5-min intervals, and were placed in individual stalls. On d 28, steers were challenged IV with LPS (0.5 μg/kg BW at 0 h) and blood samples were collected at 30-min intervals from -2 to 8 h and 24-h post-challenge. Serum was isolated and stored at −80°C until analyzed for cortisol and cytokine concentrations. Before the challenge, there was an effect of treatment ($P < 0.001$) on RT; SC-0.5 steers (39.50 ± 0.03°C) had greater RT than Cont (39.06 ± 0.04°C) and SC-5.0 (39.27 ± 0.04°C) steers. Also, Cont steers had greater ($P < 0.001$) RT than SC-5.0 steers. Therefore, RT was further analyzed as the change from baseline. In response to LPS challenge, the change in RT was affected by treatment ($P < 0.001$); Cont steers had the greatest change in RT (0.434 ± 0.0510°C) compared with SC-0.5 (-0.059 ± 0.039°C) and SC-5.0 (-0.007 ± 0.045°C) steers. There was a tendency ($P = 0.06$) for baseline cortisol concentrations to be affected by treatment; SC-5.0 steers having greater (7.8 ± 0.8 ng/mL) cortisol than Cont (4.9 ± 0.8 ng/mL) steers. Post-LPS challenge, there was a treatment × time interaction ($P = 0.005$); SC-5.0 steers had decreased ($P < 0.02$) cortisol concentrations than Cont steers from 4.5 to 7 h post-challenge. There was a treatment effect ($P \leq 0.05$) for all cytokines (tumor necrosis factor-α, interleukin-6, and interferon-γ). Cytokines were decreased in SC-0.5 and SC-5.0 steers compared with Cont steers following LPS challenge. While these data demonstrate that *Saccharomyces cerevisiae* supplementation can reduce the inflammatory response to a LPS challenge, further research is needed to determine

whether or not *Saccharomyces cerevisiae* supplementation is beneficial when animals are exposed to a live pathogen.

Key Words: cattle, immune response, live yeast

0087 Performance evaluation of calves with diarrhea in different systems supplemented with yeast culture plus enzymatically hydrolyzed yeast cell wall.

V. R. Rabassa*[1], B. Scherer[1], F. B. Del Pino[2], C. C. Brauner[2], F. M. Gonçalves[1], R. F. S. Raimondo[1], E. G. Xavier[3], C. C. Elrod[4], and M. Nunes Corrêa[2], [1]*Universidade Federal de Pelotas, Pelotas, Brazil,* [2]*Federal University of Pelotas, Brazil,* [3]*Granjas 4 Irmãos, Rio Grande, Brazil,* [4]*Vi-COR, Inc., Mason City, IA.*

The aim of this study was to evaluate the performance of calves with diarrhea in different systems supplemented with yeast culture plus enzymatically hydrolyzed yeast cell wall during the neonatal period. Seventy-eight female Holstein calves were divided into 2 groups: yeast group (Celmanax, Vi-COR, Mason City, IA), $n = 38$, which were supplemented with 8mL/d during the first 42 d of age and a control group, $n = 40$, which received no supplementation. The yeast was administered daily as an oral drench and measurements of weight, heart girth, wither height, rump width, and ADG were performed weekly. The animals were also divided into 2 systems based on the types of facilities: houses (confined) and stakes (outdoor), and monitored daily for the occurrence of diarrhea. Data were analyzed by MIXED PROCEDURES of SAS. There was no difference ($P > 0.05$) in calf performance between groups and group × collection. However, there was an interaction ($P < 0.05$) between groups and system. Control calves maintained in the stakes system had greater ($P < 0.05$) heart girth than the yeast group (83.69 ± 0.58 cm and 81.65 ± 0.68 cm, respectively) and higher ($P < 0.05$) ADG (0.44 ± 0.02 kg and 0.33 ± 0.03 kg, respectively). Calves from the yeast group kept in houses had higher averages ($P < 0.05$) than the control group in the parameters wither height (81.43 ± 0.64 cm and 79.61 ± 0.54 cm), rump width (29.44 ± 0.32 cm and 28.23 ± 0.29 cm), and ADG (0.32 ± 0.04 kg and 0.21 ± 0.02 kg), respectively. In conclusion, supplementation with yeast culture plus enzymatically hydrolyzed yeast cell wall can improve the growth performance of animals showing diarrhea housed in confined environments.

Key Words: dairy, health, system

0088 Variations in the survival of *Listeria monocytogenes* to grow in bile from porcine gallbladders.

J. G. Wilson*, S. J. White, and J. R. Donaldson, *Mississippi State University, Mississippi State.*

Listeria monocytogenes is a facultative intracellular, Gram-positive bacterium that can cause disease, including abortion, in sheep, goats, cattle, pigs, and poultry. These animals are also known reservoirs for this pathogen and it is primarily acquired through ingestion of contaminated silage or soil. This bacterium's ability to survive within the gastrointestinal tract and cross the intestinal lining is directly related to the ability of the pathogen to cause disease. However, it is not clear whether there are variations in the ability of this pathogen to survive. The purpose of this study was to determine whether variations exist in the ability of different serotypes of *L. monocytogenes* to survive within porcine gallbladder bile and if survival affected the ability of these bacteria to invade epithelial cells in vitro. Avirulent strain HCC23 (serotype 4a) and virulent strain 10403S (serotype 1/2a) were cultured in brain-heart-infusion (BHI) broth media to mid-logarithmic ($OD_{600} = 0.5$), then transferred to bile collected from pigs 30 d of age (6.7 ± 0.1 kg BW). Anaerobic growth was monitored by viable plate counts on BHI agar. The influence of bile on invasion potential of *L. monocytogenes* was tested in colon epithelial cells (GPC-16) cultured in Eagle's Minimal Essential Media with 20% fetal bovine serum. Cell culture media was supplemented with 10% bile and HCC23 or 10403S was inoculated at a multiplicity of infection of 100:1. Cultures were incubated at 37°C, 5% CO2. At 1 h and 2 h post infection, cells were washed to remove extracellular bacteria then lysed to release intracellular bacteria. Lysates were serially diluted and plated onto BHI agar. Survival of HCC23 in bile did not change ($P = 0.3$), though a decrease ($P = 0.05$) in survival of 10403S was observed 24 h after bile exposure. Virulent strain 10403S also had a decrease ($P = 0.05$) in invasion potential in the presence of bile. In contrast, avirulent strain HCC23 did not decrease ($P = 0.08$) in invasion potential in the presence of bile. Together with previous reports of variations in the intracellular presence of *L. monocytogenes* in the gallbladder, these results suggest that avirulent and virulent strains respond differently to the gastrointestinal environment and this difference may influence the outcome of the infectious process.

Key Words: gallbladders, *Listeria monocytogenes*, pig

0089 Yeast probiotics vary in their potential to bind to Gram-positive or Gram-negative bacteria.

G. Posadas*[1], J. A. Carroll[2], J. R. Corley[3], A. Lawrence[1], and J. R. Donaldson[1], [1]*Mississippi State University, Mississippi State,* [2]*USDA-ARS, Livestock Issues Research Unit, Lubbock, TX,* [3]*Lesaffre Feed Additives, Milwaukee, WI.*

Probiotics are widely used in the livestock industry to improve health and overall productivity. Despite the extensive amount of research performed on examining the mechanisms by which probiotics confer positive effects on hosts, their use is still highly debated and are undoubtedly under characterized. The hypothesis for this study was that variations exist in the binding potential of probiotics to Gram-negative and Gram-positive bacteria. To test this hypothesis, the binding capability of 5 different types of live yeasts or yeast cell wall products to 2 Gram-negative bacteria (*Salmonella typhimu-*

rium and *Escherichia coli* O157:H7) and 3 Gram-positive bacteria (*Listeria monocytogenes, Clostridium perfringens*, and *Bifidobacterium bifidum*) was determined using an adhesion assay and subsequent analysis by scanning electron microscope. The probiotics were incubated on cover slips and then challenged with the array of different pathogens. To assess each probiotic's propensity toward adhesion, extensive washings of the cover slips were done. This removal of unbound bacteria determined that any bacteria remaining resulted from direct interactions between the pathogens and probiotics, inferring antagonistic behavior of adhesion displayed by the probiotics. Though *S. typhimurium* bound well to all probiotics tested (> 90%, $P = 0.3$), *E. coli* O157:H7 had a preference ($P = 0.003$) to bind to the yeast cell wall products in comparison to live yeast. The opposite was observed for the Gram-positive bacteria tested, which exhibited an improved binding potential to live yeast ($P = 0.01$). A sample size of > 20 yeast cells or cell wall products was analyzed. These data suggest that combining both live yeast probiotic and yeast cell product probiotic will allow for an increase in binding to different enteric bacteria. To test the binding capability of this combination mixture to colon epithelial cells, another adhesion assay was performed and prepared for analysis by fluorescent microscope (1 fluorochrome-labeling epithelial DNA and another staining yeast actin filaments). A sample size of > 30 epithelial cells was analyzed. The data determined that no variations were observed in the ability of these probiotics to bind to epithelial cells, indicating that the antagonist activity observed is specific to the pathogen tested and not a general defect of the product. Together, these data suggest that mechanisms of action of the yeast-based probiotics are dictated by variations of direct adhesion to pathogens. Further research is warranted to determine how these variations in binding potential influence the activity of these yeast-based probiotics in vivo.

Key Words: bacteria, probiotics, yeast

0090 An analysis of *Giardia lamblia* and *Cryptosporidium parvum* in bucket calves at the University of Findlay's animal science barn. S. M. Waibel*, F. D. McCarthy, R. M. Wood, and B. Henderson-Dean, *The University of Findlay, OH.*

Giardia lamblia and *Cryptosporidium parvum* are protozoal parasites that can cause gastroenteritis in dairy calves and are zoonotic diseases that cause intestinal enteritis in humans. The initial objective of this study was to determine the presence of *G. lamblia* or *C. parvum*, and if environmental stressors promote shedding of *G. lamblia* cysts or *C. parvum* oocysts in male dairy calves ($n = 35$). The environmental stressors considered were arrival to the facility, transfer from isolation to the main barn, and processing (castration, dehorning, vaccination). Fecal samples were analyzed using rapid immunochromatographic assay. Data analysis of Group 1 ($n = 17$) suggested environmental stressors failed to influence shedding and isolation may not be effective at preventing the spread of disease. Subsequently, the objective of the study on Group 2 ($n = 18$) was to determine the effectiveness of isolation and if the same environmental stressors promote shedding of *G. lamblia* cysts or *C. parvum* oocysts. For both groups, fecal samples were collected within 24 h of arrival (IN), 24 h before isolation removal (BIR), 36 to 60 h after isolation removal (AIR), 24 h before processing (BP), and 36 to 60 h after processing (AP). Group 2 had additional fecal samples collected at the end of wk 1 (W1) and 2 (W2) in isolation. Results indicated there was no degree of significance between environmental stressors and shedding of *G. lamblia* or *C. parvum*. Isolation appeared ineffective at preventing *G. lamblia* or *C. parvum* from spreading. Results did not detect *G. lamblia* or *C. parvum* in Group 1 calves at IN. However, at BIR, calves showed an increase in measured incidence of 27%. Fecal samples from calves in Group 2 tested positive for *G. lamblia* or *C. parvum* at IN of 22% and BIR of 56%. The average for both groups was 12% at IN and 42% at BIR. Overall, 11% of calves were positive for *G. lamblia* and *C. parvum* simultaneously; 31% tested positive for *C. parvum*, 72% tested positive for *G. lamblia*, and 86% tested positive for either parasite at least once. Given the potential for infection, increased hygiene measures are recommended. The isolation procedure should be examined for plausible breeches. Potential source of infection for calves needs to be investigated.

Key Words: *Cryptosporidium parvum, Giardia lamblia*

ANIMAL HEALTH III: **PERIPARTURIENT AND LACTATION HEALTH**

0091 Milk quality and milk components in lactating dairy goats fed OmniGen-AF from dry-off through the entire lactation. A. D. Rowson*, T. J. Boyle, D. J. McLean, S. A. Armstrong, and S. B. Puntenney, *Prince Agri Products, Inc., Quincy, IL.*

In the United States, the legal somatic cell count (SCC) limit for dairy goat milk is 1500,000 mL^{-1}. However, it is common for SCC to be much higher than this. Production of milk with a SCC higher than the legal limit results in farms being unable to ship their milk and lost income. The objective of this study was to evaluate the supplementation of OmniGen-AF to dry and lactating dairy goats on milk quality and milk components over an entire lactation. Thirty-five, 2-yr-old does housed on a commercial goat dairy located in south central Wisconsin were randomly assigned to 1 of 2 groups: 1) Control-fed (n = 18) and 2) OmniGen-AF-fed (n = 17). Animals in Group 1 were fed a complete feed pellet twice a day and ad libitum alfalfa hay. Animals in Group 2 were fed the same diet but with 6 g/h/d of OmniGen-AF added to the pellet. The project started at dry-off (~40 to 60 d before kidding) and continued for the full lactation. Breeds of does were Alpine, Saanen, Nubian, and La Mancha, and all breeds were equally represented in both groups. Monthly Dairy Herd Improvement Association (DHIA) milk testing was performed on all animals for 9 mo. The SCC, percent milk fat, percent milk protein, and milk production data were collected at each test. The mean SCC for OmniGen-AF-supplemented does was 585,000 mL^{-1}, which was significantly lower ($P < 0.05$) than the mean SCC for control-fed does, which was 894,600 mL^{-1}. These differences were more pronounced as does approached the end of lactation where the mean SCC was 1669,000 mL^{-1} less in OmniGen-AF-fed does compared with controls (2094,000 mL^{-1} vs. 3763,000 mL^{-1}, respectively). Milk percent fat ($P < 0.01$) and percent protein ($P < 0.05$) were different between the OmniGen-AF-fed and control-fed does. Specifically, mean milk percent fat was 3.21% from control-fed does and 3.45% from OmniGen-AF-fed does. Mean milk percent protein was 2.93 and 3.08% from control and OmniGen-AF-fed does, respectively. There was no difference in milk production between groups. Data from this trial demonstrate that OmniGen-AF fed goats experienced benefits in milk components and attenuation of the dramatic increase in SCC that normally occurs late in lactation, both of which are indicative of improved mammary gland health.

Key Words: goats, OmniGen-AF, SCC

0092 Modulation of innate immune function and phenotype in bred dairy heifers during the periparturient period induced by feeding an immunostimulant 60 d before delivery. E. L. Nace, S. C. Nickerson*, F. M. Kautz, S. Breidling, D. Wochele, L. O. Ely, and D. J. Hurley, *University of Georgia, Athens.*

The purpose of this study was to evaluate the effect of an immunostimulating feed additive on innate immunity and health events during the periparturient period in dairy heifers when mammary immunity is suppressed. From 60 d prepartum through day of calving, supplemented heifers (n = 20) received OmniGen-AF daily and were compared with unsupplemented controls (n = 20). Blood leukocyte innate immune activity [phenotypic markers, phagocytic activity, and reactive oxygen species (ROS) production] was measured before feeding (60 d prepartum), 30 d later, and on d 1, 7, 14, and 30 postpartum. Health parameters and milk production were measured at calving and early lactation. Expression of CD62L among leukocytes from supplemented heifers was greater during the periparturient period than controls. Specifically, on d 1 postpartum, mean percentage of neutrophils exhibiting CD62L surface markers was 95.3% for OmniGen-AF treated heifers vs. 91.4% for controls ($P < 0.10$), and the percentage decreased from 98.3% 30 d prepartum to 91.4% on d 1 postpartum among controls ($P < 0.05$); values for supplemented heifers did not decrease. Likewise, leukocyte phagocytic activity against *Escherichia coli* and *Staphylococcus aureus* was greater in heifers supplemented with OmniGen-AF; e.g., on d 30 prepartum and d 7 postpartum, mean percentage of monocytes from supplemented heifers exhibiting phagocytic activity against *E. coli* were 11.7 and 11.3%, respectively, whereas values for controls were 7.3 and 7.4% ($P < 0.10$), respectively. In controls, phagocytosis decreased from 13.7% 60 d prepartum to 7.3 and 7.5% on d 30 prepartum and d 7 postpartum ($P < 0.05$), respectively, but values for supplemented heifers did not decrease over time. Conversely, ROS production in response to PMA and killed *S. aureus* stimulation was greater among control heifers compared with supplemented animals; e.g., the quantities of ROS generated in response to *S. aureus* lysate on d 1 and 7 postpartum were 68.8 vs. 51.9 and 56.1 vs. 41.3 units ($P < 0.05$), respectively. Supplemented heifers exhibited fewer deleterious health events (retained placenta, displaced abomasum, ketosis, udder edema, death) than controls (1.25 vs. 1.93/heifer) and a lower rate of new cases of mastitis (9.6% vs. 23.2%); however, no significant differences were observed in overall prevalence of mastitis, milk SCC, or milk production. Results demonstrated a positive role of OmniGen-AF in amplifying leukocyte antibacterial activity during the periparturient period and support the continued study of dietary supplementation to enhance mammary gland health in dairy cattle.

Key Words: dairy heifer, innate immunity, periparturient period

0093 Restriction in energy or protein affects differentially behavior of lactating dairy cows.

V. Fischer*[1], E. Forgiarini Vizzotto[1], F. André Schmidt[2], D. Werncke[1], A. Susenbach de Abreu[1], and A. Thaler Neto[2], [1]*Universidade Federal do Rio Grande do Sul, Porto Alegre, Brazil,* [2]*Universidade Estadual de Lages, Brazil.*

Feed restriction adversely affects feeding and social behavior in cattle. However, data on the effects of nutrient composition on these characteristics are limited. The objective was to quantify the effects of dietary energy and protein restriction on feeding and behavior in lactating Holstein and Jersey cows. Twelve cows in mid-lactation balanced for breed and days in milking were used in a Latin square design: 3 cows × 3 periods. Each experimental period lasted 3 wk and consisted of: 1) adaptation, where all animals were fully fed according to their requirements, 2) restriction, where animals were fed to provide 50% of their daily energy (E) and protein (P) requirements, and 3) treatment, where animals were fed with 1 of the following diets: 100E + P, 50E + 100P, and 100E + 50P, to provide 100% of energy + protein requirement, 50% of energy requirement, 50% of protein requirements, respectively. On the last day of the treatment period, cows were visually observed from 0600 to 2100 h. The behavioral attributes were recorded as time spent in feeding behavior and number of social and adaptation events. Data were logarithmic transformed and submitted to analysis of variance, considering main effects of diet, cow, and period. Nutrient restriction did not change feeding and ruminating times or aggressive interactions. Energy restriction reduced time spent lying but increased tongue curling and licking events. Protein restriction reduced idling time, number of low intensity vocalizations, and tended to reduce standing time. The data are consistent with the concept that cows react differently to limitations in energy or protein in the diet.

Key Words: behavior, nutrient, restriction

Table 0093.

	Diet				
Attribute	100% E+P	50%E + 100%P	50%P + 100%E	$P > F_{diet}$	RSD (%)
Eating (min)	276.1	254.1	278.7	NS	2.2

0094 Dynamics of culling for Jersey, Holstein, and crossbred cows in large multi-breed dairy herds.

P. J. Pinedo*[1], A. M. Daniels[2], J. Shumaker[3], and A. De Vries[4], [1]*Texas A&M AgriLife Research, Amarillo,* [2]*Circle H Headquarters LLC, Dalhart, TX,* [3]*Magnolia Veterinary Services, Amarillo, TX,* [4]*University of Florida, Gainesville.*

The objective of this observational study was to describe and compare the dynamics of reason-specific culling risk for the genetic groups Jerseys (JE), Holsteins (HO), and Jersey × Holstein crossbreds (JH), considering parity, stage of lactation, and milk yield, among other variables, in large multi-breed dairy herds in Texas. The secondary objective was to analyze the association between survival and management factors, such as breeding and replacement policies, type of facilities, and use of cooling systems. After edits, available data included 202,384 lactations in 16 herds, ranging from 407 to 8773 cows calving per year during the study period from 2007 to 2011. The statistical analyses were performed through logistic regression (PROC GLIMMIX, SAS) and by estimation of hazard functions (PROC LIFETEST, SAS). The distribution of lactation records by genetic group was 58%, 36%, and 6% for HO, JE, and JH, respectively. Overall culling rates across breeds were 30.1%, 32.1%, and 35.0% for JH, JE, and HO, respectively. The dynamics of reason-specific culling were dependent on genetic group, parity, stage of lactation, milk yield, and herd characteristics. Early lactation was a critical period for "died" and "injury-sick" culling. The risk increased with days after calving for "breeding" and, in the case of HO, "low production" culling. Open cows had a 3.5 to 4.6 times greater risk for overall culling compared with pregnant cows ($P \leq 0.01$). The odds of culling with reason "died" within the first 60 d in milk (DIM) were not significantly associated with genetic group. However, both JE and JH had lower odds of live culling within the first 60 DIM compared with HO cows [OR = 0.72 ($P \leq 0.001$) and 0.82 ($P \leq 0.002$), respectively]. Other cow variables significantly associated with the risk of dying within the first 60 DIM were cow relative 305 mature equivalent (MEQ) milk yield, parity, and season of calving. Significant herd-related variables for death included herd size and origin of replacements. In addition to genetic group, the risk of live culling within 60 DIM was associated with cow relative 305 MEQ milk yield, parity, and season of calving. Significant herd-related variables for live culling included herd relative 305 MEQ milk yield, herd size, type of facility, origin of replacement, and type of maternity. Overall, reason-specific culling followed similar patterns across DIM in the 3 genetic groups.

Key Words: culling, death, Holstein, Jersey

0095 Effect of an organic-certified treatment (Optimum UterFlush) for toxic puerperal metritis on cure and reproductive performance of dairy cows. P. J. Pinedo[*1], J. S. Velez[2], H. Bothe[3], D. Merchan[3], J. M. Piñeiro[3], and C. A. Risco[4], *[1]Texas A&M AgriLife Research, Amarillo, [2]Aurora Organic Farms, Boulder, CO, [3]Aurora Organic Dairy, Boulder, CO, [4]College of Veterinary Medicine, University of Florida, Gainesville.*

The objective was to evaluate the efficacy of an organic-certified product (Optimum UterFlush, Van Beek Natural Science) on the treatment of toxic puerperal metritis (TPM) in cows in an organic dairy farm. Evaluation included clinical cure, survival, and reproductive performance. The TPM was defined as an abnormally enlarged uterus and fetid watery red-brown vaginal discharge, associated with systemic illness and fever (rectal temperature > 39.5°C), within 12 d postpartum. Cows diagnosed with TPM (n = 220) were randomly assigned to 2 intrauterine treatments (every other day for a total of 3 treatments): 1) Control (CON) = 200 mL of Povidone iodine diluted in 2 L of distilled water (n = 113) and 2) UterFlush (UF) = 15 mL diluted in 105 mL of distilled water (n = 107). All treated cows received hypertonic solution (500 mL of 25% calcium borogluconate IV) and oral aspirin (5 boluses/d). Outcome variables for treatment efficacy included fever and presence of fetid vaginal discharge at d 6 and 14 after diagnosis, survival at d 6, 14, and 30, and reproductive performance. Control variables were parity, BCS at enrollment, and calving season. Logistic regression and ANOVA were used for the analyses (PROC GLIMMIX and PROC GLM, SAS). The odds of surviving at d 6, 14, and 30 for cows in the UF treatment were 4.7 (95%, CI = 1.4 to 15.8), 2.8 (95%, CI = 1.3 to 6.1), and 3.6 (95%, CI = 1.7 to 7.7) times the odds of cows in the CON treatment. Occurrence of fever at d 6 and 14 was not different between the 2 treatments. Presence of a fetid vaginal discharge at d 6 and 14 was lower in cows treated with UF compared with cows in the CON group [11% vs. 28% (P < 0.001) and 1% vs. 8% (P = 0.017)]. The odds of breeding until 150 d in milk (DIM) and the time to first breeding were not different for the 2 treatments. The odds of pregnancy at the first breeding and at 300 DIM for cows treated with UF were 2.2 (95%, CI = 1.1 to 4.4) and 2.0 (95%, CI = 1.1 to 3.5) times the odds of cows in the CON group. Days to pregnancy were similar in both treatments. The number of breedings per pregnancy was 1.96 vs. 2.58 for cows in the UF and CON treatments (P = 0.01), respectively. Results indicated that cows with TPM treated with Optimum UterFlush had higher odds of recovering and improved reproductive performance, compared with cows treated with Povidone iodine.

Key Words: puerperal-metritis, organic, UterFlush

0096 Effects of yeast product supplementation on immunity and uterine inflammation in transition dairy cows. K. Yuan[*1], L. Mendonca[1], L. Hulbert[1], L. Mamedova[1], M. Muckey[1], Y. Shen[1], C. C. Elrod[2], and B. Bradford[1], *[1]Kansas State University, Manhattan, [2]Vi-COR, Inc., Mason City, IA.*

The objective of this study was to assess the effects of supplementing a yeast product derived from *Saccharomyces cerevisiae* on immunity and uterine inflammation in transition cows. Forty multiparous Holstein transition cows were blocked by expected calving date and randomly assigned within block to 1 of 4 treatments (n = 10) from 21 d before expected calving to 42 d postpartum. Rations were top dressed with yeast culture plus enzymatically hydrolyzed yeast (Celmanax, Vi-COR, Mason City, IA) at the rate of 0, 30, 60, or 90 g/d throughout the experiment. Blood samples collected on -21, −7, 1, 4, 7, 14, 21, and 35 d relative to calving were incubated with *E. coli* (# 51813) to assess the ability of blood to kill bacteria. Uterine samples were collected on d 7 and 42 postpartum by cytobrush technique to determine neutrophil populations and relative abundance of transcripts involved in inflammation. Fecal samples were collected on d 7 and 21 for analysis of immunoglobulin A (IgA) concentration. Data were analyzed using mixed models with repeated measures over time. The percentage of *E. coli* killed by whole blood was not affected by yeast treatments (P = 0.28). Uterine neutrophil populations were much greater in samples collected on d 7 compared with those on d 42 (32.0% vs. 7.6% ± 3.7 of cells, P < 0.01), indicating greater neutrophil infiltration immediately after calving, but no treatment (P = 0.53) effect was detected. There were significant ($P \leq 0.01$) day effects for IL-6, IL-8, neutrophil myeloperoxidase, and neutrophil elastase, reflecting greater abundance of these transcripts in uterine tissues collected on d 7 compared with d 42. Interestingly, there was a quadratic dose effect (P = 0.02) for IL-6, indicating that 30 and 60 g/d decreased uterine IL-6 mRNA. The mRNA abundance of neutrophil myeloperoxidase and elastase was increased (P < 0.05) by yeast product. Yeast product quadratically increased fecal IgA concentrations (P = 0.03), suggesting that 30 and 60 g/d doses enhanced mucosal immunity. Yeast product supplementation did not affect whole blood bacterial killing ability but modulated uterine inflammatory signals and mucosal immunity in transition dairy cows.

Key Words: immunity, transition cow, yeast

0097 Hyperketonemia in early lactation dairy cattle: Component and total cost per case.

J. A. A. McArt[*1], D. V. Nydam[2], and M. W. Overton[3], *[1]Colorado State University, Fort Collins, [2]Department of Population Medicine and Diagnostic Sciences, Cornell University Ithaca, NY, [3]Elanco Animal Health-Dairy, Athens, GA.*

The purpose was to develop deterministic economic models to estimate the costs associated with: 1) the component cost per case of hyperketonemia (HYK) and 2) the total cost per case of HYK when accounting for costs related to HYK-attributed diseases in dairy cows. Data from current literature were used to model the incidence and risks of HYK, displaced abomasa (DA), and metritis, disease associations, and milk production, culling, and reproductive outcomes. The component cost of HYK was estimated based on 1000 calvings per year, incidence of HYK in primiparous and multiparous animals, percentage of animals receiving clinical treatment, costs associated with diagnostics, therapeutics, labor, and death loss, and costs of future milk production losses, future culling losses, and reproduction losses. Costs attributable to DA and metritis were estimated based on the incidence of each disease in the first 30 d in milk, number of cases of each disease attributable to HYK, costs associated with diagnostics, therapeutics, discarded milk during treatment and withdrawal period, veterinary service (DA only), death loss, and costs of future milk production loses, future culling losses, and reproduction losses. The component cost per case of HYK was estimated at $127 and $106 for primiparous and multiparous animals, respectively; the average component cost per case of HYK was estimated at $112. Thirty-one percent of the average component cost of HYK was due to future reproductive losses, 28% to death loss, 22% to future milk production losses, 13% to future culling losses, 3% to therapeutics, 2% to labor, and 1% to diagnostics. The total cost per case of HYK was estimated at $361 and $247 for primiparous and multiparous animals, respectively; the average total cost per case of HYK was $279. Forty percent of the average total cost of HYK was due to the component cost of HYK, 32% to the cost attributable to metritis, and 28% to the cost attributable to DA. The high total cost of HYK at reported incidences of 40 to 60% highlights the importance of appropriate transition cow nutrition and management to decrease the impact of HYK on both a disease and economic basis. In addition, these estimates can be used to model the cost benefit of various preventative and treatment interventions.

Key Words: component cost, dairy cow, hyperketonemia, total cost

0098 The effects of grain-induced subacute ruminal acidosis on interleukin-6 and acute phase response in dairy cows.

S. C. Li[*1], A. M. Danscher[2], P. H. Andersen[3], E. Khafipour[1], N. B. Kristensen[4], and J. C. Plaizier[1], *[1]Department of Animal Science, University of Manitoba, Winnipeg, Canada, [2]Department of Large Animal Sciences, University of Copenhagen, Denmark, [3]Department of Clinical Sciences, Swedish University of Agricultural Sciences, Uppsala, [4]Danish Agricultural Advisory Service, Aarhus.*

Subacute ruminal acidosis (SARA) resulting from excessive grain feeding to dairy cows is accompanied by an acute phase response. Interleukin 6 (IL-6) has been proposed as a mediator of this response. We tested if the acute phase response associated with grain-induced SARA is mediated by IL-6. Six lactating Danish Holstein cows were used in an incomplete block design study that included 2 periods with 2 cows in a SARA-challenge treatment and 2 cows in a control treatment, and a third period with 2 cows in a SARA-challenge treatment. In the first 2 wk of each experimental period, all cows received a control diet (17.4% CP, 19.2% starch, 6.28 MJ NEL/kg DM). In the third week, the diet for control cows remained unchanged. For the SARA-challenge cows, 40% of the control diet was gradually substituted with grain pellets (50:50 wheat:barley) within 3 d to induce SARA. This SARA-challenge diet was fed for another 4 d. Jugular vein blood was sampled at 7 h post-feeding on Tuesday and Thursday of the second week and during the first 2 and last day of the SARA-challenge diet feeding. The ELISA kits were used for measurement of IL-6 and acute phase proteins haptoglobin (Hp), LPS binding protein (LBP), and serum amyloid A (SAA). For data analysis, a mixed model was used, in which cow was treated as a random factor, whereas treatment (SARA challenge vs. control), period, day within period, as well as the interaction between day within period and treatment, were treated as fixed factors. Compared with control cows, the SARA challenge tended to increase LBP (7.54 vs. 10.23 mg/L, $P = 0.10$) and increased SAA (4.24 vs. 11.60 mg/L, $P = 0.04$) and Hp (3.57 vs. 22.09 mg/L, $P = 0.04$) in blood, confirming that the SARA challenge caused an acute phase response. Concentrations of IL-6 were not affected by the SARA challenge and averaged 5.06 ng/mL across treatments. Our data do not confirm that IL-6 mediates the acute phase response during grain-induced SARA. This confirmation may require more frequent blood sampling around the time of the SARA challenge.

Key Words: acute phase proteins, dairy cow, IL-6

0099 Evaluation of propylene glycol and glycerol infusions as potential treatments for ketosis in dairy cows. P. Piantoni* and M. S. Allen, *Michigan State University, East Lansing.*

Our objective was to evaluate propylene glycol (PG) and glycerol (G) as treatments for ketosis. Two experiments lasting 4 d each were conducted in which cows received 1 bolus infusion per day. All data were analyzed by ANOVA. Experiment 1 used 6 ruminally cannulated cows [28 ± 7 d in milk (DIM)] randomly assigned to 300-mL infusions of PG or G (both ≥ 99.5% pure) in a crossover design experiment. Within each period, cows were randomly assigned to sequence in a crossover for site of infusion in the abomasum (A) or reticulorumen (*R*). Treatments were infused in the cranial reticulorumen (R-PG and R-G) to simulate drenching and abomasum (A-PG and A-G) to prevent metabolism by ruminal microbes. Treatment did not affect DMI or milk yield. Glycerol infused abomasally increased plasma glucose concentration the most (15.2 mg/dL; interaction $P < 0.05$), followed by R-PG (12.0 mg/dL), A-PG (9.7 mg/dL), and R-G (7.9 mg/dL). Glucose area under the curve (AUC) was also highest for A-G (1480 min × mg/dL; interaction $P < 0.10$), followed by A-PG (1167 min × mg/dL), R-PG (1009 min × mg/dL), and R-G (302 min × mg/dL). Abomasal infusions increased glucose AUC compared with ruminal infusions (1324 vs. 656 min × mg/dL; $P < 0.05$). Experiment 2 used 4 ruminally cannulated cows (23 ± 5 DIM) randomly assigned to treatment sequence in a Latin square design experiment balanced for carry-over effects. Treatments were: 300 mL PG, 300mL G, 600 mL G (2G), and 300 mL PG + 300 mL G (GPG), all infused into the cranial reticulorumen. Infusions did not affect DMI or milk yield, but affected time to reach plasma glucose baseline after maximum and glucose AUC (both $P < 0.05$). Treatment contrasts compared PG with G, 2G, and GPG. Propylene glycol increased plasma glucose concentration and glucose AUC compared with G (16.4 vs. 6.6 mg/dL and 1768 vs. 213 min × mg/dL; both $P < 0.05$), but not compared with 2G or GPG. Abomasal infusion of G elicited the best plasma glucose response followed by infusion of PG into the rumen or abomasum. Plasma glucose response to ruminal infusion of PG was better than G, likely because of greater ruminal metabolism of G, and no benefit was detected for doubling the dose of G or infusing G in combination with PG. A 300-mL dose of propylene glycol is as effective a treatment as twice the amount of glycerol when administered in the reticulorumen.

Key Words: fresh cows, glucose precursors, ketosis

0100 Integrating metabolomics and transcriptomics of liver to study susceptibility to ketosis in response to prepartal nutritional management. K. Shahzad*[1], J. S. Osorio[1], D. N. Luchini[2], and J. J. Loor[1], *[1]University of Illinois, Urbana-Champaign, Urbana, [2]Adisseo S.A.S., Alpharetta, GA.*

Postpartal ketosis is associated with body fat mobilization postpartum. Subclinical and clinical ketosis arise more frequently in cows that are overfed energy during the entire dry period or during the close-up period (i.e., last 21 d before parturition). Metabolomics (GC–MS, LC-MS; Metabolon Inc.) and transcriptomics (45K-whole-transcriptome microarray; Agilent) analyses were performed in liver tissue harvested at -10 d relative to parturition from cows that were healthy (H) on 7 d postpartum or diagnosed with clinical ketosis (Ke). Cows in Ke consumed a higher-energy diet (OVE) from -21 d to calving. Cows in H consumed OVE ($n = 8$) or a high-straw, lower-energy diet (CON; $n = 8$) from -21 d to calving. Out of 313 biochemical compounds identified, statistical analysis ($P \leq 0.10$) of metabolomics data for Ke vs. CON, OVE vs. CON, and Ke vs. OVE revealed 34, 33, and 25 affected compounds, respectively. The top-5 affected and up regulated biochemical compounds in Ke vs. CON were taurocholate, adenine, hypotaurine, γ-glutamylcysteine, and taurochenodeoxycholate. In OVE vs. CON cysteine, methylphosphate, cysteinylglycine, and taurocholate were up regulated and γ-glutamylthreonine was downregulated. In Ke vs. OVE, the top-5 affected compounds were all downregulated: xylitol, 1-palmitoylglycerophosphoglycerol, leucylaspartate, sphinganine, and glycylvaline. Bioinformatics analysis revealed that primary bile acid production through cysteine and taurine precursors, and oxidative stress-like activities were affected in both Ke and OVE vs. CON groups. In contrast, in Ke vs. OVE, ketone body production was up regulated and cell signaling pathways were inhibited. Bioinformatics analysis of 2908 differentially expressed genes (DEG; $P \leq 0.05$), using the Dynamic Impact Approach (DIA), revealed that the top-5 impacted pathways in Ke vs. OVE were "hedgehog signaling," "glycosphingolipid biosynthesis-globo series," "renin-angiotensin system," and "other glycan degradation," all of which were inhibited. The "circadian rhythm" pathway was among the most induced pathways. Furthermore, there was marked inhibition in Ke vs. OVE of pathways associated with cellular growth, communication, signal transduction, fatty acid biosynthesis, and immune-related responses. These results suggest that prepartal diet alters hepatic metabolome and transcriptome. Liver from cows developing ketosis postpartum appears to exhibit unique alterations in the transcriptome and metabolome.

Key Words: ketosis, metabolomics, systems biology, transition cows

0101 A competitive and unpredictable feeding environment pre-calving increases inflammation and endometritis in Holstein dairy cows.

K. Proudfoot*[1], S. J. LeBlanc[2], D. Weary[3], B. Bradford[4], L. Mamedova[4], and N. von Keyserlingk[3], *[1]The Ohio State University, Columbus, [2]University of Guelph, ON, Canada, [3]The University of British Columbia, Vancouver, Canada, [4]Kansas State University, Manhattan.*

Pre-calving management may influence the risk of disease after calving. Our objective was to determine the effects of a competitive and unpredictable feeding environment on inflammation and uterine health in dairy cows. Sixty-four animals were randomly assigned to a treatment (n = 4 animals × 8 groups) or control group (n = 4 animals × 8 groups). Each group consisted of 3 multiparous cows and 1 primiparous heifer. During a 1-wk baseline period (5 wk before calving), all groups had free access to 4 electronic feed bins (Insentec, Marknesse, Holland). From 4 wk before calving until calving, control cows were given ad libitum access to 6 feed bins. For treatment groups, 4 non-experimental cows were added to the pen; after 2 wk, treatment groups were moved into a pen with 4 new cows. Throughout the treatment period, morning feeding times were delayed at random 0, 1, or 2 h on alternate days. Cows were excluded if they calved twins, aborted, or calved > 2 wk early. Blood samples were taken at baseline and weekly thereafter until 1 wk after calving. Serum was analyzed for TNF-a using ELISA. A uterine cytology smear was taken 3 to 5 wk post-calving. Smears were stained and examined under 400X magnification for presence of neutrophils and uterine epithelial cells; cows were considered to have endometritis if > 5% neutrophils were identified. Preliminary analysis revealed treatment × parity × week interactions so data were analyzed separately by parity. The percentage of endometritis cases per group was compared among treatments using a Mann–Whitney U test in SAS. Log-transformed TNF-a data were analyzed using a mixed model, including baseline data as a covariate, treatment as a main effect, week as a repeated measure (wk -2, -1, 0, 1 relative to calving), and group as a random effect. There was no difference in the number of cases of endometritis or differences in TNF-a between control and treatment first-calf heifers. For cows, treatment groups had a higher percentage of endometritis cases (64% vs. 17% cases/group; P = 0.02) and higher TNF-a (2.1 vs. 1.8 ± 0.06 log pg/ml; P = 0.02), compared with controls. These results indicate that management practices that create a competitive and unpredictable feeding environment, such as regrouping, overstocking, and variable feeding times, can disrupt immune function and increase disease risk in cows but not first-calf heifers.

Key Words: endometritis, parturition, stress

ARPAS SYMPOSIUM: CUSTOMER/ CONSUMER CONFIDENCE IN THE LIVESTOCK INDUSTRY—ETHICS

0102 Perspectives on business ethics in a new-age feed industry. L. D. Bunting*, *ADM Alliance Nutrition, Lubbock, TX.*

The business of providing animal feed and nutritional services is becoming increasingly sophisticated and global in nature. As the complexity of the feed industry has increased, both livestock producers and feed suppliers alike perceive that the occurrence of unethical behavior in sales and marketing of feed products is on the rise. This perception likely originates not only from some actual decline in ethical standards but perhaps also from an increasing lack of clarity relative to what actually constitutes ethical practice. This paper will discuss the interpretation of ethical practice in the context of the rapidly evolving field of animal nutrition and the great many new feed technologies and suppliers entering the market, from both domestic and international sources. The potential ramifications of a feed industry work force that is becoming less experienced (youthful) and increasingly foreign trained will also be discussed in the context of company training programs that probably fall short in both technical depth and ethical mentoring relative to customer relationships. Feed specialists with less professional experience are more susceptible to ethical creep or ethical blindness, as they may have less appreciation for how seemingly trivial corner cutting leads to cycles of behavior rationalization that slowly progress to practices that are more egregiously unethical. A large proportion of the incidences of unethical practices that are anecdotally reported in the feed industry relate to the selling and use of feed additives, micronutrients, and other higher-cost applications. Some of the problematic practices that are more prevalent include customer confidentiality breaches, unapproved or erroneous product claims, misrepresentation of effective doses or tag dressing, undisclosed substitution of branded products, and undisclosed product commissions for parties in fiduciary roles with livestock producers. This paper will emphasize the need for greater focus on training and mentoring of feed industry employees relative to what constitutes fair business practices and how to sell feed products and programs such that they are honestly represented, both for the benefits they can potentially provide and relative to any competitive products and programs. Ethical behavior must be understood to be of collective importance to the feed industry. Unethical practices can have consequences that cause collateral damage to customer bases well beyond that of the offending sales organization. Unethical practices also undermine the trust of suppliers and other key parties that are business critical to the success of a sales organization.

Key Words: ethics, feed industry, nutrition

0103 Customer/consumer confidence in the livestock industry—ethics: University perspective. M. L. Galyean*, *Texas Tech University, Lubbock.*

Animal science researchers, particularly those working with industry-sponsored research, are under increasing scrutiny with respect to bias and conflict of interest. Following the lead of the federal government, virtually all research universities have well-defined procedures to delineate and record potential bias and conflict of interest issues for faculty members who conduct research. Faculty committees to review and recommend remediation of potential conflicts are a common feature of university procedures. Primary concerns include conflicts of interest associated with financial, professional, and personal relationships. Financial limits vary somewhat among institutions, but an aggregate interest of > $5,000 is typically the threshold for disclosure. Once the threshold is met, faculty members are typically required to list and describe potential conflicts and subsequently inform all members of their research team of business and financial interests, consultancies, and any other potential issues that might influence their objectivity in conducting research. Issues that fall below reporting guidelines can nonetheless constitute potential conflicts. For example, more subtle conflicts of interest and bias might occur as a result of associations that a faculty member might have with companies providing discretionary funding and products to support research activities, regular consultancies that fall below reporting limits, honoraria to faculty members on advisory boards or to those who give technical presentations to clients groups, and all-expense paid trips to company-sponsored activities of various types. Similar conflicts can occur through connections to commodity organizations or even professional societies that have public stands on issues related to the faculty member's research. To ensure public trust in animal science research, animal scientists must adhere fully to applicable university regulations. In addition, they should conduct rigorous self-evaluations of their professional relationships, be transparent with respect to their activities via written disclosures to colleagues and research team members, and provide clear statements of potential conflicts in publications. Peer evaluations of relationships to ascertain real or perceived bias and conflict of interest issues could be useful, particularly in cases where the issues do not meet university or federal guidelines for reporting.

Key Words: bias, conflict of interest, industry-sponsored research

0104 [Withdrawn]

0105 Regulatory definitions, processes, and functionality assessment for animal food.

M. G. Alewynse*[1] and S. A. Benz[2], [1]*Center for Veterinary Medicine, Olney, MD,* [2]*Center for Veterinary Medicine, FDA, Woodbine, MD.*

The Federal Food, Drug, and Cosmetic Act (Act) defines food as "articles used for food or drink for man or other animals." The Act defines drugs as substances intended for diagnosis, cure, mitigation, treatment, or prevention of disease, or that affect the structure or function of the body. However, the Act recognizes that food may affect the body and excludes "food" from the drug definition. The U.S. courts have determined that food provides "aroma, taste, or nutritive value." The Center for Veterinary Medicine (CVM) in the Food and Drug Administration (FDA) regulates both animal food and drugs. Animal food includes both livestock feed and companion animal food. Food and substances added to food must be safe and achieve their intended purpose. The CVM administers 2 regulatory processes for animal food. The food additive petition process is described in regulation 571 in Title 21 of the Code of Federal Regulations (21 CFR 571). The safety of the additive at the intended use rate must be addressed for the animal, environment, and food-producing animals; safety of human food products obtained from animals fed the additive must also be addressed. The second process is similar to the first, except that the information concerning the safety of the substance for the intended use and its functionality are in the public domain, i.e., published in scientific literature. When the safety and functionality of a substance's use in animal food is generally available and recognized, qualified experts may determine that this use is exempt from the premarket requirements of the Act because the use is generally recognized as safe (GRAS). A GRAS determination generally requires the same quantity and quality of information needed for a food additive petition with the added burden that the information be public. Firms cannotify CVM about a GRAS determination through the animal food GRAS notification program. Also, for substances that raise no safety concerns when used in animal food, firms can request the Association of American Feed Control Officials (AAFCO) to publish an ingredient definition in the AAFCO Official Publication. For all these processes, firms must establish what the substance does and determine how their intended use fits under the definition of food in the Act. Firms must also demonstrate that the substance achieves the intended effect.

Key Words: animal food, functionality, intended use, regulation

ASAS CELL BIOLOGY SYMPOSIUM: LONG-TERM CONSEQUENCES OF MATERNAL AND NEONATAL NUTRITION FOR PREGNANCY AND POSTNATAL OUTCOMES

0106 Lactocrine programming of postnatal reproductive tract development. F. F. Bartol[*1] and C. A. Bagnell[2], [1]*Auburn University, AL,* [2]*Rutgers University, New Brunswick, NJ.*

Lactocrine signaling occurs when bioactive factors are communicated from mother to offspring as a consequence of nursing. In the pig (*Sus scrofa*), relaxin was identified as a prototypical lactocrine-active factor in colostrum. Administration of exogenous relaxin from birth [postnatal day (PND) = 0] increased neonatal uterine estrogen receptor-α (ESR1) expression. Using multispectral immunofluorescence imaging, expression of ESR1 is detectable in nascent endometrial glandular epithelium and stroma within 2 d of birth, and supports uterine gland genesis. Imposition of a lactocrine-null condition for 2 d from birth by substitution of porcine milk replacer for colostrum retarded endometrial development and uterine gland genesis. Compared with nursed gilts, replacer feeding from birth reduced stromal ESR1 expression and endometrial cell proliferation, and increased endometrial relaxin receptor expression by PND 2. Effects of transient imposition (48 h) of the lactocrine-null state on endometrial morphology were pronounced by PND 14, when cell proliferation, reflected by patterns of proliferating cell nuclear antigen immunostaining, and development of nascent endometrial glands were markedly reduced. Collectively, the observations suggested a lactocrine-driven mechanism regulating establishment of the uterine developmental program and endometrial adenogenesis in the neonatal pig. The lactocrine hypothesis for maternal programming of reproductive tract development predicts that neonates deprived of colostrum will have reduced uterine capacity to support conceptus development as adults due to disruption of the uterine developmental program shortly after birth. Results of a retrospective study involving 381 gilts indicated that lifetime fecundity (number of piglets born alive over ~4 parities per gilt) was reduced in animals that consumed minimal amounts of colostrum as indicated by low serum immunocrit values on PND 0. To the extent that the first 2 d of neonatal life constitute a critical period for establishment of the uterine developmental program, effects of replacer feeding for 2 d from birth on global patterns of uterine gene expression were evaluated using whole uterine transcriptome analysis via RNA sequencing (RNA-seq). Analyses were performed on uteri (n = 4/group) obtained on PND 2 from gilts that were either nursed (PND 2N) or fed porcine milk replacer from birth (PND 2R). Using RNA-seq, 896 genes were determined to be differentially expressed (> twofold) between the PND 2N and PND 2R groups. Thus, disruption of lactocrine signaling has profound effects on neonatal uterine gene expression. The results indicate that lactocrine support is required to establish a normal uterine developmental program in the neonatal pig.

Key Words: development, lactocrine programming, neonate

0107 Long-term consequences of maternal and neonatal nutrition for pregnancy and postnatal outcomes. D. G. Burrin[*1] and B. Stoll[2], [1]*USDA-ARS Children's Nutrition Research Center, Houston, TX,* [2]*Baylor College of Medicine, Houston, TX.*

The nutritional environment during fetal and neonatal life is a key determinant affecting the risk for adult-onset diseases, such as diabetes and obesity. Studies show that preterm infants experience increased risk for glucose intolerance as adolescents and young adults. Preterm infants often receive parenteral nutrition for several days or weeks after birth as a lifesaving form of clinical support. Considerable evidence shows that the normal and dysfunctional secretion of gut hormones play a key role in metabolic health and diseases, including diabetes and obesity. We have used the model of parenterally fed neonatal pig to test whether the modality of nutritional support (enteral vs. parenteral) significantly impacts both the pattern of gut hormone secretion and metabolic function. We first showed (J. Nutr.140:2193) that chronic parenteral (PN) compared with enteral (EN) nutrition in neonatal pigs for 2 wk leads to an adverse metabolic phenotype marked by increased glucose intolerance, insulin resistance, body fat deposition, and reduced pancreatic β-cell proliferation. We also showed (JPEN.36:538) that the pattern of enteral nutrition (intermittent vs. continuous) is a stronger determinant than modality of nutrition to optimize glucose utilization and insulin sensitivity. We also showed that the secretion of gut incretin hormones, glucose-dependent insulinotropic polypeptide (GIP), and glucagon-like peptide 1 (GLP-1) correlated closely with glucose utilization and insulin sensitivity. An important question is whether the adverse metabolic phenotype that results from that chronic PN during the first 2 wk of neonatal life persists into late infancy and adolescence. We recently tested this in newborn pigs by feeding either PN or EN for 2 wk, followed by ad lib feeding of a high-fat (30%) and sucrose (20%) diet for 5 mo. We measured body composition by dual-emission X-ray absorptiometry at 2 and 8 wk, and 5 mo, and performed an IVGTT at 5 mo. Our results showed that PN during the neonatal period increased adiposity transiently into early infancy, but PN-induced glucose intolerance, adiposity, pancreatic β cell number, and hepatic steatosis were not sustained into adolescence, even when challenged with an obesogenic diet. This presentation will highlight the link between enteral nutrition as a key trigger for gut hormone secretion and function, and how these hormone-signaling pathways may be relevant to domestic animal growth.

Key Words: nutrition, pregnancy, signaling pathways

0108 The epigenetic landscape of the β-cell in IUGR rats. S. Pinney and R. A. Simmons*, *Perelman School of Medicine, University of Pennsylvania, Philadelphia.*

The abnormal intrauterine milieu of intrauterine growth retardation (IUGR) permanently alters gene expression and function of pancreatic b-cells, leading to the development of diabetes in adulthood. Expression of the pancreatic transcription factor Pdx1 is permanently reduced in IUGR and epigenetic modifications are responsible for this decrease. The Pdx1 encodes a homeobox transcription factor, critically important for β-cell function and development. The fetal IUGR state is characterized by loss of USF-1 binding at the proximal promoter of Pdx1, with deacetylation of histones H3 and H4, due to recruitment of the histone deacetylase (HDAC1) and the co-repressor Sin3A. After birth, H3K4 is demethylated and H3K9 is methylated. During the neonatal period, the reduction in Pdx1 expression and these epigenetic changes can be reversed by HDAC inhibition. Finally, once diabetes occurs, DNA methylation of the CpG-island in the proximal promoter ensues, resulting in permanent silencing of the Pdx1 locus. Exendin-4 (Ex-4), a long-acting glucagon-like peptide 1 (GLP-1) analog, given on d 1 to 6 of life increases Pdx1 expression and prevents the development of diabetes in the IUGR rat. The Ex-4 increases USF-1 and PCAF association at the proximal promoter of Pdx1, thereby increasing histone acetyl transferase (HAT) activity, which leads to a permanent increase in histone H3 acetylation and H3K4 methylation. Normalization of these histone modifications precludes DNA methylation, thereby preventing silencing of Pdx1 in islets of IUGR animals. These studies demonstrate a novel mechanism whereby a short treatment course of Ex-4 in the newborn period prevents diabetes in adulthood by restoring Pdx1 promoter chromatin structure, thus preserving Pdx1 transcription. Finally, using the HELP assay, we generated the first DNA methylation map of the rat genome in normal and IUGR β-cells. We validated candidate dysregulated loci with quantitative assays of cytosine methylation and gene expression. The IUGR changes cytosine methylation at 1400 loci in male rats at 7 wk of age, preceding the development of diabetes and thus representing candidate loci for mediating the pathogenesis of metabolic disease that occurs later in life. Epigenetic dysregulation occurred preferentially at conserved intergenic sequences, frequently near genes regulating processes known to be abnormal in IUGR islets, such as vascularization, β-cell proliferation, insulin secretion, and cell death, associated with concordant changes in mRNA expression. These results demonstrate that epigenetic dysregulation is a strong candidate for propagating the cellular memory of intrauterine events, causing changes in expression of nearby genes and long-term susceptibility to type 2 diabetes.

Key Words: diabetes, epigenetic, programming

ASAS GRADUATE STUDENT SYMPOSIUM: RESEARCH ETHICS: WHAT ARE THEY AND WHY ARE THEY NEEDED?

0109 What are research ethics? M. S. Calvo-Lorenzo*, *Oklahoma State University, Stillwater.*

Due to the diversified nature of research, there is no universal manner in which scientific investigations are conducted. Thus, the responsible conduct of research will vary from discipline to discipline, and from laboratory to laboratory. Society's expectations for research responsibility are complex and guidelines for conducting responsible research are not always clearly defined. Some responsible practices are defined and mandated at the professional, institutional, and/or governmental level, whereas other non-binding guidelines and best practices are informally defined and executed through the mentor/trainee relationship. The culmination of these various practices, including responsible behaviors and attention to conducting the best research by scientists, has established that research ethics must be built on a commitment to the essential values of honesty, accuracy, precision, efficiency, and objectivity. These values represent research integrity and are the basis for ethical decisions and actions, regarding data management, mentor and trainee responsibilities, collaborative research, use of humans and animals in experimentation, authorship and publication, public accountability, and the peer review process. "Ethics" is often defined as the study of moral values and ethical decision-making aids us in the critical consideration of such values to make decisions we consider to be "right." However, "ethics" is often used interchangeably with the term "morals" and our ability to ethically analyze our actions should not be confused with the ability of our conscience to differentiate right from wrong. Moreover, ethical behavior implies adherence to principles that underlie a specific context or profession, whereas the use of morals in the work place or research setting implies conformity with a behavioral code generally accepted in some defined setting or culture. This distinction is important in understanding what research ethics are, especially as research enters the realm of moral reasoning. One must determine what is ethically (vs. legally) right and wrong. Ultimately, making well-reasoned ethical and moral responses to dilemmas in the conduct of science should consider: 1) all issues and points of conflict, 2) the interests and expectations of all parties, 3) recognition of possible consequences that may arise from proposed actions, and 4) identification of the professional and moral obligations of scientists. Researchers and trainees can gain more insight and knowledge by using case studies to discuss the elements of critical thinking, ethical decision making, and moral reasoning as it pertains to situations that scientists encounter during the course of a research career.

Key Words: research ethics

0110 Why are research ethics important and how do they affect academia? M. L. Galyean*, *Texas Tech University, Lubbock.*

Animal welfare and associated animal care and use issues have been at the forefront of ethical concerns for animal science researchers for many years. More recently, animal science researchers, particularly those working with industry-sponsored research, have come under increasing scrutiny with respect to bias and conflict of interest in their research programs. Universities and most corporate research units have well-defined procedures that must be followed when vertebrate animals are used in research. Similarly, most universities have established policies for assessing, reporting, and remediating conflicts of interest of a personal, financial, or professional nature. In terms of financial conflicts, a collective interest of > $5,000 is typically the threshold for disclosure of potential conflicts to colleagues and research team members. More subtle conflicts of interest and bias that do not require reporting might affect faculty members who receive discretionary funding and products to support research, consulting activities, honoraria for work on advisory boards or for giving technical presentations to industry clients groups, and trips to company-sponsored activities of various types. In terms of animal research, responsible conduct that will instill public confidence requires more than following minimum guidelines. Faculty researchers, graduate students, and research staff should work together to provide the highest possible standards of animal care; however, ultimately the principal investigator must be responsible and devote appropriate time to oversight of research projects and animal care. Delegating oversight of research activities and animal care to graduate students or staff members without proper training and instruction is unwise and inappropriate. All members of research teams should be dedicated to optimal experimental design and methods of collection, analysis, and interpretation of data. To do otherwise is an unethical defiance of public trust. Busyness is never an appropriate excuse for principal investigators to shirk their responsibilities to research team members in terms of providing proper oversight of research activities. Research teams should conduct regular, transparent self-evaluations of whether they are providing the highest standards of animal care and also assess potential conflicts of interest and bias for all team members. Including peers outside the research team to help evaluate real or perceived bias and conflict of interest issues might be useful. Graduate students and research staff can play a key role in ensuring ethical conduct of research by asking for training and instruction, and questioning potential bias and conflict of interest issues.

Key Words: animal care, bias, conflict of interest, research integrity

0111 Importance and impact of research ethics on industry. M. Brown[*1] and D. Smith[2], [1]*Global Animal Products, Inc., Amarillo, TX,* [2]*Performance Plus Liquids, Inc., Sterling, CO.*

Ethics is commonly defined as the rules of behavior or norms of conduct that differentiate between acceptable and unacceptable practices. Guidance of scientists by an appropriate ethical compass is paramount in research because scientists occupy a unique position of trust with the readers/users of their data. One end of the research ethics spectrum is typified by descriptors, such as error-free, accurate, precise, repeatable, well-documented, transparent, objective, and unbiased, whereas the opposite end of the spectrum involves misconduct in some form. A wealth of resources is available that illuminate the principles of ethics in the context of responsible conduct in research. Full awareness and evolution of one's own understanding of ethics arises from daily use of these principles and periodic reflection. In the scope of this presentation, the impact of research ethics of a given applied research program on industry is a function of the quality of the data generated and conveyed, and on the cultivation of skills and attributes of graduate students from that program that will be carried into future careers. Herein, industry refers to beef cattle production and the professionals that provide service to this sector of agriculture. Discussion will encompass quality assurance considerations in the execution of applied studies and generalized examples that illustrate the potential impact of low-quality data on certain aspects of industry. A comprehensive survey of employers of master's and doctoral graduates in the cattle feeding sector from 20 states in the United States and 1 Canadian province indicates that the area of greatest discrepancy between employer desires and employee preparation involved elements of character, followed by interpersonal and communication skills. Efforts to conduct and report high-quality data garner the highest value and appreciation by industry. Greater emphasis on fostering good character and communication skills of developing scientists will be beneficial to industry, academia, and society.

Key Words: applied science, ethics, quality assurance

BEEF CATTLE REPRODUCTION SYMPOSIUM: **REBUILDING THE U.S. COW HERD: RETHINKING THE WAY INDUSTRY SELECTS AND DEVELOPS REPLACEMENTS**

0112 Rebuilding the U.S. cow herd: Rethinking the way industry selects and develops replacements. D. S. Brown* and D. J. Patterson, *University of Missouri, Columbia.*

The U.S. beef industry is confronted with a significant long-term decline in cattle numbers driven in part by record input costs and severe drought conditions in many major cattle-producing states. These recent challenges only add to the long-term issues the industry has faced, which include an aging producer population, increased global competition, increased competition from other meat proteins, weak domestic demand for beef, and a perceived lack of economic incentives to expand the cattle herd. The weakness in beef demand provided impetus for the industry to begin the Beef Quality Assurance program. Although the industry has experienced more consistency in beef products over the last 3 decades, there are major strides left when today < 5% of cattle grade Prime. In comparison with other domestic livestock sectors in the United States, tradition and segmentation within the U.S. cattle industry has hindered the adoption of newer production and marketing strategies. Coordinating the various industry segments (cow-calf, stocker, feedyard, processor) with allied industry (AI companies, seed stock suppliers, feed and pharmaceutical industries) offers the potential to enhance technology adoption and contribute to increases in production efficiency. As the U.S. cattle industry moves to rebuild its declining numbers, the focus of much of the industry will turn to heifer retention and appropriate practices related to beef heifer development. The industry has provided better beef quality signal transmission through available marketing grids in the industry today. Yet, these grids generally require cow-calf producers to maintain some ownership stake in the cattle through the feedyard. Producers who have invested in developing higher quality cattle and beef in the past often found genetic improvement to be slow and inconsistent, which oftentimes reduced economic incentives of quality focus. The technologies that have come online over the past few years and new genomic advances on the horizon appear poised to rapidly increase genetic improvement and consistency. The combination of better market incentives for higher quality beef coupled with technologies that allow producers to more easily invest in genetics focused on quality provide the industry a unique opportunity to increase the cow herd with a more refined focus on the genetic potential of the herd as it relates to efficiency and higher quality. It would appear these technologies have the added value of reducing producer risk by providing more consistency in the beef produced.

Key Words: economic, quality, technologies

0113 Physiology and endocrinology of puberty in heifers. J. Atkins*[1], K. G. Pohler[2], and M. F. Smith[2], [1]*American Simmental Association, Bozeman, MT,* [2]*University of Missouri, Columbia.*

Most beef producers expect their heifers to be able to calve for the first time at 2 yr of age. Frequently, the breeding season for heifers begins 2 to 3 wk before the beginning of the breeding season for cows. Furthermore, the fertility associated with the first pubertal cycle is reportedly lower than subsequent cycles. Therefore, having heifers that reach puberty 6 to 9 wk before the start of the breeding season can have a positive impact on conception rates and ultimately profit for producers. Additionally, heifers that conceive earlier in the breeding season, calve earlier in the calving season and have a better chance of conceiving the following breeding season. Early-calving heifers produce more calves in their lifetime and remain in production longer than later-calving heifers. Understanding the physiology and endocrine maturation leading to onset of puberty is critical to maximizing heifer development. Puberty, defined as the first ovulatory estrus, is preceded by progressive growth and development of the uterus, ovaries, and hypothalamic-pituitary-ovarian axis. Follicle waves endure longer, dominant follicles become larger, and oocyte competence improves as heifers approach puberty. The CL formed after the first ovulation and luteinization is short lived due to a premature release of $PGF2_{\alpha}$. This short exposure of progesterone followed by a rise in estradiol is important in establishing the appropriate timing of $PGF2_{\alpha}$ release and can be mimicked using a progestin in estrous synchronization protocols. Estradiol shifts from having a strong negative feedback on the hypothalamus and pituitary to a reduced negative feedback, and finally a positive feedback, causing the gonadotropin surge and ovulation (gonadostat hypothesis). The switch in the hypothalamic response to estradiol may be due to a drop in estradiol receptors, coupled with increased concentrations of kisspeptin and increased sensitivity to existing kisspeptin molecules by GnRH neurons. Producers can use reproductive tract scoring (RTS), a subjective measurement of the uterus and ovaries, to assess heifers' sexual maturity before the breeding season (4 to 6 wk, ideally). This gives producers enough time to make management decisions based on the RTS assessment. In summary, this paper/presentation provides a review of the research into the physiological and endocrine maturation leading up to puberty in beef heifers.

Key Words: beef, heifer, puberty

0114 Beef heifer replacement considerations related to breed and biological type. A. L. Van Eenennaam*, *University of California-Davis, Davis.*

The reproductive fitness of females is a major driver of profitability and fertility considerations should be given high priority when selecting the best replacement heifers. Selection for replacement heifers is based on their readiness and ability to conceive in the proposed breeding season, which places indirect selection on dam fertility, as fertile cows tend to conceive early and generate early-born heifers that are more likely to be selected as replacements. Age at puberty is variable among breeds and biological types (British < Continental < *Bos indicus* influenced), and is moderately heritable. The choice of breed(s) and breeding system play an important role in overall ranch profitability and before making a commitment to any breed or breeding system, the logistics, costs (including opportunity costs), benefits, and feasibility should be objectively evaluated for a given set of environmental, resource, management, and marketing constraints. Expected progeny difference (EPD) genetic merit estimates for heifer pregnancy (HP), stayability (STAY), and scrotal circumference (SC) are available for some breeds, and have all been positively associated with female fertility. Heterosis (also known as hybrid vigor) occurs when the performance of the crossbred progeny for a specific trait is greater than the average of their parents. Heterosis effects are significant and important for low heritability fitness and survival traits, such as longevity, lifetime production, and reproduction rate. Improvements in cow-calf production due to heterosis result from both the improved maternal performance of the crossbred cow and individual performance of the crossbred calf. Complementarity results from crossing breeds of different but complementary biological types. This occurs when specialized sire and dam breeds are used in terminal systems to optimize performance levels. Properly designed crossbreeding systems, based on heterosis and complementarity, will generally out produce those based on straight breeding in productivity, but the challenge is to manage the program to produce progeny that meet market specifications and acceptance. The combination of AI and gender-selected, or "sexed" semen, offers the opportunity to rethink the logistics and economics associated with different breeding systems. Gender-selected semen provides the opportunity to develop novel breeding scenarios and avoid some of the logistical problems associated with the various crossbreeding systems. Emerging reproductive and genomic technologies offer exciting possibilities for innovative approaches to heifer selection and breeding program design; but as with all new technologies, enthusiasm needs to be tempered with a realistic evaluation of the costs and expected benefits.

Key Words: breed, complementarity, heterosis

0115 Nutritional development and the target weight debate. J. B. Hall*, *University of Idaho, Carmen.*

Postnatal nutrition has a profound effect on reproductive efficiency and lifetime productivity of beef heifers. A nutritional management strategy that focuses on allowing a high percentage of heifers to achieve puberty before the breeding season while reducing feed costs is the goal of most operations. Both preweaning and postweaning nutrition affect age at puberty. Preweaning nutrition may have a greater effect than postweaning nutrition on the onset of puberty, but the impact of management is limited preweaning. Creep feeding or creep grazing may increase the incidence of precocious puberty in heifers. Similarly, exposure to high concentrate diets during early weaning may increase precocious puberty, but early weaning has variable effects on pregnancy rates in heifers. To some extent, postweaning gain can overcome preweaning nutrient deficiencies. However, it is currently unknown if postweaning nutrition can alleviate negative prenatal nutritional effects on reproduction. Energy is the primary limiting nutrient in beef heifer diets; however, protein must be adequate and may be the limiting nutrient in certain circumstances. A few studies indicate that heifers may benefit from supplementation with rumen undegradable protein. In general, the source of nutrients does not appear to be important as long as animal requirements are met. The nutritional requirements listed in the Beef NRC appear to be adequate for heifer development, but more studies validating the Beef NRC requirements for growing heifers are needed. Altering pattern of growth during the postweaning developmental period may offer opportunities for decreased development costs and perhaps enhanced cow longevity. The most practical benchmark for proper heifer development at the ranch level has been the target weight method. Recently, the traditional target weight of 65% of mature weight at breeding has been challenged. Achieving a target weight of 65% of mature weight by the beginning of the breeding season ensures nutrition does not limit reproductive success of heifers; however, it appears a target weight of 55% has application for some operations and may have positive effects on heifer longevity. At present, multiple nutritional tools are available to design systems or respond to environmental factors (i.e., drought) for developing replacement beef heifers. Proper analyses of the impact of these systems need to include long-term effects on cow reproduction and longevity.

Key Words: heifer, nutrition, reproduction

0116 Management strategies for adding value to replacement beef heifers: A working model—The Missouri Show-Me-Select Replacement Heifer Program. D. J. Patterson*[1], J. M. Thomas[1], D. S. Brown[1], J. E. Decker[1], W. J. Sexten[1], and S. E. Poock[2], [1]*University of Missouri, Columbia,* [2]*University of Missouri-College of Veterinary Medicine, Columbia.*

Utilization of existing and emerging management technologies enable beef producers to improve breeding performance of heifers during the first breeding season and during subsequent calving and rebreeding periods as 2-yr-olds. These practices ensure that heifers that enter herds as raised or purchased replacements contribute to the general performance and productivity of an entire cow herd immediately, and cumulatively long term. In 1996, extension specialists, veterinarians, beef producers, and allied industry in Missouri linked arms to develop and implement a plan that would impact long-term sustainability of beef herds across the state. This plan was focused on the cyclical reproductive process in beef cattle and involves 5 basic steps: 1) create an understanding of the importance of heifer development based on reproductive outcomes; 2) implement changes in heifer development that eventually spill over into the cow herd; 3) emphasize the importance of reproductive management, which becomes apparent as changes are implemented; 4) expand producer focus to genetic improvement; and 5) emphasize to participating herds that creation of a value-added product requires a re-evaluation of marketing strategies. These 5 steps have built equity in herds that embraced the plan; 17 yr later the Missouri Show-Me-Select Replacement Heifer Program has impacted the cattle industry statewide. The program objectives include: 1) a total quality management approach for health and management of heifers from weaning to late gestation; 2) increased marketing opportunities for and added value from Missouri-raised heifers; and 3) creation of reliable sources of quality commercial and purebred replacement heifers. The program incorporates all available tools to support long-term health, reproduction, and genetic improvement of replacement beef heifers and includes provisions for ownership, health and vaccination schedules, parasite control, implant use, weight, pelvic measurement, reproductive tract score, estrous synchronization, AI, service-sire requirements for BW- or CE-EPD, early pregnancy diagnosis, fetal aging, fetal sexing, and BCS. In a state that ranks second in total number of beef cows in production, the Missouri Show-Me-Select Replacement Heifer Program is a working model that integrates improvements in selection, management, health, and genetics into a total development, management, and marketing program through emphasis on reproductive outcomes. Impact in Missouri stemming from the Show-Me-Select program and the proof of concept it demonstrates raises the question as to whether it is time to standardize requirements used in the program to broaden its scope to other major beef cattle-producing states.

Key Words: Missouri, replacement beef heifer, Show-Me-Select

BEEF SPECIES: MAKING MORE BUT USING LESS: THE FUTURE OF THE U.S. BEEF INDUSTRY WITH A REDUCED COW HERD AND THE CHALLENGE TO FEED THE UNITED STATES AND WORLD. *SESSION 1:* THE U.S. STOCKER AND FEEDLOT INDUSTRIES

0117 Nutritional strategies to improve efficiency in the stocker and feedlot industries in a consumer-conscious market. M. S. Kerley*, W. J. Sexten, and A. M. Meyer, *University of Missouri, Columbia.*

Biological efficiency potential and nutrient supply synchrony are primary determinants of feed efficiency when converting feed to beef carcass yield. Feedlot diets have historically been formulated to have a minimum roughage inclusion to maintain rumen health and a minimum protein level (crude, metabolizable, or degradable protein) for targeted growth rates. While historically effective, we have asked if poorly digested and increasingly expensive roughage could be eliminated. We have also asked why diets are formulated for protein when calves have specific requirements for AA. When no-roughage diets were formulated to match absorbable AA supply to diet effective energy density (AAEE), net energy equations were found to overestimate energy required for gain and feed efficiency was improved in growing cattle. Recently developed, commercially available, in-pen weighing technology offers further opportunity to improve feed efficiency and reduce diet costs by formulating diets to supply absorbable AA equal to requirements, based on animal growth rate. Further improvement in efficiency has been demonstrated via selection for efficiency, based on residual feed intake (RFI). Our research to date has led us to conclude that nutrient requirement is influenced by RFI phenotype. More accurate estimates of biological energy requirement, real-time growth performance measurement capability, and increased biological efficiency selection can improve postweaning feed efficiency of cattle to a greater magnitude than generally thought possible, but full potential will not be realized if diet formulations do not support the potential for improvement.

Key Words: beef, efficiency, nutrition

0118 What is the future of genetic selection and cattle sorting technologies in the stocker and feedlot industries? R. L. Weaber*, *Kansas State University, Manhattan.*

The U.S. beef industry has experienced dramatic change over the past several years. The persistent drought throughout much of the United States has resulted in a reduction in cow inventory. The USDA reported that the 1 January 2014 all cattle and calves inventory was down 2% from 2013, now totaling 87.7 million head, the lowest since 1951. In the same report, USDA inventory of cows and heifers that calved totaled 38.3 million, the smallest since 1941. Contraction of cow inventory and resulting calf crop have created challenges all along the beef value chain. Large vacant capacity exists in the U.S. feedlot and packing sectors. As a result of tight inventories, whole sale beef and fed and feeder cattle prices have reached record highs. High prices are shrinking per capita beef consumption to an expected 24 kg in 2014, decreasing 4.5 kg in the last decade. An estimated 60% of domestic beef consumption is ground product. Consumers continue to be value driven, choosing more ground beef in the marketplace for price and convenience. The U.S. all steak price to ground beef price ratio has trended downward over the last decade from 2.5 in early 2004 to < 1.7 in late 2013, indicating that all steak price hasn't kept pace with the price increase in ground beef. Some suggest whole muscle beef cuts are becoming luxury items. While consumers continue to seek lower cost protein sources and lower cost beef, the industry's production model remains unchanged. Most cattle are fed and marketed to maximize the value captured from middle meats, which comprise roughly 20% of the beef carcass, targeted to grade Choice average or better. This leads to substantial inefficiencies in the feeding and packing sector through overfeeding of cattle. In some cases, the additional fat decreases the red meat yield and value of end meats, which comprises the remaining 80% of the carcass. The beef industry's current issues in product demand, high retail prices, and lack of market-targeted products call for substantial changes in the beef value chain in terms of cattle sourcing, genetics, management, pricing, and marketing. Early targeting of cattle to an appropriate end use, based on genetic potential to efficiently meet a specified market target, could substantially change the way cattle are managed in terms of backgrounding and feedlot nutrition, growth-promoting technologies, and sorting for optimal marketing to maximize individual animal profitability.

Key Words: beef cattle, genetics, selection

0119 Beef quality vs. quantity in today's market. B. J. Johnson*, *Texas Tech University, Lubbock.*

Exogenous growth-enhancing compounds, such as steroidal implants and β-adrenergic agonists (βAA), have been used to improve growth rate and efficiency in meat animals for more than a half century. In cattle, these compounds enhance efficiency of growth by preferentially stimulating skeletal muscle growth at the expense of adipose tissue accretion. These compounds have additive effects on carcass gain. Combined use of both these technologies have been shown to increase carcass gain > 35 kg during a typical feeding period. Consequently, these growth-enhancing compounds have been shown to reduce intramuscular fat (marbling) in beef cattle compared with non-treated cattle. This reduction in marbling score has been

associated with lower beef quality. These cellular events may in part be responsible for the negative effects observed with the use of these compounds in terms of marbling development in beef cattle. Markers of adipogenic differentiation were also affected by TBA/E_2. In adipose tissue, an enzyme important for energy balance, AMPKα, may also be affected by anabolic steroids and βAA. These data indicate that in adipose tissue compared with skeletal muscle, anabolic steroids and βAA may have opposite effects on cellular growth and differentiation. This inverse relationship may contribute to changes in beef quality. Balance is needed to maintain beef quality in light of demands to increase beef production, globally.

Key Words: adipose tissue, beef quality, skeletal muscle

0120 Economic considerations related to rebuilding the U.S. cow herd. G. T. Tonsor*[1] and L. L. Schulz[2], *[1]Kansas State University, Manhattan, [2]Iowa State University, Ames.*

The entire U.S. cattle industry is in the middle of several structural changes with pending (or perhaps ongoing) herd expansion at the heart of each current and possible industry adjustment. These changes coupled with issues more external to the industry are effectively increasing the overall uncertainty of profitability for not only cow-calf producers but stakeholders throughout the industry. This increased uncertainty will be welcomed by some producers, who in turn may choose to expand their herds in coming years. Conversely, other producers uncomfortable with this uncertainty or facing favorable alternatives to cow-calf production will stabilize or further reduce their herds. The net impacts of these adjustments will dictate the collective make-up of the U.S. cattle industry for years to come. The ability of cattle producers to grasp the profitability and overall risk situation of their operations and broader industry trends is critical for long-term business success. Farmers and ranchers considering expansion need to make sound decisions to make sure their operations are economically sustainable and well positioned to succeed. In addition, opportunities exist for integration of young producers and future generations into cattle production, but these individuals need knowledge and tools to help them thrive in the industry. These expansion and entry into the industry decisions are best made when working with current and accurate understanding of broader economic trends. This presentation will discuss the broad economic situation motivating growing interest in herd expansion and subsequently outline key trends that are likely to influence realized national herd expansion. Throughout the presentation, a host of decision aides and related educational resources will be highlighted, enabling attendees to act on information they receive and apply it to their own operations and situations.

Key Words: beef cattle herd expansion, cow-calf production, economics, management

BEEF SPECIES: MAKING MORE BUT USING LESS: THE FUTURE OF THE U.S. BEEF INDUSTRY WITH A REDUCED COW HERD AND THE CHALLENGE TO FEED THE UNITED STATES AND WORLD. *SESSION 2:* THE COW-CALF INDUSTRY

0121 Where can we support more cows? Overview of the beef cow herd and land use. J. A. Paterson*, *National Cattlemen's Beef Association, Centennial, CO.*

The U.S. cow herd population has declined from 45 million in 1975 to 29 million in 2014. Record-setting drought in the Southern United States caused beef cow herd liquidation, fewer calves on cereal grain pastures, and more cattle in feedlots. All cattle and calves in the United States totaled 90.8 million head (2012) and was the lowest inventory since 1952. The recent drought caused cow numbers to decline by 13% in Texas, 14% in Oklahoma, and 11% in New Mexico. The consequence of low supply has been the closure of packing plants in Texas and California. When there is a return to normal pasture conditions, there will be more of a willingness to increase heifer retention and increase the nation's cow herd inventory. How many beef cows does the beef industry need to remain sustainable? It has been predicted that the cattle industry may not grow beyond 32 million cows because of the availability of growth-promoting technologies, improved cattle genetics, nutritional and health management practices, and new generation antibiotics and anthelmintics. The reasons for future expansion include better pasture conditions in most areas of cow-calf country, higher feeder calf prices, record high beef prices, lower corn prices, and lower debt in mature ranching operations. The reasons for not increasing cow numbers include advancing age of ranchers, EPA regulations in the Eastern United States, Forest Service and BLM regulations on public lands in the West, and continued fear of drought. A significant increase in the beef cow herd is not expected until 2016 or 2017. With expansion likely underway, it will be 2017 or 2018 before a trend of larger fed cattle supplies will be measured. As a percentage of the nation's cow herd population, the Great Plains increased from 27 to 34.2% and the Corn Belt increased slightly from 13.3 to 14%, whereas the Southern Plains (-3% units), West (-1.2% units), Southern Plains (-3% units), and Southeast (−4.4% units) have all decreased. A decrease in cow numbers is predicted to be more pronounced in the states of Illinois, Indiana, Iowa, Minnesota, Missouri, Kentucky, and Tennessee, where competition with crops is greater. As a result, it is projected that an increasing share of the total beef cow herd will be located in the Great Plains, with a smaller increase in the Western Corn Belt.

Key Words: cattle, drought, retention

0122 How can we improve replacement heifers as we rebuild the cow herd? S. L. Lake*, *University of Wyoming, Laramie.*

The beef industry is currently experiencing a climate that few, if any, generations have ever encountered. Beef demand is soaring, both nationally and internationally, cattle prices continue to break all-time highs, and environmental conditions in many regions of the United States have put a premium on calves and replacement females. One of the areas of greatest potential to increase profitability and sustainability in livestock operations is to capitalize on the heifer enterprise. However, to rebuild the national cow herd in the current economic climate, producers and scientists are going to have to increase the use of technology and outside-the-box thinking to remain competitive in the global market. Applicable research is needed to answer relevant production questions that will enable the U.S. cow herd to grow and remain competitive in global markets.

Key Words: heifers

0123 Can we improve cow efficiency or manipulate feeding strategies to reduce inputs? H. C. Freetly*, *USDA-ARS, U.S. Meat Animal Research Center, Clay Center, NE.*

In most temporal environments, nutrient availability does not match the nutrient requirement of the cow; and for part of the year, nutrient availability is less than what is required to keep a cow at maintenance. Intensively managed agriculture production systems use mechanically harvested feed to fill the deficit between nutrient availability and nutrients required to maintain cow weight. These harvested feeds are often expensive. In open and pregnant cows, the energetic efficiency of allowing cows to lose and gain body energy does not differ from holding cows at constant body energy. This common energetic efficiency allows for the development of management strategies that allow cows to decrease BW during periods of low nutrient availability and subsequently gain BW when grazed forages are available. However, these strategies do not decrease the total energy required by a cow in a production cycle. Production efficiency does not differ between cows that lose BW in the second trimester and regain BW in the third trimester, and cows managed to maintain maternal BW throughout pregnancy. The nutrient management strategy chosen for the pregnant cow may influence productivity of the subsequent generation through developmental programing. The timing of nutrient restriction during pregnancy may be a trigger that alters lifetime productivity of heifers that have experienced a restricted nutrient environment in utero. Nutrient restriction in early pregnancy has been associated with reduced fertility in daughters; however, heifers born to cows that receive elevated nutrients in the third trimester breed earlier than heifers born to cows fed to maintain maternal BW. Recent emphasis on the development of tools to select for

feed efficiency in the growing animal may impact subsequent performance of the cow. Residual feed intake (RFI) is a popular measure of feed efficiency in growing and lactating cattle, and EPD are being developed to allow for its selection. One of the outcomes of selecting for lower RFI is a decrease in feed intake. The consequence of selecting for low RFI in growing cattle in the cow herd needs to be explored. The USDA is an equal opportunity provider and employer.

Key Words: beef, cow, nutrition

0124 Can we build the cow herd by increasing longevity of females? A. Roberts*[1], M. Petersen[1], and R. N. Funston[2], *[1]USDA-ARS Fort Keogh Livestock and Range Research Laboratory, Miles City, MT, [2]University of Nebraska, West Central Research and Extension Center, North Platte.*

Increasing longevity of beef cows by decreasing proportion culled due to reproductive failure reduces the number of replacements needed to sustain a constant herd size. Rate of reproductive failure varies with cow age, where failure in cows younger than 4 yr of age can be twofold greater than in cows 4 yr and older. In addition, BW of cow and calf at weaning also increase as cows advance from 2 to 5 yr of age. Cumulative effect of improving retention in young cows is greater production efficiency through decreased replacement rate and a consequent change in age structure of the herd toward a greater proportion of cows at their maximal production potential for calf BW at weaning and cow BW at time of culling. Calculations from cow age-specific culling and BW data from commercial and research herds indicate that reducing replacement rate from 20 to 15% can result in annual increases of 20% of total calf crop weight and 10% in cull cow BW. Although improving longevity can foster increases in efficiency, genetic advancement in longevity is challenging, as it is the sequential culmination of the annual repetition of numerous discrete physiological processes, each ending in a qualitative response, including puberty, ovulation, transport of male and female gametes, fertilization, implantation, pregnancy maintenance, parturition, and calf survival. Successful completion of 1 process is the prerequisite to evaluate subsequent processes. Comparisons among different biological types of cattle maintained under varying levels of nutritional inputs provide evidence for genetic variation in prioritization of nutritional partitioning among production traits (i.e., milk, growth, and reproduction) and the apparent nutritional threshold required for initiation of reproductive processes indicating genetic-by-nutrition interactions. This is in contrast to traits for which EPD exist, where genetic-by-environmental interactions are not substantial. The impact of nutrition on reproduction has been extensively studied. Results for this research led to recommendations that heifers and cows be fed to a threshold BW or BCS to ensure reproductive success. This is a process that basically overrides nutritional interactions, resulting in reproductive failure, thereby minimizing selection of animals better suited for sustained reproductive function under limited nutrition. Rearing and managing cows under nutritionally limited environments can result in adaptation leading to relatively high levels of reproduction with lower levels of input. These management strategies may result in fetal programing that improve chances for longer retention in their offspring.

Key Words: beef cow, efficiency, longevity

0125 Can we develop a cowless cow herd? Beef production without mature cows. G. E. Seidel*, *Colorado State University, Fort Collins.*

A beef production system is being studied that eliminates the mature cow herd. Nulliparous heifers are bred with sexed semen enriched to > 90% X-sperm, so most heifers replace themselves with a heifer calf. Weaning will occur at about 100 d of age, after which the dam is fattened for ~2 mo and slaughtered at 28 to 30 mo of age. Research objectives are: 1) determine profitability by evaluating capital requirements, expenses, and income; 2) evaluate ways of initiating such a program, e.g., starting with weaned heifer calves, open heifers, or bred heifers; and 3) determine if carcasses produced are of a quality that avoids market discounts. There is no cow herd to feed year round and all cattle are growing. In traditional cow-calf systems, ~50% of consumed feed energy goes to metabolic maintenance of mature cows with no accretion in meat. The other ~50% is for calf replacement-heifer maintenance, growth, and fattening, and for cow pregnancy and lactation. In the new system, all cattle are growing, so a high percentage of feed energy goes to growth. The net result is a significant decrease in feed required per pound of beef produced, manure, greenhouse gas production, and excretion of nitrogen and phosphorus. Fringe benefits include: eliminating low pregnancy rates in first-calf heifers that are lactating and still growing; minimizing health problems, such as cancer eye, foot and leg ailments, mastitis, etc., which are more prevalent in older cows; almost eliminating bull calves needing castration; and decreased generation interval. Fringe costs include: increase in dystocia if all calvings are from heifers, which is expected to be minor, because heifer calves average 2 kg lighter than bull calves at birth, and calving ease AI sires will be used. Early weaning requires increased management and heifers gain weight less efficiently than steers, which can be compensated by using anabolic implants. This system is not entirely self-sustaining because of: imperfect gender-selected semen, inevitable deaths, and non -pregnancy or late pregnancy of some heifers. Thus, to maintain herd numbers, 25 to 30% of heifers need to be replaced annually from outside of the system. Fringe benefits appear to outweigh fringe costs, but the main advantage is that more beef can be produced with given feed resources.

Key Words: efficiency, heifer beef, sexed semen

BEEF SPECIES: **COW-CALF**

0126 Changes in body composition during winter gestation of mature beef cows grazing different herbage allowances of native pastures.

A. Casal[*1], A. L. Astessiano Dickson[1], A. I. Trujillo[1], P. Soca[2], A. C. Espasandin[2], and M. Carriquiry[1], *[1]Facultad de Agronomia, Universidad de la Republica, Montevideo, Uruguay, [2]Departamento de Producción Animal y Pasturas-Facultad de Agronomía-UdelaR, Paysandú, Uruguay*.

The aim of this study was to evaluate the effect of controlling the intensity of grazing native pasture (*Campos biome*), through control of herbage allowance (HA), on body composition (water, protein, and fat) of beef cows of different genotype during the winter gestation period. Mature beef cows (n = 32) were used in a complete randomized block design with a factorial arrangement of HA (2.5 vs. 4 kg DM/d; LO vs. HI) of native pastures (52% DM, 8.4% CP, 39.7% ADF) and cow genotype (CG; Angus-Hereford vs. F1 reciprocal crosses; PU vs. CR). The experiment was conducted during 3 yr and at the end of the third year at 150, 210, and 240 ± 10 d of gestation (during winter) and 190 ± 10 d postpartum (fall). Body composition was estimated using the urea dilution technique. In addition, at 192 ± 10 d postpartum, cows were slaughtered and weight and samples of all tissues and organs were collected for chemical composition analyses. Multiple regressions, using urea space volume and other animal characteristics as predictors, were adjusted by the regression procedure (SAS Institute Inc.), using data obtained at slaughter to estimate body components (kg) during the winter gestation period. Data of body composition during gestation were assessed using a mixed model repeated measures analysis. During the winter gestation period, maternal live weight (LW) and BCS tended (P = 0.09) or were greater (P = 0.02) in HI than LO cows and in CR than PU cows. Maternal LW and BCS decreased (P < 0.05) 18 ± 5 kg and 0.5 ± 0.1 unit from 150 to 210 d of gestation. Total body water and fat and protein mass were greater ($P \leq 0.05$) in CR than PU cows. Body fat and protein mass tended ($P \leq 0.10$) to be greater in HI than LO cows. Total body water and protein mass decreased (P < 0.01) from 150 to 210 d of gestation. Body water was affected (P = 0.03) and body fat tended (P = 0.07) to be affected by the interaction between CG and days of gestation, as they were greater (P < 0.05) in CR than PU cows only at 150 d of gestation and decreased from 150 to 210 d of gestation only in the former ones. Body composition during winter gestation depended on both HA and CG. Changes in the composition of body weight lost or retained would influence energy maintenance requirements and could provide metabolic advantages under periods of negative energy balance.

Key Words: cattle, fat, protein, rangelands

0127 Prepartum supplement level and age of weaning: I. Effects on prepartum and postpartum beef cow performance and calf performance through weaning.

L. M. Shoup[*1], A. C. Kloth[2], D. Gonzalez-Peña Fundora[2], F. A. Ireland[1], S. L. Rodriguez Zas[1], T. L. Felix[2], and D. W. Shike[1], *[1]University of Illinois, Urbana, [2]University of Illinois at Urbana-Champaign, Urbana.*

Objectives were to determine the effects of prepartum supplement level and age of weaning on BW, BCS, milk production, reproduction, and calf performance up to weaning in a fall-calving system over 2 yr. Mature multiparous Angus × Simmental cows (yr 1, n = 326; yr 2, n = 383) were used in a split-plot design that included 3 supplement levels: no supplement (NS), 2.16 kg/d per animal (LS), or 8.61 kg/d per animal (HS). (The supplement = 70% dried distillers grains plus solubles and 30% soybean hulls; fed 103 ± 11 d prepartum to 3 ± 11 d postpartum.) The 2 ages of weaning were: early at 80 ± 11 d of age (EW) and normal at 188 ± 11 d of age (NW). Cow BW for cows fed HS was greater ($P \leq 0.04$) at pre-calving (55 ± 11 d prepartum), post-calving (27 ± 11 d postpartum), and post-breeding (81 d post-breeding), compared with NS and LS cows. Cows fed HS had increased ($P \leq 0.02$) pre-calving, post-calving, and post-breeding BCS, relative to cows fed NS, with no effects ($P \geq 0.60$) on calf birth weight or calving ease. Prepartum supplementation tended (P = 0.09) to improve AI conception. Early weaning resulted in increased ($P \leq 0.05$) AI conception and post-breeding BW and BCS, relative to normal weaning. A significant supplement level × weaning interaction existed (P = 0.03) for overall pregnancy. For cows fed HS, EW improved (P = 0.02) overall pregnancy; however, weaning age did not affect ($P \geq 0.10$) overall pregnancy for NS and LS cows. At time of early weaning, BW increased (P = 0.02) for steers from LS cows compared with steers from NS cows. Steer BW at time of normal weaning and ADG between early and normal weaning was greater (P < 0.01) for EW steers, compared with NW steers. A year × weaning interaction (P < 0.01) occurred for ultrasound marbling score at time of normal weaning. In yr 1, marbling decreased (P = 0.04) in EW steers compared with NW steers; however, in yr 2, marbling increased (P < 0.01) in EW steers compared with NW steers. These data suggest prepartum supplementation and early weaning improved cow BW, BCS, and reproduction. There were minimal effects of dam prepartum supplement on calf performance up to weaning. Early weaning improved calf growth but had inconsistent effects across years on ultrasound measurements.

Key Words: beef cattle, early weaning, prepartum supplementation

0128 Prepartum supplement level and age of weaning: II. Effects of developmental programming on performance and carcass composition of steer progeny. L. M. Shoup*, D. Gonzalez-Peña Fundora, F. A. Ireland, S. L. Rodriguez Zas, T. L. Felix, and D. W. Shike, *University of Illinois, Urbana.*

Objectives were to determine the effects of prepartum cow supplement level and age of weaning on growth performance, feed efficiency, glucose and insulin concentrations, and carcass characteristics of steers (yr 1, n = 134; yr 2, n = 147). Mature multiparous Angus × Simmental cows were used in a split-plot design that included 3 supplement levels: no supplement (NS), 2.16 kg/d per animal (LS), or 8.61 kg/d per animal (HS). (The supplement = 70% dried distillers grains plus solubles and 30% soybean hulls; fed 103 ± 11 d prepartum to 3 ± 11 d postpartum.) The 2 ages of weaning were: early at 80 ± 11 d of age (EW) and normal at 188 ± 11 d of age (NW). Dam prepartum supplement level did not affect ($P \geq 0.15$) growth performance, respiratory health, or carcass traits, with the exception of percentage ≥ Average Choice. A greater ($P = 0.03$) percentage of steers from cows fed HS graded ≥ Average Choice when compared with steers from cows fed NS. Early weaning increased ($P < 0.01$) initial BW and final BW, and reduced ($P < 0.01$) G:F compared with normal weaning. A year × weaning interaction ($P = 0.02$) occurred for ADG; early weaning resulted in reduced ($P < 0.01$) ADG compared with normal weaning in yr 2. Although EW steers were younger ($P < 0.01$) at harvest, they had greater ($P \leq 0.02$) HCW, yield grade, backfat, and marbling scores, compared with NW steers. A year × weaning interaction ($P \leq 0.04$) occurred for quality grade distribution; carcasses from EW steers had increased ($P < 0.01$) proportions ≥ Low Choice and ≥ Average Choice than carcasses from NW in yr 2. The EW steers had greater ($P \leq 0.04$) occurrence of single medical treatments and death due to respiratory disease than NW steers. A year × weaning interaction ($P = 0.03$) occurred for insulin concentration and insulin:glucose; EW steers had greater ($P < 0.01$) insulin concentrations and insulin:glucose than NW steers in yr 1. These data suggest overfeeding supplement to the dam did not affect feedlot performance but did improve steer quality grades. Although EW steers had increased respiratory illness, they were younger at harvest and had greater HCW and marbling scores, compared with NW steers. The absence of supplement level × weaning interactions indicates that these effects may have an additive effect on developmental programming.

Key Words: developmental programming, early weaning, maternal nutrition

0129 Efficiency and performance of primiparous Angus cows raised in a range system. J. S. Lemes*, C. C. Brauner, R. Z. Vaz, and M. A. Pimentel, *Universidade Federal de Pelotas, Brazil.*

The aim of this study was to evaluate the efficiency and performance from calving to weaning of primiparous beef cows in 3 different biotypes in a range system. Forty-two primiparous Angus cows (3 yr of age) with BCS 3 (on a 1 to 5 scale) were classified into 3 groups according to body weight at calving: heavy (431 kg on average, ranging from 405 to 485 kg); medium (388 kg on average, ranging from 373 to 403 kg); and light (348 kg on average, ranging from 293 to 369 kg). Milk production was estimated by weight-suckle-weight method. Calf production efficiency was determined by the adjustment of calf weaning weight (CWW) and pregnancy rate (PR) of cows, resulting in calf production index (CPI) = kg of weaning calves per cow (CWW × PR/100). Data were analyzed using GLM procedures in SAS software. Total weight gained from calving to weaning was affected ($P < 0.05$) by biotype. Once, light and medium cows had 51 and 25 kg gain, respectively, whereas the heavy group had a 3 kg loss during the same period. Calves from heavy and medium groups were heavier ($P < 0.05$) at weaning as compared with light cow calves, being 166.5 ± 4.0; 166.0 ± 3.7, and 151.9 ± 4.3 kg, respectively. The CPI evaluation demonstrated that light and medium cow groups were able to produce more ($P < 0.05$) calf kilograms (16.0 ± 0.4; 15.1 ± 0.4 kg, respectively) than the heavy group (14.0 ± 0.4 kg). There was no difference ($P > 0.05$) in calf production efficiency among groups, being 63.4% ± 1.6; 62.2% ± 1.4; and 59.6% ± 1.5, respectively, for light, medium, and heavy cows. However, light cows had lower ($P < 0.05$) milk production and, as a result, lighter ($P < 0.05$) calves at weaning (151.9 ± 4.3 kg) than medium and heavy groups, 166.0 ± 3.7, 166.5 ± 4.0 kg, respectively. In conclusion, cows in small and moderate biotypes are more efficient, as compared with larger frames in graze production systems.

Key Words: milk production, reproduction, weaning weight

0130 Effect of an injectable trace mineral on reproductive performance of beef cows grazing irrigated pasture. C. J. Brasche*[1], J. B. Hall[2], and M. E. Drewnoski[1], [1]*University of Idaho, Moscow,* [2]*University of Idaho, Carmen.*

Injectable trace minerals can be used to increase trace mineral status of cows and may result in improved reproductive performance. Beef cows (n = 174) were blocked by age and expected calving date, and randomly assigned to treatment in a 2 × 2 factorial of either an injectable trace mineral containing copper, manganese, selenium, and zinc (TMI), or no injection (CON), and timed AI at either 72 or 80 h post controlled-internal-drug-release device (CIDR) removal.

Thirty-8 d before the start of the calving season and again 23 d before AI, cows in the TMI group were injected with Multimin 90 (0.68 mL/68 kg of BW). Liver biopsies were taken before pre-calving injection, before pre-breeding injection, and again 15 d after pre-breeding injection to assess mineral status. All cows were estrous synchronized, using a 5-d CoSynch plus CIDR protocol, in which cows were given an injection of GnRH and inserted with a CIDR 8 d before AI. The CIDR was removed 5 d later and a shot of PG was given, followed by a second PG injection 5.6 h later. Cows were given an injection of GnRH and inseminated either 72 or 80 h after CIDR removal with gender-selected semen. Cows were exposed to fertile bulls for natural service breeding 17 d after AI and remained with the bulls for 45 d. Pregnancy was determined by rectal palpation at 105 d post AI. For the responses measured, there was no interaction ($P \geq 0.19$) between TMI and AI timing; therefore, only the effect of injection will be reported. At 15 d post pre-breeding injection, TMI had no effect on liver concentration of manganese ($P = 0.26$), zinc ($P = 0.22$), or copper ($P = 0.11$); however, TMI cows had elevated concentrations of selenium ($P = 0.01$) when compared with CON. Liver concentrations of the trace minerals measured in both treatments were considered adequate at all time points. There was no difference between CON and TMI in the number of days post calving ($P = 0.21$) or BCS ($P = 0.95$) at AI. Trace mineral injection did not affect reproductive performance of cows as both conception to AI ($P = 0.41$) and overall pregnancy rate did not differ ($P = 0.19$) due to TMI treatment. These data suggest that the use of an injectable trace mineral may not improve reproductive performance of cows that have adequate trace mineral status before injection.

Key Words: cows, injectable trace mineral, reproduction

0131 Effect of injectable trace mineral supplementation in yearling bulls on serum and semen trace mineral levels and reproductive parameters.

A. A. Kirchhoff* and K. E. Fike, *Kansas State University, Manhattan.*

We hypothesized that administration of an injectable trace mineral would cause a short-term increase in circulating trace mineral concentrations but not alter semen quality nor ability to pass a breeding soundness exam (BSE). Sixteen Hereford, 52 Angus, and 22 Simmental bulls were blocked by breed and stratified by age (277 ± 20 d) and weight (377 ± 42 kg), and administered subcutaneously, either a commercially available trace mineral supplement (TM; $n = 45$; 15 mg Cu/mL, 60 mg Zn/mL, 10 mg Mn/mL, and 5 mg Se/mL; Multimin 90, Multimin USA, Inc., Ft. Collins, CO) or sterilized saline (Control; $n = 45$) at 1mL/45 kg BW. Bulls were maintained in a drylot and fed a grower ration that included trace minerals at NRC-recommended levels. Blood was collected via jugular venipuncture immediately before treatment (h 0) and at 8 and 24 h. The BW and scrotal circumferences were measured on the day of treatment (d 0) and d 20, 42, 59, and 91. Semen was collected via electroejaculation on d 42 and 91, and a BSE conducted on d 91. Serum samples from h 0, 8, and 24, and semen samples d 42 and 91, on a subset of 26 bulls per group, were analyzed using inductively coupled mass spectroscopy for concentration of Cu, Zn, Mn, and Se. Data were analyzed using PROC MIXED, PROC GLIMMIX, and PROC FREQ in SAS, with fixed effects of treatment, breed, and time of sampling, and interactions with bull as experimental unit. The TM and Control bulls had similar scrotal circumferences and BW throughout the trial ($P \geq 0.10$). Time and treatment interacted ($P < 0.01$) to affect serum trace mineral concentrations with TM bulls having greater ($P < 0.01$) trace mineral concentrations at 8 h post-treatment than Control bulls. Semen trace mineral concentrations on d 42 and 91 were similar ($P \geq 0.05$) between TM and Control bulls. Sperm motility, percent normal morphology, concentration, and percentage proximal droplets improved ($P < 0.05$) from d 42 to 91, but did not differ between TM and Control ($P \geq 0.05$). A similar ($P \geq 0.05$) percentage of TM (51%) and Control (49%) bulls passed their BSE 91 d post-treatment. A supplemental trace mineral injection is successful at raising circulating trace mineral levels but does not alter semen trace mineral levels nor improve semen quality.

Key Words: bull, semen, trace mineral

0132 Effect of an injection of a fat-soluble vitamin mix (E, A, and D) to newborn beef calves on markers of cell oxidative damage and calf performance.

W. A. Sutton* and M. E. Drewnoski, *University of Idaho, Moscow, ID.*

Early calf death is 1 of the major contributors to economic loss. Muscle lesions not related to white muscle disease may contribute to reduced vigor of calves suffering from weak calf syndrome. The objective of the current study was to determine the effects of a vitamin E, A and D injection on calves exposed to cold temperature. Thirty-two newborn calves from spring calving multiparous Charolais cows (age 3 to 10 yr) were blocked within gender by date of birth and assigned to treatment in a 2 × 2 factorial design. At birth, calves were administered an injection of 4 mL of saline (SAL) or 4 mL VITAL E-A+D (EAD; 300 IU/mL vitamin E as D-α-tocopherol, 100,000 IU/mL vitamin A as retinyl-palmitate, and 10,000 IU/mL vitamin D as cholecalciferol). At 5 h of age, calves were placed in a chamber at 0 or 25°C for 90 min and rectal temperature was recorded every 10 min. At 24 h of age, an injection of Bo-Se (2 mg of selenium as sodium selenite and 136 IU of Vitamin E as D-α-tocopheryl acetate) was administered to all calves. Plasma samples were collected at birth, 5, 6.5, 24, and 48 h, and 45 d. Plasma creatine kinase and 8-isoprostane concentrations at 24 h were not affected ($P > 0.48$) by injection or environmental treatment, showing no effect of treatment on markers of cell damage. Regardless of temperature treatment,

calves receiving the EAD had greater rectal temperatures (P = 0.04) than those calves receiving SAL (38.85 vs. 38.75 ± 0.03°C, respectively) at birth. Calves subjected to cold temperature had greater (P = 0.05) rectal temperatures than calves subjected to thermo-neutral conditions. Calves receiving EAD had lower (P = 0.02) ADG during the first 5.5 wk of life than those receiving SAL (0.93 vs. 1.14 ± 0.06 kg/d). However, 205-d adjusted weaning weights were not different (P = 0.58) between injection treatments (254 vs. 260 ± 8.2 kg for EAD and SAL, respectively). Calves receiving EAD had greater rectal temperatures and lower ADG than calves receiving SAL. There was no detectable difference in markers of cell damage due to treatments. Calves receiving EAD may have had increased metabolic rates, which could have contributed to the increase in rectal temperature and decreased ADG. Injection of EAD at birth may be beneficial to calf health in terms of body heat production.

Key Words: calf, injectable vitamin

0133 Relationships between maintenance energy EPD and performance measures of progeny from Red Angus sires divergent for maintenance energy EPD.

C. M. Welch*[1], S. E. Speidel[2], D. H. Crews[3], J. K. Ahola[3], J. B. Hall[4], W. Price[1], and R. A. Hill[1], *[1]University of Idaho, Moscow, [2]Department of Animal Sciences, Colorado State University, Fort Collins, [3]Colorado State University, Fort Collins [4]University of Idaho, Carmen.*

The Red Angus Association of America (RAAA) developed the maintenance energy (ME_M) EPD as an estimator of maintenance requirements, in an attempt to lower cow maintenance costs within the breeding herd. However, no studies have evaluated the selection and incorporation of ME_M EPD into breeding programs, and the resulting effects on progeny postweaning performance. Conducted as part of a larger study, postweaning performance measures were recorded in 3 birth year contemporary groups from the progeny (n = 222) of sires (n = 12) divergent for ME_M EPD. The objective was to evaluate relationships between various phenotypic performance measurements and EPD of progeny and sires. Sires were partitioned into high and low ME_M EPD groups, based on the RAAA breed average for ME_M EPD. Sire ME_M EPD was found to be positively correlated (P < 0.05) with progeny phenotypic performance measurements, including ADG (r = 0.32), DMI (r = 0.21), and metabolic BW (MBW; r = 0.22). Sire ME_M EPD was negatively correlated with progeny feed-to-gain ratio (r = -0.21). In addition, sire ME_M EPD was also positively correlated (P < 0.05) with progeny ADG EPD (r = 0.43) and MBW EPD (r = 0.24). No association (P > 0.05) was observed between sire ME_M EPD and progeny DMI EPD. Therefore, our data analyses indicate that sire ME_M EPD is associated with growth and BW in Red Angus-sired cattle.

Key Words: maintenance energy, performance, Red Angus

0134 Effects of breeding system of origin (natural service or AI) on growth, attainment of puberty, and pregnancy rates in crossbred beef heifers.

M. R. Schook*[1], P. L. Steichen[1], V. R. G. Mercadante[2], G. C. Lamb[2], B. W. Neville[3], and C. R. Dahlen[1], *[1]North Dakota State University, Fargo, [2]University of Florida, Marianna, [3]North Dakota State University, Streeter.*

The objective of this study was to compare growth, attainment of puberty, and pregnancy rates in beef heifers, originating from 2 different breeding systems. One hundred ninety crossbred Angus heifers were born to dams that were exposed to 1 of 2 treatments: 1) natural service (NS, cows were only exposed to herd bulls for the duration of the breeding season), or 2) fixed-time AI (TAI, cows exposed to ovulation synchronization and AI followed by natural service bulls). Body weights were taken on d 0 and 189, with a mean age of 209 ± 1.2 d at the initiation of the trial (d 0). Blood samples were collected at d 0, 10, 112, 122, 219, and 229, and progesterone concentrations were used to determine the proportion of females that had attained puberty during the development period. On d 229, synchronization of ovulation was initiated: 7-d CO-Synch + controlled-internal-drug-release device (CIDR) and all heifers were inseminated with a single TAI at 54 h after CIDR removal. Clean-up bulls were placed in breeding pastures 10 d after AI and remained with heifers until 56 d after AI. Pregnancy rates were determined via transrectal ultrasonography on d 27 and 91 after AI. Body weight at initiation of the experiment was greater (P = 0.01) for heifers in the TAI treatment (239.9 ± 2.8 kg) compared with heifers in the NS treatment (229.6 ± 2.8 kg). However, no differences ($P \geq 0.14$) between treatments were observed in weights of heifers taken at the time of pasture turnout (d 189; 345.1 ± 3.4 and 338.0 ± 3.4 kg for TAI and NS, respectively) or ADG (0.56 ± 0.01 and 0.58 ± 0.01 kg/d for AI and NS, respectively). At the initiation of the experiment, a greater proportion of the NS heifers (11.6%) tended (P = 0.06) to be cyclic compared with TAI heifers (4.2%). However, no differences ($P \geq 0.40$) were observed between treatments in the proportion of heifers cyclic at the interim evaluation (d 112 and 122, 27.5% cyclic) or at the initiation of the breeding season (d 219 and 229, 85.5% cyclic). No differences ($P \geq 0.81$) were present between treatments in either pregnancy rates to AI (32.9%) or season-ending pregnancy rates (91.1%). Breeding system of origin did not influence growth rate during the development phase, attainment of puberty, or pregnancy rates in crossbred beef heifers.

Key Words: artificial insemination, heifer development, natural service

0135 Simulation and economic analysis of beef cattle natural service and induced twinning via embryo transfer, following AI breeding and 2 calf management systems. D. G. Aherin*, P. J. Ebert, J. R. Shearer, R. L. Weaber, J. M. Bormann, D. W. Moser, and M. D. MacNeil, *Kansas State University, Manhattan.*

The objective of this project was to compare operation profitability, through simulation, of alternate breeding and calf management strategies. Mating systems considered included: 1) 60-d natural bull service and 2) fixed-timed AI program with implanted embryos 7 d following AI to create twins. A 42-d natural service followed embryo transfer (ET). The effect of a preweaning calf nutrient supplementation system that excludes cows (creep feeding) was also of interest. The combination of mating system and calf nutritional management system yielded different management systems for comparison, including: 1) induced twin calving system with calf creep feeding, 2) induced twin calving system without calf creep feeding, 3) natural service (single calving) system with calf creep feeding, and 4) natural service (single calving) system without calf creep feeding. Microsoft Excel was used to develop a spreadsheet that processed input cost and revenue projections, and predicted profitability of each management system. Equations to predict breeding and calf performance allowed entry of different parameters for fertility rates, input costs, and price expectations, which vary across different cattle operations, management, and economic environments. Assumptions incorporated into the simulation included: 1) all natural service cows have single births; 2) no change in stocking rate/pasture usage; 3) simulation in second year of twin production; 4) no heifers involved; 5) if a calf dies, it died the day it was born; and 6) no difference in genetic potential between AI/ET calves and natural service calves. Sensitivity analysis of the simulation model suggests that variation in labor, creep feeding, and reproductive costs between twin and single calving had the greatest impact on profitability. Creep feeding had a substantially greater positive effect on the performance of twin calves compared with single-born calves; thus creating a much greater impact on overall profitability of that management system. Through simulation using common production input costs, creep feed at $220/ton, it was found that management system 1 (induced twinning with creep feed) was the most profitable, if reproductive costs could be held to < $170 per head.

Key Words: beef cattle, management systems, twinning

0136 The indirect effects of horn flies and sire breed on calf preweaning and postweaning performance traits. A. R. Mays*[1], M. A. Brown[2], and C. F. Rosenkrans[3], *[1]Department of Animal Science, University of Arkansas Division of Agriculture, Fayetteville, [2]ARS-USDA, Grazinglands Research Laboratory, El Reno, OK, [3]University of Arkansas, Fayetteville.*

Horn flies negatively impact weaning weight and ADG of beef cattle, but the indirect effect of horn flies on preweaning and postweaning performance traits is less understood. Therefore, the objective of this study was to assess the indirect effects of horn flies on calf performance traits. Angus-sired calves (n = 51) from crossbred cows (n = 53) from Brangus dams sired by either Bonsmara (BONS; n = 7), Brangus (BRAN; n = 13), Charolais (CHAR; n = 8), Gelbvieh (GELV; n = 5), Hereford (HERF; n = 12), or Romosinuano (ROMO; n = 8) bulls were evaluated. Total horn fly counts were recorded on individual cows while in pasture from 0700 to 0900 h, beginning in May and ending in October. Horn fly counts were transformed to natural log horn fly counts before data analysis. Data for preweaning ADG, postweaning ADG, 365-d adjusted yearling weight (YWT), and birth to yearling ADG were analyzed by mixed model least squares. The linear model included sire breed, calf gender, and sire breed × calf gender. Effects of horn fly count on these traits were estimated by including a linear covariate of log horn fly count and log horn fly count × sire breed. Preweaning ADG was affected ($P < 0.002$) by sire breed of dam. Romosinuano, BONS, and CHAR calves had greater preweaning ADG (1.00 ± 0.05, 0.99 ± 0.04, 0.99 ± 0.04 kg/d; respectively), compared with BRAN and HERF calves (0.88 ± 0.03 and 0.81 ± 0.03 kg/d), with GELV calves intermediate to ROMO, BONS, CHAR, and BRAN (0.98 ± 0.05 kg/day). Preweaning ADG was dependent on an interaction of cow sire breed and log horn fly count ($P < 0.10$), with results indicating preweaning ADG being reduced 0.19 kg/d per unit increase in log horn fly count in BONS calves ($P < 0.05$). A 1 unit increase in log horn fly count resulted in 0.07 kg/d ($P < 0.10$) increase in postweaning ADG, 19.52 kg increase ($P < 0.10$) in 365-d adjusted YWT, and 0.05 kg/d ($P < 0.02$) increase in birth to yearling ADG. Horn flies indirectly had a negative impact on preweaning performance of calves from certain cow sire breeds. However, a positive indirect effect on postweaning calf performance was documented in this study. Postweaning management and compensatory gains may explain the results reported, but continued research of indirect effects of horn flies on calf performance traits is needed.

Key Words: average daily gain, calf performance, horn fly

BEEF SPECIES: STOCKER AND FEEDLOT

0137 Effect of crude protein levels and metaphylaxis on growth and performance of newly received stocker calves. T. J. Braud*[1], B. B. Karisch[1], D. R. Smith[1], C. L. Huston[1], R. Vann[2], and S. G. Genova[1], *[1]Mississippi State University, Mississippi State, [2]MAFES-Brown Loam, Mississippi State University, Raymond.*

Newly received stocker calves may have low feed intake and are at risk for bovine respiratory disease (BRD) and other causes of morbidity and mortality. The objectives of this study were to evaluate the effects of: 1) metaphylactic antibiotic administration (none or Excede on arrival); and 2) receiving diet CP levels (12% or 18%) on respiratory disease incidence, mortality, and growth performance of beef calves received into a stocker calf system. Steer calves (n = 244) were stratified by weight and randomly assigned to 20 pens. Treatments were randomly assigned to pen in a 2 × 2 factorial study design. Cattle were examined daily for signs of BRD and fed once daily (NEg = 0.94 MCal/kg). Cattle receiving metaphylactic treatment were not treated for BRD during the first 7 d; otherwise, BRD was diagnosed at the first clinical signs and body temperature > 40°C. Calves were weighed at arrival and every 14 d through d 55 of the 60-d trial. Days at risk for BRD was the number of days from arrival until a calf: 1) first diagnosed with BRD, 2) died, or 3) finished the trial. Overall, 176 calves were treated for BRD over 6410 d at risk (BRD incidence density = 27.4/10^{3}calf-days). The effects of metaphylaxis and diet on BRD incidence density were tested by Poisson regression, accounting for clustering by pen. Cattle receiving metaphylaxis were 60% less likely to be diagnosed with BRD (RR = 0.4, $P < 0.0001$) and every additional 45 kg at arrival reduced incidence of BRD 45% (RR = 0.54, $P = 0.004$). Neither diet nor the interaction between diet and metaphylaxis were significantly associated with BRD incidence. The effects of metaphylaxis, diet, and incoming BW on mortality from all causes were tested in a log-binomial model, accounting for clustering by pen. Mortality totaled 32 calves (13%). Neither diet, metaphylaxis, nor incoming BW were significantly associated with risk for mortality. The effects of metaphylaxis and diet on ADG were tested in a generalized estimating equations model, accounting for clustering by pen. Overall, for the 212 cattle finishing the trial, ADG was 0.72 kg/d. Accounting for metaphylaxis, cattle receiving 18% protein gained an additional 0.19 kg/d ($P = 0.008$). Metaphylaxis did not affect ADG ($P = 0.10$). Metaphylactic treatment reduced the incidence of BRD and increasing CP in the receiving ration to 18% resulted in higher ADG.

Key Words: beef cattle, BRD, metaphylaxis

0138 Effect of growth rate and placement weight of stocker-feeder cattle on subsequent finishing performance and carcass characteristics: A meta-analysis. P. A. Lancaster*, C. R. Krehbiel, and G. W. Horn, *Oklahoma State University, Stillwater.*

Many studies have been conducted evaluating the effect of forage species, stocking rate, supplementation strategies, and length of grazing on subsequent finishing performance and carcass characteristics; however, it is still difficult to ascertain the impact of stocker programs on subsequent finishing performance. The objective of this study was to use meta-analysis methods to determine the effect of 2 important factors of stocker programs, ADG, and placement BW on subsequent finishing performance and carcass characteristics. Following a literature search, a data set was compiled of 24 studies comprising 29 research trials, where stocker treatments differed significantly in rate of gain by ≥ 0.10 kg/d during the stocker phase. Regression analyses were conducted using a mixed model (PROC MIXED of SAS) that included ADG or placement BW as fixed effects, and intercept by ADG or placement BW cross product terms, when slopes differed among trials, as random effects and trial as the subject. The squared standard error for the dependent variable was used as a weighting factor to compute regression coefficients. Stocker ADG and placement BW had a negative relationship ($P < 0.10$) with finishing G:F; but when both ADG and placement BW were included in the model, neither were significant ($P > 0.10$). Stocker ADG and placement BW had positive relationships ($P < 0.05$) with LM area but not 12th-rib fat thickness or yield grade. When both ADG and placement BW were included in the model for rib fat-adjusted marbling score, neither were significant ($P > 0.10$). However, addition of HCW to the model indicated that HCW had a positive relationship ($P < 0.05$) with rib fat-adjusted marbling score, even though ADG and placement BW were included. Stocker ADG had a negative relationship ($P < 0.05$) with rib fat-adjusted HCW, whereas placement BW had a positive relationship ($P < 0.05$). These data suggest that slower rates of gain during the stocker phase, but with longer grazing periods to increase placement BW, can increase rib fat-adjusted HCW and marbling score.

Key Words: carcass characteristics, finishing performance, stocker-feeder cattle

0139 Performance impacts of feeding bermudagrass (*Cynodon dactylon*) or ryegrass (*Lolium multiflorum*), plus rye (*Secale cereale*) baleage to weaned crossbred beef calves. R. M. Martin[*1,2], R. Walker[3], B. Buttrey[3], and C. C. Williams[4], [1]*Louisiana State University, Baton Rouge,* [2]*School of Animal Sciences, LSU AgCenter, Baton Rouge,* [3]*LSU AgCenter, Hill Farm Research Station, Homer,* [4]*LSU AgCenter, Baton Rouge.*

Two hundred forty Angus and Angus × Charolais cross calves (BW = 217 ± 20.6 kg) were used to evaluate performance and ruminal pH from feeding bermudagrass (*Cynodon dactylon*) or ryegrass (*Lolium multiflorum*), and rye (*Secale cereale*) baleage in hay rings. Calves were stratified by BW, age, gender, and breed, and assigned to 1 of 12 paddocks (0.40 ha each) with 4 treatment diets and fed for a 7-d adaption and 60-d backgrounding period. Diets included: early boot stage bermudagrass harvested for hay, CP = 8.2%, TDN = 59.9%, and DM = 88.8%, (BERH); early boot stage ryegrass and rye harvested for baleage, CP = 12.8%, TDN = 64.5%, and DM = 37.2%, (ERRG); bloom stage ryegrass and rye harvested for baleage, CP = 9.2%, TDN = 62.7%, and DM = 55.7%, (LRRG); and early boot stage bermudagrass harvested for baleage, CP = 9.2%, TDN = 57.4%, and DM = 49.1%, (BERB). Calves on BERH, LRRG, and BERB had free-choice access to a 34% CP (as-fed basis) liquid protein supplement. Two-day BW were collected on d -1, 0, 29, 30, 59, and 60 for comparison of BW, BW gain, and ADG. Ruminal pH was measured from randomly selected calves (n = 5/paddock) on d 0, 30, and 60. There was a treatment by day interaction ($P < 0.01$) for BW and ruminal pH. Initial BW was similar among treatments ($P > 0.05$). Calf BW was heavier ($P < 0.05$) for LRRG compared with BERB and BERH, and heavier ($P = 0.01$) for ERRG compared with BERB on d 60, respectively. Body weight gain and ADG were greater ($P < 0.01$) for calves fed LRRG (34.6 ± 1.2 kg and 0.58 ± 0.02 kg), compared with calves fed ERRG (27.9 ± 1.2 kg and 0.46 ± 0.02 kg), BERH (22.2 ± 1.2 kg and 0.37 ± 0.02 kg), and BERB (19.2 ± 1.2 kg and 0.32 ± 0.02 kg). The BW gain and ADG were greater ($P < 0.01$) for ERRG compared with BERB and BERH, but similar among BERB and BERH, respectively. There was a treatment effect for ruminal pH where ERRG calves had higher ($P < 0.01$) pH compared with LRRG, BERH, and BERB calves. Performance of backgrounded calves fed ryegrass and rye baleage with or without supplementation, based on harvest stage, was improved over feeding bermudagrass hay with supplementation.

Key Words: backgrounding, baleage, beef cattle

0140 Early metabolic imprinting for improvements in finishing feed efficiency and beef carcass characteristics. J. K. Smith[*], M. D. Hanigan, S. P. Greiner, and M. A. McCann, [1]*Virginia Polytechnic Institute and State University, Blacksburg.*

Recent research has indicated the ability of early nutritional intervention to metabolically imprint beef steers for enhanced carcass marbling. As such, metabolic imprinting (IMP) has been suggested as an alternative management strategy to enhance beef quality. The objectives of this experiment were to evaluate the impact of early IMP on finishing average daily residual feed intake (RFI), residual ADG (RADG), and carcass characteristics of backgrounded steers. Angus- and Simmental-sired steer progeny from 4 calving seasons were stratified by sire and age within contemporary group and randomly assigned to metabolically imprinted (MI; weaned at 105 ± 18 d of age; n = 63) or conventionally weaned (CW; weaned at 210 ± 18 d of age; n = 42) treatment groups. Following weaning, MI steers were adapted to and received a concentrate-based ration in a feedlot setting for 105 ± 45 d immediately before commingling with previously unsupplemented CW steers at the time of conventional weaning. Commingled steers were then backgrounded for 150 ± 60 d before being finished on a concentrate-based ration for 110 ± 34 d. Finishing ADFI and metabolic body weight collected at 28-d intervals were used to calculate RFI and RADG. Steers were harvested in groups on reaching an ultrasound-predicted common 12th rib subcutaneous fat thickness (SFT) of ~1 cm. Hot carcass weight was measured immediately before chilling. Chilled (24 h) carcasses were evaluated by a trained panel of analysts to determine ribeye area, SFT, KPH, and marbling score, as well as to calculate yield grade. All statistical analyses were conducted using the Fit Model procedure of JMP Pro. Analysis of a compiled data set for main effects of treatment revealed that IMP resulted in an improvement in RFI ($P < 0.05$; -0.13 vs. 0.19 kg of TDN for MI and CW steers, respectively) without affecting RADG ($P = 0.50$; -0.01 vs. 0.01 kg for MI and CW steers, respectively). Although ribeye area, SFT, KPH, marbling score, and yield grade did not differ ($P > 0.05$) for carcasses of MI steers when compared with those of CW steers, IMP increased HCW ($P < 0.05$; 341 vs. 332 kg). Collectively, interpretation of these results suggests the ability of IMP to increase HCW and decrease the amount of TDN required by finishing steers without negatively impacting ADG.

Key Words: beef, efficiency, imprinting

0141 Linear and nonlinear estimates of the efficiency of metabolizable energy use for maintenance and gain in beef cattle. C. A. Old[*1] and H. A. Rossow[2], *[1]A3 Cattle Company, Le Grand, CA, [2]Veterinary Medicine Teaching and Research Center, University of California, Tulare.*

Efficiencies of ME utilization for maintenance (k_m) and gain (k_g) have historically been determined using ordinary least squares (OLS); these differ from efficiencies determined from known biochemical pathways. We evaluated the relationship between retained energy (RE) and ME intake, using OLS and nonlinear (NL) regressions, using the data set from which the California Net Energy System (CNES) was developed. Parameter estimates from OLS regression were similar to classical estimates. In the nonlinear estimate, ME required for maintenance (ME_m) was a first order function of ME intake; efficiency of ME used for maintenance was calculated as the first derivative of that function. Efficiency of ME use for gain was linear and calculated as (ME intake– ME_m) × k_g. Parameter stability was evaluated using Markov Chain Monte Carlo (MCMC) simulation for both linear and nonlinear estimates. Linear and nonlinear estimates of ME_m, k_m and k_g were different ($P < 0.05$); the nonlinear equation fit the data better ($R^2 = 0.850$) than the linear equation ($R^2 = 0.777$). Linear estimates of ME_m, k_m and k_g were $0.133BW^{0.75}$ (a static estimate), 0.588, and 0.432, respectively. A lack of fit F test indicated that the OLS model was correctly specified. However, parameter estimates for OLS solutions, determined by MCMC simulation, were highly unstable, an indication that the model is incorrectly specified. Nonlinear estimates of ME_m were dynamic and, on average, greater than OLS estimates. Efficiency of ME use for maintenance was 0.382, a value similar to the efficiency of ATP synthesis. Efficiency of ME use for gain was 0.614; theoretical estimates of gain for growing beef cattle are from 0.70 to 0.75. A lack of fit F test indicated that the NL model was correctly specified. Nonlinear parameter estimates were stable, indicating that the model is correctly specified. While it was possible to describe the NL relationship used in this study in the 1960s, the solution of that equation was extremely difficult to perform due to the lack of computing power at that time. This analysis indicates that, while OLS models are adequate to the task for which they were developed, prediction of animal output from feed input, and vice versa, efficiencies calculated for these models are not in concert with animal biology. Efficiencies determined for NL models are similar to those calculated for biochemical pathways and may improve prediction of animal performance.

Key Words: efficiency, metabolizable energy, nonlinear

0142 Relationships among feeding behaviors and performance traits of growing and finishing phase Red Angus cattle. M. McGee[*1], C. M. Welch[1], J. A. Ramirez[2], G. E. Carstens[2], W. Price[1], J. B. Hall[3], and R. A. Hill[1], *[1]University of Idaho, Moscow, [2]Texas A&M University, College Station, [3]University of Idaho, Carmen.*

The progeny ($n = 37$) of Red Angus bulls were performance evaluated during both growing and finishing phase residual feed intake (RFI) tests. Data for RFI evaluation and 7 behavior traits were collected, using a feed intake monitoring system (GrowSafe Systems) over standard 70-d RFI test periods for both phases (BW growing: initial 331 ± 28 kg, final 451 ± 37 kg; finish: initial 499 ± 39 kg; final 587 ± 44 kg). Seven feeding behavior traits: bunk visit frequency (BVFREQ), bunk visit duration (BVDUR), feed bout frequency (FBFREQ), feed bout duration (FBDUR), meal frequency (MFREQ), meal duration (MDUR), and average meal intake (AMINT), and their relationships with RFI, DMI, and ADG were evaluated. Dry matter intake was correlated with BVDUR and FBDUR ($r = 0.44$; $P = 0.01$ for both behaviors) during the growing phase. Residual feed intake and BVDUR or FBDUR showed little to moderate correlations in growing phase ($r = 0.30$, $P = 0.07$; and $r = 0.27$, $P = 0.10$, respectively). There were no significant correlations between ADG and the 7 behavior traits during the growing phase RFI test. However, during the finishing phase RFI test, ADG was correlated with BVFREQ and FBFREQ ($r = 0.43$, $P = 0.01$ for both behaviors). Neither DMI nor RFI were correlated with any of the 7 feeding behavior traits during the finishing phase RFI test. Combining correlated traits into the RFI base model to predict DMI reduced the mean standard error by 13% for growing phase and 17% for finishing phase RFI tests. As these animals were offered different diets during growing and finishing phases (roughage-based vs. concentrate, respectively), the relative contribution of feeding behaviors in predicting DMI may be partially diet-type dependent. Inclusion of correlated feeding behaviors improved feed intake prediction by 13 to 17%, providing evidence that the study of behavior traits has potential to improve our understanding of the biological drivers of feed intake.

Key Words: feeding behavior, Red Angus, RFI

0143 Phenotypic relationships between residual measurements of finishing feed efficiency and visceral organ mass of backgrounded beef steers. J. K. Smith[*1], A. R. Murray[1], D. D. Harmon[2], M. D. Hanigan[2], S. P. Greiner[1], and M. A. McCann[2], *[1]Virginia Tech, Blacksburg, [2]Virginia Polytechnic Institute and State University, Blacksburg.*

Residual measurements of feed efficiency for beef cattle have recently gained popularity among producers, breed associations, and researchers, alike. Efforts devoted toward identify-

ing the underlying physiological mechanisms have been met with limited success. Visceral organs play major roles in nutrient digestion, absorption, and metabolism, and are considered to be substantial contributors to animal energy requirements for maintenance. As such, an experiment was conducted to determine phenotypic relationships between individual visceral organ mass (VOM) and residual measurements of finishing feed efficiency of backgrounded beef steers. Conventionally and early-weaned steer progeny (n = 105) from 4 calving seasons within a single herd were finished on a concentrate-based ration for 110 ± 34 d within contemporary group, immediately following a 150- ± 60-d backgrounding period. Finishing ADFI and BW were collected at 28-d intervals throughout the duration of the finishing period and used to calculate average daily finishing residual feed intake (RFI) and residual ADG (RADG), using a relatively large sample population. A subsample of steers (n = 28) from the sample population used to determine RFI and RADG were harvested on reaching an ultrasound-predicted 12th rib subcutaneous fat thickness of 1 cm and used to measure emptied and cleaned individual VOM. Visceral organs measured included heart, liver, gallbladder, lungs, kidneys, spleen, rumen, reticulum, omasum, abomasum, small intestine, pancreas, cecum, and colon and rectum. All statistical analyses were conducted using JMP Pro. Multivariate analysis of VOM and RFI, as well as VOM and RADG using the multivariate and correlations procedure, revealed inverse relationships ($P < 0.05$) between RFI and mass of lungs, spleen, and rumen (r = -0.57, -0.44, and -0.46, respectively), as well as a correlation ($P < 0.05$) between RADG and lung mass (r = 0.42). No relationships existed ($P > 0.05$) between RFI and mass of the heart, liver, gallbladder, kidneys, reticulum, omasum, abomasum, small intestine, pancreas cecum, and colon and rectum, or between RADG and mass of the heart, liver, gallbladder, kidneys, spleen, rumen, reticulum, omasum, abomasum, small intestine, pancreas, cecum, and colon and rectum. Collective interpretation of these results suggests a direct phenotypic relationship between mass of the lungs and residual measurements of finishing feed efficiency for backgrounded steers. Further research is necessary to evaluate the metabolic implications of the lungs and spleen to nutrient metabolism, cattle growth, and feed efficiency.

0144 Comparison of feed technologies for backgrounding of weaned beef calves. M. J. Hersom*, T. A. Thrift, and J. V. Yelich, *University of Florida, Gainesville.*

The use of feed technologies in supplements is a means to positively affect performance and health status of newly-weaned calves during backgrounding. Our objective was to evaluate the response of weaned calves to different feed technologies in a supplement (CP = 14.6%, TDN = 67%) to improve calf performance and mitigate the stress response observed during weaning and subsequent backgrounding period. At weaning 160 calves (227 + 2.5 kg) were stratified by BW, sex, and breed and were randomly allotted to 1 of 4 treatments (n = 40 calves/treatment): 1) supplemented without feed technologies or control (CON); 2) supplement with added chlortetracycline, 350 mg/d (CTC); 3) supplement with added Rumensin, 175 mg/d (RUM); 4) supplement with added Actigen, 5 g/d (ACT). Calves were held in 1 of 4 drylot treatment pens (n = 40 calves/pen) for 7 d after weaning and offered ad libitum access to hay and 2.27 kg/d of supplement before placement in 1 of 32 0.8-ha pastures (5 calves/pasture) for a total of 8 pastures/treatment and supplemented at 1.0% BW. Calf BW were collected on d 0, 1, 3, 7, 14, 50, 52, 55, 59, and 65. After 44 d on pasture, calves were placed on 2 trucks and transported for 24 h. Upon return, calves were placed in 4 pastures with hay and fed their respective supplements for 14 d. Data were analyzed by the MIXED procedure of SAS. The model included the main effect of treatment, pasture was the experimental unit. During the 7 d after weaning, BW change did not differ (P = 0.65, -0.53 kg/d) among treatments. Over the 50-d post-weaning period there was no difference (P = 0.20, 0.52 kg/d) in BW gain response among treatments. After transportation, 7- and 14-d BW change were least (P < 0.005) for ACT and CTC (0.04 and -0.13 kg/d) compared to CON and RUM (-0.64 and -0.48 kg/d). Feed cost of gain and profitability ($P \geq$ 0.15, mean = \$2.49/kg and \$73.51) were not different among treatments. Use of feed technologies did not improve calf performance over CON during a backgrounding period and ACT was as effective as CTC or RUM during a post-transportation period.

Key Words: beef, backgrounding, supplement

0145 Effects of dose and duration of ractopamine hydrochloride supplementation on growth performance and carcass characteristics of feedlot heifers. B. M. Edenburn*[1], N. A. Pyatt[2], and T. L. Felix[1], [1]*University of Illinois at Urbana-Champaign, Urbana,* [2]*Elanco Animal Health, Greenfield, IN.*

Previous work has shown that ractopamine hydrochloride improves live BW gains, G:F, and HCW; however, data are lacking regarding duration of feeding 300 mg to heifers on growth performance and carcass characteristics. Objectives of this study were to determine the effects of dose, 0 or 300 mg/hd d^{-1}, and duration, 28 or 41 d, of ractopamine hydrochloride (RAC, Optaflexx, Elanco Animal Health, Greenfield, IN) supplementation on growth performance and carcass characteristics of feedlot heifers. Charolais cross heifers (n = 128) were blocked by BW into 2 blocks and allotted to 20 pens. Pens were randomly assigned 1 of 4 treatments in a 2 × 2 factorial arrangement: (1) 0 mg RAC/hd d^{-1} for 28, (2) 0 mg RAC/hd d^{-1} for 41 d, (3) 300 mg RAC/hd d^{-1} for 28, or (4) 300 mg RAC/hd d^{-1} for 41 d. Heifers were fed a basal diet of 50% dry rolled corn, 20% DDGS, 20% corn silage, and 10% supplement. Ractopamine hydrochloride was top dressed immediately following feed delivery. Cracked corn was removed from the diet and 300 mg RAC per 0.454 kg of ground corn carrier was top dressed. Data were analyzed using the mixed procedures in SAS. There were no day × RAC interactions ($P \geq$ 0.31) for heifer growth performance. There was no effect ($P \geq$ 0.22) of RAC on DMI, ADG, or G:F; however, feeding 300 mg RAC to increased (P = 0.03) final BW by 8.4 kg, regardless of duration fed. There were no day × RAC interactions ($P \geq$ 0.27) for heifer carcass characteristics. Furthermore, there were no effects ($P \geq$ 0.11) of duration of RAC feeding on heifer carcass characteristics. However, heifers fed RAC had an average increase (P < 0.01) of 9 kg of HCW, regardless of duration fed. Heifers fed RAC also had greater ($P \leq$ 0.03) LM area and dressing percentage. There was no effect ($P \geq$ 0.14) of RAC on marbling, 12th rib fat, KPH, or YG. Therefore, supplementing RAC at 300 mg/hd d^{-1} to heifers increased HCW, LM area, and dressing percentage and increased final BW without affecting other measures of performance.

Key Words: beef, carcass, heifers, ractopamine

0146 A meta-analysis of zilpaterol and ractopamine effects on feedlot. I. J. Lean[1], J. M. Thompson[2], and F. R. Dunshea*[3], [1]*SBScibus, Camden, Australia,* [2]*The University of New England, Armidale, Australia,* [3]*The University of Melbourne, Parkville, Australia*.

This study is a meta-analysis of the effects of the β-agonists zilpaterol hydrochloride (ZH) and ractopamine hydrochloride (RAC) on feedlot performance, carcass characteristics of cattle and Warner Bratzler shear force (WBSF) of muscles. It was

conducted to provide data that would be useful in considerations on the effect of these agents on meat quality in Meat Standards Australia evaluations. We conducted a comprehensive literature search and study assessment. Data were extracted from more than 50 comparisons for both agents and analyzed using a random effects meta-analysis and meta-regression using Stata (Stata 13.0). Results included forest plots, funnel plots, raw and weighted means, and estimates of effects size for each of ZH or RAC, independently. There was little evidence of publication bias on evaluation of funnel plots. Both agents markedly increased final body weight as indicated by the effect size (ES) 0.45 95% confidence interval (95% CI) 0.28 to 0.62 and weighted mean difference (wmd) 8.15 kg, (95% CI 5.63 to 10.67 kg) for ZH, RAC ES 0.40 (95% CI 0.24 to 0.56) and wmd 7.67 kg (95% CI 5.58 to 9.55 kg), hot carcass weight for ZH ES 1.32 (95% CI 1.03 to 1.61) and wmd 15.18 kg (95% CI 13.62 to 16.74 kg), RAC ES 0.47 (95% CI 0.31 to 0.63) wmd 6.18 kg (95% CI 4.55 to 7.82 kg) and longissimus muscle area (ZH ES 2.30 (95% CI 1.90 to 2.71) wmd 8.01 cm^2 (95% CI 7.05 to 8.96 cm^2), RAC ES 0.39 (95% CI 0.20 to 0.58) wmd 1.84 cm^2 (95% CI 1.17 to 2.52 cm^2) and increased the efficiency of gain:feed ratio (ZH ES 0.88 (95% CI 0.67 to 1.11) wmd 0.15 kg (95% CI 0.11 to 0.19), RAC ES 0.77 (95% CI 0.58 to 0.96) wmd 0.018 kg (95% CI 0.014 to 0.022). These effects were particularly large for ZH; however, ZH decreased fatness (by either ribfat or marbling score) with an ES of about -0.8 SD. For RAC the effects on fatness were much smaller with an ES of 0.0 and -0.1 for ribfat and marbling score, respectively. Zilpaterol also markedly increased WBSF by 1.2 standard deviations and more than 0.8 kg, while RAC increased WBSF by 0.43 standard deviations and 0.2 kg. This work has provided critically needed information on the effects of ZH and RAC on production, efficiency and meat quality.

0147 Evaluation of objective and subjective mobility variables in feedlot cattle supplemented with zilpaterol hydrochloride.

W. C. Burson*[1], A. J. Thompson[1], M. A. Jennings[1], J. A. Carroll[2], N. C. Burdick Sanchez[2], B. J. Ragland[1], J. E. Hergenreder[1], J. O. Baggerman[1], K. S. Sharon[1], T. R. Schmidt[1], E. S. Murray[1], F. R. B. Ribeiro[1], B. J. Johnson[1], and R. J. Rathmann[1], *[1]Texas Tech University, Lubbock, [2]USDA-ARS, Livestock Issues Research Unit, Lubbock, TX.*

The objective of this study was to examine the effects of zilpaterol hydrochloride (ZH) on mobility in feedlot cattle. Black-hided steers and heifers (n = 96) were sourced from a commercial feedlot and transported to the Texas Tech University Beef Center in New Deal, TX. Cattle were weighed and scanned using real-time ultrasound. Resulting data were used to predict empty body fat percentage (pEBF %). Steers (n = 48; BW = 520 ± 30.4 kg; pEBF % = 26.2 ± 1.9) and heifers (n = 48; BW = 466 ± 29.5 kg; pEBF % = 26.7 ± 1.7) were blocked within gender by pEBF % in a completely randomized block design and randomly assigned to pen (2 pens/block; 4 hd/pen) and treatment (6 pens/treatment): 1) control heifers (HC), 2) ZH heifers (HZ), 3) control steers (SC), 4) ZH steers (SZ). Movement differences were objectively assessed on Day 0, 5, 10, 15, and 20 with several measures of mobility: exit velocity from chute (EV), velocity traveling from the pen to chute (VT) and velocity traveling from chute to pen (VF). Chute scores (CS) were assigned to all cattle based on a scale ranging from 1 to 5 (1 = no distress, 5 = high distress). Before shipping, individual locomotion scores (LS) were recorded based on a 1 to 4 scale (1 = no lameness, 4 = severe lameness). No significant gender × treatment interactions were found for any measured variable ($P \geq 0.46$). A significant treatment × day interaction ($P = 0.03$) was detected for EV, indicating that ZH cattle became progressively slower throughout the treatment period. No significant effects were found for VT or VF ($P \geq 0.31$). Fisher's exact test for count data was used to analyze the frequency distributions for both subjective measures. On d 20, a greater proportion ($P = 0.01$) of ZH cattle exhibited elevated chute scores (CS $\geq$ 3) relative to control. There was a tendency ($P = 0.09$) for increased locomotion score (LS $\geq$ 2) in ZH fed cattle. However, the proportion of cattle with locomotion scores indicating sufficiently sound movement (LS = 1&2) versus cattle that were moderate or severely lame (LS = 3&4) was not significantly different between treatment groups ($P = 0.24$). These data suggest that ZH supplementation may slightly limit mobility of cattle; nonetheless, the magnitude of these effects is not sufficient to deduce a detriment to cattle soundness.

Key Words: cattle, zilpaterol hydrochloride, mobility

0148 Comparison of real-time ultrasound measurements for body composition traits to carcass data in feedlot cattle fed zilpaterol hydrochloride.

B. J. Ragland, F. R. B. Ribeiro*, W. C. Burson, B. J. Johnson, and R. J. Rathmann, *Texas Tech University, Lubbock.*

The objective of this study was to compare measurements of real-time ultrasound (RTU) and carcass data to determine body composition in feedlot cattle (n = 96) fed zilpaterol hydrochloride (ZH). Black-hided cattle were weighed and scanned using RTU 32 d before the start of the ZH treatment period. Resulting data were used to predict empty body fat (EBF %). Steers (n = 48; BW = 520 ± 30.4 kg; EBF % = 26.2 ± 1.9) and heifers (n = 48; BW = 466 ± 29.5 kg; EBF % = 26.7 ± 1.7) were blocked within gender by EBF % in a complete randomized block design and randomly assigned to pen (2 pens/block; 4 hd/pen) and treatment (6 pens/treatment). Measurements of RTU were taken by a certified ultrasound technician approximately 24 h before slaughter using an Aloka 500-V instrument with a 17-cm 3.5 MHz transducer. Hair was clipped

to less than 0.64 cm and vegetable oil was applied. The RTU measured traits consisted of 12-13th rib backfat thickness (uBF, mean = 12.4 mm), 12--13th LM area (uREA, mean = 93.9 cm^2), and marbling score (uMARB, mean = 5.1). Intramuscular fat was converted to uMARB by using the equation: uMARB = ((769.7 + (56.69×uIMF))/100)– 5. Overall means for carcass data were 12-13th rib backfat thickness (cBF, 13.6 mm), 12-13th LM area (cREA, 92.0 cm^2; measured using tracing paper), and marbling score (cMARB, 5.2). Marbling scores were converted to a numeric cMARB ($Slight^{00}$ = 4, $Small^{00}$ = 5, and $Modest^{00}$ = 6). Data were analyzed using the PROC REG, MEANS and CORR procedures of SAS. Results show that both methods were highly correlated to each other. Overall correlations were 0.83, 0.61, and 0.69 for BF, REA and MARB, respectively. The accuracy statistics for cattle (heifers and steers pooled together) fed ZH and Control were almost identical. Correlations for ZH and control cattle were 0.83, 0.60, 0.68 and 0.83, 0.59, 0.70 for BF, REA, MARB for ZH, respectively. The low correlation for REA could be a result of the method of collecting carcass REA data. Overall RTU underpredicted BF and MARB and overpredicted REA (bias = -1.32, -0.18 and 1.47, respectively). These results show that RTU can be used to predict carcass traits before slaughter and feeding ZH seems to have no effect in predicting carcass traits using RTU in live animals.

0149 The effect of zilpaterol supplementation and RFI on growth performance. L. J. Walter*[1], T. J. McEvers[1], N. D. May[1], J. A. Reed[1], J. P. Hutcheson[2], and T. E. Lawrence[1], [1]*West Texas A&M University, Canyon,* [2] *Merck Animal Health, Summit, NJ.*

Supplementation of zilpaterol hydrochloride (ZH) impacts live cattle performance. Research has not focused on individual intake or the impact on residual feed intake (RFI) when cattle are supplemented ZH. A 308 d serial-harvest trial was conducted in Holstein steers (n = 110) blocked by 11 harvest dates (d 252−534) and assigned to ZH or control treatments (n = 5 per treatment per harvest). Individual DMI was collected using the GrowSafe system and rations were sampled monthly for proximate analysis (CP = 14.5 ± 0.7; NE_m = 2.2 ± 0.1 Mcal/kg; NE_g = 1.5 ± 0.03 Mcal/kg). Every 28 d, DMI, ADG and SBW (BW*0.96) were calculated. Within each 28 d period, before ZH supplementation, RFI was calculated for each steer with a regression equation (coefficients of metabolic BW and shrunk BW gain); steers were assigned to a high or low RFI. Statistical analysis for data generated before ZH supplementation was conducted using a mixed model with fixed effects of RFI and days on feed (DOF) and random effects of harvest group and head count per feeding node; DOF was a repeated measure. Analysis of data during the ZH supplementation period was conducted using a mixed model with the fixed effects of ZH, DOF, and RFI and the random effect of harvest group. Intake before ZH supplementation was associated with RFI ($P < 0.01$); the high group consumed more DM than the low group (10.7 vs. 9.4 kg). A quadratic relationship between DMI and DOF was observed ($P < 0.01$); an inflection point occurred at Day 392. Gain efficiency (G:F) was also influenced ($P < 0.01$) by RFI; steers in the high RFI exhibited a G:F of 0.13 whereas low RFI steers were 0.15. As DOF increased, ADG and G:F exhibited a linear decrease ($P < 0.01$). During the ZH supplementation period, steers of the high RFI consumed more DM ($P < 0.01$; 10.6 vs. 9.5 kg) than those of the low RFI. However, steers supplemented ZH consumed less ($P = 0.03$) DM (9.7 vs. 10.3 kg). No ZH x RFI interaction ($P = 0.42$) was observed for DMI. Daily gain was not different ($P \geq 0.22$) between ZH treatments or RFI group. However, G:F tended ($P = 0.07$) to be greater for steers supplemented ZH; RFI did not affect G:F ($P = 0.39$).

Key Words: DMI, RFI, zilpaterol

0150 Effects of zilpaterol hydrochloride on internal body temperature and respiration rate of black-hided feedlot steers and heifers during moderate heat stress. W. C. Burson*[1], A. J. Thompson[1], M. A. Jennings[1], J. A. Carroll[2], N. C. Burdick Sanchez[2], J. E. Hergenreder[1], J. O. Baggerman[1], B. J. Ragland[1], E. S. Murray[1], T. R. Schmidt[1], K. S. Sharon[1], F. R. B. Ribeiro[1], B. J. Johnson[1], and R. J. Rathmann[1], [1]*Texas Tech University, Lubbock,* [2]*USDA-ARS, Livestock Issues Research Unit, Lubbock, TX.*

The objective of this study was to examine the effects of zilpaterol hydrochloride (ZH) on the internal body temperature and respiration rate of feedlot cattle during moderate heat stress. Black-hided steers and heifers (n = 96) were sourced from a commercial feedlot and transported to the Texas Tech University Beef Center in New Deal, TX. Cattle were weighed and scanned using real-time ultrasound. Resulting data were used to predict empty body fat percentage (pEBF %). Steers (n = 48; BW = 520 ± 30.4 kg; pEBF % = 26.2 ± 1.9) and heifers (n = 48; BW = 466 ± 29.5 kg; pEBF % = 26.7 ± 1.7) were blocked within gender by pEBF % in a completely randomized block design and randomly assigned to pen (2 pens/block; 4 hd/pen) and treatment (6 pens/treatment): 1) control heifers (HC), 2) ZH heifers (HZ), 3) control steers (SC), and 4) ZH steers (SZ). During the ZH treatment period the climatic conditions were: mean maximum temperature, 29.67°C; mean minimum temperature, 15.18°C; mean relative humidity, 60.69%; mean wind velocity, 8.37 km/h. Immediately preceding the ZH treatment period (d -1), cattle were fitted with an indwelling rectal temperature probe. Rectal temperatures (RT) were recorded at 5-min intervals throughout the treatment period. Panting scores (PS) were assigned to cattle every other day from 1500

to 1700 h during the ZH treatment period based on a scale ranging from 1 to 4 (1 = normal respiration, 4 = extremely elevated respiration). Repeated measures analysis of RT revealed a significant treatment × gender interaction ($P < 0.0001$). The HC group recorded higher RT relative to the HZ group ($P \leq 0.0009$; 38.83°C versus 38.76°C, respectively). Alternatively, the SC group recorded lower RT relative to the SZ group ($P \leq 0.0009$; 38.96°C versus 38.98°C, respectively). Although highly significant differences were detected for RT, the marginal effect size may be insufficient to deduce biologically significant implications. Fisher's exact test for count data was used to analyze the frequency distribution of PS. No differences were detected in PS between treatments at any single point of data collection or for the entire treatment period ($P \geq 0.32$). Collectively, the variables measured in the present study do not provide compelling evidence to suggest that ZH treated black-hided cattle of either sex have more difficulty coping with moderate heat stress relative to their control counterparts.

Key Words: cattle, zilpaterol hydrochloride, heat stress

0151 Effects of zilpaterol hydrochloride on blood gas, electrolyte balance and pH in feedlot cattle.

W. C. Burson*[1], A. J. Thompson[1], M. A. Jennings[1], J. A. Carroll[2], N. C. Burdick Sanchez[2], J. E. Hergenreder[1], J. O. Baggerman[1], B. J. Ragland[1], K. S. Sharon[1], T. R. Schmidt[1], E. S. Murray[1], F. R. B. Ribeiro[1], B. J. Johnson[1], and R. J. Rathmann[1], *[1]Texas Tech University, Lubbock, [2]USDA-ARS, Livestock Issues Research Unit, Lubbock, TX.*

The objective of this study was to examine the effects of zilpaterol hydrochloride (ZH) on blood gas, electrolyte balance and pH in feedlot cattle. Black-hided steers and heifers ($n = 96$) were sourced from a commercial feedlot and transported to the Texas Tech University Beef Center in New Deal, TX. Cattle were weighed and scanned using real-time ultrasound. Resulting data were used to predict empty body fat percentage (pEBF %). Steers ($n = 48$; BW = 520 ± 30.4 kg; pEBF % = 26.2 ± 1.9) and heifers ($n = 48$; BW = 466 ± 29.5 kg; pEBF % = 26.7 ± 1.7) were blocked within gender by pEBF % in a completely randomized block design and randomly assigned to pen (2 pens/block; 4 hd/pen) and treatment (6 pens/treatment): 1) control heifers (HC), 2) ZH heifers (HZ), 3) control steers (SC), 4) ZH steers (SZ). Venous blood was collected in lithium heparinized tubes through the use of jugular venipuncture on Day 5, 10, 15, and 20 of the ZH treatment period. Blood samples were placed on ice and transported to an on-site station for prompt analysis. Data were analyzed as repeated measures to assess effects due to treatment. ZH treatment significantly increased potassium (K) concentration ($P < 0.0001$). Calcium (Ca) concentration was reduced in both genders, but, a significant gender × treatment interaction ($P = 0.0376$) revealed that ZH decreased Ca with a greater magnitude in steers relative to heifers. ZH treated cattle expressed a tendency for a lower partial pressure of oxygen (pO_2; $P = 0.082$) relative to control. No significant gender × treatment interactions or main effects were detected ($P \geq 0.14$) for blood pH, partial pressure of carbon dioxide (pCO_2), oxygen saturation (SO_2C), sodium (Na) concentration or percentage of hematocrit (Hct). Collectively, these data suggest that only minor differences exist between ZH and control cattle with respect to blood gases and pH, such that a causative effect cannot be assumed. The alterations in K and Ca indicate that biologically significant differences in the cation-anion difference (CAD) may exist when comparing treatment groups. Furthermore, the significant reduction in blood Ca concentration in ZH treated cattle provides more insight to the well-known reduction in post-mortem tenderness associated with cattle fed a β-adrenergic agonist.

BREEDING AND GENETICS: APPLICATIONS AND METHODS IN ANIMAL BREEDING—DAIRY I

0152 Calculation and delivery of US genomic evaluations for dairy cattle. G. R. Wiggans*[1], T. A. Cooper[1], P. M. VanRaden[1], D. J. Null[1], J. L. Hutchison[1], O. M. Meland[2], M. E. Tooker[`], and H. D. Norman[2], [1]*Animal Improvement Programs Laboratory, Agricultural Research Service, USDA, Beltsville, MD,* [2]*Council on Dairy Cattle Breeding, Columbus, OH.*

In April 2013, the responsibility for calculation and distribution of genomic evaluations for dairy cattle was transferred from the USDA to the US dairy industry's Council on Dairy Cattle Breeding; the responsibility for development of evaluation methodology remained with the USDA. The Council on Dairy Cattle Breeding has implemented a fee schedule to provide operational funds as well as an incentive for continued submission of phenotypic data necessary for estimation of genomic effects. Since April 2013, substantial improvements have been made to the evaluation system. The number of SNP used for all evaluations has been increased to 61,013 from 45,195. The Jersey reference population has been increased by 1186 Danish bull genotypes obtained through an exchange with Viking Genetics International (Skara, Sweden). Genomic evaluations for Ayrshires were released to the industry. Cutoff studies to assess the accuracy of data available 4 yr earlier for predicting current data showed the mean gain in reliability across traits for Holsteins was 0.5% points from adding 15,818 SNP, 1.2% points for adding the Jersey bulls, and 8.2% points over parent average for Ayrshires. The weighting for cow evaluations used to estimate SNP effects has been reduced. Also, the deregression of the traditional PTA is jointly across animals instead of 1 animal at a time. Each animal gets credit for its own records and for records of its non-genotyped progeny. This prevents double counting of traditional information when parents and progeny are both genotyped. For yield traits, genotyped-daughter evaluations are not removed because the cow adjustment made them incompatible. Adjustment of cow weights improved the regression of genomic evaluation on future performance and reduced bias. Multitrait traditional evaluations for heifer and cow conception rates are used to estimate SNP effects for those traits. Imputed values are now provided for gene tests for bovine leucocyte adhesion deficiency, complex vertebral malformation, deficiency of uridine monophosphate synthase, syndactyly, Weaver Syndrome, spinal dismyelination, spinal muscular atrophy, red coat color, and polledness. Four tests for haplotypes that affect fertility or stillbirth rate were added (HH4 and HH5 for Holsteins, BH2 for Brown Swiss, and AH1 for Ayrshires). As of February 2014, over 538,000 genotypes are used in genomic evaluation with a mean of 18,000 added monthly. Genomic evaluations are released for animals from 36 countries, an indication of the global demand for them.

Key Words: dairy cattle, genomic evaluation, holstein

0153 An updated version of lifetime net merit incorporating additional fertility traits and new economic values. J. B. Cole* and P. M. VanRaden, *Animal Improvement Programs Laboratory, Agricultural Research Service, United States Department of Agriculture, Beltsville, MD.*

Lifetime net merit (NM$) is an economic selection index intended for use by commercial dairy producers. The current version of NM$ was most recently updated in 2010 and includes information from 13 traits in Holsteins, 11 in Brown Swiss, and 9 in the other dairy breeds. A new version of the index, 2014 NM$, now includes heifer (HCR) and cow (CCR) conception rates to provide more complete information about fertility. Additional benefits of fertility that are not included in productive life (PL) are earlier age at first calving, decreased units of semen needed per pregnancy, decreased labor and supplies for heat detection, synchronization, inseminations, and pregnancy checks, additional calves produced, and higher yields because more optimal lactation lengths are achieved. The total value of HCR including age at first calving, insemination costs, heat detection, pregnancy checks, and reproductive culling was $2.25; CCR was $2.25; and DPR was $11. Replacement heifers were previously assumed to cost $1940, but current prices are only about $1200 to 1500. Lower replacement prices will reduce the value of PL and daughter pregnancy rate (DPR) because fewer lactations are needed to recover costs. Fertility traits will receive a combined emphasis of 8.6%, less than the 11% on DPR in 2010 NM$. Relative emphasis for PL will decrease to 17% from 22% in 2010. DHI mean SCC has decreased from 230,000 in 2002 to 200,000 in 2012. Therefore, the actual change in SCC from a 1-unit change in SCS and actual SCC differences among bull daughters are now much less than when SCC premiums were introduced. The premium/1,000 cells increased only slightly since 2010 and contributes much of the SCS economic value, but the smaller phenotypic mean and SD for SCC will decrease the relative emphasis to 8% on SCS from 10% in 2010. Only slight revisions are needed to the milk and components prices forecast in 2010 NM$, but yield traits will receive more relative emphasis if PL, SCS, and fertility get less emphasis. These changes will increase the relative emphasis on yield to 42% from 35% in 2010. The 2014 NM$ index is correlated by 0.966 with 2010 NM$ for recent progeny-tested bulls. An increase in genetic progress worth $8 million/year is expected on a national basis, assuming that all of the changes are improvements and that all breeders select on NM$.

0154 Gains in reliability with genomic information in US commercial holstein heifers. F. A. Di Croce*, J. B. Osterstock, D. J. Weigel, and M. J. Lormore, *Zoetis Inc., Kalamazoo, MI.*

Genomic selection allows producers to accurately identify genetically superior animals at a much earlier age than traditional parent averages. The objective of this study is to quantify the gain in reliability from including genomic information in a commercial US Holstein dairy female population. Genomic Predicted Transmitting Abilities (GPTAs) from two Zoetis Low Density Panels consisting of 6836 markers (LD) and 10,932 markers (ZLD) and Parent Averages (PAs) for 73,480 Commercial US Holstein heifers were available for this study. Predicted transmitting abilities (PTAs) from the December 2013 USDA-CDCB evaluation for non-parent animals born in 2012 and 2013 were compared to corresponding GPTA from the December 2013 predictor population. Means were derived and daughter equivalents (DE) were estimated as described by VanRaden and Wiggans (1991). Mean reliabilities for the LD and ZLD panels were 66.85%, 71.15%, 71.15%, 71.15%, 64.48%, 67.45% and 63.10% for Lifetime Net Merit (NM$), Milk, Fat, Protein, Productive Life (PL), Somatic Cell Score (SCS) and Daughter Pregnancy Rate (DPR), respectively (not shown). Average gains in reliability above parent average ranged from 42.69% to 45.44% for LD and from 44.93% to 47.62% for ZLD across the selected yield, health and fertility traits. Mean Daughter Equivalent (DE) above Parent Average across the selected traits ranged from 23.9 to 142.0 and 24.9 to 147.5 for LD and ZLD, respectively (Table 0154). These results suggest that including genomic information in the genetic evaluation of young commercial Holstein females substantially increases reliability over the traditional parent averages.

0155 Genome-wide association analysis in Italian Simmental cows for lactation curve traits using a low density (7K) SNP panel. N. P. P. Macciotta*[1], D. Vicario[2], C. Dimauro[1], G. Gaspa[1], M. Cellesi[1], A. Puledda[3], S. Sorbolini[1], and P. Ajmone-Marsan[4], *[1]Università di Sassari, Sassari, Italy, [2]ANAPRI, Udine, Italy, [3]Dipartimento di Agraria, Università di Sassari, Sassari, Italy, [4]Università Cattolica del Sacro Cuore, Piacenza, Italy.*

In genomic selection (GS) programs of dairy cattle breeds, bulls are currently genotyped using medium or high density SNP platforms. Genome wide association studies (GWAS) are then performed on variables (as polygenic breeding values or deregressed proofs) that are derived from phenotypes recorded on females. It could therefore be of interest to perform GWAS directly on cows that now are being genotyped in GS programs, often by using low density SNP panels. In this study, GWAS was performed on 1211 lactations of 337 Italian Simmental cattle, genotyped with the 7K Illumina bead-chip. Edit on markers was performed on call rate (> .99) and minor allele frequency (> .01). After edits, 6891 markers were retained for the analysis. Phenotypes were scores of the first two principal components obtained by performing principal component analysis on the test day records (seven for each lactation) for milk yield, fat and protein percentages, and somatic cell scores (SCS). The first component describes the average level (LEVEL) of the lactation curve, i.e., the average level of milk yield and percentages along the whole lactation, whereas the second is related to the shape of the lactation curve (SHAPE). Data were analyzed with a mixed linear model that included fixed effects of calving month, calving year, parity, SNP genotype (coded as 0,1,2), and random effects of herd, animal additive, permanent environment. Multiple testing was accounted for by performing the Bonferroni correction (uncorrected P × number of tests). Two markers were associated to LEVEL for milk yield according to the Bonferroni corrected statistical significance ($P < 0.05$). One was located on BTAs 6, close to the casein cluster. Nine significant SNPs were highlighted for LEVEL of fat percentage. Most important ($P < 0.001$) were on BTA23, close to the desmoplakin gene, which is involved in the turnover of epithelial cells, and on BTA7 close to the Ring Finger protein 145. Moreover, two significant SNP were located on BTA14, close to the CYP11B1 gene, previously reported to be associated to dairy traits in Holstein. Six markers were associated to protein percentage. The most significant was on BTA12, close to the HSTRA locus, reported to be associated to type traits in Chinese Holstein. Finally, one marker was found to affect SCS on BTA22, close to the LANCL2 locus. No markers were found to be associated to the SHAPE component for any of the four considered traits

0156 Genetic parameters for pre-calving feed intake.
B. N. Shonka* and D. M. Spurlock, *Iowa State University, Ames.*

The objective of this study was to estimate genetic parameters for dry matter intake (DMI) measured during lactation and the dry period in Holstein cows. Daily individual feed intake data collection started approximately 30 d before the expected calving date and continued through the first half of lactation. Pre-calving DMI traits were defined as average DMI on d -17 through -15 (cows) or d -10 through −8 (heifers) relative to parturition (DRYDMI), average DMI for d -1 through -3 relative to parturition (CALVEDMI), and the slope of the regression line fit through the last 14 (cows) or 7 (heifers) days before parturition (DECLINE). These traits were compared to DMI during lactation, defined as average DMI for 100 through 102 d in milk (LACDMI). The final data set included 242 and 214 primiparous and multiparous cows, respectively. Genetic parameters were estimated by mixed model analyses using a 5-generation pedigree. Fixed effects included lactation, year by season of calving, age at calving, sex of calf (male, female or twin), and status of calf (live or dead). Heritability estimates were 0.37, 0.60, 0.28, and 0.41 for DRYDMI, CALVEDMI, DECLINE, and LACDMI, respectively. Genetic correlations between all traits except DECLINE and LACDMI were significantly greater than zero. The correlation between DRYDMI and DECLINE was 0.37, but all other correlations were greater than 0.70. In particular, the genetic correlation between DRYDMI and LACDMI was 0.93. Results from this study demonstrate that DMI measured during the dry period or lactation is a moderately heritable trait. The high genetic correlation between DRYDMI and LACDMI was unexpected because DMI during lactation is also highly influenced by milk production. However, results of this study suggest the genetic regulation of DMI during the dry period and lactation is very similar. This result has potential implications for the measurement of feed intake for the purpose of calculating feed efficiency because in some situations, measurement of feed intake during the dry period is more feasible than measurement during lactation. However, this study is based on a relatively small number of cows and would benefit from verification in a larger population.

Key Words: Holstein cow, heritability, pre-calving intake

0157 Phenotypic and genetic correlations among milk energy output, body weight, and feed intake, and their effects on feed efficiency in lactating dairy cattle.
M. J. VandeHaar*[1], Y. Lu[1], D. M. Spurlock[2], L. E. Armentano[3], K. A. Weigel[3], R. F. Veerkamp[4], M. Coffey[5], Y. de Haas[4], C. R. Staples[6], E. E. Connor[7], M. D. Hanigan[8], and R. J. Tempelman[1], *[1]Michigan State University, East Lansing [2]Iowa State University, Ames, [3]University of Wisconsin, Madison, [4]Animal Breeding and Genomics Centre, Wageningen UR Livestock Research, Wageningen, Netherlands, [5]Scottish Agriculture College, Edinburgh, United Kingdom, [6]Dep. of Animal Sciences, University of Florida, Gainesville, [7]USDA-ARS, Bovine Functional Genomics Laboratory, Beltsville, MD, [8]Virginia Polytechnic Institute and State University, Blacksburg.*

Continued improvements in feed efficiency are essential for a thriving and sustainable dairy industry. Gross efficiency (GrEff) is defined as the energy captured in milk and body tissues as a percentage of gross energy intake. Our objective was to characterize the relationships among component traits for feed efficiency in lactating Holsteins and to determine their relationships to GrEff. Milk energy output per day (MilkE), calculated from milk, fat, protein, and lactose yields, dry matter intakes (DMI), body weights (BW), and body condition scores (BCS), were collected on 4452 lactating Holstein cows ranging from 50 to 200 d in milk from Scotland, the Netherlands, and the United States. The first 42-d records were analyzed with multivariate animal model in ASREML 3.0. Daily body energy change (dBE) was estimated from body weight change and BCS. Metabolic BW (MBW) was BW to the 0.75 power. GrEff was calculated as (MilkE + dBE)/Gross Energy intake, assuming all diets were 4.5 Mcal/kg. For these cows, MilkE was 26 ± 6 Mcal/d, BW was 600 ± 70 kg, DMI was 22 ± 5 kg/d, and intake as a multiple of maintenance was 3.9 ± 0.6. Genetic correlations for feed efficiency traits were 0.07 ± 0.04 for MilkE and MBW, 0.73 ± 0.03 for MilkE and DMI, and 0.40 ± 0.03 for MBW and DMI. Phenotypic correlations for feed efficiency traits were 0.16 ± 0.02 for MilkE and MBW, 0.60 ± 0.01 for MilkE and DMI, and 0.37 ± 0.01 for MBW and DMI. All correlations were reasonably consistent across countries. Genetic correlations of GrEff with MilkE, MBW, and DMI were 0.61 ± 0.04, -0.14 ± 0.05, and 0.04 ± 0.06, respectively. Phenotypic correlations of GrEff with MilkE, MBW, and DMI were 0.47 ± 0.01, -0.05 ± 0.02, and -0.17 ± 0.01, respectively. We conclude that, for Holsteins at a multiple of maintenance around 4, selection for milk component yield remains the overwhelming determinant of feed efficiency, and that selection for smaller body size may benefit feed efficiency but its impact will be slight compared to selection for more milk. Moreover, selection for greater milk will have a

Table 0158. Conception rate (CR) by month for lactating Holstein (HO) and Jersey (JE) cows

Year Month	2011 Apr	2011 May	2011 Jun	2011 Jul	2011 Aug	2011 Sep	2011 Oct	2011 Nov	2011 Dec

[a,b,c] different letters within rows ($P < 0.05$).

greater impact on profitability than would selection for BW. We suggest that that direct selection for body size (either larger or smaller) is likely not warranted as a means to enhance milk production or feed efficiency.

Key Words: lactating dairy cow, feed efficiency, body weight

0158 Benchmarking reproductive efficiency in commercial dairy herds in California.

A. H. Souza*[1], N. Silva-Del-Rio[2], E. O. S. Batista[3], W. VerBoort[4], P. S. Baruselli[3], and P. J. Ross[2], *[1]University of California Cooperative Extension, Tulare, [2]University of California, Davis, [3]University of Sao Paulo-VRA, Sao Paulo, Brazil, [4]AgriTech Analytics, Visalia, CA.*

Our objective was to benchmark reproductive efficiency for both Holstein (HO) and Jersey (JE) dairy herds in California (CA). Reproductive records from DHIA's database (AgriTech Analytics) for all cows that calved in CA in 2011 were used. The initial dataset included artificial insemination records from 511 dairy operations and 554,523 lactating cows (501,616-HO; 52,907-JE) in a total of 1377,729 breedings (1262,926-HO; 114,803-JE). Only herds reporting at least 200 breedings and having overall conception results within 15% to 75% were included in the analysis. Breeding intervals that were less than 3d or greater than 150 d were discarded from final analysis. In addition, cows that were sold or died before pregnancy confirmation or re-inseminated (and assumed non-pregnant) were disregarded. Conception rate (CR) was defined as number cows pregnant by total number of AIs. Service rate (SR) was calculated based on the average interval between breedings (Woods-index). Statistical analyses were performed with the Proc HPMIXED of SAS (version 9.3), with herd and cow used as random effects in the model. Overall, milk production level 305ME did not affect ($P > 0.10$) CR or SR results for either HO or JE cows. However, CR and SR from JE cows (CR = 38.8%; SR = 66.7%) were better ($P < 0.05$) than in HO-cows (CR = 32.8%; SR = 60.1%), but with great variation in milk production and reproductive performance within each breed. As suspected, CR was drastically affected ($P < 0.05$) by season, with a major decrease for both breeds during the warmer months of the year—as shown in Table 0158. In contrast, SR remained fairly constant throughout seasons and this was independent from cow breed. In summary, these results indicate a major detrimental effect of summer heat stress on fertility of California dairies that seems to disturb both HO and JE cows.

BREEDING AND GENETICS: GENETIC AND GENOMIC METHODS

0163 Evaluation of predictive ability of Cholesky factorization of genetic relationship matrix for additive and non-additive genetic effect using Bayesian regularized neural network. H. Okut*[1], D. Gianola[2], K. A. Weigel[2], and G. J. M. Rosa[2], [1]*University of Yuzuncu Yil, Van, Turkey,* [2]*University of Wisconsin, Madison.*

This study aimed to explore the effects of additive and non-additive genetic effects on the prediction from using Bayesian regularized artificial neural network (BRANN). The data sets were simulated for two hypothetical pedigrees with five different fractions of total genetic variance accounted by additive (σ^2_a/σ^2_G), additive x additive (σ^2_{aa}/σ^2_G) and additive x additive x additive ($\sigma^2_{aaa}/\sigma^2_G$) genetic effects. A feed forward artificial neural network (ANN) with Bayesian regularization (BR) was used to assess the performance and predictive ability of different nonlinear ANNs and linear models for genetic architectures. Effective number of parameters (γ) and sum of squares error (SSE) in test data sets were used to evaluate the performance of ANNs. Distribution of weights (w_{ij}) and correlation between observed and predicted values in the test data set were used to evaluate the predictive ability. There were clear and significant improvements in terms of the predictive ability of linear (equivalent Bayesian ridge regression) and nonlinear models when the proportion of additive genetic variance in total genetic variance (σ^2_a/σ^2_G) increased. On the other hand, nonlinear models outperformed the linear models at each genetic architecture. The weights for the linear models were larger and more variable than for the nonlinear network, where distributions were leptokurtic, indicating strong shrinkage towards 0. In conclusion, our results showed that: a) inclusion of non-additive effects did not improved the prediction ability compared to purely additive models, b) The predictive ability of BRANN architectures with nonlinear activation function were substantially larger than the linear models for the scenarios.

Key Words: artificial neural networks, Bayesian regularization, additive and non-additive genetic effects

0164 Using recursion to compute the inverse of the genomic relationship matrix. I. Misztal*[1], A. Legarra[2], and I. Aguilar[3], [1]*University of Georgia, Athens,* [2]*INRA, Castanet-Tolosan, France,* [3]*INIA, Las Brujas, Uruguay.*

A traditional algorithm to invert the numerator relationship matrix is based on the observation that the conditional expectation for an additive effect of one animal given the effects of all other animals depends on the effects of its sire and dam only, each with a coefficient of 0.5. With genomic relationships, such an expectation depends on all other genotyped animals, and the coefficients do not have any set value. For each animal, the coefficients plus the conditional variance can be called a genomic recursion. If such recursions are known, the mixed model equations can be solved without explicitly creating the inverse of the genomic relationship matrix. Several algorithms were developed to create genomic recursions. In an algorithm with sequential updates, genomic recursions are created animal by animal. That algorithm can also be used to update a known inverse of a genomic relationship matrix for additional genotypes. In an algorithm with forward updates, a newly computed recursion is immediately applied to update recursions for remaining animals. The computing costs for both algorithms depend on the sparsity pattern of the genomic recursions. An algorithm for proven and young animals assumes that the genomic recursions for young animals contain coefficients only for proven animals. Such an algorithm generates exact genomic EBV in GBLUP and is an approximation in single-step GBLUP. That algorithm has a cubic cost for the number of proven animals and a linear cost for the number of young animals. All algorithms were evaluated with a simulated data set of 1500 genotypes and ssGBLUP. In the algorithm with sequential updates, setting very small elements in recursions to zero resulted in little sparsity. Setting larger elements to zero caused large errors in G^{-1} due to accumulation of errors. However, this algorithm worked very well for inv(A_{22}), especially when the pedigree depth was limited. When complete recursions were computed and small elements were set to 0, the accuracy of GEBVs was almost unaffected but the sparsity level was moderate. The sparsity level increased to > 60% when G was blended with 20% of A_{22}. In all computations involving the algorithm for proven and young animals, the correlations of GEBV with those using the regular algorithm were > 0.99. The genomic recursions can provide new insight into genomic evaluation and possibly reduce costs of genetic predictions with extremely large numbers of genotypes.

Key Words: genomic selection, single-step GBLUP, efficiency

0165 Advantage of supernodal methods in restricted maximum likelihood when dense matrices are involved in a coefficient matrix of mixed model equations. Y. Masuda*[1,2], S. Tsuruta[2], and I. Misztal[2], [1]*Obihiro University of Agriculture and Veterinary Medicine, Obihiro, Japan,* [2]*University of Georgia, Athens.*

The objective of this study was to determine speed-up of an average-information (AI) REML algorithm with a supernodal sparse-matrix package. Comparisons included twenty-three models with data sets from broiler, swine, beef and dairy cattle. Models included single-trait, multiple-trait, maternal, and random regression models with phenotypic data; selected models

used genomic information as a genomic relationship matrix in single-step GBLUP. The AIREMLF90 program was used to compare two sparse-matrix packages: FSPAK and YAMS; the latter package used supernodal methods for faster computing when sparse matrices contain large dense blocks. The program was compiled with the Intel Fortran Compiler 13.1 using the Intel Math Kernel Library and ran on a computer with 16-core CPUs. Computations with YAMS were on average over 10 times faster than with FSPAK and had greater advantages for large data and more complicated models including multiple traits and random regressions and with genomic effects. The highest speed-up with YAMS over FSPAK was over 20 times faster in AI REML iteration and over 80 times faster in sparse inversion. In a model with 213,297 pedigreed and 15,723 genotyped animals, a single-trait analysis with FSPAK took about 5 h and multiple-trait analyses did not converge in 1 d. With YAMS, a single-trait analysis took about 20 min and a 4-trait analysis took about 5 h. Supernodal methods dramatically improve the computing cost if the AI REML for larger and more complex analyses, especially when genomic information is included in the single-step GBLUP models.

Key Words: AIREML, supernodal methods, sparse-matrix package

0166 Use of genomic recursions and APY algorithm for single-step GBLUP analyses with large number of genotypes. B. D. Fragomeni*[1], I. Misztal[1], D. Lourenco[1], S. Tsuruta[1], and Y. Masuda[1,2], [1]*University of Georgia, Athens,* [2]*Obihiro University of Agriculture and Veterinary Medicine, Obihiro, Japan.*

The purpose of this study was to examine accuracy of genomic selection in single-step genomic BLUP (ssGBLUP) when the inverse of the genomic relationship matrix (G) is derived by the algorithm for proven and young animals (APY). This algorithm implements the inversion of G by genomic recursions, with recursions for young animals involving only the proven animals. With efficient implementation, the algorithm has a cubic cost for proven animals but only a linear cost for young animals. Simulated data set included 142k phenotypes in 6 generations under selection for EBV, with 170k animals in the relationship matrix. Genomic data consisted of 20k animals genotyped for 45k SNP; the simulated genomic data mimicked the bovine genome. The proven animals were 10k genotyped parents selected from the first 5 generations, and the young 10k genotyped animals were selected from the last generation. For animals treated as young, 5k had a single record and 5k had no records. Comparisons involved GEBVs obtained by ssGBLUP evaluation with either the exact G (G-REG) and the G inverted by APY algorithm (G-APY). The correlations between GEBV with the G-REG and G-APY were 0.97 overall, 0.94 for animals treated as young without records, and 0.98 for animals treated as young with records. The true accuracies for the animals with records with G-REG and G-APY were 0.57 and 0.58, respectively; for the animals without records, the accuracies for REG and APY were both 0.43. When the status of the young and proven animals was switched, the accuracies remained identical. A separate analysis involved a national data set for final score in Holsteins. Out of 74,980 genotypes for bulls, 29,552 for bulls with daughters were treated as proven and 45,428 without daughters were treated as young. The correlations of GEBV obtained with the REG and APY algorithms were > 0.99 for both groups of bulls. When the number of high-accuracy animals with genotypes is limited (< 100k), the APY algorithm may drastically reduce the cost of the ssGBLUP evaluation without affecting the accuracy. The APY algorithm may allow using all the available genotypes in one ssGBLUP analysis to reduce biases due to preselection of young animals.

Key Words: single step method, genomic selection, genetic evaluation

0167 Genomic prediction accounting for residual heteroskedasticity. Z. Ou*[1], R. J. Tempelman[2], J. P. Steibel[2], C. W. Ernst[2], R. O. Bates[2], and N. M. Bello[1], [1]*Kansas State University, Manhattan,* [2]*Michigan State University, East Lansing.*

Classical genomic selection (GS) models that use single-nucleotide polymorphism (SNP) marker information to predict genetic merit of animals and plants usually assume homogeneous residual variance. However, this assumption seems questionable as environmental variability can be heterogeneous and it may affect the genetic control of a given quantitative trait. This study extends classical GS models, namely RR-GBLUP, BayesA, BayesB and BayesC, to explicitly account for residual heteroskedasticity using a hierarchical Bayesian mixed-models framework implemented with Markov Chain Monte Carlo methods. Competing GS models assuming homogeneous or heterogeneous residual variances were fitted to training data under simulation scenarios reflecting a gradient of increasing residual heteroskedasticity. Model fit of competing homoskedastic and heteroskedastic GS models was compared using prediction accuracy of genomic breeding values and pseudo-Bayes factors, both computed on a validation data subset one generation removed from the training dataset. Competing models were also fitted to two quantitative traits selected from a Michigan State University swine resource population dataset, namely carcass temperature and loin muscle pH 45 min after slaughter. These traits had been pre-screened for homoskedasticity and heteroskedasticity, respectively. Using a fivefold cross-validation approach, competing GS models were compared based on predictive ability of phenotypes. Overall, under the conditions considered in this study, heteroskedastic GS models showed improved model fit and enhanced prediction accuracy compared to homoskedastic GS models under conditions of extreme residual variance

heterogeneity; however, the magnitude of the improvement was too small (approximately 1% to 2% net gain in prediction accuracy) to confer practical relevance.

Key Words: genomic selection model, heterogeneous residual variance, genomic breeding values.

0168 Are past generations contributing to evaluations on young genotyped animals? D. Lourenco*[1], I. Misztal[1], S. Tsuruta[1], I. Aguilar[2], T. J. Lawlor[3], S. Forni[4], and J. I. Weller[5], *[1]University of Georgia, Athens, [2]INIA, Las Brujas, Uruguay, [3]Holstein Association USA Inc., Brattleboro, VT, [4]Genus Plc, Hendersonville, TN, [5]ARO, The Volcani Center, Bet Dagan, Israel.*

Datasets of US and Israeli Holsteins and pigs from PIC were used to evaluate the impact of different number of generations on ability to predict GEBV of young genotyped animals. The inclusion of only two generations of ancestors (A2) or all ancestors (Af) was also evaluated. A total of 34,506 US and 1305 Israeli Holsteins bulls, and 5236 pigs were genotyped. The evaluations were computed by traditional BLUP and single-step GBLUP, with respective computing performance recorded. For the two Holstein datasets, coefficients of determination and regression of deregressed evaluations from a full dataset with records up to 2011 on EBV or GEBV from the reduced dataset (up to 2006 for Israeli and 2007 for US) and truncations were computed. The thresholds for old data deletion were based on generation intervals of 5 yr. For the PIC dataset, correlations between corrected phenotypes and EBV or GEBV were used to evaluate the predictive ability on young animals born in 2010 and 2011. The reduced dataset contained data up to 2009 and the thresholds were based on generation interval of 3 yr. The number of generations that could be deleted without reduction in accuracy was dependent on data structure and trait. For US Holsteins, removing 3 and 4 generations of data did not reduce accuracy of evaluations for final score in Af and A2 scenarios, respectively. For Israeli Holsteins, the accuracies for milk, fat, and protein yields were the highest when only phenotypes recorded on year $\geq$ 2000 and full pedigrees were included. Of the 135 Israeli validation bulls with genotypes and daughter records only in the complete dataset, 38 and 97 were sons of Israeli and foreign bulls, respectively. While more phenotypic data increased the prediction accuracy for sons of Israeli bulls, the reverse was true for sons of foreign bulls. For PIC dataset, removing data up to five generations did not erode predictive ability for genotyped animals for litter size and number of stillborn. Given the data used in this study, truncating old data does not decrease the accuracy on young genotyped animals, while reducing computation requirements and helping to find problems due to population structure. For populations that include local and imported animals, the truncation may be beneficial for one group of animals and detrimental to another.

Key Words: ssGBLUP, pedigree depth, genomic selection

0169 Use of linear models with normal, Student-t or Slash distributed error for the analysis of quantitative traits. B. Mestav*[1], K. Kizilkaya[2], and S. O. Peters[3], *[1]Canakkale Onsekiz Mart University, Canakkale, Turkey, [2]Adnan Menderes University, Aydin, Turkey, [3]Berry College, Mount Berry, GA.*

Some symmetric and heavy-tailed distributions, such as Student's-*t* and Slash, have been suggested for robust inference in linear mixed models. These robust models are characterized by the degrees of freedom of these distributions and include the normal distribution when the degrees of freedom approach infinity. The objective of this this study was to investigate joint estimation of degrees of freedom for the residual and all other genetic and non-genetic parameters. In a simulation study, five different populations with five replicates were simulated using multivariate linear mixed effects animal models with Normal (NOR), three (ST3) or ten (ST10) degrees of freedom Student-t, and one and half (ST1.5) or three (SL3) degrees of freedom Slash distributions. Multivariate data within each replicate were generated for 18,000 progeny from 10 sires and 20 dams mating, which is selected through three generations. Models with multivariate Student's-*t*, Slash and Normal residuals were fitted to each dataset using a hierarchical Bayesian approach. Predictive log-likelihood (PLL) values strongly favored the multivariate Student's-*t* and Slash models over the Normal models for simulated heavy-tailed datasets. Posterior mean estimates of degrees of freedom parameters seemed to be accurate and unbiased. Estimates of sire and herd variances were similar, if not identical, across fitted models. Posterior mean and 95% posterior probability interval (PPI) estimates of error variances in simulated datasets were found to be (downwardly or upwardly) biased when the fitted model was not the true model. Reliable estimates of degrees of freedom were obtained in all simulated heavy-tailed and normal datasets. The predictive log-likelihood was able to identify the correct model among the models fitted to heavy-tailed datasets. The results obtained indicated that there was no disadvantage of fitting a heavy-tailed model when the true model was normal.

Key Words: multivariate heavy-tailed distributions, robust linear mixed model, MCMC

BREEDING AND GENETICS: APPLICATIONS AND METHODS IN ANIMAL BREEDING—LIVESTOCK II

0170 Genetic gain and economic weights in selection for boar fertility traits in a cross-breeding system. D. Gonzalez-Peña Fundora[*1], R. V. Knox[1], J. Pettigrew[1], M. D. MacNeil[2], and S. L. Rodriguez Zas[1], *[2]University of Illinois, Urbana, [2]Delta G, Miles City, MT.*

Four boar fertility traits: semen volume (VOL, mL), semen concentration (CON, x10^3/mm^3), progressive motion of spermatozoa (MOT, %), and abnormal spermatozoa (ABN, %) provide complementary information about boar fertility. It is now feasible to include these traits in genetic improvement programs. However, there is limited information on the genetic and economic parameters necessary to assess the impact of selection for these traits. Objectives of this study were to estimate economic weights for these traits and to evaluate genetic gain that results from including them in a three-tier, three-way crossbreeding scheme (maternal nucleus lines A and B and paternal nucleus line C). Three cases were simulated in ZPLAN. Case I (baseline case) encompassed genetic selection for number of pigs born alive (NBA), litter birth weight (LBW), adjusted 21-d litter weight (A21), number at 21 d (N21), days to 113.5 kg (D113), backfat (BF), average daily gain (ADG), feed efficiency (FE), and lean carcass % (LEAN). Case II included Case I and a novel fertility indicator called DOSES that combines the four boar fertility traits (VOL * CON/1000) * (MOT/100 * (1 − (ABN/100))/(number of spermatozoa per dose). Case III included Case I and the four boar fertility traits individually. Estimated economic weights represent the net economic gain per unit of genetic improvement in VOL, CON, MOT, ABN, and DOSES ranged from 0.21 to 1.44 $/ml, 0.12 to 0.83 $/x$10^3$/$mm^3$, 0.61 to 12.66 $/%, -0.53 to -10.88 $/%, and 2.01 to 41.43%/dose as number of semen collections per week was reduced from 7 to 1. Average genetic gains remained stable for the maternal traits (NBA, LBW, A21, N21) in Case II and III, relative to Case I. Genetic gains in Cases II and III relative to Case I dropped by 59.2% and 25.8% (BF), 50% and 50% (FE), and 84.4% and 59.4% (LEAN), respectively. The relative economic weights decreased in Case II and III relative to I by 21% and 15% (line A), 18% and 12% (line B) and 32% and 23% (line C), respectively. Selection including the four boar fertility traits separately (Case III) was preferable to using one combined indicator (Case II) by enabling genetic gains in these traits without compromising the genetic gains in the maternal traits.

Key Words: boar fertility traits, economic weights, three-way crossbreeding scheme

0171 A genome-wide association study for egg shell strength in the genome of brown-egg layers. R. A. Ghebrewold[*1,2], M. Heidaritabar[1], A. Vereijken[3], B. J. Ducro[4], and J. W. M. Bastiaansen[4], *[1]Wageningen University, Wageningen, Netherlands, [2]Norwegian University of Life Sciences, Ås, Norway, [3]Hendrix Genetics, Boxmeer, Netherlands, [4]Animal Breeding and Genomics Centre, Wageningen University, Wageningen, Netherlands.*

Egg shell quality is important for commercial egg production. The objective of this study was to identify single nucleotide polymorphisms (SNPs) that are significantly associated with egg shell strength using either own phenotype or deregressed estimated breeding values (DEBV) in brown-egg laying chickens. In this study egg shell strength data were available for 8113 purebred line chickens, of which 2220 had 60k SNP genotype data. Genetic background of shell strength was confirmed by a heritability estimate of 0.29 (SE = 0.03) from this data. The number of chickens with both genotypes and phenotype was 650. Three genome wide association analyses (GWAS) were performed. Single SNP regression (SSR) was used to estimate the SNP effects. The first GWAS analysis was performed on 650 chickens and the model for SSR used own phenotype as the response variable and identified no significant associations (FDR $\leq$ 0.05). To increase the statistical power, DEBV, with their weights, were used as the response variable for two additional association analyses. Chickens with reliabilities of DEBV less than 0.05 were removed from the data set, resulting in 1429 chickens and 36,103 SNPs. In the second GWAS study, we found two significant SNP (FDR $\leq$ 0.05) associated with egg shell strength on GGA1 and GGA2. The third GWAS analysis was performed with a more stringent data filtering, only chickens with reliabilities of DEBV greater than 0.08 were kept (N = 1147). With the more stringent filtering, no significant SNP associations were found (FDR $\leq$ 0.05). Less stringent data filtering can lead to more significant results, probably due to higher power from including more animals, but could also indicate false positive results from including unreliable data points. In addition, GWAS analysis with DEBV as phenotypes may not be a simple solution that works well in any species. The utility of DEBV for GWAS in chickens may be smaller because more information comes from half and full sib families in comparison to for instance cattle.

Key Words: egg shell strength, GWAS, deregression

0172 The identification of a putative mutation for SLICK hair coat in Senepol cattle.

T. S. Sonstegard[*1], D. Bickhart[2], H. J. Huson[3], A. Landaeta[4], L. R. Porto-Neto[5], A. Reverter-Gomez[6], W. Barendse[7], D. J. Null[8], M. P. Morales[9], P. J. Hansen[10], D. Serdal[11], J. F. Garcia[12], R. W. Godfrey[13], and C. P. Van Tassell[1], *[1]USDA, ARS, BFGL, Beltsville, MD, [2]USDA-ARS-AIPL, Beltsville, MD, [3]Cornell University, Ithaca, NY, [4]Universidad del Zulia, Maracaibo, Venezuela, [5]CSIRO Food Futures Flagship, Brisbane, Australia, [6]Food Futures Flagship, CSIRO Animal, Foodand Health Sciences, Brisbane, Australia, [7]CSIRO Animal, Health and Food Science, St. Lucia, Australia, [8]Animal Improvement Programs Laboratory, Agricultural Research Service, United States Department of Agriculture, Beltsville, MD, [9]University of Puerto Rico, Mayaguez, [10]Department of Animal Sciences, University of Florida, Gainesville, [11]University of Florida, Gainesville, [12]Faculdade de Medicina Veterinária de Araçatuba, Univ Estadual Paulista, Araçatuba, Brazil, [13]University of the Virgin Islands, St Croix, US Virgin Islands.*

The slick hair coat (SLICK) is a dominantly inherited trait typically associated with tropically adapted, Criollo-derived cattle breeds. The trait is of interest relative to climate change, due to its association with improved thermo-tolerance and subsequent increased productivity. The goal of this work was to identify the mutation underlying the *SLICK* locus, which was previously mapped to a 4 cM region on chromosome (Chr) 20. To refine this map position, BovineHD genotypes were generated from a sampling (N = 195 animals) of Senepol, Carora, Romosinuano, three additional slick-haired cross-bred lineages and a group of non-slick ancestral breeds. Genome-wide association analysis narrowed the SLICK locus to a 0.8Mb (37.7-38.5 Mbp UMD 3.1) consensus region, which contains *SKP2* and *SPEF2* as possible candidate genes. Three specific haplotype patterns were identified in slick individuals, all with zero frequency in non-slick individuals. In an attempt to identify candidate causative mutations in this region, whole genome re-sequencing was completed for one Romosinuano and five Senepol animals. SNP discovery and annotation analyses revealed a putative causative polymorphism within *prolactin receptor* (*PRLR*), which would truncate an encoded domain involved in JAK/STAT5 signaling. Validation testing of this SNP and 37 others was done across a DNA panel (N = 466) that included representation from five SLICK and seven non-SLICK breeds. The results strongly suggest the frameshift mutation in *PRLR* is the causative mutation underlying SLICK in Senepol and some Romosinuano cattle. However, no associations between this SNP and SLICK animals from Limonero and Carora breeds were found. This information along with accompanying population structure information supports potentially two independent SLICK mutations, one common to Senepol and Romosinuano and another in Limonero and Carora.

Key Words: slick hair coat, cattle, prolactin receptor

0173 Genomic selection of Nili-Ravi buffalo.

M. Moaeen-ud-Din[*1], G. Bilal[1], and M. S. Khan[2], *[1]PMAS-Arid Agriculture University, Rawalpindi, Pakistan, [2]University of Agriculture, Faisalabad, Pakistan.*

Among three well-documented breeds of buffalo dairy breeds in Pakistan, Nili-Ravi is the best milk producer owing to its characteristic of disease and parasitic resistance, and a better convertor of roughages into useful products than cattle. A selection program to enhance the genetic potential for milk production of Nili-Ravi using progeny testing program is going on. Traditional progeny testing program has made a remarkable improvement in the genetic potential of dairy cattle in the developed world. However, this program faces severe implementation issues in buffalo improvement due to limitation of resources and basic infrastructure. Simulated studies have shown the potential of genomic selection in shortening generation interval and increasing the accuracy of selection (especially young bulls) that can bring a relatively rapid genetic improvement. The current study intends to explore the application of genomic selection in a typical buffalo breeding perspective using Nili-Ravi in Pakistan as an example. The assumed size of the training population for genomic selection was 15,860 present with BRI, Pattoki. Our calculations indicated that genomic selection can reduce the generation intervals in the male to male selection pathway from 9.5 yr down to 3.3 yr. It can result in almost 2 times increase in response to selection compared to that in a progeny testing program. Furthermore, it reduced the costs of proving bulls by 88%. The present study suggests the initiation of the program of genomic selection for Nili-Ravi in Pakistan and may serve as an example for other developing countries. The findings of the current study may encourage researchers and policymakers to use genomic selection for improvement in the productivity of dairy cattle of developing countries.

Key Words: developing country, genomic selection, Nili-Ravi buffalo

BREEDING AND GENETICS: APPLICATIONS AND METHODS— MOLECULAR BIOLOGY

0174 Variation in toll-like receptor genes and susceptibility to clinical mastitis in Holstein cows. C. M. Seabury[1], K. N. Galvao[2], K. Lager[3], and P. J. Pinedo[*4], *[1]Department of Veterinary Pathobiology, College of Veterinary Medicine & Biomedical Sciences, Texas A&M University System, College Station, [2]Department of Large Animal Clinical Sciences and D. H. Barron Reproductive and Perinatal Biology Research Program, College of Veterinary Medicine, University of Florida, Gainesville, [3]Iowa State University, Extension and Outreach, Ames, [4]Texas A&M AgriLife Research, Amarillo.*

Toll-like receptor proteins (TLRs) recognize conserved pathogen-associated molecular patterns (PAMPS) and initiate signaling pathways that coordinate the innate immune response. The primary objective of this study was to investigate potential associations between bovine single nucleotide polymorphisms (SNPs) and insertion-deletion (indel) mutations occurring in 7 bovine *TLR* genes (*TLR*s 1, 2, 4, 5, 6, 9, and 10) and clinical mastitis (CM) in dairy cows. Clinical mastitis cases were diagnosed by herd personnel in the milking parlor if milk from one or more quarters was abnormal in color, viscosity, or consistency, with or without accompanying heat, pain, redness, or swelling of the quarter, or with generalized illness, and all treatments were recorded in the on-farm software. Cows were considered as cases if they had at least two CM episodes in the current lactation with the first case occurring within the first 100 d after calving. Cows were included in the control group if they had no CM events during the complete lactation. Each case was matched with 3 control herd-mates in the same parity and with a calving date within 2 mo relative to the case cow. The final study population consisted of 686 Holstein cows (269 primiparae; 417 multiparae) in three farms located in Florida and Texas, including 510 cases and 176 controls. Custom allele-specific genotyping assays derived from multiple bovine *TLR* sequencing studies were utilized. Genotypes for 110 loci (SNPs and indels) that are known to be variable in domestic cattle were determined, resulting in 46 monomorphic loci and 64 loci with two alleles. Collectively, 35 loci did not meet our case-control inclusion criterion for minor allele frequency (MAF $\geq$ 0.10). The association between specific *TLR* genotypes and CM was evaluated by logistic regression with evaluation and correction for potentially confounding variables including: year and season of calving; parity; ME 305 d milk yield; and farm. Overall, five SNPs (*TLR2, TLR9*) produced uncorrected *P*-values $\leq$ 0.05 with respect to CM; four of these SNP associations (3 in *TLR2*, 1 in *TLR9*) endured corrections for multiple testing (*P*-values $\leq$ 0.05). Several confounding variables including year and season of calving, and milk yield remained significant after correction for multiple testing. Our analysis of these data suggests that naturally occurring bovine *TLR2* and *TLR9* variation may potentially elicit tangible effects on udder health in Holstein cows.

Key Words: mastitis, toll-like receptors, candidate gene

0175 Experimental intramammary challenge with *Staphylococcus chromogenes* in dairy heifers with specific *CXCR1* genotypes. J. Verbeke*, K. Piccart, S. Piepers, M. Van Poucke, L. Peelman, and S. De Vliegher, *Ghent University, Ghent, Belgium.*

The *CXCR1* gene encodes one of the two receptors for interleukin 8 (IL-8), named chemokine (C-X-C motif) receptor 1 (CXCR1). Foregoing experiments suggested that single nucleotide polymorphism (SNP) *CXCR1*c.980A > G (rs43323012) influences mammary gland immunity and mastitis resistance. To further investigate these findings, 8 mid-lactating Holstein heifers were challenged intramammarily with coagulase-negative staphylococci (CNS) species. Four heifers had genotype c.980AG and 4 heifers had genotype c.980GG. Each heifer was inoculated with 1.0×10^6 colony-forming units (CFU) of *Staphylococcus chromogenes*, originating from a chronically infected quarter. The quarter bacterial count (qBC) and quarter milk somatic cell count (qSCC) were measured at 4, 6, 9, 12, 18, 24, 28, 32, 36, 48, 54, 60, 72, and 78h post inoculation. Additionally, quarter milk production (qMP) was recorded at 12, 24, 36, 48, 60, and 72h post inoculation. Differences in the three outcome variables between c.980AG and c.980GG heifers were analyzed using linear mixed regression models with heifer as random effect and genotype, sampling time and their interaction as fixed effects. None of the quarters/heifers showed symptoms of clinical mastitis. All heifers cleared the inoculated *S. chromogenes* before the end of the trial. No significant differences in qBC and qMP were observed between c.980AG and c.980GG heifers. However, the change of qSCC over time tended to be associated with the heifer's genotype (interaction sampling time × genotype: $P = 0.06$). The increase in qSCC was more pronounced and persistent in c.980AG heifers compared to c.980GG heifers. In conclusion, increase in qSCC following an intramammary challenge with *S. chromogenes* tended to be associated with SNP *CXCR1*c.980A > G. Heifers expressing genotype c.980AG showed a higher immune response than heifers expressing genotype c.980GG.

Key Words: *CXCR1* genotype, *Staphylococcus chromogenes*, intramammary challenge

0176 Association of *CXCR1* gene polymorphisms with incidence rate of clinical mastitis, somatic cell count, and milk production in dairy cattle.
J. Verbeke*, M. Van Poucke, L. Peelman, S. Piepers, and S. De Vliegher, *Ghent University, Ghent, Belgium*.

The objective of this study was to analyze associations between single nucleotide polymorphisms (SNPs) in the *CXCR1* gene (NCBI Gene ID: 100125580), potential genetic markers for mastitis resistance, and the incidence rate of clinical mastitis (IRCM), test-day somatic cell count (SCC) and test-day milk production (MP). Clinical mastitis was monitored on 50 randomly selected Flemish dairy herds for a period of 1 yr. Each case was sampled and cultured according to NMC (National Mastitis Council) guidelines. Incidence rate of clinical mastitis (cases/days at risk) was calculated independently of the culture results and for *Staphylococcus aureus*, *Streptococcus uberis*, *Streptococcus dysgalactiae*, and *Escherichia coli*, separately. Dairy herd improvement records including SCC and MP were available on 32 herds. A fluorescent multiprobe PCR assay was designed to genotype simultaneously SNP *CXCR1*c.735C > G (rs208795699) and SNP *CXCR1*c.980A > G (rs43323012). In total, 3107 cows were genotyped. Associations between the SNP and (pathogen-specific) IRCM were analyzed using mixed Poisson regression models. Linear mixed regression models were fit to test associations between the SNP and SCC and MP. In total, 681 CM samples were analyzed with *S. uberis* (23% of the culture positive samples), *E. coli* (20%), *S. aureus* (10%), and *S. dysgalactiae* (9%) being the most frequently isolated pathogens. Both SNPs were significantly associated with MP ($P < 0.05$) but not with (pathogen specific) IRCM or SCC. Milk production was higher in c.735GG cows (28.6 kg/day, $n = 571$) compared to c.735CG (28.1 kg/day, $n = 1043$) and c.735CC (28.0 kg/day, $n = 516$) cows. Additionally, MP was higher in c.980GG cows (28.4 kg/day, $n = 1277$) compared to c.980AG cows (27.9 kg/day, $n = 743$). In conclusion, SNP *CXCR1*c.735C > G and *CXCR1*c.980A > G were not associated with the studied udder health traits but were with test-day MP.

Key Words: *CXCR1* genotype, udder health, milk production

0177 *Calpastatin* and μ-*calpain* differ in their control of genotype specific residual variance of beef tenderness in Angus and MARC III steers.
R. G. Tait, Jr.*[1], S. D. Shackelford[2], T. L. Wheeler[2], D. A. King[2], E. Casas[3], T. P. L. Smith[1], and G. L. Bennett[1], *[1]USDA, ARS, U.S. Meat Animal Research Center, Clay Center, NE, [2]USDA/ARS, Clay Center, NE, [3]USDA. ARS, National Animal Disease Center, Ames, IA*.

Genotype variant effects of *calpastatin* (*CAST*) and μ-*calpain* (*CAPN1*) on mean beef tenderness have been widely characterized. We have tested whether these genetic variants also control residual (non-genetic) variation, and subsequently total phenotypic variation, of tenderness. Observation of rare genotypes is important for understanding the role of these genetic markers on beef tenderness. Two populations at USMARC (Angus and MARC III) were subjected to marker-assisted selection for multiple years to equalize allele (*CAST*) and haplotype (*CAPN1*; CAPN1_316 with CAPN1_4751) frequencies. Within each population, analyses were conducted for 14-d slice shear force (SSF) in steers (Angus, $n = 199$; MARC III, $n = 254$) to estimate genotypic effect size, mode of inheritance, and polygenic effects utilizing 5-generation pedigrees. Beyond the traditional analyses with a single residual variance (Angus, $\sigma_e = 1.79$ kg; MARC III, $\sigma_e = 3.58$ kg), *CAST* and *CAPN1* genotype specific residual variance models were tested. In both populations, *CAST* genotype specific residual variance models fit significantly better (Angus, $P < 0.001$; MARC III, $P < 0.001$) than single residual variance models and were progressive in their effect. Across populations, *CAST* genotype specific residual variance models identified the homozygous tender genotype as having the smallest residual variance (Angus, $\sigma_{e\text{-}TT} = 1.22$ kg; MARC III, $\sigma_{e\text{-}TT} = 2.54$ kg), the heterozygous genotype had intermediate residual variance (Angus, $\sigma_{e\text{-}CT} = 1.99$ kg; MARC III, $\sigma_{e\text{-}CT} = 3.98$ kg), and the homozygous tough genotype had the largest residual variance (Angus, $\sigma_{e\text{-}CC} = 2.82$ kg; MARC III $\sigma_{e\text{-}CC} = 4.86$ kg). In comparison, *CAPN1* genotype specific residual variance models were not as well supported (Angus, $P = 0.05$; MARC III, $P = 0.03$) and in both populations the effects were not progressive, with a heterozygous *CAPN1* genotype (having an intermediate effect on mean) having the smallest residual variance. Effects of *CAST* and *CAPN1* on mean tenderness were maintained under all genotype specific residual variance analyses. These results indicate that beyond changes in the mean, *CAST* also influences phenotypic variation in beef tenderness, which may be important for management and marketing of beef. USDA is an equal opportunity provider and employer.

Key Words: carcass quality, marker effects, tenderness

0178 Investigation of polymorphisms at the *MUC4*, *MUC13*, *MUC20*, and *TFRC* candidate genes for *F4ab/ac* resistance in South African pig populations.
N. S. Chaora*, *Agricultural Research Council, Pretoria, South Africa*.

Selection for *E. coli* F4*ab/ac* resistance has become common due to the increasing resistance of the bacteria to antibiotics. Four candidate genes were studied in three South African breeds, Exotic (Large White, Landrace and Duroc), indigenous and crossbred (Exotic × indigenous), to identify polymorphisms conferring resistance to *E. coli* F4*ab/ac*. A total of 225 pigs aged 3-12 wk were genotyped to target restriction sites in *MUC4*, *MUC13*, *MUC20* and *TFRC* candidate genes. Four polymorphisms of c.8227G > C for *MUC4,* c.576C > T for

MUC13, g.191C > T for *MUC20* and c.291C > T for *TFRC* were detected. The susceptible allele *C* was close to fixation at over 90% in all three breeds for the *TFRC* and *MUC13* loci and there was a genic and genotypic significant difference ($P < 0.05$) amongst breeds for the *TFRC* loci. The resistant *TT* genotype was found in less than 2% of the entire population for the *TFRC* locus and was not found in any pigs for the *MUC13* locus. Both *TFRC* and *MUC13* were not polymorphic in the studied population. The *MUC4* and *MUC20* genes were polymorphic in the population. The resistant alleles *G* for *MUC4* and *C* for *MUC20* were present in the population with the highest frequency observed in the Exotic pigs. There was a significant difference in genotypic distribution amongst breeds at the *MUC20* and *MUC4* loci ($P < 0.05$). An excess of homozygotes in *TFRC* and *MUC20* was observed, leading to a deviation from HWE in the Exotic pigs at these loci. All three breeds were in HWE at the *MUC4* loci although an excess in heterozygotes was observed. The subpopulations at the *TFRC*, *MUC13* and *MUC20* loci were inbred and those at the *MUC4* locus were outbred. There was no significant linkage disequilibrium observed amongst the loci analyzed. The results showed that *MUC4* and *MUC20* were informative and the presence of the resistant alleles makes it possible to use them as markers for selection against susceptibility to F4 *E. coli*.

Key Words: pigs, polymorphisms, *E. coli* F4

0179 Buffalo and cattle sequence diversity and molecular evolution. M. Moaeen-ud-Din* and G. Bilal, *PMAS-Arid Agriculture University, Rawalpindi, Pakistan.*

Identification of genes of importance regarding production traits in buffalo is impaired by a paucity of genomic resources although buffalo genome is sequenced. An alternative to fill this gap is to exploit the plenty of data available for cow, including SNPchips. The cross-species application of comparative genomics tools, i.e., microarrays and comparative sequencing, to identify single nucleotide polymorphisms are potential gear to investigate the buffalo genome. However, both tools are dependent on nucleotide sequences similarity between the two species. Therefore, the objective of this study was to explicate the sequence diversity between cattle and buffalo for comprehending buffalo genome using available cattle genomic resources. In this study, gene diversity between buffalo and cattle was determined by applying 86 gene orthologues taken from NCBI consisting of over 273 kb of aligned sequences using MEGA program V6.0. Results for relative rate test were assessed with the chi-squared test using all available sites (over 273 kb) using MEGA program V6.0. There was approximately 3% difference in all genes in terms of nucleotide diversity; and 0.267 ± 0.134 in amino acids, indicating the possibility for successfully using cross-species strategies for genomic studies. There were significantly higher non synonymous substitutions both in cattle and buffalo. This higher rate of non-synonymous substitutions at similar level in buffalo and cattle indicates a similar positive selection pressure in both species. Results for relative rate test revealed no significant difference in unique mutations between cattle and buffalo lineages at synonymous sites. However, there was a significant difference in unique mutations for non synonymous sites. This indicated that the mutagenic process that generates substitutional mutation is taking place at approximately the same rate at silent sites in cattle and buffalo. However, there was greater variation in mutation rates at non-synonymous sites in both species. Moreover, despite common ancestry, our results indicate a different divergent time among genes of cattle and buffalo. The present study, for the first time, revealed that variable rates of molecular evolution may be present between cattle and buffalo suggesting usefulness in comparative genomics analysis.

Key Words: buffalo, cattle, gene diversity, molecular evolution

COMPANION ANIMALS:
COMPANION ANIMAL NUTRITION AND PET FOOD PROCESSING

0180 [Withdrawn]

0181 Indirect calorimetry, real-time interstitial glucose monitoring, and blood sampling to determine effects of low, medium, and high glycemic index cat foods. K. D. Berendt*[1], A. K. Shoveller[2], and R. T. Zijlstra[1], [1]*University of Alberta, Edmonton, AB, Canada,* [2]*Procter & Gamble Pet Care, Mason, OH.*

The amount and source of dietary starch affects glucose and insulin responses and contributes to dietary glycemic index (GI) in omnivorous monogastrics. However, limited information exists for GI in carnivorous monogastrics such as cats. Thus, the objective was to study a range in dietary GI in relation to indirect calorimetry and postprandial serum glucose and insulin and interstitial glucose. We used 19 domestic shorthair cats in an incomplete replicated 3 × 3 Latin squares for 19 observations per diet. Initial BW averaged 4.9 kg and ranged from 3.4 to 7.1 kg. Three premium cat diets varying in GI based on ingredient composition (chicken & rice, chicken & chicken by-product meal, and turkey & chicken for high, medium, and low GI respectively) and starch content (36.8, 30.7, and 23.6%, respectively) were fed. Diets contained 38 & 23%, 36 & 22%, and 42 & 16% CP and ether extract, respectively. The respiratory quotient (RQ) decreased ($P < 0.001$) with decreasing GI (0.78, 0.77, and 0.76 for high, medium and low GI, respectively), indicating increased lipid oxidation. Daily resting energy expenditure (REE) did not differ among diets. Postprandial (22 h) fat oxidation was inversely related to GI (0.64, 0.68, and 0.69 g/h for high, medium and low GI, respectively; $P < 0.05$). Postprandial carbohydrate oxidation decreased with reducing GI (0.61, 0.52, and 0.46 g/h for high, medium and low GI, respectively; $P < 0.001$). Postprandial (20 h) interstitial glucose decreased with reducing GI (73.4, 64.4, and 59.7 mg/dL d^{-1} for high, medium and low GI, respectively; $P < 0.05$). Postprandial (10 h) serum glucose did not differ among diets and did not peak postprandially followed by return to baseline as expected based on data from responses of omnivorous monogastrics. Interstitial glucose may be more sensitive than a limited number of sequential blood samples to study starch metabolism in cats. Postprandial serum insulin was greatest ($P < 0.05$) for the high GI diet and lowest for the medium GI diet. In conclusion, responses of cats to changes in dietary starch content are unique, i.e., more prolonged and less pronounced than in humans or dogs.

Key Words: glycemic index, calorimetry, cat

0182 The effect of extrusion and elevated storage temperatures on vitamin retention in pet food. A. K. Mooney*, *Kansas State University, Manhattan.*

Little research has been published in recent years regarding the magnitude of vitamin losses through extrusion manufacturing and storage of pet food. The matrixes of pet diets have changed dramatically within the past twenty years since vitamin degradation was last published. Therefore the objective of our research was to determine the effects of processing conditions and dietary protein content on vitamin retention (vitamin A, vitamin D_3, vitamin E, folic acid and thiamine) during extrusion and drying and the subsequent effect during storage at elevated temperatures. Three diets differing in protein (21.7, 25, and 30% CP; Low, Medium, and High, respectively) were produced. Diets were extruded at 350 and 450 rpm screw speed on a Wenger X-20 single screw extruder (Wenger Mfg, Sabetha, KS) and dried at 104°C for 6 min at each pass or 127°C for 10 min at each pass in a Wenger (Wenger Mfg, Sabetha, KS) triple pass dryer. Samples from each treatment were analyzed immediately following production. Without current established criterion for accelerated shelf life studies of pet food, conditions by industry laboratories were practiced using 50°C and 75% relative humidity for 3, 6, 12, and 18 wk before vitamin analysis. Retention of all vitamins evaluated in this study was not affected ($P > 0.05$) by extruder screw speed or dryer conditions. As time in storage (50°C) increased through 3, 6, 12, and 18 wk vitamin A ($P < 0.05$; 153,708, 95,542, 62,491, 21,713, and 6689 IU/kg, respectively), vitamin D_3 ($P < 0.05$; 6956, 4652, 3572, 1824, and 1421 IU/kg, respectively), vitamin E ($P < 0.05$; 855, 970, 834, 837, and 803 mg/kg, respectively), folic acid ($P < 0.05$; 1.75, 1.81, 2.37, 1.45, and 0.98 mg/kg, respectively), and thiamine ($P < 0.05$; 22.9, 19.7, 16.1, 7.4, and 3.3 mg/kg, respectively) concentrations decreased. These results suggest that the processing parameters in this study had little effect on vitamin losses; but, elevated temperature during storage for 18 wk could reduce vitamin content from initial by 95.65, 79.57, 6.08, 44.00, and 85.86% for vitamin A, vitamin D_3, vitamin E, folic acid and thiamine, respectively. Vitamin fortification of extruded pet diets must take into account these changes to avoid deficiency diseases.

Key Words: vitamin stability, effects of thermal processing, vitamin retention

0183 Effects of processing on water soluble B-vitamins in a canned cat diet. S. DeNoya*, G. Aldrich, and C. K. Jones, *Kansas State University, Manhattan.*

There has been very little research published regarding the degradation of B-vitamins in a canned cat food. The objectives of these experiments were to evaluate the effect of batter temperature and moisture, or retort-cooking time on B-vitamin retention. In Exp. 1, cat food was produced at a batter temperature of 60°C and moistures of 65, 75, and 85%. In

Exp. 2, cat food was produced at a batter moisture of 78% and temperatures of 50, 60, and 70°C. All foods were held in the retort (121°C) for 45, 60, and 90 min. In Exp. 1, (n = 3) thiamine concentration decreased (P = 0.0031; 5.11, 4.30, and 2.96 mg/kg for 45, 60, and 90 min, respectively) as time in the retort increased. As batter moisture decreased, thiamine (P = 0.0072; 3.57,3.67, and 5.12 mg/kg for 65,75, and 85% moisture, respectively), riboflavin (P = 0.0320; 10.41,9.89, and 13.00 mg/kg for 65, 75, and 85% moisture, respectively), pantothenic acid (P = 0.0240; 46.32, 49.52, and 67.31 mg/kg for 65, 75, and 85% moisture, respectively), and vitamin B-12 (P = 0.0004; 0.0220, 0.0180, and 0.0400 mg/kg for 65, 75, 85% moisture, respectively) concentration decreased. In Exp. 2, (n = 3) thiamin (P = 0.0002; 5.11, 3.86, and 2.53 mg/kg for 45, 60, and 90 min, respectively), and niacin (P = 0.0170; 228.51, 200.51 and 202.60 mg/kg for 45, 60, and 90 min respectively) decreased as retort time increased. Pantothenic acid (P = 0.0360) concentration initially increased slightly at 60 min, but returned back to its initial level by 90 min. Folic Acid declined (P = 0.0330; 0.85, 0.83, and 0.03 mg/kg for 50, 60, and 70°C, respectively) as batter temperatures increased. In both experiments, thiamine and folic acid losses exceeded 90%, while vitamin B12 losses exceeded 50%. Fortification of canned cat food diets must take these substantial losses into account to avoid nutrient deficiencies.

Key Words: B-Vitamins, pet food, thermal processing

0184 Feeding frequency and dietary water content affect voluntary physical activity in young lean adult female cats. M. R. C. de Godoy*[1], K. Ochi[2], L. F. de Oliveira Mateus[3], A. C. C. de Justino[3], and K. S. Swanson[1,4,5], *[1]Department of Animal Sciences, University of Illinois, Urbana, [2]Nippon Pet Foods Co. Ltd, Tokyo, Japan, [3]Department of Animal Sciences University of São Paulo State, Jaboticabal, Brazil, [4]Division of Nutritional Sciences, Urbana, IL, [5]Department of Veterinary Clinical Medicine, Urbana, IL.*

Obesity is the most common form of malnutrition in the pet population in western countries. Approximately 58.3% of cats are considered overweight or obese in the U. S. It is imperative that in conjunction with the development of effective strategies to manage obesity, preventive measurements for this disease are also exploited. Therefore, the objective of this study was to investigate whether increased dietary water content and feeding frequency increased voluntary physical activity of young lean adult female cats. A replicated 4 × 4 Latin square design with a 2 × 2 factorial treatment arrangement (feeding frequency and water content) was used. The four treatments consisted of: 1) One meal daily dry (without added water); 2) One meal daily wet (dry diet with added water to reach 70% moisture); 3) Four meals daily dry; and 4) Four meals daily wet. Eight healthy adult, lean, intact, young, female domestic shorthair cats were used in this experiment. Voluntary physical activity was evaluated using Actical activity monitors placed on collars and worn around the cat's neck for the last 7 d of each experimental period of 14 d. Food anticipatory activity (FAA) was calculated based on 2h before feeding periods and expressed as a percentage the total daily voluntary physical activity. The interaction between feeding frequency and water content was not statistically significant (P > 0.05). Increased feeding frequency (four vs. one meal daily) resulted in greater average daily activity (P = 0.0147), activity during the light period (P = 0.0023), and light:dark activity ratio (P = 0.0002). In contrast, physical activity during the dark period was not altered by feeding frequency (P > 0.05). Cats fed four meals daily had increased afternoon FAA (P = 0.0029) compared with cats fed once daily. Dietary water content did not affect any measure of activity. Increased feeding frequency is an effective strategy to increase the voluntary physical activity of cats. Thus, it may assist in the prevention and management of obesity.

Key Words: feline, meal frequency and moisture content, physical activity

0185 Effects of graded dietary resistant starch concentrations on apparent total tract macronutrient digestibility, fecal characteristics, and fecal fermentative end-products in healthy adult dogs. A. N. Beloshapka* and K. S. Swanson, *Department of Animal Sciences, University of Illinois, Urbana.*

Resistant starch (RS) is fermentable by gut microbiota and effectively modulates fecal short-chain fatty acid (SCFA) concentrations in pigs, mice, and humans. Resistant starch may have similar beneficial effects on the canine gut; however, the dose of a single source of RS that is effective in manipulating fecal fermentative end-products but does not negatively affect stool quality has yet to be determined. Thus, the objective of this study was to evaluate the effects of 0, 1, 2, 3, and 4% dietary high-amylose maize cornstarch (HI-MAIZE 260; RS) on apparent total tract macronutrient digestibility, fecal characteristics, and fecal fermentative end-product concentrations in healthy adult dogs. An incomplete Latin square design was used, with each treatment period lasting 21 d (d0-17 adaptation; d18-21 fresh and total fecal collection) and each dog serving as its own control. Seven dogs (mean age = 5.3 yr; mean BW = 20 kg) were randomly allotted to one of five treatments, which were formulated to be iso-energetic and consisted of graded amounts of 100% amylopectin cornstarch, RS, and cellulose, and fed as a top dressing on the food each day. All dogs were fed the same amount of a basal diet throughout the study and fresh water was offered ad libitum. Data were evaluated for linear and quadratic effects using SAS. Because the RS used in this study is approximately 40% digestible and 60% indigestible starch, the dogs received the following amounts of indigestible starch daily: 0% = 0 g; 1% = 1.8 g; 2% = 3.6 g; 3% =

5.4 g; and 4% = 7.2 g. Dry matter, organic matter, crude protein, fat, and gross energy digestibilities were linearly decreased ($P < 0.05$) in dogs with increased consumption of RS. Fecal output was linearly increased ($P < 0.05$) in dogs with increased consumption of RS. Fresh fecal pH was linearly decreased ($P < 0.05$) in dogs with increased consumption of RS. Fecal scores and fecal fermentative end-product concentrations, including ammonia, SCFA, branched-chain fatty acids, phenols, and indoles, were not affected by the consumption of RS. The results observed in this study compared to previous studies performed in other animal models and humans seem to indicate that RS is slowly fermentable in dogs and may not greatly impact large bowel health in this species.

Key Words: resistant starch; canine; digestibility

0186 Evaluation of common analysis methods for oxidation in rendered protein meals used to produce pet foods. M. Gray*, G. Aldrich, and C. K. Jones, *Kansas State University, Manhattan.*

A significant amount of rendered protein meal is used in pet food to meet the pets' dietary protein and fat needs. These protein meals contain approximately 15-20% fat, which can oxidize and lead to unusable material. Peroxide value (PV) is a common method used to evaluate oxidation in commercial proteins, but it has been criticized as inconsistent and imprecise. Therefore, our objectives were to evaluate alternative methods to measure fat quality in rendered protein meals and to compare the results among different animal sources and rendering plants. It was hypothesized that PV was an inconsistent and unrepresentative method of analysis for measuring fat stability for rendered protein meals. In this experiment, samples of five chicken byproduct meals (CBPM) from each of three locations, and five beef meat and bone meals (BMBM) from each of two locations were evaluated. Samples were analyzed for proximate constituents, anisidine value (AV), thiobarbituric acid reactive substances (TBARS), PV via titration by two laboratories and PV via rapid method (SafTest; peroxysafe). Fat content differed among plants ($P < 0.0001$; BMBM = 8.44 vs. 11.87% and CBPM = 13.24 vs. 15.11 vs. 16.59%) and when aggregated into protein meal type, the ash concentration was greater for BMBM and protein concentration greater for CBPM ($P < 0.0001$). Again, for compiled least square means between the protein meal types, the peroxide values for the BMBM and CBPM were 10.42 and 58.08 meq/kg, respectively from laboratory 1; 4.65 and 3.01 meq/kg, respectively from laboratory 2; and 11.52 and 42.96 meq/kg, respectively from the rapid method test. There was a direct correlation ($r = 0.98$) between PV titration results from laboratory 1 data and the rapid method, but not with titration results from laboratory 2 ($r = 0.46$). This variation among labs is consistent with the anecdotal field evidence and our hypothesis. As expected, the PV from laboratory 1 did not correlate to the AV ($r = 0.61$); a measure of secondary oxidation products. Oxidation indicated by TBARS differed among both protein meal and plant ($P < 0.0001$). Our data corroborate the inconsistencies noted from commercial quality control laboratories. Combined with the results from the AV and TBARS, there is a clear need for further research to create a more accurate and precise analytical method for fat oxidation in rendered protein meals.

Key Words: oxidation, rendered protein meal, pet food

0187 Broken beans (*Phaseolus vulgaris*) use on extruded diets for cats. B. P. Neto[1], F. C. Sa[2], N. Musco[3], A. P. Maria[2], B. Agy[2], B. A. Kamimura[4], R. S. Vasconcellos[1], and A. C. Carciofi[*5], *[1]Universidade Estadual de Maringa, Maringa, Brazil, [2]Sao Paulo State University, Jaboticabal, Brazil, [3]Universitá degli Studi di Napoli Federico II, Napoli, Italy, [4]Universidade de Campinas, Campinas, Brazil, [5]Sao Paulo State University- UNESP, Jaboticabal, Brazil.*

Broken beans (BB) is the result of bean selection for human consumption, mainly composed of open seeds in good sanitary and nutritional quality, with a potential use as protein and energy source for companion animals. Beans have antinutritional factors, among them protease inhibitors (PI) and hemagglutinin (HA) that reduces the ingredient nutritional value. These factors are thermolabile, and the extrusion process used to produce kibble diets for cats may possibly inactivate them. We evaluated the inclusion of BB on extruded diets for cats, and the effect of the extrusion process on PI and HA inactivation. Thirty adult cats, with 7.6 ± 0.3 yr old and 5.0 ± 0.3 kg of BW were used. Five diets with similar composition (average: 94% DM, 30% CP, 16% fat, 2.8% crude fiber, 7% ash) were formulated for cat maintenance, presenting increasing amounts of BB: 0.0%, 7.5%, 15.0%, 22.5% and 30.0%. The BB sample presented 22.1% of CP, 1.5% of fat, 3.7% of crude fiber, and 2.9% of ash, and was included at the expense of the poultry by-product meal. Diets were extruded under similar conditions in a laboratory scaled complete extrusion system, with a single screw extruder. Samples from the mash diet and the food after the preconditioner, extruder, and dryer were collected and used to measure TI and HA. The experiment followed a complete randomized block design, with 2 blocks of 15 cats, and 3 cats per diet in each block, totaling 6 cats per diet. The blocking factor was time. The coefficients of apparent total tract digestibility and nitrogen balance was determined through total collection of feces and urine. Cats were kept in metabolism cages during 14d, and feces and urine were totally collected on the last 7d. Data were submitted to analysis of variance, and means compared by polynomial contrasts ($P < 0.05$). The extrusion process was very efficient

in inactivating the PI and HA of the BB. After the preconditioner, the activity of these compounds was reduced in 40% to 50%, after the extrusion, they were reduced more than 90%, and after the dryer their values were practically zero. Addition up to 30% BB did not change food intake, nutrient and energy digestibilities (average digestibility: DM, 81%; OM, 84%; CP, 85%; acid-hydrolyzed fat, 89%; gross energy, 86%), fecal traits (dry matter, production, and score), and nitrogen balance, suggesting that bean is a suitable ingredient for extruded diets for cats.

Key Words: co-products, protein, antinutritional factors

COMPANION ANIMALS: **COMPANION ANIMALS AND SUSTAINABILITY: TODAY'S IMPACT ON THE FUTURE**

0188 Nutritional sustainability of pet foods.

R. A. Carter*[1], P. R. Buff[1], K. S. Swanson[2], T. P. Yount[1], and J. H. Kersey[1], [1]*The Nutro Company, Franklin, TN,* [2]*Department of Animal Sciences, University of Illinois, Urbana.*

The ability to provide adequate, safe nutrition is a critical component of a food system's sustainability. Nutritional sustainability is the ability of a food system to provide sufficient energy and the amounts of essential nutrients required to maintain good health of the population without compromising the ability of future generations to meet their nutritional needs. The intention of nutritional sustainability is to advance health and nutrition in parallel to advances in food system sustainability. Nutritional sustainability can be influenced by several factors, including ingredient selection, nutrient composition, digestibility, and consumption rates of diets. The pet food system is unique in regard to sustainability because it is based largely on secondary products and tightly interlinked with livestock production and the human food system. Secondary products of the human food system vary widely in their quality and food safety. The concept of nutritional sustainability calls for the evaluation of these ingredients from a nutritional perspective, and to use ingredients with the appropriate quality and food safety to support pet health. The use of secondary products also introduces challenges to the assessment of the environmental impact of a diet. Consequently, the principles used for human food system sustainability in regard to ingredient selection or dietary nutrient composition may not directly apply to the pet food system. An additional uniqueness of the pet food system is the influence of anthropomorphism on pet owner preferences for specific pet food products. Promoting more sustainable practices from an environmental perspective may not have the greatest overall impact on sustainability because of varying penetration into the marketplace. Therefore, it is critical to balance consumer expectations and pet health considerations in advancing sustainability initiatives. The complexities of pet owner preferences introduce challenges with ingredient selection and dietary nutrient composition, given the increasing preference for ingredients that compete with the human food chain and diets that contain high concentrations of protein and animal-based products. Additionally, as the prevalence of human obesity increases, so does the prevalence of pet obesity, along with the impacts on pet health and food wastage associated with food overconsumption. Companion animals play an important role in our lives, providing a positive impact on the emotional and physical health of people with whom they have contact. Advancing the sustainability of the pet food system through nutritional sustainability is a key enabler to maintaining responsible pet ownership in the future.

Key Words: companion animal, nutrition, pet food, sustainability

0189 How sustainability influences ingredient sourcing, quality, and safety.

D. L. Meeker*, *National Renderers Association, Alexandria, VA*.

The rendering industry collects and safely processes approximately 50 billion pounds of animal byproducts each year in the U.S. Rendering plants process a variety of raw materials from animal agriculture, principally offal from slaughterhouses, but including whole animals that die on farms or in transit and other materials such as bone, feathers, and blood. By recycling these byproducts into various protein, fat and mineral products, including meat and bone meal, hydrolyzed feather meal, blood meal, and various types of animal fats and greases, the sustainability of animal agriculture is greatly enhanced. The rendering industry is conscious of its role in the prevention of disease and microbiological control while providing safe feed ingredients for livestock, poultry, aquaculture, and pets. A HACCP-based Code of Practice is followed to ensure that cooking destroys microbes, and that recontamination does not occur after the rendering process. Recently published FDA animal feed safety regulations follow the same hazard analysis and prevention concepts renderers have used for many years. The processing of otherwise low value organic matter from the livestock production and meat processing industries through rendering drastically reduces the amount of waste. If not rendered, biological materials would be deposited in landfills, burned, buried, or inappropriately dumped with large amounts of carbon dioxide, ammonia, and other compounds polluting air and water. When rendered, these products are dried, stabilized, and recycled for animal feed, energy, fertilizer, and other uses. Even though cooking these high moisture materials is an energy intensive process, for each metric ton of CO_2 produced (scope 1 emissions) by operating rendering plants, 5.68 metric tons of CO_2 are removed from the environment. The majority of rendered protein products are used as animal feed. Rendered products are especially valuable to the livestock and pet food industries because of their high protein content, digestible amino acid levels (especially lysine), mineral availability (especially calcium and phosphorous), and relatively low cost in relation to their nutrient value. Rendering facilities produce many species specific meals as well as mixed species meals, and often meet special specifications required by pet food manufacturers by devoting individual plants or processing lines to certain products. The use of these reclaimed and recycled materials in pet food is a much more sustainable model than using human grade food for pets.

Key Words: rendering, sustainability, ingredients, byproducts

0190 Sustainability of non-traditional companion animals. G. Ballam*, *Purina Animal Nutrition, St Louis, MO.*

In the next 10 yr, the changing demographics within the United States will play an important role in the diversity of food selection and agricultural practices. In addition consumer attitudes will continue to demand products that are locally grown, fresh, safe and sustainable. Changes in attitudes and purchasing behaviors over the last 10 yr are reflected in the emergence of retailers and Farmer's Markets providing a greater variety of natural and sustainable foods. The change in purchasing behavior provides an opportunity for small producers to provide sustainable and non-conventional sources of food such as specialty eggs, meats and fish, free-range or pasture-raised chickens, and artisanal cheese from goats and sheep. The entrepreneurial spirit of sustainability is not limited to food production. There is rising interest in using nutrition to increase pond and lake productivity and sustainability to meet the needs of the recreational sport fisherman. Agricultural professionals have the opportunity to provide information on nutrition, health, and management to help these enterprises develop innovative products, meet the challenges of their industry and affect their sustainability.

Key Words: non-traditional, sustainable, companion

0191 Sustainable ecosystems: Free-ranging cats and their effect on wildlife populations. S. E. Kitts-Morgan*, E. I. Parsons, and K. A. Hilburn, *Berry College, Mount Berry, GA*

Feral and domestic cats are estimated to kill billions of small mammals and birds each year. In certain areas of the world, it is not uncommon for either feral or domestic cats to have high population densities, creating concern regarding their level of hunting. Interest centers on free-ranging cats, as they roam freely and receive care and food from humans. Arguments abound regarding the presence of cats in the habitats of native small mammals and birds, and whether or not local ecosystems can sustain this predator-prey relationship. Studies have attempted to determine the effects of cats on local wildlife populations using various methods. Some research has focused on determining the home range of free-ranging cats using either radio telemetry techniques or the Global Positioning System (GPS). Because home-range size differs for each cat, we can estimate the size of an area where potential damage on local wildlife might occur. Another technique used to determine the effects of cats on wildlife includes evaluating feline scat for prey items. This is a valuable tool, as prey teeth can usually be used to identify the genus and sometimes species of the prey. Unfortunately, it is impossible to accomplish complete collections of all scat from each cat, as they usually eliminate in multiple latrine areas within their home range. Incomplete scat collections increase the difficulty of estimating the true kill rate of prey by free-ranging cats. However, scat analysis has allowed us to determine that cats receiving cat food from humans continue to hunt and at least partially consume prey. Furthermore, the prey species identified in the scat often represent native species killed and consumed by the cats. Lastly, live animal trapping is another technique that may be used to estimate the population of small mammals in an area where cats are known to reside and hunt. Along with determination of home-range size and feline scat analyses, trapping provides another tool to help estimate the effect of free-ranging cats on native wildlife populations. Free-ranging cats certainly have the potential to roam and hunt in very large areas inhabited by native small mammals and birds. It remains questionable as to whether or not local ecosystems can sustain hunting by free-ranging cats.

Key Words: cats, wildlife, hunting

0192 Future aspects and perceptions of companion animal nutrition and sustainability. K. S. Swanson*, *Department of Animal Sciences, University of Illinois, Urbana.*

With an increasing world human population and resources becoming scarce, sustainable practices are of utmost importance. The world pet population also continues to grow. Because pet foods are based largely on secondary products from the human food system and often compete with the human food and livestock feed industries for ingredients, sustainability is also an important issue for the pet food industry. Land, water, air, and waste management, species biodiversity, and energy use are key issues to consider. Although the environmental impact of an ingredient or food usually receives the most attention, one cannot ignore the social and economic factors involved, especially when it comes to pet foods. The anthropomorphism of pet dogs and cats greatly impacts the expectations and purchases of consumers and marketing strategies and products sold by pet food companies. Pet owner preferences introduce challenges in regard to ingredient selection and dietary nutrient composition, with increasing preference for ingredients that compete with the human food chain, including many high-protein, animal-based products. Research focused on pet food sustainability is seriously needed in the future. The carbon- or water-footprint comparisons of animal- vs. plant-based ingredients for human foods have received a lot of attention. However, not only are the published footprint values hotly contested, but they are only applicable to human-grade ingredients. To date, nobody has provided insight as to the footprint of secondary products, an issue that needs to be addressed to provide accurate calculations for pet foods. Further research is also needed to compare farm-raised vs. wild-caught fish, livestock raised under conventional vs. free-range systems, and ingredient processing, packaging, storage, and handling

practices, and to search for acceptable alternative protein sources. Finally, even if an ingredient source is available for use, its nutritional quality, safety, price, and marketability must also be considered. Although many challenges exist, a coordinated effort across the industry, including ingredient buyers, formulators, and nutritionists may result in a more sustainable pet food system.

Key Words: pet food, canine, feline

COMPANION ANIMALS: GEORGE C. FAHEY COMPANION ANIMAL NUTRITION SYMPOSIUM: PREPARING FUTURE COMPANION ANIMAL BIOLOGISTS

0193 Challenges in training companion animal biologists: Missing the research component, how to overcome it? J. P. McNamara*, *Washington State University, Pullman.*

The basic missions of Departments of Animal Sciences are to train leaders in endeavors related to domesticated animals and to conduct and disseminate research related to domesticated animals. For agricultural animals we have been successful and society has benefitted greatly. Yet, as a result of this success and many other factors, the number of people involved in agriculture has declined over half in the last 50 yr. We have seen a major change in demographics of our undergraduate and graduate students, who are now overwhelmingly suburban and urban and interested in companion animals. Yet we still have a mission and a need to train and do research with agricultural animals. Many departments have responded to the changing demographics with expanded course offerings related to companion animals, by including examples from companion animals in our core disciplinary classes and in some cases by opening and expanding research into the biology of companion animals. The future, as always, does hold some great promise and great challenges for furthering these efforts. The research and teaching endeavors will not be similar across states. A few states will maintain significant activity in agricultural animals and have some effort in companions. But many more states will (if they have not already done so) shift significant effort to study and training with companion animals. Recent research and applications with animal behavior, welfare and training; use of service and therapy animals; the social and economic relevance and challenges with companion animals (the horse slaughter issue and increases in drop-offs to animal shelters as examples); the equine, canine and feline genome projects; and the revival of 'dual purpose' animal research at the federal level provide many opportunities for classroom learning and undergraduate research. Many of our undergraduates have experience at animal shelters, with service and therapy animals and in animal training. We should tap that expertise, provide education, and work with the communities (service learning courses; community outreach by faculty and students) to improve and expand the use of such animals and reduce the unwanted animal population. The "Masters in Agriculture" programs that train individuals to improve production provide a successful model that can be adapted to companion animals. Dogs, cats and horses make up the vast majority of 4H projects and this is an opportunity to expand the role of Animal Sciences.

0194 Extension outreach: Use of technology in companion animal biology and nutrition. L. Karr-Lilienthal*, *University of Nebraska, Lincoln.*

Today's technology has changed the way teaching and extension programs are provided and will continue to do so. With changes in technology, we must evaluate the best practices for providing companion animal biology information to youth and students globally. Distance education has become increasingly popular with universities and students. Using technology effectively in the classroom should foster relationships between student and instructor to continue to provide a personal connection. It should be easily accessed from a variety of platforms and locations. There are many options available to educators looking to use technology. Using a combination of tools is probably most effective in student learning. Repetition, practice, and variety of delivery methods will help to reinforce concepts students may struggle with. Student performance in the Companion Animal Nutrition course offered at the University of Nebraska-Lincoln does not differ between online and in class sections. However, different approaches must be taken to ensure student connections and participation. Students tend to ask questions for clarification less frequently in the online section. Providing clear methods to obtain feedback helps to open lines of communication. Often university teaching and outreach programs have limited personnel resources. Technology is a key way to improve collaboration between experts at other universities and within the industry. Online meeting rooms can increase your pool of guest speakers and decrease costs related to speaker fees for programs. Using programs such as Adobe Connect that allow for streaming video and an audio connection will improve the learner experience. The Companion Animal Community of Practice at eXtension.org is one way to improve collaborations among extension and outreach professionals. The use of eXtension provides educators with a simple system for delivering online material to the general public through webinars, articles, and short courses. Published content on eXtension is peer reviewed and is based in science. Effective use of technology should provide ease of use, accessibility, and allow for increased target audience. For learners to feel comfortable with technology, a sense of community should be established both for online teaching as well as online extension efforts. Community can be developed through social media tools, discussion posts, regular communication, and videos. Requesting feedback from the learners improves use of technology in classroom.

Key Words: companion animal, technology, teaching, outreach

0195 A circuitous route: Preparing for a career in the companion animal industry. A. K. Shoveller*, *The University of Guelph, Guelph, ON, Canada.*

Today's companion animal industry refers to food and products for the pet owner and predominantly includes products for dogs and cats. US Pet Industry expenditures in 2012 were ~53.3 billion and have been steadily increasing over the past 20 yr, suggesting a large growth opportunity. There is also growing interest from undergraduate and graduate students to pursue companion animal biology. Professionals are needed to do research in animal biology (health, metabolism, behavior); communicate complex findings to academics, industry professionals and pet owners; develop and market food and products; and maintain the regulatory requirements that tend to be different between countries. "Pet passion" is a necessary attribute for a career in the pet care industry. Individuals need to be effective in multi-functional teams, have strong communication skills and thought processes. These processes also require collaboration outside of internal teams with academic, government and business partners and effective professionals need to be able to utilize a diverse knowledge set. These individuals need to be strategically and operationally agile, enabling them to see the big picture yet know when to be detail oriented. Successfully acquiring knowledge and experience in animal biology will put you in a solid position to compete in the companion animal industry. Despite this requirement, there are still few companion animal programs in North America outside of veterinary school, and because of that, the majority of professionals in the companion animal industry are trained in production animal or human biology. While an individual can build and continue to acquire new knowledge and skills outside of a formal academic program, academia has historically been, and continues to be, responsible for teaching the base of knowledge in undergraduate programs and deeper knowledge and problem-solving skills in graduate school. Programs and funding that encourage collaboration between government, industry and academia, with a solid commitment to generate the next generation of highly-trained technologists and future leaders for the pet care industry, are needed. Furthermore, long-term strategic programs with greater levels of collaboration among academic institutions may help to provide continuity in basic training. Educated and experienced individuals working together across government, academia and industry can help set strategies that would further enable advancements in companion animal health and well being and enhance our knowledge of the role of companion animals in improving the lives of their families.

0196 How to effectively communicate science with pet owners and society: Understanding pet owner purchasing decisions and sensory characteristics of pet foods. K. Koppel*, *Kansas State University, Manhattan*.

Science communication to targeted communities is a topic that has received a great deal of attention and published research. For the sake of human health there has been an emphasis on food-related communication and comprehension in publications such as human nutrition guidelines, labeling, and risk management of different types of foods. Only recently have pet food related issues been covered extensively in the media. There is a growing awareness of pet owners regarding pet food ingredients and health concerns surrounding pet obesity issues. While traditional animal science has focused on efficiency and yield, companion animal science redirects the target to perceptions about quality, animal wellness, and the pet-owner relationship. This changes the opportunities in research and communication through to the classroom. Recent trends in companion animal and pet food research include understanding drivers behind purchase decisions, relating pet owner behavior characteristics to issues with pets' weight management, and understanding pet food characteristics in association with food composition and animal preference. At Kansas State University our lab is focusing research activity on sensory properties and volatile compounds of pet food, ingredient effects on sensory and palatability aspects, and pet owner behavior studies. This research is being transferred to the classroom and shared with the scientific community and the pet food industry. This presentation describes how pet food science is being studied, taught, and communicated at Kansas State University in the Sensory Analysis Center and Department of Grain Science to educate and train the next generation of companion animal specialists.

Key Words: companion animals, pet food, ingredients

COMPARATIVE GUT PHYSIOLOGY SYMPOSIUM: COMPARATIVE PHYSIOLOGY OF LOWER GUT

0198 Integrated responses to feeding, comparative aspects. J. Furness*, *University of Melbourne, Parkville, Australia.*

The optimal utilization of nutrients requires an integrated response of the gastrointestinal tract to ingested food. Broad mechanisms are similar in all mammals and involve sensing food components through olfaction, taste and specialized receptors within the stomach and intestines. The sensing of food components leads to release of gut hormones and activation of nerves, which in turn modify digestive functions. Bacteria, viruses, fungi and potentially injurious substances in foods activate tissue defense mechanisms. While the responses to nutrients lead to broadly similar changes in appetite, satiety and food-seeking behavior, gastrointestinal motility, release of digestive enzymes and induction of nutrient transporters, the requirements in different animals differ. To simplify discussion, we can divide species into ruminant foregut fermenters (such as cattle and sheep), non-ruminant foregut fermenters (e.g., kangaroo, colobus monkey), hind-gut fermenters (such as horse), and auto-enzyme dependent digesters (pig, human) that also gain nutrition from hind-gut fermentation. Ruminants are efficient digesters because the rumenal movements are able to stratify food into gas, fluid and particle components, retaining food to be digested in the forestomach and passing more fully digested material into the abomasum and duodenum, and also being able to return food from the forestomach to the mouth for mastication and limited enzyme exposure. Poultry have multiple stomachs that allow for storage, digestion and tituration, but not fermentation. Ruminants lose efficiency in that most carbohydrate is utilized by gastric bacteria and very little glucose reaches the small intestine. Thus glucose must be synthesized from short chain fatty acids produced by bacteria, whereas species such as pig and human convert carbohydrate to glucose enzymatically. Thus ruminants are more prone than other groups to enter into negative glucose balance, for example during post-partum lactation. Obligatory by-products of fermentation are carbon dioxide and methane. Foregut fermenters are also advantaged by being able to readily utilize vitamins produced by fermentation. It is thought that coprophagy by hind-gut fermenters, such as rabbits, provides access to such vitamins. Foregut fermentation also contributes to detoxification, for which hindgut fermenters and autoenzymic digesters rely primarily on the liver. With these differences in mind, it is necessary to closely consider what information can be readily extrapolated between species. Conversely, we can point to similarities in neural and hormonal signaling systems and products of digestion, achieved in different ways that are available for energy utilization and incorporation into tissues.

Key Words: digestive physiology, fermentation, glucose, comparative

0199 Expression of nutrient transporter mRNA in the jejunum of high and low efficiency steers. H. C. Cunningham[1], Z. T. L. Gray[1], S. I. Paisley[1], K. J. Austin[1], K. M. Cammack[1] and A. M. Meyer*[2], *[1]Department of Animal Science, University of Wyoming, Laramie, [2]Division of Animal Sciences, University of Missouri, Columbia.*

We hypothesized that small intestinal expression of nutrient transport-related genes contributes to differences in metabolic efficiency in beef cattle. The objective was to investigate jejunal expression of glucose transporter 2 (GLUT2), glucose transporter 5 (GLUT5), sodium-dependent glucose transporter 1 (SGLT1), and peptide transporter 1 (PepT1) in finishing steers classified as high and low efficiency based on residual feed intake (RFI). Hereford-Angus crossbred steers (yr 1, $n = 59$, 461 ± 4.5 kg initial BW; yr 2, $n = 75$, 412 ± 3.8 kg initial BW) from a single contemporary group in each year (birth through slaughter) were used. Steers were fed a finishing diet (yr 1, 11.4% CP, 2.0 Mcal NE_m/kg, 1.35 Mcal NE_g/kg; yr 2, 13.2% CP, 1.8 Mcal NE_m/kg, 1.19 Mcal NE_g/kg; DM basis) for 57 (yr 1) or 80 d (yr 2) using the GrowSafe system. Residual feed intake was calculated as the difference between actual and expected feed intake of each individual, where expected intake was determined by regressing ADG and metabolic midweight on actual intake. Following the intake test in each year, the 20% most efficient (low RFI, $n = 8$/yr) and 20% least efficient (high RFI, $n = 8$/yr) steers with 12th rib fat thickness $\geq$ 1.02 cm were slaughtered between 5 and 8 d after the feed intake test conclusion. At slaughter, jejunal mucosa was flash-frozen for real-time RT-PCR determination of GLUT2, GLUT5, SGLT1, and PepT1. Data were analyzed with PROC MIXED in SAS 9.2 using RFI class (high vs. low efficiency), year, and their interaction as fixed effects. Expression of SGLT1 was affected ($P = 0.02$) by the RFI class × year interaction, although there were no differences ($P \geq 0.12$) within each year. Jejunal expression of GLUT2, GLUT5, and PepT1 were not affected ($P \geq 0.18$) by RFI class; however, expression of each was greater ($P \leq 0.03$) in yr 2 than yr 1. It was previously reported in this study that jejunal expression of y^+LAT2, a basolateral membrane cationic AA transporter, was greater for low efficiency than high efficiency steers in yr 2. Additionally, low efficiency steers had greater jejunal expression of vascular endothelial growth factor (VEGF, a major regulator of angiogenesis) than high efficiency in both years. These data suggest that nutrient absorption and transport in the small intestine may play a role in whole animal feed efficiency of beef cattle.

Key Words: feed efficiency, nutrient transport, small intestine

0200 Comparative physiology of glucagon-like peptide 2—Implications and applications for production and health of ruminants. E. E. Connor*, M. P. Walker, C. M. Evock-Clover, T. H. Elsasser, and S. Kahl, [1]*USDA-ARS, Bovine Functional Genomics Laboratory, Beltsville, MD*.

Glucagon-like peptide 2 (GLP-2) is a 33-amino acid peptide derived from proteolytic cleavage of proglucagon by prohormone convertase 1/3 in enteroendocrine L-cells. Studies conducted in humans, rodent models, and in vitro indicate that GLP-2 is secreted in response to the presence of molecules in the intestinal lumen including fatty acids, carbohydrates, amino acids, and bile acids, which are detected by luminal chemosensors. The physiological actions of GLP-2 are mediated by its G protein coupled receptor expressed primarily in the intestinal tract on enteric neurons, enteroendocrine cells, and myofibroblasts. The biological activity of GLP-2 is further regulated by dipeptidyl peptidase IV, which rapidly cleaves the N terminus of GLP-2 that is responsible for GLP-2 receptor activation. Within the gut, GLP-2 increases nutrient absorption, crypt cell proliferation, and mesenteric blood flow, and decreases gut permeability and motility, epithelial cell apoptosis, and inflammation. Outside the gut, GLP-2 reduces bone resorption, can suppress appetite, and is cytoprotective in the lung. Thus, GLP-2 has been studied intensively as a therapeutic to improve intestinal function of humans during parenteral nutrition and following small bowel resection, and more recently, as a treatment for osteoporosis, obesity-related disorders, and to reduce cellular damage associated with inflammation of the gut and lungs. Recent studies demonstrate that GLP-2 has many similar biological actions and properties in ruminants as in monogastrics, including the potential to reduce intestinal nitro-oxidative stress in calves caused by parasitic diseases like coccidiosis. Due to its beneficial impacts on nutrient absorption, gut healing, and normal gut development, GLP-2 therapy offers significant opportunities to improve calf health and production efficiency. However, GLP-2 therapies require an extended time course to achieve desired physiological responses, as well as daily administration due to the hormone's short half-life. Thus, practical means of administration and alternative strategies to enhance basal GLP-2 secretion (e.g., through specific feed additives), which are more likely to achieve consumer acceptance, are needed. Opportunities to address these challenges are discussed.

0201 Differential subcellular and cellular storage of GLP-1 and PYY and its implications. J. Furness*[1], H. J. Cho[1], S. Kosari[1], and D. M. Bravo[2], [1]*University of Melbourne, Parkville, Australia,* [2]*PANCOSMA SA, Geneva, Switzerland.*

Intestinal L cells have key roles in the detection of the chemical environment in the gut lumen, to which they react by the release of hormones that influence appetite, proximal gut motility, insulin secretion and mucosal function (Furness et al., Nature Gastroenterology, 10, 729–740, 2013). Important amongst L cell hormones are glucagon-like peptide1 (GLP-1) and peptide tyrosine-tyrosine (PYY), which are products of separate genes. The conventional description of their localization is that GLP-1 and PYY are in the same storage vesicles in the same cells. However, GLP-1 and PYY have different functions, particularly in relation to insulin secretion and mucosal function. We have used super-resolution (3D-SIM) microscopy and double-labelling immunohistochemistry to investigate the subcellular localizations of the hormones, and digital scanning microscopy to investigate cell populations. Super-resolution microscopy revealed that GLP-1 and PYY are in separate storage organelles in enteroendocrine cells from mouse, rat, pig and human. The majority of the organelles were 150-170 nm or less in diameter, and are concluded to be secretory vesicles. Only 10-20% of organelles had immunoreactivity for both hormones. Even this may be an overestimate, as touching or very close vesicles may not be effectively resolved, even with super-resolution microscopy. In investigating co-localisation at the cell level, we included glucagon-like insulinotropic peptide (GIP), an incretin of K cells, in the analysis. The work shows that there is a K/L cell gradient in the mouse intestine. From the duodenum to the distal colon, there are populations of cells with GIP alone, GLP alone, PYY alone and all combinations of the three hormones. Greatest numbers of GIP cells were in the doudenum and jejunum, where 30—40% contained only GIP and the remainder also contained GLP-1. A small proportion also contained PYY. Similar patterns of overlap occurred in the proximal and distal ileum, where GLP-1 was the dominant peptide, which was often alone, or co-localised with PYY. In the large intestine the majority of cells contained both GLP-1 and PYY, but cells with only one of these and cells with all three hormones were found. The findings reveal a structural basis for the separate or preferential control of GLP-1, PYY (and possibly GIP) release. A number of physiological studies imply that there can be differential release of GLP-1 and PYY. This should be investigated further.

Key Words: enteroendocrine cells, incretins, glucagon like peptide, peptideYY

0202 The role of the microbiome in gut immune system development in newborn and mature cattle. P. J. Griebel[*1], N. Malmuthuge[2], G. Liang[2], M. Zhou[2], and L. L. Guan[2], *[1]Vaccine and Infectious Disease Organization, University of Saskatchewan, Saskatoon, SK, Canada, [2]University of Alberta, Edmonton, AB, Canada*.

There is increasing evidence in a variety of mammalian species that the commensal microbiome has diverse effects on mucosal immune system development and function. It is difficult, however, to clearly delineate the effects of the microbiome from other contributing factors, such as diet, environment, and host genetics. The bovine gastrointestinal tract (GIT) is rapidly colonized during birth and these pioneer species are then replaced by a succession of changes, involving both increased microbioal density and diversity. This succession occurs rapidly during the first week of life and then progresses much more slowly. Characterization of the microbiome in the neonatal bovine GIT at both a family and species level revealed marked bacterial variation among individual animals. Furthermore, the composition of the microbiome varied significantly when comparing ingesta- and mucosa-associated communities within individual GIT regions. The first week postpartum is also a very dynamic developmental period in the bovine GIT with significant changes in both mucosal barrier and immune function. These developmental changes were analyzed by profiling miRNAs expressed throughout the small intestine. This analysis confirmed the greatest changes in GIT development occurred during the first week of life with differential expression of miRNAs involved in regulating a broad range of GIT developmental and immunological processes. Relatively few miRNAs were differentially expressed when comparing tissues collected from 6 wk old calves and 3 wk old calves. Correlation analyses between total bacterial numbers and specific families revealed significant associations between the commensal microbiome and the expression of genes involved in regulating both mucosal barrier and innate immune function. It appears the microbiome is an important factor influencing age-dependent changes in the expression of immune function genes. These correlation analyses also suggest that regional differences in the microbiome may be associated with significant regional differences in the expression of innate immune genes. This information provides the baseline to begin analyzing the role of individual bacterial species and interactions among bacterial species in regulating mucosal immune system function in healthy animals and during enteric infections. New experimental models will be required, however, to clearly delineate the role of specific bacterial species in the complex interaction between microbiome and host.

Key Words: microbiome, innate immunity, miRNA

0203 The effects of intentionally-induced leaky gut on metabolism and production in lactating Holstein dairy cows. S. K. Stoakes[*1], M.Abuajamieh[1], D. B. Snider[1], M. V. Sanz Fernandez[1], J. S. Johnson[1], P. J. Gorden[1], N. K. Gabler[1], H. B. Green[2], K. M. Schoenberg[2], and L. H. Baumgard[1], *[1]Iowa State University, Ames, IA, [2]Elanco Animal Health, Indianapolis, IN.*

Presumably, intestinal barrier dysfunction negatively affects productivity, but it has never been studied in a controlled lactation experiment. Objectives were to elucidate consequences of leaky gut in otherwise healthy mid-lactation dairy cows. Twelve Holstein cows (170.0 ± 15.1 DIM, 670 ± 13 kg BW, parity 1 to 5) were enrolled in two experimental periods. Period 1 (P1) lasted 5d and served as baseline for period 2 (P2), which lasted 7d in which cows received one of two treatments I.V. twice daily: 1) sterile saline (control) or 2) γ secretase inhibitor (GSI; 1.5 mg/kg BW). GSI specifically inhibits crypt stem cell differentiation into enterocytes via disrupting Notch signaling. Control animals were pair-fed (PF) to GSI-treated cows (to eliminate the confounding effects of dissimilar feed intake). GSI administration caused a progressive reduction in DMI ($P < 0.01$; 82%) and milk yield ($P < 0.01$; 57%), but there was no treatment effect on milk components. Cows in both treatments lost a similar amount of BW (56 kg) by the end of P2. Histological analysis indicated GSI increased jejunum goblet cell area (3.3 vs. 1.0%; $P = 0.02$), tended to: deepen villous crypts ($P = 0.06$), reduce villous height ($P = 0.07$) and alter villous height to crypt depth ratio ($P = 0.08$). No treatment effects were detected in ileum or colon morphology, but manure score (a measure of fecal consistency) was decreased 36% ($P < 0.01$) in the GSI-treated vs. PF controls. By d5−7 of P2, circulating lipopolysaccharide (LPS) was increased > threefold in PF controls compared to GSI-treated cows. Plasma LPS binding protein (LPB) levels progressively increased in both treatments but were increased (42%, $P < 0.01$) in GSI-treated vs. PF controls by d5−7 of P2. By the end of P2, the LPS:LPB ratio was increased 3.6-fold ($P < 0.05$) in PF controls compared to GSI-treated cows. Haptoglobin and serum amyloid-A concentrations progressively increased (> 400 and > fivefold, respectively) similarly in both treatments. Circulating IFNγ, TNFα and IL-6 were unaffected by treatment or time. GSI-treated cows tended to have increased plasma insulin ($P = 0.07$) and decreased circulating NEFA ($P = 0.06$) vs. PF cows. For both treatments, plasma glucose decreased with time ($P = 0.05$), while BHBA progressively increased (87%; $P = 0.08$). There were no treatment differences in spleen weight, liver weight, liver moisture, or liver lipid content. In summary, based on all the data, GSI-treatment compromised intestinal integrity and markedly reduced feed intake and milk yield. Further, we have demonstrated progressive feed reduction also negatively influenced intestinal integrity.

Key Words: lipopolysaccharide, insulin

0204 Manipulating goblet cell function to protect against enteric infection. M. Wlodarska*, *University of British Columbia, Vancouver, BC, Canada.*

Mucus production by goblet cells serves as one of the crucial mucosal defenses at the interface between the eukaryotic and prokaryotic cells and yet the immunoregulatory pathways involved remain uncharacterized. The inner mucus layer of the intestine functions as a barrier, which serves to minimize microbial translocation, prevents excessive immune activation, and decrease infection. Here we have described methodology to alter the thickness of the inner mucus layer through treatment with antibiotic or a phytochemical. We showed that the antibiotic metronidazole caused a significant thinning of the inner mucus layer accompanied by a dramatic change in the microbial community structure. In contrast, treatment with the phytochemical eugenol resulted in a significant thickening of the inner mucus layer that was accompanied by a change in the microbial community. These changes in community structure were complimentary; sequencing showed that groups depleted by metronidazole treatment were more abundant with eugenol treatment. To investigate how changes in the integrity of the inner mucus layer affect intestinal defense, Citrobacter rodentium (Cr) was used to examine susceptibility to enteric-induced colitis. Metronidazole-induced reduction in mucus thickness correlated with exacerbated severity of Cr-induced colitis. Thickening of the inner mucus layer with eugenol treatment resulted in protection from Cr-induced colitis. Further, we identified a novel innate immune pathway involved in regulation of goblet cell function and mucus layer production. The NLRP6 inflammasome was shown to regulate mucus secretion and deficiency in any component of the NLRP6 inflammasome resulted in impaired goblet cell function preventing mucin granule exocytosis and mucus layer formation. Abrogated mucus secretion led to increased invasiveness and pathology of Cr infection. Mechanistically, NLRP6 deficiency led to stalled autophagy in goblet cells, providing a link between inflammasome activity, autophagy, mucus exocytosis, and antimicrobial barrier function.

Key Words: mucus, goblet cell, *Citrobacter rodentium,* phytochemical, eugenol

0205 Nutritional immunology in swine. Y. Liu*[1], D. M. Bravo[2], and J. Pettigrew[1], [1]*University of Illinois at Urbana-Champaign, Urbana,* [2]*PANCOSMA SA, Geneva, Switzerland.*

The immune system of pigs is vital as its proper functioning protects the pig from disease and health. It also causes inflammation, which contributes to the animal's ability to fight off infection but also inhibits growth performance by reducing feed intake and diverting amino acids and nutrients away from growth to the immune response. It is now clear that reducing inflammation would benefit pig health. We have shown that several plant extracts can do just that, as shown here. Our in vitro study reported that several plant extracts (anethol, capsicum oleoresin, carvacrol, cinnamaldehyde, eugenol, garlicon, and turmeric oleoresin) suppressed ($P < 0.05$) pro-inflammatory cytokines' secretion from lipopolysaccharide-stimulated porcine alveolar macrophages, which indicates the in vitro anti-inflammatory effects of these plant extracts. Results from an in vivo *Escherichia coli* (*E. coli*) challenge study showed that feeding capsicum oleoresin, garlicon, or turmeric oleoresin reduced ($P < 0.05$) diarrhea of *E. coli*-challenged pigs. Feeding these 3 plant extracts also decreased inflammatory responses of *E. coli*-challenged pigs, as indicated by reduced ($P < 0.05$) white blood cell numbers, serum pro-inflammatory cytokines, and acute phase proteins when pigs were fed plant extracts compared with pigs fed control diet. A potential mechanism of action is that plant extracts may enhance gut mucosa health and attenuate the overstimulation of the immune system. The microarray data from the same in vivo study indicated that these plant extracts counteracted ($P < 0.05$) the effects of *E. coli* by reducing the expression of genes involved in antigen presentation or other biological processes of immune responses. Another in vivo study was conducted with porcine reproductive and respiratory syndrome virus (PRRSV) challenge. The results of this study indicated that feeding these 3 plant extracts to nursery pigs enhanced the pigs' immune responses to a PRRSV challenge and may help alleviate negative impacts of infection, as indicated by reducing ($P < 0.05$) viral load and serum concentrations of inflammatory mediators, and shortening ($P < 0.05$) the time of fever in PRRSV-infected pigs. In conclusion, feed additives, such as certain plant extracts, may potentially improve pig health and disease resistance by modulating inflammation.

Key Words: immunology, pigs, plant extracts

0206 Mucosal IgA responses to members of the gut microbiota in healthy vs. malnourished Malawian children. A. Kau*, *Center for Genome Sciences & Systems Biology, St. Louis, MO*.

Childhood malnutrition is a major contributor to childhood morbidity and mortality worldwide. While inflammatory conditions, such as recurrent infection and environmental enteropathy, have been implicated in pathogenesis, the role of the interaction between the host immune system and the gut microbiota in shaping the outcomes remains poorly understood. To identify microbes that were targeted by the host gut mucosal immune response, we developed a flow cytometry-based method to recover and characterize viable gut microbes based on their binding to immunoglobulin A (IgA). Fecal microbiota from Malawian twins discordant for a form of severe acute malnutrition (Kwashiorkor) were transplanted into different groups of adult germ-free C57BL/6J mice that were fed a representative Malawian diet deficient in macro- and micronutrients. IgA-targeted microbes in the fecal micro-

biota of these 'kwashiorkor-Malawian diet–fed' (KM) mice were purified by FACS and transferred to a second group of germ-free mice, also fed the Malawian diet. KM-IgA+ consortia produced (i) dramatic weight loss; (ii) pronounced gut barrier dysfunction manifest by sepsis, and histopathologic changes that were most severe in the colon but also manifest in the small intestine where disruption of the intracellular pattern of epithelial cell adhesion molecule (EpCAM) staining and evidence of extrusion of cells along the length of villi rather than just at the apical region was evident, and (iii) high mortality phenotype in recipient animals. This phenotype was both diet-dependent and microbiota dependent: we did not observe it in mice fed a macro- and micronutrient replete diet or those receiving IgA targeted taxa from mice harboring the healthy co-twin's microbiota. The barrier dysfunction and mortality phenotypes transmitted by the IgA+ consortium could be mitigated through the administration of IgA-targeted microbes from a mouse colonized with a healthy microbiota, including *Akkermansia muciniphila* and *Clostridium scindens*. Applying this FACS-based approach directly to the fecal microbiota of two cohorts of Malawian children, we found that members of Enterobacteriaceae are prominent targets of IgA responses in individuals with severe acute malnutrition. Targeting to other bacterial taxa, including members of Veillonellaceae and Lactobacillaceae, were correlated with the degree of stunting. These findings indicate that this approach for identifying and quantifying mucosal immune responses to members of the fecal microbiota has potential diagnostic and therapeutic applications to childhood malnutrition, and perhaps other diseases affecting the gut mucosal immune system.

0207 Gut immune system: A new frontier for nutritional modulation of gut health.

H. Lillehoj*, *ARS USDA, Beltsville, MD.*

The gut represents a continuously evolving ecosystem consisting of trillions of commensal bacteria living in symbiosis with the host. This host-microbe interplay plays a crucial role in host physiological development and health. There is increasing evidence that shows a dynamic interaction between the gut microbiota and the development and function of the host immune system. Particularly, the intestinal microflora influences diverse aspects of host metabolic and immunological functions and this "crosstalk" with the various immune component of mucosal immunity, comprising cellular and soluble elements, is critical in maintaining gut homeostasis and gut health. Various chronic inflammatory conditions and metabolic diseases are closely associated with altered symbiotic relationship. Furthermore, probiotics, when used for the treatment of diseases caused by the dysregulation of the immune system, can exert a beneficial immune response. In this regard, as shown in our recent studies, the dietary immunomodulation of gut immunity in broiler chickens using natural dietary supplements, such as TLR ligands, DFMs and plant-derived phytochemicals that interact with innate sensing molecules to stimulate innate immunity, is a promising alternative strategy that can be applied to many infectious diseases where traditional prevention methods show limitations. Furthermore, application of high-throughput functional genomics tools in delineating detailed immune mechanisms associated with alternative disease control strategies will lead to enhanced understanding of how different alternative strategies function. As we move into the 21st Century and the demands for animal food products increase to meet the nutritional needs of a growing world population, developing drug-free alternative strategies to prevent and control animal diseases and to maintain gut homeostasis is a global issue and a critical component of our long-term efforts to alleviate poverty and world hunger.

Key Words: gut health, innate immunity, antibiotic alternatives

0208 Effect of dietary supplementation of *Capsicum* extract on immune responses, blood cell counts, blood chemistry, and oxidative stress markers in lactating dairy cows.

J. Oh*[1], S. Walusimbi[1], F. Giallongo[1], H. L. Weeks[1], T. W. Frederick[1], A. N. Hristov[1], J. L. Pate[1], R. J. Elias[2], L. Tao[2], and E. H. Wall[3], *[1]Department of Animal Science, The Pennsylvania State University, University Park, [2]Department of Food Science, The Pennsylvania State University, University Park, [3]Pancosma, Geneva, Switzerland*

The objective of this experiment was to investigate the effects of dietary *Capsicum* extract (CE) on T cell phenotypes, phagocytotic and oxidative burst activity of neutrophils, blood cell counts, blood chemistry, and oxidative stress markers in lactating dairy cows. Eight multiparous Holstein cows (DIM, 50 ± 9.6 d; BW, 591 ± 32.6 kg), including 3 ruminally-cannulated, were used in a replicated 4 × 4 Latin square design with 25-d periods. Treatments were 0 (CON), 250, 500, and 1000 mg CE/cow/d, in which the principal active compounds were capsaicin and dihydrocapsaicin. The CE was mixed with a small portion of the TMR and topdressed. Compared with CON, CE did not affect concentration of cluster of differentiation antigen (CD) 4 positive, $CD8^+$, $CD25^+$, and $\gamma\delta^+$ cells. The phagocytosis of neutrophils tended to quadratically increase ($P = 0.07$) with CE. Relative to CON, total white blood cells, neutrophils, and eosinophils were linearly increased ($P = 0.04$, 0.01, and 0.03, respectively) with CE supplementation. Treatments had no effect on lymphocytes, monocytes, and basophils. Red blood cells quadratically increased ($P = 0.04$) with CE. Hemoglobin was higher ($P < 0.01$) for CE than CON and responded quadratically to CE level of supplementation. Platelets were lower for CE than CON and linearly decreased ($P = 0.04$) with CE supplementation. Glucose, creatinine, al-

bumin, and total protein in blood plasma were not affected by CE. Blood urea N was increased ($P = 0.02$) by CE relative to CON and blood plasma P concentration tended to be lower ($P = 0.09$) for CE than CON. Although there was no effect of CE on oxygen radical absorbance capacity (ORAC) and thiobarbituric acid reactive substances (TBARS), CE tended to decrease ($P = 0.09$) 8-isoprostane relative to CON (14.7 vs. 16.5 pg/mL, respectively). In conclusion, dietary supplementation of CE did not affect T cell phenotypes and neutrophil activities in this study. However, CE increased total white blood cells, neutrophils, and eosinophils, and tended to decrease 8-isoprostane. It is suggested that CE may facilitate cells with function in innate immunity and reduce blood oxidative stress markers in lactating dairy cows.

Key Words: capsicum extract, immune response, oxidative stress

0209 Host-microbiome interactions during gut development across species: the role of milk.

T. B. McFadden*, *University of Missouri, Columbia.*

In humans, the benefits to babies of consuming whole colostrum and breast milk are now universally recognized. As a result, colostrum and breast milk are in high demand and are even donated and banked for use by mothers who are unable to lactate but still want to feed their babies breast milk instead of formula. Despite numerous studies on the functions and properties of human colostrum and breast milk, we have only scratched the surface in describing the specific bioactive factors and the mechanisms by which they protect the baby and promote GIT development, as well as programming future health and function. The same is true of all mammals as all mammalian offspring rely on mammary secretions (colostrum and milk) to provide nutrients and bioactive factors necessary for survival and subsequent growth and development. Although young of various species can be reared successfully on milk from other species, it is generally accepted that homologous milk provides the optimal match of components to requirements of the young. From this perspective, there is much potential to gain understanding from comparative studies of the unique relationships between milk composition and requirements of the suckling young across various species. In addition, recent recognition of the role of the gut microbiome as a key determinant of immunological and digestive system development opens new avenues by which milk components can have long term effects on future health and vitality of offspring. This paper will review current knowledge of milk composition and bioactive components and the effects they have on the young of various species. In addition, the effects of these components and temporal changes in the gut microbiome will be considered.

Key Words: gut microbiome, milk

CSAS GRADUATE STUDENT ORAL COMPETITION

0212 Effects of butyrate during subacute ruminal acidosis on VFA transport capacity in the rumen epithelium of holstein dairy cows. A. H. Laarman[*1], L. Dionissopoulos[1], O. AlZahal[2], S. L. Greenwood[3], M. A. Steele[4], and B. W. McBride[2], *[1]University of Guelph, Guelph, ON, Canada, [2]Department of Animal and Poultry Science, University of Guelph, Guelph, ON, Canada, [3]University of Vermont, Burlington, VT, [4]Nutreco Canada, Guelph, ON, Canada.*

This study examined the effects of exogenous butyrate during subacute ruminal acidosis (SARA) on the membrane VFA-transport proteins in the rumen epithelium. Sixteen mid-lactation Holstein cows fed a TMR including a pelleted concentrate supplement consisting of 60% barley grain, 20% corn grain, and 20% wheat grain on a dry matter basis. For 2 pre-trial days, all cows were adapted to the full amount of concentrate supplement to increase the dietary NFC to 44.0%. Cows were blocked by DIM and assigned either a butyrate treatment or control treatment for 7 d. Cows assigned the butyrate treatment were ruminally dosed twice daily with a calcium butyrate salt at 2.5% of their pre-trial DMI. Cows assigned the control treatment were ruminally dosed with a carrier. On Days 1 and 7, blood, rumen fluid, and rumen biopsies were sampled for serum BHBA concentrations, VFA profiles, and transport protein abundance, respectively. Rumen pH was continuously measured on Days 6 and 7 using an in-dwelling pH-measuring device. There was no difference in SARA between control and butyrate treatments (rumen pH < 5.6 for 598 ± 97 min/d vs. 536 ± 89 min/d, $P = 0.65$). Ruminal butyrate concentration were higher in the butyrate treatment compared to control treatment on both Days 1 (9.88 vs. 22.60 ± 0.94 mM, $P < 0.05$) and 7 (8.60 vs. 21.60 ± 0.94; $P < 0.05$). Serum BHBA was also elevated in the butyrate treatment animals on Day 1 (910 vs. 4201 ± 265 μM, $P < 0.05$) and Day 7 (800 vs. 3262 ± 265 μM, $P < 0.05$) compared to control animals. Immunofluorescence showed an increase in the abundance of monocarboxylate co-transporter isoform 1 (MCT1), sodium/proton exchanger isoform 3 (NHE3) and sodium/bicarbonate co-transporter isoform 1 (NBC1) in all cows between Days 1 and 7. By Day 7, butyrate dosing increased the abundance of MCT1 (11,275 ± 953 vs. 14,747 ± 953 A.U., $P < 0.05$) and decreased the abundance of NBC1 (15,065 ± 992 vs. 11,122 ± 992 A.U., $P < 0.05$) compared to control cows. These results suggest SARA increases the capacity for proton expulsion from the cytosol as well as VFA export into the bloodstream. Butyrate increases the capacity for VFA uptake by increasing the abundance of MCT1 on the basolateral membrane and decreasing NBC1 to maintain intracellular pH.

Key Words: butyrate, epithelium, transport

0213 Nutrient composition and degradation characteristics of anthocyanidin containing alfalfa transformed with Lc, C1, and Lc × C1 regulatory genes. R. G. Heendeniya Vidanaral[*1], M. Y. Gruber[2], Y. Wang[3], D. A. Christensen[1], J. J. McKinnon[1], B. Coulman[1], and P. Yu[1], *[1]University of Saskatchewan, Saskatoon, SK, Canada, [2]Agriculture and Agri-Food Canada, Saskatoon, SK, Canada, [3]Agriculture and Agri-Food Canada, Lethbridge, AB, Canada.*

Alfalfa (*Medicago sativa* L.) is rich in nutrients. However, utilization of its nutrients in ruminants is restricted due to rapid rumen degradation of protein. This may be prevented if adequate protein binding proanthocyanidins are present in the aerial part of the plant. Proanthocyanidins are synthesized by the flavonoid pathway. The Lc gene and C1 genes synthesize bHLH and MYB transcription factors associated with the flavonoid pathway regulation. The objective of this study was to investigate the influence of single gene (Lc and C1) and double gene (Lc × C1) transformation on chemical composition and degradation characteristics of protein and carbohydrate compared to non-transgenic (NT) parental plants. Samples were collected from plant populations of C1 genotype, two Lc genotypes (Lc1 and Lc3), two Lc × C1 genotypes (Lc1C1 and Lc3C1), NT and AC-Grazeland (ACGL) and maintained in a growth chamber. Plants were harvested at late-bud stage, freeze-dried and ground (1 mm). Chemical composition was determined by AOAC methods. Protein and carbohydrate sub-fractions were estimated according to Cornell Net Carbohydrate and Protein System (CNCPS ver. 6.1). Anthocyanidin was extracted with aqueous acetone and hydrolyzed with butanol-HCl to measure spectrometric absorbance. The extractable anthocyanidin contents in Lc alfalfa and Lc × C1 averaged 149 ± 85 and 185 ± 74 μg/g DM, respectively. The single gene had a higher total carbohydrate (CHO; 70% vs. 68%; $P = 0.03$) and non-fiber carbohydrate (NFC; 44% vs. 40%; $P < 0.001$) than double gene transformed alfalfa. There was no difference ($P > 0.05$) in structural carbohydrate (ADF and NDF) content. The single gene alfalfa had a lower CP (19% vs. 21%; $P = 0.02$) than double gene transformed alfalfa. The profiles of protein (PA, PB1, PB2, and PB3), and carbohydrate (CA, CB1, CB2, and CB3) varied among different genotypes, resulting in different degradation profiles. Double gene genotypes had a higher ($P < 0.01$) rumen degradable crude protein (RDCP) but lower ($P < 0.01$) RD-CHO than single gene genotypes. This caused an increase ($P < 0.01$) in total degradable N to CHO ratio in double gene transformation by 10 g N/kg CHO. In conclusion, the gene transformation influenced anthocyanidin accumulation in aerial parts as well as accumulation of nitrogenous compounds and non-structural carbohydrates, thereby changing chemical composition and degradation characteristics. The single gene transformed alfalfa had a lower N to CHO balance than double gene alfalfa.

The C1 gene influences nutrient composition of alfalfa differently, when co-expressed with two Lc lines (Lc1 and Lc3).

Key Words: alfalfa, Lc and C1 genes, gene transformation

0214 Comparative analyses of the bovine rumen microbiota using RNA and targeted DNA-based sequencing approaches. F. Li*[1], X. Sun[2], G. Henderson[3], F. Cox[3], P. H. Janssen[3], and L. L. Guan[2], *[1]Department of Agricultural, Food and Nutritional Science, University of Alberta, Edmonton, AB, Canada, [2]University of Alberta, Edmonton, AB, Canada, [3]AgResearch Limited, Grasslands Research Centre, Palmerston North, New Zealand.*

The bovine rumen microbiota comprises diverse populations, including bacteria, archaea, protozoa, and fungi. Defining rumen microbiota structures and their activities can enhance our understanding of the role of microbes in regulating rumen fermentation. We hypothesized that sequencing total RNA without rRNA removal (RNA-Seq) can be used to study the active microbiota, avoiding potential biases introduced by PCR-amplification of bacterial and archaeal 16S rRNA genes before sequencing. Total DNA and total RNA were isolated from the rumen contents of five steers maintained on a feedlot diet. Partial amplicons of bacterial and archaeal 16S rRNA genes were sequenced (Amplicon-Seq). RNA-Seq was performed in parallel. The data were processed using a QIIME-based pipeline in combination with Greengenes and SILVA-derived taxonomic frameworks. In total, five major bacterial phyla, with a relative abundance greater than 0.1% in any one sample, were identified in both Amplicon-Seq and RNA-Seq datasets; namely *Proteobacteria*, *Bacteroidetes*, *Firmicutes*, *Spirochaetes*, and *Synergistetes*. *Bacteroidetes* was more abundant in Amplicon-Seq than RNA-Seq datasets (52.6 ± 8.8% versus 23.7 ± 7.7%, mean ± SEM), whereas *Proteobacteria* was predominant in RNA-Seq datasets (45.7 ± 14.1% versus 13.0 ± 7.7%). *Euryarchaeota* was the most abundant archaeal phylum in both Amplicon-Seq (100.0 ± 0.0%) and RNA-Seq (94.2 ± 2.5%) datasets. Despite some differences in individual animals, microbial community compositions obtained using Amplicon-Seq and RNA-Seq techniques were broadly comparable. Of particular interest is that *Proteobacteria* appear to be more abundant in RNA-Seq datasets. Whether they are indeed more active relative to their abundance (Amplicon-Seq) than other bacteria warrants further investigation. Our results suggest that total RNA sequencing without rRNA removal can be used to study the active rumen microbiota.

Key Words: Amplicon-Seq, RNA-Seq, rumen microbiota

0215 Effect of pelleting at different conditions on ruminal degradation kinetics and intestinal digestion of canola meal in dairy cattle. X. Huang* and P. Yu, *Department of Animal and Poultry Science, University of Saskatchewan, Saskatoon, SK, Canada.*

Pelleting has been adopted and widely used in the animal feed industry with its positive improvements in feed quality. Canola meal, an important protein source for ruminants in Canada, is usually prepared in mash or in pellets in feed mills. The objective of this study was to investigate the effects of pelleting at different conditions on in situ ruminal degradation kinetics and in vitro intestinal digestion of canola meal. Two batches of canola meal were pelleted after conditioning at different temperatures (70, 80, and 90°C) for different time (30s and 60s). Five rumen-cannulated lactating Holstein cows were used in an in situ trial to determine ruminal degradation kinetics. Intestinal digestibility was detected using a three-step in vitro method. Samples conditioned at 80°C had highest degradation rates (K_d) for crude protein (CP) and dry matter (DM) among pellets due to the quadratic effect of conditioning time ($P < 0.05$). The soluble fraction (S) of protein in pellets was greater than that in the unprocessed mash (9.84 vs. 5.68% CP, $P < 0.01$). The unprocessed mash had a greater content of bypass CP (BCP) but a lower content of effectively degraded CP (EDCP) than pellets (BCP: 44.20 vs. 39.30% CP; EDCP: 55.81 vs. 60.70% CP), indicating pelleting reduced ($P < 0.01$) BCP but increased ($P < 0.01$) EDCP contents of canola meal. However, bypass carbohydrates (BCHO) and effectively degraded CHO (EDCHO) were not affected by pelleting. The unprocessed mash had a lower ratio of effective degradability of N to carbohydrates (ED_N/ED_CHO) than pellets (126.17 vs. 142.85; $P < 0.01$). Conditioning temperature had a significant impact on ED_N/ED_CHO among pellets ($P < 0.05$). In the in vitro trial, intestinal digestible protein (IDP) content was greater in the unprocessed mash than in pellets (113.28 vs. 94.85 g/kg DM, $P < 0.05$), indicating that pelleting decreased IDP content of canola meal. There was no difference detected among samples on intestinal digestion characteristics for carbohydrates. In conclusion, pelleting increased ruminal degradation of protein while intestinal digestion of protein decreased in the current study. However, ruminal degradation and intestinal digestion characteristics of carbohydrates were not affected.

Key Words: pelleting, canola meal, rumen degradation, intestinal digestion kinetics

0216 Evaluation of corn and barley varieties in backgrounding grazing programs for beef calves.
S. A. McMillan*[1], B. Lardner[2], J. J. McKinnon[1], K. Larson[2], and G. B. Penner[1], *[1]University of Saskatchewan, Saskatoon, SK, Canada, [2]Western Beef Development Centre, Humboldt, SK, Canada.*

A study evaluated the effects of grazing either swathed barley (*Hordeum vulgare;* cv. Ranger*)* or standing corn (*Zea mays;* cv. Pioneer P7443R) as compared to drylot calves fed barley hay on forage quality, dry matter intake (DMI), calf backgrounding and feedlot performance, and backgrounding production costs. Each year, 120 spring born Angus calves (278.2 ± 5 kg) were fall weaned, stratified by body weight and randomly allocated to 1 of 3 replicated (n = 2) backgrounding systems: 1) field grazing standing whole plant corn (CORN); 2) field grazing swathed whole plant barley (BAR); or 3) dry lot (DL) bunk fed processed barley hay. CORN and BAR calves were limit grazed in 4-ha paddocks for 3 d grazing periods using electric fencing for 68 d, with all groups receiving a pelleted supplement (78% TDN, 16% CP) daily at 0.8% BW. Forage samples were collected every 21 d to determine CP, TDN, ADF, and NDF. DMI was estimated using the herbage weight disappearance method. After backgrounding, replicates of calves were divided into 2 and placed in a feedlot. Calves were fed a barley silage based diet with either barley or corn grain for 203 d to a target weight of 615 kg, at which point they were slaughtered and carcass data was collected. Data were analyzed as a one-way ANOVA using the Proc Mixed Model procedure of SAS. Protein content was greatest (P < 0.05) for DL and BAR (12.6% and 12.3%, respectively) compared to CORN (8.0%). Forage TDN, ADF, NDF, and forage DMI did not differ *(*P > 0.02) among backgrounding systems. Final BW and ADG were greatest (P < 0.05) for DL calves compared to CORN and BAR (331.7 vs. 311.9 and 311.2 kg, respectively) and (0.9 vs. 0.6 and 0.6 kg/d, respectively). There was no difference in costs of gain among systems but the total cost of production was greatest (P < 0.05) for DL calves ($2.20/calf/day). Feedlot performance and carcass characteristics did not differ among systems, suggesting that backgrounding calves by field grazing either standing whole plant corn or swathed barley can result in lower backgrounding production costs compared to feeding in drylot.

Key Words: backgrounding, barley, corn

0217 Transcriptomic analysis of rectal-anal junction tissue from super-shedders vs. cattle negative for *E. coli* O157:H7.
O. Wang*[1], G. Liang[1], X. Sun[1], B. Selinger[2], K. Stanford[3], G. S. Plastow[1], T. A. McAllister[4], and L. L. Guan[1], *[1]University of Alberta, Edmonton, AB, Canada, [2]University of Lethbridge, Lethbridge, AB, Canada, [3]Alberta Agriculture and Rural Development, Lethbridge, AB, Canada, [4]Agriculture and Agri-Food Canada, Lethbridge, AB, Canada.*

E. coli O157:H7 is a foodborne pathogen that causes hemorrhagic colitis and hemolytic uremic syndrome in humans. Cattle are the main reservoir for *E. coli* O157:H7 and individuals shedding > 10^4 CFU/g of feces are defined as super-shedders. To date, the molecular mechanisms responsible for the high level of carriage and shedding in super-shedders is unknown, but presumably is mediated by a host-microbial interaction. We hypothesized that changes in gene expression related to immune responses in tissues from the rectal-anal junction (RAJ) may be associated with the super-shedder phenomenon. In this study, we performed transcriptomic analysis of tissues from the RAJ, the reported main colonization site of *E. coli* O157:H7. Total RNA was extracted from RAJ tissues collected from five super-shedder steers and four non-shedder pen mates. RNA sequencing was done using Illumina sequencer Hiseq 2000 with average of 29.7 M ± 4.2 M paired-end reads generated from each sample. After mapping the reads to the bovine genome using Tophat, a total of 15,614 expressed genes (FPKM > 0.3) were detected at least once in at least one of the steers, with expression of 13,047 of genes (FPKM > 0.3) detected in non-shedders and 11, 846 (FPKM > 0.3) in super-shedders. The top functions of these genes enriched by GO terms include metabolic process, cellular process, and biological regulation which were not different between the two groups. In total, 20 genes were downregulated in super-shedders as compared to non-shedders (FDR < 0.1, using EdgeR). Of those genes downregulated in super-shedders, 11: CXCL13, CCL21, CCR7, IL2RA, LTB, S100A12, CD19, BANK1, CD19, MS4A1, KLHL6 were predicted to be associated with traits related to immune function; including movement of T cells, recruitment of leukocytes as well as the levels of B-cells and IgG. This is the first study to report transcriptomic analysis of the RAJ as it relates to the shedding status of the host. Our results suggest that immune homeostasis in super-shedders may play a role in the high levels of shedding observed in these individuals.

Key Words: *E. coli* O157, super-shedder, transcriptomic analysis

0218 Influence of steeping DDGS on growth performance and digestive function in liquid fed weanling pigs. M. Wiseman*, J. Zhu, D. Wey, and C. F. de Lange, *University of Guelph, Guelph, ON, Canada.*

Liquid feeding of high-fiber co-products with supplementary fiber-degrading enzymes may increase feeding value and influence gut development. This study assessed the effect of extended steeping of DDGS on performance and digestive function in newly-weaned pigs (weaned at 20 d) fed corn-soybean meal based liquid diets (28% DM). Enzymes (67.2 IU/g DDGS β-glucanase; 15.36 IU/g DDGS Xylanase; AB Vista) were used in both treatments: steeped (sDDGS; DDGS with enzymes fed between Day 5 and 14 of steeping in 39°C water at 16% DM) and unsteeped (usDDGS; DDGS and supplement mixed with water at time of feeding). Diet DDGS inclusion levels were 7.5% in phase 1 (d 0−7) and 25% in phase 2 (d 7-20) and 3 (d 21-35). The study was a randomized block design (n = 6 pens, 14 pigs/pen). Results are lsmean ± SEM (sDDGS vs. usDDGS, respectively), except fermentation characteristics (mean ± SD). On d 7, 14, and 35, 3 pigs per pen were euthanized for determination of liver, stomach, and small intestine (SI) weights, SI length, and digesta pH. VFA concentration was determined in d14 and d35 jejunal, ileal, and cecal digesta pooled among pigs in a pen. sDDGS batch (n = 5) characteristics (d5 and d14, respectively) revealed average pH 3.54 ± 0.16 and 3.04 ± 0.08, lactic acid 127.1 ± 22.3 and 72.5 ± 26.6 mM, and n-Butyric acid 38.7 ± 14.5 and 41.6 ± 27.1 mM. Unsteeped diets had pH 5.97 (n = 1), lactic acid 11.9 ± 11.8 mM (n = 3),and n-Butyric acid 7.1 ± 6.5 mM (n = 3). Steeping did not affect (P > 0.10) growth performance (Day 0-35 ADG 289 ± 15.8 and DMI 416.9 ± 10.3 g/d (n = 6) vs. ADG 290 ± 17.5 and DMI 415.7 ± 11.4 g/d (n = 5)), d7 physiological parameters (P > 0.10), or any gastrointestinal section weights (P > 0.05). Liver weight relative to BW was higher (P < 0.05) in sDDGS pigs on d14 while absolute liver weight was higher (P < 0.05) on d35 (30 vs. 27 ± 1 g:kg BW and 638 vs. 542 ± 21 g). sDDGS increased (P < 0.05) d14 jejunal formic and n-butyric acid (84.6 vs. 9.0 ± 16.8 and 61.8 vs. 42.1 ± 6.0 mM) without altering pH (P > 0.10). On d35 sDDGS increased (P < 0.05) cecal formic acid and decreased pH (P < 0.05) (71.7 vs. 153.7 ± 18.8 mM and 5.49 vs. 5.74 ± 0.07). No other VFA concentrations were affected (P > 0.05). sDDGS decreased (P < 0.05) d35 colon pH (5.64 vs. 5.85 ± 0.07) without altering pH elsewhere (P > 0.10). Results indicate steeping DDGS with enzymes results in altered enteric fermentation without affecting growth performance.

Key Words: digestive function, enzymes, liquid feeding pigs

0219 Selection of hybrid bromegrass for increased NDF digestibility. C. L. Rosser*[1], B. Coulman[1], and G. B. Penner[2], [1]*University of Saskatchewan, Saskatoon, SK, Canada,* [2]*Department of Animal and Poultry Science, University of Saskatchewan, Saskatoon, SK, Canada.*

The objective of this study was to determine whether selecting hybrid bromegrass for improved NDF digestibility would improve NDF digestibility and the performance of growing lambs. In 2010, 128-hybrid bromegrass (*Bromus riparius Rehm. × Bromus inermis Leyss.;* cv. AC Knowles) plants were clipped (5-cm stubble height) and used to determine 24-h in situ NDF digestibility (NDFd). Individual plants with the greatest (HNDFd; n = 20) and least (LNDFd; n = 20) digestibility values were selected (34.5 and 23.5%, respectively; P < 0.001) and polycrossed in isolation to produce seed. Seedlings were established in a field nursery June 8, 2011 and harvested July 23, 2012 and July 11, 2013 for in situ NDF digestibility determination. The DM yield tended to be greater for the LNDFd population (350 vs. 380 g/plant; P = 0.072) than HNDFd, while the degradable DM (37.2 vs. 33.6%; P = 0.098) and OM (39.8 vs. 35.7%; P = 0.092) fractions tended to be greater for HNDFd than LNDFd. Degradation rates for DM, OM, CP, NDF and ADF were not affected by treatment ($P \geq 0.398$). Additional plots of the HNDFd and LNDFd hybrid bromegrass populations were swathed on July 11, 2013, dried, and baled for an in vivo digestibility experiment. Twelve Suffolk × Canadian Arcott wether lambs were randomly assigned to the HNDFd or LNDFd treatments. The bromegrass hay was fed ad libitum and all lambs were supplemented with a pellet fed at 0.88% of initial BW. Total DMI and forage intake were not affected by treatment (P = 0.219). Nutrient intake (OM, CP, NDF, ADF, and ether extract; $P \geq 0.143$) was also not different between lambs fed LNDFd or HNDFd. However, NFC intake tended to be greater for HNDFd than LNDFD (0.34 vs. 0.29 kg/d; P = 0.070). Feeding the HNDFd or LNDFd bromegrass for 21 d did not affect final body weight or ADG ($P \geq 0.189$), but cumulative weight gain was greater for lambs fed HNDFd (P = 0.013). Total tract digestibility of DM, OM, NDF, ADF and NFC were not affected by treatment ($P \geq 0.328$), but CP and ether extract digestibility values tended to be greater for LNDFd than HNDFd ($P \leq 0.068$). These data suggest that although there were improvements in the degradable fractions of DM and OM and cumulative weight gain of the lambs fed HNDFd, the hybrid bromegrasses did not differ in NDF digestibility.

Key Words: digestibility, forage intake, hybrid bromegrass

0220 Effect of feeding different sources of nitrogen on performance of growing pigs fed diets deficient in non-essential amino acid nitrogen.

W. D. Mansilla[*1], J. K. Htoo[2], and C. F. de Lange[1], *[1]University of Guelph, Guelph, ON, Canada, [2]Evonik Industries AG, Hanau-Wolfgang, Germany.*

When formulating diets with low nitrogen (N) content, the supply of dietary non-essential amino acids (NEAA) is reduced and essential amino acid (EAA) may be catabolized to supply N for endogenous synthesis of NEAA, which can lead to compromised pig performance. The objective of this study was to evaluate the effect of supplementing different sources of N in diets deficient in NEAA-N on performance of growing pigs. In total 36 barrows (BW 15.5 ± 1.0 kg) were randomly assigned to 9 different diets: a basal cornstarch and casein-based diet, not deficient in EAA but low in CP (N × 6.25; 8.01%); and the basal diet supplemented with 4 different sources of N (urea, ammonium citrate, glutamic acid and a mix of NEAA) at 2 levels each, supplying 1.37 and 2.75% additional CP, respectively. The mix of NEAA was based on body composition of NEAA of 20 kg pigs, and aimed to minimize endogenous synthesis of NEAA. Pigs were housed individually and fed at 3.0 × maintenance requirement for ME during 3 consecutive weeks. BW gain was monitored weekly. BW gain and gain:feed of pigs fed urea were lower than any other sources of N ($P < 0.05$), but they were similar across the other treatments ($P > 0.10$). As the level of N increased, BW gain and gain:feed increased ($P < 0.05$). Feeding ammonium to pigs is as efficient as supplementing glutamate or NEAA mix to support growth performance when diets are deficient in NEAA-N, while utilization of urea-N is lower.

Key Words: growth, nitrogen, pig

Table 0220. BW gain, feed intake and gain:feed in growing pigs fed a diet deficient in NEAA-N supplemented with different sources of N at different levels of N supplementation

		BW gain, g/d	Feed intake, g/BW$^{0.6}$/d	Gain:feed

0221 Comparison of winter feeding systems for the evaluation of beef cow performance, reproductive efficiency and system costs.

D. Jose[*1], G. B. Penner[1], J. J. McKinnon[1], K. Larson[2] and, B. Lardner[1,2], *[1]University of Saskatchewan, Saskatoon, SK, Canada, [2]Western Beef Development Centre, Humboldt, SK, Canada.*

Extensive winter grazing has been proven as a successful strategy to reduce production and labor costs in a cow-calf operation without much adverse effects on animal health and performance. Two experiments were conducted during the winter of 2012-2013, to evaluate 3 winter feeding systems: (i) field grazing standing whole plant corn (SC; TDN = 59.5%, CP = 7.8%), (ii) field grazing swathed barley hay (SB; TDN = 66.2%, CP = 8.5%) and, (iii) barley hay bales fed in drylot pens (DL; TDN = 60.1%, CP = 12.7%). The specific objectives were to compare beef cow performance, reproductive efficiency and system costs in experiment 1 (EXP 1), and ruminal pH parameters in experiment 2 (EXP 2). In EXP 1, dry pregnant Angus cows ($n = 60$, body weight (BW) = 651.2 ± 7 kg), stratified by body weight and days pregnant were randomly allocated to 1 of 3 replicated ($n = 2$) winter grazing treatments for 77 d. Cow BW, body condition score (BCS), and rib and rump fats were measured at the start and end of the trial. Increases in rump fat were greater ($P = 0.002$) for SC cows compared to DL cows (1.90 mm vs. 0.55 mm, respectively). Calves born to cows on SC were heavier ($P < 0.001$) at birth compared to calves from SB cows (42 vs. 40 kg respectively). In EXP 2, 9 cannulated beef heifers were cycled through the 3 winter systems concurrently within EXP 1, in a replicated 3 × 3 Latin square design, for 63d to evaluate effect of forage type on rumen pH. Results from EXP 2 indicated that SB heifers had the lowest ($P < 0.003$) mean, minimum and maximum rumen pH and greatest duration and area under pH < 5.8 ($P < 0.001$) compared to heifers on SC and DL winter systems. Economic analysis revealed that total costs were greatest for the DL ($2.29/head/d) compared to SC ($1.78/head/d) and SB ($1.65/head/d) systems. Results suggest that both SC and SB systems are cost effective alternatives to DL system, and do not negatively affect cow body weight or reproductive performance in winter.

Key Words: winter grazing, corn grazing, swath grazing, reproductive performance

0222 Dietary supplementation with excess leucine transiently improved whole body nitrogen retention in young pigs challenged with bacterial lipopolysaccharide.

M. Rudar* and C. F. de Lange, *University of Guelph, Guelph, ON, Canada.*

The increase in circulating pro-inflammatory cytokines following a bacterial lipopolysaccharide (LPS) challenge causes a disruption in normal nitrogen (N) and amino acid (AA) me-

tabolism. The reduction in whole body N retention during inflammation can be attributed to an increase in hepatic protein synthesis at the expense of muscle protein synthesis, which may be modulated by leucine (Leu) intake. The objective of this study was to explore the effect of excess dietary Leu on the dynamics of N retention in young pigs following an LPS challenge. A total of 24 starter pigs (13.93 ± 2.05 kg) were used in a 2 × 2 factorial design (n = 6). Pigs were fed isoenergetic and isonitrogenous diets formulated to contain all essential AA 10% above requirements for protein deposition (Con; 1.36% SID Leu) or Leu supplemented at twice that amount (+Leu; 2.72% SID Leu). Pigs were housed in metabolic crates and fed six times daily according to their body weight. Pigs were challenged with either saline (−LPS) or repeated and increasing doses of LPS (+LPS; 30 μg·kg^{-1} injected intramuscularly on Days 1, 3, 5, and 7 of a 7-d N-balance period). Blood was collected on Days 1 and 7 1 h after feeding to determine plasma AA concentrations. Whole body N retention was determined daily. Pigs fed +Leu had higher plasma Leu than pigs fed Con (319 vs. 159 μmol·L^{-1}, SE 10.3, $P < 0.01$). There was no effect of diet on N retention across the 7-d N balance period ($P > 0.10$). However, LPS reduced N retention during the first 3 d of the N balance period ($P < 0.05$). For +LPS pigs, the effect of diet on N retention changed over time ($P < 0.05$); on Day 2, N retention was lower in +LPS pigs fed Con than +LPS pigs fed +Leu (10.5 vs. 12.3 g/d, SE 0.66, $P < 0.05$). Moreover, N retention was higher in −LPS pigs than in +LPS pigs fed Con (13.0 vs. 10.5 g/d, SE 0.66, $P < 0.01$) whereas N retention was not different between–LPS pigs and +LPS pigs fed +Leu (12.3 vs. 12.3 g/d, SE 0.66, $P > 0.10$) on Day 2 post-challenge. In this study, excess dietary Leu partly attenuated the reduction in body protein gain after an LPS challenge.

Key Words: endotoxin, leucine, nitrogen retention

0223 The relationship between trailer motion and carcass bruising in market cows during transport.

C. E. Kehler[*1,2], K. H. Ominski[1], L. L. Connor[1], T. G. Crowe[3], and K. S. Schwartzkopf-Genswein[4], *[1]University of Manitoba, Winnipeg, MB, Canada, [2]Agriculture and Agri-food Canada, Lethbridge, AB, Canada, [3]University of Saskatchewan, Saskatoon, SK, Canada, [4]Agriculture and Agri-Food Canada, Lethbridge, AB, Canada.*

Increased trailer motion, coupled with large accelerations and decelerations, have been associated with decreased carcass quality and increased stress indicators in cattle, sheep and hogs. However, motion of livestock trailers has not been measured in North-American cattle semi-trailers over long distances (> 1000 km). The objective of this study was to describe the acceleration within each of the 5 compartments of a cattle semi-trailer and to determine the relationship between trailer acceleration and bruising severity. The root mean square (rms) of acceleration was measured at a sampling rate of 200 Hz in 3 orthogonal axes; x (vertical, positive upward), y (front-to-rear, positive forward) and z (lateral, positive leftward as viewed from rear) by rigidly clamping an accelerometer to the cross beam below each of the five compartments of 8 trailers transporting 331 animals from assembly yard to a processing facility. Journeys ranged in duration from 780 min to 942 min. A bruise severity score was obtained before trimming for n = 291 carcasses using the number of bruises weighted by the size of bruise on a 3-point scale (1 $\leq$ 6.5 cm; 2 = 6.5 to 12 cm and 3 $\geq$ 12 cm). Due to limitations in the battery capacity of the sensors, the acceleration was only measured for the first half of the journey for all but 2 journeys. The percent difference in rms between the entire journey and the first half of those 2 journeys ranged from 7.22% to 14.54%. The mean rms of acceleration for all trailers (34 accelerometers) was 1.43 ± 0.42 m/s^2, 1.32 ± 0.53 m/s^2 and 1.67 ± 0.50 m/s^2 for x, y and z axes, respectively. Mean bruise number and severity per carcass were 4.52 ± 2.43 and 5.31 ± 2.84, respectively. When measured by trailer a quadratic relationship was observed between acc (rms) and bruise severity in the z-axis (r = 0.69, P = 0.09) however, no relationship was observed between either the x or y axes and bruise severity. Acceleration varied slightly between trailer compartments in the z (P = 0.10) and y-axes (P = 0.10) but not in the x axis. Bruising also varied slightly by trailer compartment (P = 0.11). Results indicate that reductions in side to side trailer movements could decrease bruising, thereby improving carcass quality and animal welfare. Extension and replication of this research is required to further understand the relationships between trailer motion, carcass bruising and overall animal welfare.

Key Words: cattle, transport, acceleration

0224 Impact of reducing dietary crude protein concentration on serum lysine concentration and lysine utilization efficiency in lactating sows.

L. A. Huber[*1], C. F. de Lange[1], U. K. Larsen[2], D. Chamberlin[3], and N. L. Trottier[3], *[1]University of Guelph, Guelph, ON, Canada, [2]Aarhus University, Foulum, Denmark, [3]Michigan State University, East Lansing*.

It was hypothesized that reducing dietary crude protein (CP) concentration while maintaining available Lys intake will improve Lys utilization efficiency for milk production in sows. Forty lactating multiparous Yorkshire sows were used to determine the effect of reducing dietary CP concentration and supplementing with crystalline amino acids on dietary Lys utilization efficiency during early (d3−7) and peak (d14-18) lactation. Sows were assigned to 1 of 4 diets: [1] 16.0% CP (as-fed; analyzed contents; HCP); [2] 15.7% CP (0.1% crystalline Lys; MHCP); [3] 14.3% CP (0.2% crystalline Lys; MLCP); [4] 13.2% CP (0.3% crystalline Lys; LCP); diet HCP was formulated using soybean meal and corn as the only Lys sources. Across diets, standardized ileal digestible (SID) content of Lys was 0.77%, based on analyzed

content and estimated SID. Other essential amino acids were included to exceed requirements. Litters were standardized to 10 piglets within 24h of birth. Milk yield was estimated based on litter size and growth rate. Blood was collected from fasted sows on d3, 7, 14, and 18 for free amino acid analysis. The efficiency of using SID Lys intake for Lys output in milk (Klys) was calculated according to NRC (2012), accounting for maternal maintenance requirements and the contribution of maternal body protein mobilization based on sow BW change. Sow feed intake and litter growth rate during the 21d lactation period did not differ between dietary treatments (overall means: 5670 ± 138 and 2263 ± 94 g/d, respectively). Serum Lys concentration was influenced by day in lactation ($P < .0001$); there tended ($P = 0.08$) to be a quadratic effect of dietary CP concentration (142.8, 105.6, 127.5, and 167.7 ± 22.7, and 84.8, 63.2, 61.7, and 79.6 ± 11.9 µmol/L; HCP, MHCP, MLCP, and LCP on d7 and d18, respectively). In early lactation, reduced dietary CP concentration did not affect Klys (67.5, 70.9, 64.2, and 66.7 ± 6.63%; HCP, MHCP, MLCP and LCP, respectively; $P > 0.10$). In peak lactation Klys was higher for MHCP than HCP ($P < 0.05$), but a further reduction in diet CP concentration did not affect Klys ($P > 0.10$; 59.8, 68.3, 65.1, and 67.6 ± 2.92%; HCP, MHCP, MLCP and LCP, respectively). There appears to be an association between plasma Lys levels and Klys, which needs to be explored further. In peak lactation the use of up to 0.1% crystalline Lys to replace protein bound Lys in the diet improved Klys.

Key Words: amino acids, lactating sows, lysine utilization

0225 Diurnal variations in enteric methane emissions from non-lactating dairy cows offered diets differing in forage to grain ratio. A. J. Kotz*[1], S. C. Li[2], E. J. McGeough[1], E. Khafipour[3], and J. C. Plaizier[2], *[1]University of Manitoba, Winnipeg, MB, Canada, [2]Department of Animal Science, University of Manitoba, Winnipeg, MB, Canada, [3]Department of Medical Microbiology and Infectious Diseases, University of Manitoba, Winnipeg, MB, Canada*.

This experiment determined how level of dietary grain inclusion affected daily enteric methane emissions and their diurnal variation in dairy cows. Six mature non-lactating Holstein dairy cows were offered one of three diets with forage to grain ratios of 100:0 (F), 75:25 (M), and 50:50 (H). The forage portion of the diet consisted of 80% grass hay and 20% alfalfa hay (DM basis). The concentrate was a barley-corn based ration (DM = 893 g/kg, CP = 198 g/kg DM). Feed was offered three times daily at 0900, 1300, and 1700. The experiment was a replicated 3 × 3 Latin Square Design, with each animal receiving each of the three diets over the course of the three 5-wk periods. Experimental diets were switched gradually during the first week of every period. This was followed by 3 wk dietary adaptation. Sample collection and enteric methane output measurement were conducted on two separate days during the fifth week of every period. Rumen fluid was collected using a stomach tube and a fecal grab sample was taken to determine pH at 0830 and 1500 on the day preceding enteric methane output. An open-circuit hood calorimetric system was used to determine methane output over a 24 h period. Increasing the grain content of the diet decreased rumen pH (F = 7.02, M = 6.82, H = 6.77, $P < 0.01$) and fecal pH (F = 7.09, M = 6.85, H = 6.66, $P < 0.01$) and increased DMI (F = 12.2, M = 14.3, H = 16.6 kg/d, $P < 0.01$). Increasing the dietary grain content increased daily enteric methane emissions (F = 361.6, M = 423.0, H = 445.0 L/Day, $P < 0.01$). However, when methane production was expressed per kilogram of DMI, increasing the dietary grain inclusion reduced daily emissions (F = 29.8 L/kg DMI, M = 29.7 L/kg DMI, H = 27.2 L/kg DMI, $P < 0.01$). Methane emissions clearly exhibited a diurnal pattern that coincided with feeding events, irrespective of diet offered. The highest rate of methane production observed was concurrent with afternoon feeding at 1300 (0.38 L/min); while the lowest rate of methane production was observed 2 h before morning feeding (0.20 L/min). The diurnal pattern differed among diets ($P < 0.01$). In conclusion, dietary grain inclusion increased daily methane production and altered the diurnal pattern of methane emission rate.

Key Words: cattle, enteric methane emission, grain to forage ratio

---

0226 Long-term supplementation of diets with 3-nitrooxypropanol resulted in a sustained reduction in methane production in beef cattle. A. Romero-Perez*[1,2], E. K. Okine[1], S. M. McGinn[2], L. L. Guan[1], M. Oba[1], S. M. Duval[3], and K. A. Beauchemin[2], *[1]Department of Agricultural, Food and Nutritional Science, University of Alberta, Edmonton, AB, Canada, [2]Agriculture and Agri-Food Canada, Lethbridge Research Centre, Lethbridge, AB, Canada, [3]DSM Nutritional Products France, Research Centre for Animal Nutrition and Health, Saint Louis Cedex, France.*

The objective was to evaluate whether long-term supplementation of diets with 3-nitrooxypropanol (NOP), a synthetic compound proven to reduce enteric CH_4 emissions in short-term studies, results in a sustained reduction in enteric CH_4 emissions in beef cattle. Eight ruminally cannulated heifers (637 ± 16.2 kg of BW) were used in a completely randomized design with 2 treatments: Control (0 g/d of NOP) and NOP (2 g/d of NOP). Treatments were mixed by hand into the TMR (60% forage, DM basis) at feeding time. Feed offered was restricted to 65% of ad libitum DM intake (DMI; maintenance energy intake) to avoid excessive growth. Duration of the experiment was 146 d, including an initial covariate period without NOP supplementation (18 d), 4 periods with NOP supplementation (28 d each), and a final recovery period without NOP supplementation (16 d). Methane was measured at the

end of each period for 3 d using metabolic chambers. Volatile fatty acid (VFA) concentration and microbial populations were measured using rumen samples collected 0, 3, and 6 h after feeding. Data were analyzed using the PROC MIXED procedure of SAS. Average DMI for the experiment was 7.0 ± 0.2 kg. Methane intensity was reduced by 60% when NOP was supplemented (22.6 vs. 8.9 g/kg DMI; $P < 0.01$) with no signs of adaptation (period × treatment, $P = 0.2$). Total VFA concentrations were not affected ($P = 0.12$); however, acetate concentration was reduced and propionate concentration increased when NOP was supplemented ($P < 0.01$), which led to a reduction in the acetate to propionate ratio (3.9 vs. 2.9; $P < 0.01$). NOP had no effect on the copy number of the 16S rRNA gene of total bacteria ($P = 0.5$) but the copy numbers of the 16S rRNA gene of methanogens ($P < 0.01$) were reduced and copy numbers of the 18S rRNA gene of protozoa ($P = 0.03$) were increased. All effects of NOP observed during the measurement periods were absent during the recovery period when supplementation was discontinued. These results showed that reduction of CH_4 production in ruminants is sustained with long-term dietary supplementation of NOP.

Key Words: 3-nitrooxypropanol, beef cattle, methane

0227 Measuring animal productivity and rumen efficiency from extensively overwintered beef cows on the Canadian prairies.

G. R. Donohoe*, K. M. Wittenberg, D. N. Flaten, B. D. Amiro, and K. H. Ominski, University of Manitoba, Winnipeg, MB, Canada.

Many producers in the Prairie region have adopted the use of low-cost, extensive overwintering strategies. Although the economic benefits of these practices are well-documented, rumen efficiency and animal productivity have not been fully characterized. Evaluation of such strategies is challenging because of our limited capacity to measure individual animal intake in extensive overwintering systems. In an attempt to address these knowledge gaps, sixty mature, non-lactating, pregnant beef cows were fed low-quality forage (8.8% crude protein and 4.3 Mcal kg^{-1} gross energy (GE), DM basis) ad libitum and monitored over two, 28-d periods. Cows were divided into three treatment groups: intensively overwintered (drylot; DL), extensively overwintered (bale grazed; BG) and extensively overwintered supplemented with dried distillers' grains with solubles (DDGS) at a rate of 8.31 kg DM every third day (BG+DDGS). Measurements included temperature, body weight, DM intake, enteric methane emission, and serum urea nitrogen (SUN). Average daily air temperature over the trial was -17.1 ± 6.5°C (± SD). Localized temperatures, measured with iButtons near the animal body surface, showed that cows in the extensive treatments were exposed to colder temperatures, at -14.7 ± 0.6°C, compared to cows overwintered intensively, at -11.9 ± 1.4°C (± SD). Average daily gain over the trial was greater ($P < 0.01$) for DL cows when compared to BG cows, but not different ($P > 0.20$) when comparing DL to BG+DDGS. Intake was greater ($P = 0.04$) in period one for DL cows compared to BG cows, measured using GrowSafe and alkane bolus techniques, at 13.4 ± 0.38 and 12.1 ± 0.44 kg DM d^{-1}, respectively (± SE). This resulted in greater ($P < 0.01$) enteric methane emission from the BG cows in period one, at 5.62 ± 0.49 and 8.46 ± 0.49%GEI, for the DL and BG treatments, respectively (± SE). The addition of DDGS every third day in the extensive treatment reduced enteric methane in both periods. Average SUN concentrations over the trial were below the acceptable range of 2.1 mmol L^{-1} at 1.00 ± 0.40 and 1.40 ± 0.60 mmol L^{-1} for cows in the DL and BG treatments, respectively (± SD). When measured at 24 and 72 h after feeding DDGS, SUN concentrations for cows in the BG+DGSS treatment were 5.14 ± 1.67 and 2.65 ± 0.57 mmol L^{-1}, respectively (± SD), indicating that supplemental DDGS was an effective strategy to increase SUN when feeding low-quality forage. This data demonstrates that animal nutrient requirements may differ in intensive and extensive overwintering environments, and therefore require further characterization to improve metabolic and production efficiency of cattle.

Key Words: enteric methane, beef cows, overwintering

0228 Adding sera enriched in PUFA with different n-6/n-3 ratio advanced bovine in vitro embryo development from both high- and inferior-quality oocytes.

R. Salehi*[1], A. Ruiz-Sanchez[1], M. G. Colazo[2], M. Oba[1], M. Dyck[1], and D. J. Ambrose[3], *[1]University of Alberta, Edmonton, AB, Canada, [2]Alberta Agriculture and Rural Development, Edmonton, AB, Canada, [3]Alberta Agriculture and Rural Development, Livestock Research Branch, Edmonton, AB, Canada.*

Diets containing sunflower (SUN; high linoleic acid, LA) or flaxseed (FLX; high α-linolenic acid, ALA) positively affect early embryonic development (EED) in dairy cows. Also, a FLX-based diet decreased the proportion of non-viable embryos in vivo. Oleic acid (OLA), abundant in canola (CAN), improves oocyte competence in vitro but its influence on EED is not known. Our objectives were to: (1) compare the effects of adding serum collected from cows fed CAN, SUN or FLX on in vitro development of bovine embryos derived from high-quality oocytes (Exp-1), and (2) determine the effect of FLX-fed-cow-serum on development of embryos derived from inferior-quality oocytes (Exp-2). Estrus-cow-serum was harvested from Holsteins fed hay (8.8 DM kg/d) and concentrates (3.8 DM kg/d) supplemented with 1 of 3 rolled oilseeds (8% of total DM) for ≥ 21 d: CAN ($n = 4$); SUN ($n = 4$); or FLX ($n = 4$). Cumulus-oocyte-complexes (COC) aspirated from abattoir ovaries were categorized into Grade 1+2 (high-quality) and Grade 3 (inferior-quality) for Exp1 and 2, respectively. The COC were matured and fertilized (Day-0) in vitro; presumptive zygotes ($n = 977$ from Grade 1+2, Exp-1; $n = 359$ from Grade 3 COC, Exp-2 in 5 replicates each) were cultured with corresponding sera (5%) until Day-8. Se-

rum fatty acid profile (% total fatty acid) were OLA 12.1, total polyunsaturated fatty acids (PUFA) 49.4, n-6/n-3ratio 4.7 (CAN); LA 52.5, PUFA 57.5, n-6/n-3ratio 10.5 (SUN); ALA 17.9, PUFA 54.3, n-6/n-3ratio 2.0 (FLX). In Exp-1, SUN (78.0) and FLX (78.8) increased ($P < 0.05$) % cleaved compared with CAN (65.0) but not with fetal calf serum (FCS; 72.1). Blastocyst (BL) developmental rate (%) was higher ($P < 0.05$) on Day-7 in FLX (15.5) and SUN (15.5) than in CAN (9.1) and FCS (9.2) treatments, but not on Day-8 (overall, 23.3). More ($P < 0.05$) advanced stage embryos (expanded- and hatched-BL, %) were present on Day-8 in SUN (85.0) compared to FLX (69.8), CAN (61.5) and FCS (64.0). In Exp-2, although % cleaved did not differ (41.8), FLX tended ($P = 0.12$) to increase BL developmental rate on Day-7 (6.73) compared to FCS (3.01). More advanced stage embryos (BL and expanded-BL) were present in FLX vs. FCS (84.6 vs. 0.0%). In Exp-2, BL developmental rate (11%) and advanced stage embryos (95%) did not differ on Day-8. In summary, adding serum from cows fed FLX or SUN enhanced BL developmental rate on Day-7 and the proportion of advanced stage embryos on Day-7, even from inferior quality oocytes.

Key Words: oilseed, embryo, serum

CSAS SYMPOSIUM: **UNDERSTANDING FEEDING BEHAVIOR TO IMPROVE ANIMAL WELL-BEING AND PRODUCTIVITY**

0229 The psychology and sociology of feeding behavior. J. J. Villalba*, *Agricultural Experiment Station, Utah State University, Logan.*

Food intake (how much to eat) and preference (what to eat) dictate nutrient balance and ultimately an individual's fitness and productivity. Emerging evidence suggests that the mechanisms underlying hunger and satiety are not only governed by physiological signals associated with the homeostatic control of food intake but also by their interaction with pathways involved in the control of food reward and hedonics. The hedonic value of a food—or how pleasurable to the animal such food results—is in part motivated by the individual's previous experiences with its orosensorial and biochemical properties. Taste (as well as smell and sight) allows animals to discriminate among foods and is a source of hedonic sensations. Postingestive feedback calibrates such sensations with its homeostatic utility, influencing food preference and chemical composition of the diet. This mechanism identifies foods adequate in nutrients (or in chemicals that enhance health) and foods with nutrient deficiencies/imbalances (or in chemicals that are toxic), thereby increasing or decreasing preference, respectively. The cultural inflection is manifest through mother and peers, representing a model from which naïve observers learn new behaviors and are exposed to novel environmental experiences. These experiences begin in utero and continue after birth, priming individuals to learn from their individual orosensorial and postingestive experiences. In turn, the new knowledge created within a social group is maintained and transmitted by mothers across generations. It is proposed that a strategic management of an animal's experiences with food, i.e., a certain target food presented early in life with mother/peers, or in close temporal association with other nutritious/medicinal foods, has the potential to enhance animal health, productivity and well-being.

Key Words: food choice, behavior, preference

0230 Physiological mechanisms controlling feeding behavior. M. S. Allen* and P. Piantoni, *Michigan State University, East Lansing*.

Mechanisms controlling feed intake are dependent on the interaction between diet and physiological state of animals. Physiological state is affected by age, pregnancy, lactation, and adiposity and is characterized by differences in insulin sensitivity of tissues and plasma concentrations of insulin, growth hormone, and leptin. The interaction between diet and physiological state affects feeding behavior (e.g., meal size and frequency) depending on the type and temporal supply of absorbed fuels. These fuels (e.g., glucose, fatty acids, amino acids) derive from the diet directly or indirectly as a result of gastrointestinal fermentation and are metabolized or stored by different tissues at different rates. Other fuels (e.g., long chain fatty acids, glycerol, amino acids) originate from body reserves. Effects of fuels on endocrine response and gene expression affect energy partitioning, which in turn affects feeding behavior by altering clearance of fuels from the blood. Various signals are integrated in brain feeding centers and dominant mechanisms controlling feed intake change with physiological state. Signals that affect feeding behavior include those from gut distension, which likely dominates control of feed intake under conditions of high-energy requirements with low-energy diets, as well as those from the release of gut peptides stimulated by certain nutrients. There is a growing consensus of the importance of fuel-based sensing among tissues. Signals to brain feeding centers via hepatic vagal afferents are also affected by oxidation of fuels. While oxidation of fuels has been linked to feeding behavior, evidence suggests that the mechanism is specifically related to hepatic energy charge (degree of phosphorylation of adenine nucleotides). Synergistic effects of metabolic inhibitors have been demonstrated in rodents, which suggests an integrated mechanism with a common signal related to hepatic energy status from oxidation of a variety of fuels. Utilization of high-energy phosphate bonds vary with liver function and their production is determined by the flux of carbon through acetyl CoA and activity of the tricarboxylic acid cycle. Hepatic concentration of acetyl CoA varies diurnally and is highly variable across cows, depending on lipolytic state (e.g., early postpartum period, shipping stress). Therefore, acetyl CoA is likely a key metabolite involved in both circadian control of feeding behavior and control of feed intake across physiological states. This presentation will discuss control of feed intake in animals varying in physiological state considering the effects of diet on energy partitioning and hepatic oxidation of fuels.

Key Words: feeding behavior, hepatic oxidation, metabolic fuels

0231 Feeding behavior, productivity and welfare of dairy cows. M. A. G. von Keyserlingk* and D. M. Weary, *University of British Columbia, Vancouver, BC, Canada.*

Over the last decade there has been a growing scientific interest in feeding behavior of dairy cattle, in part because dairy nutritionists are now becoming interested in how changes in feed intake are mediated by changes in behavior and, in part, because changes in feeding behavior are increasingly recognized as a useful indicator of cow health. Feeding behavior can be described using several measures, including the number and duration of meals, as well as intake and feeding rate. However, it is now clear that changes in feeding behavior are mediated in part by changes in other primary behaviors such

as social and lying behavior. It is also well established that the delivery of fresh feed is a primary factor stimulating feeding behavior by intensively housed dairy cows. Moreover, management factors such as competition at the feed bunk and regrouping can profoundly affect feeding behavior, with subordinate animals often showing the most pronounced effects. Many types of diseases are common after calving; these include illnesses caused by infectious agents and disturbances in metabolism. Much of our work has focused on identifying links between feeding behavior and a common infectious disease of the uterus, metritis. For example, over a series of studies, we now provide solid evidence that feeding behavior is altered in cows during the period of illness, but even more interesting is that this behavior is altered in the weeks leading up to parturition, long before clinical signs are evident, compared to healthy cows. We also review the relationship between lying, social, and feeding behavior as work now indicates that each of these behaviors impacts the other and collectively they play a role in expression of sickness behavior by cattle.

Key Words: social behavior, lying behavior, disease

0232 Good eating habits lead to good growth and welfare of dairy calves. T. J. DeVries*, *University of Guelph, Kemptville, ON, Canada.*

The dairy calf needs access to milk in sufficient quantities to maintain health and high-levels of growth. In addition, solid feed consumption must also occur early in life to establish fermentation in the rumen, and initiate the process of physical and metabolic development of the rumen. There is good empirical evidence that the feeding behavior patterns of adult dairy cattle, in meal patterning and dietary selection, can impact health, productivity, and welfare. It has also been demonstrated in more recent research that the feeding behavior patterns of dairy calves may also be just as important. In particular, feeding behavior can have immediate impact by influencing nutrient consumption and growth. Further, as behavior patterns are learned early in the life of a ruminant, these may have long-term implications if and when they persist over time. Thus, there is potential for various nutritional, housing, and management factors early in the life of a dairy calf to impact both short- and long-term feeding behavior patterns. This review will provide several examples of early-life factors influencing the eating habits of dairy calves and, in turn, influencing calf growth and welfare. For example, providing continuous, ad libitum access to milk may result not only in greater growth, but also in more natural feeding patterns, both of milk and solid feed. As another example, there is new data to reinforce the idea that providing forage to calves is important for rumen development, and consequent growth and efficiency. However, the physical form and presentation of that forage may also have a significant impact on the feeding patterns of calves, in particular feed sorting, impacting both their immediate nutrient intakes as well as the development and persistence of that behavior. Housing management also has the potential to impact calf feeding behavior and growth. Housing calves in pairs (vs. individually) can promote intake and growth, particularly at weaning. However, competition for feed access for grouped calves can impact the expression and learning of less desirable feeding patterns. Continued research in this area is needed to assess how long some of these learned behaviors persist and what factors may influence their persistence or diminishment.

Key Words: calves, behavior, sorting

DAIRY FOODS SYMPOSIUM: ADVANCES IN DELIVERY OF DAIRY INGREDIENTS FOR HEALTH AND FUNCTIONAL BENEFITS

0233 Market opportunities for dairy proteins. A. Bienvenue*, *U.S. Dairy Export Council, Arlington, VA.*

The protein trend, popular among athletes for decades, has now reached several mainstream segments. Consumers – especially in the United States and Western Europe – have become increasingly aware of the benefits of protein in the diet for satiety, weight management and muscle-related benefits such as exercise recovery and healthy aging. Food manufacturers now offer beverages, bars, cereals, meals and yogurts formulated to deliver increased levels of protein, while maintaining a good taste profile. In Asia and the Middle East, the protein trend is at the cusp of what we are seeing in the United States and Europe. Growth in demand for protein-rich foods is expected as consumers in these regions achieve greater financial prosperity, become aware of health trends in other countries, and move toward a more Western diet. The demand for protein-rich foods presents a huge opportunity for dairy's many products and ingredients. Dairy protein can deliver good taste, functionality, fast and/or slowly digested proteins and superior nutrition in a product formulation. In order to capitalize on formulators' desire to increase protein levels in foods and beverages, dairy suppliers must offer ingredients that will meet buyers' specifications, consistently perform and deliver a high-quality finished product. Dairy ingredient performance depends on the protein type, structure, pH, ionic strength, interactions with other ingredients in the formula and processing conditions of the finished product. Therefore, it is crucial for suppliers to understand formulators' parameters to help in selecting the best dairy ingredient functionality for a food system. In a highly competitive marketplace, formulators have choices of ingredients to increase protein levels in food formulation. The Digestible Indispensable Amino Acid Score (DIAAS), the new FAO-recommended method, demonstrates the higher bioavailability of dairy proteins when compared to plant-based protein sources. Dairy proteins can therefore distinguish themselves by the excellence of the nutrition they deliver. To allow for more dairy protein to be used in a wide variety of food applications, the dairy industry must accelerate innovation to expand the offering of cost-effective ingredients that will perform consistently under diverse processing conditions and challenges. Examples of the attributes requested include: for beverages, improved heat stability across a wide pH range, greater clarity and a very clean flavor profile; in bar applications, a dairy protein that can resist hardening over time. Dairy protein ingredients that maintain flavor, color, solubility and flowability throughout their shelf life, even in hot and humid environments, are highly desired for export markets..

Key Words: dairy protein, functionality, export.

0234 Using charged membranes to improve dairy protein ingredients. M. Etzel*, *University of Wisconsin, Madison*.

This research examines two hypotheses: (1) negatively charged ultrafiltration (UF) membranes can be used to manufacture whey protein and milk protein ingredients at enhanced flux, and (2) positively charged UF membranes can be used to make dairy protein fractions without the use of chromatography. Charged UF membranes are fabricated from normal uncharged UF membranes. The membrane charge combines with the membrane molecular weight cutoff to control whether or not proteins permeate or are retained by the membrane. At the neutral pH of milk and whey, the major proteins are charged negative and are rejected by a negatively charged UF membrane, allowing the use of wide pore size membranes that operate at high flux. Compared to current uncharged 10 kDa membranes, 100 to 300 kDa charged UF membranes have a 2−5× higher flux at the same or increased protein retention. We scaled up this technology 1400× from 50-1000 cm^2 flat sheet systems to 70,000 cm2 spiral wound systems. In the fractionation of proteins from milk or whey, chromatographic purity can be obtained without the use of chromatography. For example, by attaching a positive charge to a 300 kDa UF membrane, selectivity increased by a factor of 3 for fractionating bovine α-lactalbumin from β-lactoglobulin in milk-serum, compared to an unmodified membrane. Thus, like-sized proteins that differed only somewhat in isoelectric point and size and that were about 15-20 times smaller than the membrane molecular weight cutoff were fractionated using charged UF membranes.

Key Words: proteins, membranes, processing

0235 Emerging uses of new dairy ingredients in cheese, yogurt, beverages, and other products. L. Metzger*, *Midwest Dairy Foods Research Center, South Dakota State University, Brookings.*

The application of membrane based filtration processes to isolate and concentrate a variety of protein fractions present in milk has led to the development of a new generation of dairy protein based ingredients. These new protein based ingredients can be broadly classified into three groups: protein isolates containing milk proteins in the same ratio as found in milk, protein isolates fractionated into casein or whey protein; and isolates of individual milk proteins. Protein isolates containing milk proteins in the same ratio as milk have been further modified with enzyme treatments as well as modifications in the mineral content. These modifications have led to improved functionality in process cheese applications, protein bars and UHT processed beverages. Protein isolates that primarily con-

tain casein or whey protein created a new class of ingredients that take advantage of the unique properties of these two categories of protein. For example clear acidic beverages can be produced with whey protein isolates whereas heat stable high calcium meal replacement beverages can be made with casein isolates. Individual protein fractions such as β-casein or α-lactalbumin can also be isolated from milk using a combination of several filtration processes. These individual protein fractions have unique functional or nutritional properties and can be used in produce specialty products such as whipped toppings and beverages that target for stress reduction. The availability of filtration based processes to isolate a wide variety of protein based ingredients containing different fractions of milk proteins in conjunction with enzyme and mineral modification has provided product developers with a tool kit of new ingredients that can be utilized to modify the functionality of existing products as well as create new products.

Key Words: proteins, processing, filtration

0236 An update on carrier and delivery systems using casein micelles from bovine milk. F. Harte*, *University of Tennessee, Knoxville.*

Although the structure-function relationships of casein micelles remain under discussion, there is strong evidence suggesting that casein micelles in bovine milk are natural delivery systems not only for calcium but also for other biomacromolecules. Recent research and development in the structure-function properties of casein micelles has put emphasis on processing operations to improve the binding of low molecular weight hydrophobic molecules. Improved binding properties of casein micelles has been achieved by using enzymatic processes (e.g., transglutaminase) or through environmental modifications including pH, ionic strength, solvent properties, pressure, and shear. Researchers are starting to understand the mechanisms that trigger delivery (e.g., pH, enzymatic digestion) and the role that individual casein proteins play in binding and delivery of bioactives compounds important in the food (e.g., flavor and color delivery), and pharmaceutical (drug delivery) fields. This symposium is designed to update the academic and industry communities on current and future developments on the use of a natural nano-delivery system such as the casein micelles from bovine milk.

Key Words: casein, encapsulation, delivery

0237 Protein modification for health benefits. J. A. Lucey*, *Department of Food Science, University of Wisconsin, Madison.*

Proteins can be modified by the covalent attachment of polysaccharides utilizing the Maillard reaction. Recently, a novel method was developed at University of Wisconsin where conjugation was achieved in (liquid) batch processed mixtures. Protein denaturation/aggregation was inhibited by conducting the process in the presence of a crowding agent (such as dextran). A food-grade chromatography method was developed to purify these conjugates. Conjugated proteins produced by this method had excellent solubility and heat stability and did not exhibit browning or off-flavors. Using an in vitro infant digestion model (i.e., physiological amounts of enzymes that matched in vivo infant digestion rate of β-lactoglobulin), we also demonstrated that conjugated proteins were digested more slowly than unmodified proteins, which could help avoid the high titers of immunoreactive proteins for sensitive infants. We obtained blood sera from patients that had cow's milk protein allergy. The IgE binding capacity of conjugates was tested using the ImmunoCap method. Conjugation of allergenic protein significantly reduced IgE binding but we observed large individual (patient) differences for the level of reduction in IgE binding. Conjugation may be helpful in reducing the allergenicity of food proteins.

Key Words: Maillard, digestion, allergenicity

0238 Microbial production of conjugated linoleic acid: Development of functional dairy products-an overview. S. Abd El Ghani* and W. K. Bahgaat, *National Research Centre, Giza, Cairo, Egypt.*

Conjugated linoleic acid (CLA) is a generic name for a group of positional and geometric isomers of linoleic acid (LA), *cis*-9, *cis*-12, octadecadienoic acid) in which the double bonds are conjugated instead of the methylene interrupted configuration of LA. Of these isomers, *cis*-9, *trans*-11 and *trans*-10, *cis*-12 octadecadienoic acid (C 18: 2) has been reported as the most biologically active fatty acids that confer beneficial health effects on human. CLA isomers are found mostly in milk, dairy products and meat of ruminant animals. Interest in the beneficial health effects of CLA was reported over the years since the 1990s. Such benefits are: increased metabolic rate, decreased abdominal fat, enhanced muscle growth, lower cholesterol and triglycerides, lower insulin resistance, reduced risk of vascular diseases and anticarcinogenic effect. Microbiological production of CLA has recently attracted considerable research studies. The capability of several bacterial genera to convert linoleic acid in the forage of ruminants into CLA has been highlighted in many studies. The major CLA producing bacteria are lactic acid bacteria (LAB), bifidobacteria, and propionibacteria. Lactic acid bacteria (LAB) comprised 13 genera namely,*Carnobacterium*,*Enterococcus*, *Lactobacillus*, *Lactococcus*, *Lactosphaera*, *Leuconostoc*, *Melissococcus*, *Oenococcus*, *Pediococcus*, *Streptococcus*, *Tetragenococcus*, *Vagococcus* and *Weissella*among phylum Firmicutes. LAB were isolated from milk, fermented milk, cheese and other plant sources. They inhabit human and animal intestinal tracts and positively affect the health of the host. LAB are regarded as a unique group of bacteria having probiotic effect due to their capability to produce bioactive compounds such as peptides including antimicrobials, fatty acids, vitamins, and antioxidants. Probiotics refer to a live microbial feed or food supplement that beneficially affects the host by improving its intestinal microbial balance. LAB metabolites play a significant role in metabolism and detoxification of foreign substances and free radical entering the body of the host. Recently, manufacture of functional dairy products such as cheese and yogurt rich in CLA, using unique adjunct probiotics as vehicles to provide adequate dietary CLA for human consumption, has received considerable interest by dairy processors. The aim of the present overview was to highlight some aspects in the production of functional dairy products to satisfy modern consumer interest looking for their life betterment through increased tendency toward functional food consumption.

Key Words: microbial CLA, probiotic bacteria, functional foods, LAB

0239 Chemical and organoleptic characteristics of cheese from dairy cows supplemented with soya and partially hydrogenated vegetable oils. E. Vargas-Bello-Pérez*[1], G. Iñiguez-González[1], K. Fehrmann-Cartes[1], and P. C. Garnsworthy[2], *[1]Pontificia Universidad Católica de Chile, Santiago, Chile, [2]The University of Nottingham, Loughborough, United Kingdom.*

Lipid supplements have been used to improve the fatty acid profile of dairy products; however, little information is available concerning the effect of dietary vegetable oils on the sensorial properties of cow's milk cheese. The objective of the present study was to examine the effects of soya (SO) and partially hydrogenated vegetable (PHVO) oils supplementation in dairy cow diets on the chemical composition of milk and cheese and organoleptic characteristics of cheese. Nine multiparous Holstein cows averaging 169 ± 24 DIM (average ± SD) at the beginning of the study were used in a replicated (n = 3) 3 × 3 Latin square design that included three periods of 21 d. All cows received a basal diet formulated with a 56:44 forage:concentrate ratio. Dietary treatments consisted of the basal diet (C; no fat supplement), and fat-supplemented diets containing SO (unrefined oil; 500 g/d/cow) and PHVO (manufactured from palm oil; 500 g/d/cow). Individual milk samples were taken at 0700 h on Day 20 of each period. Milk collected on Day 21 from the same treatment and period across Latin squares was pooled and made into cheese. Three cheeses per treatment per period were allowed to mature for 14 d and analyzed for moisture, ash, fat and total protein contents. Sensory evaluation of cheeses was performed in relation to 16 attributes: appearance (color homogeneity and holes), odor (overall odor, ripe cheese odor and cow milk odor), flavor (salty, acid, bitter, overall flavor and ripe cheese flavor), and texture (sharpness, toughness, graininess, screeching, moisture and greasiness). Except for ash, milk composition was not affected by treatments. Cheese chemical composition was not affected by dietary treatments. Sensory attributes were not affected by treatments, however four principal components explained around 0.64 of the overall variance in the data. The outcome of this study showed that supplementing dairy cow diets with SO or PHVO do not have detrimental effect on the chemical composition of milk and cheese and the organoleptic characteristics of cheese. *This study was sponsored by a research grant from FONDECYT 11121142 (Fondo Nacional de Desarrollo Científico y Tecnológico, Chile).*

Key Words: cheese, milk, organoleptic characteristics

0240 Comparison of the effect of Holstein-Friesian and Jersey milk on Cheddar cheese production. J. H. Bland*, C. C. Fagan, and A. S. Grandison, *University of Reading, Reading, United Kingdom.*

The objective of this study was to compare the effect of using Holstein-Friesian or Jersey milk on the Cheddar cheese mak-

ing process, cheese composition and sensory quality. Cheddar cheese was produced using Jersey and Holstein Friesian milk and various blends ($n = 11$) in the University pilot plant (100L vat) each month over a year to take into account seasonal variation. A significant difference in actual yield and moisture adjusted yield (37% moisture) was found between the two breeds with Jersey milk yielding 34.6% and 40.9% more respectively ($P < 0.001$). The yield of whey for Jersey milk was significantly lower (−3.7%, $P < 0.001$), as was the yield of protein in whey (−13.5%, $P = 0.014$). However, concentrations of lactose and solids in whey for Jersey milk were higher (+3.6% and +3.8% respectively, $P < 0.001$) and no difference was detected in the yield of fat in whey. The recovery of both fat and protein in cheese was higher for Jersey by 22.9% ($P < 0.001$) and 11.9% ($P = 0.026$), respectively, compared to Holstein-Friesian. Cheese making time for Jersey milk was significantly higher (+13.1%, $P = 0.008$) even though coagulation time was significantly shorter (−44.5%, $P = 0.002$). The longer cheese making time was due to the increase in time required for acidity development, which has not been observed previously. In terms of cheese composition, Jersey milk produced cheese with higher levels of fat (+15.5%) and lower moisture content (−7.54%, $P < 0.001$). No differences in protein, pH and salt were observed. Jersey milk showed a higher suitability for cheese making with higher recovery of component and higher yield. The influence of seasonality on yield was studied and neither the actual yield nor moisture adjusted yield were significantly affected by season. Fat in whey was lowest in summer (−23.8%), while protein in whey was lowest in winter (−18.1%, $P < 0.05$). These changes in recoveries had, however, no significant effect on cheese composition. Results to date suggest that using Jersey milk to produce Cheddar cheese may be more efficient than using Holstein-Friesian. Differences in the fat and moisture content of the cheese could impact on the sensory quality of the cheese. Sensory analyses are still in progress and will include texture, color and standardized grading tests.

Key Words: Cheddar cheese, cheese yield, breed

0241 Adding citrate to ice cream mix for enhanced protein functionality.

A. Gilbert, J. Prost, and H. D. Goff*, *University of Guelph, Guelph, ON, Canada.*

High-pressure processing has been shown to greatly improve the structure and texture of ice cream by modifying casein micelles, the net effect of which is to enhance protein functionality through increased air adsorption and enhanced protein-protein interactions in the aqueous phase. The addition of citrate to milk also modifies casein micelles, enhancing soluble casein levels through the chelation of calcium from within the micelle. This has been shown to enhance foamability in skim milk. It has been documented that citrate will decrease fat partial coalescence in ice cream mix, through enhanced soluble protein adsorption to the fat globule. Given these established relationships, the effect of citrate addition to ice cream mix was re-examined to determine if advantage could be gained from enhanced soluble proteins at air interfaces or within the serum phase, to either provide enhanced structure and air bubble stability and/or enhanced mouthfeel and texture. In this study, citrate triphosphate/citric acid was added to a typical ice cream mix at 0.1M/kg milk solids-not-fat (SNF) or 0.2M/kg SNF, balanced to keep the pH at 6.8, in the presence of either 0.15% saturated or unsaturated monoglyceride. Ice cream mix was batch pasteurized and batch frozen. Analyses included fat droplet size, soluble protein and protein adsorption to fat droplets in the mix; and structural collapse during melting, fat destabilization and structural analyses by transmission electron microscopy in the ice cream. Results indicated that serum proteins were enhanced in the mix due to citrate addition. However structural collapse during melting was enhanced by citrate in the presence of either surfactant, due to reduced fat partial coalescence. Adsorbed protein levels to the fat droplet were reduced by the addition of citrate, but TEM analyses indicated that the proteins were more homogeneously distributed around the fat droplets in the mix and emulsifiers were less able to displace these proteins than they were native casein micelles. Thus the soluble caseins over-stabilized the emulsion by creating a more continuous thin layer around the fat globules, which prevented the formation of a partially coalesced fat globule network necessary for air stabilization in ice cream. Consequently, while the citrate did successfully modify the casein micelles by increasing soluble casein, it did not result in enhanced foamability or protein structure in the aqueous phase.

Key Words: casein, citrate

0242 The nutritional value of kishk: dried wheat fermented milk Egyptian native dairy food.

S. Abd El Ghani*[1] and W. K. Bahgaat[2], *[1]National Research Centre, Dairy Department, Giza, Cairo, Egypt, [2]National Research Centre, Giza, Cairo, Egypt.*

Kishk is dried wheat fermented milk mixture originated during Pharonic period since 3200 B.C. in Upper Egypt and continued until nowadays. It is considered a good source of carbohydrates, proteins, vitamins and minerals. Egyptian farmers prepared kishk as a home made product mainly for their consumption. However, considerable amounts of the product may be marketed to gain additional profit. The aim of this proposal was to evaluate the nutrition value of kishk. Therefore, gross composition and minerals content were determined. Quality and quantity of fatty acids as parameters of functionality were also analyzed. Forty kishk samples were procured from four provinces encoded as A, B, F, and G located in Upper Egypt (10 samples from each). Gross composition and minerals were examined according to (APHA, 2004). Moreover, quality and quantity of FAs methyl ester were pursued using

Agilent Technologies 6890 N GC/MS equipped with a flame ionization detector (FID) and a HP-5% Phenyl Methyl Silixane capillary column. Helium was used as a carrier gas. The oven temperature was 70°C with a 2 min. hold. Injector and detector temperatures were 250° and 280°C, respectively. FAMEs were identified by comparing its retention times with those of standard FAMEs mixture (Sigma, USA). Mean gross compositions were: moisture, 6.82, 7.24, 7.02 & 7.23; total solids, 93.18, 92.69, 92.98 & 92.77; and total carbohydrates, 65.43, 69.83, 73.09 & 69.43 g/100-g sample for A, B, F, and G kishk, respectively. Mean protein and fat contents were 18.84, 11.60, 11.87, 11.43; and 4.85, 3.21, 3.51 & 3.43 g/100 g dry matter in the same order, respectively. Po, K, Ca, Mg, Na, Fe, Mn, Zn and Cu were determined in varying concentrations. FA profile includes saturated, monounsaturated and polyunsaturated fatty acids from C10 to C21. Octadecadieonic and octadecatrienoic acids were detected in all kishk samples examined. However, Kishk A contained conjugated linoleic acid 10*t*,12*c*CLA. Perhaps this was the first report to document presence of beneficial CLA isomer in kishk. In conclusion, kishk is a very nutritive functional food containing carbohydrates, protein, fat and minerals. Moreover, occurrence of essential PUFA and CLA ensure its functionality for human health.

Key Words: kishk, CLA, functional food

0243 Bacterial community shifts in geriatric subjects in response to probiotic intervention revealed by high throughput DNA sequencing. G. H. Meletharayil[1], S. Senan[*2], P. Jashbhai[2], and C. G. Joshi[3], *[1]South Dakota State University, Brookings, [2]SMC College of Dairy Science, Anand Agricultural University, Anand, India, [3]Faculty of Veterinary Science, Anand Agricultural University, Anand, India*

Evidences on the association between bacterial shifts in human gut microbiota and disorders such as inflammatory bowel disease, diabetes and obesity are mounting. A comprehensive catalogue of gut microbiota is thus essential for personalized microbiome focused treatments. The microbiota of older people displays greater inter-individual variation than that of younger adults. Gastrointestinal disorders are a major cause of morbidity in the geriatric population. Probiotic interventions are known to have been shown to inñuence the composition of the intestinal microbiota in the geriatric. As most of the bacteria present in the gut are non culturable, we attempted to study the bacterial community structure of the geriatric gut using Ion torrent 16s rRNA sequencing. There remains considerable variability in response to probiotic intervention among subjects, hence we hypothesized that a signature gut metagenome could be the deciding biomarker for a successfully probiotic therapy. Among the 72 geriatric subjects who participated in the trial, we could identify 10 respondents who showed positive results in the primary outcome of cholesterol reduction and 10 who showed an increase in cholesterol with a decreasing lactobacilli population indicating non response to probiotic therapy. DNA from the fecal samples of these 20 respondents during baseline and end of feeding was analyzed. Amplicons from the hypervarialbe region of the 16S rRNA gene were generated and sequenced each on a 316 chip. Sequencing reads were clustered into operational taxonomic units described by community metrics and taxonomically classified. Reads per sample were clustered and studied for diversity and richness using MG-RAST. All the community members in our samples were from the domain bacteria. The most prevalent phyla in all samples were: *Firmicutes*, *Proeobacteria*, *Actinobacteria* and *Bacteroidetes,* with *Firmicutes* dominating in all samples. All the samples taken before treatment showed an abundance in *Blautia, Bifidobacterium, clostridium, Escherichia, Eubacterium, Fecalibacterium, Lactobacillus, Prevotella, Roseburia, Ruminococcus* and *Shigella*. It was strikingly evident that the non respondents harbored more *Shigella, Escherichia* and less *Runinococcus and Clostridium* (compared to positive respondents). *Lactobacilli and Prevotella* showed an increase in abundance values after probiotic treatment with a decrease in *Shigella, Ruminococcus, Bacillus* and *Bifidobacterium*. Such metagenomic analysis gives new insights into differences in response towards the same probiotic intervention due to host community profiles. Modulation of the community structure using probiotics can prove beneficial for geriatric intestinal well-being and cholesterol reduction.

Key Words: metagenome, probiotic, gut, geriatric

0244 Microbial population dynamics during aging of Cheddar cheese. B. Ganesan*, C. Brothersen, and D. J. McMahon, *Western Dairy Center, Utah State University, Logan.*

The dynamics of bacterial microflora changes in Cheddar cheese during ageing are largely unknown. Normally, the unwanted bacteria may die out and not survive through 60 d of storage of hard and semi-hard cheeses. However, the beneficial flavor producers such as starter and adjunct LAB may survive longer, as may some unwanted bacteria that have a competitive advantage due to shorter growth times and fewer nutritional requirements. Traditional estimates of bacterial populations depended on the ability to grow bacteria from cheese on specific media. While this is possible for the dominant bacterial species, it still does not define the breadth of the bacterial diversity adequately. A slightly broader picture of bacterial classes can be obtained by culture-independent techniques such as quantitative PCR analysis (qPCR) or phylogenetic microarrays, which are based on the levels of a gene of a particular organism estimated from DNA extracted from cheese. Challenges for DNA extraction such as interference from dairy components such as milk fat and protein in not allowing DNA separation and inability to lyse bacteria inside solid matrices have been tackled. We recently demonstrated that probiotic bacteria survive up to 6 mo of aging without

population reduction by measuring their levels using qPCR. However, the high number of simultaneous assays needed to define the diversity of bacteria and the necessity for prior knowledge of bacteria that may exist in cheese are both limitations for qPCR's or microarrays' applicability to cheese. Currently, the bacterial ecology research arena largely depends on sequencing of amplified 16s ribosomal gene segments at a very high throughput to characterize the populations in diverse extreme environments. This approach surmounts some of the drawbacks of array-based technologies where we only target short (11 probes that are each 20-25 bases long), discontinuous portions of the gene sequences, whereas with sequencing, we seek to identify bacteria based on 200 base-long continuous DNA sequences. Our objective was to study the changes in bacterial populations in cheese during manufacture and aging using the 16s pyrosequencing approach. While lactococci and lactobacilli were the dominant microbial species ($P < 0.05$) as expected, the presence of hitherto unknown species was also identified. This demonstrates that 16s DNA sequencing is a nonrestrictive approach towards surveying both known bacterial types and relatively unknown or previously unexpected cheese microflora members.

Key Words: Cheddar cheese, mciroflora, lactococcus, lactobacillus

0245 The influence of protein content of milk protein concentrates on the rheological properties of Greek style acid skim milk gels. G. H. Meletharayil[*1], H. A. Patel[2], and T. Huppertz[1], [1]*South Dakota State University, Brookings,* [2]*Dairy Science Department, South Dakota State University, Brookings.*

Greek-style yogurt (GSY) derives its popularity from combining nutritionally desired high protein content with a rich smooth texture. The straining process traditionally applied in GSY manufacture leads to large amounts of acid whey, which is an industrial concern in terms of further processing or disposal. An alternative process, preventing the creation of acid whey, is producing GSY from suitable milk protein ingredients for attaining the desired protein concentration. The aim of this study was to evaluate the rheological properties of Greek-style acid milk gels prepared from milk protein concentrates (MPCs) of varying protein content. MPC powders containing 50% (MPC50) to 85% (MPC85) protein were prepared by ultrafiltration and spray-drying from the same lot of milk. Solution (7.5% protein and 15% total solids) were prepared with these MPCs and lactose and pH was adjusted to pH 6.7 before preheating at 90°C for 10 min. Acid gels were prepared using glucono-δ-lactone to obtain final pH 4.6 after 4h of incubation at 30°C. Small amplitude oscillatory rheology (SAOR) measurements at 1% strain and a frequency of 1 Hz were performed for rheological characterization. pH was also monitored continuously during acidification. The pH of gelation (pH_G) and time of gelation were taken as the point where elastic modulus (G') was > 1 Pa. Statistical significance ($P < 0.05$) of effects observed was tested by ANOVA. The SAOR measurements showed a significant differences ($P < 0.05$) in G' of acid milk gels prepared from MPC60–MPC85 compared to gels prepared with MPC50. This was also reflected in a significant increase ($P < 0.005$) in the gelation pH and decrease in gelation time of acid gels. Such differences in the rheological properties, gelation time and gelation pH could be attributed to increased diafiltration during the preparation of MPC powders with higher protein contents, thereby reducing serum calcium and phosphate, increasing calcium ion activity and increasing the amount of denatured whey proteins associated with the casein micelles after heating. From these studies, it can be concluded that the use of MPC60−MPC85 in the manufacturing of GSY has a positive influence on G', gelation pH and gelation time. There was no significant differences in the rheological properties of gels manufactured with MPCs with > 60% protein. Hence, opportunities exist to produce GSY without acid whey as a by-product using MPC like MPC60 or MPC70, which are not prone to excessive solubility loss during storage.

Key Words: Greek style yogurt, milk protein concentrate. rheology

0246 Investigating the refrigerated performance shelf-life of high pressure treated, reduced sodium, low moisture part skim Mozzarella cheese. M. Ozturk[*1], S. Govindasamy-Lucey[2], Y. Lu[2], J. J. Jaeggi[2], M. E. Johnson[2], and J. A. Lucey[1,2], [1]*University of Wisconsin, Madison,* [2]*Wisconsin Center for Dairy Research, Madison.*

Physical, or performance, properties of low moisture part skim (LMPS) Mozzarella cheese are acceptable for only a relatively short time period (e.g., 4−6 wk) when stored under refrigeration conditions (4°C). During longer term storage (such as for exporting), cheese becomes soft and pasty due to physicochemical changes in para-casein matrix and ongoing protein breakdown, which results in poor shredding properties for unmelted cheese. We proposed that the performance and sensory properties of reduced Na LMPS-Mozzarella cheese could be extended by decreasing microbial and enzymatic activity with the application of high hydrostatic pressure (HHP). Camel chymosin was also used as a coagulant to help reduce cheese proteolysis. Average composition of reduced Na (1.0 ± 0.1% NaCl) LMPS-Mozzarella cheeses were 48.6 ± 0.7% moisture, 22.6 ± 0.4% fat, and 24.4 ± 0.7% protein. Cheeses were divided into three groups randomly after manufacture and stored at ~4°C. One group was non-pressurized and kept as control. Two wk after manufacture, the two groups of cheese samples were HHP-treated at 500 or 600 MPa for 3 min. Analysis was performed at 2, 4, 6, 8, 12, 16, and 20 wk after cheese manufacture. Texture profile analysis (TPA) and dynamic low-amplitude oscillatory rheology was used to

monitor cheese functionality during ripening. Quantitative descriptive analysis was conducted with 9 trained panelists to evaluate texture and flavor attributes using a 15 point scale. Pressure treatments at 500 and 600 MPa resulted in ~1 and ~2 log reduction in starter culture numbers at 2 wk of ripening, respectively, compared to control cheese. High pressure treatment of LMPS-Mozzarella cheese resulted in an initial (at 2 wk of ripening) increase ($P < 0.05$) in pH values; however, by 4 wk of ripening we did not observe any statistical difference in pH values between control and HHP-treated samples. At 2 wk of ripening, pressure treatment significantly ($P < 0.05$) decreased cheese hardness; however, by 16 wk the 600 MPa HHP-treated cheeses exhibited significantly ($P < 0.05$) higher TPA hardness values compared to control. Sensory panels also indicated that by 16 wk of age, the 600 MPa HHP-treated sample was significantly ($P < 0.05$) firmer than the control. Pizza panels indicated that 600 MPa HHP-treated cheese was significantly ($P < 0.05$) chewier and exhibited lower blister quantity and higher strand thickness compared to control. Pressures of 600 MPa produced LMPS-Mozzarella cheese with acceptable performance on pizza for a greatly extended refrigerated storage period.

Key Words: high pressure, reduced sodium, camel chymosin

0247 Impact of potassium substitution for sodium on pH, proteolysis, organic acids, and microbial populations during storage of Cheddar cheese.

D. J. McMahon*[1], C. J. Oberg[2,3], M. Drake[4], N. Farkye[5], L. V. Moyes[2], and M. R. Arnold[5], *[1]Western Dairy Center, Utah State University, Loga, [2]Department of Microbiology, Weber State University, Ogden, UT, [3]Western Dairy Center, Utah State University, Ogden, [4]Southeast Dairy Foods Research Center, North Carolina State University, Raleigh, [5]Dairy Products Technology Center, California Polytechnic State University, San Luis Obispo.*

Sodium reduction in cheese can assist in reducing dietary Na intake, yet saltiness is an important aspect of cheese flavor. Our objective was to evaluate impact of substitution of KCl for NaCl on cheese pH, organic acid content, extent of proteolysis as water soluble nitrogen (WSN) and protein profiles using urea-PAGE in Cheddar cheese in relation to changes in starter lactic acid bacteria (LAB) and nonstarter LAB (NSLAB) during 9 mo storage. Cheddar cheeses with molar salt contents equivalent to 1.7% salt and Na replacement of 0% (control), 10%, 25%, 50% and 75% were manufactured as well as a low-salt (0.7% NaCl) negative control cheese. The 1.7%-salt cheeses had mean composition of 352 g/kg moisture, 259 g/kg protein, 17.5 g/kg salt (measured as Cl^-) and 50% fat on a dry basis. After salting there was a faster initial drop in pH in the 0.7%-salt cheese and cheeses with high levels of K substitution, and the pH remained lower throughout storage. No difference in intact casein levels or %WSN levels between the various cheeses was observed with %WSN increasing from 5% at d 1 to 25% after 9 mo. There was a greater decrease in intact α_{s1}-casein than β-casein, and a linear relationship was observed between the ratio of α_{s1}-casein (f121–199) to α_{s1}-casein and storage time suggesting this ratio could be used as an index of cheese ripening. Lactic acid content increased with K substitution and throughout storage. Propionic acid concentration in the cheese increased earlier in the control cheese than in cheeses with $\geq$ 25% K substitution or cheese with only 0.7% salt. This increase corresponded to the time after NSLAB numbers in the cheeses became dominant. There were few other obvious trends in organic acid concentration observed as a function of Na or K content. Typical changes in bacteria microflora occurred during storage with lactococci gradually decreasing and NSLAB increasing. Lowering the Na content, even with K replacement, extended crossover time when NSLAB became the dominant microflora from 4.5 mo to 5.2, 6.0, 6.1 and 6.2 mo for cheeses with 10%, 25%, 50% and 75% K substitution. This was, however, still shorter than the 7.3 mo for the low-salt cheese. By 9 mo, NSLAB levels in all cheeses had increased from initial levels of $\leq 10^2$ to ~10^6 CFU/g. Lactococci remained at 10^6CFU/g in the low-salt cheese even after 9 mo storage.

Key Words: cheese, sodium, potassium

DAIRY FOODS SYMPOSIUM: PROTEIN FUNCTIONALITY IN CHEESE SYSTEMS: NATURAL, PROCESS CHEESE AND ANALOGS

0248 Commercial and functional considerations when formulating foods with dairy proteins. T. McCarthy*, *Schreiber Foods, Green Bay, WI.*

Global milk production is estimated at 1600 bn lbs/yr. and cheese production at 45 bn lbs/yr. The dairy industry is among the most highly regulated when it comes to international trade and only about 5% of production is traded internationally. The greatest surpluses of milk being found in New Zealand, US, Germany, France, Australia and Ireland, whereas the greatest deficits are in China, Italy, the Russian Federation, Mexico, Algeria and Indonesia. This presentation will explore some of the commercial and technical challenges in moving dairy proteins around the globe and formulating them into cheese and related products

Key Words: milk production, cheese production, markets

0249 A model for the formation of the aggregated network in process cheese products that can be used to predict functional properties. L. Metzger*, *Midwest Dairy Foods Research Center, South Dakota State University, Brookings.*

Process cheese products are produced by mixing and heating natural cheese and other dairy and non-dairy ingredient in the presence of emulsifying salts. It is well established that during manufacture of process cheese, the para-casein network in natural cheese is modified as a result of calcium chelation by emulsifying salts. This modification results in an increase in the emulsion capacity of the casein and gives process cheese its unique functional characteristics. Extensive research on process cheese has been conducted and the critical formulation parameters (composition, intact casein, calcium content, pH, type and amount of emulsifying salt) and critical manufacturing parameters (mixing speed, cooking temperature, cooking time and cooling rate) have been identified. Although we know these parameters are important, a model that links these parameters to the functional properties of process cheese has not been developed. The objective of this work is to propose a theoretical model to predict the impact of formulation and manufacturing parameters on the functionality of process cheese. The proposed model divides process cheese manufacture into four stages: 1) para-casein network de-aggregation; 2) para casein hydration and induction of casein-fat and casein-casein interactions; 3) casein re-aggregation and gelation; and 4) re-orientation of the gelled network. The theoretical impact of critical formulation and manufacturing parameters on each stage of the model and their relation to functional properties are also proposed.

Key Words: cheese, models, casein

0250 Autocatalytic multistage gel formation reaction in dairy based systems in relation to compositional factors. U. Kulozik*, *Technische Universität München, Freising-Weihenstephan, Germany*.

A multistage structure formation reaction is described in this paper that seems to be typical for the gel formation process in protein model system similar to products such as fresh cheese or processed cheese. Therefore, it was the objective of this study to identify and to assess the influencing factors driving the reaction. The effect of the fat and protein content, rework as well as the fat globule size influenced by an upstream treatment were studied in this work to develop a deeper understanding of the complex reactions taking place in such systems, where the underlying reaction mechanisms are insufficiently understood so far. It is shown that a fat level of 15-20% is required for the multistage structure formation course to occur. By means of an upstream homogenization of the fat phase and with an increasing protein content, the structure formation can be accelerated. It can be concluded that two parallel or partially sequential reactions seem to take place, inducing the formation of a finely dispersed emulsion as well as a protein network in the continuous phase, the latter one being sourced from proteins at the emulsion droplet interfaces. Compositional factors including the addition of rework affect the structure formation process, rework probably acting as a starter in an autocatalytic reaction.

Key Words: gel, protein, fat

0251 Protein functionality in processed cheese—Fundamental principles and practical observations. D. C. Reid*, *Fonterra Research and Development Centre, Palmerston North, New Zealand.*

Functionality of the protein in the raw materials determines the outcome of processed cheese manufacture. However, making processed cheese is fundamentally an exercise in cost optimization. The biggest cost is the young cheese. This provides unproteolysed casein, sometimes known as intact casein or functional protein, that will form the structural backbone of the processed cheese. Innovation around functional protein is often hindered by cost, regulation or IP. One concept that is often overlooked by manufacturers is optimization of functional protein. Optimizing and standardizing the functional protein not only minimizes the cost of the formulation but increases product quality, increases throughput and reduces rework generation. The challenge is that natural cheese is inherently variable due to proteolysis. Standardization requires measurement of

the functional protein in cheese. There are several approaches to measuring functional protein. Graders can gauge the body of cheese using finger and thumb. Others map the composition of the cheese against its history and predict the maturity. Wet methods are available such as relative casein content or water soluble nitrogen. Gold Peg markets Caseus Pro—a package that combines an NIR-based measurement system with optimization software. Fonterra has been working on a new method that uses viscosity to predict functional protein. To simplify standardization, manufacturers have developed ingredients that are slower to ripen or are more consistent sources of functional protein. One approach is to slow maturation of cheese while another is to use dry proteins. Using powders brings some challenges—not the least of which is hydration in a competitive and moisture-constrained environment. The problem is exacerbated by short processing times in cookers. MPCs have been developed with improved hydration characteristics that help alleviate this problem. Manufacturers have also looked at ways to increase the functional protein value for an ingredient beyond its casein content, for example functionalizing the whey protein component. Fonterra developed an MPC that delivers the same body to processed cheese as rennet casein, despite 20% of the protein being whey. An alternative approach is to functionalize the whey protein during manufacture of the processed cheese. In the future, optimum levels of functional protein could be totally redefined if work with casein fractions comes to fruition. Ingredients enriched in a_s–casein could deliver significantly more body to processed cheese without compromising other properties.

Key Words: intact casein, functional protein, processed cheese

0252 Impact of emulsifying salts on milk proteins and process cheese properties. J. A. Lucey*, *University of Wisconsin, Madison.*

Emulsifying salts, like citrate and phosphates, are widely used to modify the properties of caseins via a range of chemical and physical reactions. During the manufacture of process cheese, emulsifying salts have the ability to influence several critical events, such as Ca^{2+} binding (including complex formation), pH adjustment, casein dispersion (or crosslinking), fat emulsification, and structure formation. The impact of single emulsifying salts on casein properties and process cheese functionality has been studied. However, in many cases confounding effects like pH changes due to variation in the amount/type of emulsifying salt were not addressed in the experimental approach. Trisodium citrate and disodium phosphate are widely used to make many process cheese products whereas pyrophosphates are used for restricted melt applications. Pyrophosphates are very efficient at causing an initial casein dispersion of cheese, but during the heating phase they can cross-link these dispersed caseins to greatly increase viscosity (creaming). Mixtures of emulsifying salts alter casein properties and process cheese functionality in a complex fashion depending on the proportion, concentration and type of emulsifying salts present in these mixtures.

DAIRY FOODS SYMPOSIUM: MILK PROTEIN-HYDROCOLLOID INTERACTIONS: RECENT IMPACTS

0253 Exopolysaccharides from lactic acid bacteria—A world of opportunities. A. Hassan*, *South Dakota State University, Brookings*.

Exopolysaccharides (EPS) are polysaccharides secreted outside the cell wall of microorganisms. Exopolysaccharide-producing lactic acid bacteria are used to modify the textural and functional properties of fermented milk. The selection criteria of EPS-producing cultures depend on the desired physical properties of the fermented product. Exopolysaccharides provide functions that also benefit reduced-fat cheeses. They bind water and increase the moisture in the nonfat portion, reduce rigidity, and increase viscosity of the serum phase. Whey, the cheese byproduct, is concentrated or fractionated by membrane separation, and dried to produce a variety of products. The residual EPS in cheese whey have been demonstrated to enhance the functional properties of whey protein concentrate. On the other hand, application of EPS-producing cultures in cheese making may impact biofouling of whey filtration membranes. Exopolysaccharide can either enhance or prevent biofilm formation, depending on their characteristics and interaction with the membrane surface. Fermented milks made with some EPS-producing strains have also shown chemopreventive effects against azoxymethane-induced tumors in rats. In conclusion, EPS from lactic acid bacteria can improve body and texture of dairy products and modify functionality of whey protein concentrates. As functional foods are gaining popularity, EPS as natural chemopreventive agents become an attractive choice.

Key Words: lactic acid bacteria, exopolysaccharides, functionality, dairy

0254 A tale of in-body magnetic resonance imaging of foods and gut feelings. L. Marciani*, *University of Nottingham, Nottingham, United Kingdom.*

Assessment of the behavior and transit of food materials in the human gastrointestinal (GI) tract adds value when manipulating food design and improves the understanding of satiety mechanisms. Previous methods to assess the macroscopic, physiological impact of foods in the GI tract were invasive, used ionizing radiation and had a number of other limitations. Magnetic resonance imaging (MRI) is a non-invasive, high resolution, dynamic imaging technique that is developing rapidly in this field. MRI can provide in-body imaging of food materials and assess gastric emptying, intestinal fluid volumes and the colonic response in combination with other physiological and behavioral techniques. This paper presents an overview of the technique with specific examples from human healthy volunteers' studies using fat emulsions, hydrocolloids, milk-based products, poorly digested carbohydrates and dietary fiber supplements.

0255 Functionality and structure of hydrocolloids in dairy foods. H. D. Goff*, *University of Guelph, Guelph, ON, Canada.*

Stabilizing gums, e.g., guar or cellulose gum or modified starches, have been used in dairy products such as yogurts and ice cream mix for many years, for thickening and enhanced eating pleasure and for enhanced stability and shelf-life. Some unique gums rely on specific milk protein interactions, e.g., carrageenan in chocolate milk or pectin in acidified milk beverages. Many of the polysaccharide stabilizers are incompatible with milk proteins, particularly casein micelles, and carrageenan plays a unique role in inhibiting phase separation. While this body of knowledge regarding "traditional" usage of hydrocolloids is well established, there has been much research to expand the understanding and scope of hydrocolloid utilization in dairy products. Novel dairy products have been introduced into the markets, an example could be squeezable-tube products, and these products create unique demands for physical functionality, which leads to creative product development in the application of hydrocolloids. Novel hydrocolloids, particularly from agricultural by-products such as flaxseed gum or soy soluble polysaccharide, are continually being examined for potential applications. Hydrocolloids have been shown to form complexes with both casein and whey proteins under certain conditions of processing, and these complexes offer potential for new structures in dairy products. Hydrocolloid addition is also being viewed for health benefits, as most are soluble dietary fibers. Hydrocolloids in dairy products offering enhanced glycemic index reduction is an area of exciting research and product development potential, particularly in the light of rapidly rising Type II diabetes rates in the population. Hydrocolloids such as sodium alginate can also help to confer post-prandial satiety, which may present another opportunity for dairy product positioning in the context of rising rates of obesity in the population. Given this growing demand for more functional and nutritional foods, it is critical that opportunities from within the hydrocolloids sector continue to be exploited in dairy products.

0256 Impact of starch on milk protein functionality in food applications. M. E. Yildiz*, *Ingredion, Bridgewater, NJ*.

Dairy foods are increasingly formulated with several functional ingredients such as milk proteins, starch and hydrocolloids. Functional ingredients provide several key properties to dairy

foods, including process robustness, texture, eating quality and shelf stability. Starch has been a very important component of dairy foods including yogurt, cheese and dairy beverages. To formulate consumer winning dairy products, it is very important to understand the mechanisms and interactions as well as true synergies between functional ingredients. However, both starch and milk proteins are very complex and shedding light to the precise nature of the starch-milk protein interactions requires fundamental studies focusing on physic-chemical properties of starch and milk proteins, starch base and granular nature (intact vs. fragmented/solubilized), starch surface properties (protein content/location, etc.) to list the few key points. Additionally, it is very important to understand the processing parameters such as temperature and pressure on starch-protein interactions. In this presentation we will review the current understanding of starch-protein interactions. We will discuss the impact of starch base (waxy corn, tapioca and dent corn) on bulk properties of fermented dairy products, and relate the starch gelatinization temperature, granular integrity, process temperature and pressure on starch protein interactions and bulk properties of fermented dairy products. We will also discuss the instrumental and sensory measurements of observed behavior and propose mechanisms of starch impact on protein functionality.

DAIRY FOODS: **TECHNICAL ORAL SESSION: ANALYTICAL/PROCESSING**

0257 Modification of the functionality of micellar casein concentrates by changing the structure of casein micelles using high pressure processing. C. I. Moraru[*1], M. Walkling-Ribeiro[1], I. Aprodu[2], and M. V. Karwe[3], *[1]Cornell University, Ithaca, NY, [2]Dunarea de Jos University, Galati, Romania, [3]Rutgers University, New Brunswick, NJ.*

Growing interest in food products with high protein content has led to an increased demand for protein ingredients. Micellar casein concentrate (MCC) is an emerging dairy ingredient obtained by membrane filtration. MCC is characterized by a bland, clean taste and has potential for use in applications ranging from beverage fortification to manufacturing of soft gel products. High pressure processing (HPP) is a physical process that can be used to induce controlled changes in the structure of casein micelles and thus modify the properties and functionality of MCC. In this study, MCC suspensions with 2.5, 5, 7.5, and 10% protein content were processed at 150, 250, 350, and 450 MPa for 15 min, at cold (4-24°C) and warm (53−60°C) temperatures. Particle size, turbidity, and viscosity were assessed directly after HPP and during refrigerated storage. The study was replicated and data analyzed statistically. Under cold HPP conditions, casein micelle size decreased significantly with increasing pressure ($P < 0.05$) due to disruption of the casein micelle structure. The average micelle diameters ranged from 192 to 81 nm for 2.5% MCC and from 216 to 173 nm for 10% MCC after treatment at 150 and 450 MPa, respectively. These effects were concentration dependent, indicated by increased micelle size and turbidity in samples with higher casein concentration ($P < 0.05$). By contrast, HPP under warm conditions led to an increase in particle size, indicating a re-association of caseins. The increase in particle size was concentration dependent: for 2.5% MCC treated under warm conditions, particle sizes ranged between 175 and 216 nm, while for 10% MCC they ranged between 192 and 778 nm when treating the samples at 150 and 350 MPa, respectively. Particle size and turbidity did not change significantly during storage at 4°C of cold HPP treated samples, whereas samples treated under warm HPP conditions were less stable. Interestingly, cold HPP treated 10% MCC formed a weak gel above 250 MPa. The present study suggests that HPP is effective for modifying MCC functionality by inducing structural changes of the casein micelles. Most notably, cold HPP can induce shelf-stable size reduction of casein micelles and improved transparency at low casein concentrations, and gel-like structure at high casein concentrations. This data can be used as a basis for developing new food applications involving HPP treatment of MCC.

Key Words: micellar casein concentrate (MCC), high pressure processing (HPP), nonthermal processing

0258 Microfiltration of milk protein concentrate using ceramic membranes: Determination of limiting flux and serum protein removal at 8, 9, or 10% protein in the recirculation loop. E. E. Hurt[*1,2], M. C. Adams[1,2], and D. M. Barbano[1,2], *[1]Cornell University, Ithaca, NY, [2]Northeast Dairy Foods Research Center, Ithaca, NY.*

In designing a MF process to separate SP. from casein, both the amount of SP. removed and flux are likely to be a function of the protein concentration in the recirculation loop (RL). Our objective was to determine the limiting flux and SP. removal at 8, 9 or 10% protein in the RL using 0.1µm ceramic graded permeability membranes with 4 mm channel diameters. The MF feed was an 85% milk protein concentrate diluted to an average protein of 5.5 ± 0.1%. The concentration factor was chosen to achieve 8, 9 or 10% protein in the RL. The MF was operated with a longitudinal pressure drop of 220 kPa at 50°C. The MF was started at an average flux of 55 ± 2kg/m^2 per h and flushed until the protein concentration in the RL was near the target. Once the target protein was reached, the MF was run at 55 kg/m^2 per h for 1h, the flux was then increased in steps and run for 1h at each new flux. The flux was increased until the new flux could not be maintained. The limiting flux was the last flux the MF could run at for 1h. Transmembrane pressure averaged 66 kPa at 55kg/m^2 per h and 190 kPa at the limiting flux and transmembrane pressure did not vary with protein concentration in the RL ($P > 0.05$). Retentates and permeates at each flux were analyzed for true protein (TP) using Kjeldahl methods. SP. removal as a percentage of theoretical removal (SPR) was calculated as TP in the permeate divided by SP. in the permeate portion of the feed. TP concentrations in the RL averaged: 8.2 ± 0.1, 9.2 ± 0.1 and 10.1 ± 0.2%. Cross-flow velocities depended on the protein concentration in the RL ($P < 0.05$) and were: 7.09, 7.01 and 6.90m/s at 8, 9, and 10% protein, respectively. Limiting fluxes decreased with increasing protein in the RL ($P < 0.05$) and were: 154 ± 1, 133 ± 1 and 117 ± 6kg/m^2 per h. SPR was not a function of the protein concentration in the RL ($P > 0.05$), but SPR decreased ($P < 0.05$) from 80% at 55 kg/m^2 per h to 75% at the limiting flux, indicating fouling may have impacted passage of SP. through the membrane. The protein concentration in the RL that the MF operated at had an impact on the limiting flux, but not passage of SP. However, as flux increased to the limiting flux, there was reduced SP. passage through the membrane, likely caused by membrane fouling.

Key Words: limiting flux, microfiltration, milk protein concentrate

0259 Impact of membrane channel diameter on limiting flux and serum protein removal during milk protein concentrate microfiltration. M. C. Adams*, E. E. Hurt, and D. M. Barbano, *Cornell University, Ithaca, NY.*

The design of a ceramic microfiltration membrane will impact its ability to remove serum proteins (SP) from milk. Our objectives were to determine the limiting fluxes and SP. removal as a percentage of theoretical (SPR) of 0.1 μm ceramic graded permeability membranes with either 3 mm or 4 mm diameter flow channels. A microfiltration process was fed with an 85% milk protein concentrate that had been standardized to 5.62 ± 0.06% protein with reverse osmosis water. Retentate and permeate were continuously recycled to the feed tank. Limiting fluxes were determined by incrementally increasing flux once per h from 55 kg/m^2 per h until flux became independent of transmembrane pressure. Experiments were replicated 3 times and the Proc GLM procedure of SAS was used for statistical analysis. Temperature, longitudinal pressure drop (ΔP), and protein concentration in the retentate recirculation loop were maintained at 50°C, 220 kPa, and 9.16 ± 0.08%, respectively. Because the graded permeability membranes are designed to operate at ΔP between 200 and 220 kPa, ΔP was controlled. Consequently, 3mm cross-flow velocity was lower ($P < 0.001$) than 4 mm cross-flow velocity (5.48 vs. 7.00 m/s). In both membranes, cross-flow velocity decreased ($P < 0.05$) between the initial and limiting fluxes. The 3 mm membrane limiting flux was lower ($P < 0.001$) than the 4 mm membrane limiting flux (105 vs. 133 kg/m^2 per h). SPR was calculated by dividing true protein in the permeate by SP. in the permeate portion of the feed to describe the ease of SP. passage through the membrane. In the 4 mm membrane, SPR decreased ($P = 0.03$) between the initial and limiting fluxes due to fouling. No decrease in SPR was detected ($P > 0.10$) in the 3 mm membrane between the initial and limiting fluxes. Experimental variation and the fact that 3mm SPR was lower ($P = 0.07$) than 4 mm SPR at the initial flux contributed to this finding. Despite a lower limiting flux and a higher rejection of SP, the modular SP. removal rate (kg SP. removed/module per h) of 3mm membranes would be higher than that of 4mm membranes because 46% more membrane surface area can be housed in a 3mm membrane module. This relationship could change if the retentate protein concentration were different. A processor should consider both the increased performance of the 4 mm membrane and the reduced cost per module of the 3 mm membrane before proceeding with a purchasing decision.

Key Words: microfiltration, serum protein removal, limiting flux

0260 Using membrane filtration techniques to fractionate acid whey into value added ingredients. B. Chen*, K. E. Smith, J. A. Lucey, R. Kalscheuer, and M. Molitor, *University of Wisconsin, Madison.*

There has been a huge expansion in acid whey production due to the rapid growth in Greek yogurt manufacture; therefore it is critical to find an environmentally friendly and economically feasible way to process acid whey. Membrane filtration techniques have been used for many decades in the dairy industry to fractionate components into different streams. The objective of this study was to determine the suitability of nanofiltration (NF) membranes for fractionating acid whey into value added streams that could potentially be used in food products. Because of the relatively low protein content of Greek yogurt acid whey, our research focused on possible value added components in the UF permeate of acid whey. Potential end products include lactose, lactic acid, dairy minerals, peptides and oligosaccharides. Our initial focus was on reducing the calcium and lactic acid content of this UF permeate. Approximately 1000 L of acid whey was obtained from a Greek yogurt manufacturer for each trial. A 10,000 daltons UF membrane was used to fractionate the protein. The UF permeate was then processed by one of two different NF membranes. An experimental NF membrane was evaluated for divalent ion permeation and compared to a control NF membrane. Permeates were concentrated to 1× and 2×, and sampled at 1380, 2760, and 4140 kPa processing pressures, and at temperatures 4, 21, 43, and 54°C. Flux also was recorded. Total solids, lactose, galactose, lactic acid and calcium were determined. Higher temperatures and higher pressures yielded higher rates of component permeation for each membrane. The experimental NF membrane had higher permeation on all analyzed components compared to control NF membrane. Lactose and calcium were permeated on the experimental NF membrane, in contrast to the control NF membrane. By utilizing various membranes with very different permeation properties, fractionated products could potentially be achieved. We are exploring other membranes to evaluate the potential creation of purified value added fractions from acid whey.

Key Words: acid whey, membrane processing, nanofiltration

0261 Polymerization of lactose to polylactose by twin-screw extrusion. T. C. Schoenfuss*, C. E. Tyl, and E. M. Reid, *University of Minnesota, St. Paul.*

Our objective is to create a value-added product from lactose. We successfully polymerized lactose into polylactose, a mixture of oligosaccharides, via extrusion. Previously, we evaluated one extruder feed rate and two citric acid catalyst concentrations. We hypothesized that a lower residence time in the extruder would achieve similar fiber contents while reducing caramelization side-reactions. The objectives of this project

were to further evaluate acid catalyst concentrations and extruder conditions on fiber yield. We hypothesized that concentrations above 2% citric acid would yield more fiber. We tested the hypotheses by extruding lactose with 2, 4, and 6% citric acid and 20% glucose. Extruder feed rate was at 15 and 30kg/hour for all formulas. Product was extruded on a Buhler twin-screw 44 mm extruder and the screw configuration, rpms and temperature profile were kept constant between runs. Process (temperature, motor torque and specific mechanical energy (SME)) and product responses (color, dietary fiber, degree of polymerization (DP), and residual lactose) were measured in response to the formula and process changes. Color and brown pigments were determined by HunterLab (10° observer and D65 illuminant) and spectrophotometry (420 nm) of an aqueous extrudate solution. Liquid chromatography (LC)-evaporative light scattering detector analysis was used to quantify dietary fiber by the AOAC integrated dietary fiber method (2009.01). DP was determined by LC-Mass Spectrometry with positive electrospray ionization. Residual lactose was quantified enzymatically using a commercial test kit. The higher feed rate resulted in lower SME and higher motor torque, indicating the material had higher viscosity. The higher feed rate resulted in less brown pigmentation, lower b-values, higher *L*-values and more residual lactose and glucose. These results indicate that at the lower feed rate more lactose and glucose were converted to caramelization products. Citric acid concentration effects were more pronounced at the lower feed rate with higher concentrations leading to more browning and higher *b*-values. Residual lactose decreased with higher citric acid concentrations. Dietary fiber profiles were similar between formulas with DPs of generated oligosaccharides ranging from 3–5. In contrast to the higher feed rate, the HPLC profiles at the lower feed rate of 6% citric acid formulas had lower oligomer peak areas when compared to 2% citric acid. This was not the case for the high feed rate. Overall, the higher feed rate resulted in more favorable processing parameters, less caramelization, and maintained dietary fiber concentrations.

Key Words: extrusion, lactose, oligosaccharides, dietary fiber

0262 A proficiency test system to improve laboratory and method performance and produce reference values for component calibration samples for infrared milk analysis.

D. M. Barbano*[1,2], K. L. Wojciechowski[1,2], and C. Melilli[1,2], [1]*Cornell University, Ithaca, NY,* [2]*Northeast Dairy Foods Research Center, Ithaca, NY.*

Our objectives were: 1) utilize data from 10 to 12 laboratories running duplicate chemical analyses of 14 milk samples with an orthogonal matrix of fat, protein, and lactose concentration to calculate all-lab mean reference values for fat, protein, lactose, and total solids for each sample, 2) monitor the analytical performance of the reference chemical analysis methods, and 3) evaluate and improve the analytical performance of individual laboratories conducting chemical reference methods. The chemical reference methods used were Mojonnier ether extraction for fat, Kjeldahl for true protein, spectrophotometric enzymatic assay for anhydrous lactose, and forced air oven drying for total solids. Statistical outliers were removed and all-lab mean reference values and within and between laboratory variation (i.e., Sr and SR) were calculated for each sample for each component. The set of 14 milk samples with all lab mean reference values was used to run diagnostic performance evaluation and calibrate infrared milk analyzers. The proficiency of each lab was evaluated utilizing Z-scores, Pareto diagrams, and Euclidian distance (ED) plots. Performance of the ether extraction, Kjeldahl true protein, and oven drying total solids methods were improved ($P < 0.05$) due to the improved ability to identify and trouble shoot between laboratory differences in results when using the modified milks with the orthogonal design of variation in composition. Residual plots of an individual lab's results minus the all-lab mean for each sample provides an evaluation of individual lab bias and proportional deviations from the all-lab mean over a wide range of concentration of each component. Residual and ED plots allow an experienced evaluator to identify the sources of poor performance by an individual lab and recommend corrective measures. Over a period of years, the feedback and method performance trouble shooting based on residual and ED plots has improved within (Sr) and between (SR) laboratory and method performance.

Key Words: proficiency testing, infrared milk analysis, method performance

---

0263 A relatively rapid method for the estimation of the amount of exopolysaccharide produced by lactic acid bacteria during milk fermentation.

S. N. Khanal*[1] and J. A. Lucey[2,3], [1]*Department of Food Science, University of Wisconsin, Madison,* [2]*University of Wisconsin, Madison,* [3]*Wisconsin Center for Dairy Research, Madison*.

The available methods for estimation of exopolysaccharide (EPS) produced in fermented milks are very lengthy (several days). A relatively shorter ($\leq$ 1 d) method has been investigated for the estimation of EPS produced during fermentation of non-fat milk at 40°C by two strains of *Streptococcus thermophilus* (St–143 and St–10255y). Milk samples were analyzed for EPS concentration every 30 min over a fermentation period of 300 min (final pH 4.6). Samples with pH > 5 were adjusted to pH ~5 before protein was removed by heat and acid precipitation. Excess ethanol was added to the neutralized supernatant and precipitated at -20°C for 3 h. The pellet was dissolved in water at 55°C and centrifuged before residual lactose in the supernatant was removed by repeated precipitation by ethanol. The EPS concentration in the final pellet was estimated by the phenol sulfuric acid method. In milk fermented by *S. thermophilus* St–143, the EPS content significantly increased

($P < 0.05$) from 24 to 68 mg/L during the fermentation period from 150 to 300 min. EPS concentration in samples fermented with *S. thermophilus* St–10255y also significantly varied ($P < 0.05$) from 16 to 52 mg/L during a similar fermentation period. Interestingly, both of the strains appeared to start producing significant amounts of EPS after 150 min of fermentation time, which corresponded to pH ~5.2 and was close to when milk gelation occurred. Thereafter, the EPS concentration continued to increase up to pH ~4.6 (end of fermentation). The total amounts of EPS obtained were comparable to the previously reported results in milks fermented by similar bacterial strains. To explore the recovery of EPS by this method, we added different concentrations of dextran (mol wt: 2×10^6 Da) to milk and found that up to ~70% of the added dextran could be recovered, suggesting that this method was reasonably effective in extracting most of the EPS produced in fermented milk.

Key Words: exopolysaccharides, yogurt, fermented milk

0264 Raw milk quality in the dairy industry: Compositional changes correlated with somatic cell counts. C. R. T. Júnior[1], G. C. Ribeiro[2], R. M. Longo[2], M. C. P. P. Oliveira[2], L. M. Fonseca[*3], M. O. Leite[2], and M. P. Cerqueira[2], *[1]Ministry of Agriculture, Poços de Caldas, Brazil, [2]Universidade Federal de Minas Gerais (School of Veterinary Medicine), Belo Horizonte, Brazil, [3]University of Wisconsin, Madison*.

The aim of this study was to evaluate the seasonal correlation of somatic cell count (SCC) and composition of raw milk. A total of 287,000 samples of raw milk were analyzed during twelve consecutive months by the UFMG Milk Quality Laboratory (UFMG/Veterinary School; LabUFMG) for composition and SCC. The data were analyzed using descriptive statistics, according to the months of production and SCC ranges: Range 1: SCC $\leq$ 200,000 cells/mL; 2: SCC from 201,000 to 400,000 cells/ml; 3: SCC from 401,000 to 750,000 cells/ml, and 4: SCC > 750,000 cells/mL. The least significant difference between treatments was evaluated using Tukey's test, with significance level of 5% in a randomized complete block design. SCC indexes (SCC Log/mL) were higher from January to April and from October to December, with peaks of SCC in February and March (rainy season). The lowest results for SCC ($p < 0.05$) were observed from May to September (dry season), with lower average results during the month of May. The highest fat, protein and total solids contents, and the lowest SCC were found during the dry season ($p < 0.05$), while the lowest concentrations were observed during the rainy season (spring and summer). The increase in SCC was correlated with reduction in lactose, solids, nonfat and protein concentrations ($p < 0.05$), except for SCC range higher than 750,000 cells/mL. In this range, protein content was higher if compared to the levels found in SCC range of 401,000 to 750,000 cells/mL ($p < 0.05$), but similar to the levels found in milk with SCC range from 201,000 to 400,000 ($p > 0.05$). This fact may be related to a reduction in milk secretion, and passage of serum proteins into the milk due to a more pronounced inflammatory process. Fat contents were higher ($p < 0.05$) for elevated SCC, which may be linked to lower milk secretion because of mastitis.

Key Words: milk quality, composition, somatic cells

0265 The effect of immunoglobulins and somatic cells on the gravity separation of fat, bacteria, and spores in pasteurized whole milk. D. M. Barbano[*1,2] and S. R. Geer[1,2], *[1]Northeast Dairy Foods Research Center, Ithaca, NY, [2]Cornell University, Ithaca, NY.*

Our objective was to determine the role that Ig and somatic cells (SC) play in the gravity separation of milk. There were 9 treatments: (1) low temperature pasteurized (LTP) (72°C for 17.31s) whole milk, (2) LTP (72°C for 17.31s) whole milk with added bacteria and spores, (3) recombined LTP (72°C for 17.31s) whole milk with added bacteria and spores, (4) high temperature pasteurized (HTP) (76°C for 7 min) whole milk with added bacteria and spores, (5) HTP (76°C for 7 min) whole milk with added bacteria and spores and added colostrum, (6) HTP (76°C for 7 min) centrifugal-separated gravity-separated (CS GS) skim milk with HTP (76°C for 7 min) low SC cream with added bacteria and spores, (7) HTP (76°C for 7 min) CS GS skim milk with HTP (76°C for 7 min) high SC cream with added bacteria and spores, (8) HTP (76°C for 7 min) CS GS skim milk with HTP (76°C for 7 min) low SC cream with added bacteria and spores and added colostrum, and (9) HTP (76°C for 7 min) CS GS skim milk with HTP (76°C for 7 min) high SC cream with added bacteria and spores and added colostrum. The milks in 9 treatments were gravity separated at 4°C for 23 h. Five fractions were collected by weight from each of the columns treatments starting from the bottom of the column: 0 to 5%, 5 to 90%, 90 to 96%, 96 to 98%, 98 to 100%. The SC, fat, bacteria, and spores were measured in each of the fractions. The experiment was replicated in 3 different weeks using a different batch of milk and colostrum. Portions of the same batch of the frozen bacteria and spore solutions were used for all 3 replicates. The presence of both SC and Ig were necessary for normal gravity separation (i.e., rising to the top) of fat, bacteria, and spores in whole milk. The presence of Ig without somatic cells was not sufficient to cause bacteria, fat and spores to rise to the top without SC. The interaction between SC and Ig was necessary to cause aggregates of fat, SC, bacteria, and spores to rise during gravity separation. The SC may provide the buoyancy required for the aggregates to rise to the top due to gas within the SC. More research is needed to understand the mechanism of the gravity separation process.

Key Words: immunoglobulin, somatic cells, gravity separation

DAIRY FOODS: **TECHNICAL ORAL SESSION: PROTEIN/ POLYSACCHARIDE INTERACTIONS**

0266 Production and purification of whey protein glycate conjugated with low molecular mass dextrans. L. Xu[*1], Y. Gong[1], and J. A. Lucey[2,3], *[1]Department of Food Science, University of Wisconsin, Madison, [2]Wisconsin Center for Dairy Research, Madison, WI, [3]University of Wisconsin, Madison.*

An increasing number of people are suffering from food protein allergies, which have become a growing concern around the world. One possible helpful approach could be to glycate food proteins via Maillard reaction, which may block the IgE binding epitopes of the allergen that are responsible for eliciting an immune response. The goal of this research was to optimize processing conditions for creating and purifying whey protein isolate (WPI) glycate with dextran (DX) of 3 different molecular masses. Purification involved a combination of isoelectric precipitation and ion exchange chromatography. Glycates were characterized using size-exclusion chromatography coupled with multi-angle laser-light scattering (SEC–MALLS), glycoprotein analysis using SDS–PAGE and periodic acid Schiff's glycoprotein staining test with fluorescence laser densitometry. The optimal conjugation condition chosen from these experiments were 10% WPI–30% Dextran (DX), pH 6.5, 62°C for 24h for DX of molecular mass = 10 and 3.5 kDa, and 50°C for 12h for 1 kDa DX. The optimal purification process was performed by ion-exchange chromatography: for G10 (glyate with 10 kDa DX) we used pH 2 running buffer, followed by 0.55M NaCl elution buffer; for G3.5 and G1 (glycate with 3.5 and 1 kDa DX, respectively) we used pH 3 running buffer, followed by 0.52 and 0.5M NaCl running buffer for G3.5 and for G1, respectively. The resulting protein–DX molar ratios were estimated as 1:1.6 and 1:1.8 for G10 and G3.5 with a purity of 91% and 88%, respectively. Future work will focus on examining the allergenicity of the different molecular masses of WPI–DX glycates, using blood sera from cow's milk protein allergic patients.

Key Words: dextran, whey protein isolate, Maillard reaction

0267 Impact of Maillard modification on the in vitro carbohydrate digestibility of WP-dextran glycates. Y. Gong[*1], L. Xu[1], and J. A. Lucey[1,2], *[1]Department of Food Science, University of Wisconsin, Madison, [2]Center for Dairy Research, University of Wisconsin, Madison.*

Whey protein (WP) conjugation with dextran (DX) by the Maillard reaction might provide an alternative approach to decrease the immunogenicity of milk proteins. Protein digestibility of whey protein-dextran (WP-DX) glycates has recently been investigated by our group using an in vitro infant digestion model. The digestibility of carbohydrate part of the glycates is unknown. According to human colonic fermentation models, DX can be entirely degraded by the colonic microflora. In this study, we investigated the in vitro carbohydrate digestibility to find out the impact of conjugation on the glucose release of dextran from WP-DX glycates compared with maltodextrin and a mixture with dextran and whey protein isolates (WPI). WP-DX glycates were made with dextran (molecular weight 10 kDa) and WPI via our patented aqueous Maillard reaction method. The glycates were separated and purified by chromatography. The glycates were digested at 37°C by in vitro model using an enzyme mixture including pepsin, pancreatin and amyloglucosidase, which represent enzymes in the digestion system of animals and humans. The free glucose was measured at 0, 10, 20, 60, 120, 180 min and 24 h by HPLC with ion-exchange chromatography and RI detector. The percentage glucose release of dextran and maltodextrin were 6.3 and 64.5% (g glucose/100 g carbohydrates) respectively, during the first 10 min. The glucose release from WP-DX glycates was 9.5, 13.2 and 16.1% at 60, 120, and 180 min, respectively. The glucose release of glycates were lower ($p < 0.05$) than that of dextran alone at 60, 120, and 180 min of digestion. However, no difference was observed in glucose release rate between WP-DX glycates and dextran alone at 0, 10, and 20 min of digestion. The results indicated that both dextran and WP-DX glycates can be digested into glucose by this mixture of digestion enzymes. The rate of glucose release and extent of release were lower for DX compared to maltodextrin. The conjugation of dextran and WP slowed down the glucose release of dextran. Slower digestion of dextran in conjugates might help maintain a possible protective impact of the polysaccharide for reducing WP allergenicity during digestion.

Key Words: in vitro, digestion, WP-DX glycates

0268 Effects of mineral salts and calcium chelating agents on the functionalities of milk protein concentrate prepared by ultrafiltration. X. Luo*, L. Ramchandran, and T. Vasiljevic, *Victoria University, Melbourne, Australia.*

Functionality of milk protein concentrates can be tailored by modifying state of casein micelles through manipulation of processing conditions including temperature, pH and/or addition of calcium chelators. The objective of this study was to investigate the effect of calcium and calcium chelating agents (EDTA and citrate) on the performance of membrane ultrafiltration (UF) process and the functionalities of resulting milk protein concentrates (MPC). Skim milk adjusted to pH 5.9 was pre-treated with EDTA or citric acid (10, 20 or 30 mmol) and ultrafiltered using a polyethersulfone (PES) membrane at 15°C to five times concentration factor. The membrane performance was measured by the permeate flux during UF process. Used membranes were examined using scanning electron microscopy (SEM). The MPC samples were freeze dried and powders were assessed for physical functionalities including solubility, heat stability and emulsification.Addition of chilators led to a shift in a protein-mineral equilibrium and calcium dissociation from the casein micelle. The total calcium in the final MPC was reduced ($p < 0.05$) from 191 (control) to 131 mM or 135 mM for skim milk pre-treated with 30 mmol of EDTA or citrate, respectively. The casein micelle particle size was subsequently reduced ($p < 0.05$) from 200 nm (control) to 28 nm or 24 nm for the milk pre-treated with EDTA or citrate at concentrations equal to or greater than 20 mmol. Consequently, solubility of the MPC increased ($p < 0.05$) from 92% (control) to 98% (ETDA, $\geq$ 20 mmol) or 98.9% (citrate, 30 mmol); heat stability was also enhanced ($p < 0.05$) from 78% (control) to 83% (EDTA, 20 mmol) or 87% (citrate, $\geq$ 20 mmol). The emulsion capacity has increased from 1170 (control) to 1392 or 1459 (g oil/g protein) ($p < 0.05$) when 30 mmol of EDTA or citrate were added, respectively. Addition of EDTA or citrate hindered the membrane performance as observed by reduced permeate flux from 10.5 kg/h.m^2 (control) to 7.9 kg/h.m^2 (EDTA, $\geq$ 20 mmol) and 8.6 kg/h.m^2(citrate, $\geq$ 20 mmol) at the start of UF. Consequently UF processing time increased from 5 h (control) to 7 h (EDTA) or 6 h (citrate). This work has provided new insights into the relationship between calcium, calcium chelators and their influence on the casein micelle size and the physicochemical properties of MPC produced using UF, and also demonstrated the potential of using EDTA and citrate acid to manipulate MPC product functionality using UF.

0269 Storage stability of sodium caseinate stabilized oil-in-water emulsions as affected by severe heat treatment and storage temperatures. Y. Liang*[1], G. Gillies[2], H. G. Patel[3], L. Matia-Merino[1], A. Ye[4], and M. Golding[1,4], *[1]Massey University, Palmerston North, New Zealand, [2]Fotnerra Research and Development Centre, Palmerston North, New Zealand, [3]South Dakota State University, Brookings, [4]Riddet Institute, Palmerston North, New Zealand.*

Oil-in-water emulsions are an important basis of many food products such as soup, sauces, salad dressing, processed cheese and whipped cream. In many cases, liquid emulsions are processed at high temperature (e.g., retort or UHT processing) and may be stored at different temperatures. There is little information on how high heat treatment and storage temperatures influence the creaming stability of caseinate-stabilized emulsions. In this study, we investigated the effects of heating and storage conditions on the structural, mechanical and rheological properties of caseinate-stabilized emulsions. The stock emulsion was prepared by mixing a reconstituted sodium caseinate solution (2% w/w) with 60% w/w oil and subjecting it to a high pressure homogenization. Caseinate solutions of different concentration were heated separately at 120°C as a function of time up to 60 min. These heated caseinate solutions were then mixed with the stock emulsion in different ratios to form the model emulsions with 1−8% protein. The creaming stability of unheated emulsions was determined between 20 and 60°C. All experiments were performed at least in duplicate. The creaming kinetics determined by Turbiscan showed that the phase separation of model emulsions was markedly dependent on the duration of the heat treatment. The differences between unheated and heated emulsions were attributed to the heat-induced physicochemical changes in sodium caseinate nanoparticles. At low and moderate caseinate concentrations (2% and 4% respectively), the droplet-droplet interactions were weakened while the droplet-droplet interactions increased at high Na-CN concentration (6%) by the addition of heated sodium caseinate. It seems that the former structural change is predominantly due to reduced depletion attraction, whereas both reduced depletion attraction and decreased continuous phase viscosity influenced the later structural change. Unheated emulsions stored at higher temperature (60°C) resulted in an accelerated phase separation compared to those stored at lower storage temperatures. The main cause was attributed to the weakened depletion energy and decreased viscosity at accelerated temperatures. Both changes lead to a rapid droplet network formation and rearrangement.

Key Words: emulsion, heat-induced degradation, depletion flocculation

0270 Understanding mechanisms of the plasmin-induced dissociation of the casein micelle. H. Bhatt*[1], A. Cucheval[1], C. Coker[1], H. G. Patel[2], A. Carr[3], and R. Bennett[3], [1]*Fonterra Research & Development Centre, Palmerston North, New Zealand,* [2]*South Dakota State University, Brookings, SD,* [3]*Massey University, Palmerston North, New Zealand.*

Bovine plasmin is a highly heat-resistant enzyme that is naturally present in milk. Plasmin can survive severe heat treatments such as UHT and may act on casein during the storage of milk products and lead to proteolysis, gelation, and bitterness. We explored the plasmin-induced dissociation of the casein micelle to achieve a better understanding of gelation and sedimentation mechanisms in different milk products. Sodium dodecyl sulfate polyacrylamide gel electrophoresis (SDS-PAGE) and reverse phase high performance liquid chromatography (RP-HPLC) were used to monitor the extent of hydrolysis of casein. The particle size, turbidity, mineral level in the serum phase, and sedimentation were also analyzed and were correlated with different extents of hydrolysis. The particle size and turbidity decreased during the initial hydrolysis, but increased dramatically towards the end of hydrolysis. This indicated that casein micelle dissociation occurred during early stages and that aggregation of hydrolyzed peptides occurred towards the final stages of hydrolysis. The total calcium and phosphorus level in the serum phase increased linearly with an increase in the extent of hydrolysis, suggesting the release of peptides containing colloidal calcium phosphate from the casein micelle. The SDS-PAGE and RP-HPLC results indicated that hydrophilic peptides, e.g., proteose peptones, were the first to dissociate from the casein micelle on plasmin-induced hydrolysis; hydrophobic peptides, e.g., γ-caseins, dissociated slowly and with dissociation patterns that were identical to those of κ-casein, suggesting that, even after breakage of the anchor points, the release of κ-casein from the micelle was too slow to cause gelation. These results provide new insights into the dissociation pattern of the casein micelle and how this relates to plasmin-induced sedimentation or gelation of UHT milk systems.

Key Words: plasmin, UHT milk, gelation

0271 Heat-induced changes in milk proteins in high-carbohydrate media. T. Huppertz*[1,2] and H. G. Patel[2], [1]*NIZO food research, Ede, Netherlands,* [2]*South Dakota State University, Brookings.*

Casein micelles in milk are unique association colloids, sterically stabilized by a polyelectrolyte brush consisting of κ-casein, and are crucial structure elements in the creation of desirable texture and stability in dairy products such as cheese and yogurt. Casein micelles show remarkable colloidal stability, but when treatment conditions extreme or solvent quality is reduced, the micelles lose their colloidal stability and aggregate. This study investigated the colloidal stability of casein micelles and whey protein at high temperature and in the presence of a high level of carbohydrate, conditions commonly encountered in caramels, sweetened condensed milk and Dulche de Leche. Adding 10−50% carbohydrate to milk reduced their colloidal stability of casein micelles. These effects are more extensive for carbohydrates of lower molar mass. Heating milk at > 110°C increased casein micelle size and turbidity as a result of the aggregation of casein micelles, with contributions from heat-induced denaturation and aggregation of whey proteins. Heat-induced increases in particle size and turbidity were more extensive at higher heating intensity, with increasing carbohydrate concentration and decreasing molar mass of the carbohydrate. The presence of a free aldehyde group in reducing sugars also strongly influence the heat stability of milk through Maillard reaction products. The positive effect of Maillard reaction products on the heat stability of milk was derived from the formation of reductones, which can facilitate the covalent cross-linking of milk proteins and hence increase the heat stability. Whey protein denaturation was impaired by the presence of carbohydrates. Denaturation temperature increased with increasing carbohydrate content, effects being larger for low-molecular-mass carbohydrates. The size of heat-induced whey protein aggregates could be tailored by a combination of carbohydrate type and concentration. The results presented facilitate the extension of our understanding of the behavior of milk proteins in environments strongly deviating from natural physiological conditions. Such insights can be applied to understand and tailor the behavior of milk proteins in environments of high carbohydrate content, e.g., caramels, sweetened condensed milk and Dulche de Leche, and facilitate the design of rules for attaining maximum milk protein functionality in these systems.

Key Words: casein, whey protein, heat, carbohydrate, heat stability, denaturation

0272 Effects of pH on the morphology and mechanical property of heat-induced whey protein aggregates. C. W. Y. Lam* and S. Ikeda, [1]*University of Wisconsin, Madison.*

Whey proteins denature and aggregate when they are heated in aqueous environments. It is known that the morphology of resulting aggregates varies depending on pH. However, the structure-property relationship of heat-induced whey protein aggregates has not been fully understood. The objectives of this study were to study the effect of pH on the morphology of heat-induced whey protein aggregates and to seek correlations between their morphologies and mechanical properties. Whey protein was dissolved in deionized water adjusted to pH 3−7 and heated at 80 ± 0.2°C. Subsamples were taken at pre-specified time intervals and quenched in a 0°C water bath. The sample solutions were diluted to a protein concentration of 10-100 ppm, deposited on to freshly cleaved mica

surfaces, air-dried, and imaged using atomic force microscopy (AFM) operated in peak-force tapping mode in air. Further mechanical tests were done with AFM force spectroscopy, where the whey protein aggregates were indented directly to obtain interaction forces. These force curves were analyzed where the Young's modulus (E) of the samples can be fitted and calculated using the Hertzian model. The data were used to verify the mechanical and surface properties of the samples with different pH obtained with AFM imaging. At pH 3, a relatively small fraction of protein aggregates revealed fibrillar morphologies, while the majority of aggregates appeared to be particulate. At other pHs, only particulate aggregates were observed. All of these particulate aggregates were composed of smaller elementary particles, suggesting that the heat-induced aggregation was a two-step process regardless of pH, consisting of the formation of primary aggregates, followed by the secondary aggregation between primary aggregates. The Feret's diameter, representing the diameter of the smallest circle that entirely covers an individual whey protein aggregate, became more dependent of the aggregate size with increasing pH, indicating that whey protein aggregates became more extended, coarse, or anisotropic with increasing pH. Furthermore, the surface roughness evaluated based on the cross-sectional height data decreased by a factor of 2 with increasing pH from 5.5 to 7. This suggested that the protein aggregates collapsed, meaning that the primary aggregates were denser and more tightly packed within the aggregate. From the force spectroscopy analysis, the samples prepared at pH 7 showed larger E values than the samples prepared at pH 5.5. This suggested that the samples at pH 7 were stiffer, which conformed with the previous morphological results.

Key Words: whey protein, heat-induced aggregation, AFM

0273 Strengthening interfacial whey protein films by conjugation with gellan. B. Cai* and S. Ikeda, *The University of Wisconsin, Madison.*

Whey protein can be used as an emulsifier that forms nanometer-thick rigid layers at hydrophobic-hydrophilic interfaces in dispersed systems and provides stability against coalescence of the dispersed phase. If another surfactant is added, however, whey protein will be displaced competitively from the interface, leading to a loss of stability of the dispersed system. Gellan is a network-forming polysaccharide widely used in the food industry. Whey protein-gellan conjugates are expected to show enhanced resistance against surfactant-induced competitive displacement because gellan is considered to form additional networks at the interface. The objectives of this study were to conjugate whey protein either covalently or electrostatically with gellan and to investigate the effect of the different conjugation methods on interfacial structure and resistance to the surfactant-induced competitive displacement from the interface. Whey protein was conjugated either covalently or electrostatically with gellan. The conjugate was dissolved in water and spread on the air-water interface formed on a Langmuir trough. Food-grade nonionic surfactant Tween 20 was then injected into the aqueous phase to induce competitive displacement. Langmuir-Blodgett interfacial films were sampled at pre-specified surface pressures by dipping a freshly cleaved mica sheet in and out through the interface. The interfacial films thus transferred on the mica surface were imaged using atomic force microscopy. Both covalent and electrostatic conjugates formed close-packed interfacial films at the air-water interface. String-like structures of gellan attached to globular protein molecules were also evident. The thickness and surface pressure of the interfacial films were approximately 0.2-0.4 nm and 8-12 mN/m, respectively. Upon the addition of Tween 20, the surface pressure increased further due to the adsorption of the surfactant to the interface. Nanometer-sized surfactant domains first appeared at a surface pressure around 20 mN/m, and expanded their areas with increasing surface pressure. The thickness of protein domains increased with increasing surface pressure, consistent with the previously proposed orogenic displacement mechanism. At a certain surface pressure (e.g., 23 mN/m), the covalent conjugate occupied a larger interfacial area (83%) than both electrostatic conjugate (74%) and the WPI control (61%), The interfacial area occupied by the covalent conjugate displaced from interface less rapidly than electrostatic conjugate demonstrating a more resistant interfacial structure. These results suggest that covalent conjugation of whey protein with gellan is a more effective approach than electrostatic conjugation in strengthening interfacial protein layers and enhancing their resistance against surfactant-induced competitive displacement from the interface.

Key Words: whey protein, gellan, interface

0274 Enhancement of radical quenching ability of sweet whey and casein hydrolyzate: mutual supplementation with thermally generated maillard reaction products. Z. Z. Haque* and D. Mukherjee, *Food Science, Nutrition & Health Promotion, Mississippi State University, Mississippi State.*

Copiously available sweet whey is a source of nutritious proteins, peptides, free amino acids, and lactose. Abundant N-terminal, ε-amino-groups and the reducing sugar, allows thermal generation of Maillard reaction products (MRPs) on heating. With an aim to develop powerful natural antioxidative foods, this research investigates the enhancement of short (Antioxidative Activity; AA) and long term (Antioxidative Persistence; AP) ROS quenching ability of two types of sweet whey, Cheddar (ChWPC) and Edam (EWPC) whey and enzymatic hydrolyzate of casein (CH) through mutual supplementation with freshly heat-generated MRPs. Whey and CH dispersions (3 and 2%, respectively, w/v) were heated for 0 to 4 h at 90°C in McIlvaine's iso-ionic buffer (pH 7.0), with and without

added lactose (1%, w/v), to generate MRPs. AA and AP were determined from luminol-induced chemiluminescence (CL) caused by unquenched hydroxyl radicals generated by pyrolysis of 2,2'-azobis(2-methylpropionamidine) dihydrochloride (ABAP). Decrease in CL, measured as relative light units (RLU), compared to control (without the test materials) at maximal radical generation within one and 2 h, were respectively measures of AA and AP. Thermal generation of MRPs tended to enhance AA and AP in both sweet wheys though this effect was more dramatic for ChWPC. This was conceivably due to its greater peptide content. CWPC and EWPC heated for 1 h exhibited radical induced CL maxima of 99 and 141 RLU, respectively. Whereas values for ChWPC + lactose and EWPC + lactose were 90 and 140 RLU, respectively. Furthermore, a direct correlation was observed between added lactose induced MRP formation and AA of ChWPC, though this was not so clear for EWPC. AA of CH after heating for 4 h showed a CL of 79 RLU. However, this decreased when lactose, ChWPC and EWPC were added to CH as seen from increasing CL of 164, 107, and 121, respectively. The AP values for the same treatments were 53, 87, 57, and 62 RLU, respectively. The study not only indicated the variable effect of MRPs on antioxidative properties of the sweet wheys and CH, but also depicted the dramatic time-dependent thermal enhancement of AA and AP of ChWPC on MRP formation with added lactose. These data can potentially lead to the development of powerful new antioxidants to alleviate the detrimental effects of cellular oxidative stress.

Key Words: antioxidants, free radicals, reactive oxygen species.

0275 Impact of heat treatments on the functionalities of milk protein concentrate 80. R. M. Horak*, J. A. Lucey, and M. Molitor, *University of Wisconsin, Madison.*

Processing conditions impact the properties and functionality of milk protein concentrate 80 (MPC80). Nonfat dry milk is categorized according to the processing temperatures (low, medium, high) as these treatments greatly influence its functionality and end use. It is unknown how MPC80 properties will be affected by increased pasteurization temperatures of skim milk (before concentration). Increased pasteurization temperatures will denature more whey protein, which could impact solubility, foam stability, and viscosity of the reconstituted powder. Raw skim milk received heat treatments of 72°C for 16 s or 77, 82, or 87°C for 1 min, immediately before ultra- and diafiltration. The retentate (23% TS) was spray dried and outlet temperature was adjusted to maintain consistent moisture content between powders (~4.4%). The powders had similar composition including fat contents (< 2%). Functionality testing included solubility, foaming, tapped bulk density, and reconstituted viscosity. Tests were conducted within 1 wk of production. Powders were also stored at 30°C for 6 mo with functionality tested every 30 d. SDS-PAGE results show higher heat treatments produced more di-sulfide linked aggregates. For all powders, solubility slightly decreased during storage, but higher heating temperatures did not have a significant impact on solubility. Initial foaming experiments indicated that heat treatments of 82°C or 87°C for 1 min produced foams that were stiffer and more stable than samples treated at temperatures of 77°C for 1 min. Bulk density decreased over storage but was not significantly affected by heat treatment. Experiments investigating the viscosity of reconstituted powders are ongoing; however, initial results indicate that viscosity slightly increased with an increase in heating temperature. Based on preliminary results, it was concluded that increased heat treatments had the greatest impact on the foaming properties of MPC80 but has less impact on other functional properties.

Key Words: milk protein concentrate, processing, functionality

DAIRY FOODS SYMPOSIUM: DAIRY FOODS CONSUMPTION, GUT MICROBIOTA, AND HUMAN HEALTH

0276 Probiotics and health benefits with reference to synthesis of γ-aminobutyric acid by selected probiotic bacteria. N. Shah* and Q. Wu, *The University of Hong Kong, Hong Kong.*

Traditionally, probiotics have been added to yogurt and other fermented foods for health benefits. Currently 56 species of *Lactobacillus,* including *L. acidophilus* and *L. casei* and 32 species of *Bifidobacterium,* exist. These probiotic cultures are able to restore the normal balance of microbial populations in the intestine and offer several therapeutic benefits. There has been an increasing demand for health-promoting food ingredients. Different milks fermented with bacteria, yeasts, molds or enzymes offer a broad range of possibilities to cover different health aspects with new bioactive components such as lactoferrin, micronutrients, CLA, sphingolipids and bioactive peptides or synthesize exo-polysaccharides. In particular, milk-proteins and associated bioactive peptides released during microbial or enzymatic fermentation of milk offer a broad spectrum of new functional properties including anti-hypertensive, anti-microbial, anti-oxidative, and immuno-modulatory properties. Gamma-aminobutyric acid (GABA), a non -protein amino acid, is mainly found in the brain and regulates vertebrate physiological and psychological behaviors such as anxiety and depression blood pressure and hormone secretion. The synthesis of GABA in the brain decreases with age, especially in elders. Hence, there has been increasing interest in use of probiotics for GABA production. In this study, several GABA-producing LAB isolates have been isolated from naturally fermented foods such as Korean kimchi. Previous screening methods are time-consuming and inefficient. In the present study, we have developed a novel screening and identification method for GABA-producing LAB from Korean kimchi. Acid treatment was applied to screening procedure to obtain acid-tolerant LAB isolates, and then a simple identification of GABA-producing LAB based on release of gas by these bacteria has been developed. The amount of GABA produced by LAB isolates at various monosodium glutamate (MSG) concentrations and incubation times in MRS medium was quantified by HPLC. Genetic identification of high GABA-producing LAB was performed by both 16S rRNA gene and glutamate decarboxylase gene. Nine potential GABA-producing LAB isolates were selected by observing gas release during fermentation. The conversion ability of MSG into GABA for all nine LAB isolates was 100% (supplementation level 10 g/L MSG, incubation time 24 h), over 80% (supplementation level 30 g/L MSG, incubation 48 h), over 60% (supplementation level 50 g/L MSG, incubation time 72 h) and over 50% (supplementation level 70 g/L MSG, incubation time 72 h). These nine LAB isolates were genetically identified as *Lactobacillus brevis* by 16S rRNA gene and confirmed by glutamate decarboxylase gene.

Key Words: probiotics, γ-aminobutyric acid, health benefits

0277 Gut micrcobiota, probiotics, bioactives (such as CLA, USFA), trans-fatty acids and their relationship to health. H. Gill*, *RMIT University, Melbourne, Australia.*

The human gastrointestinal tract harbors ten times more microorganisms than somatic cells in the human body. These organisms are part of a diverse and complex ecosystem comprising over 3.3 million genes that encode a vast repertoire of enzymes and metabolites with the ability to significantly influence human health and wellbeing. While a majority of these microbes exert health-promoting effects on the host, some possess the potential to cause disease. In a healthy state, the gut microbiota is known to confer a range of health benefits relating to immune function, nutrition, host metabolism and protection against pathogens. Alterations in the normal composition of the gut microbiota are associated with an enhanced predisposition to immunoinflammatory, autoimmune, metabolic and degenerative disorders. Consequently, there has been an increasing interest in developing nutrition/diet-based strategies for correcting gut microbiota dysbiosis. The use of probiotics is one such strategy that has been found to be effective in restoring perturbed gut microbiota composition and function and promoting/restoring optimal health. Amongst the many health benefits associated with probiotics, a large proportion of research attention over the last two decades has focused on their immunomodulatory and anti-infection properties. There is evidence that specific probiotics strains are effective in preventing and/or managing a range of enteric infections and modulating the functioning of the immune system. In healthy subjects and subjects with suboptimal immunity, specific strains are able to boost immune function, whilst in subjects with dysregulated immune system, such as allergy and inflammatory bowel disease, probiotics are effective in restoring immune homeostasis and reducing the severity of immunoinflammatory disorders. A variety of mechanisms by which probiotics mediate their health-enhancing or disease-preventing effects have been suggested. These include direct interaction with the host immune system and through the production of diverse array of bioactive molecules/metabolites. Dairy-based products are common vehicle for delivering probiotics. Being a rich source of essential nutrients and a variety of biologically active substances with synergistic physiological effects, these products offer a significant advantage over other non-dairy products. Milk also contains trans-fatty acid, vaccenic acid, which humans convert into rumenic acid, the biologically active form of CLA. Other fatty acids in milk are also known to exert beneficial health effects. This

presentation will provide an overview of recent advances in health-promoting effects of gut microflora, probiotics and bovine milk fatty acids, especially related to immunoregulation, and novel health-enhancing food products.

Key Words: micrcobiota, probiotics, bioactives

0278 Overview of whey protein based bioactivities (including colostrum) in gut and health promotion.
A. M. Pihlanto* and R. M. Tahvonen, *MTT Agrifood Research Finland, Jokioinen, Finland.*

The high nutritive value and diverse functional properties of milk proteins are well known. In recent years, intense scientific research has focused on the identification of factors within bovine milk that may be relevant to improving human health. The best characterized whey-based bioactive proteins include α-lactalbumin, β-lactoglobulin, immunoglobulins, lactoferrin, lactoperoxidase and growth factors. These proteins exhibit a wide range of biological activities that may influence the digestive function, metabolic responses to absorbed nutrients, growth and development of organs and disease resistance, as well as gut microbiota and microbiome. Some whey proteins may reduce the risks of chronic human diseases. Whey protein constituents have been reported to have functional roles in various biological processes and organ systems in geriatrics, and thus help in the management of geriatric health problems through proper nutrition. Whey components have beneficial effects on intestinal health in four areas: prebiotic effects, antimicrobial and antiviral properties, anticancer properties and gut associated lymphoid tissue. Whey proteins are a good source of various bioactive peptides that are encrypted within the proteins and can be released during gastric digestion or food processing by enzymes or microbes. Whey protein-derived peptides have been shown to exert a wide range of bioactivities affecting the cardiovascular, immune and nervous systems. The efficacy of a few peptides has already been established in animal and human studies. A number of commercial whey-protein based products with potential health effects are on the market and their number is envisaged to increase on global markets.

Key Words: whey protein, bioactivity, health

0279 Milk fat globule membrane components and gut health effects.
R. Ward* and K. Hintze, *Utah State University, Logan, UT.*

Milk fat globule membrane (MFGM) is a complex biopolymer that is primarily composed of polar and neutral lipids and membrane glycoproteins. MFGM is present in all dairy products to some degree, but may be isolated as a co-product from the manufacture of butter and cheese. Based on its composition, it has been suggested that MFGM may have value as a nutraceutical ingredient, yet relatively few studies have been conducted to test this assumption. Individual components of MFGM, such as sphingomyelin and gangliosides, have been shown to reduce the development of preneoplastic lesions in rodent models of colon cancer, and a recent study from our lab extended this finding to MFGM itself. In addition, MFGM itself, and isolated components have been shown to protect the barrier properties of the gut against stress-induced permeability development. Several groups have shown MFGM has antiviral and antibacterial properties, and recent data from our lab indicates MFGM may affect the microbiome composition and metabolism. Lastly, we have recently conducted an acute and a chronic human trial investigating the effects of MFGM on gut health and resilience.

Key Words: milk fat globule, nutraceuticals, gut health

0280 Human gut microbiota, diet and health.
M. Lefevre*, N. Hergert, and G. Rompato, *Utah State University, Logan.*

It is well established that gut microbiota composition and metabolic capabilities can have far reaching effects on host physiology. Further, diet composition can play a major role in modifying gut microbiota. However, the extent to which beneficial effects of dietary modification are mediated through changes in gut microbiota is largely unknown. The Gut Check study was a cross-sectional investigation of the relationship between gut microbiota, habitual diet, intestinal inflammation and selected health biomarkers. Fifty males and eighty-two females between the ages of 18 and 79 provided photograph assisted 3-d food intake records along with stool and blood samples collected immediately following the food records. Diet records were analyzed for selected foods and macro and micronutrient content. Fecal samples were processed for microbiota composition and additionally analyzed for calprotectin levels (a marker of intestinal inflammation). Blood samples were processed for biomarkers of inflammation, insulin sensitivity and endotoxin levels. Despite the recognized limitations associated with assessing dietary intake (even with photo assisted food intake records), strong associations were identified between selected dietary factors and microbiota composition. As an example, we identified a strong positive linear trend ($P < 0.0001$) between tertiles of total milk intake and the relative abundance of the Ruminococcaceae family. A weaker negative association was found between tertiles of milk intake and the Alcaligenaceae family. The relative abundances of the gut microbiota were also associated with parameters of health. Thus the Ruminococcaceae family (members of which have been shown to be higher in controls versus individuals with type 2 diabetes) was negatively associated with diastolic and systolic blood pressure (DBP, SBP) and circulating endotoxin levels. Thus, one would expect that increasing total milk intake would increase Ruminococcaceae and lower blood pressure. Conversely, the relative abundance of the Alcaligenaceae family was negatively associated with BMI, triglycerides, fasting glucose and waist circumference suggesting that increasing milk consumption would adversely affect parameters of metabolic

syndrome. Effects associated with calcium intake were minor, suggesting a primary effect of dairy intake as opposed to generalized effect of calcium intake. In total, these data emphasize the complicated interactions between diet, gut microbiota composition and health parameters and a need to conduct carefully controlled diet intervention studies.

Key Words: microbiota, metabolism, intake

EAAP EQUINE SYMPOSIUM: KNOW-HOW AND FUTURE CHALLENGES FOR DEVELOPING THE HORSE SECTOR IN EUROPE: THE ACTIVITY OF THE EAAP HORSE COMMISSION

0281 Recent aspects in stallion sperm preservation for artificial insemination. M. Magistrini*, *INRA, Nouzilly, France*.

Equine industry needs more and more to improve long-term sperm storage (chilled or frozen) to optimize artificial insemination (AI) and fertility rates and consequently genetic exchanges. In most domestic animal species, sperm extenders are composed of animal products such as milk and/or egg yolk (EY). However, these products are potential sources of bacterial contaminations and have a variable composition. In equine species, milk and egg yolk have been used for years in the composition of extenders. In our laboratory, we have decided to focus our research on the composition of extenders and our objective was to adapt extenders free of milk and or egg yolk for both chilled and frozen sperm. For chilled transported sperm, milk or milk based extenders have been used to dilute and store stallion sperm for AI. However, all milk components are not optimal for sperm protection. So milk fractions were tested and finally we developed an extender named INRA96, containing the purified fraction of native milk caseins, for long-term sperm storage at 4°C or 15°C. INRA96 is a ready to use extender and it can maintain fertility potential for up to 24–72 h. INRA96 has proved itself and many of breeders use it nowadays in many countries. Since the first insemination with frozen semen, the low or fluctuating fertility results have limited the use of this technology. Our objective was to develop a new freezing extender, easy to use and able to improve the success of artificial insemination with equine frozen semen. We first demonstrated that INRA96 extender, used previously for chilled transported sperm, supplemented with EY and glycerol significantly improved significantly the fertility rates of equine frozen sperm. More sterilized EY-plasma afforded the same protection as EY. These results lead to the commercialization of an extender available ready to use and called INRA Freeze. Our next objective was to identify the cryoprotective molecule(s) in egg yolk plasma. EY and more precisely LDL, composed mainly of phospholipids, have long been considered as cryoprotective agents. In our analytical approach to develop a new freezing extender, we have tested the effect of EY-phospholipids instead of EY or EY-plasma. Our results demonstrate that EY-phospholipids as cryoprotective agents are a promising approach that we have to finalize.

Key Words: Equine, INRA 96, sperm storage

0282 The growth of social sciences in equine research: Essential to create new understandings of the horse industry's growth and evolution. C. Vial[1] and R. Evans*[2], [1]*INRA Montpellier, Montpellier, France,* [2]*Norwegian University College of Agriculture and Rural Development, Jaeren, Norway.*

The equine sector is currently growing and evolving worldwide. In Europe, it is estimated that there could be at least 6 million horses in the 27 member countries, grazing 6 million hectares of permanent grassland. 400,000 full time jobs equivalent would be provided by the sector and the numbers of horses and riders are growing in the approximate range of 7% a year. Today, little is known about the horse industry but there is a growing consensus that it has changed from a primarily agricultural and industrial sector activity to one firmly rooted in sports, leisure and consumption. It is impossible to understand these transformations without understanding the society within which they are embedded. Horse welfare, population size, behaviors and potentials depend on those of the societies in which their owners and riders live. Further, contemporary society is changing as it never has before. There is no single 'society.' Different peoples and different places all constitute unique economies, unique social values and mores, and unique formations of the horse industry. To understand the future of the horse sector we must understand these varied social and economic formations. In this context, and given the importance of and the challenges faced by the horse industry, the number of socio–economic studies devoted to this sector has recently multiplied all over the world. The social sciences undertake research, analysis and the development of new understandings of changes in the economy, in cultural values, and in social organization of contemporary society. Working together with traditional equine sciences, we are creating new interdisciplinary knowledge that helps us understand how we got to where we are now and where the equine sector might go in the future. That's why a working group in socio-economy has been created within the EAAP Horse Commission. Today, it includes 67 members from 20 countries. The goal of this group is to share ideas, research and experiences, but also to think about new topics of interest for research and development and to build common projects. This presentation addresses the social and economic issues faced by equine and social scientists who are exploring the contemporary shape of the equine sector, and whose research and analysis can help begin a discussion that enables us to understand what it might become in the future.

Key Words: equine, future of horse sector

0283 Equids contribution to sustainable development in Europe: Modern aspects and transfer of knowledge. N. Miraglia*, *Molise University, Campobasso, Italy.*

Sustainability as a concept comprises the combination of economic, environmental and social elements, never more importantly than when looking at the achievement of local sustainability. The achievement of sustainable development is not only dependent on the sustainability of the environment and its natural resources, but also on the level of economic and social conditions reached by the people using the environment and its natural resources. Europe's rural areas face significant challenges and, between them, the capacity to create sustainable development. In recent years there have been considerable worldwide changes in rural environment, agricultural and feeding systems that affected horse breeding considerably. Farming and forestry remain crucial as the use and the management of natural resources in the EU's rural areas. Rural development is the key tool for the restructuring of the agriculture sector and to encourage diversification and innovation. Equids match an important role in this context because they can make good, productive use of less-favored lands; they are able to develop considerable adaptation mechanisms to resist to very difficult climatic conditions and to low food availability. Diet selection needs to be analyzed to understand livestock performance and their impact on the vegetation in the different sites. So far, the studies concerning the integration between horses and territory are of considerable importance in the recovery of marginal lands and in maintaining their biodiversity. In this context grazing represents a major tool for conservation management because of its effects on habitat structure and biodiversity. Moreover, such activities are more and more linked to the maintenance of population in rural areas, to new relationships between citizen and cultural rural life and consequent preservation of traditional socio-cultural life. This paper will emphasize the role of equids in the rural development from past to future, identifying the farming systems in a general context of environment and landscape safeguard and of biodiversity preservation. It will emphasize the diversity of the "equine culture" and the equine-related activities such as leisure and tourism activities, the preservation of rural socio-cultural life and the most relevant socio–economic issues.

Key Words: equine, sustainability, rural development

0284 Genomic research in horses in Europe — EAAP Interstallion Working Group. K. F. Stock[1]*, L. Jönsson[2], S. Mikko[3], S. Brard[4], B. Ducro[5], S. Janssens[6], and J. Philippson[3], *[1]Vereingte Informationssysteme Tierhaultung, Verden, Germany, [2]University of Copenhagen, Department of Veterinary Clinical and Animal Sciences, Copenhagen, Denmark, [3]Swedish University of Agricultural Sciences, Department of Animal Breeding and Genetics, Uppsala, Sweden, [4]Institut National de la Recherche Agronomique (INRA), Génétique, Physiologie et Systèmes d'Elevage, Castanet-Tolosan, and Génétique Animale et Biologie Intégrative, Jouy-en-Josas, France, [5]Wageningen University, Animal Breeding and Genomics Centre, Wageningen, The Netherlands, [6]KU Leuven, Livestock Genetics, Department Biosystems, Heverlee, Belgium.*

With completion of the horse genome sequence in 2007, the potential of close international collaboration of researchers was impressively demonstrated, and an important step for genomic research in horses was taken. Since then, several European scientists have significantly contributed to the development of tools and strategies for using genomic information in the study of hereditary conditions and for improvement of breeding programs. An overview will be given of projects and initiatives in Europe in the field of equine genomics including prospected routine applications. Equine genetic and genomic research in Europe is carried by several strong and experienced research groups with high expertise and access to the latest methods and technologies, such as high-density SNP genotyping and next generation sequencing. The long standing European horse breeding organizations are in transition and have realized the potential of genomics for future practical horse breeding. Some progressive studbooks have accordingly shown considerable engagement and support in recent genomic projects. Because of their importance for the usability and overall quality of horses, health and performance have been and are still in the focus of genomic research in horses in Europe. Skeletal conditions are highly relevant for sport horses, so results of radiological screenings of young horses have been used for identifying ways to improve locomotory health by breeding. Quantitative trait loci have been identified and their routine use for selection purposes has been envisaged in, for example, Dutch, French and German horse populations for osteochondrosis, the most extensively studied single disease condition. Promising results for gaits and jumping have indicated the potential of using genomic approaches for improving complex performance traits in sport horses. However, limited accessibility of high-quality phenotype data has retarded the development of routine genomic applications in horse breeding, which is expected to significantly benefit from the recent initiatives addressing refinement and extension of the phenotypic information basis and R&D collaborations. The exchange of genetic material

between European Warmblood populations, the similarities of breeding goals and the relatively well developed infrastructure in the European horse sector make a good starting point for collaborative work across countries in the field of genomics. Synergistic effects of linking national projects and resources are obvious and have allowed prospecting a joint European genomics project aiming at improved selection for health and performance traits in Warmblood horses.

EXTENSION EDUCATION

0286 Developing, marketing and branding mobile apps for the horse industry. K. L. Martinson[*1], R. J. Coleman[2], and M. E. McCue[1], [1]*University of Minnesota, Saint Paul,* [2]*University of Kentucky, Lexington.*

An app is software that runs on the internet, a computer or phone. There are millions of apps available with about one billion downloads annually. However, relatively few apps have been developed for use in the horse industry. The objective of this abstract is to outline developing, marketing and branding of two mobile apps for use in the horse industry. In 2012, researchers developed a more accurate method for estimating horse body weight, a new equation for estimating ideal horse body weight, and a percentile that resulted in a body weight score to help assess over- and under-weight horses. Since the equations were complex, researchers decided to develop an app, named "Healthy Horse," to encourage use and adoption of the equations. During the same time period, hay prices around the U.S. were at all-time highs. Horse owners normally purchase hay by the bale, which can result in further exaggeration of prices. To help horse owners convert price per bale to price per ton, representing a more economical hay purchasing strategy, the "Hay Price Calculator" app was also developed. In January 2013, a computer science graduate student was hired to develop both apps in collaboration with the research team. App development took about 4 mo and cost approximately $8,000. Because grant funds were used to pay for the development of the apps, the University of Minnesota Office of Technology and Commercialization was consulted and decided to brand and market the apps under the University of Minnesota Board of Regents. In May 2013, both apps were released for use with Apple operating systems at a cost of $1.99 and $0.99 for the Healthy Horse and Hay Price Calculator apps, respectively. In November 2013 and March 2014, the Android version of Hay Price Calculator and Healthy Horse, respectively, were released. During the summer of 2013, the research team was approached by a nutrition company to co-brand the Healthy Horse app. After consulting with University Relations and the Office of the General Council, a contract was finalized to co-brand the app with the company logo and website address in exchange for a monetary contribution and marketing efforts. Since May 2013, over 1100 apps have been sold. Funds from the sale of the apps will help support future equine research at the University of Minnesota.

Key Words: mobile app, horse, body weight

0287 Calving management education program for dairy and beef workers and producers. L. G. D. Mendonça[*1], L. Hollis[1], J. M. Zeller[2], and J. P. Harner[2], [1]*Department of Animal Sciences and Industry, Kansas State University, Manhattan,* [2]*Department of Biological and Agricultural Engineering, Kansas State University, Manhattan.*

Stillborn is defined as a calf born dead or death within 24 h after calving. A stillbirth event is costly to a cattle producer because of the calf loss and the effects on the dam. Calving management education programs in English and Spanish were organized and delivered across Kansas with the objective to educate cattle producers and their workers. Furthermore, the program addressed other important areas; participants learned about management of cows during the pre- and postpartum period, and newborn calf care. A tool was designed and built to assist with the hands-on demonstration part of the educational program. Faculty from the Department of Animal Sciences and Industry collaborated with faculty and staff from the Department of Biological and Agricultural Engineering, Kansas State University, to build a tool to simulate a cow giving birth. A pelvic bone was placed inside a stainless steel box with a plexiglass side panel to allow participants to visualize a number of obstetrical procedures. A dead calf was used for the demonstrations and it was discarded at the end of each session. To date, there were 167 attendees in the educational program; it impacted approximately 15,000 dairy and 5000 beef cows in the state. In 2 training sessions, attendees' perception of the educational program was assessed using a survey, and pre- and post-test questions were used to evaluate participants' knowledge. Audience response system clickers (Turning Point Technologies) were used to collect answers of the pre- and post-test questions. Among the participants that responded, 72% answered they never participated in any "calving school training" before. The survey found that knowledge of understanding calving management increased from 2.8 to 4.0 (scale 1−5) in the first session and 2.0 to 2.6 (scale 1-3) in the second training session. Eighty-six percent of the attendees answered that the information presented about calf presentation and in the hands-on assistance demonstration was new and useful information. In the training sessions, 16% of respondents reported they were very likely, 70% likely and 14% not likely to make management changes. The mean scores for the pre- and post-tests were 51% and 81%, respectively. The mean difference of 30% indicates that using an interactive slide lecture and hands-on demonstration was effective in teaching producers and workers about calving management.

Key Words: calving management, producers and workers, education

0288 Premium beef semen on dairy calculator. G. Lopes*[1] and V. Cabrera[2], [1]*Accelerated Genetics, Baraboo, WI,* [2]*University of Wisconsin Madison, Madison.*

Producers are searching for alternatives to increase net income of their operations. Genetic companies are partnering with livestock sales companies and offering premium alternatives for crossbred calves when using beef semen. Our objective was to develop a decision support tool to analyze the net income of switching inseminations from conventional or sexed sorted dairy semen to beef semen. This partial budgeting calculation is performed considering the genetic value of animals to be inseminated and the expected premium to be received for crossbred offspring. The tool was conceived as an aid to help producers in their decision-making regarding the use of beef semen. Inputs from the herd such as herd size and herd structure, culling rate, pregnancy rate, number of virgin heifers inseminated with female sex-sorted semen, percentage stillborn, and calf mortality are used to calculate the number of replacements needed to maintain herd size and to determine the number of eligible animals for the beef program. Different prices of semen (conventional dairy, sex-sorted dairy, and conventional beef), and different prices paid for the offspring (dairy and beef crossbred) are taken into consideration. Animals are grouped according to parity (nulliparous, first, second, and greater than two lactations), and then further sub-divided according to the number of inseminations to receive (one, two, three, and greater than three). The selection of animals could be made in two different ways: (1) by genetic merit or (2) by reproductive performance. After selection, the tool calculates and shows the number of replacements that will remain in the herd to maintain herd size. Further, the tool estimates the profitability of selling crossbred calves at a premium price, presenting the dollar net return for the crossbred animals, and the net return for the herd as a whole. Herds using beef semen strategies enhance their genetic gain by generating future replacements from genetically superior heifers and cows. The tool will soon be freely available from the UW-Dairy Management Website (DairyMGT.info).

Key Words: premium, beef, dairy

0289 A decision support tool to estimate the economic potential of SCC hot sheet data. D. T. Nolan* and J. M. Bewley, *University of Kentucky, Lexington*.

A DHIA hot sheet ranks cows from the highest to lowest percent of bulk tank somatic cell count (BTSCC) based on their SCC and milk yield. The objective of the Southeast Quality Milk Initiative (SQMI) Hot Sheet Dashboard was to develop a farm specific tool that producers could use to make economic decisions from DHIA hot sheet data. Producers enter production information for the top SCC cows from the DHIA hot sheet including: milk production (kg/d), and percentage of the BTSCC, and herd based inputs including: amount of milk shipped/d, BTSCC, current milk price, and bonus opportunities for milk quality. Producers also determine whether they want to discard or ship milk from a cow with a high percentage of the BTSCC. Results are displayed to show how the current BTSCC and the economic opportunity would change depending on which cows' milk was discarded. An example scenario is presented in Table 0289. The net opportunity for this herd is $24.05/d. This value represents the difference in economic opportunity when milk from the top 2 cows is being shipped compared to being discarded. The price was higher when the cows' milk was discarded because the producer received the bonus opportunity for having a lower BTSCC. The SQMI Hot Sheet Dashboard can be beneficial to producers by allowing producers to make economic decisions from their DHIA hot sheet data. The Southeast Quality Milk Initiative project is supported by Agriculture and Food Research Initiative Competitive Grant no. 2013–68004–20424 from the USDA National Institute of Food and Agriculture.

Key Words: decision support tool, SQMI, hot sheet

Table 0289. Example herd inputs and results generated from the SQMI Hot Sheet Dashboard for a 100-cow herd, shipping 3402 kg of milk per day, with a BTSCC of 492,000 cells/mL and a current milk price of $0.41/kg, with a bonus opportunity of $0.01/kg*

	Cow Information				
	Milk Yield (kg)	% BTSCC	Decision	BTSCC after decision (cells/mL)	Bonus Opportunity ($/L)
Cow #1	19.1	25.6	Discard	284,376	.005
Cow #2	13.7	15.9	Discard	171,708	.01
Cow #3	37.0	10.1	Milk	171,708	.01
Cow #4	28.4	6.8	Milk	171,708	.01
Cow #5	36.9	5.9	Milk	171,708	.01
Economic Opportunity $24.05/d**					

*Bonus opportunity will increase with a decrease in BTSCC depending on producer inputs.
**Net opportunity does not assume discard milk is used as milk replacer substitute.

0290 The Kentucky Master Stocker Program. J. W. Lehmkuhler*[1], W. R. Burris[2], S. R. Smith, Jr[1], G. Halich[1], K. Burdine[1], M. Arnold[1], S. F. Higgins[1], A. Gumbert[1], and K. Laurent[1], [1]*University of Kentucky, Lexington* [2]*University of Kentucky, Princeton*.

The upper Mid-South is home to a large number of farms that utilize available forage and feed resources to add weight to lightweight feeder calves. With the change in the market conditions, it was evident that an outreach program was needed to provide this segment of the industry information related to management of feeder calves. An interdisciplinary team was assembled to develop curriculum related to all aspects of the feeder cattle industry. A total of eight sessions comprised the curriculum including: enterprise budgeting, economic risk management, health, nutrition, handling and welfare, forages, marketing and environmental management. The program was

offered twice during 2011 and 2012. Approximately 380 participants from 30 of the 120 counties attended. A random subsample of 150 were mailed a 50 question survey in 2013 to assess post-program impact. A total of 47 questionnaires were returned (31% return rate). The majority (93%) of respondents indicated the program Exceeded or Far Exceeded expectations. Awareness was increased (95%) related to management and marketing and 66% of respondents indicated they implemented changes. The majority (62%) Agreed or Strongly Agreed that their perception of the impact livestock have on water quality and the environment changed with an outcome of agriculture water quality management plans being completed by 79% and 61% indicating they developed streamside buffers or alternative watering sources for cattle. Increases in knowledge for livestock health were noted where 89% Agreed or Strongly Agreed they had a better understanding of how to use various antibiotic products available, 87% had a better understanding of selecting vaccines, 83% an improved understanding of health risk classification and 71% indicated they were better able to diagnose and properly treat feeder calves. Of those surveyed, 53% made changes to their health protocols and 60% indicated they have seen improvements in the health or response from administered products after having attended the session. Cattle handling was altered with only 19% indicating their handling techniques were unchanged and 57% indicated the use of an electric prod was Slightly or Much Lower. The majority (58%) Agreed or Strongly Agreed to have made changes to their feeding program. Economic risk management tools were utilized by 40% of respondents with 88% indicating the strategy limited their risk. The delivery of an educational program for the stocker and backgrounding industry in Kentucky was well received and increased producers' awareness and adoption of management changes.

Key Words: education, feeder cattle, stocker

0291 The North Dakota Beef Industry Survey; Enterprise management, risk factors, and risk management strategies of beef cattle operations.

D. N. Black*[1], J. C. Hadrich[2], G. P. Lardy[1], and C. R. Dahlen[1], *[1]North Dakota State University, Fargo, [2]Colorado State University, Fort Collins.*

In the spring of 2012 a survey was distributed to 2500 randomly selected North Dakota beef producers to evaluate their attitudes concerning risk factors and risk management on their operations. Five hundred twenty-seven surveys were returned (21.1% response rate), of which, 436 (82.7%) respondents indicated that they were active beef producers. Commercial cow-calf production (94.5%), and backgrounding (37.8%), were the most common enterprises on respondents' operations. Thirteen percent of respondents grazed cattle on federal grasslands, 54.4% grazed crop residue, and 17.7% grazed cover crops. When asked about expansion plans, the majority of respondents indicated they would focus on commercial cow-calf (82.8%) followed by backgrounding (36.6%), feedlot (21.9%), stocker (19.4%), and purebred (15.4%) enterprises, respectively. For recordkeeping, most operations use a paper record book (60.4%), followed by computer spreadsheets (36%), and management software (9.6%), whereas 2.9% do not have a formal recordkeeping method. To determine per-cow cost of production, 23.9% of respondents balanced checkbooks, 22.7% use management software, 22.1% use tax returns, 15.5% do not calculate, 5.1% use a consultant, and 29.3% use other methods not categorized in the survey. On a scale of 1−5 (1 = small negative impact, 5 = large negative impact) respondents identified animal health issues (4.1) and severe weather (4.1) as having a large negative impact on profitability, and labor availability (3.0) was viewed as being a neutral factor. Variability in cattle price (4.3) and input cost (4.3) were factors identified as having the greatest potential negative impact on profitability, whereas variability in soybean price (2.8) had neither a small nor large negative impact on profitability. When asked about the effectiveness of management strategies in reducing risk (scale of 1−5, 1 = not effective, 3 = neutral, 5 = very effective), respondents identified maintaining good animal health (4.6), financial reserves (4.0), and having off farm income (3.7) as being effective strategies, whereas herd management programs (2.8) and hiring ranch management consultants (2.8) were viewed as neither effective nor ineffective strategies to reduce risk. Survey results identify the degree of risk that producers associate with different factors and highlight strategies used to mitigate losses from identified risks.

Key Words: beef industry, profitability, risk management

0292 History and development of the Bovine Estrus Synchronization Planner. S. K. Johnson[*1], G. Dahlke[2], and D. R. Strohbehn[2], [1]*Kansas State University, Colby,* [2]*Iowa State University, Ames.*

The Bovine Estrus Synchronization Planner is an Excel-based tool that aids in the selection and delivery of synchronization protocols. The development was a response to vocal concerns expressed by technicians, veterinarians and producers to Iowa State University extension beef specialists on the difficulty in managing the product delivery and timing elements of estrus synchronization protocols. Errors in protocol follow through were common and the resulting poor conception rates unfairly discredited the technology. As a multi-state extension group (now the Beef Reproduction Task Force) was coming together to deal with similar issues related to clear communication on research-based synchronization protocols, an Iowa State specialist approached the group about working together to update the existing planner with the new task force recommendations. This has been a successful partnership as the group has worked together to improve and update the planner for 10 yr. The original program contained six protocols, but now almost 40 recognized protocols are included. However, the short list of protocols recommended by the task force is highlighted. At one point there was a charge for the software, but over time the group has achieved enough industry sponsorship to provide the program as a free download at http://www.iowabeefcenter.org/estrus_synch.html. Today, the planner has more independent users than any of the other Iowa State University Animal Science software. The most recent development is a shortened version for use on handheld devices (www.estrussynch.com). Through the following steps: identification of research proven protocols, designation of most appropriate use of protocols, direction on proper implementation and stressing the importance of timing through the use of a calendar printout, the Estrus Synch software has clarified the necessary details to the end user. An online survey of AI users in 2013 (42 states represented) indicated 36% had downloaded the planner; of which 41% used it frequently, 15% used it 3−5 times, 31% used it less than twice and 13% had not used it. Users strongly agreed or agreed that the planner was easy to use (79%), made scheduling easier (77%), reduced errors (68%), improved communication (71%), helped achieve timely planning and preparation (73%), and directed them to a more appropriate protocol (57%). Suggestions made by users were included in the 2014 version. The Estrus Synchronization Planner has been a useful tool in the proper implementation of synchronization protocols. Efforts to inform potential users of its availability must continue.

Key Words: estrous synchronization, decision tools, evaluation

0293 Impact of decision support tools available for dairy farm management. V. Cabrera*, *University of Wisconsin, Madison.*

A number of decision support tools are available for dairy farm management and are being used for practical decision-making. The objective of this analysis was to document the level of adoption of decision-support-tools available at the University of Wisconsin-Madison Dairy Management Website (http://DairyMGT.info; > 35 tools) including the *Repro Money*, a Wisconsin extension program to improve reproductive performance. Since its inception in 2008, the DairyMGT.info, conceived as a mechanism to deliver science-based, user-friendly, and practical-application decision-support-tools, has accumulated a number of tools in nutrition, heifer rearing, reproduction, production, replacement, financial, and environment. The domain DairyMGT.info was registered with *Google Analytics* in December 2009 (http://www.google.com/analytics) to record the number of visitors and pageviews. Later, a system to track tool-specific usage by registering user emails was implemented in March 2011. Data indicate that the DairyMGT.info domain has consistently received > 1000 visits and > 3000 pageviews per month with a total of > 55,500 visits and > 179,000 pageviews in the period December 2009 to January 2014. Around 55% of visitors were from the US and the rest from more than other 150 countries, counting as the most important: Australia, Mexico, Brazil, Canada, Argentina, UK, and Italy. To January 2014, a list of 4500 users were registered with the DairyMGT.info domain and there were > 35,000 tool effective uses (a rate of > 1000 accessions a month or > 30 a day). As the number of visitors, tools usage is consistently increasing. The top 5 most popular tools are: FeedVal 2012-feed price valuation, grouping strategies for feeding lactating dairy cattle, value of sexed semen programs, economic reproductive analysis, and the economic value of dairy cow. A special tool for improving dairy herd reproductive management, *Repro Money* consists on facilitating 4+ farm-team meetings with the goal of diagnosing, prioritizing needs, and taking effective actions to improve reproductive performance. *Repro Money* was launched in late 2010 and since then 45 farmers have enrolled. Data from farms that finished the program by January 2014 (n = 30) indicate that reproductive performance (before vs. after) improved significantly at key reproductive indicators such as conception rate (+3%, $P < 0.01$), service rate (+5%, $P < 0.01$), interbreeding interval (−5 d, $P < 0.01$), and overall 21-d pregnancy rate (+3%, $P < 0.01$). This improved reproductive performance was estimated to increase economic gains in an average amount of $55/cow per yr (range $0 to $278) with an estimated overall impact of > $358,000/yr on 11,340 cows.

Key Words: online tools, decision-making, reproductive economic performance

0294 Assessing the need, project development and impact of the National Swine Reproduction Troubleshooting and Management Guide.

D. Levis*[1], M. Estienne[2], W. Flowers[3], R. Baker[4], R. Knox[5], K. Stalder[4], T. Safranski[6], M. Knauer[3], W. Singleton[7], D. Meisinger[8], C. Branderhorst[8] and W. Winkelman[9], *[1]Levis Worldwide Swine Consultancy, Lincoln, NE, [2]Virginia Tech, Suffolk, VA, [3]North Carolina State University, Raleigh, [4]Iowa State University, Ames, IA, [5]University of Illinois, Urbana, [6]University of Missouri, Columbia, [7]Purdue University, Lafayette, [8]US Pork Center of Excellence, Clive, IA, [9]National Pork Board, Clive, IA.*

An assessment of university Cooperative Extension swine programs in the United States revealed lack of a tool for troubleshooting reproductive problems at the farm level. Moreover, there are an extremely small number of extension specialists academically trained in reproductive physiology of pigs who are able to conduct troubleshooting and ongoing educational programs at the farm level. Thus, pork producers rely on themselves, veterinarians, or other consultants to improve reproductive performance of the breeding herd. A major role of university Cooperative Extension/Outreach is to provide scientific based information to help pork producers and consultants solve swine reproductive problems. The United States Pork Center of Excellence organized a group of nine university Extension swine specialists to develop a National Swine Reproduction Troubleshooting and Management Guide (NSR-TMG) for use by all pork producers and pork industry consultants. The NSR-TMG uses a question and answer format. The NSR-TMG has three main areas: (1) Problems with replacement gilts, (2) Problems with sows, and (3) Problems with semen quality. The replacement gilt segment focuses on problems associated with attainment of puberty and expression of estrus, problems resulting from a gilt pool that is too small, and problems that lead to poor litter size or reduced farrowing rate of gilts. The sow segment focuses on problems associated with reduced longevity due to high culling rate, low farrowing rate, low litter size, prolonged weaning-to-service interval and high pre-weaning mortality of pigs. The semen quality segment focuses on record keeping, semen delivery and storage, semen evaluation, and on-farm semen collection and processing. The program has answers for over 1000 questions. The answers are supported by a list of 648 references. Some references are available by linkage. The NSR-TMG is a web-based application, user-friendly, applicable for use by any size of sow farm, and easily accessed through personal computer, smart phones and tablets. Because the NSR-TMG is web-based, it will be easily updated. The project was partially funded by numerous pork industry partners. There is a yearly license fee to obtain access to the NSR-TMG. University and college instructors have free access to train students. The NSR-TMG is being used to improve reproductive performance of the sow herd by independent pork producers, large corporate swine operations, swine genetic companies, veterinarians, swine nutrition consultants, and university instructors. The actual financial impact of the NSR-TMG is difficult to measure at the farm-level.

Key Words: swine reproduction troubleshooting

FOOD SAFETY: **GLOBAL CHALLENGES TO A SAFE FOOD SUPPLY**

0295 Introduction—Global challenges to a safe food supply. R. J. Harmon*, *University of Kentucky, Lexington*.

As we move forward in meeting the global food demands of 2050, food safety will continue to be a high priority. Consumers have an increased interest in how their food is produced, where it is produced and is it safe and healthy for their families. In contrast, we have movements that seem to be counter to providing a safe and wholesome product to consumers, such as the raw milk movement. This symposium proposes to address several issues related to a safe global food supply, including new regulatory approaches to safe animal feeds (and thus food), raw milk issues and safety, and the retail perspective on food safety in international markets. All of these areas, and more, play important roles in assuring a safe global food supply for the future.

Key Words: food safety, raw milk, animal feed

0296 Raw milk—Is it safe? B. Jayarao* and E. Hovingh, *Penn State University, University Park.*

Over the last 20 yr, several surveys in the United States have detected food borne pathogens in raw bulk tank milk and many of the milkborne disease outbreaks have been traced to consumption of raw milk. In contrast, for the same period, fewer milkborne disease outbreaks were associated with consumption of pasteurized milk. These milkborne disease outbreaks following consumption of raw milk and milk products have raised serious public health concerns nationwide. The sale of raw milk has become more relevant than ever before due to the emergence of antimicrobial resistance in food borne pathogens such as *Salmonella* and *Escherichia coli*. Consumption of raw milk is widely prevalent among dairy farm families and their employees. In recent years, the "post baby boom" generation, comprised of a small but growing subset of urban/suburban population that consumes raw milk and raw milk products may account for the rise in the sale of raw milk. There are few reports that suggest urban/suburban consumers of raw milk believe that raw milk has more health benefits than pasteurized milk and these benefits outweigh the risks associated with foodborne pathogens in raw milk. In 1987, the FDA banned the interstate sale of raw milk; however, the sale of raw milk within state boundaries falls under the jurisdiction of each state's government. Nonetheless, in states where sale of raw milk is legal, the farms with permits to sell raw milk have to meet set bacteria count standards, periodic testing of raw milk for the presence of pathogens, and labeling of raw milk offered for sale. The Penn State Veterinary Extension and Field Investigation Team recently undertook a study involving 40 permitted raw milk producers in Pennsylvania. The study collected milk samples on a monthly basis to determine the presence or absence of pathogens, as well as various milk quality parameters. In addition to assessing farm management and milk hygiene practices, a survey of the farms' customers was also conducted. The findings of the study are as follows; 1) raw milk sale is largely driven by consumer demand, 2) farm hygiene level and presence of pathogen are not correlated, 3) most producers are cognizant of pathogens in raw and strive to address the issue of product safety, and, 4) critical points in the raw milk production continuum are yet to be clearly identified.

Key Words: raw milk, food safety

FOOD SAFETY: **ADVANCES IN FOOD SAFETY**

0299 Effectiveness of a mycotoxin binder to minimize transfer of aflatoxin from feed to milk in Nili-Ravi buffaloes. N. Aslam[1], I. Rodrigues[2], A. ul Haq[3], A. Cowling[1], H. M. Warriach[4], D. M. McGill[1], and P. C. Wynn[*1], *[1]Graham Centre for Agricultural Innovation, Charles Sturt University, Wagga Wagga, Australia, [2]BIOMIN-Singapore Pte. Ltd., Singapore,[3]Buffalo Research Institute, Bhunniky, Pakistan, [4]University of Veterinary and Animal Science, Lahore, Pakistan.*

Mycotoxins resulting from fungal contamination of feeds provide a major limitation for dairy production in Pakistan. The objectives of this study were to observe the extent of transfer of aflatoxinB1 in feed to the aflatoxinM1 metabolite in milk in Nili-Ravi buffaloes and to evaluate the efficacy of a mycotoxin binder incorporated into feed to minimize this transfer. Multiparous animals ($n = 28$) were randomly distributed to four groups corresponding to 2 treatments each with 2 levels in a factorial design. Animals were offered mycotoxin contaminated concentrate ration (2.5 or 5 kg/day) and corn (200 or 400 g/day) providing a total of 1475 µg (groups A and B) or 2950 ug (groups C and D) of aflatoxinB1 together with either 80 kg (groups A and B) or 70kg (groups C and D) of aflatoxin free fresh cut berseem clover (17.8% DM). AflatoxinB1 concentrations in feed for the low and high groups were therefore 88.7 and 171.2 ug/kg DM. Groups B and D were given 50 g of mycotoxin binder daily mixed with feed while groups A and C were kept as controls. Feed samples were analyzed by HPLC in Romer Labs Pte. Ltd., Singapore for aflatoxinB1 and milk samples were evaluated by ELISA for the liver metabolite aflatoxinM1. There was a highly significant difference ($P < 0.001$) in total daily aflatoxinM1 concentration in milk between animals fed the two concentrations of aflatoxinB1. The mean for those fed 2950 µg/day was 112.62 µg/kg of milk, almost double the concentration of 62.19 µg/kg in buffalo fed 1475 µg/day (SED = 5.99). The mean daily concentration of aflatoxinM1 in milk of animals from both treatment groups fed with 50 g of mycotoxin binder was 76.51 µg/kg, nearly 22 µg lower than those without mycotoxin binder 98.31 ± 5 µg/kg (SED = 5.99: $p < 0.01$). The interaction between the 2 treatments was not statistically significant. The total carryover of aflatoxinB1 from feed to aflatoxinM1 in milk was 5.06 and 4.14% for group A and C (without mycotoxin binder) and 3.37 and 3.50%, for groups B and D respectively fed the mycotoxin binder. Thus buffaloes are highly efficient at transferring mycotoxins in feed to the aflatoxinM1 metabolite in milk, while mycotoxin binder is capable of alleviating without preventing this contamination risk. In spite of this, the concentrations in milk still exceeded the European Union minimum standard of 0.05 µg/kg by over 150 fold. Strategies to minimize fungal contamination of concentrate feeds remains of importance for food security in Pakistan.

Key Words: aflatoxinM1, aflatoxinB1, transfer, milk, mycotoxin binder, Nili-Ravi buffaloes

0300 Use of silage bacteria as enterosorbents to reduce aflatoxin contamination. Z. Ma*, J. J. Romero, S. K. Williams, and A. T. Adesogan, *Dep. of Animal Sciences, University of Florida, Gainesville*.

The aim was to determine the effects of bacteria strain, viability and pH on the aflatoxin B_1 (AFB_1)-binding capacity of silage bacteria. In Experiment 1, each of 10 silage bacteria strains (Table 0300) was screened for their AFB_1–binding capacity by growing them on de Man-Rogosa-Sharpe broth to a population of 10^9 cfu/ml in quadruplicate. The suspension was centrifuged at 2500 × *g* for 10 min and the pellet was suspended in a 1.5-mL solution (5 µg/ml) of AFB_1 in phosphate buffered saline (PBS) for 24 h at 20°C. Bacterial (bacteria suspended in PBS) and AFB_1 Controls were also incubated. Supernatant samples after centrifuging were used to quantify the presence of unbound aflatoxin by High-Pressure Liquid Chromatography. Data were analyzed as a completely randomized design. Each bacterium bound more than 18% of AFB_1, and the greatest responses occurred with *L. plantarum* R2014 (32.95%), *L. buchneri* R1102 (30.30%) and *P. acidilactici* EQ01 (25.38%). In Experiment 2, the latter 3 strains were tested to determine how pH and bacterial viability influence their ability to bind AFB_1. Bacterial cells (10^9 cfu/ml) were incubated in either 4 mL of PBS (viable cells) or 2M HCL (dead cells) and centrifuged as described above. Pellets were incubated in quadruplicate in AFB_1 solution as above at pH 6, 2.5 and 8 to simulate the pH in the rumen, abomasum and intestine of dairy cows, and AFB_1 binding was quantified. Data were analyzed as a completely randomized design with a 3 × 2 × 3 factorial treatment arrangement. Dead cells of *L. plantarum* R2014 (32.62% vs. 24.78%) and *L. buchneri* R1102 (45.05% vs. 17.77%) bound more AFB_1 than viable cells, whereas a contrasting response was detected for *P. acidilactici* EQ01 (2.44% vs. 21.92%, respectively). The pH of 2.5 increased AFB_1 binding compared with pH 6 and 8 ($P < 0.05$). All bacterial strains showed AFB_1–binding ability but the efficacy was dependent on the bacteria strain, viability and pH. More work is required to test the ability of the bacteria to bind AFB_1 in animal feeds.

Key Words: aflatoxin, silage bacteria, enterosorbents

Table 0300. Bacterial strains tested for AFB_1 binding capacity

Bacteria	Strain
Lactobacillus plantarum	R2014

Propionibacterium acidipropionici	EQ42

0301 Effect of starter culture as a source of microbial contamination on the quality and safety of yogurt products in Egypt. M. M. Motawee[*1], W. E. D. I. Saber[2], and S. A. Ibrahim[3], [1]*National Organization for Drug Control and Research, Giza, Egypt,* [2]*Department of Microbiology, Giza, Egypt,* [3]*Food Microbiology and Biotechnology Laboratory, North Carolina A&T State University, Greensboro*.

Yogurt is one of the most common dairy foods in Egypt, yet the stability and shelf-life of yogurt remain a challenge to local producers. Thus, the objective of this study was to examine the effect of starter culture as a source of contamination on the quality and safety of yogurt product. In this study, we examined three groups of yogurt products. In group one, we collected 100 commercial yogurt products available in the marketplace. In group two, we made 10 yogurt batches ourselves using different yogurt starter cultures obtained from the local dairy industry. In group three, we made yogurt using yogurt culture from food microbiology stock culture. We then evaluated the types of microbial groups in relation to spoilage before and after storage of yogurt under chill condition and examined the microbial quality during storage at 7C for 14 d. Our results showed that during storage, there was an undesirable change in the commercial products as well as in yogurt products made with commercial starter cultures. All samples in groups one and two tested positive for *Aspergillus* spp. aflatoxin M1 and *Salmonella* spp. By contrast, the use of the control starter cultures prevented the presence of these contaminants in group three. Our results thus demonstrated that the use of a safe starter culture would be a promising approach to ensure the safety and quality of yogurt when it reaches the consumer.

Key Words: starter culture, yogurt, safety

0302 Effectiveness of pulsed light treatment on the inactivation of pathogenic and spoilage bacteria on cheese surface. J. Proulx[*1], L. Hsu[1], B. Miller[1], G. Sullivan[1], K. Paradis[2], and C. I. Moraru[1], [1]*Cornell University, Ithaca, NY,* [2]*McGill University, Montreal, QC, Canada.*

Cheese products are susceptible to post-processing cross-contamination that can lead to both food safety issues and significant losses due to spoilage. Pulsed Light (PL) treatment, consisting of short, high-energy light pulses, could represent a solution to address this issue since it is a nondestructive technology that can effectively inactivate microorganisms on surfaces. This study examined the effectiveness of PL on the inactivation of the spoilage microorganism *P. fluorescens* and the pathogen surrogates *E. coli* ATCC 25922 and *L. innocua.* The effect of inoculum level, cheese surface topography, and the presence of clear polyethylene packaging were evaluated in a full factorial experimental design. The challenge microorganisms were grown to stationary phase: *P. fluorescens* 1150 was grown at 30°C in tryptic soy broth (TSB) while *E. coli* ATCC 25922 and *L. innocua* FSL C2–008 were grown at 37°C in TSB and brain heart infusion (BHI), respectively. White cheddar and processed cheese, chosen for their different surface topography, were cut into 2.5 cm × 5 cm slices. The samples were then spot inoculated using ten droplets of 10 µL per slice, resulting in an initial concentration of either 5 or 7 log CFU/slice. Inoculated samples were dried overnight at 4°C. For treatments through packaging, sterile UV-transparent low-density polyethylene packaging was placed on top of the inoculated cheese samples immediately before the PL treatment. Cheese samples were then exposed to PL doses of 1.1 to 13.2 J/cm^2. PL-treated samples were stomached for 2 min in Butterfield Phosphate Buffer, the extract then plated on selective media and survivors enumerated by standard plate counting (SPC). When survivor counts fell below the SPC detection limit, the most probable number was used. Experiments were performed in triplicate and data were analyzed using a general linear model. PL was most effective against *E. coli*, achieving a maximum log reduction of 5.4 ± 0.3, at a dose of 13.2 J/cm^2. For *P. fluorescens*, a maximum log reduction of 3.7 ± 0.9 and for *L. innocua* a maximum log reduction of 2.9 ± 0.8 at 13.2 J/cm^2 were obtained. The process parameter effects tested showed varying statistical significance when used in different combinations, but PL treatments through packaging and without packaging consistently resulted in similar inactivation levels. This study suggests that PL has strong potential for decontamination of cheese surface.

Key Words: pulsed light, cheese, pathogenic and spoilage bacteria

0303 Evaluation of heavy metals, phenol, and polycyclic aromatic hydrocarbons on singed skin-on red Sokoto buck goats. O. A. Babatunde*[1], O. O. Olusola[2], O. J. Aremo[2], and W. Y. Akwetey[1], *[1]kwame Nkrumah University of Science and Technology, Kumasi, Ghana, [2]University of Ibadan, Ibadan, Nigeria.*

The safety of skin-on meat obtained from singed carcasses needs to be assessed. This study was therefore performed to investigate the concentration of heavy metals (Pb, Cd, Zn, Mn and Cu), phenol and polycyclic aromatic hydrocarbons (PAH) in red Sokoto buck goat carcasses singed using fire wood, kerosene, scrap tyre and liquefied gas (LG). A total of twenty four good grade red Sokoto buck goats weighing between 18-20 kg were randomly distributed into each of the four treatments in a completely randomized design. Each treatment was replicated six times. PAH levels were highest in scrap tyre singed carcasses (0.040 mg/kg) and least in LG singed carcasses (0.001 mg/kg). Pb and Mn were below detectable limit in carcasses singed with LG while the concentrations were similar ($P >$ 0.01) in the other treatments. Cd was not detected in any of the treatments. Zn concentration was highest in carcasses singed with kerosene (0.005 mg/kg). The level of phenol ranged from 0.02 Gae/kg in LG singed carcasses to 0.38 Gae/kg when scrap tyre was used. Material used in singeing was found to have profound effect on heavy metal, phenol and PAH depositions on skin-on meat from red Sokoto buck goats.

Key Words: skin-on, singed, heavy metal, phenol, polycyclic aromatic hydrocarbon, red Sokoto

FORAGES AND PASTURES I: SILAGES

0304 Effect of corn silage hybrids differing in starch and NDF digestibility on lactation performance and total tract nutrient digestibility by dairy cows. L. F. Ferraretto[*1], A. C. Fonseca[1], C. J. Sniffen[2], A. Formigoni[3], and R. D. Shaver[1], *[1]University of Wisconsin, Madison, WI, [2]Fencrest, LLC, Holderness, NH, [3]Università di Bologna, Bologna, Italy.*

The objective of this study was to determine the effect of feeding a TMR containing a floury-leafy corn silage hybrid (LFY) compared to a brown midrib corn silage hybrid (BMR) for intake, lactation performance and total tract nutrient digestibility in dairy cows. Ninety-six multiparous Holstein cows, 105 ± 31 DIM and 735 ± 18 kg of body weight at trial initiation, were stratified by DIM and randomly assigned to 12 pens of 8 cows each. Pens were randomly assigned to 1 of 2 treatments, BMR or LFY, in a completely-randomized design; a 2-wk covariate period with cows fed a common non-experimental diet followed by a 14-wk treatment period with cows fed their assigned treatment diet. Data were analyzed using Proc Mixed in SAS with covariate, treatment, period, and treatment × period interaction as Fixed effects and pen within treatment as a Random effect. Starch digestibilities, in situ, in vitro and in vivo, were 10%, 6% and 5% units greater ($P < 0.05$), respectively, for LFY compared to BMR; however, the opposite was observed ($P < 0.05$) for NDF digestibility at wk 13 of treatment. Cows fed BMR consumed 1.7 kg/d more dry matter than LFY ($P < 0.01$); feed sorting was minimal and did not differ by treatment ($P > 0.10$). Although milk yield was greater ($P < 0.01$; 49.0 vs. 46.8 kg/d) and energy- and solids-corrected milk yields tended ($P < 0.10$) to be 1.5 kg/d greater for BMR than LFY, feed conversions (kg milk or component-corrected milk per kg DMI) did not differ ($P > 0.10$). Fat-corrected milk (50.3 kg/d on average) and milk fat yield (1.84 kg/d on average) were similar ($P > 0.10$), as milk fat content was greater ($P < 0.01$) for cows fed LFY (4.05%) than BMR (3.83%). Cows fed BMR had lower ($P < 0.001$) MUN concentration and greater ($P < 0.05$) milk protein and lactose yields compared to LFY. Body weight change and condition score were unaffected ($P > 0.10$) by treatment. Total tract starch digestibility was greater for cows fed the LFY corn silage, however, dry matter intake and milk and protein yields were greater for cows fed the BMR corn silage.

Key Words: corn silage, fiber, starch

0305 The interaction of drought stress and heat stress as determinant of dry matter yield and nutritional composition of corn whole-plant for silage. G. Ferreira[*1], H. D. Behl[2], E. Hokanson[2], W. E. Thomason[2], and C. D. Teutsch[3], *[1]Department of Dairy Science, Virginia Polytechnic Institute and State University, Blacksburg, [2]Department of Crop and Soil Environmental Sciences, Virginia Polytechnic Institute and State University, Blacksburg, [3]Department of Crop and Soil Environmental Sciences, Virginia Polytechnic Institute and State University, Blackstone*.

The objective of this study was to better understand how abiotic stresses affected DM yield and nutritional composition of corn whole-plant destined for silage. We analyzed data from corn hybrids performance trials completed at two sites over the 2011 and 2012 growing seasons within the state of Virginia. The first site is referred to as the Southern Piedmont region (Blackstone, VA). The second site is referred as Shenandoah Valley region (Lynnwood, VA). Data from eight corn hybrids (110 to 117 d to maturity) were tested in both sites and years. Dry matter yield and nutritional composition was analyzed through mixed model analysis, using hybrid as a fixed effect and site-year as a random effect (i.e., blocking factor). Climate data were obtained from weather stations located in Blackstone and Elkton, VA. Whole-plant DM yields did not differ between hybrids, but varied significantly across site-years. The extremely low DM yield observed for the Southern Piedmont region in 2012 (4556 kg/ha) is partially attributed to severe drought conditions (227 mm). However, substantially higher DM yields (12,678 kg/ha) were observed in the Shenandoah Valley region with only slightly more precipitations (262 mm) during the same year. Neutral detergent fiber concentrations did not differ among hybrids, but were significantly different between site-years. That NDF concentration in 2012 was much lower for the Shenandoah Valley region (43.0% NDF) than for the Southern Piedmont region (56.6% NDF) indicates that corn crops were affected differently despite summer drought. For year 2012, the Southern Piedmont region had maximum daily temperatures above 35°C for an extended period right after corn silking, whereas maximum daily temperatures were 7.1 ± 2.3°C milder in the Shenandoah Valley region for the same corn crop stage. We concluded that heat stress had a major adverse effect on kernel development in the Southern Piedmont region, but not in the Shenandoah Valley region and that, therefore, heat stress exacerbated the effects of drought, reducing substantially DM yields and increasing whole plant fiber concentration. As an overall conclusion, low DM yields and poor quality of corn whole-plant for silage are beyond drought stress. Daily maximum temperatures should be considered when planning strategies to ensure good quality forage supply and reduce risk in dairy farming systems.

Key Words: corn, drought, heat, silking

0306 Effects of different levels of corn silage and alfalfa hay on rumen pH, VFA, and milk production in dairy cows. A. Akbari-Afjani[1], A. Zali[2], M. Ganjkhanlou[2], M. Dehghan-Banadaky[*2], and A. Emami[3], *[1]University of Zanjan, Zanjan, Iran, [2]University of Tehran, Tehran, Iran, [3]University of Birjand, Birjand, Iran.*

The present study investigated the effects of different levels of corn silage and alfalfa hay on rumen pH, VFA and milk production of Holstein cows. In this study 15 Holstein cows (39 ± 9 kg milk yield/day; 37 ± 10 d in milk) were used in a completely randomized design experiment. Animals were kept in individual tie-stalls for 9 wk. Treatments included three levels of hay and corn silage: 1) 10% alfalfa hay, 30% silage corn (CS); 2) 20% alfalfa hay, 20% silage corn (AH-CS); and 3) 30% alfalfa hay, 10% silage corn (AH), and the ratio of forage:concentrate was 60:40. Cows were fed the total mixed rations (TMR) twice daily. Individual DMI was measured daily. On 4 and 9 wk of experiment, rumen fluid from the ventral sac was sampled using the rumenocentesis technique. Rumen fluid samples were taken 4 h after morning feed. Ruminal pH measured immediately after sampling using a pH meter. The rumen fluid was stabilized with sulfuric acid (1 cc per 50 mL) and frozen at -20°C until VFA analysis by gas chromatography. Normality of distribution and homogeneity of variance for residuals were tested using PROC UNIVARIATE and adjust Tukey-Kramer (SAS Institute, 2003). Dry matter intake was higher ($p < 0.05$) when cows were fed diets AH-CS (23.20 kg per day) and diet CS (22.95 kg per day) than diet AH (18.64 kg per day). Diet affected milk production with CS and AH-CS being higher ($P < 0.01$) than AH (34.88, 35.21 and 30.78 kg/day for diets CS, AH-CS and AH, respectively. Data from ruminal pH clearly showed replacing AH with CS had a quadratic effect on the rumen acidity ($P < 0.05$). In contrast to ruminal pH, ruminal VFA concentration was not meaningfully affected by the treatments ($P > 0.05$). It is concluded that feeding alfalfa hay more than corn silage reduced dry matter intake, therefore reduced milk production.

Key Words: alfalfa hay, corn silage, dry matter intake

0307 [Withdrawn]

0308 Effects of dairy slurry on the nutritive value and fermentation characteristics of alfalfa silages. W. K. Coblentz[*1], R. E. Muck[2], M. A. Borchardt[1], W. E. Jokela[1], M. G. Bertram[3], and K. P. Coffey[4], *[1]U.S. Dairy Forage Research Center, Marshfield, WI, [2]U. S. Dairy Forage Research Center, USDA-ARS, Madison, WI, [3]University of Wisconsin, Arlington, [4]University of Arkansas, Fayetteville.*

Dairy producers frequently ask questions about the risks associated with applying dairy slurry onto growing alfalfa. Our objectives were to determine the effects of dairy-slurry application on the subsequent nutritive value and fermentation characteristics of alfalfa silages. Dairy slurry was applied to 0.17-ha plots of alfalfa; applications were made to the second and third cuttings during 2012 at mean rates of 42,437 ± 5505.6 L/ha and 41,729 ± 2503.5 L/ha, respectively. Four application strategies were evaluated. These included: i) no slurry; ii) slurry applied directly to stubble immediately after the preceding harvest; iii) slurry applied after 1 wk of regrowth; or iv) slurry applied after 2 wk of regrowth. All harvested forage was packaged in (0.9 × 0.9 × 1.8 m) large-rectangular bales that were ensiled as wrapped balage. Each bale was sampled on both a pre-ensiled (June or August 2012) and post-ensiled basis (May 2013). Yields of DM harvested from the second (2477 ± 175.8 kg/ha) and third (781 ± 73.9 kg/ha) cuttings were not affected ($P \geq 0.19$) by slurry application treatment. By May 2013, all silages appeared to be well-fermented, with no indication of undesirable odor. Only minor differences across manure application treatments were observed for post-storage nutritive value, as well as final pH, unfermented water-soluble carbohydrates, and starch. *Clostridium tyrobutyricum*, which is known to negatively affect cheese production, was not detected in any forage on either a pre- or post-ensiled basis. On a pre-ensiled basis, counts ($\log_{10}$ genomic copies/g) for *Clostridium* Cluster 1 were greater for slurry-applied plots than for those not receiving slurry, and this response was consistent across the second (4.44 vs. 3.29; $P < 0.01$) and third cuttings (4.99 vs. 3.88; $P < 0.01$). Similar ($P < 0.01$) responses were observed on a post-ensiled basis; however, post-ensiled counts also were greater for delayed applications onto growing alfalfa compared with applications onto stubble for both the second (5.51 vs. 5.17; $P = 0.02$) and third (5.84 vs. 5.28; $P < 0.01$) cuttings. For the third cutting, counts also were greater following a 2-wk application delay compared to a 1-wk application delay (6.23 vs. 5.45; $P < 0.01$). These results suggest that the risk of secondary clostridial fermentations in alfalfa silages is greater following manure applications to alfalfa, and that applications to stubble are preferred (and less risky) compared to delayed applications onto growing alfalfa.

Key Words: alfalfa silage, clostridial fermentations, dairy slurry

0309 The effects of combination of lactic acid-producing bacteria and hydrolytic enzyme inoculants on ensiling characteristics of alfalfa and corn.

J. M. Chilson*, P. Rezamand, and M. E. Drewnoski, *University of Idaho, Moscow.*

Before ensiling, inoculants containing lactic acid-producing bacteria (LAB) may be used to promote greater, more rapid lactic acid production causing a faster pH decline, possibly resulting in less DM and nutrient loss. The inclusion of hydrolytic enzymes may increase simple carbohydrate availability, further increasing fermentation rate and pH decline. To test the effects of an inoculant containing four species of LAB and four hydrolytic enzymes, green chopped whole plant corn and alfalfa were treated with water (control) or with water containing the inoculant (treatment), resulting in forage that had 33% DM or 42% DM for corn and alfalfa, respectively. Each forage was packed into mini-silos (1206 cm^3 volume; $n = 3$/treatment per date) to monitor rate of fermentation. The pH was measured on d 1, 2, 3, 7, 13, 17, 21, 28, 45 for alfalfa and on d 1, 2, 3, 7, 10, 17, 28, 45 for corn. Data were analyzed using PROC NLIN and PROC MIXED of SAS significance declared when $\alpha = 0.05$. The rate of decline to terminal pH was faster ($P < 0.01$) in the treatment than control in alfalfa, but demonstrated no difference for corn ($P = 0.91$). Additionally, buckets ($n = 5$ per treatment; 21,504 cm^3 volume) of each forage were ensiled to measure effect on nutrient composition (DM, CP, ammonia, starch in the corn, and sugar in the alfalfa) and pH after 59 d of fermentation. The pH of the treatment tended to be lower than control in alfalfa buckets ($P = 0.07$) on d 59 but did not differ between treatments in corn ($P = 0.92$). The percent DM and DM loss did not differ ($P > 0.5$) between treatments for either alfalfa or corn. The percent sugar and starch did not differ ($P > 0.58$) between treatments for alfalfa and corn, respectively. Crude protein content of alfalfa was lower ($P < 0.01$) in the treatment than control (13.3 vs. 13.0 ± 0.06%) but did not differ ($P = 0.11$) between treatments in corn. Ammonia content did not differ ($P > 0.13$) between treatments for both alfalfa and corn. The inoculant appeared to affect the rate of decline to terminal pH in the alfalfa, but not corn, while having little to no effect on nutrient composition of either ensiled forage.

Key Words: silage, pH, inoculants

0310 In vitro digestibility and gas production kinetic characteristics of corn stover treated by calcium oxide and stored under anaerobic condition.

H. T. Shi*, Z. J. Cao, S. L. Li, W. N. Shi, and Z. H. Wu, *State Key Laboratory of Animal Nutrition, College of Animal Science and Technology, China Agricultural University, Beijing, China.*

As a large agricultural country, China is rich in corn stover resource. The nutritional value of corn stover can be improved by calcium oxide (CaO) treatment. Anaerobic storage is an effective method to prevent the treated stover from molding. A 1 plus 3 × 3 design was used to investigate the effect of CaO level and moisture content on the in vitro organic matter disappearance (IVOMD) and gas production in 72h (GP_{72h}). Ground stover was treated with different levels of CaO (3%, 5%, and 7%) and moisture content (40%, 50%, and 60%). Untreated stover was used as control. Treated stover was kept under anaerobic condition for 15 d. Four Holstein cows with ruminal cannulas were used as animal donors of rumen fluid. An automated gas production system was used. Half gram of samples was added to each bottle (4 replicates/sample). Data were analyzed using single degree of freedom contrast to compare all the treatments with the control, and data excluding the control were further analyzed as a 3 × 3 factorial arrangement of treatments. There were no treatment interactions ($P > 0.01$), but differences ($P < 0.01$) were found for main effects of moisture and CaO on IVOMD. The CaO level affected ($P < 0.01$) GP_{72h}, but the moisture content and its interaction with CaO level had no effect ($P > 0.01$) on GP_{72h}. The rate, halftime, and AGPR (gas production rate when gas production is 1/2 of the maxium) of gas production were not affected ($P > 0.01$) by the moisture or CaO level. As CaO level increased from 3% to 7%, IVOMD increased from 45.36% to 52.66%.The combination of CaO level and moisture content that resulted in the highest IVOMD was 7% CaO at 50% moisture content. There were no significant differences ($P > 0.01$) in IVOMD between stover treated with 5% CaO at 50% or 60% moisture content and that treated with 7% CaO at 50% moisture content. Under 50% and 60% moisture content, the level of CaO above 5% was not able to further improve the IVOMD. When treated with 5% CaO at 60% moisture content, the IVOMD and GP_{72h} of corn stover can be improved by 25.94% and 13.91%. Based on this study, the level of 5% CaO at 50% or 60% moisture content seems to be the best treatment combination.

Key Words: corn stover; calcium oxide treatment; in vitro digestibility

0311 Effects of calcium oxide level and moisture content on the in situ degradability of the alkali treated and anaerobically stored corn stover.

H. T. Shi*, S. L. Li, Z. J. Cao, Y. He, and Q. Zhou, *State Key Laboratory of Animal Nutrition, College of Animal Science and Technology, China Agricultural University, Beijing, China.*

Corn stover is one of the most abundant agricultural residues in the world. Calcium oxide (CaO) treatment could improve the nutritional value of corn stover. Anaerobic storage is an effective way to keep the treated stover free from molding. The aim of this study was to investigate the in situ degradability of the corn stover treated with different combinations of CaO level and moisture content. Ground stover was treated with different levels of CaO (3%, 5% and 7%) and moisture

content (40%, 50% and 60%), then stored under anaerobic condition for 15 d. Four Holstein cows with ruminal cannulas were used to evaluate the in situ ruminal degradability of DM, OM, and NDF (ISDMD, ISOMD, and ISNDFD) of the corn stover. Stover samples were incubated in the rumen for 0, 4, 8, 12, 24, 36, 48, and 72h. Compared with untreated corn stover, CaO-treated corn stover had greater ($P < 0.01$) ISDMD, ISOMD, and ISNDFD. The moisture content and CaO level affected ($P < 0.01$) ISDMD, ISOMD, and ISNDFD, but no interaction of main effects existed. The greatest improvements in ISDMD, ISOMD, and ISNDFD occurred when stover was treated with 7% CaO and 60% moisture content; however, no differences ($P > 0.01$) in these in situ degradability parameters were observed between the stover treated with 5% CaO at 60% moisture content and that treated with 7% CaO at 60% moisture content. When treated with 5% CaO at 60% moisture content, the ISDMD, ISOMD, and ISNDFD of the stover were increased by 31.72%, 34.03%, and 36.50%, respectively. Based on this study, the level of 5% CaO and 60% moisture content was a proper treatment for corn stover.

Key Words: corn stover, calcium oxide, |in situ degradability

0312 Effects of different silage forages on cecal fermentation in rabbits: In vitro gas production.

M. Gonzalez Ronquillo*, A. Zetina Sanchez, O. Castelan Ortega, and J. Romero Bernal, *Universidad Autonoma del Estado de México, Toluca, Mexico*.

The aim of this study was to evaluate the cecal fermentation of beans (*Phaseolus vulgaris*), faba beans (*Vicia faba*), common vetch (*Vicia sativa*), ryegrass (*Lolium perenne*), and barley (*Hordeum vulgare*) as silages in rabbits. In vitro gas production was performed using cecal contents from three rabbits (New Zealand, LW 2.5 k). Rabbits were fed forage silage and water ad libitum before cecal content collection. The rabbit's caeca was emptied and pooled cecal contents were mixed before being used for in vitro cultures. Chemical composition of forage species was determined and samples were weighed (0.800 g of DM) in 125 mL flasks and incubated with 90 mL of solution and 10 mL of cecal content, which previously diluted (50:50 with buffer solution). Gas production (GP) was measured at 1, 2, 3, 4, 8, 10, 12, 24, 36, and 48 h in three runs of inoculations. GP was calculated (ml/g DM) to evaluate the differences between forage species. Data were analyzed as a completely randomized design with contrasts used to compare means, significance was declared at $P < 0.05$. Crude protein was greater ($P < 0.05$) in common vetch followed by faba beans and beans, than the other species. NDF and ADF contents were lower ($P < 0.05$) in beans and common vetch, ME and SCFA were greater ($P < 0.05$) in faba beans and ryegrass, and less in barley silage. In vitro GP (fraction B) was greater ($P < 0.05$) in rye grass and faba beans than the rest of the silages. Lag time has greater in common vetch ($P < 0.05$) than the rest of the silages. Results suggested that ensiling ryegrass or faba beans are suitable for rabbits feeding compared with barley forage.

FORAGES AND PASTURES SYMPOSIUM: USE OF MARGINAL LANDS AND FIBROUS BYPRODUCTS IN EFFICIENT BEEF AND DAIRY PRODUCTION SYSTEMS

0313 Improving efficiency of production in pasture/range based beef and dairy systems.
J. T. Mulliniks*[1], A. G. Rius[2], M. A. Edwards[3], K. B. Brantley[3], S. R. Edwards[3], and R. L. Nave[1], *[1]University of Tennessee, Crossville, [2]Present address: University of Tennessee, Knoxville,, [3]University of Tennessee, Knoxville*.

Despite overall advances in technology and livestock production systems in the last century, it is still critical for research to be focused on efficient nutrient and forage utilization to improve efficiency of grazing beef and dairy production systems. Beef and dairy cattle have the advantage to capitalize on the ruminant's ability to utilize these feed resources that are not usable for other production industries. However, poor forage and subsequent energy utilization are often the primary limiting factors associated with decreased efficiency in range- and pasture-based beef and dairy systems. Although forage remains the least expensive nutrient source to maintain productivity of the cow herd, energy utilization of converting forage to a marketable output can be relatively inefficient. Thus, improving energy efficiency of pasture- and range-based grazing systems is essential to maintain long-term profitability and sustainability of livestock industry. Increasing profitability by optimizing grazing management and reproduction requires a rapid adoption of grazing management practices and genetic selection criteria for animals that fit diverse environment. The task of developing efficient production systems is biologically and economically complex and not easily achieved. Forage production and utilization on pasture- and range-based grazing systems varies tremendously across regions in the United States. This variation in forage production and utilization is due to differences in environmental conditions (e.g., temperature, precipitation, humidity, topography) and genetic makeup of the cow, which creates challenges in recommendations for specific genotype and grazing management schemes. However, matching cow type or genetic potential to the production environment and grazing management scheme may provide opportunities to increase energy utilization efficiency. In addition, pasture nutritive value and production varies within forage species across regions (e.g., cool-season vs. warm-season grass), and recommendations for grazing strategies leading to greater pasture utilization should factor differences in pasture composition. Therefore, increasing ruminants' efficiency of forage utilization through selection of energy efficient animals and/or grazing management decisions (i.e., supplementation, grazing management) would result in an increased profitability and sustainability.

Key Words: pasture, range, energy efficiency

0314 Forage breeding programs aimed at increasing productivity of marginal lands.
M. Casler*, *USDA-ARS, Madison, WI.*

The definition of "marginal lands" is highly contentious, subject to a wide range of opinions and contexts. For the purposes of this paper, I define marginal land simply as land with one or more problems that reduce crop productivity or economic sustainability. Numerous production and sustainability problems may be caused by land, soil, or atmospheric issues, including drought, nutrient imbalance, toxicity, pH imbalance, air pollutants, and temperature extremes. Forage crops, particularly perennials, are often relegated to these lands, particularly when crop productivity or sustainability falls below an economic viability threshold. As such, forage breeders have been faced with numerous challenges to breed both grasses and legumes that will tolerate these stresses, providing the basis for profitable and sustainable livestock production on lands that are "marginal" for crop production. The foundation of plant breeding is genetic variation, which has been observed for nearly all of the major stresses that have presented themselves as challenges for forage breeders. Genetic variation often must be coaxed out of a species by designing the proper challenge and screening method for the plants, such as an acid soil that is sufficiently acidic to cause measurable or observable stress, but not so much as to kill all the plants. For many stresses, it is quite common to find very low frequencies of tolerant or resistant plants, sometimes as low as < 1 in 10,000. For this reason, forage breeding is often a "numbers game" in which genetic improvements are directly proportional to the population sizes and efforts expended. Numerous cultivars have been developed and released to the public, often expanding the geographic range and broadening the environmental circumstances under which a forage species can be used for livestock production.

Key Words: forage breeding, genetic variation, stress tolerance, adaptation

0315 Improving soil health and productivity on marginal lands using managed grazing livestock.
R. R. James* and J. Bisinger, *Iowa State University, Ames*.

Beyond grazing, managed grasslands can provide ecological services with indirect and direct economic benefits that offer an incentive for multi-functional uses that provide the opportunity to increase available grazing lands. Increasing biodiversity of the plant community may maximize primary production by optimizing utilization of available light, water, and nutrient resources, enhance forage nutritive value for grazing livestock, improve nutrient retention while reducing nutrient leaching or loading in surface run off, enhance stability of

production in response to disturbance, increase soil organic matter, reduce invasion of exotic species, and provide wildlife feed and habitat. Strategically managed grazing may increase biodiversity of cool season pastures by creating disturbance in the established plant community through diet selection and treading as well as increased nutrient cycling and dispersal of plant seeds. Soil organic matter will increase carbon and nutrient sequestration and water-holding capacity of soils and is greater in grazed pastures than land utilized for row crop or hay production. Studies evaluating the effects of grazing management on soil organic matter in the eastern and central United States are limited. However, greater soil organic matter has been observed in cool season pastures grazed by management intensive than continuous grazing or grazed by mob or strip grazing than ungrazed grasslands. In addition to organic residues, pasture forages provide roots that produce macropores mitigating compactive forces on soils. The reduced soil compaction and increased surface structure provided by plant shoots and residues increase water infiltration. Therefore, water infiltration in cool season pastures managed to maintain 10 cm residual height did not differ from ungrazed pastures, which limits nonpoint-source pollution of surface water resources and provides resilience to floods and droughts. Through increased diversity of the plant community, productivity of selected species, and nutritive quality of the forage with alterations of habitat structure, grazing systems can be developed that enhance habitat for wildlife and insect pollinators. Although grazing management may enhance the ecological services provided by grasslands, environmental responses are controlled by variations in climate, soil, landscape position, and plant community, resulting in considerable temporal and spatial variation in the responses. Furthermore, a single grazing management system may not maximize both forage quality for grazing livestock and each of the potential ecological services provided by grasslands. Therefore, production and ecological goals must be integrated to identify the optimal grazing management for an individual site.

Key Words: grazing, biodiversity, ecological services

0316 Optimizing the use of fibrous residues in beef and dairy diets. J. C. MacDonald*, G. E. Erickson, P. J. Kononoff, and T. J. Klopfenstein, *University of Nebraska, Lincoln.*

Increased corn prices over the past decade have altered land use away from traditional forage in favor of corn. Accordingly, beef and dairy producers have had to adopt non-traditional forage resources into their production systems, many of which have become available as a result of increased corn production. Byproducts of the wet and dry milling industries have been used to replace both corn and forage in beef and dairy diets. Byproducts containing corn bran have large amounts of readily digestible hemicellulose. The use of byproducts may increase milk production, ADG, and G:F in dairy, beef growing, and beef finishing diets, respectively. In beef finishing diets, byproducts allow for use of low quality forages or partial replacement of traditional forages with minimal losses in ADG or G:F by formulating for equal NDF concentrations. Corn residues have become more available due to increases in corn acres and yield. The individual plant components (i.e., husk, leaf, stem) vary in fiber digestibility (NDF digestibility estimates = 40.5%, 31.4%, and 0.6% ± 0.8 for husk, leaf, and stalk, respectively). Selectivity for husks and leaves by grazing cattle likely improves their performance. New technologies that allow for selective harvesting of husk and leaf may result in a higher value feed product. Alkaline treatment is another technology that may improve the feeding value of residues. Concentrations of up to 20% harvested corn residue treated with calcium oxide may be included in finishing diets with an average of 2.3% reduction in G:F when diets contain 40% wet or modified distillers grains. Conversely, when untreated corn residues are included in similar finishing diets, G:F may be reduced by 20%. Calcium oxide treated residues included in beef growing diets increases DMI and ADG without significant improvements in G:F. Calcium oxide treatment of corn residues has been evaluated in dairy diets by replacing corn or corn silage with variable results. Harvesting corn silage rather than separate harvest of corn grain and residue may allow for greater total net energy per acre to be captured. The use of wet and modified corn milling byproducts enhances the use of corn silage in finishing diets. While G:F may be reduced, feeding greater concentrations of corn silage may be economical. Efficient use of non-traditional fiber sources, like corn milling by products and corn residue, are critical to the future viability of ruminant animal production.

Key Words: alternative fiber sources, corn milling byproducts, corn residue

FORAGES AND PASTURES II: **FORAGES FOR LIVESTOCK SYSTEMS**

0317 Interseeding bermudagrass pastures with alfalfa or clovers for growing calves. P. Beck*[1], D. S. Hubbell, III[2], T. Hess[2], and J. Jennings[3], *[1]University of Arkansas SWREC, Hope, [2]University of Arkansas Livestock and Forestry Research Station, Batesville, [3]Department of Animal Science, University of Arkansas, Little Rock.*

Bermudagrass [*Cynodon dactylon* (L.) Pers.] pastures (n = 8; 0.8 ha) were interseeded with 13 kg red clover/ha (Trifolium pretense, cv. Morningstar, Cal/West Seeds, Woodland, CA) and 3.3 kg ladino white clover/ha (*Trifolium repens*, cv. Regal Graze, Cal/West Seeds) or with 28 kg alfalfa/ha (*Medicago sativa*, cv. PGI 459, Producers Choice, Woodland, CA in yr 1 and cv. Rebel, Producers Choice, Woodland, Cain yr 2). Twelve additional bermudagrass pastures received 0, 56, or 112 kg N/ha as ammonium nitrate. Beef steers (n = 283, BW = 243 ± 30.5 kg) were used for BW gain analysis and grazed treatment pastures through the summer over 4 yr in this put and take experiment. In the fifth year of the experiment, clovers and alfalfa were killed before grazing and steers (n = 80, BW = 223 ± 13.3 kg) grazed pastures to determine the carryover N benefit to the bermudagrass following these legumes. Data were analyzed as a completely randomized design with the mixed procedure of SAS. Single df contrasts were used to determine the linear N fertilization rate effect and the effects of alfalfa and clover. Over the 4-yr experiment, ADG, BW, gain per hectare and grazing days per hectare increased (P < 0.01) linearly with increasing N rate. Yet ADG and BW of alfalfa and clover additions did not differ ($P \geq 0.14$) from the 112 kg N rate or each other. During the 4-yr experiment, grazing-d/ha was greater (P < 0.01) for alfalfa than clover, which was greater than all N fertilization rates ($P \leq 0.05$). Gain/ha of alfalfa and clover did not differ ($P \geq 0.31$) but were greater (P < 0.01) than all fertilization rates. In the final year of the experiment, ADG, grazing-d/ha, and gain/ha were not affected ($P \geq 0.19$) by N fertilization rate or carryover N from previous legume stands, indicating that benefit of carryover N from legumes to subsequent grass crops is minimal. Both clovers and alfalfa produced equivalent BW to the 112 kg N/ha fertilization rate and produced more grazing-d/ha and BW gain/ha than N fertilization, indicating improvements in diet quality with greater levels of fertilization or legume additions. Increases in grazing-d/ha and gain/ha with alfalfa or clovers were primarily through extension of the grazing season due to an earlier start of grazing.

Key Words: alfalfa, bermudagrass, clover, growing steers

0318 Grazing novel endophyte-infected fescue following grazing endophyte-infected fescue to alleviate fescue toxicosis in beef calves. T. B. Wilson*, M. R. Milnamow, M. A. West, D. B. Faulkner, F. A. Ireland, and D. W. Shike, *University of Illinois, Urbana*.

The objective was to investigate the efficacy of grazing novel endophyte-infected fescue following grazing endophyte-infected fescue as a means to alleviate fescue toxicosis; exhibited as poor ADG, BCS, hair coat score (HCS; 1−5), increased respiration rate, and decreased serum prolactin (PRL). Fall-born, Simmental × Angus calves (yr 1: n = 36 steers, average BW = 182 ± 28 kg; yr 2: n = 36 heifers, average BW = 240 ± 16 kg) were stratified by BW and randomly allotted into 6 groups within each yr. In yr 1, grazing (139 d) initiated May 2, 2012; in yr 2, grazing (121 d) initiated May 5, 2013. Groups were randomly assigned to 3 treatments: 1) endophyte-infected fescue (KY-31; whole grazing season), 2) novel endophyte-infected fescue (MaxQ; whole grazing season), and 3) KY-31 (early half of season, period 1) followed by MaxQ (late half of season, period 2; KY-31/MaxQ). Groups were rotated every 5 d through 3.24 ha pastures that were subdivided into six 0.54 ha paddocks. Put-and-take cattle were used to ensure forage availability was not different (P = 0.73) between treatments. Period 1 ADG, BCS, HCS and respiration rate were analyzed using a contrast of MaxQ vs. KY-31 and KY-31/MaxQ as both treatments grazed KY-31 pastures during this time. Period 1 respiration rate was not different (P = 0.26); yet, ADG was greater (P < 0.01) for cattle grazed on MaxQ than KY-31. Period 2 respiration rate was greater (P = 0.01) for KY-31 than MaxQ, with KY-31/MaxQ being intermediate. Period 2 ADG and final BCS were greater ($P \leq 0.04$) for MaxQ and KY-31/MaxQ than KY-31. There was a year × treatment interaction (P = 0.02) for final HCS. In yr 1, MaxQ and KY-31/MaxQ had improved ($P \leq 0.01$) final HCS than KY-31. In yr 2, MaxQ had improved ($P \leq 0.04$) final HCS, with no difference (P = 0.10) between KY-31 and KY-31/MaxQ. There was a treatment × time interaction (P < 0.01) for PRL. Mid- and end of period 1 PRL for MaxQ were greater ($P \leq 0.01$) than KY-31 and KY-31/MaxQ; however, mid- and end of period 2 PRL for MaxQ and KY-31/MaxQ were greater ($P \leq 0.01$) than KY-31. Overall ADG was greater (P < 0.01) for MaxQ and KY-31/MaxQ than KY-31. Grazing MaxQ following grazing KY-31 alleviated fescue toxicosis symptoms; thus, cattle experienced compensatory gain resulting in similar overall performance to cattle that grazed MaxQ continuously.

Key Words: beef cattle, endophyte, fescue grazing

0319 Metagenomic analysis of the rumen microbiome in wheat-induced frothy bloat among steers.
D. W. Pitta*[1], W. E. Pinchak[2], B. Veiccharelli[1], R. Sinha[3], and D. Fulford[2], *[1]University of Pennsylvania, Kennett Square, [2]Texas A&M AgriLife Research, Vernon, [3]University of Pennsylvania, Philadelphia.*

Frothy bloat is a serious metabolic disorder that causes reduced performance or mortality in stocker cattle grazing hard red winter wheat forage in the Southern Great Plains. We hypothesized a dysbiosis to develop in the rumen microbiome of stocker cattle when grazed on high quality winter wheat pasture that predisposes them to frothy bloat risk. In this study, rumen contents were harvested from six cannulated steers (mean BW 450 lb; three with bloat score '2' and three with bloat score '0'), extracted for genomic DNA and subjected for shotgun sequencing on 454/Roche platform. Approximately 1.5 million reads were sequenced, assembled and assigned for phylogenetic and functional annotations. Differences in microbial communities between bloated and non-bloated steers were analyzed using Mixed procedure of SAS. Bacteria predominated up to 84% of the sequences while archaea contributed to nearly 5% of the sequences. The abundance of archaea tended to be higher in bloated animals ($P < 0.12$) dominated by *Methanobrevibacter*. Predominant bacterial phyla were *Firmicutes* (65%), *Actinobacteria* (13%), *Bacteroidetes* (10%) and *Proteobacteria* (6%). *Firmicutes* were largely represented by *Eubacteriaceae*, *Ruminococcaceae*, *Lachnospiraceae* and *Eubacteriaceae*. However, only a few genera from Firmicutes such as *Butyrivibrio* and *Lactobacillus* showed differences ($P < 0.05$) between both groups. *Bacteroidetes* showed distinct differences between both groups with lineages from *Prevotellaceae* to be higher ($P < 0.05$) in bloated animals while non-bloated animals had higher ($P < 0.05$) abundance of *Porphyromonadaceae*, and *Bacteroidaceae* members. *Actinobacteria* was dominated by *Coriobacteriaceae* lineages, which tended to be higher ($P < 0.12$) in non-bloated steers. Functional annotations of assembled reads to KEGG database revealed the abundance of several metabolic pathways, with carbohydrate and protein metabolism well represented. Among the carbohydrate metabolism, utilization of monosaccharides was higher ($P < 0.05$) in bloated animals while disaccharide degradation tended to be higher ($P < 0.12$) in non-bloated animals. Assignment of contigs to CaZy database revealed the distribution of Glycosyl Hydrolases across all samples showing the presence of a core microbiome associated with fiber digestion. Principle component analysis based on phylogenetic and functional assignments both revealed the tendency to cluster microbial communities by the incidence of bloat, however validation will require greater sample numbers. It can be concluded that the rumen microbial community structure and metabolic potential are substantially altered under moderate frothy bloat conditions.

Key Words: rumen microbiome, frothy bloat, metagenomics, wheat forage

0320 Stocking density effects in short duration grazing systems on botanical composition and soil characteristics of grasslands.
J. J. Bisinger*, *Iowa State University, Ames.*

To evaluate stocking density effects in short duration grazing systems on grassland forage and soil properties, three replicated pastures containing cool season grass and legume species without (BL1) and with (BL2) warm season grasses were divided into 5 paddocks. In each pasture, one paddock was not grazed (NG) and 4 were strip (moved once daily with a back fence) or mob (moved 4 times daily with a back fence) grazed beginning in May 2011 (BL1) and 2012 (BL2) by 10 cows at a live forage DM allowance of 2% BW/d. Within each pasture, one mob (MR) and strip (SR) paddock were rotationally stocked to remove 50% of the live forage with 35 d rest periods beginning 60 d after mob or strip grazing in yr 1 of each block and in the two (BL1) and one (BL2) subsequent grazing seasons. Water infiltration, soil penetration resistance, soil bulk density, and soil carbon were measured in May and October and botanical composition was determined in May, July, and October of each year. Compared to NG paddocks, water infiltration was lower ($P < 0.05$) in rotationally stocked paddocks in October 2011 and 2012 in BL1 and greater ($P < 0.05$) in all grazed paddocks in October 2012 in BL2. Penetration resistance at 5 cm was greater ($P < 0.05$) in rotationally stocked than NG paddocks from May 2012 to October 2013 in BL1 and in October 2013 in BL2. Bulk density to 7.5 cm was less ($P < 0.05$) in NG than grazed paddocks in BL1 in October 2012 and rotationally stocked paddocks in October 2013 in BL2. Soil carbon content to 7.5 cm was greater ($P < 0.05$) in BL1 SR and BL2 MR paddocks than NG paddocks in May and October 2013, respectively. The proportions of cool season grasses in BL1 were lower ($P < 0.05$) in grazed than NG paddocks in July 2011 and in rotationally stocked paddocks after July 2012. Conversely, in grazed paddocks there were greater proportions of annual grasses ($P < 0.05$) in July 2011 and legumes ($P < 0.10$) in May and October 2012 than NG paddocks. In BL2, proportions of warm season grasses were less ($P < 0.05$) in rotationally stocked than NG paddocks in July 2013. Strategic spring mob or strip grazing will reduce competition from cool season grasses to allow establishment of legumes in perennial grasslands.

Key Words: beef cattle, mob stocking, botanical composition

0321 Seasonal changes in DM, CP, NDF, and NDF digestibility of pasture forage in grazing production systems. J. Paulson[*1], B. J. Heins[2], and D. G. Johnson[2], *[1]University of Minnesota, Hutchinson, [2]University of Minnesota West Central Research and Outreach Center, Morris.*

Nine grazing dairy farms were utilized in a study to measure monthly changes in forage quality of pastures over a 2-yr period. Farms were from a wide geographical area across Minnesota representing a range in soil type and annual rainfall amounts as well as herd size, pasture size and pasture management. Pasture forage was sampled every 2 wk during the growing season and analyzed for DM, CP, NDF, and NDF digestibility concentrations. Data were analyzed using PROC MIXED of SAS. Independent variables for analyses were the fixed effects of farm (n = 9), season (spring, summer or fall), year (1 or 2) and their interactions. Across the 9 farms, spring pasture DM (23.96%) was higher ($P < 0.05$) than summer (23.52%) and fall (19.76%) pasture DM. Average DM for each year was 22.71% and 22.12% for 2004 and 2005, respectively and they were not different. There were ($P < 0.05$) differences in CP concentrations between farms and across seasons on all farms and averaged 21.52% in year 1 and 21.85% in year 2. Seasonal average CP concentrations were 21.01%, 20.11% and 23.93% for spring, summer, and fall, respectively. NDF concentration in the pasture forage was different ($P < 0.05$) across the 9 farms, as well as different ($P < 0.05$) for spring, summer, and fall grazing. However, there were no differences within farm and season or across year for NDF; averaging 46.91% in year 1 and 47.53% in year 2. Seasonal NDF concentrations were 46.63%, 49.25%, and 45.97% for spring, summer, and fall, respectively. There was a difference ($P < 0.05$) across farms for NDF digestibility-30 h and within farm and year. Average NDF digestibility-30 h values for year 1 were 46.33% and for year 2 were 46.55%, and 46.64%, 44.71% and 47.98% for spring, summer, and fall, respectively. In summary, fall pasture growth was higher in CP and NDF digestibility when compared to spring and summer growth across all farms. However, NDF concentrations were highest in summer but CP and NDF digestibility were lowest in summer. There are significant seasonal effects on forage quality.

Key Words: dairy, grazing, forage quality

0322 Relationship between pasture nutritive measurements and plasma urea nitrogen in lambs grazing silvopasture or open pasture. J. P. S. Neel[*1] and D. P. Belesky[2], *[1]USDA-ARS, El Reno, OK, [2]West Virginia University, Morgantown.*

Relationship of herbage energy content relative to crude protein (CP) is an important aspect in nitrogen use efficiency of grazing livestock. Plasma urea nitrogen (PUN) is an indicator of animal nitrogen status, increasing with excessive dietary nitrogen, resulting in greater urinary N excretion. Analytical procedures utilized to estimate herbage energy content can be laborious and expensive. Our objective was to evaluate the relationship between herbage CP and herbage energy content indicators of differing assessment cost (total non-structural carbohydrate [TNC]; total digestible nutrients [TDN]), with animal PUN. We utilized winter born lambs (n = 187; initial weight 28.7 ± 2.1 kg; final weight 41.4 ± 2.9 kg), grazing either open or silvopasture over 4 consecutive grazing seasons. Grazing began in mid-April each year on cool-season mixed pastures and concluded mid-September. Forage nutritive value was determined from clipped samples taken the day before grazing events. Herbage TNC was determined directly, while TDN was estimated from ME (NRC, 1996) via ADF (MAFF/ADAS, 1987). Lambs grazed fresh paddocks (minimum 35 d regrowth after initial grazing) for 2 h and held an additional 1 h in drylot before blood draw. We correlated (Pearson) the relationship of pasture nutritive measurements and PUN. After tallying across treatments and years the number of correlation coefficients within the following categories: $r > 0.5$, > 0.6, > 0.7 or > 0.8, we evaluated the relationships. All nutritive components except TDN performed similarly using the $r > 0.5$ criteria. Within this grouping, the ratio of TDN:CP (a negative relationship, −) had the greatest total number of r values > 0.5 (16 of 22, or 73%), while TDN alone (−) had just 3 of 22 (14%). Using > 0.6 criteria, sampling date (+) and TNC:CP (−) were best, with 11 of 22 (50%) being greater. They were followed closely by TDN:CP (−) and TNC (−), 10 of 22 (45%), and 9 of 22 (41%), respectively. Within the grouping $r > 0.7$, sampling date and TNC:CP remained highest at 9 of 22 (41%), while TDN:CP and TNC were 5 of 22 (23%) and 8 of 22 (36%), respectively. For $r > 0.8$, sampling date and TNC:CP still had approximately 25% of the correlation coefficients falling within this category. The use of TNC:CP appears to be a quick, economical, and useful tool to evaluate pasture energy status relative to crude protein.

Key Words: silvopasture, plasma urea nitrogen, nutritive value, total non-structural carbohydrate

0323 Effect of organic grain supplementation on production, body weight, body condition score, and fatty acid profiles of organic dairy cows. B. J. Heins[*1], M. I. Endres[2], J. Paulson[3], and R. D. Moon[2], *[1]University of Minnesota West Central Research and Outreach Center, Morris, [2]University of Minnesota, Saint Paul, [3]University of Minnesota, Hutchinson.*

Organic cows (n = 153) were used to evaluate the effect of grain supplementation levels during 2 grazing seasons (May to September 2012 and May to September 2013) on production, body weight, body condition score (BCS), and fatty acid profiles of organic dairy cows. Cows were assigned to 1 of 3 replicate supplementation groups: 1) no grain supplementa-

tion (100% pasture, GRS, $n = 51$), 2) low grain (2.72 kg/head/day, LOW, $n = 51$), and 3) high grain (5.44 kg/head/day, HI, $n = 51$), and calved at the University of Minnesota West Central Research and Outreach Center, Morris, Minnesota. Supplement (organic corn and minerals) was fed with a partial mixed ration (PMR) of corn silage and alfalfa haylage, and at least 30% of diet dry matter intake for LOW and HI cows consisted of organic pasture. Milk production, from daily milk weights, was averaged weekly for cows, and body weight and BCS were recorded bi-weekly. Milk for fatty acid analysis was collected monthly and analyzed at R-Tech Analytical Laboratory (Arden Hills, MN). The PROC MIXED of SAS was used for statistical analysis, and independent variables were fixed effects of year (2012 or 2013), season of calving (fall or spring) nested within year, parity (1, 2, 3+) nested within year, supplementation group, breed group; week nested with supplementation group, with replicate nested within year and cow nested within supplementation group and breed group as a random effect with repeated measures. The GRS (14.4 kg/d) cows had lower ($P < 0.05$) energy-corrected milk than LOW (16.2 kg/d) and HI (17.0 kg/d) cows; however, the LOW and HI cows were not different from each other. The GRS, LOW, and HI cows were not different for body weight across the grazing season (491, 498, 498 kg, respectively); however, GRS (3.05) cows had lower ($P < 0.05$) BCS than LOW (3.14) and HI (3.15) cows. Milk urea nitrogen was higher ($P < 0.05$) for GRS (19.5 mg/dl) than LOW (12.0 mg/dl) and HI (9.9 mg/dl) cows. Furthermore, omega-3 fatty acid was higher ($P < 0.05$) for the GRS (0.05%) cows compared to the LOW (0.04%) and HI (0.03%) cows. Organic dairy cows that consume 100% pasture had lower production, but milk from cows that consume 100% pasture compared to pasture and PMR had fatty acid composition of potential benefit to human health.

Key Words: organic, fatty acid profile, pasture

0324 Chemical composition and in vitro gas production of forage cereals associated with common vetch (*Vicia sativa*). M. Gonzalez Ronquillo*, E. Y. Aguilar Lopez, A. Morales, M. G. Gutierrez, and O. Castelan Ortega, *Universidad Autonoma del Estado de México, Toluca, Mexico.*

Cereal grain forages and legume silages are an important part of dairy cattle rations in many parts of the world. The increasing importance of these crops as feedstuffs has highlighted the need to understand the factors that influence their nutritive value. The use of in vitro gas production (GP) techniques to estimate digestibility of feeds was based on empirical relationships between digestibility and in vitro gas production. The objectives were to evaluate forage yield, chemical composition and in vitro gas production of some varieties of spring triticale (T-UAEMex and Siglo XXI), barley (Doña Josefa) and its association with common vetch (CV). The experimental unit consisted in seven rows, each 50 linear meters by 30 cm wide (with two lines of planting and spaced at 80 cm). The planting density was 80,000 plants/ha, harvested at 145 d (milky-dough stage) and ensiled in three repetitions, at 60 d the samples were opened from micro-silos (2 kg FM), and chemical composition was determined, GP profiles were determined using a semi-automated pressure transducer technique. Approximately 800 mg of each substrate was weighed into 125 mL serum bottles and incubated in a water bath at 39°C with 10 mL strained rumen fluid and 90 mL of medium. The volume of gas produced was recorded at 3, 6, 9, 12, 24, 36, 48, 72, and 96 h of incubation. Each sample was incubated in triplicate in three series in different weeks. Data were analyzed by a completely randomized design. There were differences ($P < 0.001$) in DM (dry matter) production, being greater T-Siglo XXI and associated with CV (6.50 and 5.4 ton DM/ha respectively), the greater CP content ($P < 0.001$) was for CV (217 g/kg) and their associations (185 g/kg). No significant differences ($P > 0.05$) were observed among varieties and their associations in NDF contents. Barley had a greater content ($P < 0.05$) of NE_l 1.5, and NE_g 0.9 (Mcal/kg DM). GP was greater for the association Barley−CV ($P < 0.05$) (124 ± 6 mL gas/g DM) compared to the rest (117 ± 3 mL gas/g DM). Considering its nutritional quality and energy content forage cereals associations with CV are an option with higher forage yield and improved nutritional content for feeding livestock.

Key Words: common vetch, silage, in vitro gas production.

0325 Improving properties of acid skim milk gels by adjusting non-micellar to micellar protein ratio and controlling protein interactions.

G. H. Meletharayil*[1], H. A. Patel[2], and S. G. Sutariya[1], [1]*South Dakota State University, Brookings,* [2]*Dairy Science Department, South Dakota State University, Brookings.*

In addition to the protein content, the type and status of milk protein in yogurt milk may affect the final rheological properties of yogurts. In the present study, we investigated the effects of altering non-micellar to micellar casein ratio on the rheological properties and microstructure of acid gels. Model acid gel formulations containing 0, 10, 30, and 60% protein substitution from carbon-dioxide-treated milk proteins (T-MPC) as a source of non-micellar casein and non-fat dry milks (NFDM) as a source of micellar casein were developed. All the samples were standardized to 4% w/w protein and 12% w/w total solids. The pH was adjusted to 6.5 before their pre-heating to 90°C/10 min. Acid milk gels were prepared using Glucono-δ-lactone to obtain final pH4.4 ± 0.05 after 4 h incubation at 30°C. The soluble (serum) phases obtained by centrifugation of heated and unheated milk samples at 25000 g/1h were characterized using sodium dodecyl sulfate polyacrylamide gel electrophoresis (SDS-PAGE). Microstructure and rheological properties of acid gels were characterized using confocal laser scanning microscopy (CLSM) in the fluorescence mode and small amplitude oscillatory rheology (SAOR) (1% strain, 0.1Hz frequency), respectively. Photon correlation spectroscopy was used to study the particle size of the heated milks. ANOVA was used to test the results and statistical significance at $P < 0.05$ was determined, using the statistical software SAS. The SDS-PAGE pattern of model formulations containing T-MPC showed significantly higher ($P < 0.05$) proportion of soluble caseins and disulfide-linked casein-whey protein complexes in the serum phase of unheated and heated milk, respectively. Particle size of formulations containing T-MPC was significantly lower than control samples containing untreated proteins. This can be attributed to the preferential interaction of whey proteins with κ-casein in the soluble phase. SAOR showed a significant increase ($P < 0.05$) in the elastic modulus (G') of acid gels formulated with T-MPC to an optimum level. CLSM images revealed that gels containing treated proteins had smaller, well-connected aggregates with uniform, homogenous pore-sizes, which explained the results of rheological characterization. It can be concluded that the soluble casein-whey protein complexes and optimum non-micellar to micellar casein ratio in the yogurt formulation yielded acid gels with significantly improved rheological properties. Overall, the results suggested that yogurt with varying texture can be made by altering the ratio of non-micellar to micellar casein and by manipulating interactions of milk proteins at soluble and micellar phase. This invention is patent pending.

Key Words: yogurt, carbon dioxide, rheology, microstructure

0326 Controlling the viscosity of milk concentrates through tailored casein-whey protein interactions.

S. G. Sutariya*[1], H. G. Patel[1], T. Huppertz[1,2], and G. H. Meletharayil[1], [1]*South Dakota State University, Brookings,* [2]*NIZO food research, Ede, The Netherlands.*

Heat-induced interactions between caseins and whey proteins form the basis for their functionality in many applications. We have hypothesized that the pH of the milk before preheat-treatment and adjusting preheating temperatures will influence the distribution of casein-whey protein complexes between the micellar and the soluble (serum or continuous) phase of milk and this will affect the viscosity of the continuous phase in concentrated milk. Therefore, the objective of the present study was to investigate the effect of pH and preheating temperatures on the viscosity of skim milk concentrates. Reconstituted milk, 10% w/w total solids (TS), adjusted to pH 6.5, 6.7 (control) and 6.9 was preheated either at 80 or 90°C for 5 min. Following these treatments, the milk was concentrated to final TS of 45 and 50% (w/w) under vacuum at 60°C using a rotary evaporator. Dynamic viscosity of the resulting concentrates was measured at 55°C at a constant shear rate of 100 s^{-1} using a Stresstech Rheometer. Particle size was determined using a Malvern Zeta-sizer-Nano-ZS. The heated and pH adjusted samples were centrifuged at 25,000 g for 1 h to obtain soluble (serum) and micellar phases. The protein interactions in these milk samples were characterized in detail using non-reduced and reduced sodium dodecyl sulfate polyacrylamide gel electrophoresis (SDS-PAGE). The experiments were repeated at least two times and results were tested by ANOVA and statistical significance at $P < 0.05$ was determined, using the statistical software SAS. Significant differences in the viscosity of milk concentrates were observed ($P < 0.05$) when the milk was pre-adjusted to different pH and pre-heated at different temperatures. The results showed that the concentrates obtained from milk preheated at pH 6.5 and 80°C for 5 min had significantly ($P < 0.05$) lower viscosity compared to that preheated at pH 6.7 and 6.9 at both TS levels studied (45 or 50% w/w). The samples pre-heated at pH 6.5 also showed increase in particle size in contrast to the samples preheated at pH 6.7 and 6.9. Such differences can be explained by differences in the interactions of casein and whey proteins and distribution of casein-whey protein complexes distributed at continuous phase and micellar phase as shown by SDS-PAGE. It can be concluded that adjusting the pH and preheating temperature of milks can be used as levers for controlling viscosity of milk

concentrate for powder manufacturing, which ultimately has an influence on the efficiency of drying.

Key Words: milk concentrate, viscosity, casein-whey proteins, pH.

0327 Partial calcium depletion during membrane filtration impacts gelation of reconstituted milk protein concentrates. H. Eshpari*[1,2], P. S. Tong[3], and M. Corredig[4], *[1]University of Guelph, Guelph, ON, Canada, [2]California Polytechnic State University, San Luis Obispo, [3]Dep. of Dairy Science, California Polytechnic State University, San Luis Obispo, [4]Dept Food Science, University of Guelph, Guelph, ON, Canada.*

Solubilization of colloidal calcium phosphate (CCP) from casein micelles during membrane filtration (e.g., through acidification) may affect the structural organization of these protein particles. The aim of this study was to investigate the effects of addition of glucono delta lactone (GDL) to skim milk during membrane filtration on the structural changes of the casein micelles by studying their functionality after reconstitution of the final powders. In particular, the renneting behavior of the casein micelles was examined, as renneting is affected by both the calcium equilibrium and their supramolecular structure. Milk protein concentrate (MPC) powders were manufactured in duplicate, either by ultrafiltration (65% protein, MPC 65) or by ultrafiltration followed by diafiltration (80% protein, MPC80), using pasteurized skim milk, either at the native milk pH (~ pH 6.6), or after addition of GDL to pH 6.0, followed by spray drying. The amount of total calcium for the MPC80 without and with GDL varied with a significant difference ($p < 0.05$) from 18,449.5 ± 265 to 15,954.5 ± 271 (μg/g), respectively. Samples were reconstituted at a 3.2% (w/w) protein to compare their gelation behavior between treatments. Both reconstituted MPC 65 and MPC 80 treated with GDL showed significantly increased amounts of soluble calcium ($p < 0.05$) and non sedimentable caseins compared to their respective controls, as measured by ion chromatography and SDS-PAGE electrophoresis, respectively. The primary phase of rennet gelation was not significantly different ($p < 0.05$) between treatments, as measured by the amount of caseino-macropeptide released, using reverse phase-high performance liquid chromatography (RP-HPLC). Rheological measurements were performed using a controlled stress rheometer on the reconstituted samples immediately after addition of rennet, both before and after dialysis against skim milk, to ensure similar serum composition for all samples. While reconstituted samples before dialysis showed no gelation (defined as tan d = 1), only control MPC 65 and 80 showed gelation after serum re-equilibration. It was concluded that the gelation properties of reconstituted MPC powders were negatively affected by the presence of soluble casein, and positively affected by the amount both soluble and insoluble calcium present after reconstitution. This work, testing the renneting behavior of various reconstituted MPC samples, clearly demonstrated that decrease in pH to 6.0 during membrane filtration affects the structure of casein micelles with important consequences to their processing functionality.

Key Words: milk protein concentrate, calcium depletion, rennet coagulation

0328 Utilizing whey protein isolate and polysaccharide complexes to stabilize aerated dairy gels. E. C. O'Chiu* and B. Vardhanabhuti, *University of Missouri, Columbia.*

Previous research has shown that heated soluble complexes of whey protein isolate (WPI) with polysaccharides can improve both foam stability and acid-induced gel strength. We utilized these complexes in aerated dairy gels, which could be formulated into novel-textured high-protein desserts. The objective of this study is to determine the effect of polysaccharide charge density and concentration within a WPI-polysaccharide complex on the properties of aerated gels. Three polysaccharides having different degrees of charge density were chosen: low methoxyl pectin (LM-12), high methoxyl type D pectin (HM-D), and guar gum. WPI-polysaccharide complexes were prepared by heating the mixed solutions (8% protein, 0 to 1% polysaccharide) at pH 7. To form aerated gels, 2% glucono-δ-lactone (GDL) was added to the solutions and foam was generated by whipping with a handheld frother. The foam set into a gel as the GDL acidified to a final pH of 4.2. The aerated gels were evaluated for overrun and rheological properties. Stability was determined by measuring drainage (the volume of liquid separated from the aerated gels). Overrun of aerated gel (179% to 14%) significantly decreased as polysaccharide concentration increased due to increased viscosity, which limited air incorporation. Increased concentration was significantly related to increased stability ($P < 0.001$) which could be due to increased viscosity of the pre-foam solutions limiting the mobility of the air bubbles. A negative logarithmic relationship was found between solution viscosity and drainage. However, charge density played an important role on stability. Plot of drainage against solution viscosity revealed that drainage was lowest in samples with high charge density pectin (LM-12) followed by those with low charge density pectin (HM-D). Aerated gels with guar gum (no charge) did not show improvement to stability as separation still occurred even at highest guar concentration. Rheological results showed no significant difference in gelation time among samples; therefore, stronger interactions between WPI and high charge density polysaccharide were likely responsible for increased stability. Rheological results also revealed that aerated gels with LM-12 pectin had the highest final elastic modulus, followed by guar gum, then HM pectin gels. Stable dairy aerated gels can be created from WPI-polysaccharide complexes. High charge density polysaccharides, at concen-

trations that provide adequate viscosity, are needed to achieve stability while also maintaining solution overrun capabilities. This can inform the formulation of dairy-based gels set by acid or calcium such as whipped yogurts and mousses.

Key Words: acid-induced gelation, aeration, whey protein

0329 pH-triggered intragastric gelation of whey protein/alginate and its effect on sucrose release.

S. Zhang* and B. Vardhanabhuti, *University of Missouri, Columbia, MO.*

Protein digestion is highly influenced by gastric conditions, protein structures, and the presence of other food components in the gastrointestinal tract. Protein and dietary fibers are common food ingredients; however, the effect of dietary fiber on protein digestion is not fully understood. Our previous study showed that whey protein/pectin mixture formed intragastric gel under simulated gastric conditions, which slowed the degradation of protein and could potentially affect the digestion and release of other nutrients. The objective of this study was to investigate the in vitro gastric behavior of mixed whey protein and alginate, and its effect on the digestion pattern of protein and sucrose release. Mixed solutions of 5% whey protein isolate (WPI), alginate (0.01 to 0.05 alginate to WPI wt. ratio) and 10% sucrose were prepared by heating them together at 85°C for 30 min. Simulated gastric fluid (SGF) consisted of 0.034 M NaCl, 3.2 mg/g pepsin, and pH was adjusted to 1.2, 2, 3, and 4. The in vitro digestion was performed using reciprocating cylinder dissolution apparatus, with 10-g sample added to 78 g SGF (pepsin: protein = 1: 2). Rheological properties and electrophoresis were performed to evaluate the gastric behavior of the mixture, and HPLC was used to measure sucrose release during digestion. At low alginate to WPI ratios, alginate did not significantly affect the degradation of whey protein and the bioavailability of sucrose, as shown by SDS-PAGE and HPLC, respectively. Increasing biopolymer ratio to 0.05 led to extensive intragastric gelation immediately when samples were mixed with SGF at pH 1.2. The mechanism behind intragastric gelation is believed to be the cross-linking between oppositely charged protein and alginate molecules when pH was reduced to lower than the pI of protein. Sucrose was entrapped in the gel network since no sucrose was detected in the digestion media once the intragastric gel was formed. During dissolution, physical movement and proteolysis by pepsin led to slow degradation of the gel, which also resulted in the slow release of sucrose from the matrix in 20 min. Intragastric gelation was only observed in SGF at pH 1.2 and 2.0. This study indicated that at certain conditions whey protein and alginate mixtures could form intragastric gel, which delayed protein digestion and sucrose release from the matrix. These results can potentially lead to formulation of whey protein beverage having lowered postprandial glycemic response.

Key Words: intragastric gelation, digestion, sucrose

0330 Evaluation of an adsorbent for the removal of aflatoxin M1 from contaminated milk.

E. D. Womack*, D. L. Sparks, A. Brown, and S. H. Ward, *Mississippi State University, Mississippi State.*

Lactating cows that consume aflatoxin B_1 (AFB_1) contaminated feed containing approximately 20 parts per billion (ppb) may produce aflatoxin M_1 (AFM_1) contaminated milk that exceeds the FDA maximum allowable limit of 0.5 ppb. Current detoxification methods for the reduction of AFM_1 include the use of sequestering agents added to feed. The sequestering agents act as an enterosorbent to ameliorate the toxicity of AFB_1 by reducing intestinal absorption. However, not all AFB_1 is bound and the residual can be metabolized to AFM_1. Once this tolerance level of 0.5 ppb AFM_1 is surpassed, the milk must be discarded because it cannot be used for human consumption resulting in economic losses. The current study examines the proficiency of an adsorbent, powdered activated carbon (PAC) to bind AFM_1 in various milk types as PAC has excellent adsorption properties in an aqueous environment. A total of 24 samples ($r = 3$) contained artificially spiked AFM_1 (0.5 ppb) and 0.1%, 0.25%, and 0.4% PAC in whole, skim, and raw milk. Samples were shaken, extracted using Agilent QuEChERS extraction salts, and analyzed via liquid chromatography with mass spectrometry detection. A concentration of 0.5 ppb AFM_1 was spiked into 10 mL to yield a final concentration in whole (0.54 ± 0.07 ppb), skim (0.46 ± 0.01 ppb), and raw milks (0.56 ± 0.03 ppb). The highest concentration of PAC (0.4%) resulted in a significant decrease in AFM_1 contamination ($p < 0.05$) with a reduction of 65% (0.18 ± 0.08 ppb), 91% (0.05 ± 0.01 ppb), and 52% (0.24 ± 0.03 ppb) of AFM_1 from the whole, skim, and raw milks, respectively. No milk showed any significant difference in percent protein, lactose, or total fat relative to their milk blanks ($p > 0.05$) suggesting that PAC has no effect on milk constituents. Preliminary results show that the use of PAC can reduce the amount of AFM_1 below the FDA safety limit and, as a result, prevent the dumping of milk.

Key Words: AFM_1, activated carbon, milk

0331 Application of FT-IR and flow cytometry to evaluate the effect of sodium chloride on probiotic bacteria.

N. Shah and A. Gandhi*, *The University of Hong Kong, Hong Kong.*

The aim of the study was to investigate the effect of varying sodium chloride concentrations on cell membrane, viability and proteolytic activity of probiotic bacteria. Reconstituted skim milk was inoculated with *Lactobacillus acidophilus* at varying salt concentrations (0-10% NaCl) and pH levels (4.0, 5.0 and 6.0) and ACE-inhibitory activity and proteolytic activity were determined. Additionally, the effects of NaCl reduction and its substitution with KCl on cell membrane of certain probiotic bacteria (*Lb. acidophilus*, *Lb. casei* and *B. longum*) and

a pathogenic bacterium, *Escherichia coli* were investigated using Fourier transform infrared spectroscopy (FT-IR). A critical NaCl concentration that inhibited the growth of *E. coli* without significantly affecting the growth of probiotic bacteria was determined by monitoring cell growth and FT-IR spectra. To evaluate the effect of substitution of NaCl with KCl, substitution was performed at critical total salt concentration at varying concentrations (0%, 25%, 50%, 75% and 100% KCl). Furthermore, the effects of varying NaCl concentrations on viability, membrane integrity and metabolic activity of these probiotic bacteria were studied using conventional technique and flow cytometry. The findings revealed that in *Lb. acidophilus* degree of proteolysis increased with higher salt concentration at pH 5.0 and 6.0 and ACE-inhibitory activity was highest at pH 5.0 at all salt concentrations. Fourier transform infrared spectroscopy results demonstrated significant shifts occurring in amide-I and amide-III regions when *Lb. acidophilus* was subjected to varying salt concentrations. Further, the conventional technique revealed that 2.5% was the critical level of NaCl to inhibit the growth of *E. coli* without significantly affecting the growth of most probiotic bacteria. The FT-IR analysis also highlighted the changes that occurred mainly in amide regions on increasing NaCl concentration from 2.5 to 3% in most bacteria. The findings suggest that 50% substitution of NaCl with KCl at 2.5% total salt could inhibit *E. coli*, without affecting the probiotic bacteria. Lastly, the observations from conventional culture technique were compared with the findings from flow cytometric analysis on metabolic activities of the cells and it was revealed that there was a correlation between culturability and dye extrusion ability of *Lb. casei* and *B. longum*. However, a certain population of *Lb. acidophilus* was viable as per the plate count method but the efflux activity was compromised. The metabolic activity of *Lb. casei* was found to be highest among the three probiotic bacteria.

Key Words: FTIR, flow cytometry, probiotic bacteria

0332 Genomic insights into high exopolysaccharide-producing dairy starter bacterium *Streptococcus thermophilus* ASCC 1275. N. Shah, Q. Wu* and H. M. Tun, *The University of Hong Kong, Hong Kong.*

Streptococcus thermophilus ASCC 1275 (ST 1275) is a typical dairy starter bacterium and produces the highest known amount (~1,000 mg/L) of exopolysaccharide (EPS) in milk within this species. This organism produces both capsular and ropy EPS and possesses textural modifying properties for yogurt and cheese. In this study, de novo shotgun paired-end pyrosequencing was applied to complete the whole genome of ST 1275. The genome size of ST 1275, a plasmid-free bacterium, was ~ 1.85 Mbp with an average GC content of 39.1%. A novel *eps* gene cluster for EPS assembly containing two-pair genes of *eps*C-*eps*D for determining the chain length of EPS was found in ST 1275 genome, which confirms that ST 1275 produces two types of EPSs as found in our previous studies. Compared with other sequenced *S. thermophilus* strains, ST 1275 possessed the lowest numbers of 5 rRNA operons and 55 tRNAs suggesting that this organism may have a more effective protein synthesis machinery. The highest number of four separate CRISPR (clustered regularly interspaced short palindromic repeats)-Cas (CRISPR-associated) loci was found in ST 1275 genome indicating that this organism may have a better adaptive immunity against various bacteriophage infections. Further analysis including carbohydrate utilization, effective proteolytic system, sophisticated stress response systems and defense systems in ST 1275 was performed to provide genomic insights into its adaptation to milk and as a cell factory for EPS production during milk fermentation. The elucidation of ST 1275 genome makes this organism as a model dairy starter bacterium for the research of high EPS yield and capsular/ropy EPS producer from the species of *S. thermophilus*.

Key Words: genome sequencing; EPS biosynthesis; *Streptococcus thermophilus*

0333 Effectiveness of pulsed light treatment on the inactivation of pathogenic and spoilage bacteria on cheese surface. J. Proulx*[1], L. Hsu[1], B. Miller[1], G. Sullivan[1], K. Paradis[2], and C. I. Moraru[1], [1]*Cornell University, Ithaca, NY,* [2]*McGill University, Montreal, QC, Canada.*

Cheese products are susceptible to post-processing cross-contamination that can lead to both food safety issues and significant losses due to spoilage. Pulsed Light (PL) treatment, consisting of short, high-energy light pulses, could represent a solution to address this issue since it is a nondestructive technology that can effectively inactivate microorganisms on surfaces. This study examined the effectiveness of PL on the inactivation of the spoilage microorganism *P. fluorescens* and the pathogen surrogates *E. coli* ATCC 25922 and *L. innocua*. The effect of inoculum level, cheese surface topography, and the presence of clear polyethylene packaging were evaluated in a full factorial experimental design. The challenge microorganisms were grown to stationary phase: *P. fluorescens* 1150 was grown at 30°C in tryptic soy broth (TSB) while *E. coli* ATCC 25922 and *L. innocua* FSL C2–008 were grown at 37°C in TSB and brain heart infusion (BHI), respectively. White cheddar and processed cheese, chosen for their different surface topography, were cut into 2.5 cm × 5 cm slices. The samples were then spot inoculated using ten droplets of 10 μL per slice, resulting in an initial concentration of either 5 or 7 log CFU/slice. Inoculated samples were dried overnight at 4°C. For treatments through packaging, sterile UV-transparent low-density polyethylene packaging was placed on top of the inoculated cheese samples immediately before the PL treatment. Cheese samples were then exposed to PL doses of 1.1 to 13.2 J/cm^2. PL-treated samples were stomached for 2 min in Butterfield Phosphate Buffer, the extract then plated on selective media and survivors enumerated by standard plate

counting (SPC). When survivor counts fell below the SPC detection limit, the most probable number was used. Experiments were performed in triplicate and data were analyzed using a general linear model. PL was most effective against *E. coli*, achieving a maximum log reduction of 5.4 ± 0.3, at a dose of 13.2 J/cm^2. For *P. fluorescens*, a maximum log reduction of 3.7 ± 0.9 and for *L. innocua* a maximum log reduction of 2.9 ± 0.8 at 13.2 J/cm^2 were obtained. The process parameter effects tested showed varying statistical significance when used in different combinations, but PL treatments through packaging and without packaging consistently resulted in similar inactivation levels. This study suggests that PL has strong potential for decontamination of cheese surface.

Key Words: pulsed light, cheese, pathogenic and spoilage bacteria

0334 Nutrient utilization and metabolism by lactating dairy cows fed high-forage diets with protein supplements. K. Neal[*1], J. S. Eun[1], A. J. Young[1], and K. Mjoun[2], [1]*Utah State University, Logan,* [2]*Alltech, Brookings, SD.*

Due to the increasing cost of soybean meal and concerns of excess N being excreted into the environment, new protein supplements have been developed. Two products that have shown potential in increasing N utilization efficiency are slow release urea (SRU; Optigen, Alltech, Nicholasville, KY) and ruminal escape protein derived from yeast (YMP; DEMP, Alltech). The objective of this study was to assess the effects of feeding these 2 supplements in high-forage (54% of total dietary DM) dairy diets on nutrient utilization, feed efficiency, lactational performance of dairy cows, and their impacts on income-over feed costs (IOFC). Twelve multiparous dairy cows were used in a triple 4 × 4 Latin square design with one square consisting of ruminally cannulated cows. Treatments included: 1) control, 2) SRU-supplemented TMR (SRUT), 3) YMP-supplemented TMR (YMPT), and 4) SRU and YMP-supplemented TMR (SYT). The control consisted only of a mixture of soybean meal and canola meal (SBMCM) in a 50:50 ratio. The SRU and the YMP were supplemented at 0.49% and 1.15% DM, respectively. The experiment consisted of 4 periods lasting 28 d each (21 d of adaptation and 7 d of sampling). Cows fed YMPT and SYT had decreased DMI, and all supplemented treatments had lower CP intake compared to those fed the control. Milk yield tended ($P = 0.08$) to have the greatest increase in YMPT compared with the control (41.1 vs. 39.7 kg/d) as well as a tendency for increased milk fat ($P = 0.10$) and protein yields ($P = 0.07$). Feed efficiencies were improved in all diets with protein supplementation at 10–16% ($P < 0.04$). Cows fed with protein supplements partitioned less energy toward BW gain, but tended ($P = 0.08$) to partition more energy toward milk production. Efficiency of use of feed N to milk N increased by feeding SRUT and YMPT, and milk N to manure N ratio increased in YMPT. Cows fed SRUT or YMPT tended ($P < 0.10$) to improve IOFC. Overall results from this experiment indicate that replacing SBMCM with SRU and YMP in high-forage dairy diets can be a good approach to enhance farm profitability through improved nutrient utilization efficiencies by lactating dairy cows.

Key Words: dairy profitability, high-forage dairy diet, protein supplement

0335 Individual and additive value of conventional and non-conventional technologies in beef steers housed in small research pens. A. R. Harding[1], G. K. Jim[2], C. W. Booker[2], E. J. Behlke[2], S. L. Parr[2], S. J. Hannon[2], T. M. Greer[2], Z. D. Paddock[2], M. L. May[2], L. O. Burciaga-Robles[2], and C. R. Krehbiel[1, 1]*Oklahoma State University, Stillwater, Feedlot Health Management Services, Ltd., Okotoks, AB, Canada.*

This trial was conducted at a research feedlot in Alberta, Canada to evaluate the effects of conventional and non-conventional production technologies identified from previous research in feedlot steers. The study utilized 960 steers stratified by BW and randomly allocated to one of four treatments: rumensin/tylan/growth-promotant free (RT), Oleo/growth-promotant free (O), negative control (NC), or conventional (CON). The RT cattle received Rumensin and Tylan (Elanco Animal Health), and did not receive an implant or β-agonist. The O cattle were fed 1 g/animal/day of Oleobiotec Ruminant (Oleo; Laboratoires Phodé, Terssac, France), and did not receive an implant or β-agonist. The NC cattle received a non-medicated supplement of vitamins and minerals and did not receive an implant or β-agonist. Cattle in the CON group received a hormonal implant (Revalor-200; Merck Animal Health, Intervet Canada Corp., Kirkland, Québec), Rumensin, Tylan and Optaflexx (Elanco Animal Health) at the end of the feeding period. All study animals received a barley-based finishing diet and were housed by treatment in 48 research pens. Data were analyzed using the GLIMMIX procedure (SAS Institute Inc, Cary, North Carolina). Final BW and HCW were lower for the RT, O, and NC ($P < 0.001$) cattle relative to the CON cattle. In addition, RT, O, and NC cattle had decreased ADG and poorer G:F on both a live and carcass adjusted basis ($P < 0.001$) relative to the CON cattle. The RT cattle had improved G:F compared to the O and NC cattle on a live weight basis ($P < 0.001$). The RT cattle also had better G:F compared to the NC cattle on a carcass adjusted basis ($P < 0.001$). Cattle in the O group tended ($P = 0.051$) to have improved G:F compared to NC cattle on a carcass weight basis. No differences in carcass quality or animal health were detected between experimental groups. These results indicate that animal performance can be improved with conventional (implant, β-agonist, ionophore, and antimicrobial) or non-conventional (Oleobiotec) production technologies relative to a negative control.

Key Words: feedlot, cattle, technology

0336 The effects of supplementing two pasteurized milk balancer products to pasteurized whole milk on the health and growth of dairy calves.
K. M. Glosson*[1], B. A. Hopkins[1], S. Washburn[1], S. Davidson[1], G. Smith[1], T. Earleywine[2], and C. Ma[1], [1]*North Carolina State University, Raleigh,* [2]*Land O'Lakes Animal Milk Products, Shoreview, MN.*

Neonatal Holstein heifer calves (n = 72) received one of three dietary treatments: M (no supplement), MB (Land O'Lakes Pasteurized All-Milk Balancer), or MPB (Land O'Lakes Pasteurized Protein-Blend Balancer) from d 1 through weaning at d 56. Two locations were used in this trial, NCSU Lake Wheeler Dairy (Raleigh, NC) and NCDA Piedmont Research Station (Salisbury, NC), with 36 calves on trial at each site. All calves were removed from their dams after birth (d 0) and fed 3.8 L pasteurized colostrum. All calves were fed pasteurized whole milk from d 1 through d 56. Calves were fed 3.8L milk divided into 2 equal feedings from d 1 through d 14 and 5.7L milk divided into 2 equal feedings from d 15 through weaning at d 56. Supplements given to MB and MPB were included at a rate of 0.23kg of their respective balancer per 3.8L of pasteurized whole milk. Calves were weighed and measured for wither height (WH), hip height (HH), and hip width (HW) every 7 d from birth until weaning at d 56. Average daily gain (ADG) and feed efficiency (FE) were calculated from d 0 through d 56. Feed efficiency is the ratio of total gain to total dry matter intake (DMI), which included milk balancer DM and calf starter DM consumed. A contrast statement was used to compare M to the average of MB and MPB, and a second contrast compared the two supplemented treatments, MB versus MPB. Calves fed MB and MPB had greater body weight (BW), ADG, HW and WH when compared to calves fed M. Calves fed MB or MPB performed similarly.

Key Words: calf, milk balancer, pasteurized

Table 0336. BW, HH, HW, WH, ADG and FE as affected by treatment for 72 Holstein heifer calves from birth through weaning at 56 d

	Treatment				M vs. 1/2 (MB+MPB)	MB vs. MPB
	M	MB	MPB	SEM	$P \leq$	$P \leq$
BW, kg	53.8	56.7	58.19	1.0	0.01	0.3
HH, cm	85.0	85.5	86.3	0.7	0.2	0.3
HW, cm	18.8	19.0	19.4	0.2	0.04	0.1

FE, total gain/ total DMI	0.75	0.69	0.64	0.04	0.09	0.4

0337 Relationship between fertility and postpartum changes in body condition and body weight in lactating dairy cows.
P. D. Carvalho*[1], A. H. Sousa[2,3], M. C. Amundson[2], K. S. Hackbart[2], A. R. Dresch[2], L. M. Vieira[2], J. N. Guenther[2], R. R. Grummer[2,4], R. D. Shaver[1], P. M. Fricke[2], and M. C. Wiltbank[1], [1]*University of Wisconsin, Madison,* [2]*Department of Dairy Science, University of Wisconsin-Madison, Madison,* [3]*University of California Cooperative Extension, Tulare,* [4]*Balchem Corporation, New Hampton, NY.*

The relationship between energy status and fertility in dairy cattle was analyzed retrospectively by: analyzing the effect of early postpartum changes in body condition score (BCS; Expt 1) and post-partum changes in body weight (Expt 2) on fertility. To reduce the effect of cyclicity status, all cows were presynchronized with Ovsynch before to a second Ovsynch and timed AI (TAI after Double-Ovsynch; Expt 1; First GnRH at 53 ± 3 DIM; TAI at 80 ± 3 DIM) or synchronized superovulation (Expt 2). Data were analyzed by logistic regression with GLIMMIX and ANOVA using the MIXED procedure of SAS. In Expt 1, lactating dairy cows on two commercial dairies (n = 1887) were divided by BCS change from calving until third week postpartum. Overall, P/AI at 70 d pregnancy diagnosis differed dramatically ($P < 0.001$) by BCS change and were least for cows that lost BCS, intermediate for cows that maintained BCS, and greatest for cows that gained BCS (22.8% [180/789], 36.0% [243/675], and 78.3% [331/423], respectively). Effects of BCS change on fertility were similar for primiparous and multiparous cows, but differed by farm with BCS change dramatically affecting ($P < 0.001$) P/AI on one farm however there was no effect ($P = 0.35$) on the other farm. In Experiment 2, body weight of lactating dairy cows (n = 71) was measured weekly from first to ninth week postpartum. Cows were divided into quartiles by percentage of body weight change from calving until third week postpartum. (Q1 = +2.39%; Q2 = -0.07%; Q3 = -3.50%; Q4 = −6.84%). Cows were superovulated (TAI = 70 ± 3 DIM) and there was no effect of quartile on number of ovulations (17.9), total embryos/oocytes collected per cow (8.5), or percentage of oocytes that were fertilized (77.5%). In contrast, the percentage of fertilized oocytes that were transferable embryos was greater ($P = 0.04$) for cows in Q1, Q2 and Q3 than Q4 (83.8%, 75.2%, 82.6%, and 53.2%, respectively). In addition, percentage of degenerated embryos was less ($P = 0.02$) for cows in Q1, Q2, and Q3 compared to Q4 (9.6%, 14.5%, 12.6%, and 35.2% respectively). In conclusion, change in BCS during the first 3 wk postpartum had a profound effect on P/AI to first TAI. This effect could be partially explained by the reduction in embryo quality and increase in degenerate embryos 7 d after AI in cows that lost more body weight from first to third week postpartum. Supported by Hatch project WIS01171.

Key Words: BCS loss; body weight loss; embryo quality; fertility

0338 Effect of serum calcium status at calving on survival, health, and performance of postpartum dairy cows and calves. A. Hunter*[1], M. G. Maquivar[2], S. Bas[1], T. A. Brick[1], W. P. Weiss[3], J. S. Velez[4], H. Bothe[4], and G. M. Schuenemann[1], [1]*Department of Veterinary Preventive Medicine, The Ohio State University, Columbus,* [2]*Department of Animal Sciences, Washington State University, Pullman,* [3]*Department of Animal Sciences, The Ohio State University, Wooster,* [4]*Aurora Organic Farms, Platteville, CO.*

Limited evidence is available in the literature about the effect of hypocalcemia (HYPO) of dams at calving on survival and health of calves. The objective was to assess the effect of clinical and subclinical HYPO ($\leq$ 8 mg/dL) at calving on survival, health, and performance of lactating dairy cows and calves. Prepartum dairy cows (primiparous, n = 450; multiparous, n = 334) from one dairy herd were monitored (close-up pen) for imminent signs of birth (appearance of amniotic sac outside the vulva) until birth. Calving ease, time of birth, single or multiple calves, calf sex, and stillbirth (born dead or died within 24 h after birth), BCS immediately after calving, and hygiene score of the perineum were recorded. All female calves were subject to the same newborn care and colostrum management. Total serum Ca (HYPO) of cows was determined within 2 h after calving. The effect of HYPO on survival (died or culled within 30 DIM), metritis, and pregnancy per AI (P/AI) for first services of lactating cows were assessed using GLIMMIX. The effect of HYPO on calf survival, failure of passive transfer (FPT; serum total proteins $\leq$ 5.5 mg/dL), and diarrhea within 10 d of age were assessed using GLIMMIX. Diarrhea was defined as a calf presenting fluid or bloody feces (scores 2-3; 0-3 scale) and > 5% dehydration or fever ($\geq$ 39.5°C). The overall prevalence of HYPO was 15%. Cows experiencing HYPO at calving had greater proportion ($P < 0.05$) of metritis (29.4%) and culling within 30 DIM (23.5%) compared to non-hypocalcemic cows (17.3% and 6.9%, respectively). The proportion of P/AI at first service was not different between HYPO (30%) and non-HYPO cows (37%; $P > 0.05$). The proportion of stillbirth and FPT was not different ($P > 0.05$) between calves born from HYPO or non-HYPO cows. However, calves born from HYPO cows had greater (49%; $P < 0.05$) proportion of diarrhea than those calves born (33.3%) from non-HYPO cows. Dairymen, consultants, and veterinarians often trouble-shoot transition cow diseases and this process requires constant monitoring and comprehensive assessment of several events. Findings from the present study showed that HYPO at calving had significant health implications for both dams and calves.

Key Words: hypocalcemia, cow and calf health, dairy

0339 Sodium salicylate decreases glucose turnover rate in periparturient dairy cows, likely through enhanced liver insulin sensitivity. S. R. Montgomery*, L. Mamedova, A. J. Carpenter and B. Bradford, *Kansas State University, Manhattan*.

Low-grade inflammation has been implicated as a contributor to metabolic disease during the transition to lactation. However, in previous work, administration of sodium salicylate (SS) for 7 d led to hypoglycemia in mature dairy cows in early lactation. The purpose of this study was to identify the mode of action underlying this response to SS. Twenty mature (3+ parity) cows were assigned alternately at time of calving to either control (CON) or SS treatments. CON treatment received a molasses carrier in drinking water while the SS received 2.5 g/L SS with the molasses carrier in drinking water for 7 d after parturition. Blood samples were collected daily. A glucose turnover assay was performed on Day 7, followed by liver, muscle, and adipose tissue biopsies. Results were analyzed in the MIXED procedure of SAS with significance declared at $P < 0.05$. There were no treatment effects on DMI ($P = 0.98$) or water intake ($P = 0.61$). Tumor necrosis factor α (TNFa) mRNA expression was decreased by SS in adipose tissue ($P = 0.09$), but not in muscle ($P = 0.97$) or liver ($P = 0.52$), and plasma haptoglobin was not altered by treatment ($P = 0.34$). Though treatment did not alter plasma glucose or insulin concentrations, RQUICKI, a measure of insulin sensitivity, and plasma glucagon tended to be increased by SS ($P = 0.08$ for both). The insulin:glucagon ratio was increased by SS ($P = 0.01$). Cows on SS had a 25% decrease in glucose turnover rate ($P = 0.05$). There were no differences in mRNA expression of gluconeogenic genes in liver or of GLUT4 transporters in any of the tissues. These results indicate that SS may increase insulin sensitivity in mature fresh cows. This increase in sensitivity of insulin could explain the lower glucose turnover rate because of increased post-transcriptional inhibition of gluconeogenesis by insulin during SS treatment.

Key Words: NSAID, transition cow, insulin resistance

0340 Effects of elevated subcutaneous fat stores on serum nonesterfied and milk fatty acid profile and peripheral blood mononuclear cells gene expression of pro-inflammatory markers and production measures in periparturient dairy cows. C. M. Scholte*, K. C. Ramsey, C. Y. Tsai, A. Hendrickson, Z. M-Amiri, B. Shafii and P. Rezamand, *University of Idaho, Moscow, ID.*

Dairy cows with greater subcutaneous fat stores release greater concentrations of nonesterified fatty acids (NEFA) into the blood during the periparturient period. The objective of this study was to determine the effect of elevated lipid mobilization during the periparturient period on serum NEFA and milk fatty acid (FA) profile, peripheral blood mononuclear cells

(PBMC), gene expression of selected markers of inflammation and production measures. Thirty-four cows were blocked by parity; treatment received a dry cow ration with an additional 10 kg of corn/head per day starting -28 d relative to parturition. The control received the dry cow ration (no additional corn) with 400 mg of monensin/head per day. Immediately postpartum, cows were fasted for 8 h. Serum samples were collected on -28, −7, +1, +6, +15, and +21 d for FA analysis of specific lipid fractions. Milk samples were obtained on +1, +3, +6, +15, and +21 d for composition, yield, and FA analyses. Real-time q-PCR gene analysis for intercellular adhesion molecule 1 (*ICAM-1*), interleukin (*IL*) 1β and 6, and tumor necrosis factor-α (*TNF-α*) was performed on PBMC collected on -28, +3, +12, and +21 d. Data were analyzed as repeated measures analysis of variance using mixed model procedures in SAS (9.3) and significance was declared at $P \leq 0.05$. Within serum NEFA fraction, C16:1, sum of C18:1 *trans*, and C18:3n3 were greater in control than in treatment prepartum, but no significance was detected in postpartum. In contrast, sum of C18:1 *trans* was greater in treatment compared with that of control during postpartum period. Serum concentration of C20:4n6 tended to be greater in treatment compared with that of control (1.12 vs. 0.86 ± 0.11%; $P = 0.06$). In milk fat, C16:1 and C18:2 *cis* were greater for treatment and C15:0, C18:3n3 and C22:2 were lower for treatment compared to with control. Gene expression for *IL-1β* in PBMC was greater for control, whereas *ICAM-1*, *IL-1β*, *IL-6*, and *TNF-α* were greater in primiparous than multiparous cows, without a detectable treatment effect. Prepartum, control cows consumed more feed than treatment. Postpartum intake indicated a marginal treatment × time interaction, with intake wavering until d +11 and treatment consuming relatively more thereafter. In summary, increased subcutaneous fat stores altered FA profile of serum NEFA fraction and milk as well as gene expression of PBMC in periparturient dairy cows.

Key Words: lipid mobilization, fatty acid profile, peripheral blood mononuclear cells

0341 Effect of prophylactic and therapeutic antibiotic administration on fecal excretion of antibiotic resistance genes by dairy cows. L. R. Caudle*, H. M. Littier, A. Pruden, X. Feng, and K. F. Knowlton, *Virginia Tech, Blacksburg.*

The objective of this study was to determine the effect of prophylactic and therapeutic antibiotic administration on fecal excretion of antibiotic resistance genes (ARG) in dairy cows. Twelve primiparous lactating Holstein cows were used in a completely randomized design. Four treatments included the administration of cephapirin (intramammary), pirlimycin (intramammary), or ceftiofur (subcutaneous), as well as a control group where no antibiotic was given. Fecal samples were collected from all cows before antibiotic administration on d 0 and then on d 1, 3, 5, 7, 14, 21, and 28 following treatment. Fecal samples were freeze-dried and DNA was extracted using the FastDNA Spin Kit for Soil. Extracted DNA was analyzed using quantitative polymerase chain reaction for genes encoding for resistance to tetracyclines (*tet*O and *tet*W) and β-lactams (*amp*C) as well as a housekeeping gene (16S rRNA) to monitor bacterial abundance. Statistical analysis was performed using Proc Glimmix in SAS with a model including treatment, day, and their interaction with pre-treatment (d 0) abundance as a covariate. Absolute (log10 copies/g feces) and relative (gene copies/16S rRNA) abundance of *tet*O, *tet*W, and *amp*C were not influenced by antibiotic treatment. Absolute abundance of 16S rRNA was lower ($P < 0.04$) in feces of pirlimycin-treated cows than in feces of cephapirin-treated cows and also tended to be lower ($P < 0.06$) than in feces of control cows. This suggests effects of pirlimycin on total fecal bacterial numbers. There was an effect of day on relative abundance of *tet*W ($P < 0.04$) and *amp*C ($P < 0.04$) in all cows, with fecal excretion highest on d 3 post-treatment. Absolute abundance of *tet*W in feces was influenced by day ($P = 0.01$), with excretion highest 28 d post-treatment. In this study, prophylactic and therapeutic antibiotic administration did not increase excretion of the three target ARG by dairy cows. The observed temporal pattern in ARG excretion will help identify the most useful time frame for possible interventions to reduce dissemination of ARG from dairy farms. These results will inform further analysis of the entire complement of known ARG using shotgun metagenomics.

Key Words: antibiotic resistance genes, dairy cow, feces

0342 Effects of oscillating the crude protein content in dairy cow rations. A. N. Brown*[1] and W. P. Weiss[2], *[1]The Ohio State University, Wooster, [2]Department of Animal Sciences, The Ohio State University, Wooster.*

Overfeeding crude protein (CP) is a common practice in the dairy industry to reduce the risk of a loss in milk; however, overfeeding CP increases costs and negatively impacts the environment. We hypothesized that oscillating dietary CP concentrations to equal the average concentration of a diet limited in metabolizable protein (MP) for lactating dairy cows will improve milk protein yield and milk N efficiency because oscillating CP should stimulate nitrogen recycling to the rumen. Twenty-one Holstein dairy cows averaging 123 DIM were randomly assigned to a treatment sequence in seven 3 × 3 Latin Squares with 28-d periods. The control diet contained 16.4% CP (MP allowable milk = 47 kg/d), the low protein diet contained 13.4% CP (MP allowable milk = 31 kg/d), and the oscillating treatment consisted of a diet with 10.3% CP fed for 2 d followed by a diet with 16.4% CP fed for 2 d repeated over the 28 d period to average 13.4% CP. The cows were fed once daily and milked twice daily. Cows on the low protein diet had greater DMI than cows on the oscillating treatment (24. 8 kg/d vs. 24.3 kg/d; $P = 0.04$) but were similar in DMI compared to

cows on the control diet (24.8 kg/d). There was no treatment difference ($P > 0.05$) for milk yield (avg. 34.6 kg/d), feed efficiency, milk fat yield, milk fat content, and milk protein content. Milk protein yield showed a treatment effect; however, treatment contrasts showed no difference between the oscillating treatment and low treatment and between the high and low treatments. Milk urea nitrogen (MUN) increased with protein content of the diet (14.5 mg/dl vs. 9.1 mg/dl; $P < 0.0001$) with no difference in MUN between cows fed the low and oscillating treatments except that MUN followed a cyclic pattern for oscillating cows. Given that cows on the low diet produced more milk than MP allowable milk, cows on the low protein diet used nitrogen more efficiently than expected or the NRC overestimated the requirements. Although milk and milk protein production were not affected by the oscillating treatment, very little research has been done on oscillating CP content of dairy cows rations; therefore, this study is a first step in understanding how oscillating protein affects dairy cows.

Key Words: dairy cow, metabolizable protein, oscillating protein

0343 Interaction among energy status and retinoid status in periparturient dairy cows: production, milk retinoid, and metabolic response.

K. C. Ramsey*, J. D. Blickenstaff, C. Y. Tsai, C. M. Scholte, W. Price, M. A. McGuire, and P. Rezamand, *University of Idaho, Moscow.*

An objective of this study was to determine the effect of feeding various amounts of dietary vitamin A (0 or 110 IU/kg BW), crude protein (12.5% or 16%), and an ionophore (monensin at 0 or 400 mg/d per head) on performance measures, retinoid metabolism, immune system, and metabolic response. Multiparous Holstein dairy cows ($n = 80$) were studied from day -35 to +21 relative to expected parturition, in a complete randomized block design with a 2 × 2 × 2 factorial arrangement of treatments. Milk samples were obtained at the first, second, third milking, and every 3 d thereafter, and processed for components, somatic cell count (SCC), retinol, α-tocopherol, and β-carotene. Serum samples were collected on d -35, −7, +3, +9, +21 and processed for NEFA, BHBA, haptaglobin, and thiobarbituric acid reactive species (TBARS). Peripheral blood mononuclear cells (PBMC) were also isolated on d +7. Real time qPCR gene analysis for intercellular adhesion molecule (*ICAM-1*), interleukin (*IL*) 1β and 6, and tumor necrosis factor-α (*TNF-α*) were performed on PBMC. Significance of treatments was declared at $P \leq 0.05$. Results indicated vitamin A reduced ($P = 0.05$) milk SCC with no effect on milk yield or composition, DM intake both pre- and postpartum. An effect of CP × monensin on milk retinol concentration was observed (2.19, 1.72, 2.12, and 2.35 ± 0.16 µg/mL for low CP + monensin, low CP– monensin, high CP + monensin, and high CP– monensin, respectively; $P = 0.03$), but no differences in milk α-tocopherol and β-carotene were found. Furthermore, serum haptoglobin was lower ($P = 0.03$) with greater dietary CP. Also, cows that received monensin had lower ($P = 0.013$) serum haptoglobin postpartum compared with the prepartum concentrations observed. No differences in serum NEFA, BHBA, or TBARS were detected. Cows that received greater CP had increased gene expression of *TNF*-α ($P = 0.04$) in PBMC, but not effect on gene expression of *ICAM-1*, *IL-1β*, and *IL-6* was found. Overall, these observations show that dietary vitamin A, monensin and protein affect retinol and SCC in milk without affecting performance measures. Further studies are needed to fully understand the retinoid metabolism in the transition dairy cow.

Key Words: transition cows, retinoids, gene expression

0344 Reproductive performance of timed artificial insemination and activity-based estrus detection.

K. A. Dolecheck*, W. J. Silvia, G. Heersche Jr., and J. M. Bewley, *University of Kentucky, Lexington*.

A study comparing reproductive management programs without visual estrus detection was conducted using 268 cows from 2 commercial dairy herds in Kentucky between October 2012 and November 2013. Before enrollment, resumption of ovarian activity was confirmed and BCS was evaluated. Eligible cows (BCS ≥ 2.5) were balanced for parity and predicted milk yield then randomly assigned to 1 of 2 treatments: TAI or activity. Ovulation synchronization using G7G/Ovsynch and Resynch occurred up to 3 times for all cows assigned to the TAI treatment. Cows assigned to the activity treatment received a leg-mounted accelerometer (AfiTag Pedometer Plus, S.A.E. afimilk, Kibbutz Afikim, Israel) and were bred according to estrus alerts created by the system algorithm for up to 90 d after the voluntary waiting period (VWP). Pregnancy diagnosis via ultrasound occurred 33 to 46 d after insemination and pregnancy loss was determined between 60 and 74 d bred. The GLM procedure of SAS (SAS Institute, Inc., Cary, NC) was used to evaluate the effects of treatment (TAI or activity), herd (1 or 2), temperature humidity index (THI), parity (primiparous or multiparous), BCS (≤ 2.75 or ≥ 3.00), summit milk, and their interactions on days to first service, first service conception rate (CR1), repeat service conception rate (≥ 2CR), days open (DO), pregnancy loss (PL), and percent pregnant at the end of the 90 d study period (%P90). Stepwise backward elimination removed all nonsignificant interactions ($P \geq 0.05$). Main effects remained in each model regardless of significance. Days to first service was lower ($P < 0.01$) for the TAI group than for the activity group (6.21 ± 0.98 vs. 18.30 ± 0.99 d after the VWP, respectively). Treatment was not a predictor of CR1 (TAI: 46.89 ± 4.43% vs. activity: 43.78 ± 4.47%, $P = 0.61$), ≥ 2CR (TAI: 41.15 ± 4.88% vs. activity: 39.92 ± 4.95%, $P = 0.86$), DO (TAI: 33.16 ± 3.09 vs. activity: 33.08 ± 3.02 d after the VWP, $P = 0.98$), PL (TAI: 16.97 ± 3.33% vs. activity: 10.77 ± 3.43%, $P = 0.14$), and %P90 (TAI: 65.54 ± 4.57% vs. activity: 66.11 ± 4.43%, $P = 0.92$). These

results indicate that continuous activity monitoring can produce similar reproductive performance to TAI.

Key Words: activity monitoring, timed artificial insemination, estrus detection

0345 Energy content of reduced-fat distillers grains for lactating dairy cows. A. Foth*[1], G. Garcia Gomez[1], T. Brown-Brandl[2], H. C. Freetly[3], and P. J. Kononoff[1], *[1]University of Nebraska, Lincoln, [2]ARS-USDA, Clay Center, NE, [3]USDA, ARS, US MARC, Clay Center, NE.*

The corn-ethanol industry has started to produce distillers grains and solubles that contain a reduced concentration of fat (RFDDGS), but the impact of this feed on the supply of energy to the cow has not been studied in depth. Eight Holstein and 8 Jersey multiparous, lactating cows were used to complete 56 energy balances to determine the energy content of rations containing RFDDGS. A repeated switchback design was used to compare treatments with and without RFDDGS. On a DM basis, treatments consisted of 24.2% corn silage, 18.4% alfalfa hay, 6.94% brome hay with either 22.9% rolled corn and 14.8% soybean meal, or 4.51% rolled corn, 14.5% RFDDGS, and 0% soybean meal (DM basis). The inclusion of RFDDGS increased DMI from 21.7 ± 0.70 kg/d to 23.3 ± 0.68 kg/d ($P < 0.01$) but did not affect milk production (30.4 ± 1.46 kg/d; $P = 0.11$). However, 3.5% FCM tended ($P = 0.10$) to be different (33.0 ± 1.27 and 34.2 ± 1.25 kg/d for Control and RFDDGS treatment, respectively). Milk energies were 1.44 ± 0.50 Mcal/d higher with RFDDGS ($P = 0.01$). Energy lost as methane was reduced ($P = 0.01$) by 0.28 Mcal/d with the addition of RFDDGS. Heat loss averaged 30.4 ± 0.55 Mcal/d and did not differ by treatment ($P = 0.94$). Energy retained as tissue energy was found to be -0.22 ± 1.48 Mcal/d for the Control and 6.78 ± 1.43 Mcal/d for the RFDDGS treatment ($P < 0.01$). Intakes of digestible and metabolizable energies were lower ($P < 0.01$) for the Control (2.70 and 2.36 ± 0.05 Mcal/kg DM, respectively) compared to RFDDGS (2.86 and 2.54 ± 0.05 Mcal/kg DM). There was also a treatment by breed interaction for digestible, metabolizable and lactational net energies ($P < 0.01$) with a greater difference between treatments with Holstein cows than Jersey cows. Differences between treatments in Holsteins were 12.0 ± 2.09, 11.7 ± 1.98 and 11.3 ± 1.90 Mcal/d ($P < 0.01$), and Jerseys were 4.16 ± 2.14, 4.32 ± 2.04 and 5.47 ± 1.96 Mcal/d ($P = 0.06$, 0.04 and 0.01), for digestible, metabolizable and lactational net energies, respectively. These energy estimates suggest higher energy content of diets containing RFDDGS than diets containing a mixture of corn and soybean meal in lactating dairy cows.

Key Words: reduced-fat distillers grains with solubles, energy balance, methane

0346 Relationship between digestibility and residual feed intake in lactating Holstein cows fed high and low starch diets. S. E. Burczynski*, J. P. Boerman, A. L. Lock, M. S. Allen, and M. J. VandeHaar, *Michigan State University, East Lansing.*

We determined if differences in digestibility among cows explained variation in residual feed intake (RFI) in 3 crossover design experiments. Lactating Holstein cows ($n = 89$; 107 ± 27 DIM) were fed diets high (HI) or low (LO) in starch. LO diets were ~38% NDF and ~14% starch; HI diets were ~26% NDF and ~32% starch. Each experiment consisted of two 28-d treatment periods, with digestibility measured during the last 5 d. Individual DMI and milk yield were recorded daily, BW was measured 3−5 times per wk, and milk components were analyzed twice weekly. DMI was modeled as a function of milk energy output, metabolic BW, body energy gain, and fixed effects of parity and cohort, with the residual being RFI. High RFI cows are less efficient because they eat more than expected for a given multiple of maintenance based on requirements. RFI was negatively correlated with digestibility of starch for both HI ($r = -0.25$; $P = 0.02$) and LO diets ($r = -0.20$; $P = 0.07$), and with digestibility of DM ($r = -0.30$; $P < 0.01$) and NDF ($r = -0.24$; $P = 0.03$) for LO diets but not HI diets ($P > 0.4$). Cows with the highest RFI (HiRFI) and the lowest RFI (LoRFI) were those greater or less than 1 SD of the mean for each cohort. For HI diets, LoRFI cows tended to have greater starch digestibility than HiRFI (96 vs. 94%; $P = 0.08$), but similar digestibilities ($P > 0.2$) of DM (67%) and NDF (37%). For LO diets, LoRFI cows tended to have greater DM digestibility (66 vs. 64%; $P = 0.08$), but similar starch (95%; $P > 0.2$) and NDF (50%; $P > 0.3$) digestibilities. Apparent NE_L concentrations for HI and LO diets, based on cow performance, were 21 and 12% greater ($P < 0.01$), respectively, for LoRFI cows than HiRFI cows. LoRFI cows had 3% greater DM digestibility than HiRFI cows for LO diets, which accounted for 25% of their greater ability to extract NE_L from the same diet. Although digestibility differed for LoRFI and HiRFI cows, some of the differences were expected because high RFI cows eat at a higher multiple of maintenance, which should depress digestibility. Based on these data, we conclude that a cow's digestive ability explains none of the variation in RFI for cows eating high starch diets but may explain as much as 25% of the variation in RFI among cows eating low starch diets.

Key Words: residual feed intake, digestibility, dietary starch

0347 Evaluation of the effects of vitamin D and toll-like receptor signaling pathways on expression of antibacterial β-defensin genes in bovine neutrophils and mammary epithelial cells.

K. E. Merriman* and C. D. Nelson, *Department of Animal Sciences, University of Florida, Gainesville.*

Bacterial infection in the udder stimulates synthesis of 1,25-dihydroxyvitamin D_3 ($1,25(OH)_2D_3$) from 25-dihydroxyvitamin D_3 in macrophages that are in the mammary glands. The $1,25(OH)_2D_3$, along with toll-like receptor (TLR) recognition of pathogen associated molecules, enhances the expression of β-defensin 3 (*DEFB3*), *DEFB6, DEFB7,* and *DEFB10* genes in bovine macrophages. The β-defensin genes encode for small cationic peptides that have potent bactericidal and immunomodulatory activity. Neutrophils and mammary epithelial cells (MEC) are additional sources of β-defensin peptides in the udder. It was hypothesized that $1,25(OH)_2D_3$ and TLR agonists also would promote expression of the β-defensins in neutrophils and MEC. Therefore, the objective of this study was to determine the contribution of vitamin D and TLR signaling pathways on expression of *DEFB3, DEFB4, DEFB6, DEFB7*, and *DEFB10* genes in bovine neutrophils and MEC. Peripheral blood neutrophils from cattle and primary bovine MEC cultures were treated with 0 or 1 μg/mL lipopolysaccharide (LPS) in combination with 0 or 10 nM $1,25(OH)_2D_3$. The mRNA transcripts of *DEFB3, DEFB4, DEFB6, DEFB7,* and *DEFB10* genes were quantified by real-time PCR. The threshold cycle (Ct) for each gene was normalized to ribosomal protein S9 transcript abundance and the normalized Ct values for each treatment were analyzed with a general linear model to test for effects of $1,25(OH)_2D_3$ and LPS treatments. In contrast to macrophages, $1,25(OH)_2D_3$ did not upregulate expression of the *DEFB3, DEFB6, DEFB7,* or *DEFB10* genes in either non-stimulated or LPS-stimulated neutrophils or MEC ($P > 0.05$). However, the $1,25(OH)_2D_3$ treatment increased *DEFB4* gene expression 5 ± 1-fold ($P < 0.05$) in MEC not treated with LPS, and 3 ± 1-fold ($P < 0.05$) in MEC treated with LPS. Furthermore, LPS combined with $1,25(OH)_2D_3$ upregulated *DEFB4* 30-fold ($P < 0.05$) compared to MEC cultured in the absence of LPS and $1,25(OH)_2D_3$. The LPS treatment alone upregulated *DEFB3, DEFB4*, and *DEFB7* in MEC ($P < 0.05$; 3 ± 1, 11 ± 3, and 8 ± threefold change ± SE, respectively), and *DEFB3, DEFB4, DEFB6, DEFB7*, and *DEFB10* in neutrophils ($P < 0.05$; 121 ± 44, 10 ± 7, 144 ± 85, 112 ± 51, and 56 ± 22, fold change ± SE, respectively). In conclusion, $1,25(OH)_2D_3$ does not enhance β-defensin gene expression in bovine MEC or neutrophils as it does in macrophages. However, LPS does strongly enhance several of the β-defensins in MEC and neutrophils. Therefore, activation of the TLR pathway in neutrophils and MEC, combined with activation of the vitamin D pathway in macrophages, may serve to boost the innate defense system of the udder.

Key Words: vitamin D, innate immunity, mammary

GRADUATE STUDENT COMPETITION: ADSA PRODUCTION ORAL COMPETITION, PhD

0348 Antioxidant activity after in vitro gastrointestinal digestion of cheese containing catechins encapsulated within liposomes. A. Rashidinejad*[1,2], D. Everett[1,2], J. Birch[1], and D. Sun-Waterhouse[3], [1]*University of Otago, Dunedin, New Zealand,* [2]*Riddet Institute, Palmerston North, New Zealand,* [3]*Plant and Food Research, Auckland, New Zealand.*

Two important green tea phenolic compounds, (+)-catechin and (−)-epigallocatechin gallate (EGCG) were first encapsulated in soy lecithin liposomes and then incorporated into a low-fat hard cheese to determine the effect of cheese ripening and simulated digestion on the antioxidant activity and recovery of incorporated catechins. The total antioxidant activity (TAA) was measured after in vitro gastrointestinal digestion of cheese that was ripened over 90 d at 8°C to evaluate the efficacy of added antioxidants. Total phenolic content (TPC) was measured using the Folin-Ciocalteu assay, while TAA by both ferric reducing antioxidant power (FRAP) and oxygen radical absorbance capacity (ORAC) assays. The correlation coefficients among the TPC and TAA assays, and the recovery of the encapsulated phenolics for cheese fortification (measured by HPLC), were calculated. Fortification of low-fat cheese with either catechin or EGCG encapsulated in liposomes, led to a significant increase ($p < 0.01$) in TPC, FRAP, and ORAC values measured within the digesta matrix, with no significant impact on cheese composition, pH, and yield. Catechin and EGCG were not detected in the cheese whey, indicating their complete retention in the cheese curd. The phenolic recovery from the digesta was about half of the initial concentration for catechin, i.e., 51.3, 53.9, and 46.0% for the fresh (Day 0) cheese and cheese ripened for 30 and 90 d (Day 30 and 90 cheese), respectively, and more than one third for EGCG, i.e., 38.8, 33.7, and 33.5% for Day 0, 30, and 90 cheese, respectively. TPC values were highly correlated with both the FRAP values (i.e., correlation coefficient was 0.97, 0.98, and 0.96 for Day 0, 30, and 90 cheese, respectively) and ORAC values (i.e., correlation coefficient was 0.98, 0.98, and, 0.97 for Day 0, 30, and 90 cheese, respectively). Moreover, the corresponding FRAP and ORAC values were also highly correlated with the coefficients being 0.98, 0.97, and 0.98 for Day 0, 30, and 90 cheese, respectively, suggesting the suitability of these assays for evaluating the TAA of fortified cheese. Thus, the manufacture of a low-fat hard cheese fortified with encapsulated catechin and epigallocatechin gallate in liposomes is feasible with good retention of phenolics and high antioxidant activity. Further investigations on aspects such as bioavailability of fortified phenolics, dose for phenolic consumption, and sensory attributes of fortified cheese are still required before product commercialization.

0349 Effects of mineral salts and calcium chelating agents on the functionalities of milk protein concentrate prepared by ultrafiltration. X. Luo*, L. Ramchandran, and T. Vasiljevic, *Victoria University, Melbourne, Australia*.

Functionality of milk protein concentrates can be tailored by modifying state of casein micelles through manipulation of processing conditions including temperature, pH and/or addition of calcium chelators. The objective of this study was to investigate the effect of calcium and calcium chelating agents (EDTA and citrate) on the performance of membrane ultrafiltration (UF) process and the functionalities of resulting milk protein concentrates (MPC). Skim milk adjusted to pH 5.9 was pre-treated with EDTA or citric acid (10, 20 or 30 mmol) and ultrafiltered using a polyethersulfone (PES) membrane at 15°C to five times concentration factor. The membrane performance was measured by the permeate flux during UF process. Used membranes were examined using scanning electron microscopy (SEM). The MPC samples were freeze dried and powders were assessed for physical functionalities including solubility, heat stability and emulsification. Addition of chilators led to a shift in a protein-mineral equilibrium and calcium dissociation from the casein micelle. The total calcium in the final MPC was reduced ($p < 0.05$) from 191 (control) to 131 mM or 135 mM for skim milk pre-treated with 30 mmol of EDTA or citrate, respectively. The casein micelle particle size was subsequently reduced ($p < 0.05$) from 200 nm (control) to 28 nm or 24 nm for the milk pre-treated with EDTA or citrate at concentrations equal to or greater than 20 mmol. Consequently, solubility of the MPC increased ($p < 0.05$) from 92% (control) to 98% (ETDA, $\geq$ 20 mmol) or 98.9% (citrate, 30 mmol); heat stability was also enhanced ($p < 0.05$) from 78% (control) to 83% (EDTA, 20 mmol) or 87% (citrate, $\geq$ 20 mmol). The emulsion capacity has increased from 1170 (control) to 1392 or 1459 (g oil/g protein) ($p < 0.05$) when 30 mmol of EDTA or citrate were added, respectively. Addition of EDTA or citrate hindered the membrane performance as observed by reduced permeate flux from 10.5 kg/h.m^2 (control) to 7.9 kg/h.m^2 (EDTA, $\geq$ 20 mmol) and 8.6 kg/h.m^2(citrate, $\geq$ 20 mmol) at the start of UF. Consequently UF processing time increased from 5 h (control) to 7 h (EDTA) or 6 h (citrate). This work has provided new insights into the relationship between calcium, calcium chelators and their influence on the casein micelle size and the physicochemical properties of MPC produced using UF, and also demonstrated the potential of using EDTA and citrate acid to manipulate MPC product functionality using UF.

Key Words: milk protein concentrate (MPC), functionality, ultrafiltration (UF), membrane, calcium chelator, casein micelle

0350 Effects of slow-release urea, rumen-protected methionine, and histidine on performance of dairy cows fed metabolizable protein-deficient diets.
F. Giallongo*[1], J. Oh[1], T. Frederick[1], H. Weeks[1], A. N. Hristov[1], H. Lapierre[2], R. A. Patton[3], A. Gehman[4], and C. Parys[5], *[1]Department of Animal Science, The Pennsylvania State University, University Park, [2]Agriculture and Agri-Food Canada, Sherbrooke, QC, Canada, [3]Nittany Dairy Nutrition Inc., Mifflinburg, PA, [4]Alltech Inc., Nicholasville, KY, [5]Evonik Industries AG, Hanau, Germany.*

The main objective of this experiment was to investigate the effects of slow-release urea and rumen-protected (RP) Met and His supplementation of a metabolizable protein (MP)-deficient diet on lactation performance of dairy cows. Sixty Holstein cows (DIM, 87 ± 40 and BW, 640 ± 70 kg) were used in a 10-wk randomized complete block design trial. After a 2-wk covariate period, cows were blocked by parity, DIM, and milk yield, and randomly assigned to 1 of 5 dietary treatments: MP-adequate diet [AMP; 107% of MP requirements (NRC, 2001)]; MP-deficient diet [DMP; 95% of MP requirements]; DMP supplemented with slow-release urea as Optigen (Alltech Inc.; DMPO); DMPO supplemented with RPMet as Mepron (Evonik Industries AG; DMPOM); and DMPOM supplemented with RPHis (Balchem Corp.; DMPOMH). The basal diet consisted of (DM basis): 43% corn silage, 8% grass hay, 4% cottonseed hulls, and 45% concentrate and contained 16.7, 15.8, and 14.8% CP for AMP, DMPO, and DMP, respectively. Total-tract apparent digestibility of nutrients, and urinary N and urea excretions were decreased ($P < 0.01$) by DMP compared with AMP. Relative to AMP, milk N secretion as a proportion of N intake tended to be higher ($P = 0.07$) for DMP. DMI was not affected by MP level but tended to be higher ($P = 0.09$) for the DMPOMH (28.4 kg/d) compared with DMPOM (27.0 kg/d). Yields of milk and milk fat were not affected by treatment, averaging 44.0 kg/d and 1.56 kg/d, respectively; milk fat content tended to be lower ($P = 0.06$) for DMPOMH (3.36%) than DMPOM (3.78%). Milk true protein content was increased (3.26 vs. 3.16%, $P = 0.04$) and milk protein yield was numerically increased (1.49 vs. 1.39 kg/d, $P = 0.14$) by DMPOMH, compared with DMPOM. Cows fed DMP gained 14 g/d BW whereas cows on all other treatments gained on average 267 g/d ($P \leq 0.10$). Supplementation of the DMPO diet with RPAA increased ($P = 0.03$) plasma glucose and numerically increased ($P = 0.12$) plasma insulin. In conclusion, feeding a 5% MP-deficient diet did not decrease DMI and yields of milk and milk components, despite the reduction in nutrient digestibility. Supplementation of the DMPOM diet with RPHis tended to increase DMI and increased milk protein content. These results confirm previous data and suggest that His may have a positive effect on voluntary feed intake in high-yielding dairy cows.

Key Words: metabolizable protein, slow-release urea, rumen-protected methionine, rumen-protected histidine

0351 Effect of dietary phosphorus on intestinal P absorption in growing Holstein steers.
X. Feng*, E. T. Ronk, H. H. Schramm, M. D. Hanigan, M. A. McCann, and K. F. Knowlton, *Virginia Polytechnic Institute and State University, Blacksburg.*

The effect of dietary phosphorus (P) intake on intestinal P absorption was evaluated in growing steers. Diets varying in P content (0.15%, 0.27%, 0.36% and 0.45%, DM basis) were fed to 8 growing Holstein steers (174 ± 10kg BW) fitted with permanent duodenal and ileal cannulas in a replicated 4 × 4 Latin square with 14 d periods. Ytterbium-labeled corn silage and cobalt-EDTA were used as particulate and liquid phase markers, respectively, to measure digesta flow. Duodenal and ileal samples and spot samples of urine were collected every 9 h from d 11 to 14. Total fecal collection was conducted on d 11 to 14 with fecal bags. Blood samples were collected from the coccygeal vessel on d 14. Feed, digesta, and fecal samples were analyzed for total P and Pi using the molybdovanadate yellow method and blue method, respectively. Data were analyzed using PROC GLIMMIX in SAS with a model including treatment, square, period and interaction of treatment and square. Preplanned contrasts were used to evaluate linear and quadratic treatment effects. Results are reported as least square means. Dry matter intake (mean = 4.90 kg/d, 2.8% of BW) and apparent DM digestibility (mean = 78.1%) were unaffected by treatment. Duodenal and ileal flow of total P increased linearly with increasing P intake (13.4, 18.5, 23.0 and 27.4 g/d, $P < 0.01$; 6.80, 7.87, 8.42, and 10.4 g/d, $P < 0.05$). Increasing P intake linearly increased the quantity of P absorbed from the small intestine (6.96, 11.1, 14.6 and 17.2 g/d, $P < 0.01$) but absorption efficiency was unchanged (mean = 59.6%). Phosphorus was absorbed on a net basis from the large intestine, but this was not affected by treatment and was a small percentage of total P absorption. Blood Pi increased linearly with increased dietary P (4.36, 6.31, 7.68, and 8.5 mg/dL, $P < 0.01$) and salivary P secretion was unchanged (mean = 5.79 g/d) suggesting that rumen function was prioritized during short-term P deficiency. The absence of change in absorption efficiency and salivary P secretion in the face of short term P deficiency may be used to improve published models of P digestion, absorption, and metabolism.

Key Words: phosphorus, absorption, growing steers

0352 A survey of calving and colostrum management practices on Irish dairy farms.
C. Cummins*[1,2], R. Sayers[1], I. Lorenz[2], and E. Kennedy[1], *[1]Teagasc, Animal and Grassland Research and Innovation Center, Moorepark, Fermoy, Co. Cork, Ireland, [2]School of Agriculture, Food Science & Veterinary Medicine, University College Dublin, Belfield, Dublin, Ireland.*

This study aimed to identify calving and colostrum management practices on Irish dairy farms that may compromise neonatal

calf health. The study population was randomly selected from the Irish Cattle Breeding Federation (ICBF) HerdPlus group (n = 320) and balanced for herd size and geographical location. The survey consisted of four sections: cow management, calving management, colostrum management and calf management (calving and colostrum are described here). Questions related to hygiene, type of calving pens used, and colostrum collection, storage, and feeding management. Surveys were mailed between 11 July and 15 August 2013. Responses were entered onto the online package SurveyMonkey (www.surveymonkey.com). Coded responses were downloaded to one file and data were collated using Microsoft Excel. A univariable chi-square analysis (significance $P < 0.05$) was performed using 'PROC FREQ' in SAS (v9.3), with two independent variables: milk production (MP), and enterprise. Milk production category one (MP1) included suppliers with a milk production limit (quota) of $\leq$ 380,000L; MP2 > 380,000L and < 600,000L; and MP3 $\geq$ 600,000L. Enterprise was divided into specialist dairy farms (SD) and dairy farms with another enterprise (DO). The final response rate was 85%. On univariable analysis, group calving pens were more common among MP3 (60%) than MP1 (37%; $P < 0.05$), who tended to use individual pens (24% MP3; 47% MP1; $P < 0.05$). Cleaning of calving pens was infrequent across all study herds (42% $\leq$ 1 × month), while 81% left calves in calving pens for $\geq$ 2 h after birth. Regarding colostrum, MP3 respondents more commonly collected colostrum at first herd milking post-calving compared to MP1 and MP2, the majority of which collected within 2 h ($P < 0.05$). Most SD herds collected colostrum at the first scheduled milking post-calving compared to DO herds (43% SD; 26% DO; $P < 0.01$). More MP1 herds allowed calves to consume own dam colostrum (79%), compared to MP2 (56%) and MP3 (44%), however they also allowed calves suckle their dam (48% MP1 vs. 40% MP2 and 32% MP3). Consequently, MP1 calves received colostrum earlier compared to MP3 (45% MP1 vs. 35% MP3 within 1 h; $P < 0.05$). Of farms not feeding calves colostrum from their own dam, 32% of MP3 used pooled colostrum for the calf's first feed compared to MP1 (13%) and MP2 (15%). The most common storage method was freezing (46%), mainly for 1−6 mo (44%). This study indicates that calving and colostrum management practices on many Irish dairy farms are suboptimal and may lead to compromised calf health.

Key Words: colostrum, calving, survey

0353 Effects of supplementing lipid-encapsulated echium oil on lactational responses and milk fatty acid composition.

M. Bainbridge*[1], A. L. Lock[2], and J. Kraft[3], [1]*University of Vermont, Burlington,* [2]*Michigan State University, East Lansing,* [3]*Department of Animal Science, University of Vermont, Burlington.*

Echium oil is a terrestrial source of n-3 fatty acids (FA) that is particularly high in the n-3 FA stearidonic acid (SDA; 18:4 6c,9c,12c,15c) which bypasses the rate limiting step of delta-6-desaturase in conversion to eicosapentaenoic acid (EPA) and docosahexaenoic acid (DHA) in mammalian tissues. The objective of this study was to evaluate the impact of feeding a lipid-encapsulated echium oil (EO) supplement on animal production and milk fatty acid concentrations. Twelve Holstein dairy cattle (229 ± 62 d in milk) were assigned randomly to treatment sequence in a 3 × 3 Latin Square design. Treatments were a control diet (CON; no added EO), 1.5% EO (1.5% EO), or 3.0% diet dry matter (DM) added EO (3.0% EO). Treatment periods were 14 d with the final 4 d used for sample and data collection. The statistical model included the random effect of cow nested within square and the fixed effects of treatment and period. Compared with CON, EO treatments had no effect on dry matter intake (26.6 kg/day; $P = 0.93$), milk yield (30.5 kg/day; $P = 0.34$), or milk protein yield (1.1 kg/day; $P = 0.84$). Increasing EO supplementation increased milk fat concentration (4.1, 4.2, 4.3%; $P < 0.05$) and fat yield (1.24, 1.27, 1.32 kg/day; $P < 0.05$) but decreased milk protein concentration (3.56, 3.54, 3.47%; $P < 0.01$) for CON, 1.5% EO, and 3.0% EO, respectively. Compared with CON, the concentration of total saturated FA in milk fat decreased with increasing EO supplementation (73.7, 72.4, and 71.1 g/100 g FA, $P < 0.0001$). Increasing EO supplementation increased milk fat concentration of total n-3 FA (0.49, 0.65, 0.81 g/100 g FA, $P < 0.0001$), α-Linolenic acid (18:3 n-3) (0.38, 0.47, 0.58 g/100 g FA, $P < 0.0001$), and SDA (0.02, 0.06, 0.09 g/100 g FA, $P < 0.001$) for CON, 1.5% EO, 3.0% EO, respectively. For 1.5% EO and 3.0% EO milk fat concentration of EPA was 0.05 g/100 g FA vs. 0.03 g/100 g FA for CON ($P < 0.0001$). DHA was not detected in milk fat. Transfer of SDA from the EO supplement into milk fat was 3.4% and 3.2% for the 1.5% and 3% EO treatments, respectively. In conclusion, supplementation with a lipid-encapsulated EO did not negatively impact lactational responses and increased the concentration of n-3 FA in milk fat. The concentration of n-3 FA in milk fat however, was still a minor component of total milk FA.

Key Words: n-3 fatty acid, milk fat, echium oil

0354 Effects of dietary crude protein level on nitrogen use efficiency and urinary nitrogen excretion during a twelve-week period in late lactation dairy cows.

T. Barros*[1], M. A. Quaassdorff[1], J. J. Olmos Colmenero[2], M. J. Aguerre[1], S. J. Bertics[1], and M. A. Wattiaux[1], [1]*University of Wisconsin, Madison,* [2]*University of Guadalajara, Tepatilan, Mexico.*

Our objectives were to determine the impact of decreasing levels of dietary CP and whether there was a treatment by week interaction on intake-N, milk-N (DHI true protein), N use efficiency (NUE, milk-N/intake-N), MUN, and responses related to urinary excretion in late lactation cows. One hundred twenty-eight Holstein cows (means ± SD; 736 ± 18 kg BW; 224 ± 54 DIM) were used in a 16-pen study with 8 cows

per pen, and fed a TMR once per day (at 8:00 am) for 12 wk (pen = experimental unit). Treatments which included diets of 11.8, 13.1, 14.6, or 16.2% CP (DM basis) were randomly allocated to pen for the entirety of the experiment. Rations consisted of approximately 67% forage (half corn silage; half alfalfa silage); soy hulls replaced soybean meal to achieve the desired dietary CP levels for each treatment. Urine volume was estimated using creatinine concentration in spot urine samples collected 6 h before feeding for a group of four randomly selected cows in each pen. This protocol was repeated 6 h after feeding. LS-means of pen-level data presented in the table were obtained on week 2, 8, and 12. Except for urine volume, there was a linear effect for all responses but there were no quadratic effects. There was a treatment by week interaction for most responses. Regardless of treatment, NUE was high and urinary urea-N excretion was low. Under the conditions of this experiment, the 14.6% CP diet allowed for a reduction in urinary urea-N without affecting milk-N.

Key Words: protein nutrition, MUN, urinary urea

Table 0354. Effect of dietary CP on measured responses

	Dietary CP (DM basis)					*P*-value[1]	
Item	11.8	13.1	14.6	16.2	SEM	L	Trt*wk

0355 Evaluation of a handheld device for the detection of β-hydroxybutyrate pre-calving in dairy cattle.

E. H. Tatone*, J. L. Gordon, S. J. LeBlanc, and T. F. Duffield, *University of Guelph, Guelph, ON, Canada.*

Individual and herd ketone levels are commonly monitored in dairy cattle post-partum to identify individuals at-risk of metabolic disease and to identify potential improvements to management factors. The Precision Xtra handheld meter has been validated for use in β-hydroxybutyrate (BHBA) measurements post-calving as a convenient cow-side test for ketonemia. Recent research has identified BHBA cut points pre-partum associated with increased risk of post-partum disease, but at much lower cut-offs than those indicating hyperketonia after calving: 0.6 to 0.8 mmol/L in comparison to 1.0 to 1.4 mmol/L. The objective of the current research is to validate the handheld device, Precision Xtra, in the measurement of BHBA in whole blood against the gold standard method, laboratory evaluation of serum, to assess its diagnostic accuracy in detecting BHBA pre-calving in the range of 0.6 to 0.8 mmol/L. As part of a larger study, 212 cows in 6 herds across southern Ontario were sampled between 3 and 9 d before the expected calving date. Blood was collected and tested on-site with the Precision Xtra device. The serum portion of the sample was separated and sent to a laboratory for measurement of BHBA and non-esterified fatty acid (NEFA) concentrations. The results of the two BHBA measurement methods were compared and evaluated with concordance coefficients. The sensitivity and specificity of the Precision Xtra were determined with receiver operator characteristic curves at cut points of 0.6, 0.7 and 0.8 mmol/L. The two tests had a moderate concordance correlation of 0.77 ± 0.03 (CI_{95}: 0.72 − 0.83) and the area under the curve for each cut point was high with values between 0.90 and 0.93. The Precision Xtra had sensitivities of 85 to 93% and specificities of 76 to 87% depending on the cut point tested. The level of agreement between Precision Xtra cut points and at-risk pre-calving NEFA concentrations of 0.4 and 0.5 mEq/L was calculated. The level of agreement between Precision Xtra BHBA concentrations ≥ 0.8 mmol/L and NEFA concentrations ≥ 0.5 mEq/L was substantial, with a kappa of 0.64. Based on the moderate level of correlation and the good level of sensitivity and specificity, the Precision Xtra is a valid tool in the detection of elevated BHBA pre-calving and may be helpful in identifying individuals at risk of metabolic disease.

Key Words: ketosis, β-hydroxybutyrate, diagnostic test evaluation

0356 Effects of dietary nitrate supplementation on enteric methane and nitrous oxide emissions from beef cattle.

C. J. Neumeier*[1], Q. Wang[1], A. R. Castillo[2], Y. Zhao[1], Y. Pan[1], and F. M. Mitloehner[1], *[1]University of California, Davis, [2]University of California Cooperative Extension, Merced.*

Feeding nitrate has been proposed as a means to reduce enteric greenhouse gas emissions from ruminants. Nitrate can compete with methanogens for hydrogen in the rumen and therefore reduce methane from eructation. However, increasing the nitrate concentration in the rumen could induce enteric nitrous oxide emissions, potentially nullifying the greenhouse gas reduction achieved from lowering methane emissions. The present study investigated the effects 2% nitrate (on DM basis) versus an isonitrogenous concentration of urea supplemented to finishing steers on enteric methane and nitrous oxide emissions. Sixteen steers were allocated to nitrate and urea treatments in a randomized complete block design ($n = 8$). Eructated emis-

sions were collected using head chambers for 12 h following the morning feeding. Methane was measured using the TEI 55C direct methane analyzer and nitrous oxide using the 46i nitrous oxide analyzer (both were Thermo Environmental Instruments, Franklin, MA). All data were analyzed using the Proc Mixed Model in SAS. The nitrate versus urea treatment lowered methane production at measurement h 1 and 2 ($P < 0.01$), but did not lower overall methane production during the 12 h measurement period. The nitrate versus urea treatment increased nitrous oxide production at h 1, 2, and 3 ($P < 0.05$) of measurement and the overall 12 h measurement period ($P < 0.0001$). Nitrous oxide was detected in both treatments at each time point, with a sixfold increase in production in the nitrate (~600 mg/12 h) versus urea treatment (~100 mg/12 h). Overall, combined greenhouse gas production expressed as carbon dioxide equivalents was similar between treatments. This study indicates that nitrate supplementation in finishing beef cattle is effective at reducing eructated methane in the time immediately following feeding, and might need to be supplemented at a higher concentration and/or more frequently to achieve more optimal methane reduction. Furthermore, this study suggests that cattle could be a source of the potent greenhouse gas nitrous oxide, which is further stimulated by nitrate supplementation. Additional research is necessary to evaluate more effective means of reducing methane with nitrate in finishing beef cattle and the production of nitrous oxide with and without supplementation of nitrate.

Key Words: greenhouse gas, hydrogen sink, ruminant

0357 Early pair housing influences the feeding behavior and development of dairy calves. J. H. C. Costa*, R. K. Meagher, M. A. von Keyserlingk, and D. M. Weary, *Animal Welfare Program—University of British Columbia, Vancouver, BC, Canada.*

Calves are social and gregarious animals. Pre-weaned calves are typically kept in individual pens but little is known about how individual versus social rearing affects development of feeding behavior. The aim of this study was to assess the effects of early and late pairing feeding behavior and weight gain before and after weaning. Holstein bull calves were reared individually ($n = 8$ calves) or paired with another calf at 3 d of age ($n = 8$ pairs) or 42d of age ($n = 8$ pairs). All calves were fed 8 L of milk/d for 4 wk, 6 L/d from 4 to 6 wk and weaned at 8 wk of age. Calves were provided ad libitum access to calf starter and a total mixed ration (TMR). Body weight and feed consumption were followed weekly from 6 wk until 10 wk of age. At 6 wk, intake of TMR averaged (± SEM) 0.25 ± 0.05 Kg/d, 0.41 ± 0.12 Kg/d, 0.32 ± 0.09 Kg/d, for individual, and early paired late paired housed calves, respectively. Starter intake was similar for the individually reared and late-paired calves (0.09 ± 0.03 Kg/d and 0.04 ± 0.01 Kg/d) but higher for the early-paired calves (0.23 ± 0.07 Kg/d). Consumption increased after weaning in all treatments, but this increase was greatest for the early-paired calves. At 10 wk of age, TMR intake averaged 2.89 ± 0.54 Kg/d, 3.27 ± 0.72 Kg/d and 3.08 ± 0.46 Kg/d for individual, early paired and late paired housed calves, respectively. Starter intake averaged 1.26 ± 0.33 Kg/d, 2.20 ± 0.22 Kg/d and 1.09 ± 0.25 Kg/d for the same three treatments. Calves in the early pair treatment showed higher average daily gains (1.13 ± 0.05 Kg/d versus 0.92 ± 0.04 Kg/d and 0.84 ± 0.05 Kg/d for the individual and late-paired calves). Pair housing soon after birth increased calf feed intake and weight gains in comparison with late pairing and individual housing.

Key Words: feeding behavior, group housing, dietary transition

0358 Epigenetic differences of cows classified with biased antibody and cell mediated immune response traits. M. A. Paibomesai*[1] and B. Mallard[2], [1]*University of Guelph, Guelph, ON, Canada,* [2]*Dept Pathobiology, University of Guelph, Guelph, ON, Canada.*

The identification of cattle that are better able to respond immunologically to pathogens would be useful to reduce the incidence of disease on commercial dairy farms. High Immune Response (HIR) technology provides a unique tool to rank animals based on their ability to respond to test antigens, and high ranking dairy cows have been shown to have a lower incidence of disease. HIR evaluates two branches of the adaptive immune response: the antibody mediated immune response (AMIR, prominent IL-4 production) which responds primarily to extracellular pathogens, and the cell mediated immune response (CMIR, prominent IFN-g production), which responds primarily to intracellular pathogens. Genetic control of the immune response has been well studied in past years, but epigenetic influences on phenotype remain to be defined. Epigenetics is defined as modifications to DNA that control gene expression without changing the DNA sequence. Specifically, DNA methylation, an epigenetic modification, is associated with a decrease in gene transcription, while the lack of DNA methylation is associated with increased gene expression. CD4+ helper T cells are mediators of AMIR and CMIR, producing cytokines, such as IL-4 and IFN-γ, for the direction of an appropriate response. Biased immune responder cattle respond strongly with either high AMIR (H-AMIR) or high CMIR (H-CMIR) to test antigens. Cows with H-AMIR/L-CMIR (H-AMIR; $n = 10$) and H-CMIR/L-AMIR (H-CMIR; $n = 11$) phenotypes were used to investigate mechanisms of immune response variation and the role of epigenetics in cattle immune response traits. Isolated CD4+ helper T cells from H-CMIR and H-AMIR cows were stimulated with a T cell mitogen (ConA) and cell culture supernatants were harvested at 24 h to quantify IL-4 and IFNγ by ELISA. DNA was extracted from unstimulated and stimulated cells and bisulfite pyrosequencing was used to quantify DNA methylation for both IL-4 and IFNγ promoters. CD4+ T cells from H-CMIR cows pro-

duced more IFN-γ ($P = 0.059$), and significantly more IL-4 ($P = 0.02$) than T cells from H-AMIR cows, when sampled 21 d into lactation. In H-CMIR cows higher secretion of IFN-γ was associated with decreased methylation in the promoter region of the IFNγ gene compared to H-AMIR cows ($P = 0.01$). In contrast, there was no difference in DNA methylation at the IL-4 promoter observed between the two immune response phenotypes. This study is the first to show an association between DNA methylation and specific phenotypes.

Key Words: immune response, epigenetics, dairy cows

0359 Changes in activity and milk components around onset of clinical mastitis. A. S. Griffith*, M. L. McGilliard, and C. S. Petersson-Wolfe, *Virginia Tech University, Blacksburg.*

The objectives of the current study were to identify early indicators of naturally-occurring clinical mastitis in the first 30 DIM using peripartum daily activity, postpartum milk components, and milk yield data. A total of 200 cows that consisted of 136 Holstein (60 primiparous, 76 multiparous), 59 Jersey (24 primiparous, 35 multiparous), and 5 Crossbred (5 multiparous) animals were followed from January 2013 through September 2013. Daily activity was collected from 21 d prepartum to 30 d postpartum for all animals with a behavioral monitoring system (Afi PedometerPlus, S.A.E. Afikim, Israel), which collected rest bouts, rest duration, rest time and step activity. Daily milk lactose % and fat:protein ratio were collected from 4 to 30 DIM for all animals, using an in-line milk analysis system (AfiLab, S.A.E. Afikim, Israel) and daily yield was collected from the milk meter. Mastitis was defined as visual changes in milk appearance (flakes, chunks, or color) in one or more quarters as detected by the milk harvesters at the time of milking. Controls were defined as any animal in the same group, parity (1 or $\geq$ 2), and breed on the same date as the diseased cow, that did not experience any disease within the first 30 DIM. Differences between diseased and controls from d -7 to d 7 relative to disease, were examined using PROC GLIMMIX in SAS (Cary, NC). Lactation number, day relative to disease, disease status, and their interactions were included in the model. Significance was determined at $P \leq 0.05$. Animals that experienced mastitis ($n = 15$) showed more daily steps from d -5 to 0 and fewer daily rest bouts on d -1 and 0 relative to disease, compared to controls. Additionally, diseased cows showed reduced milk lactose % compared to controls from d -1 to 2 relative to disease and daily yield was decreased from d -2 to 1. Finally, no differences were found in daily rest time, rest duration or fat:protein ratio. This is the first study to show changes in activity and milk components before the onset of naturally-occurring clinical mastitis in early lactation. The identification of animals at risk for periparturient disease may allow producers to implement a proactive strategy for disease treatment, improve animal well-being and alleviate the economic losses associated with health problems during the transition period.

Key Words: mastitis, daily activity, milk components

0360 Predicting impending calving using automatically collected measures of activity and rumination in dairy cattle. M. R. Borchers*, A. E. Sterrett, B. A. Wadsworth, and J. M. Bewley, *University of Kentucky, Lexington*.

The objective of this study was to monitor behavioral changes in prepartum dairy cattle and predict impending calvings through the automated observation of activity and rumination. Data collection for 29 primiparous and 46 multiparous Holstein dairy cattle occurred from September 13, 2011 through May 16, 2013 at the University of Kentucky Coldstream Dairy. The HR Tag (SCR Engineers, Ltd., Israel) was used to automatically collect neck activity and rumination data in 2-hour increments. The IceQube (IceRobotics, Ltd., Scotland) collected hourly step number, hours lying, hours standing, lying bouts, and total motion data. Data collection occurred for 7 wk prepartum and retrospective data analysis was performed using SAS (Cary, NC). Data summed by day for each cow was included in the calculation of a 7-d backward moving average and standard deviation to establish each cow's baseline values. Least-squares means were calculated from moving averages using the MIXED procedure of SAS. Parameters exhibiting significant differences ($P < 0.05$; mean ± SE) on the day of calving (DAY^0) versus the day before (DAY^{-1}) included: hours lying (DAY^0: 10.15 ± 0.25 vs. DAY^{-1}: 10.50 ± 0.25), hours standing (DAY^0: 13.79 ± 0.25 vs. DAY^{-1}: 13.47 ± 0.25), lying bouts (DAY^0: 11.36 ± 0.38 vs. DAY^{-1}: 9.86 ± 0.38), and minutes ruminating (DAY^0: 319.29 ± 12.01 vs. DAY^{-1}: 336.86 ± 12.01). Neck activity, step number and total motion showed no significant differences between DAY^0 and DAY^{-1}. Z-scores were calculated using data summed by day for each cow, moving averages, and moving standard deviations. Deviations $\geq$ 1.5 from the mean dictated alert creation. The percent of cows ($n = 61$) showing an alert by parameter on DAY^0 was: lying bouts (75.4%), minutes ruminating (45.9%), step number (39.3%), total motion (39.3%), hours standing (32.8%), hours lying (31.1%), and neck activity (21.3%). In comparison, the percent of cows ($n = 57$) showing an alert by parameter on DAY^{-1} was: lying bouts (15.8%), minutes ruminating (15.8%), step number (17.5%), total motion (15.8%), hours standing (28.1%), hours lying (28.1%), and neck activity (12.3%). Changes in least-squares means and alerts relative to calving indicate that these measures may be useful in predicting impending calvings without adding new technologies or parameters, but further research is necessary.

Key Words: calving prediction, days before calving, activity and rumination

0361 Glucose metabolism by bovine neutrophils characterized by mass spectrometry and [$^{13}C_6$] glucose. Y. Qu*[1], B. J. Bequette[1], T. H. Elsasser[2] and K. M. Moyes[1], [1]*Department of Animal and Avian Sciences, University of Maryland, College Park,* [2]*USDA/ARS Growth Biology Lab, Beltsville, MD.*

At the present time, the metabolic priority for and subsequent pathway fate of glucose by bovine blood neutrophils (BBN) is unknown. During early lactation, glucose availability is low. Consequently, a resulting energy-compromised state may partly explain the lack of robust immune response observed at this time. The objective of this study was to characterize the metabolic utilization of glucose by BBN from dairy cows in early and mid-lactation by incubation of BBN with [$^{13}C_6$] glucose followed by gas chromatography–mass spectrometry (GC–MS). Jugular blood (~150 mL) was collected from 4 healthy multiparous dairy cows in early (n = 2; < 21 d in milk) and mid-lactation (n = 2; > 90 d in milk). The BBN were isolated and adjusted to a final concentration of 6×10^6 cells/mL using RPMI/5% fetal bovine serum containing 4 mM of a 50:50 mix of unlabeled and ^{13}C-labeled glucose. Cells were incubated for 2 h at 37°C, 95% humidity, and 5% CO_2. Nonessential AA in metabolic equilibrium with Krebs cycle intermediates and lactate in BBN were monitored by GC–MS. Data were analyzed by the student's t test for unpaired comparison. Significance was declared at $P \leq 0.05$. No stage of lactation effect was observed. Although 43% of the pyruvate pool derived from glucose, a small proportion of this pool entered the Krebs cycle. Our results suggest that the pyruvate carboxylase flux was minimal and only 5% of the acetyl-CoA pool was derived from the pyruvate pool. In conclusion, although BBN exhibit high rates of glycolysis, glucose is not the main substrate oxidized for energy in the Krebs cycle, and perhaps other extracellular substrates (e.g., fatty acids, glutamine, aspartate) are preferred. Future studies are needed to examine the metabolic utilization of other substrates and their influence on the function of BBN.

Key Words: cow, glucose, neutrophil

0362 Exploring the Molecular diversity and density of the rumen microbiome within the impala (*Aepyceros melampus melampus*) from Pongola, South Africa. L. M. Cersosimo*[1], B. St-Pierre[1], W. van Hoven[2], and A. D. G. Wright[1], [1]*The University of Vermont, Burlington,* [2]*University of Pretoria, Pretoria, South Africa.*

The rumen microbiome of domesticated ruminants has been studied extensively, but few studies have explored the microbiome of wild ruminants and no studies have used a metagenomic approach to examine the rumen microbiota within the impala (*Aepyceros melampus melampus*). Impala, like all domesticated ruminants, have a consortium of anaerobic microorganisms inhabiting their foregut (i.e., the rumen) that contribute to the feed efficiency of the animal, as well as greenhouse gas emissions. The present investigation seeks to expand our knowledge about the rumen microbial community of the impala while drawing comparisons to their domesticated relatives that could lead to advances in both feed efficiency and methane mitigation strategies. The rumen contents from 4 male impala culled in the Kwazulu-Natal province of Pongola, South Africa, were collected postmortem. Once bacterial and archaeal amplicons were generated, next-generation sequencing techniques (i.e., Roche 454-pyrosequencing) were used to identify the diversity of bacterial and methanogenic archaeal (i.e., methanogens) 16S rRNA gene sequences. Real-time PCR amplification of the 16S rRNA gene was used to estimate the density of the bacterial population (R^2 = 0.997), while the mcrA (methyl coenzyme-M reductase) gene was used to estimate the density of the methanogen population (R^2 = 0.997). Using the bioinformatic platform, MOTHUR, a total of 20,124 methanogen sequence reads were assigned to 344 operational taxonomic units (OTUs) using a sequence identity cutoff of 3%. A high sampling efficiency was observed with OTU coverages > 99% for each individual impala, along with similar Shannon indices of 1.90 ± 0.003. The Ribosomal Database Project (RDP) Classifier classified 94.3% of the reads to the genus *Methanobrevibacter,* 4.2% of the reads to the genus *Methanosphaera*, with the remaining 1.5% of the reads being unclassified. Most notably was the abundance of *Methanobrevibacter thaueri*-related methanogen sequence reads in all 4 impala samples, representing > 30% of each animal's total sequences. This high abundance of *Methanobrevibacter thaueri*-related methanogen sequences has not been observed in previous studies of domesticated or wild ruminants, suggesting that either the diet and/or the rumen physiology of the impala may differ from previously studied ruminants. The diversity of the rumen bacteria will also be elucidated and discussed. Future studies to look at other factors that affect the rumen environment, like gender, should be performed to see if these findings are consistent.

Key Words: methanogens, bacteria, impala, rumen, *Methanobrevibacter*, operational taxonomic units

0363 Effects of ground flaxseed on milk production, milk composition, and methane emissions in organically-managed Jersey cows during the grazing season. B. J. Isenberg*[1], A. F. Brito[1], A. B. D. Pereira[1], N. L. Whitehouse[1], R. B. Standish[1] and K. J. Soder[2], *[1]University of New Hampshire, Durham, [2]USDA-Agricultural Research Service, University Park, PA*

Our previous research feeding incremental levels of ground flaxseed (GFLAX; 0, 5, 10, or 15% of diet DM) to organically-managed Jersey cows linearly reduced yields of milk and milk components, DMI, and enteric CH_4 emissions. While milk yield did not differ significantly between 0 and 10%, 10% GFLAX significantly increased n-3 fatty acids and conjugated linoleic acid. Flaxseed is rich in n-3 fatty acids and energy; energy is a limiting factor to milk production in pasture-based diets. This study evaluated impacts of supplementing pasture with 10% of diet DM as GFLAX to Jersey cows on milk production and composition, and enteric CH_4 emissions. Twenty multiparous lactating organically managed Jersey cows, averaging 408 kg BW and 112 d in milk (DIM), were blocked by milk production and DIM and randomly assigned to 1 of 2 treatments: (1) control (soybean meal and ground corn grain mix as 10% of total DMI) or (2) ground flaxseed as 10% of total DMI. Treatments were top-dressed onto a 25% mixed grass-legume baleage, 23% grain meal, and 2% liquid molasses TMR (% of diet DM); pasture composed the remaining 40% DMI. The study extended from June 8 to September 27, 2013 with four 28-d periods, with the last 7 d used for data and sample collection. Data were analyzed using the MIXED procedure of SAS (SAS Inst. Inc., Cary, NC) with repeated measures over time; no treatment × period interaction was observed. Cows had access to mixed grass-legume pastures for about 16 h daily in a rotational strip grazing system. Cows were milked twice daily with milk production recorded each time. Milk samples were collected for 2 consecutive days and analyzed for fat and protein. A portable automated head chamber system was used for assessing CH_4 fluxes. Milk production did not differ significantly in cows supplemented (17.6 kg/d) or not (18.2 kg/d) with GFLAX. Similarly, concentration and yield of milk components did not differ significantly, averaging 4.20% and 0.76 kg/d for milk fat and 3.45% and 0.61 kg/d for milk protein. Intake of TMR was lower ($P < 0.01$) in cows with (10.5 kg/d) or without (10.8 kg/d) GFLAX supplementation. Methane emissions did not differ significantly, averaging 299 g cow^{-1} d^{-1} (control diet) and 295 g cow^{-1} d^{-1} (GFLAX diet). Feeding 10% of total DMI as GFLAX to grazing dairy cows had no negative impact on milk production and composition, but did not mitigate CH_4emissions under conditions of the current experiment.

Key Words: pasture, ground flaxseed, methane

0364 Farm-level evaluation of implementing feeding best management practices (BMP) on Pennsylvania dairy farms. H. L. Weeks*, T. W. Frederick, L. M. Hagan, K. S. Heyler, and A. N. Hristov, *Department of Animal Science, The Pennsylvania State University, University Park, PA*

Feeding best management practices (BMP) can have a significant impact on the environmental footprint of dairy farms. The objective of this study was to evaluate the environmental and productive effects of implementing feeding BMP on commercial dairy farms in Pennsylvania. Fifteen farms (124.8 ± 20.5 ha, 169 ± 39 cows, and 31.4 ± 0.2 kg cow^{-1} d^{-1} milk production) in central and southeast Pennsylvania participated in the study. A set of 4 background total mixed ration (TMR), forage, milk, feces, urine samples, as well as feed intake and production data, were collected from each cooperator farm biweekly between January and March of 2013 (preBMP period). Following the implementation of applicable feeding BMP, chosen by the producer, including reduction of dietary crude protein (CP; $n = 9$) and P ($n = 5$), adjusting rations for changes in forage dry matter ($n = 10$), and group feeding of the lactating herd ($n = 2$), another set of 4 sampling and data collection events took place between June and August of 2013 (postBMP period). Data were analyzed using the MIXED procedure of SAS (SAS Inst. Inc., Cary, NC) with farm as a random effect. On farms in which dietary CP was reduced (from 17.2 to 15.9%; $P < 0.01$), fecal N (FN; 2.78 vs. 2.63%; $P = 0.01$), total urinary N (UN; 0.071 vs. 0.055%; $P < 0.01$), urinary urea N (UUN; 52.2 vs. 44.4mg/dL; $P < 0.01$), and milk urea N (MUN; 16.9 vs. 13.9 mg/dL; $P < 0.01$) decreased (pre- vs. postBMP, respectively). Only 3 farms successfully decreased dietary P (from 0.42 to 0.40; $P < 0.01$), which resulted in decreased fecal P concentration (0.85 vs. 0.69; $P < 0.01$). Group feeding was implemented on 2 farms. The average CP of the rations fed on these farms decreased from 15.7 to 14.4% ($P = 0.03$), which resulted in decreased, UN (0.077 vs. 0.048%; $P < 0.01$), UUN (56.1 vs. 36.9 mg/dL; $P < 0.01$), and MUN (17.4 vs. 13.7 mg/dL; $P = 0.03$). Milk production and DMI were not affected by BMP implementation. Bulk tank milk fat (3.91 vs. 3.56%; $P < 0.01$) and milk protein (3.13 vs. 2.98%; $P < 0.01$) decreased from pre- to postBMP on all farms, perhaps due to seasonal effects. In conclusion, reduced dietary CP decreased N concentrations in urine and feces and reduced dietary P decreased fecal P concentration on commercial dairy farms.

Key Words: dairy farm, dietary protein, dietary phosphorus

0365 The impact of dairy advisory teams on farm improvement in Pennsylvania dairies. M. H. Buza*, L. Holden, and R. C. Goodling, *The Pennsylvania State University, University Park, PA*

Dairy producers continuously seek ways to improve their farm, and many choose to form a dairy advisory team (DAT) to improve management. The objectives were: (1) to compare key measures before and after the team to determine if the use of a DAT was effective, and (2) to compare a group of 20 herds with a DAT to Pennsylvania (PA) averages for key measures. Teams were formed between May 2008 and January 2013. The range for herd size was 42 to 694 ± 139 cows. Herd size, milk yield, somatic cell score (SCS), peak milk yield, age at first calving (AFC), days in milk (DIM), pregnancy rate, and cull and mortality rate were key measures analyzed. The changes in key measures, after using DAT for at least 1 yr, were analyzed using a paired *t* test. After DAT use, herds had higher ($P < 0.01$) herd sizes (187 vs. 177 cows) and higher ($P = 0.066$) milk yields of 31.3 vs. 32.1 kg, as well as lower ($P = 0.077$) AFC of 24.9 vs. 25.4 mo and lower ($P = 0.054$) percent of herd with SCS $\geq$ 4 of 21.7 vs. 23.9%. The DAT herds' January Dairy Herd Improvement Association (DHIA) test data were compared with Dairy Metric's PA average for January 2014 using a 1-sample *t* test. Farms with DAT had significantly ($P < 0.05$) higher milk yield of 33.9 vs. 31.9 kg and peak milk yield for lactation 1 with 36.1 vs. 33.9 kg. There was no significant difference between the averages for DAT herds and PA herds for peak milk yield in older cows, but DAT herds had numerically higher peaks (44.3 vs. 42.7 kg and 47.4 vs. 45.9 kg for second and third lactation, respectively) in older cows. Herds with DAT had significantly ($P < 0.001$) lower AFC of 24.4 vs. 25.6 mo and lower percentage of herd with SCS $\geq$ 4 with 20.15 vs. 26.6%. There were no differences for pregnancy rate, DIM, or cull or mortality rate. Use of DAT led to larger herd size, greater milk yield, lower AFC, and better SCS. Herds with DAT had higher milk yield, lower AFC, and better SCS compared with PA averages. Use of a DAT was beneficial to dairy farms.

Key Words: dairy advisory team, dairy herd improvement, dairy herd key measures

0366 Plant-derived compounds, trans-cinnamaldehyde and eugenol, reduce adhesion and invasion of *Staphylococcus aureus* in bovine mammary epithelial cells in vitro. D. Jaganathan*[1], A. Kollanoor-Johny[1], K. Vekitanarayanan[1], G. W. Kazmer[1], L. Kuo[2], Y. B. Wang[2], and K. E. Govoni[1], *[1]Department of Animal Science, University of Connecticut, Storrs, [2]Department of Statistics, University of Connecticut, Storrs.*

Staphylococcus aureus is 1 of the major bacterial pathogens involved in ruminant mastitis globally. The disease has major impacts on animal health and milk quality leading to severe economic losses to the dairy industry. *S. aureus* adhesion to and invasion of mammary epithelial cells (MEC) is critical for the establishment of the disease. We hypothesized that 2 plant-derived antimicrobials, *trans*-cinnamaldehyde (TC) and eugenol (EG), would reduce *S. aureus* adhesion to and invasion of primary bovine MEC in vitro. Mammary epithelial cells were isolated from mammary glands of lactating cows postslaughter and were characterized using multicytokeratin immunostaining. Confluent MEC monolayers were inoculated with 4 *S. aureus* strains (Strain ST 35, Thorn 17, 15, and M9175) at mid-log phase separately (multiplicity of infection– 100:1) either in the presence or absence (control) of subinhibitory concentrations (SICs: greatest concentration that did not inhibit bacterial growth) of TC (0.006%) and EG (0.03%), and incubated for 2 h for bacterial adhesion. Infected cells were treated with gentamicin (100 µg/mL) for 1 h at 37°C for enumerating invaded bacteria. All experiments included duplicate samples and were repeated 3 times. Data were analyzed using PROC ANOVA and significance determined at $P < 0.05$. For strain Thorn 17, pre-exposure of *S. aureus* (5 h) and MEC (12 h) to EG reduced *S. aureus* adhesion to and invasion of MEC by ~1.6 ± 0.01 $\log_{10}$ CFU/mL (control = 6.67 ± 0.01 $\log_{10}$ CFU/mL; $P < 0.0001$) and 2.8 ± 0.11 $\log_{10}$ CFU/mL (control = 3.9 ± 0.02 $\log_{10}$ CFU/mL; $P < 0.0001$), respectively. Preexposure of *S. aureus* and MEC to TC reduced *S. aureus* adhesion to and invasion of MEC by ~2.2 ± 0.02 $\log_{10}$ CFU/mL (control = 6.7 ± 0.02 $\log_{10}$ CFU/mL; $P < 0.0001$) and 2.85 ± 0.08 $\log_{10}$ CFU/mL (control = 3.94 ± 0.01 $\log_{10}$ CFU/mL $P < 0.0001$), respectively. Similar results were observed with strains ST 35, M9175 and Thorn 15. In conclusion, SICs of TC and EG reduced *S. aureus* adhesion to and invasion of MEC. In vivo studies using a mammalian model to validate these results are warranted.

Key Words: mammary epithelial cells, plant compound, *Staphylococcus aureus*

0367 Effect of dietary supplementation of *Capsicum* extract on feed intake, milk production and composition, rumen fermentation, and rumen microbial populations in dairy cows. J. Oh*[1], F. Giallongo[1], H. L. Weeks[1], T. W. Frederick[1], A. N. Hristov[1], and E. H. Wall[2], *[1]Department of Animal Science, The Pennsylvania State University, University Park, PA, [2]Pancosma, Geneva, Switzerland*.

Dietary supplementation of *Capsicum* extract (CE) has been reported to increase feed intake and modify ruminal fermentation in cattle. The objective of this experiment was to investigate the effects of CE on feed intake, digestibility, N utilization, milk performance, ruminal fermentation, and ruminal microbial diversity in lactating dairy cows. Eight multiparous Holstein cows (days in milk, 50 ± 9.6 d; BW, 591 ± 32.6 kg), including 3 ruminally-cannulated, were used in a replicated 4

× 4 incomplete Latin square design with 25-d periods. Treatments were 0 (CON), 250, 500, and 1000 mg CE cow^{-1} d^{-1}. The CE was mixed with a small portion of the TMR and top-dressed. Apparent total tract digestibility was not affected by treatment. Treatments also had no effect on urinary-N, urea-N, urinary purine derivatives, and fecal-N excretions. Milk yield tended to quadratically increase (P = 0.08, SEM = 0.86) with CE: 50.5, 51.9, 51.5, and 50.3 kg/d, respectively. Dry matter intake was not affected by CE (27.0 ± 0.64 kg/d). Feed efficiency tended to increase quadratically (P = 0.08; SEM = 0.047) with CE supplementation: 1.90, 1.93, 2.02, and 1.96 kg/kg, respectively. Milk fat yield increased (P = 0.05) for CE treatments compared with CON (1.58 vs. 1.46 kg/d, respectively). Relative to CON, CE increased (P = 0.04) 4% FCM and tended to increase (P = 0.06) energy corrected milk yields. Concentration of milk lactose was decreased (P = 0.01) by CE. Compared with CON, concentration of β-hydroxybutyrate (BHBA) in blood plasma tended to be higher (P = 0.07) for CE and quadratically responded (P = 0.02) to CE supplementation level. Plasma NEFA was not affected by CE. Ruminal pH tended to be decreased (P = 0.06) by CE compared with CON. Ruminal ammonia and VFA concentrations were not affected by treatment, although acetate tended to linearly decrease (P = 0.11) with CE. Predominant bacteria in rumen contents were *Ruminococcaceae* spp. and *Prevotella* spp. (10.8 to 22.6% of the total population). Compared with CON, *Prevotella* spp., *Butyrivibrio* spp., and *Roseburia* spp. were decreased ($P \leq$ 0.05) by CE. In conclusion, feed intake, total tract digestibility of nutrients, and N utilization were not affected by dietary CE supplementation. However, CE increased milk production, milk fat yield, and plasma BHBA concentration. Collectively, these results suggest that CE may increase lipid mobilization for milk fat synthesis in dairy cows.

Key Words: capsicum extract, feed intake, milk production

0368 The effects of CO_2 and HEPES buffer on in-vitro chemotaxis assays of bovine neutrophils.

A. M. Barnard*, R. Nebenhaus, R. M. Dyer, and T. F. Gressley, *University of Delaware, Newark.*

Neutrophil (PMN) chemotaxis can be measured in vitro with or without 5% CO_2. The production of carbonic acid during incubation with 5% CO_2 may reduce pH, possibly affecting cellular migratory function. The goals of this study were to determine whether incubation with 5% CO_2 impacts PMN chemotactic function, and if the addition of HEPES buffer affects response to CO_2. Neutrophils were isolated from 12 lactating cows over 5 different test dates and cell concentration adjusted to 2 × 10^6 cells/mL. Media consisted of HBSS containing 5% FBS with or without the addition of 10 mM HEPES. The bottom wells of a 48-well chemotaxis chamber (Neuro Probe Inc., Gaithersburg, MD) contained 28 µL of media supplemented with 50 ng/mL of complement component 5a (C5a) or 100 ng/mL of Interleukin-8 (IL-8). A 5 µm polycarbonate membrane separated the top and bottom wells. Neutrophil suspension (50 µL) was added to the top wells, and the chambers were incubated at 37°C for 1 h, in the presence or absence of 5% CO_2. Negative controls did not contain chemoattractant in either well while positive controls contained 50 ng/mL C5a in both top and bottom wells. Raw adherence (RawAd) was determined by counting PMN adhered to the bottom of the membrane in 5 microscope fields per well. Relative adherence (RelAd) was calculated as (RawAd test well)/(RawAd negative control well) × 100%. Data were analyzed using the Glimmix procedure of SAS (SAS Inst. Inc., Cary, NC) with the fixed effects of HEPES, CO_2, chemoattractant and all interactions and random effects of date and cow within date. RawAd and RelAd were both affected by CO_2 (P = 0.03; 0.002, respectively) and chemoattractant (P = < 0.0001 and 0.0002, respectively). The presence of CO_2 caused a decrease in both RawAd and RelAd. For both RawAd and RelAd, chemotaxis towards C5a or IL-8 did not differ but both were greater than chemotaxis to controls. RawAd was also affected by CO_2 × chemoattractant (P = 0.02) and HEPES × CO_2 (P = 0.0001). RawAd for C5a or IL-8 wells was approximately twice that of control wells in the absence of CO_2, but was not significantly different from controls in the presence of CO_2. RawAd decreased in the presence of CO_2 when HEPES was not present, but was unaffected by CO_2 in the presence of HEPES. These results suggest that incubating PMN with CO_2 reduces the chemotactic response and that HEPES partially ameliorated this effect.

Key Words: neutrophils, chemotaxis, bovine

0369 The 2001 Dairy NRC Ration Evaluation Software effectively predicts dietary strong ion and DCAD concentrations in lactating dairy cow diets.

M. E. Iwaniuk* and R. A. Erdman, *University of Maryland, College Park*.

Recent research suggests that increasing DCAD concentration using buffers in lactating dairy cow diets results in increased milk yield and milk fat percentage. Dietary buffers, such as $NaHCO_3$ and K_2CO_3, alter DCAD concentration and have been used in lactating dairy cow diets for decades. However, most of the published work on buffer supplementation was conducted before the development of the DCAD concept. Thus, these data have not been included in previous metaanalyses of DCAD effects on dairy cow performance. One problem with the use of these data is the lack of measured concentrations for each of the minerals required for calculation of DCAD (Na + K– Cl, meq/kg DM). To overcome this obstacle, a study was conducted to determine if the 2001 Dairy NRC Ration Evaluation Software could be used to estimate missing dietary ion concentrations. Data from 44 journal articles on the effects of buffers and DCAD that were published from 1965 to 2011 were used in the study. Experimental diets where Na, K, and Cl concentrations were analyzed were used as test ob-

servations. Ingredient information for each diet was extracted from each article and entered into the 2001 NRC software to estimate dietary mineral concentrations. The NRC predicted Na, K, Cl, and DCAD were regressed on the respective measured concentrations and the regression statistics are reported. The root mean prediction square error (RMPSE) expressed as a fraction of the mean concentration was small. Chloride data were clustered in 2 distinct populations (0.25 to 0.5 and > 1.0%) which may have resulted in slope confidence intervals different from 1. However, the regression slopes for Na, K, and DCAD were not different from 1 ($P > 0.05$). Intercept values when significant (Na and Cl) were small compared with the mean concentration for each mineral. Residual plots indicated no mean or linear bias. In conclusion, the NRC software accurately estimated mineral and DCAD concentrations and could be used to estimate missing ion concentrations in future metaanalyses of DCAD experiments.

GROWTH & DEVELOPMENT

0370 Whole or ground oats in calf starters: Effects on rumen fermentation and rumen development.
F. X. Suarez-Mena*[1], A. J. Heinrichs[1], C. M. Jones[1], T. M. Hill[2], and J. D. Quigley[2], [1]*The Pennsylvania State University, University Park,* [2]*Provimi North America, Brookville, OH.*

A series of 3 trials were conducted to determine effects of whole or ground oats in starter grain on rumen fermentation and development of preweaned calves. Male Holstein calves (43.1 ± 2.3 kg BW at birth; n = 8, 9, and 7 for trials 1, 2, and 3 respectively) were housed in individual pens in a heated facility; bedding was covered with landscape fabric to avoid any consumption of bedding. In trials 1 and 2 only, calves were fitted with a rumen cannula by wk 2 of life. Water was offered free choice, and milk replacer was fed to 12% of birth BW. In all trials, a fixed amount of starter (containing 25% oats either ground and in the pellet or whole; 18.7% CP, 12.7% NDF) was offered daily based on average intakes of calves on similar milk replacer diets; orts were fed through the cannula in Trials 1 and 2. Calves were randomly assigned to all pelleted starter (Ground, n = 11) or pellets plus whole oats (Whole, n = 13). Rumen contents (Trials 1 and 2) were sampled weekly at −8, −4, 0, 2, 4, 8, and 12 h after grain feeding for pH and VFA determination. Calves were euthanized 3 wk (Trial 1) or 4 wk (Trials 2 and 3) after grain was offered; organs were harvested, emptied, rinsed, and weighed to gauge digestive organ development. Experimental design was complete randomized block. Starter intake was not different between treatments by design (P > 0.05); weekly intakes were 481 ± 24, 1575 ± 30, 3176 ± 48, 4656 ± 143 g for wk 1 to 4 of grain feeding. Weekly measurements of rumen digesta pH and molar proportion of individual VFA did not change with diet. Molar proportion of butyrate and pH linearly decreased with age, while acetate proportion increased. Reticulorumen weight (569 ground vs. 503 whole ± 24 g) and papillae length (0.75 ground vs. 0.68 whole ± 0.03 mm) tended to be greater for ground (P < 0.1) while abomasum weight (240 ground vs. 274 whole ± 9 g) was greater for whole (P < 0.05). Liver and omasum weights were not different. Under the conditions of this study, physical form of oats in starter grain did not affect rumen fermentation parameters; greater rumen weight and papillae length in Ground may be a result of greater nutrient availability of ground oats.

Key Words: rumen-development, oats

0371 Rumen epithelial gene expression in periruminant holstein bull calves fed a fermentation extract of *Aspergillus oryzae*.
T. T. Yohe*, K. M. O'Diam, and K. M. Daniels, *Department of Animal Sciences, The Ohio State University, Wooster.*

A fermentation extract of *Aspergillus oryzae* has previously been utilized as a direct fed microbial (DFM) to promote starter intake and feed efficiency in calves. Potential effects of this DFM on rumen epithelial gene expression are unknown, and may help explain some benefits of supplementation. The objective was to determine if age and dietary inclusion of an extract of *A. oryzae* alter relative abundance of select rumen epithelial genes in periruminant Holstein bull calves. The genes investigated encode proteins that specialize in: VFA transport (*MCT1*, *MCT2*, *MCT4*), intracellular regulation of pH (*NHE1, NHE2, NHE3, DRA, PAT1*), and epithelial barrier function (*GJA1, CLDN1*). Individual calves (n = 52) were randomly assigned to a slaughter age, 4 wk (n = 16) or 8 wk (n = 36), and treatment, control (CON; n = 27) or direct fed microbial (DFM; n = 25). Calves were housed with no bedding and fed individually. Liquid DFM was delivered in milk replacer (2 g per day) for the first 4 wk of the trial; solid DFM (2 g per day) was top-dressed on grain thereafter. Calves were fed nonmedicated milk replacer twice daily (22.0% CP, 20.0% fat DM basis; 680 g/d) and had ad libitum access to texturized grain (20% CP, 2.0% fat) and water. At slaughter, rumen tissue was obtained from the cranial ventral region of each calf; the epithelial portion was separated and preserved for later RNA extraction and cDNA synthesis. cDNA was used in quantitative reverse transcription PCR assays. *UXT, RPS9, RPS15, and RPS26* were endogenous control genes. All transcripts were detectable in all calves. Relative mRNA abundance of *NHE3* was shown to decrease with age (P < 0.05); no other genes were affected by age or treatment. In summary, dietary inclusion (2 g/d) of an extract of *A. oryzae* did not result in altered rumen epithelial gene expression when supplemented animals were compared with cohorts not fed DFM. More differences were expected due to age, as selected genes are related to metabolic development of the rumen, but it is important to point out that gene level data do not always correlate with protein abundance. Further, it is possible that the dose used here was not high enough to elicit treatment effects. Regardless, we provide new data about ruminal gene expression in periruminant dairy calves.

Key Words: dairy calf, rumen, gene expression

0372 Performance and rumen development of artificially reared calves to dietary butyrate supplementation. A. K. Kelly[1], J. V. O'Doherty[1], D. A. Kenny[2], T. M. Boland[3], and K. M. Pierce*[3], *[1]School of Agriculture and Food Science, University College Dublin, Dublin, Ireland, [2]Teagasc Grange, Meath, Ireland, [3]School of Agriculture and Food Science, University College Dublin, Dublin 4, Ireland*.

Recently, there has been increased interest in the potential of certain diet-derived chemicals to enhance immune response, gastrointestinal health, and growth potential of young livestock. Of those evaluated thus far, the short-chain fatty acid butyrate has shown significant potential as an antipathogenic immune stimulant. The aim of this study was to determine the effect of sodium butyrate supplementation on calf performance, intestinal development, and volatile fatty acids profiles in preweaned calves. Forty-four Holstein Fresian male calves with a mean age of 13 ± 5 d were divided into 2 equal groups and fed milk replacer supplemented with 4 g of coated sodium butyrate (SB)/d or with no-coated sodium butyrate (CON). Calves were allocated to a standard 56 d calf rearing requiem: Milk offered at 6 L/d (125 g/L) for 10 to 49 d and weaning over 7 d (49 to 56 d) by gradually reducing the allowance. Concentrate and water was offered to calves on an ad libitum basis thoughout the trial period. Milk replacer and concentrate intake was recorded daily using a computerized calf rearing system (Forster Technik, Germany). Bodyweight was measured weekly. Respiration rate, rectal temperature, and fecal scores were recorded daily. At weaning (d 56), 8 animals from each treatment (SB vs. CON) were euthanized. Rumen digesta and tissue was harvested for VFA and rumen development analysis. Calves supplemented with SB tended ($P = 0.08$) to have higher preweaning growth rates compared with CON (0.69 vs. 0.59 kg/d). At weaning, SB calves (80.2 kg) were 3.2 kg heavier than the CON group (76.9 kg), with bodyweight difference detected from d 42 to weaning. Bodyweight differences between treatments were not evident before this ($P > 0.10$). Total DMI was not different between dietary treatments, but preweaning SB supplementation tended ($P = 0.08$) to improve feed conversion rate of the calves. There were no significant differences on rectal temperature, respiration rate, and fecal score between the treatments. Rumen papillae length, width, and perimeter were not affected by SB supplementation of milk replacer. Similarly, rumen concentrations of total VFAs were not altered by dietary treatments. In conclusion, the supplementation of milk replacer with coated sodium butyrate could improve preweaning performance of dairy calves.

Key Words: butyrate, dairy calf, rumen development

0373 Nongenomic effects of trenbolone acetate on bovine satellite cell proliferation. K. J. Thornton*, E. Kamanga-Sollo, M. E. White, and W. R. Dayton, *University of Minnesota, Saint Paul.*

Androgen treatment improves skeletal muscle growth in a number of species; however, the mechanism responsible for this improved muscle growth has not been fully elucidated. Trenbolone acetate (TBA), a testosterone analog that does not undergo aromatization to estradiol, has been shown to increase proliferation and protein synthesis rates and decrease protein degradation rate in bovine satellite cell (BSC) cultures. This is particularly significant because satellite cells are the source of nuclei needed to support postnatal muscle fiber hypertrophy and are thus crucial in determining the rate and extent of muscle growth, although the mechanism responsible for these effects of TBA on BSC has not been fully determined. The classical genomic actions of testosterone in which the androgen receptor acts as a ligand inducible transcription factor modulating target gene transcription has been well characterized. However, our recent studies have indicated that TBA may also initiate a quicker, nongenomic response that involves release of membrane-bound heparin-binding epidermal growth factor-like growth factor (hbEGF), which then binds to and activates the epidermal growth factor receptor (EGFR). To determine whether this nongenomic pathway is involved in TBA-stimulated BSC proliferation, we analyzed the effects of treating BSC with AG1478, a specific EGFR tyrosine kinase inhibitor, and CRM197, a specific inhibitor of hbEGF, on TBA-stimulated proliferation rate (3H-thymidine incorporation). As expected, BSC cultures treated with 10 nm TBA showed significantly ($P < 0.05$) increased proliferation rate when compared with control cultures. Additionally, treatment with 5 ng hbEGF/mL stimulated proliferation in BSC cultures ($P < 0.05$). Treatment with AG1478 significantly ($P < 0.05$) suppressed TBA-induced increases in proliferation. Additionally, in the presence of CRM197, TBA induced increases in proliferation were significantly ($P < 0.05$) decreased. These data indicate that hbEGF and the EGFR may play a role in TBA-mediated increases in BSC proliferation. Further, these findings demonstrate that testosterone and/or TBA may stimulate increases in skeletal muscle growth utilizing a nongenomic mechanism.

Key Words: epidermal growth factor receptor, satellite cells, trenbolone acetate

0374 Effects of recombinant bovine somatotropin on performance and biological activity of skeletal muscle over the finishing phase of feedlot heifers.
J. E. Hergenreder*[1], J. O. Baggerman[1], A. J. Thompson[1], M. A. Jennings[1], K. S. Spivey[1], W. C. Burson[1], A. J. Laurent[1], G. J. Vogel[2], and B. J. Johnson[1], *[1]Texas Tech University, Lubbock, [2]Elanco Animal Health, Greenfield, IN.*

Our objective was to determine if recombinant bovine somatotropin (rBST) enhanced performance and biological activity in skeletal muscle over the finishing phase of feedlot heifers. Heifers (n = 16; initial BW = 457 ± 3 kg) were randomly assigned to pens (4 pens/treatment; 2 heifers/pen) and treatment: (1) no rBST (control); (2) 500 mg/animal of sometribove zinc at d 0 and 14 (rBST; Posilac, Elanco Animal Health). Upon arrival, heifers were acclimated for 14 d. *Longissimus* muscle biopsies for gene expression and protein abundance were performed on d 0, 14, 28, 42, and 56. On d 88 (102 d on feed) heifers were harvested and carcass data were collected. Average daily gain, DMI, and G:F were not affected by treatment ($P > 0.05$). There was no change in final BW, HCW, or dressing percentage (DP; $P > 0.05$); however, there was a tendency for control cattle to have greater marbling and decreased KPH ($P \leq 0.08$). Loin muscle area, fat thickness, and yield grade did not differ ($P > 0.05$). Using quantitative reverse transcription PCR, genes of interest were quantified: AMPKα, β_1AR, β_2AR, β_3AR, MHC-I, MHC-IIA, MHC-IIX, IGF-I, GPR43, GPR41, Glut4, SCD, CEBPβ, and PPARγ. The rBST cattle had the greatest quantity of AMPKα mRNA ($P < 0.05$) on d 0. There was a day effect on MHC-IIA, MHC-IIX, β_2AR, PPARγ, and SCD ($P < 0.05$). All cattle had the greatest concentration of MHC-IIA mRNA on d 56 and the greatest concentration of MHC-IIX mRNA on d 14, 28, and 42 ($P < 0.05$). Concentration of β_2AR mRNA were the greatest on d 56 ($P < 0.05$), while the greatest concentration of PPARγ and SCD mRNA were on d 0 and 56 ($P < 0.05$). No differences ($P > 0.05$) were observed in mRNA between treatments for MHC-I, β_3AR, GPR41, or Glut4. Protein quantification was performed utilizing western blotting procedures to assess the abundance of β_1AR, β_2AR, and β_3AR. There was a day effect on protein abundance ($P < 0.05$). The βAR were quantified at their greatest abundance on d 0 for β_1AR, d 0 and 42 for β_2AR, and d 0 and 28 for β_3AR ($P < 0.05$). These data indicate that as days on feed increase, the effects of skeletal muscle biological activity may not be solely dependent on rBST administration. However, further investigation is needed to elucidate interactions that effect muscle metabolism during the finishing period.

Key Words: β-adrenergic receptor, myosin heavy chain, recombinant bovine somatotropin

0375 Identification of potential serum biomarkers for feed efficiency in young pigs.
J. K. Grubbs*, S. M. Lonergan, J. C. M. Dekkers, and C. K. Tuggle, *Iowa State University, Ames.*

Identification of biomarkers for feed efficiency is important for increasing overall productivity of animal production. Early indicators of feed efficiency would be of particular value. The purpose of this project was to establish serum biomarkers for feed efficiency in young pigs. Serum was collected from 5-wk-old pigs from generation 8 of the Iowa State Residual Feed Intake (RFI) project. The pigs were then finished on either a high energy, low fiber diet or low energy, high fiber diet. The RFI was calculated using feed intake data from FIRE Performance Testing System (Osborne Industries, Osborne, KS). Serum protein samples were analyzed using 2D Difference in Gel Electrophoresis (2D-DIGE). Separate 2D-DIGE experiments were carried for each diet using pigs from the more efficient low RFI line (n = 8) or the less efficient high RFI line (n = 8). Selected proteins were identified through mass spectrometry. Both 2D-DIGE comparisons yielded several potential protein biomarkers for feed efficiency including gelsolin, vitronectin, serpinA3–6, and serpinA3–8. Gelsolin and vitronectin were significantly increased (13 to 57%) in abundance in the low RFI line. SerpinA3–6 and A3–8 were identified in 14 protein spots, and the protein abundance in most of these SerpinA3–6 or A3–8 spots was > 100% higher in the low RFI line as compared with the high RFI line pigs. These differences were consistent between the diet comparisons. SerpinA3 is a serine protease inhibitor that has promise as a biomarker to many disease states. In young pigs, an increase in serine protease inhibition could result in lower protein turnover. A decrease in protein turnover indicates less metabolic energy is being used for cellular repair and replacement. These data indicate further investigation is needed into serpinA3 as a biomarker for feed efficiency. This project was supported by Agriculture and Food Research Initiative Competitive Grant no. 2011–68004–30336 from the USDA National Institute of Food and Agriculture.

Key Words: 2D-DIGE, residual feed intake, SerpinA3

0376 Enhanced protein accretion and vital organ growth with intermittent bolus compared with continuous feeding in neonatal pigs.

S. W. El-Kadi*[1,2], C. Boutry[1], A. Suryawan[1], M. C. Gazzaneo[1], R. A. Orellana[1], N. Srivastava[1], H. V. Nguyen[1], S. R. Kimball[3], M. L. Fiorotto[1], and T. A. Davis[1], *[1]USDA/ARS–Children's Nutrition Research Center, Baylor College of Medicine, Houston, TX, [2]Animal and Poultry Sciences, Virginia Tech, Blacksburg, [3]Cellular and Molecular Physiology, Penn State College of Medicine, Hershey, PA*.

Enhancing the efficiency of protein utilization through dietary interventions may provide new avenues for improving profitability in farm animals. In addition, neonatal pigs can serve as dual-use models for nutrition research in animal agriculture and biomedical fields. Recently, we showed that intermittent compared with continuous feeding enhances lean tissue accretion by increasing muscle protein synthesis in neonatal pigs. The aim of this study was to determine if these feeding modalities affect vital organ protein accretion and growth. Neonatal pigs (n = 6/treatment, 6 d old) were fed the same diet in equivalent amounts continuously (CON) or intermittently (INT; meal every 4 h) for 21 d. Plasma branched-chain AA and insulin and fractional protein synthesis rates in liver, kidney, jejunum, and ileum were determined on the last day of feeding. Fractional rate of protein synthesis in organs was measured using the flooding dose method, and activation of translation initiation factors was determined by PAGE. Weight gain was greater ($P < 0.05$) for INT than for CON pigs and resulted in heavier body weights from 9 d of feeding onward. Arterial branched-chain AA and insulin concentrations measured on the last day of feeding were greater for INT after the meal than for CON pigs ($P < 0.05$). Phosphorylation of ribosomal protein S6 kinase were higher in ileum and liver in INT compared with CON fed pigs, indicating increased translation initiation signaling ($P < 0.05$). The proportion of rpS8 mRNA associated with polysomes in liver was greater in the INT compared with CON fed group ($P < 0.05$). Protein synthesis increased by 14% in jejunum, 48% in ileum, and 22% in liver ($P < 0.05$), while for the kidneys the increase was only modest. Jejunum, ileum, liver, and kidneys were 41, 36, 73, and 55% heavier for pigs in the INT as compared with the CON group ($P < 0.05$). These results suggest that intermittent feeding, as compared with continuous feeding, enhances protein accretion in vital organ growth by up-regulating protein synthesis. Supported by NIH AR444474 and USDA/ARS 6250–51000–055.

Key Words: branched-chain amino acids, protein synthesis, insulin

GROWTH AND DEVELOPMENT: JOINT MEAT SCIENCE & MUSCLE BIOLOGY, AND GROWTH & DEVELOPMENT— APPLICATIONS OF PROTEOMICS IN ANIMAL PRODUCTION

0377 Proteomics in animal science. J. Lippolis*, *National Animal Disease Center, Ruminant Disease of Cattle Research Unit , Ames, IA.*

The ultimate goal of proteomics is to detect and quantify the tens of thousands of proteins from a specific cell, tissue, or fluid. To observe protein expression, location, interaction, and modification under different experimental conditions would aid the understanding of the molecular mechanisms critical for cellular functions. In the context of animal health, better understanding of cellular functions would be the basis for rational therapeutic designs to target pathogens and correct disease conditions. The unique advantage of this technology is that a fairly large number of proteins can be identified and quantitated at one time, without any prior knowledge that any specific protein might exist in a sample. Analyzing a proteomic dataset can often lead to surprising results, and the unexpected may be the most interesting observation. In fact, most shotgun proteomic experiments are not typical "hypothesis driven" experiments, but may be better described as experiments designed to find a hypothesis. In these experiments hundreds if not thousands of proteins can be identified whose expression is altered by a defined experimental condition. Some changes in protein expression observed in a proteomics experiment may be expected and even well characterized. However, some may be unexpected or unknown and lead to new hypothesis for the connections between protein expression and cellular processes. Utilization of this technology with its potential for discovery, balanced with its limitations, is a useful tool in animal health research.

0378 Functional proteomics: Elucidation of molecular mechanisms of physiological variations of fat depots in beef cattle. J. M. Romao[1], M. He[2], T. McAllister[2], and L. L. Guan[1]*, *[1]Department of Agricultural, Food and Nutritional Science, University of Alberta, Edmonton, Alberta, Canada, [2]Lethbridge Research Centre, Agriculture and Agri-Food Canada, Lethbridge, Alberta, Canada.*

Adipose tissue plays an important role in energetics, meat quality and animal productivity, but the factors that regulate fat metabolism in beef cattle are unclear. Recent transcriptomics has identified hundreds of genes that may influence fat deposition in bovine adipocytes, but the phenotypic traits of fat are ultimately determined by the functional proteins that regulate adipogenesis and lipolysis. It is evident that gene expression does not always correspond to the levels of functional proteins produced due to differences in translation efficiency and post-translational modification. Using high throughput Label Free Quantification (LC-MS/MS), we have attempted to identify the global changes in protein expression in bovine subcutaneous and visceral fat depots of steers fed different diets at different stages of physiological maturity. Our results revealed that the proteomic profile of bovine adipocytes differs among fat depots, reflecting functional and physiological differences such as the higher metabolic activity of visceral fat. Changes in lipid profiles in the diet, altered proteomic profiles in subcutaneous fat and provide insight into mechanisms whereby the fatty acid composition of adipose tissue may be favourable altered. Moreover, proteomic changes in subcutaneous adipose tissue of feedlot cattle between 12and 15 months reflected increased adipocyte growth and proliferation, but fatty acid synthesis declined as steers approached finishing weight. These findings suggest that the rate of fatty acids synthesis is not static during growth, revealing a coordinated balance between subcutaneous fat mass and the cellular abundance of lipogenic proteins which regulate the rate and degree of fat deposition in beef cattle. Additional work suggested that miRNAs within bovine adipose tissue may play an important role in the controlling the expression of regulatory proteins within fat depots. Consequently, proteins and miRNAs may serve as markers for future selection of cattle based on their ability to generate favourable levels of adipose tissue with desirable fatty acid profiles within beef meat.

0379 Use of proteomics in animal health and disease research. P. D. Eckersall*, *Institute of Biodiversity, Animal Health and Comparative Medicine, University of Glasgow, Bearsden Rd, Glasgow, G61 1QH, UK.*

Proteomics is the application of advanced protein analytical methods to determine the individual protein components in a biological sample from cells, tissue or fluid. These technologies have application wherever proteins are investigated and are essential for a full systems biology approach for integration of omic technologies to address myriad research questions. While there have been great strides made in the applications of proteomics in research into human disease and for in vitro study there has been relatively limited application in farm animal health and disease. However the value of proteomic investigation is being recognized in animal research. The combination of two dimension electrophoresis and mass spectrometry was the initial approach to proteomic investigation and remains a powerful technology for proteome characterisation and biomarker discovery. In our laboratory, investigation of bovine nasal secretion to assess its value as a non-invasive medium for diagnosis of bovine respiratory disease has revealed the presence of glutathione S-transferase as a significant component of the secretion. γ-Glutamyl trans-

ferase and alkaline phosphatase have also been identified in nasal secretion with active host defence mechanisms being suggested. Recently non-gel based proteomics combining liquid chromatography with mass spectrometry have seen major application in farm animal research. Quantitative proteomics shows great promise in providing multiplexed assay systems for the simultaneous assay of numerous low abundance protein biomarkers. For example, it has been shown that the concentrations of cytokines, acute phase proteins and bioactive peptides can be monitored in the same micro-litre volume of milk during bovine mastitis, using standards of specific peptides derived from the respective proteins with great potential for research into this important disease (Bislev et al., 2012 J Prot Res 11:1832). Undoubtedly, the use of proteomics will become an established and valuable tool for animal health and disease research in the near future.

0380 Use of proteomics for livestock improvement.

E. Huff-Lonergan, S. M. Lonergan, S. Cruzen, K. Grubbs, J. Dekkers, N. Gabler, J. Selsby, and L. Baumgard, *Department of Animal Science, Iowa State University, Ames.*

Proteomics is a very broad term that includes a wide variety of techniques to characterize the entire protein profile of the cell or tissue (referred to as the proteome). Proteomic tools provide insight into the relative abundance of specific proteins, protein modifications (including proteolysis, phosphorylation, glycosolation, etc.), subcellular localization of specific proteins, interaction partners and protein sequence information. One of the challenges that face researchers is that differences that are noted are all with respect to a particular point in time. The very nature of the proteome dictates this because the proteome is dynamic, especially in respect to posttranslational modifications. Proteomics is very powerful in helping understand the role of proteins in various tissues/cells, it is however a challenging tool to use if the desired outcome is truly to identify the entire complement of proteins in a cell. Investigators should focus first on their research question before commencing any experiment, but this might be even more important in the "global" experiments that utilize any of the new integrated "omics" approaches. Often, researchers will choose to narrow their focus and look more specifically at a particular organelle or subcellular fraction. This decision cannot be made lightly, and interpretation of the results must take into consideration the techniques employed as well as all of the steps involved in sample preparation. The creative use of appropriate proteomics techniques has the potential to reveal many subtle changes in protein profiles that can aid in characterizing the physiological response to a wide variety of stressors to identify factors impact animals' ability to cope. In addition, proteomic techniques can be a valuable adjunct to studies that seek to understand innate differences in production characteristics.

HORSE SPECIES: **ADVANCES IN EQUINE STEM CELL BIOLOGY**

0382 Developmental progenitor cells of articular chondrocytes. J. N. MacLeod*, *University of Kentucky, Lexington.*

Articular cartilage lesions frequently compromise diarthrodial joint function and limit the performance potential of equine athletes. Cartilage is a tissue with poor intrinsic repair capabilities, a primary reason why degenerative joint disease is often progressive. New cell-based therapeutic strategies for equine joint surface injuries are generating a high level of interest. Unfortunately, fibrocartilage formation and poor anchoring of the repair tissue into the surrounding healthy tissue continue to be major challenges. Based on structural and molecular comparisons of different cartilaginous tissues and studies using primary chondrocyte cultures, it is clear that not all chondrocytes are equivalent on a cell biology level. We are trying to advance cell-based therapies for joint surface lesions by considering the unique phenotype that defines normal articular chondrocytes relative to other chondrocyte cell types, as well as the developmental processes that generate these cells. During limb formation, a morphologically distinct zone of cells in the prechondrogenic mesenchyme initiates synovial joint formation. This mesenchymal tissue is known as the "interzone" and appears as a flattened layer of cells connected by gap junctions. Interzone cells exist during early fetal development in all mammals including horses, but are present only transiently before joint space cavitation. In a developmental biology context, the interzone is the normal progenitor of all synovial joint tissues including articular cartilage. Using an amphibian model system, we have demonstrated that interzone tissue can facilitate a remarkable repair of large articular cartilage defects and even generate an entirely new diarthrodial joint *de novo*. More recently, we have been able to characterize interzone tissue in early equine fetuses and isolate primary horse interzone cells that can be expanded in culture. Experiments are being conducted to compare gene expression profiles of interzone cells to different types of chondrocytes on a transcriptome level, while also studying their response to differentiation stimuli. We believe that interzone tissue represents a cell population already developmentally positioned to form articular cartilage– true progenitor cells of articular chondrocytes. As such, they may represent a far superior cell type to focus on for optimizing cell-based therapies to repair articular cartilage defects in the horse.

Key Words: horse, cartilage, interzone

0383 Understanding the link between inflammation and muscle satellite cells in the horse. *S. A. Reed*, Department of Animal Science, University of Connecticut, Storrs.*

As an athletic animal, the horse performs a variety of activities throughout its life. With improvements in care, the equine population is living longer and remaining active and competing at increasingly older ages. Both advancing age and exercise result in increased concentrations of circulating and local cytokines, including interleukin (IL)-1β, IL-6, IL-8, interferon (IFN)-γ, and tumor necrosis factor (TNF)-α. Athletic endeavors in the aged horse may further increase the pro-inflammatory environment in the muscle, decreasing the ability to react appropriately to exercise. Poor response to exercise limits the athletic ability of geriatric horses, thus reducing their useful life span and potentially increasing the risk of injury. Satellite cells are muscle stem cells that reside adjacent to muscle fibers in skeletal muscle and are at least partially responsible for both maintenance of muscle mass and muscle hypertrophy. Normally, these cells exist in a quiescent state, becoming active, proliferating and differentiating in response to specific stimuli. Growth factors and cytokines present during hypertrophy and following exercise affect satellite cell activity. While the specific effects of cytokines on satellite cells are not well established, cytokines can both positively and negatively influence satellite cell and myoblast proliferation and differentiation. Equine satellite cells are comparable to satellite cells isolated from other species, exhibiting a fibroblast-like morphology in culture after activation and expressing desmin, an intermediate filament protein specific to muscle cells. Further, they differentiate into multinucleated myotubes which express myosin heavy chain, a fundamental property of myogenic cells. Understanding the effect of cytokines on equine satellite cell function will allow us to determine the mechanisms responsible for the poor response to exercise. Preliminary data indicates that the pro-inflammatory cytokines IL-1β and IL-6 inhibit myogenesis. C2C12 myoblasts cultured with 1.0 ng/mL IL-1β exhibit impaired fusion compared with controls ($P < 0.01$). Further, C2C12 myoblasts cultured with 10 ng/mL IL-6 exhibit decreased proliferation and decreased fusion compared with controls ($P < 0.01$). Ongoing work is examining the effects of these cytokines on satellite cells from young and adult horses. The pro-inflammatory environment in aged horses may inhibit exercise induced satellite cell activity, thereby diminishing exercise induced hypertrophy. As more horses are surviving and competing into their 20's, more research is required to understand the response of these animals to exercise during normal aging.

Key Words: cytokines, horse, satellite cells

0384 Use of mesenchymal stem cells in bone repair.

K. E. Govoni*, *Department of Animal Science, University of Connecticut, Storrs.*

Equine bone fractures are often catastrophic, potentially fatal, and costly to repair. Traditional methods of healing fractures have limited success, long recovery periods, and a high rate of re-injury. Current research in the equine industry has demonstrated that stem cell therapy is a promising novel therapy to improve fracture healing and reduce the incidence of re-injury; however reports of success in horses have been variable and limited. Stem cells can be derived from embryonic, fetal and adult tissue. However, based on the ease of collection, opportunity for autologous cells, and proven success in other models, adipose or bone marrow derived mesenchymal stem cells (MSC) are often used in equine therapies. Methods for isolation, proliferation, and differentiation of MSC are well established in rodent and human models but are not well characterized in horses. There is recent evidence that equine bone marrow MSC are able to proliferate in culture for several passages in the presence of autologous and fetal bovine serum which is important for expansion of cells. Mesenchymal stem cells are able to differentiate into osteoblasts, the bone forming cells, and this complex process is regulated by a number of transcription factors including, runt-related transcription factor 2 (Runx2) and osterix (Osx). However, it has not been well established if equine MSC are regulated in a similar manner. In the presence of L-ascorbic acid-2-phosphate, glycerol-2-phosphate, and dexamethasone, equine bone marrow MSC are able to differentiate into osteoblasts in culture as demonstrated by increased alkaline phosphatase activity and mineralization ($P < 0.05$). In addition, similar to rodent and human models, in equine bone marrow MSC, *Runx2* expression increased threefold ($P < 0.001$) during early differentiation and *Osx* expression increased ninefold ($P < 0.05$) during late differentiation. Further, expression of a novel transcription factor, *T-box3,* which is required for proliferation of mouse osteoblast cells and inhibits differentiation of osteoblasts, was reduced fourfold ($P < 0.01$) during differentiation of equine bone marrow MSC. These data demonstrate that equine bone marrow MSC may be regulated similar to rodent and human cells during osteoblast differentiation. Stem cell therapy is promising in equine bone repair, however additional research is need to identify optimal methods for reintroduction and potential manipulations to improve their ability to form new bone.

Key Words: bone, equine, mesenchymal stem cells

HORSE SPECIES

0385 Effects of high starch and sugar diets on postprandial inflammatory proteins in horses.

J. K. Suagee*[1], R. K. Splan[2], K. L. Swyers[3], R. J. Geor[4], and B. A. Corl[5], [1]*Ohio State, Wooster,* [2]*Virginia Tech, Middleburg,* [3]*Ranch-Way Feeds, Fort Collins, CO,* [4]*Michigan State University, East Lansing,* [5]*Virginia Tech, Blacksburg.*

Diets high in starches and sugars (HS) are linked to metabolic disorders in horses. Further, overconsumption of starch can result in digestive disturbances and laminitis. We hypothesize that high starch intake reduces intestinal pH and thus the integrity of the epithelial tight junctions, enabling lipopolysaccharide (LPS) to cross into the blood stream. For this experiment, plasma samples were obtained from mares ($n = 6$) consuming a diet high (HS) low (LS) in starch and sugar (Table 0385). Horses consumed 20% of their DE requirement as concentrate and 80% as mixed grass/legume hay (Table 0385). Concentrate was offered individually in 2 equal feedings (0800 and 1400 h) while hay was group fed in 2 equal feedings following concentrate consumption. Samples were collected on d 1 and on d 90 at 0, 1, 2, 3, and 4 h postconsumption of the assigned diet (0800 feeding), as part of a larger study that investigated postprandial starch responses. Plasma samples were then analyzed for LPS, tumor necrosis factor-α (TNF), interleukin (IL)-6, and IL1β. Lipopolysaccharide was analyzed using a commercial colorimetric assay, TNF and IL1β were analyzed using commercial ELISAs, and IL6 was analyzed using individual antibodies and a previously validated method. Each plasma factor was analyzed using repeated measures (SAS v. 9.3, SAS Inst. Inc., Cary, NC) for fixed effects and interactions of hour, day, and diet, with h 0 values as a covariate. Lipopolysaccharide concentrations were lower in HS horses on d 90 than on d1 ($P < 0.02$) but were otherwise unchanged. IL1β concentrations increased in HS horses 1 h postfeeding compared with LS horses ($P < 0.03$), without any differences between diets at other hours ($P > 0.55$). IL6 concentrations were influenced by hour ($P < 0.01$) but not diet ($P > 0.78$), whereby all horses had elevated IL6 concentrations 1 h postfeeding compared with h 0 ($P < 0.01$). TNF tended to be higher in HS horses than LS horses ($P = 0.07$) but was not influenced by day of study or hours postfeeding ($P > 0.51$). Consuming a high starch and sugar diet briefly elevates plasma IL1β, but this is most likely not due to elevated LPS concentrations. Of further interest was the finding that all horses, regardless of diet, had elevated postprandial IL6 concentrations.

Key Words: interleukin-1β, high-starch diet, horse, inflammation

Table 0385. Diet composition

Nutrient, %DM basis	LS	HS	Hay

0386 Evaluation of conjugated linoleic acid supplementation on markers of joint inflammation and metabolism in young horses challenged with lipopolysaccharide.

A. N. Bradbery*[1], J. Coverdale[1], K. L. Vernon[2], J. L. Lucia[3], C. E. Arnold[1], R. A. Dabareiner[1], M. K. Kahn[1], A. A. Millican[2], and T. H. Welsh, Jr.[4], [1]*Texas A&M University, College Station,* [2]*Clemson University, Clemson, SC,* [3]*Sam Houston State University, Huntsville, TX,* [4]*Department of Animal Science, Texas A&M University, College Station.*

Seventeen yearling Quarter horses were used in a randomized complete block design to evaluate potential of dietary CLA to mitigate intra-articular inflammation and cartilage metabolism following a single inflammatory insult. Horses were blocked by age, BW, and sex and randomly assigned to treatment for a 56-d trial. Treatments consisted of a commercial concentrate offered at 1% BW (as-fed) supplemented with either 1% soybean oil (CON; $n = 6$), 0.5% soybean oil and 0.5% CLA (LOW; $n = 5$; Lutalin, BASF Corp.), or 1% CLA (HIGH; $n = 6$; 55% purity) top-dressed daily. Horses were fed individually at 12-h intervals and offered 1% BW daily (as-fed) coastal bermudagrass (*Cynodon dactylon*) hay. On d 42, a lipopolysaccharide (LPS) challenge was conducted. Carpal joints were randomly assigned to receive intra-articular injections of 0.5 ng LPS derived from *Escherichia coli* 055:B5 or sterile lactated Ringer's solution as a contralateral control. Synovial fluid samples were taken via arthrocentesis at preinjection h 0 and 6, 12, 24, 168, and 336 h postinjection, and were analyzed for prostaglandin E_2 (PGE_2), carboxypeptide of type II collagen (CPII), and collagenase cleavage neopeptide (C2C) using commercial ELISA kits. Vitals, including heart rate, rectal temperature, and respiration rate were monitored at 0, 6, 12, and 24 h; and carpal circumference and surface temperatures were also recorded. Data were analyzed using PROC MIXED procedure of SAS (SAS Inst. Inc., Cary, NC). Vitals were not significantly different across treatments ($P \geq 0.13$) and remained within normal ranges throughout the LPS challenge. Synovial PGE_2 concentrations were not influenced by dietary treatment ($P = 0.15$). Synovial C2C concentrations were influenced by treatment ($P = 0.05$) with LOW and HIGH horses having lesser C2C than CON. Across all treatments C2C concentrations varied over time ($P < 0.01$) with values decreasing from 0 to 6 h, peaking at 12 h and decreasing to 336 h. Levels of synovial CPII tended to be influenced by treatment ($P = 0.10$) with LOW and HIGH horses having greater concentrations compared with CON. Regardless of diet, CPII concentrations increased over time ($P < 0.01$) with levels peaking at 24 h and decreasing to 336 h. In

conclusion, CLA supplementation did not influence PGE_2 concentrations following the LPS challenge; however, horses receiving CLA had lesser C2C and greater CPII concentrations, indicating less degradation and greater synthesis of cartilage in response to acute inflammation.

Key Words: conjugated linoleic acid, synovial, lipopolysaccharide, cartilage

0387 Age-related effects on markers of inflammation and cartilage metabolism in response to an intra-articular lipopolysaccharide challenge.

M. K. Kahn*[1], J. Coverdale[1], J. L. Lucia[2], C. E. Arnold[1], R. A. Dabareiner[1], A. Bradbery[1], A. A. Millican[3], and T. H. Welsh[4], *[1]Texas A&M University, College Station, [2]Sam Houston State University, Huntsville, TX, [3]Clemson University, Clemson, SC, [4]Department of Animal Science, Texas A&M University, College Station.*

Eighteen Quarter horses were utilized in a randomized complete design to evaluate age-related effects on inflammation and cartilage turnover after induction of a single inflammatory insult using lipopolysaccharide (LPS). Treatments consisted of age with yearlings ($n = 3$ males, $n = 3$ females), 2 and 3 yr olds ($n = 2$ males, $n = 4$ females), or mature 5 to 8 yr olds ($n = 2$ males, $n = 4$ females) for a 14-d experiment. For 14 d before the start of the experiment, all horses were housed in individual stalls and fed diets that met or exceeded NRC (2007) requirements. On d 0, horses were challenged with an intra-articular injection of LPS. Radial carpal joints were randomly assigned to receive LPS using 0.5 ng LPS solution obtained from *Escherichia coli* O55:B5, or sterile lactated Ringer's solution as a contralateral control. Synovial fluid was collected before LPS injection (0 h) and 6, 12, 24, 168, and 336 h postinjection. Samples were later analyzed using commercial ELISA kits for prostaglandin E_2 (PGE_2), collagenase cleavage neoepitope (C2C), and carboxypeptide of type II collagen (CPII). Rectal temperature (RT), heart rate (HR), and respiratory rate (RR) were monitored before sample collection over the first 24 h, and carpal circumference and joint surface temperature were recorded. Data were analyzed using PROC MIXED procedure of SAS (SAS Inst. Inc., Cary, NC). All values for RT, HR, and RR were within normal range and unaffected by treatment ($P \leq 0.21$). Joint circumference was not influenced by treatment ($P = 0.84$), but circumference and surface temperature increased ($P \leq 0.01$) across all treatments in response to intra-articular LPS. Synovial PGE_2 levels were influenced by age with yearlings tending to have lesser ($P = 0.09$) values than 2 and 3 yr olds and mature horses. This was particularly evident at 12 h, when PGE_2 values peaked for all horses and yearlings had lesser values ($P \leq 0.01$) than mature horses. Synovial C2C was influenced by treatment, with yearlings and 2 and 3 yr olds having lesser ($P \leq 0.01$) concentrations than mature horses. Synovial CPII was influenced by treatment at 24, 168, and 336 h, with yearlings having lesser concentrations ($P \leq 0.01$, $P \leq 0.06$, and $P \leq 0.03$, respectively) compared with 2 and 3 yr olds and mature horses. These results indicate that inflammation and corresponding cartilage turnover in response to LPS administration vary with age.

Key Words: lipopolysaccharide, horse, synovial fluid, prostaglandin E_2, type II collagen, collagenase cleavage neoepitope

---

0388 The effect of restricted diet and slow-feed hay nets on body weight and morphometric measurements in adult horses.

E. Glunk*, A. M. Grev, W. J. Weber, M. Hathaway, and K. L. Martinson, *University of Minnesota, Saint Paul.*

Horses evolved to consume several small, frequent meals throughout the day. However, modern horse care has resulted in many horses being stalled for large portions of the day, and meal fed, therefore decreasing their ability to forage. This management scheme has likely contributed to the increase in obesity in the equine population. The use of slow-feed hay nets represents an opportunity to extend foraging time while restricting forage intake. Therefore, the objective of this study was to determine if restricted feeding, coupled with increased time to forage, would lead to weight loss in overweight adult horses. Eight adult Quarter horses (BW 562 kg ± 2 kg) were used in a completely randomized design, with 4 horses assigned to a control (C) of feeding hay off the stall floor, and 4 horses assigned to feeding from a slow feed (3.2-cm openings) hay net (SN). Horses were fed at 1.08% BW, split evenly between 2 meals. A ration balancer was fed at recommended levels during the morning feeding. Body weight, via a livestock scale, and BCS were measured on d 0, 7, 14, 21, 28, and 35. Morphometric measurements, including neck and girth circumference and cresty neck score, a system developed to estimate the level of adiposity on the crest of the neck using a 0 to 5 scale, were taken on d 0, 14, 21, and 35. Ultrasound measurements of average rump fat, longissimus dorsi (LD) depth, and LD thickness were taken on d 0, 21, and 35. Data were analyzed using the Proc Mixed procedure of SAS (SAS Inst. Inc., Cary, NC). All horses lost weight over the 35-d period ($P < 0.0001$); however, no difference was observed between the SN and control. Horses on the SN lost an average of 40 kg, while horses on the C lost an average of 32 kg. There was no difference observed in BCS, neck and girth circumference, or cresty neck score during the study or between treatments ($P \geq 0.25$). Additionally, no differences were observed in rump fat, LD depth, or LD thickness during the study or between the treatments ($P \geq 0.32$). While all horses lost weight on the restricted diet, the use of a slow feed hay net did not have an effect on weight loss or morphometric measurements during the 35-d study.

Key Words: restricted diet, weight loss, slow-feed hay net

0389 Influence of diet fortification on mature horses at maintenance: Performance characteristics.

J. L. Lucia*[1], D. L. Parker[1], M. J. Anderson[1], K. J. Stutts[1], M. M. Beverly[1], S. F. Kelley[1], and E. D. Lamprecht[2], [1]*Sam Houston State University, Huntsville, TX,* [2]*Cargill Incorporated, Elk River, MN.*

Twenty mature horses (413 to 551 kg and 5 to 10 yr) were utilized in a randomized complete block design to evaluate the effect of dietary fortification on performance variables and immune status in mature horses. Horses were blocked by BW, with BCS, age, and sex randomly assigned and evenly distributed across treatments for a 154-d trial. Dietary treatments consisted of a pellet meeting NRC 2007 requirements (Control; $n = 10$), or the same pellet (Fortified; $n = 10$) including: enhanced AA, increased vitamin E, complexed trace minerals, prebiotic (140 g per d dehydrated *Saccharomyces cerevisiae* yeast fermentation product), and probiotic (min 2.3 million CFU/kg each of *Lactobacillus acidophilus, L. casei, Bifido bacterium bifidium,* and *Enterococcus faecium*) fermentation products dehydrated. Dietary treatments were offered individually at 0.25% BW at 12-h intervals. Horses were housed by block and maintained in adjacent dry lots with ad libitium access to coastal Bermudagrass (*Cynodon dactylon*) hay. Body weight and BCS were obtained every 14 d, with concentrate adjusted accordingly. Ultrasound images were obtained every 28 d to determine rump fat (RF), longissimus dorsi area (LDA), and longissimus dorsi fat thickness (LDF). Blood samples were also collected at 28-d intervals to determine circulating white blood cell counts (WBC) utilizing a Celdyne 3700 cell counter (Abbott Industries, Abbott Park, IL). Data were analyzed using the PROC MIXED procedure of SAS (SAS Inst. Inc., Cary, NC). Body weight and BCS were not influenced ($P = 0.11$ and $P = 0.25$, respectively) by dietary treatment. However, all horses gained BW and BCS throughout the trial ($P \leq 0.01$). Longissimus dorsi area and LDF were greater ($P \leq 0.01$) for horses fed Fortified pellets compared with Control. Similarly, RF measurements increased ($P \leq 0.01$) in the Fortified diet beginning at d 56 of the trial. Whole blood WBC was greater ($P \leq 0.01$) in the Fortified diet when compared with Control. These results indicate the addition of fortification may improve the ability of horses to mount an immune response as well as increase muscling and rump fat when fed to mature horses.

Key Words: organic trace mineral, amino acid probiotic, horse, immune response

0390 The effect of small-square feeder design on hay waste, herd weight change, and economics during outdoor feeding of adult horses.

A. M. Grev*, E. Glunk, M. Hathaway, W. Lazarus, and K. L. Martinson, *University of Minnesota, Saint Paul.*

Hay waste during feeding represents a costly expense for horse owners. Researchers have investigated hay waste associated with feeding round-bales and small-square bales in boxstalls, but none have investigated the waste of small square-bales fed outdoors. The objectives of this study were to determine hay waste, herd weight change, and economics of small square-bale feeders when used in outdoor feeding of adult horses. Feeder designs included a hayrack ($280), slat feeder ($349), basket feeder ($372), and a no-feeder control. Two feeders of each type were placed in 4 separate, outdoor, dirt paddocks. Twelve adult mares (BW 503 ± 36 kg) were divided into 4 similar groups each containing 3 mares. Groups were rotated through the 4 paddocks in a Latin Square design. Herds remained in each paddock for 7 d, including 2 d of acclimation and 5 d of data collection. Horses were weighed immediately before and after the 5 d data collection period; the difference was herd weight change. Horses were fed grass hay at 2.5% of the herd body weight split evenly at 0800 and 1600 h. Waste hay on the ground was collected daily before each feeding, dried, and weighed. Any hay remaining inside the feeder was collected, dried, weighed, and subtracted from the amount fed. The daily amount of hay removed from the ground was considered waste. The number of months to repay the feeder cost (payback) was calculated using hay valued at $250/t, and improved efficiency over the control. Mean hay waste was 13, 5, 2, and 1%, for the control, hayrack, basket feeder, and slat feeder, respectively. All feeders resulted in less hay waste compared with the control ($P \leq 0.0001$), and a difference was measured between the hayrack and slat feeder ($P = 0.0175$). Herd weight change was different among all feeders ($P \leq 0.0074$). Herds gained 10 and 7 kg when feeding from the basket feeder and hayrack, and lost 3 and 11 kg when feeding from the slat feeder and control. The basket feeder, hayrack, and slat feeder paid for themselves in 11, 11, and 9 mo, respectively, with the slat feeder resulting in a shorter payback ($P \leq 0.0140$). Use of a small square-bale feeder resulted in less hay waste compared with the control, and all feeders paid for themselves within 11 mo. This information will aid horse owners when purchasing small square-bale feeders.

Key Words: hay waste, hay feeder, payback

0391 Influence of ambient temperature and relative humidity on recovery from exercise in young horses. J. L. Lucia*[1], K. S. Carlson[1], M. J. Anderson[1], K. W. Walter[2], K. J. Stutts[1], M. M. Beverly[1], and S. F. Kelley[1], *[1]Sam Houston State University, Huntsville, TX, [2]Truman State University, Kirksville, MO.*

Heat stress affects many livestock species, but horses are a particular concern due to the regular exercise they receive. To determine the influence of ambient temperature on exercise recovery in young horses, fourteen Quarter horses (2 to 5 yr; 338 to 540 kg) were utilized in a randomized complete block design. Horses were blocked by BW, age, and sex, and randomly assigned to 1 of 2 groups that included horses performing a 25-min standardized exercise test at either 0600 h (AM; $n = 7$) or 1300 h (PM; $n = 7$). The ambient temperature for the AM was 23.31°C (83.9% relative humidity), while the ambient temperature for the PM was 34.70°C (40.8% relative humidity). Whole blood lactate (LAC), total plasma protein (TP), heart rate (HR), respiration rate (RR), rectal temperature (RT), and ocular temperature (OT) were obtained immediately following (0 min) exercise, and during a recovery period (5, 15, and 30 min post-exercise). Differences in parameters measured were determined using the PROC MIXED procedure in SAS (SAS Inst. Inc., Cary, NC). Clinical parameters, including HR, RR, and RT, were greater ($P = 0.03$) in the PM beginning at 5 min of recovery and remained elevated at 30 min postexercise when compared with the AM. Additionally, OT was higher ($P \leq 0.01$) in the PM at 0 min, and values remained higher through 30 min postexercise. Similar to OT, LAC was greater ($P \leq 0.01$) at 0 min in the PM (12.72 ± 1.84 mmol/L) compared with the AM (4.94 ± 1.84 mmol/L), with lactate values in the PM (8.79 ± 1.13 mmol/L) continuing to be greater than the AM (2.25 ± 1.13 mmol/L) at 30 min following exercise. No differences were detected in TP ($P = 0.18$) between exercise groups, suggesting the exercise intensity did not alter extracellular fluid loss within plasma. Respiration rate, OT, and RT remained elevated through recovery, demonstrating an impaired ability to dissipate heat due to the higher ambient temperature during exercise. Lactate values in the PM illustrated that horses exercising at a higher ambient temperature required an increased recovery time due to the increased demands of anaerobic metabolism. Understanding the physiological responses during recovery of exercise at different temperatures may enable industry professionals to adapt daily exercise regimens to better prepare the equine athlete to perform at their full potential.

Key Words: heat stress, exercise, equine

0392 Commercial application of the follicular ablation technique in mares. S. E. Buist*, A. K. Sexten, D. M. Grieger, C. A. Blevins, J. S. Stevenson, and J. M. Kouba, *Kansas State University, Manhattan.*

Two experiments were conducted to determine the practicality of utilizing ultrasound-guided follicular ablation in a commercial setting. The objective of the initial experiment was to investigate the efficacy of follicular ablation as a technique for ovulation synchronization when compared with a standard progesterone and estrogen (P&E) protocol. Twenty nonpregnant mares were assigned to an ablation (AB) or P&E group. Briefly, AB mares ($n = 10$) were subjected to ablation for removal of all follicles larger than 10 mm on d 0 and administered PGF2α twice on d 5. Mares were administered hCG on d 11 and subjected to ultrasound twice per day until ovulation was detected. Mares in the P&E group ($n = 10$) were scanned at initiation of the protocol and received P&E IM once a day for 10 d. On d 10, mares received PGF2α and ultrasound monitoring began on d 15. On d 18, mares were administered hCG and evaluated twice per day until ovulation was detected. The interval from initiation of synchronization to ovulation (10.4 vs. 19.1 d, $P < 0.0001$) and the interval from hCG administration (1.2 vs. 2.3, $P < 0.0001$) was shortened in the AB group. Ablation may be an acceptable nonsteroidal alternative to the conventional P&E protocol. The objective of the second experiment was to determine if ablation could lengthen the postpartum interval to ovulation to increase the chance of conception postfoaling. Eighteen postpartum mares were assigned to an AB or control (CON) group. On d 6 postpartum, AB mares ($n = 9$) were subjected to follicular ablation for removal of all follicles larger than 10 mm. Mares were administered PGF2α twice on D11 and monitored via ultrasound once per day until a follicle $\geq$ 35 mm was detected, at which time they received hCG. Following hCG, mares were monitored twice per day until ovulation was detected. The CON mares were evaluated using ultrasound, beginning d 4 postpartum and continuing every other day until a follicle $\geq$ 30 mm was detected, and scanning frequency increased to once per day. When a follicle $\geq$ 35 mm was identified, mares were administered hCG and monitored twice per day until ovulation was detected. Ablation lengthened the interval from foaling to ovulation (15.9 vs. 10.0, $P = 0.003$). Increasing the interval from foaling to ovulation is known to increase conception rates; therefore, the application of this procedure could be utilized to optimize the timing of breeding to improve conception outcomes. These experiments demonstrate commercial application of follicular ablation and are evidence for incorporating this procedure in a commercial setting.

Key Words: mares, follicle ablation, postpartum ovulation

HORSE SPECIES: **DEVELOPMENTAL PROGRAMMING: APPLICATIONS IN THE HORSE**

0393 Developmental programming in agriculturally relevant species: An overview. K. A. Vonnahme*, *North Dakota State University, Fargo.*

Postnatal growth and development of offspring can be influenced by stressors that their parents experienced before their conception, during their gestation, or during lactation. This phenomenon is known as developmental programming. Developmental programming has been shown to influence many of our large domesticated animals and may impact livestock production. An important component to developmental programming is that placental function can be influenced by many factors impacting nutrient transport. Not only does nutritional stress, such as nutrient restriction, impact fetal and placental growth, but other stressors such as transportation, extreme temperatures, and social environments influence the offspring in utero, at birth, and after weaning. Understanding the mechanisms of how these stressors impact nutrient availability to the developing offspring will help in determining potential management strategies and therapeutics that could be implemented to reduce negative consequences. This overview of developmental programming will preface equine specific presentations on how the horse is impacted by the maternal environment and the potential impact on the equine industry.

Key Words: developmental programming, livestock, placenta

0394 Glucorticoid programming of development during early life. A. Fowden*, O. A. Valenzuela, J. K. Jellyman, N. B. Holdstock, and A. J. Forhead, *University of Cambridge, Cambridge, UK.*

Human epidemiological studies have shown that low birth weight is associated with an increased incidence of adult metabolic disease. Similarly, in experimental animals, induction of fetal growth restriction alters adult metabolic phenotype. Collectively, these studies have led to the concept that suboptimal environmental conditions during early development program later metabolic dysfunction. Glucocorticoid stress hormones may mediate many of these environmental programming effects, as they inhibit fetal growth and their maternal administration is known to alter metabolic and endocrine function of the adult offspring in several species. Normally, glucocorticoids only act as prepartum maturational signals but, earlier in development, they can also act as signals of environmental adversity. However, relatively little is known about the programming effects of neonatal glucocorticoid overexposure when tissues are particularly glucocorticoid-sensitive. In horses, unlike other species, the fetal hypothalamic-pituitary-adrenal (HPA) axis develops late in gestation, with the main cortisol increment after, not before, birth. Indeed, in preterm and dysmature foals, cortisol concentrations can be high for several days after birth. Thus, horses may be more susceptible to glucocorticoid programming in the neonatal rather than fetal period of development. Administration of synthetic glucocorticoids to pregnant mares near term ($\geq$ 300 d) causes both stillbirth and early delivery of viable foals, depending on the exact gestational age at treatment (4). In ponies in late gestation ($\geq$ 270 d), this treatment causes maternal hyperinsulinaemia and hyperglycaemia, indicative of insulin resistance, but has little effect on gestational length or foal birth weight and size, although it does have minor actions on foal HPA function in the first 2 to 3 wk after birth. In contrast, raising cortisol concentrations endogenously in the foal for 5 d after birth by ACTH administration had little effect on HPA function in the young foal ($\leq$ 15 wk), but did alter basal ACTH concentrations and hypoglycaemia-induced ACTH secretion in the adult ponies at 1 and 2 yr of age, in association with sex-linked differences in adreno-cortical growth at 2 yr. In addition, neonatal cortisol overexposure reduced glucose-stimulated insulin secretion in the young foals but not in the adults, while increasing insulin sensitivity in the young foals and yearlings but not in the 2 yr olds. However, the extent to which these changes persist, resolve, or exacerbate with increasing age remains unknown. Cortisol overexposure of equine neonates, therefore, programs their subsequent endocrine and metabolic phenotype, with implications for their adult health and potential athletic performance.

Key Words: glucocorticoid programming

0395 Nutritional programming and the impact on mare and foal performance. J. Coverdale*[1], C. J. Hammer[2], and K. W. Walter[3], *[1]Texas A&M University, College Station, TX, [2]North Dakota State University, Fargo, [3]Truman State University, Kirksville, MO.*

Many environmental factors can alter phenotype of offspring when applied during critical periods of early development. In most domestic species, maternal nutrition influences fetal development, and the fetus is sensitive to nutrition of the dam during pregnancy. Large numbers of techniques have been explored including both under- and overnutrition of the dam. Both nutritional strategies have yielded potential consequences, including: altered glucose tolerance, pancreatic endocrine function, insulin sensitivity, body composition, and colostrum quality. While the impact of maternal nutrition on fetal development in the equine has not been thoroughly investigated, overnutrition is a common occurrence in the industry. Work in our laboratory has focused on effects of

maternal overnutrition on mare and foal performance, mare intake, mare hormone concentrations, foaling parameters, colostrum quality, passive transfer of immunity, and glucose and insulin dynamics. Over several trials, mares were fed either 100 or 140% of NRC requirements for DE, and supplemental Se and arginine were added to diets in an attempt to mitigate potential intrauterine growth retardation resulting from dams overfed during the last third of pregnancy. As expected, when mares were overfed, BW, BCS, and rump fat values increased. Despite this change in mare body composition, foaling parameters such as time to stand and time to nurse were unaffected. Foal growth over 150 d was also not influenced. Maternal nutrition did not alter colostrum volume, but influenced colostrum quality. Maternal overnutrition resulted in lower colostrum IgG concentrations, but did not cause failure of passive transfer in foals. Supplemental Se and arginine were unable to mitigate this reduction in colostrum IgG. Additionally, mare and foal glucose and insulin dynamics were influenced by maternal nutrition. Mare glucose and insulin area under the curve (AUC) increased with increased concentrate supplementation, and in a subsequent trial supplemental arginine was able to decrease mare insulin AUC. Foal insulin AUC and peak insulin concentrations were increased when mares were fed concentrate during the last third of pregnancy, and in a later trial, foal peak glucose values were reduced with arginine supplementation of the mare. This influence of maternal nutrition on glucose and insulin dynamics warrants further investigation, as it may be related to athletic performance and metabolic disease in the adult. Further studies will be necessary to fully elucidate the influence of mare nutrition during pregnancy on performance of the mare and resulting foal, as well as long-term consequences of developmental programming.

Key Words: horse, nutrition, foal, developmental programming

INTERNATIONAL ANIMAL AGRICULTURE: **INTERNATIONAL ANIMAL PRODUCTION**

0396 Effect of high nutrient density diets on growth performance, feed efficiency, age at puberty, and feeding economics in Nili-Ravi buffalo heifers.
M. Abdullah*[1], K. Javed[1], Z. M. Iqbal[1], M. Saadullah[1], M. A. Jabbar[1], and A. U. Haque[2], *[1]University of Veterinary and Animal Sciences, Lahore, Pakistan, [2]Buffalo Research Institute, Pattoki, Pakistan*.

Traditional buffalo raising becomes uneconomical due to poor growth and delayed age at puberty. The feeding trial was conducted to evaluate the feeding diets with varying nutrient density on dry matter intake, growth rate, age at puberty, feed efficency, and feeding economics in Nili-Ravi buffalo heifers. Thirty Nili-Ravi buffalo heifer calves between the age of 5 and 7 mo and approximately of 95 kg body weight were assigned to 3 different treatments: (A) Control (CP and ME at NRC, 2001), (B) CP and ME contents at 20% above, and (C) CP and ME 40% above NRC recommendations. The experiment continued until manifestation of puberty signs (mucous discharge) in all 3 treatment groups. The data were analyzed using SAS 9.1 (SAS Inst. Inc., Cary, NC). Dry matter intake was different ($P < 0.05$) among the treatment groups: $6.71^{a} \pm 2.69$, $7.99^{b} \pm 3.28$, and $9.11^{c} \pm 3.90$ kg for Treatments A, B, and C, respectively. The average daily CP and ME intake was also different ($P < 0.05$): $876.03^{a} \pm 348.38$, $1094.43^{b} \pm 445.84$, and $1285.98^{c} \pm 546.62$ g CP, and $15.36^{a} \pm 6.12$, $18.83^{b} \pm 7.69$, and $21.85^{c} \pm 9.31$ Mcal/kg ME for Treaments A, B, and C, respectively. There was no difference in the average daily gain of Treatments A and B ($525.88^{a} \pm 292.92$, 551.98^{a} g), while Treatment C ($612.99^{b} \pm 350.17$ g) gained higher as compared with other 2 treatment groups. The feed efficiency of Treatment A ($0.093^{a} \pm 0.06$) was higher as compared with Treatments B and C ($0.081^{b} \pm 0.05$ and $0.081^{b} \pm 0.05$). The mean body length ($111.98^{a} \pm 12.79$ and $111.35^{a} \pm 13.61$ cm) and heart girth ($142.22^{a} \pm 21.27$ and $142.89^{a} \pm 22.71$ cm) was same in Treatments A and B, while different in Treatment C ($113.07^{b} \pm 14.29$ cm) and ($144.39^{b} \pm 23.71$ cm). The height at wither was higher in Treatment C ($116.20^{b} \pm 13.18$ cm) as compared with Treatment A, whereas it was similar between Treatments A and B, and B and C ($117.07^{a} \pm 12.61$ and $116.68^{ab} \pm 12.99$ cm for Treatments A and B, respectively). There was no difference in the mean age at puberty of all the 3 treatment groups ($733.11^{a} \pm 50.55$, $716.78^{a} \pm 33.65$, and $723.50^{a} \pm 26.31$ d) while weight at puberty was same for Treatments A and B ($384.87^{a} \pm 30.47$ and $398.40^{ab} \pm 35.92$ kg) and between B and C ($423.90^{b} \pm 30.12$ kg). The averaged daily feeding cost was lower in Treatment A (Rs. 139.93a ± 28.27) as compared with Treatments B (Rs. $195.12^{b} \pm 41.92$) and C (Rs. $246.25^{c} \pm 56.39$). Buffalo heifers were found to be efficient converters and economical to raise on low-nutrient-density diet without affecting their age at puberty.

Key Words: Nili-Ravi buffaloes, age at puberty, nutrient density

0397 Environment concerns and waste management strategies of pig production in China.
J. Peng*[1], L. Liu[2], and L. Huang[1], *[1]Jiangxi Agricultural University, Nanchang, China, [2]Jiangxi Department of Agriculture, Nanchang, China.*

With the largest population in the world, the Chinese government continues to stimulate pork production to meet the increased demand for protein consumption. However, the increases in hog population and density have created various environmental problems in China. One of the issues is that it can cause water and land contamination when farm wastes being handled incorrectly. Most recently, China published the most updated waste management regulation for animal industry, effective from January 1, 2014. Waste management has become an important focus for swine industry in China. The objective of this study was designed to assess waste streams in pig production under the most current situation in China. Commercial pig farms ($n = 50$) were chosen from 11 different provinces, representing the major area of swine production in China. The size of the pig farm ranges from small, medium, and large. Data was collected through farm visit (and/or farm inspection), personal interview, focus group, meeting discussion, survey questionnaire, and farm document review. A group of Chinese swine experts, including central and local government officers, as well as educators and researchers from different universities and institutes, was selected to verify data and acquire data consensus. This study finds that daily manually scraping of pig pens, along with floor water-line flushing is a common method for solid manure collection and pen hygiene. However, the continuously increasing human labor cost in pig production has forced the solid manure collection method to change from manual to automatic. In addition, the usage of concrete slatted floors to avoid daily manually scraping and flushing is becoming more accepted. Moreover, to reduce the volume of farm slurry, newly designed farms commonly utilize underground pipe for slurry collection and to avoid mixing rainwater. This study also finds the currently government-sponsored anaerobic digester project, promoted as a method of treating slurry, is rarely found to be successful at large-scale intensive pig farms. Consequently, the Chinese government should take serious actions to enforce the disposing of farm waste in a more sustainable and environmentally friendly approach, such as compost and use in an organic fertilizer plant. In conclusion, waste water increases manure volume, which in turn may increase the cost of manure storage and distribution or increase the cost of treatment if to meet the emission standards. Therefore, pig farms should adopt new equipment and innovative technology to avoid wa-

ter wastage, as well as implement novel waste management methods to support sustainability.

Key Words: environment concerns, waste management, sustainability

---

0398 Identification of barriers of Bahamian agriculture production: An assessment of stakeholder needs.

S. J. Trojan*[1], M. T. Brashears[2], S. Morales[2], A. Echeverry[1], and M. Brashears[1], *[1]Texas Tech University, Department of Animal and Food Sciences, Lubbock, [2]Texas Tech University, Department of Agriculture Education and Communications, Lubbock*.

Land available for agriculture production in the Bahamas is roughly 191,000 acres; however, approximately 10% of production capacity is realized. To assist with augmenting Bahamian agriculture production, a team of Texas Tech University researchers worked with the Inter-American Institute for Cooperation on Agriculture (IICA) to evaluate the Bahamian food system from farm to fork to determine stakeholder needs. The team traveled to several islands; visited multiple farms, governmental agencies, a feed mill, an abattoir, a resort butcher department, and met with the Minister of Agriculture. At each stakeholder meeting, barriers to the food production and consumption system were identified. The following themes emerged within respective segments. Issues producers faced included: (1) lack of product standards and certification; (2) theft and feral dogs; (3) inconsistent availability and price of inputs; (4) land availability; and (5) unfair trade regulations. Processors indicated the following barriers: (1) lack of access to employee training; (2) equipment availability and cost; (3) consistency of governmental support; and (4) facility security. The team also conducted a workshop for livestock producers and administered an instrument to help identify audience demographics and major concerns with Bahamian agriculture production. Of the 25 individuals that responded, 50% indicated that agriculture represented 50% of household income, whereas 10 individuals indicated agriculture was the sole income source. For such households, challenges within the agriculture system can lead to significant levels of food insecurity. The instrument also identified the following challenges within the agriculture industry: lack of education in food safety, governmental challenges, lack of marketing infrastructure, and a need for new technologies and methodologies for improving agriculture productivity, transportation and handling, and animal welfare. The needs assessment conducted by the research team was the initial step in communicating barriers the country faces in becoming more food secure to IICA. Researchers made several recommendations to IICA to focus stakeholder resources. Educational efforts must be coordinated through IICA and governmental agencies to provide effective training programs and eliminate redundancy. Communication at all levels of government related to food production and consumption should be improved. The single abattoir on the island of New Providence should be evaluated for feasibility of continued operations or elimination. Alternatives for providing humane animal slaughter in multiple locations were proposed with the goal of improving processing quality to World Trade Organization food safety guidelines. Efforts to open an agricultural branch of the College of the Bahamas on Andros Island should be strongly supported.

Key Words: Bahamas, food security, needs assessment

0399 Diet-induced shifts in the rumen microbiome of Mehshana buffalo (*Bubalus bubalis*).

D. W. Pitta[1], S. Kumar*[1], B. Veiccharelli[1], N. Parmar[2], and C. Joshi[2], *[1]University of Pennsylvania, Kennett Square, PA, [2]Anand Agriculture University, Anand, India*

We investigated the diet-induced shifts in the microbiome of both solid and liquid ruminal fractions retrieved from water buffalo utilizing 16S rRNA pyrosequencing technology. The depth of coverage of metabolically active bacteria in a community using different primer pairs was also determined. To assess reproducibility, interanimal variation was considered in all phylogenetic and community comparisons. The experiment included 4 nonlactating water buffaloes fed 3 different diets for 6 wk each; diets were M1 (50% concentrate: 50% dry roughage), M2 (25% concentrate: 75% dry roughage), and M3 (100% dry roughage). A total of 333,851 pyrotags were analysed in this study. Phylogenetic analysis revealed significant differences in the rumen microbiome mediated by primer and diet ($P < 0.05$). Differences in community composition due to primer, diet, fraction, and animal were compared using unweighted and weighted UniFrac analysis. Clustering of communities was largely explained by primer differences in both weighted and unweighted UniFrac analyses ($P < 0.001$). In the weighted analysis, communities clustered by diets ($P < 0.05$) and fractions ($P < 0.08$) while no interanimal variation was observed. The identified repertoire of bacterial populations was dependent on the primer pair, as targeting the V4-V5 region resulted in greater diversity profiles of the microbiome. Within each primer pair, dietary changes altered the community composition with noticeable shifts at the genus level. Genera such as *Ruminococcus* and *Fibrobacter* ($P < 0.05$) were higher in abundance on M3 diet, while *Prevotella* dominated ($P < 0.05$) on the M1 diet.

Key Words: rumen bacterial community, hypervariable regions, UniFrac analyses

INTERNATIONAL ANIMAL AGRICULTURE: GLOBAL PROSPECTIVE OF LIVESTOCK PRODUCTION SYSTEMS TO MEET THE GROWING NEED FOR ANIMAL PROTEIN IN HUMAN DIETS: IMPACTS ON PRODUCTION AND HUMAN HEALTH

0402 Parallel comparisons of intensive meat production in developed and developing countries. What can we learn from each other's systems?.

R. Barajas Cruz*, *Universidad de Sinaloa, Culiacan, Mexico.*

The world in the short future will confront 2 important facts: the population is increasing and meat consumption by people has been increasing. The challenge will then be: how will we produce enough meat to supply this growing meat demand? It is time to review the intensive meat production strategies conducted in different regions of the world and to learn from each other. In the developed countries, meat production is based in obtaining food energy from cereal grains, and the use of extensively processed grains is the main starch source. In developing countries, food energy sources come from crop residues, grain process byproducts, high-sugar-content byproducts, low-processed grains, and alternative feedstuffs regionally available. The concept of meat quality is different, too. Lean meat is the goal in pork production; while in beef production, it is different. In several developed countries such as in the United States and Japan, meat quality has a high relationship with tenderness and marbling. In most developing countries, lean beef is well accepted and tenderness is not necessarily a condition for sale. Geographical location imposes limitations on cattle breed, age to placement in feedlots, and finishing weight. This presentation will explore what we can learn from these production systems, drawing a parallel comparison of intensive meat production in developed and developing countries.

Key Words: meat production, population

0403 Methods to improve nutrient intake in grazing cattle: Pasture management and supplementation.

F. A. P. Santos*, J. R. R. Dórea, F. Batistel, and D. F. A. Costa, *University of São Paulo, Piracicaba, Brazil.*

Most of the grassland areas in Brazil are covered with tropical grasses. The majority of the milk (Stock et al., 2011) and beef (Millen et al., 2009) are produced on pasture-based systems. In intensive grazing systems during the hot rainy season, stocking rates of 6 to 10 AU/ha (1 AU = 450 kg BW) can be achieved (Santos et al., 2014). Despite the high stock capacity, the ADG and milk production are lower than the animals' genetic potential, and this is attributed to the limited energy intake. Some of the major factors imposing limitations to energy intake by the animals in tropical grazing systems are: (a) low efficiency of the grazing process because of sward structure, and (b) rumen fill. During the last 2 decades, a considerable amount of information has been published related to new management practices of tropical pastures. The adoption of the start grazing point, based on the 95% light interception criterion, has successfully resulted in a more favorable sward structure which allows the animal to harvest a greater daily amount of forage in a shorter grazing period. However, even when all the available technology on tropical pasture management is applied, forage intake is still limited because of rumen fill. The quality of the tropical forage NDF (IVNDFD) is greater than alfalfa. However, the NDF content (51 to 65%) and its low cell fragility cause rumen fill, and they limit energy intake. Studies related on cell fragility of tropical grasses are limited, and this topic deserves more attention. Supplementing high energy concentrates for grazing cattle is, at the same time, an efficient strategy to increase energy intake and to decrease the energy expended with the grazing activity. The substitution effect observed when concentrate is fed to grazing cattle is related not only to the amount of concentrate fed, but it is also related to the pasture management practices.

Key Words: grazing, nutrient intake, efficiency

LACTATION BIOLOGY I

0404 Temporary alterations to milking frequency, immediately postpartum, modifies expression of milk synthesis and apoptosis genes in the mammary glands of grazing dairy cows.

T. M. Grala[1], J. K. Kay[2], J. R. Roche[2], A. G. Rius[3], and C. V. Phyn*[2], *[1]DairyNZ, Auckland, NZ, [2]DairyNZ, Hamilton, NZ, [3]University of Tennessee, Knoxville.*

Temporary changes to postpartum milking frequency can elicit lactation-long changes in milk production. The hypothesis tested in this experiment was that the immediate and long-term milk yield response to altered milking frequency would correspond to gene expression changes associated with mammary cell secretory activity and/or number. Multiparous, grazing Holstein-Friesian cows (n = 150) were randomly assigned to 1 of 5 groups at calving: milked once daily (1×) for 3 or 6 wk and twice daily (2×) thereafter; milked 2× for the entire lactation (control); or milked thrice daily (3×) for 3 or 6 wk and 2× thereafter. Milk yields were recorded daily and milk composition weekly. Mammary tissue was collected at 3, 6, and 9 wk postpartum (n = 12 cows/treatment), and gene expression measured using quantitative reverse transcription PCR. Data were analyzed using mixed models fitted with REML (Restricted Maximum Likelihood) in GenStat, including: treatment and contrasts to test milking frequency (1×, 2×, 3×), duration (3 wk, 6 wk), and their interaction as fixed effects, and cow as a random effect. Immediate ($P < 0.001$) and lactation-long ($P < 0.01$) decreases in milk and energy-corrected (ECM) production were recorded in cows milked 1× postpartum relative to 2×; however, cows milked 3× only produced greater ($P < 0.05$) milk volumes during the treatment period and did not differ ($P > 0.05$) in ECM production. Transcript levels from genes involved in milk fat (*ACACA*, *FASN*), protein (*CSN1S1*, *CSN2*), and lactose (*LALBA*, *B4GALT1*) synthesis were not altered in cows milked 3×, but were downregulated ($P < 0.05$) at 3 and 6 wk postpartum in cows milked 1×. Decreased ($P < 0.05$) expression of these genes was maintained after 1× cows were switched to 2× milking. Furthermore, at 9 wk postpartum, cows milked 1× for 3 wk had lower ($P < 0.05$) expression of genes involved in fat and lactose synthesis than cows milked 1× for 6 wk. In contrast, apoptotic genes (*PYCARD*, *FAS*) were up-regulated ($P < 0.05$) in cows milked 1×. This effect was still apparent at 9 wk ($P < 0.01$), indicating that greater mammary cell death was maintained post-treatment. In conclusion, greater milk volumes during 3× milking were not associated with altered expression of genes involved in milk synthesis or mammary cell death. However, changes in expression of genes involved in these processes may underpin the long-term reduction in milk and ECM yields in cows milked 1× postpartum.

Key Words: milking frequency, mammary apoptosis, gene expression

0405 Dietary anion-cation difference and daylength differently affect milk calcium secretion pathways.

M. Boutinaud*[1], A. Bondon[1], A. Narcy[2], C. Hurtaud[1], M. Johan[1], J. Couedon[1], and P. Lamberton[3], *[1]INRA, Saint Gilles, France, [2]INRA, Nouzilly, France, [3]INRA, Le Rheu, France.*

Milk is an important source of Ca for growth and development of children. However, it has been recently shown that dairy milk Ca content decreases with long-day photoperiod and varies according to the type of diet. Many proteins are involved in the secretion of Ca into milk by the mammary epithelial cell (MEC). The aim of this study was to identify the role of gene expression of these proteins in the regulation of milk Ca content. A trial was performed according to a Latin square design using 8 dairy cows averaging 103 ± 44 d in milk, with 2 treatments in a factorial arrangement with 4 periods of 14 d. The cows received 2 levels of dietary anion-cation differences (DCAD; 0 mEq/kg DM for d 0 and 400 mEq/kg for d 400) and 2 daylengths (8 h of light/d for short days and 16 h/d for long days). The DCAD treatments were conceived to mimic diets based either on corn silage or on herbage. The cows were exposed to solarium lights providing UVA and UVB. Once per period, MEC were prepared after milk centrifugation by purification using an anti-cytoketatin antibody bound to magnetic beads to study by real-time RT-PCR the mRNA level of genes involved in Ca secretion expressed related to RPLP0 housekeeping gene. Data were analyzed using Mixed procedure. There was no significant interaction between daylength and DCAD level. Milk and Ca yields did not vary with any treatments, averaging 32.7 kg/d and 41.1 g/d, respectively. With d 400 compared with d 0, milk Ca content increased ($P < 0.01$) with no link with casein content. No significant variation was observed on gene expression with DCAD treatment and on kappa casein and a-lactalbumin mRNA levels with any treatments. Milk Ca and casein content were lower with long days compared with short days ($P < 0.05$). The lower Ca secretion was associated with lower mRNA levels for SPCA1, ITPR1, and PMCA1, 3 Ca transporters in milk purified MEC ($P < 0.05$). This work suggests that Ca secretion pathways may be downregulated with long photoperiod, and that could explain a part of the seasonal decrease of milk Ca content during summer. In contrast, no significant variation of gene expression could explain the increase in milk Ca content with d 400.

Key Words: milk calcium, mammary epithelial cell, photoperid, feeding

0406 Infusion of a 5-hydroxy-L-tryptophan (5-HTP) to late-lactation cows impacts circulating calcium and glucose concentrations. J. Laporta*[1], S. A. E. Moore[1], A. P. Prichard[1], M. Olsen[1], B. P. Schnell[1], S. R. Weaver[1], C. R. Cronick[1], R. M. Bruckmaier[2], and L. L. Hernandez[1], [1]*University of Wisconsin-Madison, Madison,* [2]*Veterinary Physiology, Vetsuisse Faculty, University of Bern, Bern, Switzerland.*

Supplementation of 5-hydroxy-L-tryptophan (5-HTP) improved Ca and glucose status in lactating rodents, and serotonin was shown to be an indicator of positive Ca and glucose status in lactating dairy cows. Here, we examined the effect of intravenous infusion of 5-HTP on circulating Ca and glucose concentrations. Using a 4 × 4 latin square design, multiparous Holstein cows (avg. lactation = 3; avg. d in milk = 333 d) were infused with a sterile saline control (CON) or 1 of 3 doses of 5-HTP (TRT; 0.5, 1.0 and 1.5 mg/kg). Infusion periods were 4 d, with a 5-d washout between periods. Cows were infused at a constant rate for 1 h, and blood samples were collected at 0 min (preinfusion), and 5, 10, 30, 60, 90, and 120 min postinfusion. Heart rate (HR), respiration rate (RR), and rectal temperature (TEMP) were recorded every 15 min during infusion and 15 min postinfusion; milk yield (MY) was recorded daily, and manure score (0 to 4, MS) and frequency were recorded during infusions. Data were analyzed using PROC MIXED in SAS (SAS Inst. Inc., Cary, NC). Heart rate, RR, TEMP, and MY were not different between CON and TRT at any dose ($P > 0.05$) and MS was affected by TRT ($P = 0.013$). The MS was similar between CON and 0.5 mg/kg TRT, but different between CON and 1.0 and 1.5 mg/kg TRT (0.44 vs. 1.69 and 2.06 ± 0.33, respectively). Serum Ca and plasma glucose concentrations were measured and area under the curve (AUC) was calculated using the trapezoidal model. For Ca, all 5-HTP doses significantly decreased AUC compared with CON ($P < 0.001$), decreasing the first 30 min postinfusion, increasing and reaching initial Ca concentrations 120 m postinfusion. Mean Ca was greater for CON compared with all TRT doses (1.70 vs. 1.56, 1.60 and 1.59 ± 0.05 m*M*, respectively) and the same was observed for minimum Ca. Glucose AUC was greater for 1.0 and 1.5 mg/kg TRT compared with CON and 0.5 mg/kg TRT ($P = 0.02$). Mean glucose was greater for 1.0 mg/kg TRT compared with CON and 0.5 mg/kg TRT only at 90 m postinfusion ($P < 0.04$). These results demonstrate that 5-HTP stimulates a decrease in circulating Ca, and only the 2 higher doses of 5-HTP increased circulating glucose. In conclusion, 5-HTP differentially affects circulating Ca and glucose concentrations in dairy cattle, suggesting significant impacts on Ca and glucose metabolism during lactation.

Key Words: 5-hydroxytryptophan, calcium, glucose

0407 The dopamine antagonist domperidone increases prolactin concentration and milk production in dairy cows. P. Lacasse* and S. Ollier, *Dairy and Swine R&D Centre, Sherbrooke, QC, Canada.*

In previous studies, we have shown that inhibition of prolactin (PRL) secretion by the dopamine agonist quinagolide reduces milk production of dairy cows (Domest. Anim. Endocrinol. 43:154). The objective of this study was to determine the effects of the administration of a dopamine antagonist and feed restriction on basal and milking-induced PRL concentrations in blood and milk production in dairy cows. Twelve mid-lactation Holstein cows received daily subcutaneous injections of either domperidone (300 mg, DOMP, $n = 6$) or canola oil (CTL, $n = 6$) for 5 wk. During the fifth wk, all cows were fed at 65% of their DMI of the previous wk. Blood samples were collected before morning milking 3 d a wk from d 8 to d 42 (7 d after the last injections). In addition, blood samples were collected during morning milking at d 1 (before the first injection), 2, 29, and 35. Basal PRL concentration was similar among both groups before the start of treatments. Domperidone injection caused a gradual increase ($P < 0.001$) in basal PRL concentration which averaged, on the week prior the feed restriction, 32.2 and 13.9 ± 2.1 ng/mL for DOMP and CTL, respectively. Feed restriction did not affect basal PRL concentration in DOMP cows but reduced it in CTL cows ($P < 0.05$), averaging 28.0 and 7.9 ± 2.4 ng/mL, respectively. Concentration of PRL was still elevated ($P < 0.05$) in DOMP cows 7 d after the last injection, averaging 19.4 and 10.8 ± 2.7 ng/mL for DOMP and CTL, respectively. In CTL cows, the milking-induced PRL above premilking concentration (AUC) was similar at d 1, 2, and 29, but was reduced ($P < 0.05$) during feed restriction (d 35). In DOMP cows, AUC was similar at d 1 and 2, but was reduced ($P < 0.05$) at d 29 and 35. Milk production was similar for both groups before the start of treatments. There was time × TRT interaction ($P < 0.001$) for milk production during the treatment period. Milk production was similar during the first 2 wk of treatments, but was greater ($P < 0.02$) in DOMP cows during the 2 following weeks, averaging 38.0 and 35.0 ± 0.6 kg/d at wk 3 and 38.0 and 35.3 ± 0.7 kg/d at wk 4 for DOMP and CTL, respectively. Milk production declined in both groups during feed restriction but remained greater ($P < 0.05$) in DOMP cows. Milk production of both groups became similar again 5 d after the last injection. Milk composition and DMI were not affected by DOMP. These results support the hypothesis that PRL is galactopoietic in dairy cattle.

Key Words: feed restriction, prolactin

0408 Compensatory feeding of gestating gilts does not affect mammary development of their offspring at puberty. C. Farmer*[1], M. F. Palin[1], and Y. Martel-Kennes[2], [1]*Agriculture and Agri-Food Canada, Dairy and Swine R&D Centre, Sherbrooke, QC,* [2]*La COOP Fédérée, Animal Nutrition Division, St-Romuald, QC, Canada.*

The goal of this project was to determine if feed restriction followed by compensatory feeding of gestating gilts affects mammary development and mammary gene expression of their female offspring at puberty. Gilts were fed a conventional (CTL; $n = 5$) or an experimental (TRT; $n = 3$) dietary regimen. The experimental regimen provided 70% (restriction) and 115% (compensatory) of the protein and DE contents provided by the CTL diet. The restriction diet was given during the first 10 wk of gestation, followed by the compensatory diet until farrowing. Gilts were allowed to farrow, and female offspring from these (11 CTL, 12 TRT) were weighed at birth, weaning (d 20), and puberty (d 211), at which time they were slaughtered and had their mammary glands collected and dissected. Parenchymal tissue samples were collected for molecular biology work and blood samples were obtained the day before slaughter to measure IGF-1 concentrations. The MIXED procedure of SAS (SAS Inst. Inc., Cary, NC) with treatment as main effect and sow as a randomized effect was used for statistical analyses. Piglets from TRT sows tended to weigh less at birth (1.31 vs. 1.53 kg, SEM = 0.05, $P = 0.10$) than piglets from CTL sows, but had similar BW at weaning and puberty ($P > 0.10$). Concentrations of IGF-1 at slaughter tended to be greater in gilts from TRT than in gilts from CTL sows (167 vs. 142 ng/mL, SEM = 9, $P = 0.06$). Amounts of parenchymal (534.9 vs. 542.4 g for TRT and CTL gilts, respectively, SEM = 45.0) and extra-parenchymal tissue as well as composition of parenchymal tissue (DM, protein, fat, and DNA contents) were similar across treatments ($P > 0.10$). There were no differences in mRNA abundance for *IGF1*, *IGF2*, ornithine decarboxylase 1 (*ODC1*), prolactin receptor (*PRLR*), signal transducer and activator of transcription 5A (*STAT5A*) or 5B (*STAT5A*) in mammary parenchyma ($P > 0.10$). In conclusion, feed restriction and subsequent compensatory feeding of gestating gilts had no effects on mammary development or mammary gene expression of their female offspring at puberty.

Key Words: diet deprivation, diet over allowance, gestation, mammary development, offspring, sows

0409 Comparative 2D-DIGE proteomic analysis of mammary epithelial cells during lactation reveals protein signatures for lactation persistency and milk yield. J. Janjanam*, S. Singh, M. K. Jena, J. K. Kaushik, A. K. Dang, and A. K. Mohanty, *National Dairy Research Institute, Karnal, India.*

The mammary gland is made up of a branching network of ducts that end with alveoli which surrounds the lumen. These alveolar mammary epithelial cells (MEC) reflect the milk producing ability of farm animals. In our previous study, we reported the proteome profile of functionally differentiated mammary epithelial cells isolated from milk (Janjanam et al., 2013). In this study, we have used 2-D DIGE and mass spectrometry to identify and relatively quantify protein expression changes in MEC during early, peak, and late stages of lactation and also compared differentially expressed proteins in MEC isolated from high and low milk yielding animals. All the animals selected for these studies were in their third or fourth parity. For the comparative proteomic analysis at different stages of lactations, we selected 4 animals (Sahiwal cows) in each group of immediate early (E, d 15 to 30 postparturition), peak (P, d 75 to 100 postparturition), and late stage (L, d 210 to 250 postparturition) of lactation. For the comparative proteomic analysis of high and low milk yield samples, we selected 4 animals each of indigenous Sahiwal cows with high yielding (Hy, ~15 L/day) and low-yielding (Ly, ~5 L/day) breeds and 4 high-yielding cross bred cows (Karan Fries: KF, ~22 L/d) were selected which were at peak stage of their lactation. We have identified 44 differentially expressed proteins during lactation stages, and 28 proteins in high and low milk yielding animals. Bioinformatics analysis showed, a majority of the differentially expressed proteins are associated in metabolic process, catalytic, and binding activity. The differentially expressed proteins were mapped to the available biological pathways and networks involved in lactation. The proteins up-regulated during late stage of lactation are associated with NF-kB stress induced signaling pathways and whereas Akt, PI3K, and p38/MAPK signaling pathways are associated with high milk production mediated through insulin hormone signaling. The differentially expressed proteins reported in our present study could be potential biomarkers associated with lactation persistency and secretory diminution. The findings reported in the present study could benefit to the field of lactation biology. Reference: Janjanam et al. (2013). Proteome analysis of functionally differentiated bovine (*Bos indicus*) mammary epithelial cells isolated from milk. Proteomics 13:3189–3204.

Key Words: lactation, mammary epithelial cells, proteomics

0410 Milk protein synthesis is regulated by lysine and branched chain amino acid deficiencies in lactating bovine mammary glands. J. Doelman*[1], R. V. Curtis[2], M. Carson[1], J. J. M. Kim[2], J. P. Cant[2], and J. A. Metcalf[1], *[1]Nutreco Canada Agresearch, Guelph, ON, Canada, [2]Department of Animal and Poultry Science, University of Guelph, Guelph, ON, Canada.*

The supply of specific essential AA is tightly regulated by the lactating dairy cow to maintain milk protein production. To determine the effect of essential amino acid (EAA) deficiencies and imbalances on milk protein synthesis and metabolic parameters, early lactation fistulated dairy cows (105 ± 12 d in milk) were abomasally infused with either saline, EAA, EAA less lysine, EAA less leucine, or EAA less the branched-chain amino acids (BCAA; isoleucine, leucine, and valine) in a 5 × 5 Latin square design. Cows were fed a diet to provide an NE_L of 6.9MJ/kg DM and 11.7% crude protein. Compared with EAA, a BCAA deficiency significantly decreased plasma concentration of Leu, Val and total BCAA by 72, 67, and 66%, respectively ($P < 0.001$). In response to a leucine deficiency, plasma concentration of Ile and Val increased 71 and 62%, respectively, while plasma leucine decreased 72% ($P < 0.001$). Omission of lysine from the abomasal infusate resulted in a 72 and 77% decline in plasma lysine and asparagine, respectively ($P < 0.04$). Plasma concentrations of β-hydroxybutrytrate and NEFA were not significantly different between treatments. While no significant treatment differences were observed for daily milk production (30.1 kg/d), milk protein yield increased 18% by the EAA infusion over saline ($P = 0.001$), while the omissions of lysine, leucine, and the BCAA decreased milk yield by 10.2, 21.1, and 12.2%, respectively, compared with EAA ($P < 0.03$). In comparison with EAA, milk protein concentration was 0.23 ($P = 0.057$), 0.3 ($P = 0.01$), and 0.29 ($P = 0.01$), percentage points lower for lysine, leucine, and BCAA deficiencies, respectively. The increase in plasma concentration of Ile and Val in response to Leu deficiency suggests that compensatory measures were initiated to maintain substrate supply for milk protein synthesis. These results indicate that protein synthesis in the mammary gland is sensitive to the supply of Lys, Leu, and the BCAA.

Key Words: mammary gland, milk protein synthesis, essential amino acid

0411 Lysine and branched-chain amino acid deficiencies decrease abundances of S6K and eIF2Bε in the mammary glands of lactating dairy cows. J. Doelman[1], R. V. Curtis*[2], M. Carson[1], J. J. M. Kim[2], J. A. Metcalf[1], and J. P. Cant[2], *[1]Nutreco Canada Agresearch, Guelph, ON, Canada, [2]Department of Animal and Poultry Science, University of Guelph, Guelph, ON, Canada.*

There have been recent investigations into the potential role of mRNA translational control in the regulation of synthesis of milk protein in the lactating bovine mammary gland. An infusion subtraction protocol was used to explore effects on abundance and activity state of regulators of mRNA translation in response to specific essential amino acid (EAA) deficiencies and imbalances. Five lactating cows on a diet of 11.7% protein were infused abomasally for 5 d with saline, 563 g/d of a complete EAA mix (equivalent to EAA in 1 kg casein), or EAA without Lys, Leu, or the branched-chain amino acids (BCAA; Ile, Leu, and Val) in a 5 × 5 Latin square design. Data was analyzed using the MIXED procedure in SAS (SAS Inst. Inc., Cary, NC) where period and treatment were considered classification effects and cow considered a random effect. The translation factors examined in mammary biopsies collected on d 5 of each period were ribosomal protein S6 kinase (S6K) to indicate mTOR (mammalian target of rapamycin) activity, eukaryotic initiation factor 2 α (eIF2α) to indicate uncharged tRNA signalling, and eukaryotic initiation factor 2B epsilon (eIF2Bε) to indicate insulin effects. Milk protein yield increased in response to EAA compared with saline ($P = 0.001$), while Lys, Leu, and BCAA deficiencies depressed milk protein yield compared with EAA ($P < 0.03$). Infusion of the complete EAA mix did not affect mTOR activity ($P = 0.65$), but subtraction of BCAA from the mix decreased phosphorylated S6K abundance ($P = 0.05$) and subtraction of Leu tended to decrease phosphorylated S6K ($P = 0.10$). Similarly, abundance of total eIF2Bε was not affected by infusion of EAA ($P = 0.39$) but decreased when BCAA ($P = 0.04$) or Leu ($P = 0.06$) were subtracted. There was a correlation of 0.58 between abundances of phosphorylated S6K and total eIF2Bε. Lys subtraction had no effect on mammary mTOR/eIF2Bε signalling, but the abundance of total S6K tended to be lower during Lys deficiency compared with saline ($P = 0.06$) and EAA ($P = 0.09$). Phosphorylation state of eIF2α was not increased by any of the imbalances or deficiencies. It was concluded that Lys deficiency may impair milk protein yield through a decline in translational activation capacity, indicated by S6K abundance. The BCAA deficiencies may impair milk protein yields through deactivation of mTOR-mediated up-regulation of eIF2Bε abundance.

Key Words: milk protein synthesis; mRNA translation regulation, essential amino acid

LACTATION BIOLOGY II

0412 Intramammary glucocorticoid during a mammary immune response to lipopolysaccharide modulates the blood-milk barrier. O. Wellnitz*, S. K. Wall, M. Saudenova, and R. M. Bruckmaier, *Veterinary Physiology, Vetsuisse Faculty, University of Bern, Bern, Switzerland.*

Glucocorticoids such as prednisolone are frequently used in addition to intramammary antibiotic therapy to increase the cure rate of mastitis in dairy cows. This study aimed to investigate the effects of intramammary administered prednisolone during the mammary immune response to lipopolysaccharide (LPS). Five healthy mid-lactation Holstein dairy cows received 1 of 4 intramammary treatments in each of their 4 quarters: prednisolone (10 mg), LPS (100 μg), LPS (100 μg), and prednisolone (10 mg), or saline control. Milk samples were taken 0, 3, 6, 9, 12, 24, and 36 h after challenge. Somatic cell count (SCC), and concentrations of lactate dehydrogenase (LDH), serum albumin (SA), and tumor necrosis factor-α (TNFα) in milk and mRNA abundance of TNFα, Interleukin (IL)-8, and IL-1β in milk somatic cells were compared at each time point. Differences between quarters were tested by analysis of variance using a MIXED procedure and were considered significant if $P < 0.05$. Control and prednisolone infused quarters did not show changes of SCC, LDH, SA, and TNFα concentrations in milk and mRNA expression of TNFα, IL-1β, and IL-8 in milk somatic cells. Concentrations of SCC and TNFα in milk increased similarly in LPS challenged quarters independent of additional prednisolone application. However, the increase of LDH activity and SA concentration in LPS challenged quarters was diminished by prednisolone ($P = 0.028$ and $P < 0.001$, respectively) from 1352 ± 845 to 264 ± 107 U/L for LDH, and 8.17 ± 0.29 to 2.68 ± 0.30 mg/L for SA at 6 h after challenge, respectively. The mRNA abundance of TNFα, IL-8, and IL-1β in milk somatic cells increased in response to LPS challenge unaffected by prednisolone. In conclusion, the intramammary administration of the glucocorticoid prednisolone does not induce an increase of SCC, changes in concentrations of blood components in milk, and does not change the production of TNFα, IL-8, and IL-1β in milk cells in response to intramammary LPS challenge. However, the intramammary administration of prednisolone clearly reduces the disruption of the blood-milk barrier induced by endotoxin challenge shown by a reduced appearance of blood constituents like SA or LDH in milk. This effect could have an important influence on the severity and on the cure rate of mastitis.

Key Words: prednisolone, blood-milk barrier, mastitis

0413 Milk prolactin response after experimental infection with different coagulase-negative staphylococci in dairy heifers. K. Piccart*[1], S. Piepers[1], J. Verbeke[1], N. Melo de Sousa[2], J. F. Beckers[2], and S. De Vliegher[1], *[1]Ghent University, Ghent, Belgium, [2]University of Liège, Liège, Belgium.*

Coagulase-negative staphylococci (CNS) are the most common group of bacteria involved in subclinical bovine mastitis. Dairy heifers infected with CNS seem to produce more milk than uninfected heifers, but the underlying mechanism is yet unclear. This study investigates the response of prolactin (PRL) in milk as a potential mediator of milk yield (MY) after experimental challenge with different CNS species. Eight Holstein-Friesian heifers in mid-lactation (126 d in milk ± 66) were challenged in a split-udder design with 3 different CNS isolates: 1 *S. fleurettii* isolate from sawdust and 2 phenotypically dissimilar *S. chromogenes* isolates. The first *S. chromogenes* isolate originates from a chronic intramammary infection, while the other is cultured from a teat apex. Three quarters were simultaneously inoculated with 1.0×10^6 colony forming units. The remaining quarter was infused with sterile phosphate-buffered saline and served as a control. Milk samples were obtained for measuring PRL (by radioimmunoassay) at various time points starting 24 h preinoculation until 72 h after challenge. Furthermore, quarter MY was recorded. Milk samples were cultured to evaluate bacterial clearance. A linear mixed regression model, using heifer and quarter as random effects, was built to evaluate the PRL response after infection with sampling time and inoculation type as fixed effects. Preinoculation data were not included in the analysis. None of the quarters developed clinical symptoms and none of the heifers showed signs of illness. Milk culture results revealed that all CNS were eliminated before the end of the trial. Even though this study did not focus on MY, a decreased production was observed in all quarters. The infection status did not have a demonstrable effect on milk PRL concentration: no significant difference was found between infected and control quarters, or between different CNS-isolates ($P = 0.40$). However, milk PRL generally changed over time ($P < 0.05$). These findings suggest that milk PRL is not a likely candidate to explain any potential increase in milk production after a subclinical infection caused by *S. chromogenes* or *S. fleurettii*.

Key Words: prolactin, mastitis, coagulase-negative staphylococci

0414 Regulation of nuclear IGFBP-3 in response to intrinsic apoptotic stress in bovine mammary epithelial cells. A. Agostini-Dreyer, A. E. Jetzt, and W. S. Cohick*, *Rutgers, the State University of New Jersey, New Brunswick.*

Following peak lactation, the number of secretory mammary epithelial cells (MEC) in the bovine gland gradually

decreases due to increased apoptosis, leading to a decrease in lactation persistency. However, the mechanisms that govern apoptosis in the bovine MEC are under-investigated. We have previously shown that anisomycin (ANS), an activator of the intrinsic apoptotic pathway, is a potent inducer of IGFBP-3 production in MAC-T cells, and that knock-down of IGFBP-3 with siRNA attenuates the ability of ANS to activate apoptosis. Interestingly, IGFBP-3 is found in both the nucleus and the conditioned media in response to ANS, indicating a potential for both intra- and extracellular functions. Whether nuclear IGFBP-3 arises from secreted IGFBP-3 is controversial. In the present work, MAC-T cells were transfected with a plasmid expressing GFP-tagged IGFBP-3. Analysis using fluorescent microscopy indicated that IGFBP-3 resided basally in the cytosol and translocated to the nucleus in response to ANS. Since IGFBP-3-GFP is too large to passively diffuse through nuclear pores, this supports a role for active nuclear import. Chemical inhibition of the nuclear transport protein importin-β with importazole reduced ANS-induced nuclear IGFBP-3-GFP, indicating that IGFBP-3 utilizes importin-β for nuclear import. Endoglycosidase-H digestion of nuclear fractions showed that intracellular IGFBP-3 was glycosylated, indicating it had been transported through the secretory pathway. However, inhibition of ER to Golgi transport with Brefeldin A inhibited secretion of IGFBP-3 but increased its nuclear accumulation, indicating that secretion is not required for nuclear localization. In support of these data, inhibition of clathrin-mediated endocytosis with the chemical inhibitor Pitstop2 did not impact nuclear localization of IGFBP-3. In summary, these data show that secretion is not required for ANS-induced nuclear localization of IGFBP-3 and that its nuclear import is a regulated event.

Key Words: mammary gland, lactation, IGFBP-3

0415 Cellular composition of water buffalo mammary gland and its proliferation status during dry and mastitis.

R. K. Choudhary*[1], D. Pathak[2], D. Deka[1], and R. Verma[1], *[1]School of Animal Biotechnology, GADVASU, Ludhiana, Punjab, 141 004, India, [2]Department of Veterinary Anatomy, GADVASU, Ludhiana, Punjab, 141 004, India*

Mammary alveoli, composed of mammary epithelial cells, are the structural and functional units of a mammary gland, which secrete milk into the alveolar lumen. Milk production is directly related to secretory activity and number of alveolar cells. Alternation in cellular composition, in particular alveolar cells, thus has a direct role in volume of milk secretion. We collected mammary tissues of milking water buffalo from a slaughterhouse for the purpose of evaluation of its cellular composition, proliferation status, and identification of myoepithelial cells. Out of 21 buffaloes, ~80% of mammary samples were from the dry animals (evidenced by presence of small nonsecretory epithelial cells and virgin-like state of the gland) and ~20% of samples were from the lactating animals. All the lactating animals were affected with mastitis (suggested by the presence of fibrin clots, cellular debris, and loss of alveolar epithelium), which were also confirmed by a veterinary pathologist. The fraction of total mammary epithelium (large secretory and small nonsecretory cells; mean % ± SE) did not differ in dry vs. lactation period (22.6 ± 1.66 vs. 18.7 ± 3.59; $P > 0.05$). However, number of small nonsecretory epithelium were greater in dry period (22.6 ± 1.66 vs. 10.1 ± 2.97; $P = 0.006$) than the lactation period, likely due to differentiation of nonsecretory cells into secretory cells. Number of myoepithelial cells (identified by vimentin expression in basal layer of epithelium) were greater (23.38 ± 2.89 vs. 5.55 ± 1.10; $P = 0.004$) in mastitis-afflicted than the dry animals. Increased expression of vimentin (also a marker of migrating cells) in the stroma, suggested the role of cell migration in inflammation, tissue regeneration and immune response during mastitis. Thus, mastitis-infected animals had increased number of myoepithelial cells and stromal migratory cells in their mammary glands. A greater number of myoepithelial cells during mastitis was concomitant with increased (5×) expression of Ki-67, a marker of cell proliferation. This study demonstrates cellular composition of buffalo mammary glands as well as supports the idea that infection of mammary gland enhances proliferation of mammary epithelial cells.

Key Words: water buffalo mammary gland, cellular composition, vimentin, proliferation

0416 Use of the RatLoft in laboratory conditions decreases pup mortality in lactating mice.

S. R. Weaver*, C. R. Cronick, A. P. Prichard, J. Laporta, N. J. Benevenga, and L. L. Hernandez, *University of Wisconsin-Madison, Madison.*

Mice in laboratory conditions are under considerable stress. Lactating dams may manifest this psychological distress through a decrease in milk yield or increase in pup mortality. The RatLoft (Research Animal Welfare Equipment, LLC, Madison, WI) is a stainless steel tube that hangs over the side of the cage with access to food, allowing the dam time away from her pups. Here, we examined the effect of the RatLoft on milk yield, circulating serotonin (5-HT), pup mortality, and behavioral distress as measured by the Porsolt Forced Swim Test (FST). Pregnant mice deficient for tryptophan hydroxylase-1 ($TPH1^{-/-}$, $n = 10$) and wild-type mice (WT, $n = 10$) were randomly assigned to loft (L; $n = 5$) and no loft (NL; $n = 5$) treatment groups. Milk yield was measured daily for 21 d. The FST was performed on d 10 and pup mortality was recorded throughout the experiment. Blood was collected on d 1, 9, and 21. Data was analyzed using a 2-way ANOVA. Milk yield increased over time in all animals ($P < 0.0001$). Presence or absence of the RatLoft did not affect milk yield ($P > 0.05$). Overall, WT mice had increased milk yield compared with $TPH1^{-/-}$ mice, regardless of the presence of RatLoft ($P < 0.05$).

The FST used to evaluate behavioral distress indicated that the presence or absence of RatLoft was not significant ($P > 0.05$). Serum 5-HT concentrations were increased in WT compared with TPH1$^{-/-}$ mice. Presence or absence of the RatLoft did not affect circulating 5-HT concentrations ($P > 0.05$, 373 vs. 309 ± 55 ng/mL), but 5-HT concentrations decreased throughout lactation (455 vs. 245 ± 65 ng/mL on d 1 and 21, respectively). Serotonin concentrations were increased in TPH1$^{-/-}$ mice with the L ($P < 0.01$; 33 ± 13 ng/mL vs. 13 ± 1.4 ng/mL). The TPH1$^{-/-}$ mice with L had less 5-HT on d 1 and 9 compared with d 21 ($P = 0.005$; 21 and 17 vs. 51 ± 6.5 ng/mL, respectively). The 5-HT levels in TPH1$^{-/-}$ mice with NL did not change over time ($P > 0.05$). Pup mortality was significantly less for dams with L as compared with mice with NL ($P = 0.047$, 0.49 ± 0.16 pups/dam vs. 0.195 ± 0.06). Mortality rates were not different between WT and TPH1$^{-/-}$ mice ($P > 0.05$). These results demonstrate that access to RatLoft during lactation decreases pup mortality rates in all animals, as well as increased 5-HT concentrations in TPH1$^{-/-}$ mice. In conclusion, use of the RatLoft could prove beneficial to researchers working with lactating mouse models to decrease pup mortality rates.

Key Words: serotonin, lactation, RatLoft

0417 Addition of glycerol to lactating cow diets stimulates milk protein yield to a greater extent than addition of corn grain. D. L. Bajramaj*[1], R. V. Curtis[2], J. J. M. Kim[2], V. R. Osborne[1], T. Wright[3], and J. P. Cant[1], *[1]University of Guelph, Guelph, ON, Canada, [2]Department of Animal and Poultry Science, University of Guelph, Guelph, ON, Canada, [3]University of Guelph/OMAF, Guelph, ON, Canada.*

As the biofuel industry grows and expands, there is an increased availability of the byproduct glycerol, which could be a glucogenic feedstuff for dairy cows. The objective of this study was to determine if the addition of glycerol to the diet of dairy cows would stimulate milk protein yield in the same manner as the addition of corn grain. Twelve lactating dairy cows were assigned at 81 ± 5 d in milk to 3 diets in a repeated 3 × 3 Latin square design. The diets were a 70%-forage diet considered the base diet, the base diet with 19% ground and high-moisture corn replacing forages, and the base diet with 15% refined glycerol and 4% added protein supplements to be isocaloric and isonitrogenous with the corn diet. Diets contained 17.2, 17.9, and 17.3% CP, respectively, and 34, 28, and 30% NDF, respectively. The diets were fed for periods of 28 d each, and milk, feed, and blood samples were collected during the last week of each period for compositional analysis. Treatment differences were evaluated by ANOVA using PROC MIXED of SAS (SAS Inst. Inc., Cary, NC) with cow as a random effect. Dry matter intake increased from 23.7 kg/d on the base diet to 25.8 kg/d on the corn diet ($P = 0.007$) and to 27.2 kg/d on the glycerol diet ($P < 0.001$). There was a tendency for DMI to be higher with glycerol than corn ($P = 0.06$). Milk production increased from 39.2 kg/d on the base diet to 43.8 kg/d on the corn diet ($P < 0.001$) and to 44.2 kg/d on the glycerol diet ($P < 0.001$). There was no difference in milk yield between corn and glycerol diets. Milk protein content was 3.19, 3.33, and 3.44% on the base, corn, and glycerol diets, respectively, and the stimulation by glycerol was greater than the stimulation by corn ($P = 0.037$). Protein yield was increased 197 g/d by the addition of corn and 263 g/d by the addition of glycerol, and the glycerol effect was larger than the corn effect ($P = 0.054$). Efficiency of capture of dietary protein in milk protein, however, was lower on the glycerol diet at 29.5% compared with 32.6% on the corn diet ($P = 0.017$). It was concluded that glycerol stimulated milk protein yield to a greater extent than corn grain.

Key Words: glycerol, milk protein synthesis, dairy cow

0418 Glucose does not stimulate milk protein yield of dairy cows when essential amino acids are in excess supply. K. Nichols*[1], M. Carson[2], J. J. M. Kim[1], J. A. Metcalf[2], J. P. Cant[1], and J. Doelman[2], *[1]Department of Animal and Poultry Science, University of Guelph, Guelph, ON, Canada, [2]Nutreco Canada Agresearch, Guelph, ON, Canada.*

To determine if glucose stimulates milk protein yield when essential amino acids (EAA) are supplied in excess, 5 early-lactation, rumen-fistulated dairy cows (78 ± 13 d in milk) were abomasally infused for 5 d with EAA and glucose solutions in a 5 × 5 Latin square design. The 5 infusion treatments were saline, 844 g/d EAA in the profile of casein, 1126 g/d EAA, 844 g/d EAA + 1000 g/d glucose, or 1126 g/d EAA + 1000 g/d glucose. Cows were fed a diet containing 6.96 MJ/kg NE_L and 12% crude protein on a dry basis. Milk composition and yield during the last 2 d of each period and plasma metabolite concentrations during d 4 of infusion were subjected to ANOVA using PROC MIXED of SAS (SAS Inst. Inc., Cary, NC), where cow was a random effect. EAA infusion increased essential and branched-chain AA concentrations in plasma 3- to fourfold compared with saline ($P < 0.001$). Non-EAA concentrations decreased 11 to 17% during EAA infusions ($P < 0.001$). Addition of glucose to EAA infusates decreased essential and branched AA concentrations in plasma ($P < 0.031$) and had no effect on non-EAA concentrations. Essential amino acid infusion increased concentrations of NEFA ($P = 0.004$) and urea N ($P < 0.001$) in plasma, but had no effect on glucose concentrations. Addition of glucose to EAA infusates increased glucose concentrations in plasma 13 to 19% ($P < 0.001$), decreased NEFA 26 to 32% ($P < 0.001$) and had no effect on urea N. Dry matter intake was not affected by EAA infusion, while daily milk yield increased 16% and milk protein yield increased 27% (for an average of 262 g/d) at the highest level of EAA infusion compared with saline ($P < 0.001$). Milk protein concentration increased from 2.9% with saline to 3.3%

with EAA ($P < 0.001$). The addition of glucose to EAA infusates caused DMI to decrease 0.65 kg/d ($P = 0.040$), tended to increase milk yield ($P = 0.057$), had no effect on milk protein yields ($P = 0.318$), but tended to decrease milk protein concentration ($P = 0.097$) and decreased milk fat concentration ($P < 0.001$). Thus, increased supply of glucose at high levels of EAA supplementation did not improve milk protein yields, but because of the decline in feed intake there was an increased efficiency of capture of dietary protein into milk protein.

Key Words: milk protein, essential amino acids

MEAT SCIENCE & MUSCLE BIOLOGY

0419 Changes to the muscle proteome during acute heat stress are dependent on predominant fiber type. S. M. Cruzen*, K. B. Carlson, S. C. Pearce, L. H. Baumgard, N. K. Gabler, and S. M. Lonergan, *Iowa State University, Ames*.

The objective was to determine acute proteomic changes in muscle caused by heat stress. Crossbred gilts (n = 16) were exposed to either thermal neutral (TN, 20°C, 40% relative humidity) or heat stress (HS, 37°C, 40% relative humidity) conditions for 12 h with ad-libitum feed intake. The semitendinosus was collected, divided into red (RST) and white (WST) portions, and frozen in liquid N. Protein abundance changes due to treatment were determined ($P < 0.15$) in sarcoplasmic extracts of HS and TN animals via 2-dimensional difference in gel electrophoresis (2D-DIGE). Proteins were identified using electrospray ionization mass spectrometry. Compared with TN muscle, heat shock protein (Hsp) 70, mitochondrial Hsp70, Hsp27, Hsp20, and α-B crystallin were increased in abundance in muscle of HS pigs. However, 1 spot identified as α-B crystallin was decreased in abundance in the RST with HS. Several protein spots associated with glycolysis or the TCA cycle were changed in abundance with HS, indicating that muscle energetic metabolism is altered during HS. In the RST, these proteins included aldolase A (decreased, 1 spot), phosphoglycerate kinase 1 (increased, 2 spots), phosphoglycerate mutase 2 (decreased, 1 spot), malate dehydrogenase (increased, 2 spots), succinyl-CoA synthetase (increased, 1 spot), and creatine kinase (increased, 1 spot). In the WST, changes in the proteins aldolase A (increased, 1 spot), glyceraldehyde 3-phosphate dehydrogenase (increased, 1 spot), and creatine kinase (decreased, 1 spot) were identified. In both muscle types, β-enolase (increased, 1 spot), isocitrate dehydrogenase (increased, 1 spot), and malate dehydrogenase (increased, 2 spots) were changed in abundance with HS. Heat stress may also affect cell structure. In the WST, HS altered abundance of proteins involved in microtubule or microfilament structure, including α and β tubulin (decreased, 1 spot each) and cofilin 2 (increased, 1 spot). Finally, abundance of several peroxiredoxins was altered with HS, which may indicate that oxidation regulation is changed during acute HS. In HS pigs, peroxiredoxin 6 was increased in 1 spot in the RST, and peroxiredoxin 1 was decreased in 1 spot in the WST. Peroxiredoxin 2 was decreased in abundance in 2 spots in both muscle types due to HS. These results demonstrate that acute HS may have measurable impacts on muscle metabolism, structure, and antioxidant enzymes, which may contribute to the decreased performance generally observed in HS pigs. Additionally, muscle types may respond and adapt differently to acute HS.

Key Words: heat stress, pigs, fiber type

0420 Relationship of fat quality to meat quality traits of pork. E. D. Testroet*, C. Yoder, C. Bustos, S. M. Lei, D. C. Beitz, and T. J. Baas, *Iowa State University, Ames.*

The objectives of this research were to investigate the relationship of pork fat quality to meat quality, the effect of genetic differences on fat quality, how fat quality and adipocyte cellularity varies amongst anatomical sites, and finally how the 7 breeds performed when compared with one another. Our hypothesis was that measures of pork fat and meat quality vary with different breeds of pigs, and that a relationship exists between fat and pork quality measures. Barrows and gilts (n = 352) of 6 purebred lines and 1 commercial crossbred line were fed commercial swine diets with dried distillers grains with solubles (DDGS) inclusion at 30% of DM. Pigs began the experiment when the pen average pig weight was 31.8 kg and were harvested at a minimal weight of 111.1 kg. At harvest, carcass characteristics were measured, adipose tissue was collected from the back, belly, and jowl, and meat samples were taken from the longissimus muscle for evaluation of fat and meat quality characteristics. Iodine values varied amongst breed within anatomical site and between anatomical sites within each breed, and, therefore, the anatomical site of adipose tissue sampling may be of importance when evaluating iodine values of pork fat. Jowl fat iodine values are significant ($P < 0.0001$) predictors of back and belly fat iodine values (R^2 = 0.2922 and 0.3604 respectively). Backfat iodine values were not significantly correlated with ultimate pork chop muscle pH ($P = 0.0680$) but were significantly negatively correlated with visual color ($P = 0.0002$), visual marbling ($P < 0.0001$), and visual firmness ($P = 0.0346$), indicating that an increase in iodine value of pork fat is related to a decrease in pork quality as perceived by consumers. Finally, adipocyte cellularity was significantly affected by breed when compared within anatomical location across breeds ($P < 0.05$), but significant differences between breeds, within anatomical location, of mean cell size of adipocytes were only found for belly adipose tissues. Overall, these experimental results support our hypothesis that there is a significant relationship between pork fat and pork quality and that pork fat quality and meat quality vary by breed. Additionally, iodine values are a valuable measure of pork quality, and iodine values of jowl fat can be used to predict iodine values of back and belly fat, providing a powerful tool to meat packers for fat quality estimation.

Key Words: iodine value, pork quality, adipocyte cellularity

0421 Effects of dietary level of dried citrus pulp on growth, feed efficiency, carcass merit, and lean quality of finishing pigs. C. M. Strong*, J. H. Brendemuhl, D. D. Johnson, and C. Carr, *University of Florida, Gainesville.*

As feed costs continue to be the largest expense for producers, fibrous feedstuffs such as dried citrus pulp (DCP), previously thought to be of marginal quality, are now being explored for use in swine diets because of their availability and low cost. Previous research has focused on DCP as an energy supplement in cattle diets in Florida, but there have been limited studies investigating the effects of differing dietary levels of DCP on the growth, efficiency, carcass merit, and lean quality of finishing pigs. Pigs (n = 40) were fed 1 of 4 diets for 49 d: a corn soybean meal control diet (CON; n = 10), or the same diet with DCP replacing 15% (15DCP; n = 10), 22.5% (22.5DCP; n = 10), or 30% (30DCP; n = 10) of the total diet DM. Overall, G:F over 49 d was greater in CON and 22.5DCP than 30DCP ($P < 0.02$). Pigs were slaughtered at the University of Florida Meat Laboratory abattoir. Initial pH was taken 60 min postexsanguination from the LM and the semimembranosus (SM). Carcasses were fabricated at 24 h postmortem, where initial meat quality measurements were made at the 10th and 11th rib interface of the LM and the gluteus medius of the ham face. Fat measurements taken at the blade region of the LM received higher L* values ($P < 0.04$) in CON animals compared with 22.5DCP and 30DCP. When evaluated objectively, bellies from CON pigs were firmer ($P < 0.0001$) than all other treatment groups, but both CON and 15DCP garnered higher subjective firmness scores than 22.5DCP and 30DCP ($P \leq 0.04$). Belly thickness at both the blade and flank ends decreased as DCP percentage increased, with CON exhibiting the thickest ($P < 0.03$) and 30DCP having the thinnest ($P \leq 0.02$) measurements. Longissimus muscle chops from 30DCP pigs received higher juiciness scores from panelists than 22.5DCP and CON ($P \leq 0.03$), while 15DCP chops only earned higher values than CON chops ($P = 0.03$). There was no effect of dietary DCP inclusion on muscle pH, lightness, redness, and yellowness values, chroma, or hue angle, drip or purge loss, live or hot carcass weight, dressing percentage, back fat, loin eye area, percentage lean, shear force, cook loss, retail evaluation, or retail lightness, redness, or yellowness values. Though sensory panelists reported increased palatability (juiciness) of chops from pigs receiving 30% DCP, increasing DCP percentage of the total diet DM appeared to be economically detrimental to overall production because of negative impacts on growth performance and pork belly quality.

Key Words: pork, citrus, byproduct

0422 Effects of zilpaterol hydrochloride and implants in beef heifers I: Feedlot performance, carcass characteristics, and intramyocellular lipid accumulation. M. A. Vaughn*, S. M. Ebarb, K. J. Phelps, D. D. Burnett, J. S. Drouillard, and J. M. Gonzalez, *Kansas State University, Manhattan.*

To assess the effects of zilpaterol hydrochloride (ZH) supplementation and implants on feedlot performance, carcass characteristics, and intramyocellular lipid accumulation, 33 crossbred yearling heifers were blocked by initial BW (464 ± 2 kg) and randomly assigned to 3 treatments consisting of no implant or ZH (CON); Component TE-200 implant on d 1 of the study, no ZH (IMP); implant and 8.3 ppm of ZH for 21 d with a 3-d withdrawal period (ZIL). Animals were fed a finishing ration once daily, ad libitum, with bunks managed to leave a minimum amount of unconsumed feed. After a 75-d feeding period, cattle were harvested at a commercial abattoir. At 36 h postmortem, carcass characteristics were collected and boneless strip loins were transported to the Kansas State University Meats Laboratory. To assess intramyocellular lipid content, 13th-rib LM samples were cryopreserved, cut into 5-µm sections, and exposed to BODIPY 493–503 staining. Final BW, DMI, ADG, and KPH were not affected by treatment ($P > 0.30$). The IMP and ZIL heifers had greater G:F compared with CON ($P = 0.04$). The ZIL heifers had greater ($P < 0.01$) HCW than CON heifers and IMP heifers tended to have greater ($P = 0.07$) HCW than CON heifers. The ZIL heifers had greater ($P = 0.03$) dressing percentage (DP) compared with CON heifers, and IMP heifers tended to have a greater ($P = 0.07$) DP than CON heifers. Heifers fed ZIL also had greater LM area ($P = 0.01$) compared with CON heifers, and IMP heifers tended to have greater ($P = 0.06$) LM area than CON heifers. Heifers from the CON treatment had greater ($P = 0.01$) amounts of backfat than ZIL heifers, and CON heifers tended to have more ($P = 0.09$) backfat than IMP heifers. The CON heifers had greater ($P = 0.04$) marbling than IMP heifers, but ZIL carcasses did not differ in marbling between the 2 other treatments ($P > 0.14$). For LM area, backfat, and marbling, ZIL and IMP carcasses did not differ from one another ($P > 0.37$). Additionally, IMP heifers contained a greater ($P = 0.04$) percentage of muscle fibers with intramyocellular lipid droplets than ZIL heifers. The CON heifers tended to have a greater ($P = 0.08$) percentage of muscle fibers that contained intramyocellular lipid droplets than ZIL heifers. These data suggest that implanting cattle and ZH supplementation increase efficiency of lean meat production while decreasing adipose tissue accumulation in all depots except KPH.

Key Words: implants, zilpaterol hydrochloride, intramyocellular lipids

0423 Effects of zilpaterol hydrochloride and implants in beef heifers II: Aging effects on Warner-Bratzler shear force, collagen solubility, and fiber cross-sectional area. S. M. Ebarb*, K. J. Phelps, M. A. Vaughn, J. A. Noel, C. B. Paulk, J. S. Drouillard, and J. M. Gonzalez, *Kansas State University, Manhattan.*

To evaluate the effects of zilpaterol hydrochloride (ZH), implants, and day of aging (DOA) on Warner-Bratzler shear force (WBSF), collagen solubility, and fiber cross-sectional area (CSA), 33 crossbred heifers were blocked by weight and randomly assigned to 1 of 3 treatments: no implant or ZH (CON); Component TE-200 implant on d 1 of the study (IMP); or implant and 8.3 ppm of ZH for 21 d with a 3-d withdrawal period (ZIL). After 75 d of feeding, animals were shipped to a commercial abattoir for harvest, chilled for 36 h, and boneless strip loins were transported to the Kansas State University Meats Laboratory. To assess CSA and myosin heavy chain isoform (MHC), 13th-rib LM samples were cryopreserved, sectioned into 5-µm sections, and immunostained for MHC type I, IIA, and IIX. On d 3, 14, and 21 of aging, a 2.54-cm steak and a 0.64-cm steak were fabricated for WBSF and collagen solubility analyses, respectively. For WBSF, there was a treatment × DOA interaction ($P < 0.01$). On d 3 of aging, CON steaks had decreased WBSF compared with IMP and ZIL steaks ($P < 0.01$). At d 14, CON and IMP steaks did not differ ($P = 0.21$) in WBSF, but ZIL steak WBSF values were greater than those of the other treatments ($P < 0.01$). After 21 d aging, there were no WBSF differences between treatments ($P > 0.13$). There was no treatment × DOA interaction for percent soluble or total collagen ($P > 0.20$). Implants and ZIL increased the percentage of soluble collagen when compared with CON ($P < 0.05$), and solubility of collagen also increased between d 14 and 21 of aging ($P < 0.01$). Treatment or DOA did not affect total collagen content ($P > 0.51$). For type I muscle fibers, CSA was greatest for the IMP group ($P < 0.01$). Type IIA and IIX CSA were greater for ZIL compared with IMP and CON ($P < 0.01$). There were positive correlations between type IIX CSA and WBSF on d 3, 14, and 21 of aging ($R^2 = 0.64$, 0.58, and 0.37, respectively; $P < 0.05$). Increased CSA for type I and type IIA were positively correlated with increased WBSF for d 3 and 14 (type I $R^2 = 0.51$, 0.44, and 0.26; type IIA $R^2 = 0.51$, 0.45, and 0.27, respectively; $P < 0.05$), but not for d 21 ($P > 0.14$). Implants and ZH increase the CSA of muscle fibers, which correlate positively with WBSF values.

Key Words: growth promotants, shear force, cross-sectional area

0424 Effect of zilpaterol hydrochloride on carcass composition, subprimal yield, and meat quality of Nellore heifers. N. R. B. Cônsolo*[1], R. S. Goulart[2], F. Rodriguez[1], M. O. Frasseto[1], R. A. P. Maciel[1], J. F. Penso[1], and L. F. P. Silva[1], [1]*University of São Paulo, São Paulo, Brazil,* [2]*MSD Saúde Animal, Sao Paulo, Brazil.*

The aim of this research was to evaluate the effects of zilpaterol hydrochloride (ZH) on carcass composition, carcass subprimal yield and meat quality of Nellore heifers. Seventy-two animals were fed with ZH (Zilmax, Merck Animal Health, Summit, NJ) during 30 d, allowing for 3 d of product withdrawn before slaughter. The animals were blocked by BW and previous ADG and allocated into 2 groups: Control and Zilpaterol (8.3 mg ZH/kg of diet DM). After 24 h postmortem, left carcasses were processed and the ninth, 10th, and 11th rib sections (HH sample) were removed from the primal rib to determine carcass chemical composition. Four steak samples were collected from the longissimus muscle to determine cooking loss and Warner-Bratzler shear force (WBSF) after 0, 7, 14, and 21 d of aging. The right carcasses were processed into primal cuts, and weighed. Each primal cut was further processed into boneless subprimal cuts, minor cuts, lean trim, fat, and bone. Statistical analyses were conducted using the MIXED procedure of SAS (SAS Inst. Inc., Cary, NC) considering the fixed effects of treatment and the random effect of block. Treatments had no effect on the protein, fat, or ash content of the carcass, as estimated by water content. Cooking loss was unaffected by ZH supplementation. There was a ZH × Aging interaction for WBSF, with greater WBSF for ZH at 7 and 14 d of aging. Zilpaterol hydrochloride supplementation increased ($P < 0.05$) the weights of most of the meat cuts analyzed, especially the cuts from the hindquarter ($P < 0.01$), including top sirloin cap ($P = 0.01$), striploin ($P = 0.05$), tenderloin ($P < 0.01$), eye of rump ($P < 0.01$), knuckle ($P < 0.001$), inside round ($P < 0.001$), outside round ($P = 0.01$), and eye of round ($P < 0.05$). Additionally, ZH increased by 7.66% of the subprimal yield and by 1.94% of the debone yield of the heifers. In conclusion, ZH supplementation had no effect on chemical carcass composition, decreased meat tenderness after 7 and 14 d of aging, and increased meat cuts weights and carcass subprimal yield.

Key Words: β-agonist, shear force, subprimal yield

0425 Effects of duration of vitamin C supplementation on growth performance, carcass traits, and protein degradation of the longissimus thoracis of steers fed a 0.31 or 0.59% sulfur diet. D. Pogge*, S. M. Lonergan, and S. L. Hansen, *Iowa State University, Ames.*

Angus steers ($n = 42$) were allotted equally to 7 pens with individual feed intake monitoring technology by BW (304 ± 13 kg), and fed 1 of 7 diets: 4, high-S (0.59% S) diets, supple-

mented with 10 g vitamin C (VC)·steer^{-1}·d^{-1} for 0 d (HSCON), 56 d (HSVC56), 90 d (HSVC90), or 127 d (HSVC127), and 3 low-S diets (LS, 0.31% S) supplemented with 10 g VC·steer^{-1}·d^{-1} for 56 d (LSVC56), 90 d (LSVC90), or 127 d (LSVC127). Jugular blood (d 0, 56, 90, 127) and liver (d 121 or 122) were collected from all steers. Steers (n = 40) were harvested on d 128, and carcass data and rib-sections were collected. Steer was the experimental unit and data were analyzed using Proc Mixed. Final BW ($P < 0.01$), ADG ($P < 0.01$), and DMI ($P = 0.09$) were greater in LS steers than HS steers, but G:F was not affected ($P = 0.41$) by treatment. Total ($P = 0.06$) and reduced ($P = 0.03$) plasma glutathione (GSH) concentrations were greater, and the ratio of oxidized-to-reduced liver GSH was lesser ($P < 0.01$), in VC-fed HS steers compared with HS CON. Ribeye area and marbling score were not affected by diet ($P \geq 0.33$), but LS steers had greater ($P = 0.05$) back-fat than HS steers. a* and b* values were greater ($P \leq 0.05$) in LS steaks than HS steaks over 7 d. Steaks from HS steers had greater total ($P = 0.02$), soluble ($P = 0.06$), and insoluble ($P = 0.06$) collagen (d 2) than steaks from LS steers. Steaks (d 2) from steers fed the HS diet had a greater ($P < 0.01$) and lesser ($P = 0.04$) percentage of the 80 kDa and 76 kDa subunit of calpain-1, respectively, than the LS steers. Adding VC to the HS or LS diets linearly decreased the 80 kDa subunit ($P = 0.03$) and 76 kDa subunit ($P = 0.04$) of calpain-1, respectively. Troponin-T (TT) degradation 2 d postmortem tended to be greater ($P = 0.08$) in LS steers than HS steers, while TT 7 d postmortem did not differ ($P \geq 0.55$) by treatment. In conclusion, improved GSH indices in the VC-supplemented HS steers may be supporting increased activation of calpain-1 compared with steers fed HS alone. It appears that high-S diets may negatively affect the rate, but not extent of longissimus thoracis protein degradation.

Key Words: beef cattle, sulfur, vitamin C

0426 Interaction of various inclusion levels of dietary vitamin D2 enriched yeast cell wall with zilpaterol hydrochloride on dry matter intake and postmortem tenderness in feedlot steers.

A. J. Thompson*[1], F. R. B. Ribeiro[1], J. E. Hergenreder[1], W. C. Burson[1], B. J. Ragland[1], A. D. Hosford[1], J. R. Corley[2], and B. J. Johnson[1], *[1]Texas Tech University, Lubbock, [2]Lesaffre Feed Additives, Milwaukee, WI.*

The objectives of this study were to examine the impact of various inclusion rates of vitamin D_2 enriched yeast cell wall (YCW) on performance and carcass characteristics of cattle finished with zilpaterol hydrochloride (ZH). Crossbred steers (n = 192; BW = 546 ± 11 kg) were blocked by BW in a randomized block design and randomly assigned to pen (6 pens/block; 4 cattle/pen). Pens within block were assigned to 1 of 6 treatments (8 pens/treatment): (1) negative control (–CON; no ZH, no YCW), (2) positive control (+CON; ZH, no YCW), (3) vitamin D_2 YCW containing 100,000 IU vitamin D_2/gram (2.5 g · animal^{-1} · d^{-1}), (4) vitamin D_2 YCW (5.0 g · animal^{-1} · d^{-1}), (5) vitamin D_2 YCW (10.0 g · animal^{-1} · d^{-1}), (6) YCW C-wall product (2.5 g · animal^{-1} · d^{-1}). Steers were supplemented with respective treatments for the 51 d duration of the trial, of which ZH was supplemented d 28 to 47. Daily DMI was recorded and BW was collected at d 0, 28, and 51. Carcass data was collected on harvest and 10 choice strip loins were randomly collected from each treatment for further analysis. Strips were cut into steaks and assigned to 1 of 4 aging periods (7, 14, 21, 28 d). Tenderness was estimated using Warner-Bratzler shear force (WBSF). Data were analyzed using a randomized block design with the fixed effect of treatment and the random effect of block. Warner-Bratzler shear force values were analyzed using the same model, including aging period as an additional factor. Dry matter intake showed a significant quadratic relationship ($P = 0.01$) for increasing levels of D_2 YCW for the entire feeding period, with the greatest intake in the 10.0-g treatment (10.30, 10.27, and 10.66 kg/d, respectively). All ZH fed treatments had numerically greater WBSF values than negative control, but values among ZH treatments were insignificant across all aging periods. There was a tendency for lower WBSF values in the 10.0 g D_2 YCW treatment when compared with positive control ($P = 0.10$, 0.06, 0.10, and 0.09), and WBSF values of steaks from the 10.0 g YCW treatment ranged from 0.44 kg (d 21) to 0.69 kg (d 7) lower than positive control for all aging periods. Results indicate that yeast cell wall supplementation could increase performance of finishing steers during ZH supplementation, while vitamin D_2 supplementation may have positive effects on tenderness.

Key Words: vitamin D, yeast, zilpaterol hydrochloride

0427 Zinc methionine alters muscle and adipose gene expression and protein concentration of calf-fed Holstein steers fed zilpaterol hydrochloride.

J. E. Hergenreder*[1], J. O. Baggerman[1], M. E. Branine[2], and B. J. Johnson[1], *[1]Texas Tech University, Lubbock, TX, [2]Zinpro Corporation, Eden Prairie, MN.*

Zinc has been shown to have allosteric binding sites on β2-adrenergic receptors (β-AR), enhancing agonist affinity, and inhibiting antagonist binding. Therefore, our objective was to determine the effect of supplementing a Zn methionine complex (ZINPRO, Zinpro Corp., Eden Prairie, MN) during the last 115 d of feed, when zilpaterol hydrochloride (ZH) is fed for the final 20 d, with a 3-d withdrawal before slaughter on muscle and adipose tissue gene expression and protein concentration of calf-fed Holstein steers. Steers (n = 211; initial BW = 468.5 ± 0.5 kg) were blocked by weight and randomly assigned to pens and treatment: (1) Control; $ZnSO_4$ added to provide 90 ppm Zn, and (2) ZINPRO; 720 mg Zn · animal^{-1} · d^{-1} provided by ZINPRO at the time of terminal implant. Steers were harvested at a commercial abattoir, and 20 steers

per treatment were randomly selected for *semimembranosus* muscle and adipose tissue biochemical analysis. Messenger RNA and protein was isolated from the muscle and adipose tissue for quantitative reverse transcription PCR (RT-qPCR), western blotting, and myosin analysis. Using RT-qPCR analysis, genes of interest included AMPKα, β1AR, β2AR, β3AR, MHC-I, MHC-IIA, MHC-IIX, GPR43, GPR41, Glut4, SCD, CEBPβ, and PPARγ. No differences ($P > 0.05$) were detected in muscle tissue mRNA abundance between treatments for AMPKα, MHC-IIA, β2AR, β3AR, GPR43, GPR41, Glut4, and CEBPβ. ZINPRO-fed cattle had an increased quantity of MHC-I mRNA ($P < 0.05$) in muscle tissue. Control cattle had an increased quantity of MHC-IIX, β1AR, PPARγ and SCD mRNA ($P < 0.05$) in muscle tissue. In adipose tissue, Control cattle had an increased quantity of Glut4 mRNA ($P < 0.05$). There were no differences ($P > 0.05$) between treatments for AMPKα, β2AR, GPR43, GPR41, SCD, CEBPβ, and PPARγ mRNA in adipose tissue. Protein quantification for muscle and adipose tissue was performed via western blotting procedures to assess the abundance of the β1AR, β2AR and β3AR; however, no differences ($P > 0.05$) were detected between treatments. Muscle protein was also run on acrylamide gels to separate MHC-I and II; ZINPRO fed cattle had a greater concentration of MHC-II protein ($P > 0.05$). These results indicate that ZINPRO and ZH in combination increases MHC-I, decreases MHC-IIX gene expression, and increases myosin protein concentration in skeletal muscle.

Key Words: myosin heavy chain, zilpaterol hydrochloride, zinc methionine

0428 Muscle fiber and color characteristics of different locations within beef *Longissimus lumborum* steaks. K. J. Phelps*, M. A. Vaughn, S. M. Ebarb, D. D. Burnett, J. S. Drouillard, and J. M. Gonzalez, *Kansas State University, Manhattan.*

The objective of this study was to demonstrate the effect that muscle fiber composition differences within anatomical location of beef strip loin steaks elicit on color characteristics over a 7-d simulated retail display. Beef strip loins ($n = 120$) were collected from a commercial abattoir and before aging, steaks were removed from the 13th rib for immunohistochemical analysis of muscle fiber cross-sectional area (CSA) and myosin-heavy chain (MHC) isoform distribution. Sampling locations included medial (MED), mid-lateral (M/L), and lateral (LAT) within each steak. After 14-d of aging, steaks were fabricated, and L*, a*, surface metmyoglobin, and metmyoglobin reducing ability (MRA) were analyzed during a 7-d simulated retail display. There was a day × location interaction for all color characteristics ($P < 0.01$). Initially, LAT was darker and redder than both MED and M/L ($P < 0.04$), and M/L was redder ($P < 0.01$) than MED. On d 7, MED tended to have reduced ($P < 0.05$) L* value than the M/L and LAT area. The MED area was more ($P < 0.05$) red than LAT, while M/L did not differ in redness compared with the other areas ($P > 0.10$). On d 0, all 3 treatments differed in surface metmyoglobin percentage, with the MED possessing greater a percentage than the other locations ($P < 0.01$). At the end of display, all 3 treatments differed, with the LAT possessing 0.83 and1.75% more metmyoglobin than M/L and MED, respectively ($P = 0.01$). All locations had similar MRA on d 0 ($P > 0.10$), but treatments differed in MRA on d 7 ($P < 0.05$). The MED possessed 3.01 and 6.19% greater MRA than LAT and M/L, respectively ($P < 0.05$). Percentage of type IIA fibers was not different between the 3 locations ($P > 0.10$). The MED area tended to possess fewer Type I fibers ($P = 0.10$) than the M/L, and MED possessed less ($P < 0.01$) Type I fibers than LAT. Type I fiber number in LAT and M/L did not differ ($P = 0.25$). The MED area had more ($P = 0.02$) Type IIX fibers than the M/L and LAT ($P < 0.02$), but the M/L and LAT did not differ ($P = 0.94$). The M/L area had larger Type I and IIX fibers than MED and LAT ($P < 0.01$), and MED tended to have larger ($P = 0.08$) Type I fibers than LAT. Also, LAT had smaller ($P < 0.01$) IIA fibers than M/L and MED, but size of IIA fibers in M/L and MED were similar ($P > 0.10$). Based on fiber distribution, expected biochemistry of these locations does not accurately explain color characteristics during simulated retail display.

Key Words: fiber type, color characteristics, sampling location

0429 In utero manipulation of muscle development in beef cattle fetuses. M. S. Duarte*[1], M. P. Gionbelli[2], P. Paulino[1], N. V. L. Serão[3], S. E. Facioni[1], S. de Campos Valadares Filho[1], and M. Du[4], *[1]Universidade Federal de Viçosa, Viçosa, Minas Gerais, Brazil, [2]Instituto Nacional de Ciência e Tecnologia–Ciência Animal, Viçosa, Minas Gerais, Brazil, [3]Iowa State University, Ames, [4]Washington State University, Pullman.*

Fetal programming has been suggested as new tool in the current meat industry to produce animals with a potential to produce high quality beef. Such hypothesis is based on the fact that the main cells that compose the skeletal muscle tissue (myocytes, adipocytes, and fibroblasts) are all derived from a common pool of mesenchymal stem cells and their commitment to one of those lineages can be altered, among other factors, by maternal nutrition during the gestational period. Besides myogenesis and adipogenesis, fibrogenesis is very active during the fetal stage, during which generates connective tissue. The presence of connective tissue, primarily in the form of collagen fibrils, contributes to the background toughness of meat. Therefore, we investigated the effect of maternal nutrition on molecular mechanisms governing the early commitment of mesenchymal stem cells to either myogenic or adipogenic-fibrogenic lineages in beef cattle fetuses. Twenty-three Nellore pregnant cows were randomly assigned into 2 feeding level groups where 12 cows were fed at 1.0 times the maintenance requirement (Control, C) and 11 cows were fed at 1.5

times the maintenance requirement (Obese, OB) to evaluate effects of maternal obesity on fetal skeletal muscle development. The mRNA expression of β-catenin ($P = 0.0844$), MyoD ($P = 0.5623$), myogenin ($P = 0.7048$), and the number of muscle cells ($P = 0.9032$) was not affected by maternal obesity. Conversely, mRNA expression of adipogenic markers ZfP423 ($P < 0.0001$), C/EBPα ($P = 0.0004$), and PPARγ ($P < 0.0001$) was enhanced by maternal obesity. Indeed, mRNA expression of fibrogenic markers TGFβ ($P < 0.0001$), collagen III ($P < 0.0001$), and collagen content ($P = 0.0032$) was enhanced in OB fetuses. These data show that maternal obesity enhances fibrogenesis and likely adipogenesis without compromise myogenesis in fetal skeletal muscle of cattle.

Key Words: development, muscle, Nellore

MULTIDISCIPLINARY AND INTERNATIONAL LEADERSHIP KEYNOTE (MILK) SYMPOSIUM: WATER: CONSIDERATION FOR THE FUTURE OF ANIMAL AND FOOD PRODUCTION AND PROCESSING

0430 Drought: Lessons to learn in agriculture.
K. Matthews*, *ERS-USDA, Washington, DC.*

Drought impacts vary by commodity and region. Drought in 2012 was the most widespread since 1934. Drought has been pervasive in the West and Southern Plains since 2000, while the Midwest has experienced only 3 years of widespread drought in the same period. Most market participants are adversely affected by drought. Drought-reduced yields for commodities often result in higher prices, but higher prices may not offset lower yields and higher costs, so producer profit margins can be adversely affected. Consumers face higher prices for affected commodities and likely higher prices for substitutes for those commodities. Producers unaffected by drought are the only group who benefit from drought-reduced commodity supplies because they likely produce at least near-normal quantities of products and have access to higher prices for their products, which can boost their profit margins.

Key Words: drought, water, agriculture

0431 Water sources and chemical quality considerations for animal production and food processing.
A. M. Dietrich*, *Virginia Tech, Blacksburg.*

This presentation will focus on the varying qualities of water required for livestock consumption and food processing operations; also to be discussed are implications for changes to water quality due to natural situations (e.g., drought), engineered water treatment, and industrial activity. Quantity and quality of water are the most critical dietary elements for livestock as water directly or indirectly affects physiologic processes. Chemical water quality parameters that are important for livestock and food processing include presence of macrominerals (e.g., total dissolved solids, hardness, sodium, calcium, magnesium, chloride, nitrate, and sulfate), microminerals (iron, copper, manganese, chromium, arsenic), presence of toxic chemicals (e.g., pesticides or cyanotoxins), and whether the water is required to meet standards established by the USEPA for Primary and/or Secondary Maximum Contaminant Levels. How drinking water can enhance or exceed nutritional needs will be presented through comparison of nutritional requirements for livestock and the corresponding data and variability for specific chemical parameters in ground and surface waters. For example, the macronutrient sulfate and micronutrient iron can either negatively affect either livestock health or the taste of meat and milk. Sulfate and iron concentrations vary widely in drinking water due to local geology, as this controls which minerals are available to be dissolved into water. Another issue for livestock nutrition is its interplay with changing chemical water quality, as can be illustrated by total dissolved solids (TDS). Total dissolved solids is the composite measure of all dissolved minerals and organics in water; it is an indicator of overall water quality that is readily measured. Guidance for livestock is that TDS should be at or below 1000 mg/L, with an upper limit of 2500 mg/L, and although higher levels can be tolerated for drinking, about 3000 mg/L can cause diarrhea. Drought conditions increase TDS, both because there is insufficient water to dilute natural TDS and due to water evaporation. Total dissolved solids levels in the range of 3000 mg/L have occurred in the last few years and can negatively impact livestock health. Maintaining healthy livestock can be achieved through knowledge of which chemical parameters affect nutritional status, the natural occurrence of chemicals, plus regional and seasonal variability of water quality.

Key Words: water quality, nutrition, drinking water standards, minerals, livestock

0432 U.S. dairy water footprint in context.
Y. Wang*[1], A. D. Henderson[2], and O. Jolliet[3], *[1]Innovation Center for U.S. Dairy, Rosemont, IL, [2]University of Texas, Houston, [3]University of Michigan, Ann Arbor.*

Dairy production in the United States at the national scale is a distributed production system that entails great geographic diversity with respect to inputs and outputs. Milk therefore represents an interesting case study to develop and test spatialized life cycle approaches for both inventory and impact assessment. The study is to be used by the U.S. dairy industry to create a baseline of water footprint, helping that industry and its constituent milk producers to identify areas to target for improvement, explore the changes in impact associated with new management scenarios, and document those improvements. The result showed that water stress is 146 L in competition per 1 kg milk consumed, and 121 L in competition per 1 kg milk at farm gate (water consumption is 225 L per 1 kg milk consumed and 181 L of water consumed per 1 kg milk at farm gate).

Key Words: water footprint, spatialization, milk

0433 Rethinking the dairy supply chain: Innovative opportunities for creating value, efficiency, and sustainability.
R. T. Sirolli*, *Cargill Dairy Enterprise Group, Windsor, CO.*

In recent years, Consumer Packaged Goods (CPG) firms utilizing large volumes of dairy ingredients have ventured into new partnership models directly with dairy farms to address unmet needs relating to environmental sustainability, reducing market volatility, security of milk supply, improving the connectivity of consumers to dairy farms, and to create opportunities to en-

hance the value of the overall dairy supply chain. In the spring of 2012, the first model of this kind was implemented between a large dairy farm in Northwestern Kansas and a leading dairy CPG firm. To supply the desired products to the partnering CPG firm, the milk produced is initially processed directly on the farm. Three products are produced from the process, including heavy cream, condensed skim milk, and water. By creating a direct-supply model between the dairy farm and CPG firm, multiple opportunities are created to reduce environmental impact and improve water conservation. By removing water through a condensing process of whole milk, transportation required to move cream and condensed skim milk is reduced by > 75%. Approximately sixty thousand gallons of milk are produced per day, and of that, approximately forty thousand gallons of water are reclaimed for use on the farm. Western Kansas is an arid environment where water conservation is a critical component of the long-term sustainability of dairy production in the region. Water that is reclaimed is reused initially for watering cows or cleaning before eventually being irrigated on crops grown for feed. Water availability is one of the leading factors limiting dairy growth in the Western United States. Direct-supply models with on-farm milk condensing are growing in interest as a means of improving long-term sustainability of dairy production in arid environments, improving efficiency of the dairy supply chain, and creating opportunities for enhancing value for dairy farmers, CPG firms, and consumers.

Key Words: sustainability, water, dairy, milk

0434 Water usage at cattle feedlots and the potential for water conservation. K. D. Casey*[1], J. M. Sweeten[1], and R. Hagevoort[2], [1]*Texas A&M AgriLife Research, Amarillo,* [2]*New Mexico State University, Clovis.*

Water is increasingly valuable due to limited supply with declining aquifers and prolonged droughts, and higher water costs through infrastructure and energy costs. Environmental sustainability is an increasingly important issue for the general public, and the water use efficiency of industries is particularly topical during the current drought conditions. Water is an essential part of any beef feedlot or dairy operation. At beef cattle feedyards, fresh water is needed for cattle drinking, feed preparation, dust control, trough cleaning, system spillage, and staff amenities. While little potential exists to reduce genuine cattle water consumption, potential exists to reduce fresh water used to prevent troughs from freezing in winter and to control dust under dry conditions. Under summer conditions in the Texas High Plains, water use for dust control at feedyards has been measured at 8% of total fresh water use. Capture, treatment, and reuse of water from overflow waterers has been shown to be cost effective when compared with pumping extra fresh water. At dairies, fresh water is needed to water cows, cool cows and milk, flush alleyways, wash udders in wash pens, clean milking equipment, and increase feed moisture content. Similar to water intake requirements for cows, dairy operation water use can vary greatly depending on management practices, location, and the recycling of water on the dairy. Close attention to minimizing water wastage and a focus on reusing process water where possible can yield significant reductions in overall water use. On an open corral dairy and a freestall dairy on the Texas High Plains, monitoring on the overall facility water balance over 2 to 3 yr has shown that 30 to 40% of total fresh water usage is beneficially reused for irrigation.

Key Words: beef, water intake, reuse

NONRUMINANT NUTRITION: NUTRIENT REQUIREMENTS OF MONOGASTRICS AND AMINO ACID DIGESTIBILITY OF FEEDSTUFFS

0435 Determination of additivity of apparent and standard ileal digestibility of amino acids in different ingredients for mixed diets fed to growing pigs. P. Xue*, D. Ragland, and L. Adeola, *Purdue University, West Lafayette, IN.*

An experiment was conducted in growing pigs to investigate the additivity of apparent (AID) or standardized (SID) ileal digestibility of CP and AA in mixed diets based on multiple protein sources. Additivity refers to values calculated (predicted) from determined AID or SID of individual ingredients vs. measured values in mixed diets. Using the measured AID or SID for CP and AA in corn, soybean meal (SBM), corn distillers' dried grains with solubles (DDGS), or canola meal (CM), the AID or SID for 4 mixed diets based on corn-SBM (CS, 65% corn and 22% SBM), corn-SBM-DDGS (CSD, 57% corn, 17% SBM, and 11% DDGS), corn-SBM-CM (CSCM, 58% corn, 13% SBM, and 13% CM), or corn-SBM-DDGS-CM (CSDCM, 55% corn, 10% SBM, 10% DDGS, and 10% CM) were predicted and compared with measured AID or SID, respectively. *t* test was applied to test the difference between predicted and measured values. Eighteen pigs (initial BW = 61.3 ± 5.5 kg) were surgically fitted with T-cannula and assigned to a duplicated 9 × 4 incomplete Latin square design with 9 diets and 4 periods. The experimental diets consisted of 4 semipurified diets to determine the AID and SID in the 4 ingredients, 4 mixed diets, and a N-free diet. Chromic oxide was added as an indigestible marker. Pigs were fed 1 of the diets during each 7-d period, and the ileal digesta were collected on d 6 and 7, from 0800 to 1800. The results showed the predicted SID were consistent with determined values, except for Leu, Thr, Asp, Cys, Pro, and Ser, in CS diet; Met and Cys in CSD diet. The determined AID for total AA and 5 individual AA (Arg, His, Trp, Gly, and Pro) in CS diet were greater ($P < 0.05$) than predicted. For CSD diet, the determined AID were greater ($P < 0.05$) than predicted for CP, total AA, and all AA except for Arg, Leu, and Pro. In CSCM diet, the determined AID were greater ($P < 0.05$) than predicted for 3 AA (Arg, Cys, and Gly). When compared with determined values, predicted AID in CSDCM diet were lower ($P < 0.05$) for total AA and 4 AA (Arg, Met, Cys, and Pro). In conclusion, the results indicate that SID of AA are more consistent than AID for predicting ileal digestibility of AA in mixed diets containing multiple protein sources.

Key Words: additivity, amino acid, ileal digestibility

0436 Effects of dietary threonine:lysine ratio and sanitary conditions on performance and plasma urea nitrogen of weaned pigs fed antibiotic-free diets. B. Jayaraman*[1], J. K. Htoo[2], and C. M. Nyachoti[1], *[1]University of Manitoba, Winnipeg, Canada, [2]Evonik Industries AG, Hanau-Wolfgang, Germany*.

A growth trial was conducted to determine the optimum standardized ileal digestible (SID) Thr:Lys ratio for weaned piglets reared in clean or unclean sanitary conditions and fed antibiotic-free diets. Mixed-sex pigs (Duroc × [Yorkshire × Landrace]; average initial BW of 7.0 ± 0.5 kg) weaned at 21 ± 1 d were randomly assigned to 10 dietary treatments in a 2 × 5 factorial arrangement in a 42-d study giving 6 replicates (3 pigs per pen) per treatment. The main factors were sanitary conditions (clean, CL; unclean, UCL) and 5 dietary SID Thr:Lys ratios (55, 59, 63, 67, and 71%) in a completely randomized design. Diets were corn-wheat-soybean meal based with a constant SID Lys of 1.18% that was set to be seconding limiting AA. Pigs had ad libitum access to feed and water. For the first 21 d, CL group (90 piglets) were kept in a room that was disinfected before arrival of piglets and was cleaned weekly. The UCL group (90 piglets) followed immediately for the next 21 d in the same room. The UCL room was not disinfected and left uncleaned after CL group and manure from swine herd was added (5 kg per pen) to the pens on d 0 and d 7 of the experiment. Pigs and pen feed disappearance were recorded weekly to determine ADG, ADFI, and G:F. Blood samples were collected on d 0 and d 14 via jugular venipuncture for determination of plasma urea nitrogen (PUN). There were no significant interactions ($P > 0.05$) between sanitary conditions and dietary levels on any response criteria. Unclean conditions reduced ($P < 0.05$) ADG and ADFI throughout the experimental period, and tended to reduce ($P < 0.10$) G:F. The overall ADG was 494 vs. 404 g and ADFI was 736 vs. 579 g, for CL and UCL, respectively. Unclean group had significantly higher ($P < 0.05$) PUN (4.12 vs. 2.96) on d 14 compared with CL group. Increasing dietary SID Thr:Lys ratio had no effect on ADG and ADFI throughout the study; however, there was a linear trend ($P < 0.10$) in G:F showing that SID Thr:Lys of 71% improved G:F. The highest ADG was achieved at SID Thr:Lys of 71% for CL and 67% for UCL pigs, respectively. In conclusion, unclean conditions reduced ADG and ADFI in piglets, and increasing levels of SID Thr:Lys to 71% could improve G:F after weaning.

Key Words: threonine, sanitation, piglets

0437 Estimated lysine requirement of 25 to 50 kg growing gilts. J. K. Mathai* and H. H. Stein, *University of Illinois at Urbana-Champaign, Urbana.*

An experiment was conducted to determine the standardized ileal digestible (SID) Lys requirement of gilts (G-Performer × Fertilis 25) from 25 to 50 kg BW. Seventy gilts (G-Performer × Fertilis 25; initial BW: 24.54 ± 3.28 kg) were used in a growth

assay with 2 pigs per pen and 7 pens per treatment. Diets were formulated using corn and soybean meal as the sole sources of AA. Under the assumption that Lys is the first limiting AA in corn-soybean meal diets, soybean meal concentration was increased at the expense of corn to increase SID Lys in the diets. Five treatments with calculated SID Lys levels of 0.80, 0.93, 1.06, 1.19, and 1.32% were formulated using values from NRC (2012). Accuracy of diet formulations were confirmed by analyzing diets for total Lys. Daily feed allocations were recorded and individual pig weights were recorded at the beginning and at the conclusion of the experiment, 33 d later. Results indicated that ADG increased ($P < 0.05$) quadratically and G:F increased linearly ($P < 0.05$) as SID Lys increased from 0.80 to 1.32% (Table 0437). Broken-line and curvilinear-plateau regression analyses were used to estimate the requirement for SID Lys. Results indicated that 1.08% SID Lys was needed to maximize ADG and 1.10% SID Lys was needed to maximize G:F. Thus, results of this experiment indicate that the SID Lys requirement for 25- to 50-kg growing gilts is slightly greater than the recent estimate of 0.98% reported by NRC (2012). Under the conditions of this experiment, the requirement for SID Lys for 25 to 50 kg gilts is approximately 1.09%.

Key Words: amino acids, lysine requirement, pigs

Table 0437. Performance of pigs fed increasing levels of standardized ileal digestible Lys

	Standardized ileal digestible lysine, %					Contrasts (P-value)[1]	
	0.80	0.93	1.06	1.19	1.32	Linear	Quadratic
ADG, g	782	809	825	846	794	NS	0.03
ADFI, g	1758	1826	1738	1775	1658	NS	NS
G:F, g	432	444	462	465	467	< 0.01	NS

[1] NS indicates $P > 0.10$.

0438 Homocysteineinemia, growth performance, and immune responses in suckling and weanling piglets.

I. Audet, C. L. Girard, M. Lessard, L. Lo Verso, and J. J. Matte*, *Agriculture and Agri-Food Canada, Sherbrooke, QC, Canada.*

Homocysteine, an intermediary sulfur AA, is recognized as a powerful pro-oxidant with deleterious effects on physiological and immune functions. In piglets, there is an acute 10-fold increase of plasma concentrations of homocysteine (PHcy) during the first 2 wk of life. This project aimed to create wide ranges of PHcy by varying folates and vitamin B_{12} (B_{12}) supplies to sows and piglets. Growth, immune response, and PHcy were studied until 56 d of age. Third-parity sows were randomly assigned to a 2 × 2 split-plot design with 2 dietary treatments (S) during gestation and lactation, S^- (1 mg/kg of folates and 20 μg/kg of B_{12}, $n = 15$) or S^+ (S^- × 10, $n = 16$), and 2 treatments to piglets (P) within each half-litter, i.m. injections (150 μg) of B_{12} (P^+) at d 1 and 21 (weaning), or sham-injections of saline (P^-). Within each litter of 12 piglets, 3 P^+ and 3 P^- were studied for growth, and the others for immunological responses. During lactation, the decrease of PHcy after i.m. B_{12} was more pronounced in S^- than S^+ piglets (S × P, $P < 0.02$), values were 32% lower in S^+P^+ (16.7 ± 0.7 μM) than S^-P^- piglets (24.7 ± 0.7 μ*M*) at 21 d of age. At 56 d of age, PHcy were lower ($P < 0.01$) for P^+ (15.7 ± 0.5 μ*M*) than P^- piglets (18.7 ± 0.5 μ*M*). No treatment effect was observed on growth except for a lower postweaning G:F in S^+P^- piglets than in others (S × P, $P = 0.03$). Positive correlations were observed between PHcy and growth ($r > 0.29$, $P < 0.02$). Antibody responses to ovalbumin were not affected by treatments. Proliferation of lymphocytes in response to the mitogen concanavalin A tended to be lower in culture media with sera from S^- piglets than S^+ ($P < 0.08$) and P^- piglets than P^+ ($P < 0.10$), and this response was more marked ($P = 0.04$) with high PHcy (> 21 μ*M*) as compared with medium (17 to 21 μ*M*) or low (< 17 μ*M*). In conclusion, vitamin supplementations to sows and piglets induced large variations of PHcy in piglets. Although apparently not harmful for growth performance, the detrimental effects of S^- and P^- treatments or high PHcy on some indicators of cell mediated immunity suggest that these young animals are immunologically more fragile.

Key Words: homocysteine, growth and immunity, piglets

439 Leucine supplementation of a restricted protein diet improves lean growth in neonatal pigs.

D. A. Columbus*[1], J. Steinhoff-Wagner[1], A. Suryawan[2], M. Kao[3], A. Hernandez-Garcia[1], C. Boutry[1], H. V. Nguyen[2], M. L. Fiorotto[1], and T. A. Davis[2], *[1]Children's Nutrition Research Center, Baylor College of Medicine, Houston, TX, [2]USDA/ARS–Children's Nutrition Research Center, Baylor College of Medicine, Houston, TX, [3]Neonatology, Baylor College of Medicine, Houston, TX.*

Early weaning of neonatal pigs frequently results in a reduction in food intake due to stress, environmental changes, and a shift from liquid to solid diet. In humans, many low birth weight infants also experience growth failure due to feeding intolerance, resulting in reduced nutrient intake. The branched-chain AA, leucine, has been shown to have anabolic effects on skeletal muscle. The objective of the study was to determine if prolonged enteral leucine supplementation improves lean growth in neonatal pigs fed a restricted protein diet. Five-day-old pigs ($N = 46$; 1.8 ± 0.3 kg initial BW) were fed by gastric catheter either a normal protein (NP; 22.5% protein, 2.4% leucine) or restricted protein (RP; 11.2% protein, 1.2% leucine) milk replacement diet or RP supplemented with leucine to the same level as in the NP diet (RPL). Pigs were fed 40 mL/kg BW per meal every 4 h for 21 d. Body composition was determined by dual-energy X-ray absorptiometry on d 0 and 20. Data were analyzed using the PROC MIXED procedure of SAS (SAS Inst. Inc., Cary, NC). Feeding the NP diet resulted in greater total body weight (5.2 vs. 4.5 ± 0.20

kg) after 21 d and change in lean body mass (3.0 vs. 2.5 ± 0.17 kg) compared with RP-fed pigs ($P < 0.05$). Mass of the longissimus dorsi muscle (68 vs. 53 ± 4.2 g), heart (29 vs. 24 ± 1.2 g), and kidney (27 vs. 20 ± 2.1 g) were also greater in the NP- than RP-fed pigs ($P < 0.05$). Body weight (4.8 kg), lean body mass change (2.6 kg), and mass of the longissimus dorsi (61 g), heart (27 g), and kidney (23 g) in pigs fed the RPL diet were intermediate to the RP- and NP-fed pigs. Prolonged leucine supplementation of a restricted protein diet has the potential to improve overall growth in neonatal pigs and infants with restricted protein intake through an increase in lean tissue growth. *This project was supported by NIH HD072891 and USDA NIFA 2013–67015–20438.*

Key Words: protein, neonatal pig, body composition, lean growth, leucine

0440 Optimal sulfur amino acid to lysine ratio for weaned pigs fed antibiotic-free diets and raised under clean and unclean conditions.

R. K. Kahindi*[1], M. C. Nyachoti[1], and J. K. Htoo[2], [1]*University of Manitoba, Winnipeg, Canada,* [2]*Evonik Industries AG, Hanau-Wolfgang, Germany.*

Unsanitary production conditions can stimulate an immune response leading to increased sulfur amino acids (SAA) maintenance needs and consequently the SAA to Lys ratio, especially under antibiotic-free feeding regimen. Two 14-d experiments were conducted to determine the optimum SAA:Lys ratio in piglets when reared under clean or unclean condition and fed antibiotic-free diets. For each experiment, 90 mixed-sex pigs (Duroc × [Yorkshire × Landrace]; initial average BW of 7.3 ± 0.6 kg) weaned at 21 ± 1 d with 6 replicates of 3 pigs per pen were used. The basal diet was corn-wheat-soybean meal-based (1.18% SID Lys; 51% SID SAA:Lys). Diets 2 to 5 were the basal supplemented with 4 graded levels of DL-Met (55, 60, 64, and 68% SID SAA:Lys). Piglets were allowed free access to feed and water. In Exp. 1, piglets were raised in a clean room that was previously disinfected and washed weekly, whereas in Exp. 2, piglets were introduced into a room previously occupied by other pigs and was not disinfected. In addition, manure slurry from a sow herd was spread (5 kg per pen) on d 0 and 7 of the study and the room was not cleaned throughout the study. Blood was collected on d 0 and 14 for measurement of plasma urea nitrogen (PUN). On d 14, one pig per pen was slaughtered to collect jejunal tissue for measurement of villus height (VH), crypt depth (CD), and VH:CD. In both experiments, quadratic broken-line model was used to estimate optimum SAA:Lys ratio. The highest average daily gain was at SAA:Lys ratio of 60% (279 g) in Exp. 1 and 64% (305 g) in Exp. 2. Increasing SAA:Lys ratio linearly and quadratically increased ($P < 0.05$) VH and VH:CD in Exp. 1 and 2. In Exp. 2, increasing SAA:Lys ratio linearly reduced ($P < 0.05$) by 18% average daily feed intake and linearly and quadratically decreased PUN. Based on performance parameters, the optimum SAA:Lys ratio was 62 and 61% for piglets raised under clean and unclean conditions, respectively. However, VH and VH:CD estimates were 60 and 64% SAA:Lys ratio under clean and unclean conditions, respectively. Hence, SAA:Lys ratio for gut health was higher under unclean conditions.

Key Words: pigs, sanitation, sulfur amino acids

0441 Energy concentration and amino acid digestibility in two sources of canola meal fed to growing pigs.

N. W. Jaworski*, Y. Liu, and H. H. Stein, *University of Illinois at Urbana-Champaign, Urbana.*

Two experiments were conducted to determine DE and ME and standardized ileal digestibility (SID) of CP and AA by growing pigs in a novel canola meal (CM-HP) produced from high protein canola seeds and to compare these values with DE, ME, and SID values determined in conventional canola meal (CM-CV) and soybean meal (SBM). In Exp. 1, 32 growing barrows (initial BW: 47.25 ± 6.23 kg) were individually housed in metabolism cages and randomly assigned to 4 treatments in a randomized complete block design with 8 replicates per treatment. The 4 diets included a corn-based basal diet and 3 diets formulated by mixing corn and each source of canola meal or SBM. Fecal and urine samples were collected for 5 d following a 5-d adaptation period. The DE and ME in CM-HP, CM-CV, and SBM were calculated using the difference procedure. Concentrations of DE and ME in CM-HP and CM-CV were less ($P < 0.05$) than in corn and SBM (DE: 3419 and 3104 vs. 4012 and 4305 kcal/kg DM, respectively; ME: 2842 and 2720 vs. 3854 and 3894 kcal/kg DM, respectively). No differences in concentrations of DE and ME were observed between CM-HP and CM-CV. In Exp. 2, 8 growing barrows (initial BW: 46.4 ± 5.6 kg) had a T-cannula installed in the distal ileum and randomly allotted to a replicated 4 × 4 Latin square design, with 4 diets and four 7-d periods in each square. Three diets that contained CM-HP, CM-CV, or SBM as the sole source of CP and AA were formulated, and a N-free diet was also used. Ileal digesta were collected on d 6 and 7 of each period. The SID of CP and most AA in CM-HP and CM-CV were less ($P < 0.05$) than in SBM. The SID of CP in CM-HP was greater ($P < 0.05$) than in CM-CV. However, no differences were observed in SID of any AA between CM-HP and CM-CV. The concentration of standardized ileal digestible CP and almost all AA was greater ($P < 0.05$) in SBM than in CM-HP and CM-CV, and CM-HP contained more ($P < 0.05$) standardized ileal digestible CP and AA than CM-CV. In conclusion, increased concentration of CP in canola meal does not compromise the DE and ME and the AID or SID of AA. The novel CM-HP supplies more digestible AA than CM-CV.

Key Words: amino acid digestibility, canola meal, energy concentration

0442 Amino acid digestibility in processed soybean products and rapeseed products fed to weanling pigs. D. M. D. L. Navarro*[1], Y. Liu[1], T. S. Bruun[2], and H. H. Stein[1], *[1]University of Illinois at Urbana-Champaign, Urbana, [2]Danish Pig Research Centre, Copenhagen, Denmark.*

An experiment was conducted to determine the standardized ileal digestibility (SID) of CP and AA in 4 sources of processed soybean meal, in conventional soybean meal (SBM-CV), in rapeseed expellers (RSE), and in a fermented co-product mixture (FCM) that contained rapeseed meal, wheat, soy molasses, and potato peel. The 4 processed soybean products included 2 sources of enzyme-treated soybean meal (ESBM-1 and ESBM-2), extruded soybean meal (SBM-EX), and soy protein concentrate (SPC). A N-free diet and 7 cornstarch-based diets that contained each of the 7 protein sources as the sole source of CP and AA were prepared. Twenty-seven ileal-cannulated weanling barrows (initial BW: 9.29 ± 0.58 kg) were allotted to three 9 × 5 Youden squares with 9 pigs and 5 periods in each square. In each square, 7 pigs were each fed 1 of the 7 AA-containing diets and 2 pigs were fed the N-free diet. Results indicated that the SID of CP was greater ($P < 0.05$) in ESBM-1 than in SPC, RSE, and FCM. The SID of Arg, His, Ile, Leu, Met, and Phe were greater ($P < 0.05$) in ESBM-1 than in SPC, and the SID of Lys was greater ($P < 0.05$) in SBM-CV than in ESBM-2. The SID of Thr, Trp, Val and total indispensable AA were not different among the soybean products. The SID of most AA in RSE and the SID of all AA in FCM were less ($P < 0.05$) than in all soybean products, but the SID of all AA in RSE was greater ($P < 0.05$) than in FCM. Results of this experiment indicate that, although processing of soybean meal results in increased concentration of CP, processing may also reduce the digestibility of some AA, which is likely due to heat damage during processing. There are, however, differences among processed soy products, with some products having greater SID of AA than others. Results also indicate that fermentation of a mixture of rapeseed meal, wheat, and relatively low quality co-products does not result in SID values that are similar to those of unfermented rapeseed expellers or soybean products.

Key Words: amino acid digestibility, soybean products, rapeseed products

0443 Standardized ileal crude protein and amino acid digestibility of eight wheat genotypes fed to growing pigs. P. Rosenfelder*[1], H. K. Spindler[1], K. E. B. Knudsen[2], H. Jørgensen[2], N. Sauer[1,3], J. K. Htoo[4], M. Eklund[1], and R. Mosenthin[1], *[1]University of Hohenheim, Institute of Animal Nutrition, Stuttgart, Germany, [2]Aarhus University, Department of Animal Science, Tjele, Denmark, [3]Landwirtschaftliche Untersuchungs- und Forschungsanstalt Speyer, Speyer, Germany, [4]Evonik Industries AG, Hanau-Wolfgang, Germany.*

The objective of this study was to determine in growing pigs the standardized ileal digestibility (SID) of CP and AA of 8 currently available wheat genotypes grown in Southern Germany under standardized field test conditions. The assay diets were formulated to contain 1 of the 8 wheat genotypes each, with wheat as the sole dietary source of CP and AA. All diets were supplemented with 0.7% titanium oxide as an indigestible marker. Nine ileal cannulated barrows (32 ± 2 kg BW) were fed 8 diets in 8 periods of 6 d each at a daily intake level of 40 g/kg of their average BW, corresponding to about 3 times the animals' energy requirement for maintenance (106 kcal of ME/kg of $BW^{0.75}$). The SID of the 8 wheat genotypes was calculated using literature data for correction of basal ileal endogenous losses of CP and AA. Data were analyzed using the MIXED procedure of SAS (SAS Inst. Inc., Cary, NC) with genotype and pig as fixed effects, and periods and pigs as random effects. Effects of chemical composition of the wheat genotypes on SID of CP and AA in the wheat genotypes were analyzed by linear regression analyses. Among proximate nutrients, only small differences in DM, crude ash, and ether extract content were observed between the 8 different wheat genotypes. On as-fed basis, concentrations of CP and starch ranged from 10.9 to 13.3 and 61.5 to 64.4% in the 8 wheat genotypes, respectively. The greatest concentrations of NDF and ADF were 11.6 and 3.3% (as-fed), respectively, whereas ADL concentration did not exceed 0.7% (as-fed) in the 8 wheat genotypes. Among the 8 wheat genotypes, SID of CP, Lys, Met, Thr, and Trp ranged from 83 to 87% ($P = 0.010$), 69 to 74 ($P = 0.037$), 84 to 88 ($P = 0.010$), 78 to 82 ($P = 0.053$), and 80 to 85% ($P = 0.005$), respectively. Fiber fractions and CP contents in the 8 wheat genotypes had minor effects on SID of CP, Lys, Met, Thr, and Trp. Moreover, SID of CP, Lys, Met, Thr, and Trp of this study were up to 5, 15, 6, 8, and 8% lower when compared with current feed tables. Due to the observed variations in SID of CP and AA between wheat genotypes in the present study, differences in SID between different batches of wheat should be taken into account for pig diet formulations.

Key Words: digestibility, pig, wheat

0444 Standardized ileal amino acid digestibility in eight genotypes of rye fed to growing pigs.
E. J. P. Strang*[1], M. Eklund[1], P. Rosenfelder[1], H. K. Spindler[1], N. Sauer[1,2], J. K. Htoo[3], and R. Mosenthin[1], *[1]University of Hohenheim, Institute of Animal Nutrition, Stuttgart, Germany, [2]Landwirtschaftliche Untersuchungs- und Forschungsanstalt Speyer, Speyer, Germany, [3]Evonik Industries AG, Hanau-Wolfgang, Germany.*

A study was conducted to determine in growing pigs the standardized ileal digestibility (SID) of CP and AA in 8 currently available genotypes of rye. The rye genotypes were grown under the same standardized field conditions at the University of Hohenheim, Germany. The experiment was conducted with 8 barrows with an initial BW of 24 ± 2 kg, and fitted with a simple T-cannula at the distal ileum. The pigs were randomly allotted to an 8 × 8 Latin square design. Diets were based on 1 of the 8 rye genotypes each, with rye as the sole source of CP and AA. An N-free diet was fed to determine basal ileal endogenous losses of CP and AA in an additional period at the conclusion of the experiment. Diets were supplemented with titanium dioxide as digestible marker and fed at a daily intake level of 40 g/kg of pigs' average BW corresponding to about 3 times the pigs' energy requirement for maintenance (106 kcal of ME/kg of $BW^{0.75}$). Each experimental period consisted of 4 d for adaptation to the diets and 2 d for ileal digesta collection. Ileal digesta samples were collected consecutively for a total of 24 h. Data were analyzed by the Mixed Procedure of SAS (SAS Inst. Inc., Cary, NC) with genotype and pig as fixed effects, and pigs and periods as random effects. The CP and nonstarch polysaccharides (NSP) concentrations (as-fed) in the 8 rye genotypes ranged from 9.5 to 11.2%, and 10.7 to 12.9%, respectively. The greatest concentrations of NDF, ADF, and ADL were 15.1, 3.0, and 0.9% (as-fed) in the 8 rye genotypes. Among the 8 rye genotypes, SID of CP, Lys, Met, Thr, and Trp ranged from 70 to 74, 60 to 65, 74 to 78, 62 to 66, and 63 to 67%, respectively. The SID of CP and AA did not differ between the 8 rye genotypes, except for SID of Cys ($P = 0.044$). The SID of CP and AA were not affected by NSP and NDF content. Overall, SID of CP, Lys, Met, Thr, and Trp in rye derived from the present study were up to 13, 14, 7, 12, and 13%-units lower than the values reported in current feed tables. Using these SID values will aid for accurate AA balancing when these new rye genotypes are used in pig diet formulations.

Key Words: amino acid digestibility, growing pigs, rye

0445 Digestible phosphorus requirement of twenty-kilogram pigs—A cooperative study.
O. Adeola*[1], M. J. Azain[2], S. D. Carter[3], T. D. Crenshaw[4], M. J. Estienne[5], B. J. Kerr[6], M. D. Lindemann[7], C. V. Maxwell[8], P. S. Miller[9], M. C. Shannon[10], E. van Heugten[11], and NCCC-042 and S-1061[12], *[1]Purdue University, West Lafayette, IN, [2]University of Georgia, Athens, [3]Oklahoma State University, Stillwater, [4]University of Wisconsin, Madison, [5]Virginia Tech Tidewater AREC, Suffolk, [6]USDA-ARS, Ames, IA, [7]University of Kentucky, Lexington, [8]Department of Animal Science, University of Arkansas Division of Agriculture, Fayetteville, [9]University of Nebraska, Lincoln, [10]University of Missouri-Columbia, Columbia, [11]North Carolina State University, Raleigh, [12]Swine Nutrition Committee and Nutritional Systems for Swine to Increase Reproductive Efficiency Committee, West Lafayette, IN.*

A 28-d cooperative study involving 10 experiment stations was conducted to determine the standardized total-tract digestible (STTD) P requirement of 20-kg pigs using broken-line regression analysis. Six concentrations of STTD P were fed to 1032 pigs with an average initial BW of 19 kg in 240 pens (120 each of barrows and gilts). Monocalcium phosphate was added to a corn-soybean meal-based diet at the expense of cornstarch to establish the 6 concentrations of STTD P, ranging from 1.54 to 5.15 g/kg of diet, in increments of 0.62 g/kg. Limestone was added to maintain a constant Ca:total P at 1.5:1.0 among all diets. Average daily gain, ADFI, and G:F increased ($P < 0.05$) with increasing STTD P concentration for d 0 to 14, 14 to 28, and 0 to 28. From d 0 to 28, ADG and G:F increased ($P < 0.01$) from 639 to 809 g and 492 to 561 g/kg, respectively, as STTD P increased from 1.54 to 5.15 g/kg of diet. Barrows gained and ate more ($P < 0.05$) than gilts during d 14 to 28 and d 0 to 28. There was no interaction between gender and STTD P concentration for any of the growth performance response criteria. Metacarpal bone ash, Ca, and P increased ($P < 0.01$) from 45.6 to 52.6%, 17.6 to 19.9%, and 8.0 to 9.6%, respectively, with increasing STTD P concentration. Furthermore, Ca and P in metacarpal ash, as well as metacarpal and femur mineral density and content increased ($P < 0.01$) with increasing STTD P concentration. The STTD P requirement determined by broken-line regression using ADG as a response variable was estimated to be 4.21, 3.45, and 3.87 g/kg of diet for pigs from d 0 to 14 (19 to 28 kg BW), d 14 to 28 (28 to 40 kg BW), and d 0 to 28 (19 to 40 kg BW), respectively. Using G:F, the corresponding estimates of STTD P requirement were 4.34, 3.71, and 4.06 g/kg of diet. The STTD P requirement (g/kg of diet) using mineralization response for metacarpus and femur ranged from 3.50 for P in metacarpal ash to 4.28 for femur mineral density. Using an average of the estimates derived from ADG and G:F,

the mean STTD P requirement of pigs from 20 to 40 kg was determined to be 3.97 g/kg of diet.

Key Words: phosphorus, pigs, standardized total tract digestible, requirement

0446 The flow of inositol phosphate esters and phytate phosphorus in the proximal and distal parts of the digestive tract of broilers receiving diets adequate in available phosphorus and supplemented with high levels of phytase. L. A. Beeson*[1], C. L. Walk[2], and O. Olukosi[1], *[1]SRUC, Ayr, UK, [2]AB Vista Feed Ingredients, Marlborough, UK.*

The aim of this study was to characterize the flow of inositol phosphate (iP) esters and disappearance of phytate phosphorus (PP) in the gizzard and ileum of broilers receiving diets adequate in available phosphorus (aP) and supplemented with high levels of phytase. One-hundred-and-sixty-eight Ross 308 broilers at 1 d of age were allocated to 3 treatments (0, 1500, and 3000 FTU/kg phytase) in a randomized complete block design, where the pen was the experimental unit (6 birds per pen). Feed and water were provided ad libitum, and digesta from the gizzard and ileum were collected on d 21 and analysed for iPs and PP relative to TiO_2, the indigestible marker used. In the gizzard, iP6 and iP5 levels were lower ($P < 0.01$) and inositol higher ($P < 0.01$) in the diet supplemented with 1500 or 3000 FTU/kg phytase compared with the control. In the ileum, supplementation with 1500 or 3000 FTU/kg reduced levels of iP6 (3115, 3552, nmol, for 1500, 3000 FTU/kg respectively, $P < 0.01$) and increased that of iP4 and inositol (3115, 3552, nmol for 1500, 3000 FTU/kg, respectively, $P < 0.05$) compared with broilers fed the control diet (482 iP6, 1650 inositol), except for iP5 which was greater ($P < 0.01$) in control and with 1500 FTU/kg phytase compared with 3000 FTU/kg. There were no phytase effects on IP3 flow. In the gizzard, PP disappearance was greater ($P < 0.01$) in diets supplemented with 1500 or 3000 FTU/kg compared with control diet. No differences were seen in ileal PP disappearance between the control and diet supplemented with 1500 FTU/kg, or between supplementation of 1500 and 3000 FTU/kg; however, PP disappearance was greater in ($P < 0.01$) diets with 3000 FTU/kg than control. Total tract PP disappearance was greater ($P < 0.05$) in diets supplemented with 1500 or 3000 FTU/kg (74.5, 85.5%, respectively) than in the control diet (60.3%). The results show that the phytase rapidly hydrolysed iP6 and iP5 in the gizzard, leading to an accumulation of inositol, and the hydrolysis continued in the distal gut. It is concluded that the phytase was effective in rapidly hydrolysing phytate, releasing free inositol even in the gizzard and that higher phytase doses may lead to further phytate phosphorus hydrolysis in the ileum.

Key Words: phytase, inositol phosphate esters, phytate phosphorus

NONRUMINANT NUTRITION: NUTRIENT DIGESTIBILITY OF INGREDIENTS FOR MONOGASTRIC DIETS

0447 Digestible, metabolizable, and net energy in diets containing 0, 15, or 30% wheat bran fed to growing pigs. N. W. Jaworski*[1], D. Liu[2], D. Li[3], and H. H. Stein[1], *[1]University of Illinois at Urbana-Champaign, Urbana, [2]State Key Lab of Animal Nutrition, China Agricultural University, Beijing, [3]Ministry of Agriculture Feed Industry Centre, Beijing, China.*

An experiment was conducted to determine the effects of including 0, 15, or 30% wheat bran in a corn-soybean meal based diet fed to growing pigs. Eighteen barrows (initial BW: 54.4 ± 4.3 kg) were individually housed in metabolism cages and randomly allotted to 1 of 3 dietary treatments in a completely randomized design. The experiment had 3 periods and 6 replicate pigs per diet. The control diet contained corn, soybean meal, and no wheat bran, and 2 additional diets were formulated by mixing 15 or 30% wheat bran with 85 or 70% of the control diet, respectively. Each period lasted 15 d. During the initial 7 d, pigs were adapted to their experimental diets and housed in metabolism crates in an environmentally controlled room and fed 573 kcal/kg $BW^{0.6}$ per d. On d 8, metabolism crates with the pigs were moved into open-circuit respiration chambers for measurement of O_2 consumption and CO_2 and CH_4 production. The feeding level was the same as in the adaptation period and feces and urine were also collected during this period. On d 13 and 14, pigs were fed 225 kcal/kg $BW^{0.6}$ per day, and pigs were then fasted for 24 h to obtain fasting heat production. The apparent total tract digestibility of DM, GE, crude fiber, ADF, and NDF linearly decreased ($P < 0.01$) as wheat bran inclusion increased in the diets. The DE (3454, 3257, and 3161 kcal/kg), ME (3400, 3209, and 3091 kcal/kg), and NE (1808, 1575, and 1458 kcal/kg) of diets linearly decreased ($P < 0.01$) as wheat bran inclusion increased. The daily O_2 consumption and CO_2 and CH_4 production by pigs fed increasing concentrations of wheat bran linearly decreased ($P < 0.01$). However, there was no effect of wheat bran on daily heat production per kg $BW^{0.6}$. In conclusion, increasing inclusion of wheat bran decreased DE, ME, and NE in diets, but did not change daily heat production if expressed as kg $BW^{0.6}$.

Key Words: dietary fiber, energy concentration, heat production

0448 Effects of feeding barley on growth performance and diet nutrient digestibility of weaned pigs. Z. Nasir*[1], M. G. Young[2], M. L. Swift[3], E. Beltranena[4], and R. T. Zijlstra[1], *[1]University of Alberta, Edmonton, Canada, [2]Gowans Feed Consulting, Wainwright, AB, Canada, [3]Alberta Agriculture and Rural Development, Lethbridge, Canada, [4]Alberta Agriculture and Rural Development, Edmonton, Canada.*

Cereal grains vary considerably in price and quality. Barley is usually priced 10 to 20% lower than wheat in Western Canada. Wheat contains more NE than barley and is preferred during the energy-dependent phase of growth. We investigated if feeding of low quality barley (LB) will reduce growth performance and diet apparent total tract digestibility (ATTD) in weaned pigs compared with high quality barley (HB) or hard red spring wheat. Diets contained 20% soybean meal and 62% cereal grain varying in NE (Mcal/kg) content (2.33, 2.23, and 2.44 for HB, LB, and wheat, respectively). Grain constituents used to predict the NE value were predicted by near-infrared reflectance spectroscopy. Starting 1 wk after weaning at 28 d of age, 280 weaned pigs (initial BW 8.7 ± 0.9 kg) were fed diets for 3 wk (d 1 to 21). Five pelleted diets were formulated as (Mcal NE/kg using canola oil; g standardized ileal digestible (SID) Lys/Mcal NE using synthetic AA): (A) wheat (2.39, 4.47); (B) HB (2.39, 4.46); (C) LB (2.33, 4.57); (D) LB, corrected for NE (2.39, 4.45); and (E) LB, low NE (2.25, 4.68). Feed intake and BW were measured weekly to calculate pen ADFI, ADG, and G:F. Feces were collected to calculate diet ATTD of DM, GE, and CP and diet DE and NE value. Compared with Diet A and B, pigs fed Diet D had greater ($P < 0.05$) ADFI (542, 596 vs. 652 g/d), ADG (365, 403 vs. 443 g/d), and G:F (0.646, 0.662 vs. 0.681); while differences were not observed among diets C, D, and E. Pigs fed Diet A had ADFI and ADG lower ($P < 0.05$) than pigs fed the other 4 diets. The ATTD of CP, GE, and DM of Diet E (77.0, 77.3, 76.9%) was greater ($P < 0.05$) than of Diet B (72.4, 74.3, 74.0%) and C (74.9, 75.3, 74.7%), and similar to Diet D (75.9, 76.4, 75.8%), respectively. Pigs fed Diet A had ATTD of GE greater ($P < 0.05$) than pigs fed other 4 diets. The DE value (Mcal/kg) of diet D (3.62) and E (3.55) were greater ($P < 0.05$) than of diet B (3.46) and lower than of diet A (3.71). In conclusion, feeding LB instead of HB and wheat did not reduce growth performance. Feeding barley instead of wheat is economical and achieved greater growth performance even though diet energy digestibility was lower.

Key Words: barley, pig, digestibility

0449 Nutrient profile and in-vitro digestibility of tubers in swine. U. P. Tiwari*, A. K. Singh, H. M. Zaleski, and R. Jha, *University of Hawaii at Manoa, Honolulu.*

To assure the sustainability of swine production in areas where traditional feed ingredients cannot be grown or fed to animals, it is important to study and develop alternative feeding systems. Tubers are grown widely in the tropics and are generally rich in starch, and thus have potential as an alternative energy source. Their use, however, is limited by limited information on nutritional value and digestibility. Five tuber samples grown in Hawaii [purple sweet potato (PSP), Okinawan sweet potato (OSP), *Dioscorea alata* yam (yam), taro, and cassava] were analyzed for their nutritional profile. In vitro digestibility of samples was determined using a 3-step enzymatic assay. On a DM basis, gross energy ranged from 3332 Kcal/kg (taro) to 4272 (yam), sweet potatoes and cassava were in between (PSP = 4137, OSP = 4157, and cassava = 4196 Kcal/kg). The CP content ranged from 3.4% (cassava) to 13.6 (taro), ether extract from 2.8% (PSP) to 14.5 (cassava), ADF from 5.7% (PSP) to 10.4 (taro), NDF from 8.0% (PSP) to 11.5 (taro), ash from 2.0% (PSP) to 3.8 (taro), and in vitro DM digestibility of PSP (87.4%), OSP (87.1%), and cassava (82.3%) was significantly higher ($P < 0.05$) than yam (30.0%), while taro was in between (66.0%). In conclusion, both sweet potato and cassava are rich in energy content with high in vitro DM digestibility and can be used as an alternative source of energy in swine diets, but protein needs to be supplemented as these tubers are low in protein.

Key Words: in vitro digestibility, tubers, swine

0450 Nutritional enhancement of dried distiller's grains with solubles via *Sporobolomyces roseus* fermentation. J. M. Wilson*, *Kansas State University, Manhattan.*

Whole stillage and thin stillage from the ethanol production process were evaluated as substrate sources for the production of β-carotenes by *Sporobolomyces Roseus* (ATCC28988). This product has the potential to be used as a novel feed ingredient for poultry, swine or cattle diets. β-carotenes have been supplemented in animal diets, typically from 150 to 300 mg/kg to improve animal health, enhance meat color and quality, and increase vitamin A levels in milk and meat. By supplementing a stillage fermentation with easily consumable carbon sources and protein sources the fermentation lag time will be reduced and the protein levels of the resultant product will be unaffected or increased. Microbial growth kinetics and stillage fermentations were performed in 500-mL baffled shake flasks and in a 5-L fermentation bioreactor. The HPLC method was used to analyze and quantify the β-carotenes. A 50-L bioreactor has been specifically designed to evaluate the scalability of the process and to perform subsequent feed production trails. Media optimization was conducted in shake flasks using supplemented glucose or glycerol and ammonium sulfate or urea. By supplementing the fermentation with additional protein sources which are easily consumed by the microbes, such as urea, the protein level of the resultant feed ingredient would be unaffected. Final β-carotene concentration was found to be highest for the whole stillage, with 10 g/L added glucose and 10 g/L N added through ammonium sulfate, at 272.57 ± 4.34 μg β-carotene/g biomass. Glycerol addition yielded no significant increase ($P > 0.05$) in β-carotene yield, while urea addition significantly decreased ($P > 0.05$) the final β-carotene concentrations. The resulting fermented product can be effectively blended with regular feed to generate a premium nutritionally enhanced feed product using either whole stillage as a dry feed ingredient or thin stillage as a liquid feed additive.

Key Words: β carotene, DDGS, feed, fermentation

0451 Performance of pigs fed diets containing canola meal produced from high protein or conventional varieties of canola seeds. Y. Liu*, T. Maison, and H. H. Stein, *University of Illinois at Urbana-Champaign, Urbana.*

Two experiments were conducted to determine effects of including high protein canola meal (CM-HP) or conventional canola meal (CM-CV) in diets fed to weanling pigs or growing-finishing pigs. In Exp. 1, 405 weanling pigs (10.07 ± 1.41 kg) were randomly allotted to 9 dietary treatments, with 9 replicate pens per treatment and 4 to 6 pigs per pen. Nine diets were prepared with the control diet being based on corn and soybean meal (SBM) and 8 diets were formulated by adding 10, 20, 30, or 40% of either CM-HP or CM-CV to the control diet. The experiment lasted 21 d. Increased inclusion rate of CM-CV increased (quadratic, $P < 0.05$) ADG of weanling pigs. Increased inclusion rate of CM-HP or CM-CV decreased (linear, $P < 0.05$) ADFI, but increased (linear, $P < 0.05$) G:F of weanling pigs. Weanling pigs fed CM-CV had greater ($P < 0.05$) ADG and G:F than weanling pigs fed CM-HP. In Exp. 2, 280 pigs (27.4 ± 2.92 kg) were randomly allotted to 7 dietary treatments. A 3-phase feeding program was used with grower diets fed from 27 to 57 kg, finisher-1 diets from 57 to 85 kg, and finisher-2 diets from 85 to 112 kg. The 7 treatments consisted of a corn-SBM diet (control) and 6 diets containing a low, medium, or high level of either CM-HP or CM-CV. Low, medium, and high levels of canola meal were defined as the levels needed to replace 33, 66, or 100% of SBM in the diets. Increased inclusion rate of CM-HP decreased (linear, $P < 0.05$) pig BW at the end of phase 2 and at the end of the experiment, decreased (linear, $P < 0.05$) G:F in Phase 2 and the overall period, and decreased (quadratic, $P < 0.05$) ADG in Phase 3. Increased inclusion rate of CM-CV increased (linear, $P < 0.05$) ADFI, but reduced (linear, $P < 0.05$) G:F in Phases 2 and 3 and for the overall period. Growing-finishing pigs fed CM-CV had greater ($P < 0.05$) ADG and ADFI than pigs fed CM-HP. In conclusion, inclusion of 20 to 30% CM-HP or CM-CV have no negative effects on growth performance

of weanling pigs and CM-CV and CM-HP may replace up to 66% of the SBM in diets for growing-finishing pigs.

Key Words: canola meal, high protein canola meal, pigs

0452 Physiochemical and nutritional composition of sorghum as potential food and feed for humans and poultry. M. Mabelebele*[1,2] and P. Iji[2], [1]*University of Limpopo, Polokwane, South Africa,* [2]*University of New England, Armidale, Australia.*

Sorghum is the fifth most important grain crop after wheat, rice, maize, and barley. Sorghum is cultivated for food and beverages for humans, and for feed and fodder for animals in America, Asia, Australia, and Africa. Physical characteristics, proximate composition, total phenols and antioxidant activity, mineral content, and AA profile of sorghum were studied. Forty-eight (± 2.5 kg) adult male broiler chickens were allocated to a complete randomized design with 4 sorghum diets to determine AA digestibility and metabolizable energy. Twelve birds per diet were starved for 24 h before receiving feed allowance of 50 g. Thousand-kernel weights ranged from 33 to 28 g, with brown visual colour and texture that is somewhat corneous to floury. The sorghum grains were higher ($P < 0.05$) in total phenolic and condensed tannins contents for NS5511 and PAN8625. The antioxidant activity of sorghum varieties PAN8816 and PAN8609 were higher ($P < 0.05$) than NS5511 and PAN8625. Crude protein content of PAN8609 (9.54%) and PAN8625 (9.53%) were higher ($P < 0.05$) than those of NS5511 (8.12%) and PAN8816 (8.45%). Starch (%) and GE (MJ/kg) contents differed among sorghum varieties. Mg (mg/kg) content was significantly higher ($P < 0.05$) for PAN8625 than that of NS5511. P and Zn (mg/kg) contents of PAN8609 were higher ($P < 0.05$) than those of PAN8625, NS5511, and PAN8816. Similarly, PAN8625 had higher ($P < 0.05$) P and Zn contents than those of NS5511 and PAN8816. Thr, Leu, Phe, Val, Pro, and Ala contents of varieties PAN8625 and PAN8609 were ($P < 0.05$) higher than those of NS5511 and PAN8816, which had similar ($P > 0.05$) contents. Sorghum NS5511 had low AA digestibility values for Arg, His, Phe, Thr, and Try. Apparent metabolizable energy corrected for nitrogen (AMEn) was the highest ($P < 0.05$) for PAN8816, followed by PAN8609 with lowest value for NS5511. True metabolizable energy corrected for nitrogen (TMEn) values were similar ($P > 0.05$) for PAN8816 and PAN8609, and low in NS5511.

Key Words: sorghum, total phenols, antioxidant activity, amino acid profile, minerals

0453 Comparative digestibility of energy and nutrients in feed ingredients fed to sows and growing pigs. J. E. Lowell*, Y. Liu, and H. H. Stein, *University of Illinois at Urbana-Champaign, Urbana.*

The objective of this experiment was to determine if there is a difference between growing pigs and gestating sows in DE and ME values and apparent total tract digestibility (ATTD) of energy and nutrients in diets and feed ingredients. Eleven feed ingredients were used. Three ingredients were cereal grains (corn, sorghum, and wheat), 4 were common protein sources (soybean meal, canola meal, distillers dried grains with solubles [DDGS], and low-fat DDGS), and 4 were high-fiber ingredients (corn germ meal, corn bran, wheat middlings, and soybean hulls). Eleven diets were formulated. Three diets were based on corn, wheat, or sorghum, and 8 diets were based on a combination of corn and each of the remaining 8 ingredients. A total of 88 gestating sows (parity 2 to 6) and 88 growing barrows (40.1 ± 4.69 kg BW) were randomly allotted to the 11 diets, with 8 replicate animals per diet. Fecal and urine samples were collected for 4 d following a 5-d adaptation period. The DE, ME, and ATTD of ADF, NDF, and CP in corn, wheat, and sorghum were calculated using the direct procedure, and the DE, ME, and ATTD of ADF, NDF, and CP in the other ingredients were calculated using the difference procedure. No differences were observed in DE and ME (as-fed and DM basis) or in the ATTD of GE, NDF, and CP between gestating sows and growing pigs for any of the ingredients. Gestating sows had less ($P < 0.05$) ATTD of ADF for soybean meal and greater ($P < 0.05$) ATTD of NDF for soybean hulls compared with growing pigs, but for the average of all ingredients, gestating sows had reduced ($P < 0.05$) ATTD of ADF compared with growing pigs. These results indicate that, under the conditions of this experiment, the ATTD of CP, NDF, and GE and values for DE and ME in growing pigs are not different from values obtained in gestating sows. However, the ATTD of ADF obtained in growing pigs is not always representative of the ATTD of ADF in gestating sows.

Key Words: digestibility, gestating sows, growing pigs

0454 Performance and nutrient digestibility of weaned rabbits fed cooked albizia seed meal (*Albizia* spp.) as replacement for full-fat soybean meal. A. R. Asafa* and F. P. Agbaye, *Lagos State Polytechnic, Ikorodu, Nigeria*.

Nine weaned rabbits, 6 wk of age, were housed singly and fed cooked albizia seed meal (CASM) in a completely randomized design (CRD) to evaluate the performance and digestibility. The rabbits were randomly allotted to 3 dietary treatment groups of 3 replicates each. The control diet, T_1 (maize, maize offal, groundnut cake full fat soybean, blood meal, palm kernel cake, wheat offal, bone meal, limestone, lysine, methionine, salt, and vitamin-mineral premix), had no CASM, while T_2 and T_3 contained 50% and 100% levels of CASM, respectively, as a replacement for full-fat soya meal (FFSM) on a crude protein (CP) basis. The proximate analysis, fiber fraction, and antinutrient content of cooked *Albizia* seeds were determined. Weekly body weight and feed intake were measured. At the end of wk 3, fecal samples were collected and analyzed to determine the level of digestibility. Data collected

were subjected to ANOVA, and significant means were separated using Duncan Multiple Range Test. Results showed that rabbits fed with the T_1 had the highest ($P < 0.05$) average weight gain of 81.11 g/rabbit, as against 63.90 and 51.11 g obtained for T_2 and T_3, respectively (Table 0454). The feed intake was best ($P < 0.05$) for rabbits on T_1, with value of 930 g/wk. Rabbits on T_2 had the best feed conversion efficiency (12.41). The high crude protein value 29.84 in CASM indicated that the seed could be used as a protein source in rabbit diet. However, the saponin content may serve as an antinutrient, inhibiting its digestibility and utilization. Feed intake, weight gain, as well as a digestibility coefficient were significantly affected above 50% inclusion of CASM in the diets. Cooked albizia seed could replace FFSM up to 50% on CP basis.

0455 Nutritional evaluation of raw *Anthonotha macrophylla* seed meal as a replacement for soybean meal in the diet of broiler chickens.

A. H. Akinmutimi*, *Michael Okpara University of Agriculture, Umudike, Umuahia, Nigeria.*

The objective of this study was to develop a high quality animal protein at reduced cost through the use of alternative feedstuffs (e.g., *Anthonotha macrophylla*). One-hundred-and-twenty-day-old Marshal broiler chicks were used to assess the quantitative replacement of soybean meal with raw *A. macrophylla* seed meal. Ten birds per treatment were replicated thrice in a completely randomized design. Diet 1 was soybean-based (control), while the test feedstuff (*A. macrophylla*) quantitatively replaced 5, 10, and 15% soybean in Diets 2, 3, and 4, respectively. Feed and water were given ad libitum for 56 d. The crude protein (27.74%) and gross energy values (4.69 Kcal/g) makes it a potential feedstuff. It contains antinutritional factors, namely: phytate (0.43%), tannin (0.06%), hydrogen cyanide (13.71 mg/kg), and nitrate (0.14%). For growth performance, there were significant differences ($P < 0.05$) among the treatment means for all the parameters measured, except initial weight. The final weight, weight gain/bird, and weight gain · $bird^{-1}$ · d^{-1} supported Diet 2. The feed conversion ratio also favored Diet 2 (2.93) among others (Diet 1 = 2.96, Diet 3 = 3.07, and Diet 4 = 4.14). For cut-parts, there were significant differences ($P < 0.05$) for all parameters measured, with Diet 2 comparing favourably with the control diet (Diet 1). All the organ weight parameters showed no significant difference ($P > 0.05$). The haematological parameters measured were within the normal range established for broiler chickens, except for monocytes in all the diets and lymphocytes and neutrophils for Diets 3 and 4, respectively. For serum chemistry, Diets 1, 2, and 3 fall within the normal range established for broiler chickens for albumin and globulin, while for alkaline phosphatase, all the diets fall within the normal range established for broiler chickens. Considering the economics of the diet, Diet 2 had the least cost/kg weight gain, highest revenue, and highest gross margin, making Diet 2 an economically viable diet. Diet 2 enhanced a high-quality animal protein production at reduced cost. This will lead to an increase in animal protein intake globally. It is therefore recommended.

Key Words: nutritional, evaluation, *Antonotha macrophylla*, soybean, chickens

0456 Effect of graded levels of defatted green microalgal inclusion into broiler diets on growth performance and digestibility.

S. K. Gatrell*, T. J. Derksen, E. V. O'Neil, and X. G. Lei, *Cornell University, Ithaca, NY.*

The objective of this experiment was to determine an optimal inclusion level of a defatted marine green microalgae (*Nannochloropsis oceanica*), a byproduct of biofuel production, in broiler diets. A total of 180 hatching Ross broiler chicks were divided into 5 groups ($n = 6$) fed a corn-soybean meal diet containing 0 (Control), 2, 4, 8, or 16% algal biomass (Cellana, Kailua-Kona, HI) for 6 wk. Body weights, feed intake, organ weights, and blood samples were collected at wk 3 and 6; and water intake was measured over the first 3 wk. Over the 6-wk period, ADG, ADFI and G:F were not affected by the algal inclusion up to 8%. However, the 16% inclusion reduced ADG ($P < 0.01$) and G:F ($P < 0.001$). Water intake was increased ($P < 0.001$) by 16 and 39% in chicks fed 8 and 16% microalgae diets, respectively. Relative heart weights were increased by feeding the 16% microalgae diet at both wk 3 ($P < 0.05$) and wk 6 ($P < 0.01$). However, relative liver, breast, gizzard, proventriculus, and intestinal weights or lengths were not affected by the dietary treatments. The same was also true for plasma uric acid, inorganic phosphorus, and protein concentrations at wk 3 or 6. Dry matter concentrations of total excreta collected from 2 birds per cage over a period of 3 d at wk 6 were reduced ($P < 0.05$) in the birds consuming the 8 and 16% microalgae diets, compared with the control. However, the excreta total dry matter or N retention was similar among the 5 experimental diets. In conclusion, dietary inclusion of this new defatted microalgal biomass up to 8% did not exert

any negative effects on growth performance or nutrient metabolism, except for the elevated water intake. *Supported in part by USDA/DOE Biomass R&D Initiative Grant.*

Key Words: green microalgae, broiler nutrition, biofuel

0457 Effects of duration of mixing diets with high inclusion of cereal grain co-products on growth performance and carcass measurements in finishing pigs. M. E. Morts*, J. D. Hancock, K. L. Kohake, and J. D. McAtee, *Kansas State University, Manhattan.*

A total of 200 finishing pigs (average initial BW of 68 kg) were used in a 62-d growth assay to determine the effects of mix time in corn-soybean meal-based diets with high inclusion of distillers dried grains with solubles (32% DDGS) and wheat middlings (32% midds). The pigs were sorted by gender and ancestry and assigned to pens (5 pigs/pen and 8 pens/treatment) in a completely randomized design. A Davis and Sons horizontal ribbon mixer (model DS30) was used to mix 1-t batches of the diets. All ingredients (corn, DDGS, midds, soybean meal, crystalline AA, limestone, salt, vitamin mix, mineral mix, and tylosin) were added with the mixer stopped. Mix times were 0, 15, 30, 60, and 420 s before discharge, transfer to a surge bin, and sacking into 22.6 kg bags for delivery to the swine farm. Diets were formulated to at least 120, 120, and 110% of requirements for essential AA, vitamins, and minerals for 75 to 100 and 100 to 135 kg pigs according to NRC (2012) nutrient requirements of swine. Feed and water were consumed on an ad libitum basis until the pigs were harvested (average BW of 125 kg) and processed at a commercial abattoir. As for results, there was a trend (quadratic effect, $P < 0.07$) for ADG to decrease as mix time was increased from 0 to 30 s and increase as mix time was further increased to 420 s. There was a trend (linear effect, $P < 0.06$) for G:F to increase as mix time was increased. Mix time did not affect ($P > 0.19$) ADFI, HCW, dressing percentage, or fat thickness at the last rib (BF). In conclusion, increasing mix time from 0 to 420 s in diets with high inclusion of DDGS and midds had inconsistent effects in growth performance, and no effect in carcass measurements.

Key Words: duration of mixing, distillers dried grains with solubles, pigs

NONRUMINANT NUTRITION: FUNCTIONAL AMINO ACIDS: NEW PARADIGM SHIFTS IN UNDERSTANDING ANIMAL PROTEIN NUTRITION

0458 Amino acid signaling for embryonic and fetal development. G. Wu*, F. Bazer, R. Burghardt, G. Johnson, M. C. Satterfield, and X. Wang, *Texas A&M University, College Station*.

Embryonic death losses in mammals are estimated to range from 20 to 50%, depending on species, with two-thirds of the losses occurring during the peri-implantation period of pregnancy. Additionally, intrauterine growth restriction (IUGR) is primarily responsible for the high rates (up to 15%) of neonatal mortality in livestock species. Among litter-bearing species, swine exhibit the most severe naturally-occurring embryonic loss and IUGR. Nutrient availability, limited uterine capacity, and placental insufficiency are major factors contributing to suboptimal reproduction in mammals. Emerging evidence also shows that concentrations of several AA (arginine, glutamine, and leucine) in the uterine lumen increase markedly during early pregnancy, and are particularly abundant in fetal allantoic fluid during early and mid-gestation. Besides serving as building blocks for proteins, these AA play signaling roles to regulate intracellular protein turnover, water and ion transport, apoptosis, immune responses, and antioxidative reactions in the conceptus (embryo or fetus and extraembryonic membranes). Specifically, arginine is the precursor for synthesis of nitric oxide and polyamines (putrescine, spermidine, and spermine) that are essential to DNA synthesis and cell proliferation. Interestingly, these synthetic pathways are regulated by physiological concentrations of glutamine and leucine to coordinate the cellular actions of arginine. In addition, glutamine and leucine increase expression and activity of glutamine:fructose-6-phosphate transaminase to stimulate formation of glucosamine-6-phosphate from glutamine and fructose-6-phosphate and, therefore, for active synthesis of amino sugars and glycoproteins by trophectoderm cells. Furthermore, arginine, glutamine, and leucine activate (1) the mechanistic target of rapamycin (MTOR) cell signaling through phosphorylation of the MTOR protein and its downstream target proteins (S6K1 and 4E-BP1), and (2) osteopontin-induced cell signaling (a major mechanism for regulation of cell adhesion and implantation) through binding αvβ3 and α5β1 integrin heterodimers and the subsequent phosphorylation of MAPK3/MAPK1 (Erk1/2) and MAPK14 (p38). The beneficial outcome is to promote conceptus growth and development. Arginine and osteopontin appear to activate sequentially PI3K, Akt1, and MTOR to amplify cell signal transduction and exert their physiological effects. Translating the basic research into feeding practices, that is, supplementing 0.4 or 0.8% arginine to a typical corn- and soybean meal-based diet (containing 0.7% arginine) for gilts between d 14 and 25 of gestation, increases embryonic survival and conceptus development. As profitability of the swine industry critically depends on reproductive efficiency of sows, our findings have important implications for increasing pork production to provide high-quality animal protein for human consumption.

0459 Leucine: A potent nutrient signal for protein synthesis in neonates. T. A. Davis*[1], M. L. Fiorotto, A. Suryawan, and D. Columbus, *USDA/ARS-Children's Nutrition Research Center, Baylor College of Medicine, Houston, TX.*

Neonates are highly efficient at utilizing their dietary AA for skeletal muscle growth. In the neonatal pig, the sharp increase in muscle protein synthesis after eating is triggered by the rise in AA and insulin. Amino acids and insulin induce protein synthesis by activating independent signaling pathways that converge at mechanistic target of rapamycin complex 1 (mTORC1), leading to the activation of key regulators of translation. Leucine is the most effective single AA in triggering translation initiation factor activation. Although most information on leucine's action on mTORC1-dependent translation initiation has been generated from studies performed in cell culture, studies in the neonatal pig have identified components of the AA signaling pathway that regulate protein synthesis in vivo. Acute parenteral leucine administration at physiological levels increases muscle protein synthesis in neonatal pigs and this effect is due to the activation of mTORC1 and its downstream targets, including eukaryotic initiation factor 4E-binding protein 1 and ribosomal protein S6 kinase-1. Although acute administration of the other branched-chain AA, isoleucine and valine, are ineffective, the leucine metabolites, α-ketoisocaproic acid and β-hydroxy-β-methylbutyrate, stimulate muscle protein synthesis by activating mTORC1-dependent translation. The stimulation of protein synthesis by parenteral leucine can be sustained for prolonged periods, but is dependent on maintenance of the supply of other AA to support protein synthesis. Pulsatile administration of leucine during continuous orogastric feeding of a milk replacer enhances muscle protein synthesis by stimulating translation initiation. Enteral leucine supplementation of a low protein meal stimulates protein synthesis similar to a high protein meal, but this effect is diminished but not blocked with more prolonged supplementation. Further studies are needed to establish whether the anabolic effects of leucine can be sustained chronically to promote lean growth. *Supported by NIH AR444474, NIH HD072891, USDA NIFA 2013–67015–20438, and USDA/ARS 6250–51000–055.*

0460 Tryptophan: Functions beyond protein synthesis. S. W. Kim* and Y. Shen, *North Carolina State University, Raleigh.*

Tryptophan is a limiting essential AA for the growth of pigs. In addition to its important role to support growth, Trp also has unique physiological functions when it is metabolized to other compounds such as serotonin, melatonin, and niacin in the body. Serotonin is a cerebral neurotransmitter, playing a major role in regulating physiological processes such as appetite, stress adaptation, activity, and aggressive behavior. Tryptophan crosses blood-brain barrier, and thus increasing Trp intake is shown to elevate serotonin synthesis in the brain of pigs. However, large neutral amino acids (LNAA) compete for a same type of transporter to cross the blood-brain barrier, and thus dietary ratio of LNAA to Trp can affect Trp availability for serotonin synthesis in the brain. In a typical production environment, pigs can be under social stress conditions as they go through regrouping when they are weaned and when they are moved from nursery to finisher pens. Pigs confront with new mates when they are regrouped in a same pen, causing social mixing stress such as fighting and other aggressive behaviors. Pigs with social stress are shown to undergo increased systemic oxidative stress which is negatively related to animal productivity. In our research, increasing Trp intake up to 10.8 g/d elevated serotonin concentration in hypothalamus, reduced salivary cortisol, and enhanced growth of pigs under social mixing stress. Reducing dietary LNAA content from 4.5 to 3.8% provided similar benefits of increased Trp intake when Trp to LNAA ratio was maintained at 0.157. This allowed reducing supplemental levels of Trp from 0.8 to 0.6%. In summary, in a typical pig production, pigs can be under social mixing stress, and increasing tryptophan intake seems to help to reduce stress and thus improve performance of pigs.

Key Words: pigs, serotonin, social stress, tryptophan

0461 New insights into sulfur amino acid function in gut health and disease. D. G. Burrin*, *USDA-ARS Children's Nutrition Research Center, Houston, TX.*

The gastrointestinal tract (GIT) is a metabolically significant site of sulfur amino acids (SAA) metabolism in the body. Aside from their role in protein synthesis, methionine and cysteine are involved in many biological functions and diseases. Methionine (MET) is an indispensable AA and is transmethylated to homocysteine via S-adenosylmethionine (SAM), the principal biological methyl donor in mammalian cells and a precursor for polyamine synthesis. We have examined the role of SAA metabolism in GIT health and disease. Our studies in young pigs showed that the whole-body methionine transmethylation and remethylation rates were higher during duodenal [^{13}C]-MET than intravenous [$^{2}H_3$]-MET infusion. Thus, transmethylation and transsulfuration in the GIT represented 27 and 23% of whole-body fluxes, respectively. Additional studies show how disruption of methionine cycle activity and dietary supplementation with methionine metabolites affects the susceptibility to colitis in mice. We found that mice fed vitamin B_{12} and B_6 deficient diets are protected against colitis, with reduced inflammation and tissue injury. We also found that B-vitamin deficiency suppressed inflammatory gene expression in association with altered MET cycle activity and indices of methylation status. We also showed that supplementation with the MET cycle metabolite, methylthioadenosine (MTA), prevented inflammation during colitis in mice. These results suggest that MTA also is protective against experimental colitis and reduced tissue injury and expression of multiple inflammatory genes. The presentation will discuss the evidence of SAA metabolism in GIT and consequences of MET cycle activity in health and disease.

Key Words: methionine, cysteine, gut

0462 Glutamate and glutamine: Nonessential or essential amino acid. M. Watford*, *Rutgers, New Brunswick, NJ.*

Rose defined an essential amino acid (EAA) as one that the body cannot make in sufficient amounts to maintain growth or N balance. Despite Rose's finding that glutamate added to diets of traditionally EAA improved the maximal rate of growth, glutamate and glutamine are not usually considered as essential. In part, this is due to the almost total metabolism of dietary glutamate and glutamine in the intestine, and the very high concentration, and turnover, of these 2 AA in the body. In human medicine, however, glutamine has been recognized as a conditionally EAA during hypercatabolic states, and while such conditions are not a concern in the domestic animal industry, the question arises, "is glutamine conditionally essential at other times"? We observed that plasma and skeletal muscle glutamine concentrations fall throughout lactation in both horses, pigs, and mice, and that this was accompanied by a loss of skeletal muscle. We proposed that this was due to the high demand for glutamine (and glutamate) both for milk production and as a fuel for the enlarged maternal intestine. Furthermore, the provision of supplemental glutamine to both suckling and weaned piglets has demonstrated improvements in growth and health, most probably related to improved intestinal status and immune function. The daily supplementation of suckling piglets is not feasible on an industrial scale, and we established that supplementing lactating sows with either glutamine, or a mixture of glutamine and glutamate, increased the glutamine and glutamate content of the milk and also prevented some of the loss of lean body mass in the sow. Furthermore, sows receiving the supplement had higher concentrations of lipids in both colostrum and mature milk, and similar increases were seen in milk somatic cell count. Thus, we propose that glutamate and glutamine should be considered essential both during lactation for the health of both the mother and the neonate.

Key Words: glutamine, glutamate, lactation

NONRUMINANT NUTRITION: FAT, FIBER, FERMENTATION, AND RESIDUAL FEED INTAKE

0463 Changing the dietary omega-6 to omega-3 fatty acid ratio impacts nursery pig performance more than increasing omega-3 intake alone.
L. Eastwood* and D. Beaulieu, *Prairie Swine Centre, Inc., Saskatoon, SK, Canada.*

The objective of this experiment was to determine if either increasing the intake of omega (ω)-3 fatty acids or the amount relative to ω-6 fatty acids (ω-6:ω-3 ratio) would impact nursery pig performance. A total of 300 newly weaned pigs (26 ± 2 d of age), blocked by gender, were housed in groups of 5/pen. Pens were assigned to 1 of 5 diets (n = 12 pens/diet) consisting of a control (Con; 10:1 ω-6:ω-3 ratio, 3.5% total fat, tallow based), 3 diets with 3.5% fat (plant based) and ω-6:ω-3 ratios of 10:1, 5:1, and 1:1 (3.5/10, 3.5/5, and 3.5/1 respectively), and a plant-based 10:1 ratio diet with 5% total fat (5/10). This design allowed us to examine the effects of increasing ω-3 intake at a constant ratio (10:1 ratio; 3.5 vs. 5% fat) and the effect of reducing the ω-6 to ω-3 ratio at a constant amount (3.5% fat; 10:1, 5:1, and 1:1 ratios). Pigs were weighed weekly for 4 wks. On d 0 and d 29, 6 pigs and 6 pigs/diet respectively, were slaughtered, allowing the calculation of whole body N, fat, and water deposition. The ADFI was higher for pigs consuming the 3.5/1 diet during d 21 to 28 (1.13 vs. 0.96 kg/d; P = 0.01) when compared with pigs fed all other diets. Increasing ω-3 amount (constant 10:1 ratio) did not affect ADFI or ADG (P > 0.10); but when the ω-6:ω-3 ratio decreased (constant total fat), ADFI was highest for pigs consuming the 3.5/1 diet relative to those consuming the 3.5/5 or 3.5/10 diets during d 21 to 28 postweaning (1.13 vs. 0.97 vs. 0.93 kg/d; P = 0.02). Pigs consuming the 3.5/5 diet had increased protein (82.5 vs. 71.1 vs. 74.2 g/d; P = 0.07) and water (342.1 vs. 301.0 vs. 313.0 g/d; P = 0.06) deposition rates relative to those consuming the 3.5/10 or 3.5/1 diets. Lipid deposition was unaffected by treatment (P > 0.10). Increasing the amount of dietary ω-3 fatty acids while keeping the ω-6:ω-3 ratio constant did not affect ADG, ADFI, or carcass composition; however, when total fat was held constant, a 5:1 ratio led to improved ADFI in older nursery pigs, as well as increased protein deposition without altering lipid deposition.

Key Words: swine, omega-3, performance

0464 The dietary omega-6 to omega-3 fatty acid ratio impacts the inflammatory response in nursery pigs more than increasing omega-3 intake.
L. Eastwood* and D. Beaulieu, *Prairie Swine Centre, Inc., Saskatoon, SK, Canada.*

The objective of this experiment was to determine if the intake of ω-3 fatty acids affects the inflammatory response of nursery pigs postweaning, and if this response depends on the ratio with ω-6 fatty acids. Individually housed, newly weaned pigs (26 ± 2 d of age; n = 100) were assigned to 1 of 5 diets and 1 of 2 inflammatory challenge groups arranged as a 5 × 2 factorial with repeated measures. Diets consisted of a control (Con; 10:1 ω-6:ω-3, 3.5% total fat, tallow based), 3 diets with 3.5% fat (plant based) and ω-6:ω-3 ratios of 10:1, 5:1, or 1:1 (3.5/10, 3.5/5, and 3.5/1 respectively), and a 10:1 ratio diet with 5% total fat (5/10). This allowed for the comparison of increasing ω-3 intake at a constant ratio (10:1 ratio; 3.5 vs. 5% fat) and decreasing ratio at a constant ω-3 intake (3.5% fat; 10:1, 5:1, and 1:1 ratios). Challenge groups consisted of a saline or lipopolysaccharide (LPS; 15 μg/kg BW *Escherichia coli* lipopolysaccharide) injection. Pigs were fed their assigned diets for 22 d before the 24-h inflammatory challenge on d 23. Rectal temperatures were measured hourly for the first 6 h, then at 12 and 24 h postinjection. Blood samples were collected at 0, 2, 6, and 12 h postinjection. The ADG and ADFI from d 0 to 22 or during the challenge period were unaffected by diet (P > 0.05). During the challenge, LPS pigs had lower (P < 0.01) ADFI (0.93 vs. 0.40 kg, saline vs. LPS) and ADG (+0.44 kg vs. -0.52 kg, saline vs. LPS). Rectal temperature, blood urea N, IL-1β, IL-6, and TNFα were unaffected by diet (P > 0.05), but were increased by LPS (P < 0.01). Serum IL-8 concentration was reduced with decreasing ω-6:ω-3 ratio (16.79 vs. 11.14 pg/mL, 10:1 vs. 1:1; P = 0.03) but was unaffected by dietary ω-3 amount at a constant ratio (P > 0.05). Pigs consuming the 3.5/1 diet had lower IL-8 responses relative to those consuming the 3.5/10 and 3.5/5 diets (diet × challenge P = 0.03). Additionally, the IL-8 response of pigs fed the 1:1 diet and challenged with LPS was similar to the saline injected pigs fed the 10:1, 5:1, or 1:1 diets (P > 0.05), indicating that reducing the dietary ω-6:ω-3 ratio impacts a piglets inflammatory response postweaning.

Key Words: swine, omega-3, inflammatory response

0465 Effect of fiber and fat on calculated values for standardized total tract digestibility of calcium in fish meal.
J. C. González-Vega*[1], C. L. Walk[2], and H. H. Stein[1], [1]*University of Illinois at Urbana-Champaign, Urbana,* [2]*AB Vista Feed Ingredients, Marlborough, UK.*

The objectives of the experiment were to determine the effect of fiber and fat on the standardized total tract digestibility (STTD) of Ca in fish meal and to evaluate the effect of type

of diet (cornstarch-based diet vs. corn-based diet) and digestibility procedure (direct procedure vs. difference procedure) on calculated values for STTD of Ca in fish meal. Seventy growing pigs (BW: 19.4 ± 1.0 kg) were randomly allotted to 7 diets with 10 pigs per treatment. Two diets were formulated to determine the effect of fiber on STTD of Ca in fish meal: (1) cornstarch-based diet + fish meal and (2) cornstarch-based diet + fish meal + Solka floc. Two additional diets were formulated to determine the effect of fat on STTD of Ca: (3) corn-based diet + fish meal + 1% fat and 4) corn-based diet + fish meal + 7% fat. To evaluate the effect of type of diet on the STTD of Ca in fish meal, diets 1 and 3 were compared. The STTD of Ca in fish meal was also determined using the difference procedure with a corn-soybean meal diet (0.33% Ca) and a corn-soybean meal-fish meal diet (0.89% Ca). A Ca-free diet was used to determine basal endogenous losses of Ca. Results indicated that fiber increased ($P < 0.001$) the STTD of Ca, but the STTD of Ca was not affected by inclusion of fat in the diet. The STTD of Ca (88.99%) in the corn-based diet was greater ($P < 0.05$) than in the cornstarch-based diet (45.79%). When comparing the direct and the difference procedure, the greatest ($P < 0.05$) values for the STTD of Ca in fish meal were obtained in pigs fed the corn-based diet using the direct method, followed by values calculated by difference procedure (77.66%; $P < 0.05$), and the least ($P < 0.05$) values were obtained in pigs fed the cornstarch-based diet using the direct method. In conclusion, fiber increased the STTD of Ca, but inclusion of fat did not affect the STTD of Ca. Values for the STTD of Ca were influenced by the type of diet and by the digestibility procedure used. These data indicate that values for the ATTD or the STTD of Ca obtained in synthetic diets may not always be representative for the ATTD and the STTD of Ca in practical corn-soybean meal diets.

Key Words: calcium digestibility, fish meal, pigs

0466 Response of pigs in ileal endogenous amino acid losses to different dietary fiber types determined using the regression method. S. A. Adedokun* and O. Adeola, *Purdue University, West Lafayette, IN.*

Dietary fiber, especially fiber with high water holding capacity, is theorized to increase ileal endogenous amino acid (EAA) losses in nonruminant animals. It is not known whether dietary fiber types have different effects on ileal EAA. Increase in EAA losses would decrease apparent ileal AA digestibility and increase N excretion into the environment. Information on basal ileal EAA losses in pigs will advance diet formulation on standardized ileal AA digestibility basis. The objective of this study was to evaluate the effect of 2 fiber sources, corn fiber or pectin, on ileal EAA losses in pigs. Total AA, crude protein, and crude fiber contents of corn fiber or pectin used in this study were 9.8, 10.8, and 10.0% or 1.1, 10.8, and 0.2%, respectively. For each fiber type, 3 semipurified diets were formulated to contain 3 levels of casein (40, 80, and 120 g/kg diet) and 100 g of fiber/kg diet. All fiber within a diet was supplied by either corn fiber or pectin. The experiment consisted of 3 periods of 7 d, each with ileal digesta collection on d 6 and 7. Within each period, there were 3 pigs on 3 levels of casein (40, 80, or 120 g/kg diet) in each of 3 blocks per fiber type; and each block served as the experimental unit. There were 18 cannulated pigs with average initial BW of 30, 31, and 30 kg for Periods 1, 2, and 3, respectively. Each pig received 3.5% of the starting BW of the smallest pig within each block in 2 equal portions at 0700 and 1800 h. Basal ileal EAA losses were determined from the ordinate intercept, at 0 AA intake, of the regression of ileal digesta AA concentration in mg/kg DMI against dietary AA intake in mg/kg DM. Corn fiber resulted in higher ($P < 0.05$) ileal endogenous His, Leu, and Tyr losses. Isoleucine, Phe, Thr, and Cys showed a tendency ($P < 0.1$) for higher endogenous loss in pigs fed diets containing corn fiber. In general, the effect of highly-fibrous but low-viscosity corn fiber on ileal endogenous N and AA losses is similar to that of low-fiber but highly-viscous pectin.

Key Words: corn fiber, endogenous AA, pectin

0467 Starch and fiber characteristics of barley influence site of energy digestion in ileal-cannulated grower pigs. J. M. Fouhse*[1], S. Moehn[1], J. Gao[1], T. Vasanthan[1], M. Izydorczyk[2], A. D. Beattie[3], and R. T. Zijlstra[1], *[1]University of Alberta, Edmonton, Canada, [2]Canadian Grain Commission, Winnipeg, MB, Canada, [3]University of Saskatchewan, Saskatoon, Canada.*

Chemical components of cereal grains such as amylose, β-glucan (BG), and total dietary fiber (TDF) may influence energy digestion in the gut. The objective was to determine the association between composition of barley and wheat and the site of energy digestion in pigs. Seven ileal-cannulated barrows were allotted to a 6 (periods) × 7 (diets) Youden square. Five cereal grain diets included (% amylose, β-glucan, and TDF): 3 hulless-barley cultivars: Diet 1, CDC Fibar (0, 10, 22); Diet 2, CDC Hilose (13, 7, 18); Diet 3, CDC McGwire (11, 5, 15); 1 hulled barley, Diet 4, Xena (12, 4, 17); and 1 hard red spring wheat, Diet 5, Utmost (12, 1, 14). Two reference diets, an N-free and a protein-energy mix, were included to calculate ingredient digestibility. Test diets included 80% cereal grain and were fed at 2.5 × maintenance. Feces and ileal digesta were sampled after a 5-d adaptation. The AID of GE, DM, and starch was lowest ($P < 0.05$) for Fibar (43, 42, 73%) and Hilose (48, 47, 69%) vs. McGwire (68, 67, 84%), Xena (65, 64, 92%), and Utmost (78, 80, 93%). In contrast, hindgut fermentation of GE, DM, and starch was greatest ($P < 0.05$) for Fibar (45, 46, 26%) and Hilose (48, 41, 30%) vs. McGwire (23, 23, 16%), Xena (17, 16, 8%), and Utmost (11, 14, 7%). Thus, Fibar and Hilose did not differ ($P > 0.05$) in ATTD of DM and GE from Utmost. McGwire had the greatest ($P < 0.05$) ATTD of DM and had a greater ($P < 0.05$) ATTD of GE

than Fibar, Hilose, and Xena but equal to that of Utmost ($P < 0.05$). Specifically, ATTD of DM was 90 vs. 87, 88, 81, and 88% and ATTD of GE was 91 vs. 88, 88, 83, and 89%, respectively, for McGwire vs. Fibar, Hilose, Xena, and Utmost. Starch ATTD did not differ among cereal grains ($P > 0.05$). Hulled barley, Xena, had an ATTD of GE and DM lower ($P < 0.05$) than all other cereal grains. Thus, the DE was lower ($P < 0.05$) in Xena than all other cereal grains, which did not vary ($P > 0.05$). In conclusion, a greater content of amylose, BG, and TDF in cereal grains decreased energy digestion in the small intestine and increased hindgut fermentation of energy, which may support maintaining pig gut health.

Key Words: grain, starch, fiber

0468 Effects of three types of dietary microalgal inclusions on n-3 and n-6 fatty acid profiles in egg yolks of laying hens. J. Kim, A. Magnuson, and X. Lei*, *Cornell University, Ithaca, NY.*

Two experiments were conducted to determine if including microalgal biomass into layer diets containing 0, 3, and 5% flaxseed oil (FO) affected fatty acid profiles in their egg yolk. In Experiment I, 90 Shaver-laying hens (20-wk old) were allotted into 9 groups ($n = 10$) and fed diets containing 3 levels of FO (0, 3, and 5%) and 3 levels of full-fat *Staurosira* spp. (SS) (0, 7.5, and 10%, Cellana, Kailua-Kona, HI) for 4 wk. In Experiment II, 50 Shaver-laying hens (28-wk old) were divided into 5 groups ($n = 10$) and fed control diet (without FO and MAB) or the diets containing 3% FO with SS at 7.5%, defatted *desmodesmus* spp. (DS) at 7.5%, or defatted *Nannochloropsis ocreanica* (NO) at 7.5 or 15% for 4 wk. Body weights, feed intakes, and egg quality (albumen, egg yolk, and egg shell weight) were measured weekly, and fatty acid contents of egg yolk were determined biweekly. In Experiment I, neither FO nor SS affected feed intakes, egg production, or egg quality. While body weights were decreased ($P < 0.05$) by 5% FO, the decrease was prevented by the inclusion of SS. At wk 2, the FO inclusion increased n-3 fatty acid ($P < 0.05$), and decreased n-6 fatty acid concentrations in the yolk. The SS inclusion affected ($P < 0.05$) yolk n-6 fatty acid concentrations. At wk 4, there were interactions ($P < 0.05$) between SS and FO on the yolk n-3 fatty acid concentrations or changes over time. The yolk concentrations of n-6 fatty acids were increased by FO, but decreased by SS. In Experiment II, egg production, egg component weights, body weights, and feed intakes were not affected by the 5 dietary treatments. While the combinations of 3% FO and 3 types of microalgal biomass elevated ($P < 0.05$) the yolk n-3 fatty acid contents, the 2 doses of NO (7.5 vs. 15%) showed no difference. In conclusion, inclusions of 3 types of microalgal biomass exerted moderate effects on n-3 and n-6 fatty acid profiles and concentrations in comparison with the much stronger effects of 3 or 5% FO. However, the microalgal biomass inclusion seemed to help offset the negative effects of 5% FO on the body weights of laying hens. *Supported in part by USDA/DOE Biomass R&D Initiative Grant.*

Key Words: Microalgal biomass, omega-3 fatty acid, laying hens

0469 Dose-dependent effect of a defatted green microalgal biomass on enriching omega-3 fatty acids in broiler chicken. S. K. Gatrell*, J. Kim, T. J. Derksen, E. V. O'Neil, and X. G. Lei, *Cornell University, Ithaca, NY.*

The objective of this experiment was to determine the feasibility of creating an omega-3 (n-3) enriched chicken product using defatted green microalgae (*Nannochloropsis oceanica*), a byproduct of the biofuel production research. A total of 180 hatching Ross broiler chicks were divided into 5 groups ($n = 6$) fed a corn-soybean meal diet containing 0 (control), 2, 4, 8, or 16% algal biomass (Cellana, Kailua-Kona, HI) for 6 wk. Plasma, breast muscle (pectoralis major) and liver were collected at wk 6. Plasma n-3 fatty acid concentrations showed dose-dependent increases with the microalgal inclusion levels, and the concentration in the birds fed the 16% microalgae diet was 15-fold higher ($P < 0.001$) than that of the control. Meanwhile, liver eicosapentaenoic acid (EPA) and docosahexaenoic acid (DHA) were increased 8- to 22-fold ($P < 0.001$) and 2- to threefold ($P < 0.01$), respectively, by feeding the microalgal biomass compared with the control. Percentage of n-3 fatty acids, but not total fatty acid content, in the breast muscle was enhanced ($P < 0.0001$) by the microalgae inclusion in a dose-dependent fashion. Breast muscle EPA and DHA contents were elevated ($P < 0.0001$) by 38- and 60-fold, respectively, in the chicks fed the 8 and 16% microalgae diets compared with those fed the control diet. In conclusion, the defatted marine microalgal biomass tested in the present study was very effective in enriching n-3 fatty acids, in particular DHA and EPA, in broiler chicken tissues. Supported in part by USDA/DOE Biomass R&D Initiative Grant.

0470 In vitro digestion and fermentation characteristics and in vivo digestibility of canola co-products in the pigs. T. A. Woyengo*[1], R. Jha[1,2], E. Beltranena[1], and R. T. Zijlstra[1], *[1]University of Alberta, Edmonton, Canada, [2]Univerisity of Hawaii at Manoa, Honolulu.*

Canola coproducts serve as source of dietary AA and energy to pigs. However, fermentation characteristics of solvent-extracted canola meal (CM) in the pig intestine are unknown. Thus, we determined in vitro degradation and fermentation characteristics of *Brassica juncea* CM (JCM) and *Brassica napus* CM (NCM) in comparison to soybean meal (SBM). Samples were first hydrolyzed using pepsin and pancreatin. Subsequently, residues were incubated in a buffer with fresh pig feces as inocula in a randomized complete block design providing 12 replicates

per feedstuff per run for 2 runs. Accumulated gas production was measured for 72 h and modeled to estimate kinetics of gas production. Concentration of VFA per unit weight of feedstuff was measured in fermented solutions. In previous studies, ileal and hindgut GE digestibility values for feedstuffs were obtained (by difference method) from ileal-cannulated barrows (~50 kg BW) fed cornstarch-based diets containing 50% feedstuffs for 5 d. On DM basis, SBM, JCM, and NCM contained 50.6, 44.0, and 38.1% CP; and 8.5, 22.3, and 30.6% NDF, respectively. The in vitro DM digestibility for SBM (82.3%) was greater ($P < 0.05$) than the in vitro DM digestibility for JCM (68.5%), which was greater ($P < 0.05$) than that of NCM (63.4%). Ileal GE digestibility was greatest ($P < 0.05$) for SBM followed by JCM and then NCM. Total gas production for SBM was greater ($P < 0.05$) than that of JCM, which was greater ($P < 0.05$) than that for NCM. Total VFA production was lower ($P < 0.05$) for SBM (0.73 mmol/g DM) than for NCM (1.05 mmol/g DM), which was lower ($P < 0.05$) than that of JCM (1.37 mmol/g DM). A similar trend was observed for hindgut GE digestibility (as percentage) for feedstuffs; 15, 21.4, and 24.4% for SBM, NCM, and JCM, respectively. In conclusion, in vitro fermentation characteristics of SBM, and canola meals simulated their digestion in the pig hindgut ($r^2 = 0.979$). The NCM or JCM can contribute more energy to the pig via hindgut fermentation than the SBM, whereas JCM can contribute more energy to the pig via hindgut fermentation than the NCM.

Key Words: canola meal, in vitro fermentation, pig

0471 In vitro pig cecal fermentation with different inoculum source with diets containing *Acrocomia aculeata*.

S. L. S. Cabral Filho*, L. S. Murata, C. A. Silva Júnior, H. dos Santos Sena, F. Lopes da Silva, F. Nishimoto Gomes da Costa, T. F. Braga, and J. F. Athayde Oliveira, *University of Brasilia, Brasilia, Brazil.*

The aim of this study was to determine the potential of different inoculum sources on in vitro gas production technique. Three different types of inoculum were used for fermentation in gas production analysis: fistulated bovine ruminal liquor grazing *Brachiaria brizantha* (RL); extract from slaughtered pig cecum raised in a conventional confined system (CS) and extract from slaughtered pig cecum raised in a free range system (CF), both collected directly from the cecum. The substratum used was 3 diets containing replacement of *Acrocomia aculeata* (AA) pulp being 100% (0% AA), 90% (10% AA), and 80% (20% AA) of a basal diet with soybean meals and corn grains to meet pig growth requirements, as well as *Braquiaria brizantha* grass. The accumulated volume of gas was measured at 0, 3, 6, 9, 12, 16, 24, 48, 72, and 96 h after incubation. The mathematical model used was France et al. (1993). A completely randomized design with factorial arrangement was used. All used inocula produced gases with the studied substrates (Table 0471). The pig cecum extract (CF) showed higher gas production ($P < 0.05$) with *Braquiaria brizantha*and 20%AA as substratum than CS. However, there was no statistical difference when compared with RL. The gas production was superior ($P < 0.05$) when basal diet (0%AA) was used with LR and CS inocula. There were no significant differences in gas production when 10% AA was used as a substrate. The pig cecum extract from slaughtered pigs raised in confined and free range systems produced gas as well as bovine ruminal liquor, and can be used for further gas production evaluation, mainly to study fiber usage in pork production. The pig cecum extract from pigs raised in free range (CF) pork production showed more important gas production potential ($P < 0.05$) than CS when the substrate had high fiber level, probably due to the increase of fiber intake in livestock breeding.

Key Words: gas production, fiber fermentation, alternative feed

0472 Residual feed intake in pigs is associated with organ weight, nutrient digestibility, and intestinal nutrient transporter gene expression.

S. Vigors*[1], T. Sweeney[2], A. K. Kelly[1], C. J. O'Shea[1], D. N. Doyle[1], and J. V. O'Doherty[1], *[1]School of Agriculture and Food Science, University College Dublin, Dublin, Ireland, [2]College of Agriculture, Food Science and Veterinary Medicine, University College Dublin, Belfield, Dublin 4, Ireland.*

Increases in nutrient digestibility mediated by changes in intestinal nutrient transporter gene expression could possibly explain the differences in efficiency between animals differing in residual feed intake (RFI). The objective of this study was to examine the effect of divergent selection for RFI on organ weights, nutrient digestibility and intestinal nutrient transporter gene expression in pigs. Male pigs ($n = 75$; initial BW 22.4 kg were fed a standard finishing diet (8.3 g/kg lysine and 16.4 MJ/kg gross energy) for 43 d to evaluate feed intake and growth for the purpose of calculating RFI. Phenotypic RFI was calculated as the residuals from a regression model regressing DMI on ADG and midtest $BW^{0.75}$(MWT). Data was analysed using the GLM procedure of SAS (SAS Inst. Inc., Cary, NC). On d 43, 16 animals (average weight 85 kg sem 2.84 kg), designated as 8 high RFI (HRFI) and 8 low RFI (LRFI) were slaughtered and digesta from the ileum

and rectum were collected for the purpose of calculating the coefficient of apparent ileal (CAID) and total tract nutrient digestibility (CATTD). Tissue was collected from the jejunum, duodenum, and ileum for the purpose of examining intestinal nutrient transporter gene expression. As expected, LRFI pigs had lower ADFI (2.44kg vs. 1.87kg, sem 0.07) and improved feed conversion ratio (1.96 vs. 2.48) than HRFI pigs ($P < 0.001$) with no difference in ADG or MWT. When comparing weights of organs between RFI groups, HRFI pigs had increased weight of heart and visceral organs ($P < 0.05$) compared with the LRFI. There was a linear positive correlation between RFI and weight of large intestine ($r = 0.57$; $P < 0.05$). For the digestibility parameters measured, RFI was negatively correlated with CATTD of N ($r = -0.46$; $P < 0.05$) and GE ($r = -0.51$; $P < 0.05$). The RFI was negatively correlated with the intestinal glucose transporters SGLT1 ($r = -0.56$; $P < 0.05$) and GLUT2 ($r = -0.44$; $P = 0.09$). LRFI pigs had increased CAID of gross energy (GE) than HRFI pigs ($P < 0.05$). Similarly, LRFI pigs had improved CATTD of GE, while also having improved digestibility of N and dry matter (DM). LRFI pigs had higher gene expression of the fatty acid transporter FABP2 ($P < 0.01$) and glucose transporters SGLT1 ($P < 0.05$) and GLUT2. In conclusion differences in nutrient digestibility, intestinal nutrient transporter gene expression and differential organ weight are possibly some of the biological processes responsible for differences in feed efficiency in pigs.

Key Words: residual feed intake, nutrient transporter gene expression, pigs

0473 Effect of divergent selection for residual feed intake on cytokine gene expression in pigs following an ex vivo liposaccharide challenge.

S. Vigors*[1], J. V. O'Doherty[1], C. J. O'Shea[1], and T. Sweeney[2], [1]*School of Agriculture and Food Science, University of College Dublin, Dublin, Ireland,* [2]*College of Agriculture, Food Science and Veterinary Medicine, University College Dublin, Belfield, Dublin 4, Ireland.*

Pathogenic microbes influence pig performance by stimulating an inflammatory immune response and disrupting metabolism. To date, little research has been undertaken to examine the effect of divergent selection for residual feed intake (RFI) on the immune system. The objective of this study was to examine the effect of divergent selection for RFI on colonic inflammatory cytokine gene expression following an ex vivo lipopolysaccharide (LPS) challenge. Male pigs ($n = 75$; initial BW 22.42kg [SD = 2.03]) were fed a standard finishing diet (12.5 g/kg lysine and 14.5 MJ/kg DE) for 43 d to evaluate feed intake and growth for the purpose of calculating RFI. Phenotypic RFI was calculated as the residuals from a regression model regressing DMI on ADG and midtest $BW^{0.75}$ (MWT). On d 43, 16 animals (average weight 85 kg, Std 2.84 kg), designated 8 high RFI (HRFI) and 8 low RFI (LRFI) were slaughtered. Colonic tissue was collected and stimulated for 3 h ex vivo with LPS. QPCR was performed to analyse the expression of *IL-1, IL-6 IL-8, IL-10, Il-17, TNF-α* and *IFN-γ*. As expected, LRFI pigs had lower ($P < 0.001$) ADFI (2.44kg vs. 1.87kg sem 0.04) and improved feed conversion ratio (1.96 vs. 2.48, sem 0.01) than HRFI pigs with no difference in ADG or MWT. Stimulation of the colonic tissue with LPS increased expression of *IL-8* ($P < 0.05$), *TNF-α* ($P < 0.0001$), *IL-10* ($P < 0.05$), *IL-1* ($P < 0.001$), *IFN-γ (P < 0.05)* and *IL-6* ($P < 0.001$) in both HRFI and LRFI pigs. There was an interaction between RFI and LPS challenge for the expression of *IL-8* ($P < 0.05$) and *IL-1* ($P < 0.01$) and *IFN-γ (P < 0.05)*. Following the LPS challenge there was an increase in the expression of *IL-1* ($P < 0.01$) and *IL-8* ($P < 0.05$) and *IFN-γ (P < 0.05)* in the HRFI pigs, with no change in the LRFI pigs. There was no difference between RFI groups for *IL-10* and *IL-17*. The upregulation of pro-inflammatory cytokines has an adverse effect on the gut mucosa and the reduced expression of the pro-inflammatory cytokines in this study could partly explain the increased efficiency in LRFI pigs.

Key Words: residual feed intake, cytokine, pigs

NONRUMINANT NUTRITION: FEED ADDITIVES, ENZYMES, AND DIETARY SUPPLEMENTS

0474 Effects of a blend of essential oil compounds, feed-grade antibiotics, and their combination on the growth performance of nursery pigs.
M. J. Azain*[1], R. Dove[1], C. W. Parks[2], and J. R. Bergstrom[2], [1]*University of Georgia, Athens,* [2]*DSM Nutritional Products, Inc., Parsippany, NJ.*

A total of 72 pigs (initial wt. of 6.2 kg) were utilized in a 35-d study to evaluate the effects of feeding a blend of essential oils (EO, Crina Piglet, DSM Nutritional Products, Parsippany, NJ), a feed-grade antibiotic (AB, Mecadox, Phibro, Teaneck, NJ), and their combination (EO + AB) on the growth performance of nursery pigs. Weaned pigs (3 wks of age) were placed into 24 pens containing 3 pigs per pen and allotted to 1 of 4 dietary treatments for a total of 6 replicate pens per treatment. Gender was balanced within pens in a weight block. Treatments were arranged as a 2 × 2 factorial arrangement to evaluate possible EO × AB interactions. Treatments consisted of (1) Control without EO or AB, (2) EO (200 mg/kg), (3) AB (50 mg/kg), and (4) OE + AB. All pigs were fed the same 3-phase nursery program with the exception of the added treatments, which replaced corn when added. Diet phases were 0 to 7 d, 7 to 21 d, and 21 to 35 d. Diets were formulated to meet or exceed all nutrient requirements based on NRC (2012). Overall, there were no EO × AB interactions ($P \leq 0.05$) for any parameters measured. The EO significantly improved G:F ($P \leq 0.05$) for the d 0 to 35 period as compared with pigs fed no EO, while AB significantly improved final body weight, ADG, and ADFI compared with pigs not fed AB ($P \leq 0.05$) during the d 0 to 35 period. In summary, it appears that dietary addition of both AB and EO can improve the growth performance of nursery pigs.

Key Words: essential oils, performance, pigs

0475 Impact of zinc and arginine dietary supplements on antioxidant capacity and oxidative status in weanling piglets under conditions of commercial production.
F. Guay and N. Bergeron*, *Universite Laval, Quebec, Quebec City, Canada.*

The effects of high levels of Zn and arginine (Arg) supplementation on the antioxidant capacity and oxidative status of weanling piglets raised under commercial conditions were examined. Weanling piglets aged 21 d were fed for 15 d a diet supplemented or not with 2500 mg kg^{-1} of Zn and 1% Arg. They were distributed among the 4 treatments in a randomized complete block design based on initial body weight, 6 pens per treatment, 13 animals per pen. Access to feed was ad libitum. Data were analyzed as a 2 × 2 factorial experiment using the SAS MIXED procedure (SAS Inst. Inc., Cary, NC), with Zn and Arg supplementation as the main independent variables. Blood sampling day was included as a third factor. Blood was collected from the same 2 piglets in each pen before the morning feeding on d 8 and 15. The Zn supplement increased average daily gain (ADG) from d 0 to 7(0.194 vs. 0.140 g d^{-1}), d 7 to 15 (0.368 vs. 0.280 g d^{-1}) and for the entire experimental period (0.289 vs. 0.217 g d^{-1}), average daily feed intake (ADFI) from d 0 to 7 (0.197 vs. 0.182 g d^{-1}), d 7 to 15 (0.454 vs. 0.358 g d^{-1}) and for the entire experimental period (0.338 vs. 0.279 g d^{-1}) and ADG:ADFI ratio from d 0 to 7(0.991 vs. 0.760), and for the entire experimental period (0.860 vs. 0.777; $P < 0.001$). Both supplements decreased the malondialdehyde concentration significantly (Zn:4.37 vs. 3.91, $P < 0.005$; Arg:4.38 vs. 3.89 μmol L^{-1}, $P < 0.002$). Total antioxidant capacity increased from d 8 to 15 (0.953 vs. 1.391 μmol equivalent Trolox L^{-1}), regardless of the dietary treatment ($P < 0.05$). The reduced glutathione concentration also was higher on d 15 than on Day 8 (3.37 vs. 2.22 μmol L^{-1}), regardless of the dietary treatment ($P < 0.001$). On d 8, the concentrations of total and oxidized glutathione were increased when Arg and Zn supplements were combined (Zn2500Arg1:5.42 and 1.20; Zn0Arg0: 4.19 and 1.04 μmol L^{-1}), but decreased in the presence of either supplement alone (Zn2500Arg0:2.57 and 0.41; Zn0Arg1:3.42 and 0.67 μmol L^{-1}; $P < 0.001$). Piglets fed Zn-supplemented diets had a lower haptoglobin serum concentration than those fed a nonsupplemented diet (509.5 vs. 1417.6 mg L^{-1}; $P < 0.001$). In conclusion, although a high level of Zn improved piglet growth performance, the results do not indicate any clear association between performance and oxidative status. Arginine supplementation had a limited effect on growth performance and oxidative status under these commercial conditions.

Key Words: piglets, zinc, arginine

0476 Effect of a 6-phytase derived from *Buttiauxella* spp. expressed in *Trichoderma reesei* on apparent total tract digestibility of Ca and P, bone ash, and growth performance in weaning piglets.

A. L. Wealleans[1], Y. Dersjant-Li*[1], R. M. Bold[1], and H. H. Stein[2], [1]*Danisco Animal Nutrition, DuPont Industrial Biosciences, Marlborough, UK,* [2]*University of Illinois at Urbana-Champaign, Urbana, IL*.

Two studies evaluated the effect of a 6-phytase derived from *Buttiauxella* spp. expressed in *Trichoderma reesei* (PHY) on apparent total tract digestibility (ATTD) of Ca and P, bone ash and growth performance in piglets. Five dietary treatments were tested, including a positive control (PC) based on corn-SBM-canola meal adequate in available P and Ca, a negative control (NC) with low available P and Ca and NC supplemented with PHY at 250, 500, and 1000 FTU/kg feed with low available P (-0.2%) and Ca (-0.17%). Experiment 1 used 232 male piglets (Initial BW = 9.62 ± 1.36 kg) with 10 replicates per treatment; 3 to 4 piglets/replicate. Experiment 2 used 160 piglets (Initial BW = 8.99 ± 0.16 kg) with 8 replicates/treatment; 4 piglets/replicate. Experimental diets were fed in mash form ad libitum in 2 phases for 6 wk in Exp. 1 and from 9 to 22 kg BW in Exp. 2. Fecal samples were collected from 1 pig/pen at the end of Exp. 1 and in the last 4 d of feeding in Exp. 2; samples were measured for ATTD using a TiO_2 marker. Femurs from both forelegs were collected for bone analysis. Linear and quadratic responses were determined using the Fit Model platform of JMP; trial was used as a random effect. In both experiments, NC reduced all growth and digestibility parameters compared with PC (Table 0476). PHY supplementation resulted in linear/quadratic improvement in BWG, G:F, digestible Ca and P, as well as bone ash. In conclusion, 1000 FTU/kg 6-phytase derived from *Buttiauxella* spp., expressed in *Trichoderma reesei,* can replace 0.2% available P in weaning piglet diets, based on BWG and bone ash data.

Key Words: phytase, swine, performance

0477 Effect of supplementation of nonstarch polysaccharide-degrading enzymes on nutrient digestibility of wheat and wheat millrun based diets in growing pigs.

Z. Nasir*[1], J. Broz[2], D. Pettersson[3], and R. T. Zijlstra[1], [1]*University of Alberta, Edmonton, Canada,* [2]*DSM Nutritional Products, Basel, Switzerland,* [3]*Novozymes, Bagsvaerd, Denmark*.

Nutrient digestibility of wheat millrun (WMR) is limited by nonstarch polysaccharides (NSP) such as arabinoxylans. Supplementation of NSP-degrading enzymes may increase nutrient digestibility of WMR. Effects of supplementation of 2 endo-xylanases, fed with or without 2 arabinofuranosidases, on nutrient digestibility of a wheat and WMR-based diet were evaluated in a 6 × 6 Latin square. Six ileal-cannulated barrows were fed 5 test diets and 1 N-free diet in six 9-d periods. Five test diets contained 56.2% wheat, 40% WMR, and added enzymes as follows: (1) control (Diet C), without enzyme; (2) 10 mg enzyme protein (EP)/kg of xylanase Ronozyme WX (Diet X1); (3) 10 mg EP/kg of xylanase GH11 (Diet X2); (4) 10 mg EP/kg of xylanase Ronozyme WX + 5 mg EP/kg of arabinofuranosidase GH43 + 5 mg EP/kg of arabinofuranosidase GH51 (Diet X1A); and (5) 10 mg EP/kg of xylanase GH11 + 5 mg EP/kg of arabinofuranosidase GH43 + 5 mg EP/kg of arabinofuranosidase GH51 (Diet X2A). Feces and ileal digesta were collected sequentially for 2 d. Data were analyzed using MIXED procedure of SAS (SAS Inst. Inc., Cary, NC). Wheat and WMR contained 12.2 and 21.2% total NSP, respectively. Insoluble NSP were greater than soluble NSP, respectively, in wheat (10.8 vs. 1.4%), WMR (18.8 vs. 2.4%), and diets (14.6 vs. 5.1%). Digesta viscosity (resistance to flow) was greatest for Diet C. Compared with Diet C (377 Pa·s), digesta viscosity was reduced by 15.1% ($P < 0.05$) for Diet X2A (320 Pa·s), while viscosity was not affected for Diets X1 (362 Pa·s), X2 (354 Pa·s), and X1A (348 Pa·s). Apparent total tract digestibility (ATTD) of GE and CP were greater ($P < 0.05$) for Diets X2 and X2A than for Diet C. Specifically, ATTD of GE was 79.7, 80.3, 81.0, 80.3, and 81.3% and ATTD of CP was 81.9, 82.1, 83.3, 83.1, and 83.7%, respectively, for Diets C, X1, X2, X1A, and X2A. Diets X1A and X2A increased ($P < 0.05$) apparent ileal digestibility (AID) of NSP compared with Diets C, X1, and X2. Compared with control, Diets X1A and X2A

Table 0476. Effect of phytase supplementation on growth parameters, Ca and P digestibility, and bone ash percentage[1]

			Phytase dose, FTU					
	PC	NC	250	500	1,000	SEM	Linear	Quadratic
Body weight gain, g/d	566.8	377.1	466.2	484.3	536.3	11.84	< 0.0001	0.110
Feed intake, g/d	942.6	774.1	896.0	910.9	954.3	18.19	< 0.001	0.116

Calcium ATTD, %	54.51	38.00	40.99	67.04	56.21	2.23	< 0.0001	< 0.001
Bone ash, %	46.45	36.82	41.06	42.45	43.67	2.15	< 0.0001	< 0.0001

[1]Assessment of linear and quadratic responses excluded positive control treatments.

increased ($P < 0.05$) AID of insoluble and total NSP, insoluble and total arabinose, insoluble and total xylose by 52, 42, 86, 80, 85, and 84%, respectively. In conclusion, combined application of xylanase and arabinofuranosidase was more effective than single application of xylanase to increase the nutritional value of diets based on wheat and WMR.

Key Words: wheat co-product, xylanase, arabinofuranosidases

0478 Efficacy of novel 6-phytase derived from *Buttiauxella* spp. expressed in *Trichoderma reesei* on ileal and total tract nutrient digestibility in growing pigs fed a corn-soy based diet. D. E. Velayudhan*[1], J. M. Heo[1], Y. Dersjant-Li[2], A. Owusu-Asiedu[2], and C. M. Nyachoti[1], *[1]University of Manitoba, Winnipeg, Canada, [2]Danisco Animal Nutrition, DuPont Industrial Biosciences, Marlborough, UK.*

The current study evaluated the effect of different levels of a 6-phytase derived from *Buttiauxella* spp. expressed in *Trichoderma reesei* on ileal and total tract nutrient digestibility in growing pigs. Twelve ileal cannulated pigs (initial BW = 25 kg) were randomly assigned to 1 of 6 treatments in a 6 × 6 Latin square design to give 12 observations per treatment. The experimental diets consisted of corn soybean meal based control diet (NC), NC supplemented with 4 levels of phytase (i.e., 250, 500, 1000, and 2000 FTU/kg) and a low-protein diet (5% casein) used to quantify endogenous AA losses. All diets contained titanium dioxide as indigestible marker. Pigs were given their daily feed allowance at a rate of 4.5% of BW determined at the beginning of each experimental period. Each period lasted for 9 d, with 5 d of adaptation to the assigned experimental diet followed by 2 d fecal and 2 d ileal digesta collections. Data were analyzed using the mixed model procedures of SAS (SAS Inst. Inc., Cary, NC). The final model had treatment as the main effect since pen and period effects were nonsignificant. Increasing levels of 6-phytase supplementation linearly increased apparent ileal digestibility (AID) of DM, CP and GE ($P < 0.01$). Compared with NC, AID of Ca and P respectively increased ($P < 0.05$) by 5.9, 11.7, 9.0, and 12.3% and 12.7, 46.6, 49.1, and 77.4% with 250, 500, 1000, and 2000 FTU/kg of phytase. Mean AID of dispensable and indispensable AA improved ($P < 0.05$) by 2.5, 2.0, and 1.0% and 2.0, 1.3, and 1.2%, respectively, for diets containing 500, 1000, and 2000 FTU/kg of phytase. Mean standard ileal digestibility (SID) of dispensable and non dispensable AA improved ($P < 0.05$) by 1.7, 1.2, and 2.8% and 1.0, 0.2, and 3.4% respectively, for diets with 500, 1000, and 2000 FTU/kg of phytase. Apparent total tract digestibility (ATTD) of DM, CP, and GE responded linearly ($P < 0.01$) to increasing levels of phytase. The ATTD of Ca and P respectively increased ($P < 0.05$) by 18.2, 30.4, 24.5, and 33.8% and 46.8, 98.4, 99.7, and 124.3% for diets supplemented with 250, 500, 1000, and 2000 FTU/kg of the 6-phytase. In conclusion, supplementation with a 6-phytase from *Buttiauxella* spp. expressed in *Trichoderma reesei* significantly enhanced the AID and ATTP of Ca, P, and other nutrients in pigs, in dose-dependent manner.

Key Words: amino acid, calcium, phosphorus, phytase, ileal digestibility, pig

0479 Nutrient digestibility of growing pigs fed phytase- and xylanase-supplemented wheat-based diets with low, medium, or high lysine level. T. A. Woyengo*[1], A. Owusu-Asiedu[2], and R. T. Zijlstra[1], *[1]University of Alberta, Edmonton, Canada, [2]DuPont Industrial Biosciences–Danisco Animal Nutrition, Marlborough, Wiltshire, UK.*

An experiment was conducted to determine the effect of adding xylanase to phytase-supplemented wheat-based diets containing low, medium, or high Lys on apparent ileal digestibility (AID) and apparent total tract digestibility (ATTD) of nutrients in growing pigs. Six ileal-cannulated barrows (initial BW = 39.1 ± 1.6 kg) were fed 6 diets in a 6 × 6 Latin square design. The 6 diets were a phytase-supplemented (500 FTU/kg) wheat-soybean meal-based basal diet with a standardized ileal digestible Lys content of 0.81% (low), 0.91% (medium), or 1.01% (high) and xylanase at 0 or 2000 XU/kg in a 3 × 2 factorial arrangement. The diets were similar in NE (1.79 Mcal/kg) and CP (25%); and the dietary AA levels were based on ideal AA ratio. The diets only differed in wheat and crystalline AA; the dietary level of AA was increased by increasing the dietary level of crystalline AA at the expense of wheat. All 6 diets contained 0.5% Cr_2O_3 as an indigestible marker. Dietary Lys level and xylanase interacted ($P < 0.05$) for AID of energy and all AA except Lys and Trp such that xylanase supplementation increased ($P < 0.05$) the AID of energy by 11%, and of the AA on average by 9% when the basal diet was low in Lys, but not when the basal diet was medium or high in Lys. Also, dietary Lys level and xylanase tended to interact ($P = 0.054$) on AID of Lys such that xylanase supplementation increased the AID of Lys only when the basal diet was low in Lys. Xylanase supplementation increased ($P < 0.05$) AID of Trp from 77.6 to 79.3%, and ATTD of energy from 79.1 to 80.2% regardless of dietary Lys level. In summary, an addition of xylanase to phytase-supplemented wheat-based basal diet for growing pigs can increase the AID and ATTD of energy but also AID of AA for diets limiting in Lys. In conclusion, the results from the present study indicate that diets could be formulated with reduced AA levels to optimize the benefits of xylanase supplementation to increase nutrient and energy digestibility in growing pigs.

Key Words: lysine, pig, xylanase

0480 The effects of β-mannanase (Hemicell HT) supplementation to nursery pig diets on nutrient digestibility and retention. C. Vonderohe*[1], A. M. Jones[1], B. T. Richert[1], J. E. Ferrel[2], P. D. Matzat[2], and J. S. Radcliffe[1], *[1]Purdue University, West Lafayette, IN, [2]Elanco Animal Health, Greenfield, IN.*

Three groups of 18 barrows with an initial BW of 10 ± 2.95 kg were blocked by BW and randomly assigned to diets containing 0, 32, or 48 kU/kg of β-mannanase (Hemicell HT, ChemGen Corp., Gaithersburg, MD) to investigate energy and N digestibility and retention. Pigs were individually housed in pens (0.35 m^2) and provided ad libitum access to feed and water for 7d. Following this 7d adaptation period, 12 pigs (4 pigs/diet in each group, 12 pigs/diet in total) were selected and moved to metabolic pens (0.84 m^2) where they remained for the final 7 d of the experiment. In the metabolic pens, feed was supplied at 9% of metabolic BW ($BW^{0.75}$) split evenly in 2 daily feedings and water was supplied ad libitum. A total collection of feces and urine was conducted for the final 4 d in the metabolism pens for subsequent determination of nutrient digestibility and retention. There was no effect of β-mannanase supplementation on growth ($P = 0.23$), feed efficiency ($P = 0.84$), or feed intake ($P = 0.27$) in either the adjustment period (d 0 to 7) or the collection period (d 7 to 14). Supplementing nursery pig diets with β-mannanase resulted in increased digestible ($P < 0.001$) and metabolizable ($P < 0.001$) energy and improved DM digestibility ($P < 0.001$) and N retention ($P < 0.02$). These responses to β-mannanase were greatest when β-mannanase was supplemented at 32 kU/kg. Feeding β-mannanase at 48 kU/kg resulted in DE, ME, and DM digestibility and N retention values that tended ($P < 0.10$) to be greater than control fed pigs, but were not significantly different from pigs fed 32 kU/kg β-mannanase. The results of this experiment indicate that β-mannanase supplementation improves energy digestibility and retention and DM digestibility and N retention in nursery pigs.

Key Words: pig, digestibility, β-mannanase

0481 Nucleotide supplementation in the diet of farrowing sows and its effect on milk quality, litter weight gain, and mortality. L. A. Vitagliano*[1], M. A. Bonato[2], R. L. D. C. Barbalho[2], G. D. Santos[2], and L. F. Araújo[1], *[1]Universidade de São Paulo, Pirassununga, Brazil, [2]ICC Brazil, São Paulo, Brazil.*

It is not yet understood whether increased nucleotides in sow milk are a response to a requirement of piglets or are part of the composition of milk, as it naturally occurs during lactation. However, exogenous nucleotide supplementation is able to further increase these levels. The objective of this study was to evaluate effects of nucleotide supplementation in farrowing sows diets on performance, RNA concentration in milk, and piglet litter performance. The nucleotides were derived from a yeast source containing hydrolyzed RNA (free nucleotides/nucleosides). The trial was conducted with 80 sows (Agroceres PIC) distributed in a completely randomized design (by parity order, avg. 3.7/treatment), with 4 treatments (0, 4, 8, and 12kg/MT of yeast or 0, 0.24, 0.48 and 0.72kg/MT of free nucleotides/nucleosides) and 20 replications of 1 sow in each. The sows were fed experimental diets starting 3 d before farrowing, until weaning of piglets at 21 d of age. The number of piglets per sow (10.48 ± 0.26) and piglet weight (1.70 ± 0.04kg) was equalized at birth. The sow parameters were weight after farrowing (WF, kg), weight after weaning (WW, kg), weight loss (WL, %), and feed intake (FI,kg). The number of weaned piglets (NWP), piglet weight at weaning (PWW,kg), litter weight at weaning (LWW, kg), litter weight gain (LWG, kg), mortality (MORT, %), and milk production (MP, kg; 1kg of piglet weight = 4 kg of milk) were measured. Samples of colostrum and milk (11, 20 d of lactation) were collected for laboratory analysis of RNA (mg/mL milk). The data were analyzed using the GLM (SAS Inst. Inc., Cary, NC), and means were compared by Tukey's test ($P = 0.10$). Nucleotide supplementation in the diet of farrowing sows resulted in no difference ($P > 0.10$) in WF, WW, WL, or FI. The piglets from sows fed diets supplemented with nucleotides had improved ($P < 0.10$) NWP, LWW, LWG, MORT, and MP compared with unsupplemented diets. There were no differences ($P > 0.10$) between treatments in PWW. In general, the 8 kg/MT and 12 kg/MT levels showed best piglet performance results (6 and 4.5% higher LWG than control group) and lower MORT (41.7 and 53.5% lower than control group). Nucleotide supplementation gave no significant response ($P > 0.10$) in total RNA in colostrums, but the amount of RNA present in milk at 11 and 20 d of lactation significantly increased ($P < 0.10$). This study demonstrated that supplementation of nucleotides to farrowing sows had a positive carryover effect on milk quality which, consequently, increased the litter weight gain and the number of weaned piglets (+3.5%).

Key Words: piglet, performance, RNA

0482 Evaluation of the efficacy of *Bacillus licheniformis* or sodium butyrate in front of a *Salmonella* Typhimurium oral challenge in piglets. E. Barba-Vidal*[1], L. Castillejos[1], V. F. Buttow Roll[2], J. J. Mallo[3], and S. Martín-Orúe[1], *[1]Animal Nutrition and Welfare Service, Department of Animal and Food Sciences Universitat Autònoma de Barcelona, Bellaterra, Spain, [2]Department of Animal Science, Faculty of Agronomy Eliseu Maciel, Federal University of Pelotas, Pelotas, Brazil, [3]Norel S.A., Madrid, Spain.*

The objective of the study was to evaluate the efficacy of *Bacillus licheniformis* (PROPORC, NOREL S.A.) or sodium butyrate (GUSTOR BP70, NOREL S.A.) in weanling pigs orally challenged with *Salmonella* Typhimurium. Seventy-two piglets (28 d old, 8.21 ± 0.79 kg) were divided into 24 pens allocated to 3 experimental diets: (1) CTR, base diet without additives; (2) PRO, base diet supplemented with 1 kg/t of PROPORC (equivalent to 10^9 CFU/kg of feed of *Bacillus licheniformis*); and (3) BUT, base diet supplemented with 3kg/t of GUSTOR BP70 (containing 70% sodium butyrate protected with vegetable fat). The base diet was multicereal (corn, wheat, and barley) with selected protein sources (soybean meal 44, fishmeal, and bovine sweet whey), without antibiotics and met NRC 2012 requirements. Consumption and weight gain of the animals were monitored during the trial (16 d). After a week of adaptation, the animals were orally inoculated with *Salmonella* Typhimurium (1×10^8 CFU). Parameters evaluated after the oral challenge were fecal consistency, rectal temperature (24 and 72 h postinoculation, PI) and fecal shedding of *Salmonella* (d 0, 1, and 7 PI). Moreover, on d 4 and 8 PI, 1 animal in each pen was euthanized to evaluate the serological inflammatory response (TNFα and Pig-Map), the microscopic ileal morphology, and the presence of *Salmonella* in the colon. No significant differences between treatments were seen on performance, fecal consistency, rectal temperature, or inflammatory markers ($P > 0.05$). However, a trend to reduction was observed in *Salmonella* prevalence in feces on d 7 PI (100, 75, and 75, $P = 0.074$) and significant reduction in colon on d 8 PI (88, 50, and 63, $P = 0.043$), for CTR, PRO, and BUT, respectively. Besides, on d 4 PI crypt depth showed a tendency to increase with the 2 supplemented diets (203, 239, and 251 203 μm, SEM ± 15.9, $P = 0.107$), for CTR, PRO, and BUT, respectively. The results obtained demonstrate that the administration of *Bacillus licheniformis* (10^9 CFU/kg) or sodium butyrate (3kg/mT) could improve intestinal morphology and reduce the colonization and fecal shedding of *Salmonella*Typhimurium in piglets.

Key Words: *Salmonella*, probiotic, sodium butyrate

0483 Effects of dietary supplementation of direct fed microbial on growth performance, nutrient digestibility, blood profiles, fecal microflora, and noxious gas emission in nursery pigs. J. H. Cho*[1], E. Kiarie[2], S. Indrakumar[2], and I. H. Kim[1], *[1]Department of Animal Science, Dankook University, Cheonan, South Korea, [2]DuPont Industrial Bioscience–Danisco Animal Nutrition, Waukesha, WI.*

A total of 128 weanling pigs [(Yorkshire × Landrace) × Duroc] with an average BW of 6.75 ± 0.59 were used in a 42-d experiment to investigate the efficacy of *Bacillus* spp. direct-fed microbial (DFM) on growth performance, indices of gut health and nutrient utilization in piglets. Pigs were allotted to experimental diets based on BW in a completely randomized block design. There were 2 dietary treatments: NC, basal diet (corn-soybean meal based diet); DFM, NC + DFM (1.5×10^5 cfu/g of feed). The DFM product was based on 1 strain of *B. subtilis* and 2 strains of *B. amyloliquefaciens* specifically selected and optimized for high enzyme production (Danisco Animal Nutrition, Marlborough, Wiltshire, UK). The diets were fed during the experiment in 2 phases: d 0 to 14, and 15 to 42. All diets, in pelleted form, were formulated to meet or exceed the nutrient requirements (NRC, 1998) for weanling pigs. Feed intake and BW were monitored weekly. We used 0.20% chromium oxide as indigestible marker and fecal samples were collected via rectal massage. Incidences of diarrhea were monitored in phase using a fecal scoring system (1 hard to 5 watery). At the end of each phase, 2 pigs/pen were bled for serum and fresh fecal samples were collected. At the end of the experiment, 1 pig/pen was killed to obtain small intestinal tissues for histomorphology and large intestinal digesta for select microbial counts. In the overall (d 0 to 42), pigs fed DFM had better G:F (0.694 vs. 0.680, $P = 0.04$) and tended to have a higher ADG (425 vs. 417 g/d, $P = 0.08$) compared with the NC fed pigs. Pigs fed DFM showed lower incidences of diarrhea ($P = 0.01$) than NC fed pigs on d 4. Duodenum and jejunum villi length of pigs fed DFM diets were longer ($P < 0.01$) than for pigs fed NC diet. Cecal digesta *Lactobacillus* counts tended to be higher ($P = 0.06$) in pigs fed DFM compared with the NC pigs; however, *Lactobacillu*s and *Escherichia coli* counts in the colon digesta were unaffected by the dietary treatments. Pigs fed DFM tended ($P < 0.09$) to have higher apparent total tract digestibility of crude protein and lower fecal ammonia release coinciding with low blood urea N concentration than the NC fed pigs. In conclusion, DFM supplementation improved growth performance and efficiency in nursery pigs linked to improved nutrients utilization and indices of gut health and function.

Key Words: weanling pigs, growth performance, gut health

0484 Tributyrin, a source of butyric acid, modulates the intestinal health of weaning pigs.

B. Tugnoli, M. Bertocchi, A. Piva, G. Sarli, and E. Grilli*, *DIMEVET University of Bologna, Ozzano Emilia BO, Italy.*

Aim of this study was to evaluate the intestinal architecture and expression of inflammatory and tight junction markers in piglets fed with tributyrin as dietary source of butyric acid. Twenty-one weaned pigs (n = 7), received a basal diet (control) or the diet supplemented with tributyrin or its encapsulated form at 1750 mg/kg (TB and m-TB, respectively), both providing 960 mg/kg of butyric acid equivalents. After 21 d, pigs were euthanized to collect duodenum, jejunum, ileum, and colon samples for histo-morphology, and cytokines and tight junction markers m-RNA analysis. Data were analyzed with 1-way ANOVA. Compared with control, m-TB induced deeper crypts in the duodenum (P = 0.09) and significantly reduced villi:crypts in the ileum (P = 0.04); goblet cells tended to be reduced by TB in duodenal villi (2.4-fold, P = 0.09), by both TB and m-TB in ileal villi (1.8- to 2.2-fold, respectively; P = 0.06), and by m-TB in colonic crypts (P = 0.08). Compared with control, TB tended to have higher TNF-α expression in the duodenum and ileum (P = 0.06 and P = 0.10), and higher IFN-γ level in the jejunum (P = 0.04), whereas in the colon m-TB downregulated IFN-γ and IL-1β level (2.2-fold and 1.7-fold; P = 0.06). Jejunal claudin-1 mRNA was reduced in m-TB compared with control (2.4-fold; P = 0.05). Similarly, in the colon claudin-1 mRNA was numerically lower in m-TB (2.1-fold) than in control group. Ileal occludin mRNA was reduced in both groups receiving tributyrin compared with control (1.6–2.2-fold for TB and m-TB; $P < 0.01$). In the colon occludin mRNA was downregulated in m-TB compared with control (1.4-fold; $P < 0.05$). The supplementation of tributyrin in the diet reduced the mucous-secreting goblet cells in a tract specific manner, tributyrin affecting the upper intestine while the microencapsulated form acting in the lower gut. The differential expression of cytokines in the upper and lower intestine by TB and m-TB, would suggest a differential modulation of cellular turnover and epithelial differentiation that would reflect differences in the anatomy and functionality of the gut segments. Nevertheless, the reduced expression of proinflammatory cytokines observed in the colon of m-TB indicate a reduced inflammation by butyric acid released via microencapsulated tributyrin. This beneficial effect mediated by m-TB would be substantiated by the parallel reduction of tight junction proteins gene expression in the hindgut probably indicating, by a mechanism of negative feed-back, a relatively higher abundance of these proteins and a tighter intestinal epithelium.

Key Words: tributyrin, microencapsulation, weaning piglet

0485 Effects of salmonella inhibitors on growth performance, relative organ weight, meat quality, salmonella populations, fecal gas emission, and blood profiles in broilers.

A. Hosseindoust*, H. L. Li, and I. H. Kim, *Department of Animal Science, Dankook University, Cheonan, South Korea*.

A total of 768 male and female ROSS308 broiler chicks [1 d old, BW = 37 ± 0.08 g] were used in this 5-wk trial (6 treatments with 8 replications/treatment and 16 chicks/pen) to evaluate the effect of salmonella inhibitors on growth performance, relative organ weight, meat quality, salmonella populations, fecal gas emission and blood profiles in broilers. A corn-soybean meal-based diet was formulated as a control diet and dietary treatments were as follows: (i) NC, basal diet (without antibiotics and *Bacillus subtilis*); (ii) PC, NC + 0.1% antibiotics (virginiamycin); (iii) A, NC + 0.1% *B. subtilis* 1.0×10^{10} cfu/kg; (iv) B, NC + 0.1% *B. subtilis* RX7 1.0×10^{10} cfu/kg; (v) C, NC + 0.1% *B. subtilis* B2A 1.0×10^{10} cfu/kg; (vi) D, NC + 0.1% *B. subtilis* RX7 1.0×10^{9} cfu/kg. Broilers were weighed and feed intake were recorded on d 14 and 35 for calculating BW gain (BWG), feed intake (FI), and feed conversion ratio (FCR). At d 35, 2 birds were randomly selected from each replication (16 broilers/treatment) and slaughtered by cervical dislocation for meat quality. During d 1 to 14, BWG was higher (393, 390 vs. 375 g; $P < 0.05$) in B and C treatments than NC treatment; moreover, NC treatment got higher (1.52 vs. 1.45; $P < 0.05$) FCR than B treatment. During d 15 to 35, NC treatment group had higher FCR (1.81 vs. 1.72; $P < 0.05$) than C treatment fed broilers. Overall, chickens fed with C diet had higher (1648 vs. 1569 g; $P < 0.05$) BWG and lower (1.65 vs. 1.74; $P < 0.05$) FCR than those fed with NC diet. No significant difference ($P > 0.05$) was observed in meat quality, relative organ weight, gas emission and blood profiles among treatments. However, the salmonella populations of chickens fed with NC diet was higher (2.94 vs. 2.50, 2.47, 2.51, 2.51 $\log_{10}$ cfu/g; $P < 0.05$) compared with those fed with PC, B, C, and D diets in large intestine, moreover, the salmonella populations of NC treatment was higher (2.81 vs. 2.56, 2.48, 2.48, 2.55, 2.47 $\log_{10}$cfu/g; $P < 0.05$) compared with other 5 treatments in small intestine. In conclusion, salmonella inhibitors partially improved BWG, FCR, while decreasing salmonella populations in intestine without any adverse effect on meat quality, relative organ weight, gas emission, and blood profiles in broilers.

Key Words: blood profiles, broilers, growth performance, meat quality, salmonella inhibitors, salmonella populations

PHYSIOLOGY AND ENDOCRINOLOGY: PREGNANCY, PLACENTATION, AND REPRODUCTIVE HEALTH IN RUMINANTS

0486 Bioinformatics analysis of mammary gland and liver transcriptome in response to an intramammary *Escherichia coli* lipopolysaccharide challenge in early-lactation dairy cattle.

A. Minuti*[1], D. E. Graugnard[2], E. Trevisi[1], and J. J. Loor[2], [1]*Università Cattolica del Sacro Cuore, Piacenza, Italy,* [2]*Universty of Illinois, Urbana, IL.*

During mastitis, pathogens are detected by the receptors on the epithelial cells of the mammary tissue and an acute phase response activates the immune system to eliminate the pathogens. The liver is a central organ during inflammation and synthesizes the necessary components for immediate defense at the site of tissue damage. The objective of this study was to determine gene expression patterns in mammary and liver tissue in response to an intramammary *E. coli* lipopolysaccharide (LPS) challenge in early lactating dairy cattle. Fourteen Holstein cows were used. At ~7 d in milk, 7 cows served as controls (CTR) and 7 cows (LPS) received an intramammary *E. coli* LPS challenge (200 μg in sterile saline). For transcript profiling the mammary and liver tissue were sampled by biopsy 2 h after the challenge. A bovine oligonucleotide (70-mers) microarray with > 13,000 annotated sequences was used for profiling. Data were analyzed using the MIXED procedure of SAS (SAS Inst. Inc., Cary, NC) and a threshold of 1.5-fold change and a *P* value of 0.05 were considered to define differentially expressed genes (DEG). Bioinformatics analyses was conducted using the dynamic impact approach (DIA) and ingenuity pathway analysis (IPA; Ingenuity Systems, Inc.). In mammary tissue, a total of 189 DEG (20 downregulated, 169 upregulated) were observed in LPS vs. CTR cows. The most-impacted and activated KEGG pathways highlighted by the DIA analysis were NOD-like receptor signaling, RIG-I-like receptor signaling, apoptosis, cytosolic DNA-sensing, and chemokine signaling. The IPA analysis underscored the presence of 13 transcription regulators (2 downregulated, 11 upregulated) of which 4 upregulated (NF-kB, MYC, STAT3, and HIF1A) are key components of inflammatory response processes and are involved in cell apoptosis. In liver tissue, a total of 107 DEG (42 downregulated, 65 upregulated) were observed due to LPS. The DIA analysis highlighted the inhibition of Fatty acid elongation in mitochondria and activation of p53 signaling pathway. From IPA analysis, the most important upregulated transcription regulators (ZFP36, CEBPD, MYC, and CREM) are involved in the immune and inflammatory responses and are necessary to maintaining homeostasis of the organism during infection. Results suggest that within 2 h from intramammary LPS challenge the liver responds to stimuli and alters its transcriptome as a way to maintain homeostasis.

Key Words: system biology, mammary, liver, lipopolysaccharide

0487 The role of pH and progesterone on bovine uterine protein secretion in response to maternal recognition, interferon-tau.

J. A. Spencer*[1], K. J. Austin[2], K. G. Carnahan[1], and A. Ahmadzadeh[1], [1]*University of Idaho, Moscow,* [2]*Department of Animal Science, University of Wyoming, Laramie.*

Low uterine pH, associated with high dietary protein and blood urea, reduces fertility in dairy cows. The objective of this in vitro study was to determine the direct effects of a low pH on bovine endometrial (BEND) cells expression of Mx1 and ISG-15 in response to embryonic maternal recognition, interferon-tau (IFNτ), in the presence or absence of progesterone (P_4). In 2 experiments, using BEND cells as a model, the effects of a low pH environment was examined to determine the production of 2 IFNτ stimulated proteins, ISG-15 and Mx1. Bovine endometrial cells were grown to 80% confluency and further incubated for additional 24 h in culture media containing no P_4 (0 M; Exp. 1) or P_4 (10^{-7} M, Exp. 2). To reduce the pH, in both experiments, cells (90% confluent) were treated with dimethyldioxirane (DMD), at final concentrations of 0, 10, 15, and 20 m*M* (pH of 7.35, 7.17, 6.9, and 6.76, respectively) and subsequently, challenged with 0 or 10,000 antiviral units of rIFNτ. Cells were incubated for an additional 24 h. Once harvested, BEND cells were lysed and supernatants were analyzed and quantified for Mx1 and ISG-15, using SDS-PAGE and Western Immunoblotting protocols. Based on optical density, at 0 mM DMD, regardless of P_4 treatment, IFNτ increased ($P < 0.01$) Mx1 and ISG-15 in both experiments. In Exp. 1 (P_4 free environment), there was effect of DMD ($P < 0.01$) and DMD by IFNτ interaction ($P < 0.01$) on both Mx1 and ISG-15. The 15 and 20 m*M* DMD reduced ($P < 0.01$) IFNτ- induced Mx1 expression, whereas only 20 m*M* DMD reduced ($P < 0.01$) ISG-15 expression in response to IFNτ. In Exp. 2, in presence of P_4, there was a significant effect of DMD and IFNτ by DMD interaction ($P < 0.01$) on Mx1 expression. However, there was no effect of DMD or DMD by IFNτ interaction on protein expression of ISG-15 ($P = 0.2$ and 0.4) in a P_4 environment. These results show that in absence of P_4 and low pH, IFNτ-stimulated proteins secretion are abrogated; however, P_4 overcame pH-induced decreased of ISG-15 but not Mx1. Progesterone may regulate the secretion of IFNτ- stimulated proteins in an acidic uterine environment.

Key Words: acidic pH, progesterone, interferon, bovine endometrial cells

0488 Hepatic steroid inactivating enzymes, hepatic portal blood flow, and corpus luteum blood perfusion in lactating dairy cattle. C. G. Hart*, B. E. Voelz, K. E. Brockus, and C. O. Lemley, *Mississippi State University, Mississippi State.*

In ruminants, a decrease in pregnancy rates may be due to decreased concentrations of progesterone (P4). It is important to note that both production from the corpus luteum and/or hepatic steroid inactivation impacts peripheral concentrations of P4. Cattle with an elevated dry matter intake have increased blood flow to the digestive tract and liver. This in turn leads to an increased delivery rate of steroids to the liver, and thus increased metabolism of these substrates. Excessive hepatic steroid inactivation contributes to decreased peripheral concentrations, which can alter reproductive performance. The objective of this study was to examine the activity of hepatic steroid inactivating enzymes in pregnant vs. nonpregnant lactating Holstein cows. Cows were synchronized using the Ovsynch plus CIDR (controlled internal drug release device) protocol and bred via artificial insemination on d 0. At d 10 post-AI, hepatic portal blood flow was measured via transabdominal Doppler ultrasonography. Images of corpus luteum blood perfusion were collected using the power flow program of the Doppler ultrasound. Blood perfusion was analyzed by examining pixel density using ImageJ software. Liver biopsies were collected and frozen for later determination of cytochrome P450 1A (CYP1A), 2C (CYP2C), 3A (CYP3A), and uridine diphosphate-glucuronosyltransferase (UGT) activities via luminogenic substrates. Aldo-keto reductase 1C (AKR1C) activity was measured using the specific substrate 1-acenaphthenol. Pregnancy was determined at d 33 of gestation and treatment groups were retrospectively assigned as pregnant or nonpregnant. Data were analyzed using the mixed procedure of SAS (SAS Inst. Inc., Cary, NC). CYP1A, CYP2C, CYP3A, and AKR1C activity did not differ ($P > 0.10$) between pregnant and nonpregnant cows. Activity of UGT per kg of BW was increased ($P < 0.05$) in pregnant (60.1 ± 3.4 RLU·min^{-1}·kg^{-1}) vs. nonpregnant (50.6 ± 3.4 RLU·min^{-1}·kg^{-1}) cows. Blood perfusion of the corpus luteum did not differ ($P > 0.30$) between pregnant and nonpregnant cows. Absolute hepatic portal blood flow was increased ($P < 0.05$) in pregnant (997 ± 78 L/h) vs. nonpregnant cows (748 ± 78 L/h). Portal blood flow per kg of BW was increased ($P < 0.05$) in pregnant (1.65 ± 0.13 L/h/kg) vs. nonpregnant cows (1.27 ± 0.13 L/h/kg). The current study highlights the relevance of further investigation into steroid secretion and inactivation and their impact on the maintenance of pregnancy in dairy cattle.

Key Words: blood flow, cattle, steroid

0489 Effects of supplementing Holstein heifers with dietary melatonin during late gestation on growth and cardiovascular measurements of offspring. K. E. Brockus*, C. G. Hart, S. H. Ward, and C. O. Lemley, *Mississippi State University, Mississippi State.*

The objective was to examine the effects of supplementing dams with dietary melatonin during late gestation on offspring cardiovascular and growth measurements. On d 190 of gestation, heifers ($n = 20$) were blocked by BW and then randomly assigned to 1 of 2 dietary treatments: (1) 20 mg of dietary melatonin d^{-1} (MEL) or (2) no melatonin supplementation (CON). Dietary treatments were terminated on d 262 of gestation. At birth, calves were separated from their dams and given 3.8 L of colostrum. Calves were fed 5.7 L of whole milk daily and offered 0.9 kg/d of starter grain. Starter was increased by 0.9 kg/d when orts were 0 kg. Calf ($n = 18$) measurements of growth, blood pressure, and cortisol were collected on wk 0, 1, 2, 3, and 4 of age. Calf hepatic portal blood flow, determined by transabdominal Doppler ultrasonography, and concentrations of IGF-1 were determined on wk 0 and 4 of age. Dependent variables were analyzed using repeated-measures ANOVA of the mixed procedure of SAS (SAS Inst. Inc., Cary, NC) with the model statement containing treatment, age, and their respective interaction. Calf BW, abdominal girth, hip height, and wither height increased ($P < 0.05$) with age. An age by treatment interaction ($P < 0.01$) was observed for calf heart girth, which was decreased at wk 2 in calves from MEL treated heifers compared with calves from control treated heifers. Pulse pressure (41 ± 2 mm Hg), mean arterial pressure (90 ± 2 mm Hg), absolute hepatic portal blood flow (3137 ± 326 mL/min), and blood flow relative to body weight (74 ± 8 mL/[min × kg]) were not different ($P > 0.05$) between treatments. A main effect of calf age ($P < 0.05$) was observed for concentrations of IGF-1, which was decreased at wk 4 (9.0 ± 0.4 ng/mL) compared with wk 0 (10.8 ± 0.9 ng/mL). An age by treatment interaction ($P < 0.05$) was observed for concentrations of cortisol, which was decreased at wk 2 in calves from MEL treated dams (1.2 ± 0.8 ng/mL) compared with calves from CON treated dams (5.8 ± 0.8 ng/mL). Early postnatal growth and hepatic portal blood flow were not different in offspring born to dams supplemented with dietary melatonin. However, the difference in offspring concentrations of cortisol following maternal melatonin supplementation needs further investigation.

Key Words: cortisol, hepatic portal blood flow, melatonin

0490 Uterine blood flow, calf, and placental weights from beef cows supplemented during late gestation. V. C. Kennedy*, B. R. Mordhorst, M. L. Bauer, K. C. Swanson, and K. A. Vonnahme, *North Dakota State University, Fargo.*

Maternal nutrition impacts uterine blood flow (BF), thus offspring development. This study's objective was to investigate the effects of supplementing dried distiller's grains with solubles (DDGS) during late gestation on uterine BF, calf and placental weights. Multiparous beef cows were randomly divided into a control group (CON; $n = 15$) consuming a diet containing 90% corn stover and 10% corn silage (DM basis) ad libitum and a treatment group (TRT; $n = 12$) consuming the same diet and DDGS (0.3% BW). Corn silage inclusion was increased to 30% as gestation progressed. Intake was monitored and controlled via Insentec roughage feeders. Ipsilateral and contralateral uterine BF and cross-sectional area (CSA) at the bifurcation of each uterine artery was measured by Doppler ultrasonography on d 180, 216, and 246 of pregnancy. At parturition calves and placentas were weighed. Data analysis utilized the mixed procedure in SAS (SAS Inst. Inc., Cary, NC). Contralateral uterine artery BF and CSA increased ($P < 0.01$) as gestation advanced. For ipsilateral uterine artery BF and CSA, there was a treatment by day of gestation interaction ($P < 0.05$). The CSA was similar ($P = 0.30$) on d 181, but was greater ($P \leq 0.02$) in TRT vs. CON cows on d 216 and 246 (0.94 vs. 0.71 ± 0.07 cm^2 and 1.14 vs. 0.76 ± 0.07 cm^2, respectively). Ipsilateral BF tended to be greater ($P = 0.06$) on d 181 in TRT cows compared with CON (11.4 vs. 8.2 ± 1.1 L/min), and was greater on d 216 and 246 (21.1 vs. 15.4 ± 1.8 and 32.6 vs. 19.6 ± 2.7 L/min, respectively). There was no treatment by day interaction ($P = 0.17$) for total uterine BF, but there was a main effect of treatment ($P = 0.02$) and day ($P < 0.01$). DDGS cows had increased uterine BF compared with CON (25.5 vs. 19.1 ± 1.8 L/min). Total uterine BF increased ($P < 0.01$) as gestation advanced (12.2, 22.2, 32.7 ± 2.2 L/min for d 181, 216, and 246). While there was no effect of treatment on gestation length ($P = 0.43$) or placental weights ($P \geq 0.22$), there was a tendency ($P = 0.06$) for calves born to TRT cows to be heavier (43.3 vs. 40.5 ± 1.0 kg). Supplementation with DDGS increased uterine BF which contrasts with our previous study; protein and caloric intake differences between these studies is currently under investigation.

Key Words: beef cow, pregnancy, uterine blood flow

0491 Possible markers of uterine and metabolic health in transition dairy cows. G. Esposito*[1,2], A. Chapwanya[2], E. C. Webb[2,3], and P. C. Irons[1,2], *[1]Department of Production Animal Studies, Faculty of Veterinary Sciences, University of Pretoria, Onderstepoort, South Africa, [2]Institute of Food, Nutrition and Well-being University of Pretoria, Pretoria, South Africa, [3]Department of Animal and Wildlife Sciences, Faculty of Natural and Agricultural Sciences, University of Pretoria, Pretoria, South Africa*.

In transition dairy cows negative energy balance (NEB) status commonly leads to perturbed fertility, reduced immune function and decreased milk yield. The objective of this study was to investigate the relationship between indicators of NEB, systemic inflammation postpartum, and genital diseases in transition dairy cows. Prepartum Holstein cows ($n = 10$), from 20 d before the predicted day of calving until 35 d in milk (DIM) were assigned to 2 treatments: NEB (80% net energy requirements) and control. Dry matter intake (DMI) was recorded daily and clinical evaluation was conducted once a week. From the day of calving, milk yield, somatic cells count (scc), lactose, fat, protein, and fat/protein ratio were recorded daily. From 7 till 35 DIM, weekly endometrial samples were collected for cytological evaluation, metagenomic characterization of the endometrial DNA and measurements of the expression of inflammatory genes. Ovarian activity was monitored every other day from 7 DIM. Blood samples were collected weekly and analyzed for NEFA, β-hydroxybutyrate (BHBA) and cholesterol. Correlationship between variables was evaluated using Spearman's rank correlation test. Moreover, a stepwise regression analyses was performed to explain variability of indicators of uterine and metabolic status. As expected, NEB cows showed higher DMI ($P < 0.1$), lower milk production ($P < 0.05$) and a higher fat:protein ratio ($P < 0.05$) until 35 DIM. In addition, NEFA and BHBA were higher in the NEB cows ($P < 0.05$), while cholesterol was lower ($P < 0.001$). Moreover, even if not strong, a negative correlation was observed between BHBA levels and increment in BCS (-0.37), and between NEFA and numbers of dominant follicles observed (-0.25). In addition, a negative correlation was observed between percentage of polymorphonuclear cells (PMS), from the endometrial samples, and serum cholesterol (-0.40) supporting our hypothesis that total cholesterol level could be one of the possible markers for uterine health evaluation. In addition, a positive correlation was observed between NEFA and PMS cells (-0.40). Furthermore, the stepwise regression analysis confirmed that serum BHBA and cholesterol levels were the ones that better explained the other variables (clinical evaluation, intake, reproduction). Data regarding the metagenomic characterization of the endometrial DNA and on the expression of inflammatory genes are still pending. The preliminary results confirmed the effects of NEB on biochemical parameters with potential as

predictors of metabolic and genital diseases. Further validation based on larger data sets is required.

Key Words: negative energy balance, transition cow, uterine involution

0492 Pregnancy-induced changes in metabolome and proteome in ovine uterine flushings. T. R. Hansen*, J. J. Romero, C. Broeckling, and J. E. Prenni, *Colorado State University, Fort Collins.*

The endometrium serves as a primitive placenta by secreting histotroph, which nourishes the developing conceptus (embryo proper and extraembryonic membranes). Modern mass spectroscopy (MS) approaches allow for global analysis of proteins and metabolites in bodily fluids. We hypothesized that global MS can identify metabolites and proteins that are induced by pregnancy in uterine flushings. To test this hypothesis, uteri were collected on d 12 of the estrous cycle (n = 5 ewes not exposed to ram) or d 12 (n = 4), 14 (n = 5), or 16 (n = 5) of pregnancy (confirmed by presence of conceptus) and flushed using physiological buffered saline. Pregnancy status and Day were main effects analyzed by GLM-SAS (SAS Inst. Inc., Cary, NC). Metabolites were extracted from uterine flushings using 80% methanol and profiled using UPLC-MS. The proteome was examined by digestion with trypsin, followed by analysis of peptides with LC-MS/MS. Metabolite profiling resulted in the detection of 8510 molecular features, of which 5 were confirmed to be upregulated (> threefold and $P < 0.05$) in response to pregnancy by d 14 to 16 and were not detected on d 12: acetylcarnitine, carnitine, ecdysteroids, N-acetyl dileucine, and valine. These metabolites function in fatty acid transport (carnitines), antiapoptotic mechanisms (ecdysteroids), and availability of nutrients (amino acids). Proteome analysis resulted in the detection of 783 proteins that were differentially regulated ($P < 0.05$) by d 14 to 16 of pregnancy, 7 of which are described herein: annexin A1, A2, and A5; calcium binding protein (S100A11); profilin 1, trophoblast kunitz domain protein 1 (TKDP), and interferon tau (IFNT). These proteins have unique functions in mediating endocytosis, exocytosis, calcium signaling, and inhibition of prostaglandins (annexins and associated S100A11); protecting against maternal proteases (TKDP); remodeling cytoskeleton (profilin 1); and altering uterine release of prostaglandin F2 α, as well as inducing interferon stimulated genes in the endometrium and the corpus luteum (IFNT). It is concluded that global MS approaches are poweful in delineating the metabolome and proteome in uterine flushings and identifying differential expression in response to the conceptus by d 14 to 16 of pregnancy. *USDA NIFA AFRI 2011–67015–20067.*

Key Words: pregnancy, uterus, conceptus, proteome, metabolome

0493 Syncytin expression in uterine endometrium and fetal membranes during early pregnancy in sheep. K. J. McLean*, L. P. Reynolds, A. Grazul-Bilska, J. Haring, and J. S. Caton, *North Dakota State University, Fargo.*

Endogenous retroviruses may be involved in formation of the placental interface between the endometrium and fetal membranes (FM). When this interface is not adequately formed, fetal loss or growth retardation may occur. Syncytin is an integrated retroviral envelope gene thought to be involved in cell-cell fusion and immunosuppression within the mammalian placenta; however, in sheep the exact function of syncytin is unknown. Ewes also possess ~20 copies of another endogenous retrovirus (enJSRV) which is closely related to the exogenous Jaagsiekte sheep retrovirus. Integration and expression of enJSRV strains, in the placenta, is breed specific. To examine syncytin and enJSRV expression at the maternal-fetal interface throughout early gestation, crossbred western whiteface (primarily Rambouillet, Targhee, and Columbia) ewes were naturally mated and gravid uteri were obtained on d 14, 16, 18, 20, 22, 24, 26, 28, and 30 (n = 6 to 8/d) after mating (day of mating = d 0). Nonpregnant, mid-luteal ewes (d 10; n = 8) were used as controls. Expression of syncytin and enJSRV-18 was determined with snap-frozen caruncular (maternal placental) tissue and FM (chorion on d16 and chorioallantois thereafter) using quantitative real-time RT-PCR. Statistical analyses used PROC GLM of SAS (SAS Inst. Inc., Cary, NC) with orthogonal contrasts. Fetal length increased threefold ($P < 0.001$) from d 20 (5.50 ± 0.97 mm) to d 30 (19.29 ± 0.52 mm) of gestation. Fetal membrane expression of syncytin decreased from d 16 thru d 20, was increased from d 22 until d 26, and decreased, again, to d 30 ($P = 0.002$). Both fetal growth patterns and FM expression of syncytin had significant linear ($P < 0.005$) and cubic ($P < 0.001$) orthogonal contrasts. Pregnant ewes had greater syncytin expression ($P = 0.002$) compared with nonpregnant ewes. Syncytin expression in caruncular tissues decreased from d 14 until d 20, then increased to d 24 and remained steady to d 30 of gestation ($P = 0.009$) resulting in quadratic ($P = 0.01$) and cubic ($P = 0.001$) orthogonal contrasts. Interestingly, neither FM nor caruncular tissues of western whiteface ewes expressed detectable levels of enJSRV-18. Therefore, syncytin but not enJSRV-18 is likely involved in the regulation of placental function and growth during pregnancy in western whiteface sheep. *Supported by USDA-NRI Grant 2007–01215 to LPR and ATGB.*

Key Words: early gestation, placenta, syncytin

0494 Effect of postpartum treatment with nonsteroidal anti-inflammatory drugs (NSAID) on reproductive performance and removal from the herd in dairy cattle through mid-lactation.

A. J. Carpenter*[1], C. M. Ylioja[1], C. F. Vargas Rodriguez[1], L. G. D. Mendonça[1], L. Mamedova[1], J. F. Coetzee[2], L. Hollis[1], R. Gehring[3], and B. Bradford[1], [1]*Department of Animal Sciences and Industry, Kansas State University, Manhattan,* [2]*Pharmacology Analytical Support Team, Iowa State University College of Veterinary Medicine, Ames,* [3]*Department of Clinical Sciences, Kansas State University, Manhattan.*

Many studies have evaluated the use of postpartum NSAID treatment in dairy cattle, but few have monitored long-term responses to such treatments. To address this limitation in the literature, 153 multiparous dairy cattle were blocked by breed, dystocia, and twin births, and assigned to 1 of 3 treatments within 12 to 36 h after parturition. Treatments were 1 placebo bolus on the first day after parturition and 3 consecutive daily drenches of sodium salicylate (125 $g \cdot cow^{-1} \cdot d^{-1}$) beginning on the first day after parturition (SS); 1 bolus of the NSAID meloxicam (675 mg/cow) and 3 drenches of an equal volume of water (M); and 1 placebo bolus and 3 drenches of water (CON). As previously reported, milk production was increased in the first 9 wk of lactation by either NSAID treatment in cows experiencing dystocia, but in cows that calved normally, milk yield increased only after treatment with M. The objective of this analysis was to determine if NSAID treatment influenced reproductive performance and risk of removal from the herd in approximately the first half of lactation (up to 160 d in milk, DIM). Removal rate from the herd and time to pregnancy were evaluated by Cox regression proportional hazard analysis, and incidence of disease was tested by Fisher's exact test. Treatment, breed, dystocia, twin births, and their interactions did not ($P > 0.1$) affect time to pregnancy or first service pregnancy per AI (21.9%). A total of 33 cows left the herd during the period investigated, and M cows were ($P = 0.02$) removed from the herd at a slower rate than CON (AHR = 0.33, 95% CI = 0.13, 0.84), with no effect observed for SS ($P = 0.28$, AHR = 0.66, 95% CI = 0.30, 1.42). Treatment did not affect the risk of leaving the herd due to mastitis, low milk production, injury, lameness, or death (all $P > 0.1$). However, M tended to decrease the risk of culling due to other diseases—including respiratory disease, displaced abomasum, and suspected metabolic disorders—compared with CON ($n = 7$ CON vs. 1 M; $P = 0.06$). Furthermore, 4 of the CON cows in this category were removed from the herd before 19 DIM, whereas the M cow was removed at 149 DIM. These results indicate that in addition to elevated milk production, postpartum administration of M may have beneficial effects on dairy cow longevity.

Key Words: inflammation, NSAID, cull rate, reproduction

0495 Biology and molecular signatures of elongating preimplantation conceptuses in dairy cows.

E. S. Ribeiro*[1], L. F. Greco[1], R. S. Bisinotto[1], F. S. Lima[2], W. W. Thatcher[1], and J. E. P. Santos[1], [1]*Department of Animal Sciences, University of Florida, Gainesville,* [2]*University of Florida, Gainesville.*

The objectives were to investigate changes in transcriptome of preimplantation conceptuses during the process of elongation and associated changes in the concentration of interferon-tau (IFN-τ) in utero. Lactating dairy cows ($n = 160$) had estrous cycles synchronized and were subjected to induced ovulation and timed artificial insemination (AI). The day of AI was considered study d 0. On d 15, uteri were flushed and IFN-τ concentration in fluid measured. Recovered conceptuses were classified based on morphology and length as ovoid (OV; 1 to 4 mm), tubular (TUB; 5 to 19 mm), and filamentous (FIL; 20 to 85 mm). A subsample of conceptuses from each group had mRNA extracted and subjected to transcriptome analysis using Affymetrix Gene Chip Bovine Array (8 OV, 17 TUB, and 17 FIL). The experimental design was considered a prospective cohort study with 3 independent groups. Continuous variables were analyzed by ANOVA using the GLIMMIX procedure of SAS (SAS Inst. Inc., Cary, NC) and fitting adequate data distribution. Microarray data were analyzed using Bioconductor software in R environment. Data were preprocessed using Gene Chip Robust Multi-Array function. Limma package was used to fit a linear model and adjust variances by empirical Bayes adjustment. Moderate *t* test was performed for all pairwise comparisons, and *P* values were adjusted for multiple testing using the Benjamini and Hochberg false discovery rate. Adjusted $P < 0.05$ and fold change > 1.5 characterized significant differences. Functional analyses were performed using Ingenuity Pathway Analysis. Concentration of IFN-τ in uterine flushing differed ($P < 0.05$) among all 3 groups and was lower for cows with OV conceptus, followed by those with TUB and then FIL conceptuses (13.7, 326.8, and 2544.7 ng/mL, respectively). Transcriptome analyses revealed the upregulation of 321 and downregulation of 345 transcripts in the transition from OV to TUB, and the upregulation of 249 and downregulation of 154 transcripts in the transition from TUB to FIL. A total of 1441 transcripts were differently expressed when OV and FIL conceptuses were compared. Differently expressed genes were associated significantly with cellular movement, cell-to-cell signaling and interaction, cellular assembly and organization, lipid metabolism, small molecule biochemistry, and molecular transport. In conclusion, differences in conceptus morphology and length were associated with distinct concentrations of IFN-τ in utero and remarkable changes in transcriptome of trophectoderm cells that elucidate important cellular events occurring during conceptus elongation.

Key Words: conceptus elongation, transcriptome, dairy cow

0496 Modulation of the immune system during postpartum uterine infection. C. G. Walker*[1], S. Meier[1], J. R. Roche[1], M. D. Mitchell[2], and C. Burke[1], [1]*DairyNZ, Auckland, New Zealand,* [2]*University of Queensland, Australia.*

Postpartum uterine infection is associated with lower fertility at both the time of infection and after the infection has resolved. The objective of this study was to characterize genome-wide DNA methylation and gene expression in the endometrium of dairy cows with subclinical endometritis. It was hypothesized that aberrant DNA methylation may be involved in the subfertility associated with postpartum uterine infection. Endometrial tissues were obtained at 29 d postpartum (n = 12) and Agilent 2-color microarrays were used to characterize transcription and DNA methylation profiles. Analyses revealed 1856 probes to be differentially expressed in animals with subclinical endometritis (SUI) compared with control cows ($P <$ 0.05, Storey Multiple testing correction). No significant associations among DNA methylation and gene expression were detected. Further analysis using GeneGo Metacore and Gene Set Enrichment Analysis identified several pathways and processes enriched in the comparison. Several pathways that are involved in the innate immune response were enriched in SUI cows. Consistent with activation of toll like receptors (TLR) by microorganisms present in the uterus, there was enrichment for the TLR signaling pathway including increased expression of the transcription factor NFKB1, the proinflammatory cytokines IL1A and IL1B, downstream chemokines, cytokines, and acute phase and antimicrobial proteins in the endometrium of SUI cows. Further, the chemokine signaling pathway was enriched in SUI cows, with increased expression of genes that attract cells of the innate immune system. Increased expression of IL-8 and CXCL6, chemotactic factors for recruitment of neutrophils along with the immune cell surface marker PTPRC in SUI cows is consistent with the greater number of polymorphonuclear cells present in the uterus of these cows. Several antimicrobial peptides (LAP, TAP, DEFB1, DEFB10, DEFB103B, DEFB7) and acute phase proteins including SAA3, LBP, and the complement gene CFB had greater expression in SUI cows. Gene expression profiles in cows with subclinical endometritis in this study indicate that the immune response is activated, potentially resulting in a local proinflammatory environment in the uterus. If this period of inflammation is prolonged it could result in tissue damage or failure to complete involution of the uterus that may create a suboptimal environment for future pregnancy.

Key Words: endometritis, gene expression

0497 Carryover effects of postpartum diseases on early conceptus development in dairy cows. E. S. Ribeiro*, L. F. Greco, G. C. Gomes, R. Cerri, W. W. Thatcher, and J. E. P. Santos, *Department of Animal Sciences, University of Florida, Gainesville.*

Postpartum diseases constitute one of the major problems affecting fertility in dairy cows. The objective was to investigate the carryover effects of postpartum clinical diseases on early embryo development. From calving to first artificial insemination (AI), prevalence of calving problems, metritis, mastitis, lameness, digestive, and respiratory problems were recorded for a group of 617 dairy cows. Cows had estrous cycles synchronized and were subjected to induced ovulation and timed AI. A total of 419 cows had their uterus flushed on d 6 after AI and the structures recovered were evaluated for fertilization and embryo quality. The remaining 198 cows had their uterus flushed on d 15 after AI and interferon-tau (IFN-τ) concentration in fluid was measured and the recovered conceptuses were evaluated for size and morphology. A subsample of conceptuses (n = 22) had mRNA extracted and subjected to transcriptome analysis using Affymetrix Gene Chip Bovine Array. The experimental design was considered a prospective cohort study with 2 independent groups (healthy vs. diseased). Continuous variables were analyzed by ANOVA and binary data by logistic regression using the GLIMMIX procedure of SAS (SAS Inst. Inc., Cary, NC) and fitting adequate data distribution. Microarray data were analyzed using Bioconductor software in R environment. Data were preprocessed using Gene Chip Robust Multi-Array function. Limma package was used to fit a linear model and adjust variances by empirical Bayes adjustment. Moderate t test was performed for all pairwise comparisons, and P values were adjusted for multiple testing using the Benjamini and Hochberg false discovery rate. Adjusted $P < 0.05$ and fold change > 1.5 characterized significant differences. Functional analyses were performed using Ingenuity Pathway Analysis. Cows that had at least 1 clinical disease from calving to first AI had reduced fertilization, smaller proportion of good quality embryos on d 6, smaller size of conceptus and smaller concentration of IFN-τ on d 15 compared with cows that did not have clinical diseases. Controlling for size of the conceptuses, transcriptome analysis resulted in 41 transcripts that were differently expressed. The gene with the greatest difference in expression was FAT/CD36, which is important for cell signaling during conceptus elongation. FAT/CD36 was downregulated in conceptus recovered from cows that had diseases compared with those recovered from cows that did not have disease. In conclusion, clinical diseases prior insemination were associated with reduced fertilization and compromised early embryo development.

Key Words: embryo, dairy cow, disease

PHYSIOLOGY AND ENDOCRINOLOGY: INTERRELATIONSHIPS BETWEEN ENVIRONMENTAL, METABOLIC, AND PHYSIOLOGICAL PROCESSES I

0498 Insulin sensitivity of the lipid metabolism of precalving dairy cows across a range of body condition scores. J. De Koster* and G. Opsomer, *Department of Reproduction, Obstetrics and Herd Health, Faculty of Veterinary Medicine, Ghent University, Ghent, Belgium.*

Insulin plays a central role during the transition period of dairy cows by influencing glucose, lipid, and protein metabolism. At the adipose tissue, insulin stimulates lipogenesis and inhibits lipolysis, thereby regulating the circulating NEFA concentration. Overconditioning is known to induce insulin resistance of the glucose metabolism in dairy cows. In the present study, we identified if factors related to adiposity (BCS, BFT, NEFA concentration during the dry period) influenced insulin sensitivity of the lipid metabolism in 8 healthy dairy cows at the end of pregnancy across a range of BCS (2.75 to 5). Hyperinsulinemic euglycemic clamp tests were performed consisting of 4 insulin infusions: 0.1, 0.5, 2, or 5 $mU \cdot kg^{-1} \cdot min^{-1}$. At regular time intervals during the infusions, blood glucose concentration was determined using a glucometer and the speed of a concomitant glucose infusion was adapted to keep blood glucose concentration constant. At the end of each infusion, a steady state (SS) was maintained for 30 min. During the SS, minor changes of the glucose infusion were necessary to maintain normal blood glucose level. During the SS, blood samples were taken at 10 min interval to determine SS insulin (SSIC) and NEFA (SSNEFA) concentrations. The SSIC was 8.77 ± 3.04; 52.38 ± 16.11; 339.04 ± 122.01; 1411.5 ± 500.08 μU/mL and the SSNEFA was 0.62 ± 0.20; 0.26 ± 0.08; 0.14 ± 0.09; 0.11 ± 0.08 mmol/L for the insulin infusions of 0.1, 0.5, 2, and 5 $mU \cdot kg^{-1} \cdot min^{-1}$, respectively. The SSNEFA is the resultant of both the inhibitory effect of insulin on lipolysis and the stimulatory effect of insulin on lipogenesis. To correct for different basal NEFA levels, the NEFA lowering effect of insulin was calculated as % compared with basal values. Dose response curves were created using PROC NLIN in SAS (SAS Inst. Inc., Cary, NC) to determine maximal effect and insulin dose needed to elicit half-maximal effect (logED50). Maximal effect and logED50 were, respectively, 0.90 ± 0.07% and 1.24 ± 0.29 μU/mL. Effects on both parameters were analyzed using PROC MIXED in SAS, with parity as random factor and BCS, BFT, and NEFA concentration during the dry period as independent variables. Maximal effect of insulin was negatively influenced by NEFA concentrations during the dry period ($\beta = -0.3065$; $P < 0.05$) while the effect of BFT and BCS was not significant. None of the independent variables had a significant influence on logED50. It can be concluded that elevated NEFA concentrations during the dry period decrease the maximal effect of insulin on lipolysis and lipogenesis.

Key Words: insulin sensitivity, lipid metabolism, dairy cow

499 Effect of ractopamine hydrochloride and zilpaterol hydrochloride on the electrocardiogram and blood lactate in finishing steers. D. A. Frese*[1], C. Reinhardt[1], S. J. Bartle[1], D. N. Rethorst[1], B. S. Bawa[1], J. D. Thomason[1], G. H. Loneragan[2], and D. Thomson[1], *[1]Kansas State University, Manhattan, [2]Texas Tech University, Lubbock.*

Thirty Angus steers (506 ± 5.5 kg) were used to examine the effect of ractopamine hydrochloride and zilpaterol hydrochloride on the cardiac physiology and blood lactate concentration of finishing beef steers. Cattle were randomly assigned to 1 of 3 treatment groups: control (CON), ractopamine hydrochloride (300 $mg \cdot animal^{-1} \cdot d^{-1}$; RAC), and zilpaterol hydrochloride (8.3 mg/kg DM basis; ZIL). Cattle were allowed to acclimate to pens and Calan Gate feeders for 43 d before trial initiation. Steers were housed in outdoor dirt-floor pens with ad libitum access to feed and water. Holter electrocardiograph (ECG) monitors were placed on cattle on d -2, 6, 13, and 24 of the trial and recorded continuously for 72, 24, 24, and 96 h, respectively; d 0 was the first day of β agonist feeding. Blood samples were obtained via jugular venipuncture for complete blood count, serum chemistry, and blood lactate (BL) analysis at the time of ECG monitor application. Electrocardiogram recordings were evaluated for mean heart rate (MHR) in beats per minute (bpm), ventricular (VPB), and supraventricular arrhythmia events per day (SVPB). Cattle fed ZIL (77.6 bpm ± 1.19) and RAC (78.4 bpm ± 1.18) had greater MHR than CON (74.2 bpm ± 1.27). No differences were observed in VPB, or SVPB in the CON, RAC, or ZIL treated cattle. No differences were found among treatments in arrythmia rate when classified as single beat, paired beat, or > 2 beats per event. Single beat events represented 84% of VPB and 90% of SVPB events. No differences were observed in BL among CON (3.1 mmol/L), RAC (2.9 mmol/L), and ZIL (2.8 mmol/L). Creatinine kinase (CK) increased ($P < 0.03$) in ZIL cattle (220.3 U/L), compared with CON (111.9 U/L) and RAC cattle (120.2 U/L) at d 13. On d 24 CK was increased in ZIL (226.9 U/L), than CON (132.5 U/L) and RAC (135.4 U/L). In conclusion, RAC and ZIL increased MHR in feedlot cattle, but had no effect on arrythmia rate, arrythmia classification, or blood lactate. Also, ZIL increased CK compared with CON and RAC on d 13 and 24.

Key Words: β agonist, electrocardiogram, blood lactate, cattle

0500 Expansion and evaluation of a dynamic, mechanistic model of nutritional and reproductive processes in dairy cattle. J. P. McNamara*[1] and S. L. Shields[2], [1]*Washington State University, Pullman,* [2]*Elanco Inc, Pasco, WA.*

The effects of nutrition and genetics on fertility are multiple, and although we do have a large knowledge base and good management practices, reproductive efficiency does not match the biological potential. In part, this is because we lack a full systems approach to managing the genetics and nutrition of cows to improve reproduction. Our objective was to expand the integration of nutritional and reproductive processes in a mechanistic, dynamic model of the dairy cow; suitable for evaluation of data, concepts, and hypotheses regarding underlying genetic, nutritional, and physiological control of reproduction. A model of metabolism (Molly, UC Davis); which describes nutrient metabolism, as well as tracking energy transactions; was integrated with a model of reproductive processes, which describes growth and decay of the follicles and corpus luteum, gonadotropin releasing hormone, follicle stimulating hormone, luteinizing hormone, progesterone, estrogen, oxytocin, and prostaglandin F2α over time. The models are integrated at specific points based on available literature data, for example: glucose and IGF-I affect rates of synthesis and release of follicle stimulating hormone, luteinizing hormone, and follicular growth according: follicular_growth = {follicular_rate_constant = hp_fsh_mod + [follicular_ rate_factor_IGF_1(0.001833) × (IGF_1– average_IGF_1)]}, where follicular_rate_constant is the rate of follicular growth, hp_fs_mod is a Hill function describing the effect of FSH on growth, and follicular_ rate_factor_IGF_1 which affects follicular growth. Degradation of estrogen and progesterone is a function of metabolic rate in visceral tissues of Molly (AtAdV), for example: progesterone degradation = 0.0005669 (deg_const_P4 = progesterone degradation factor (0.0005669) + [metab_rate_degradation_factor_P4 × (AtAdV–avg_ATADV)]. During pregnancy, cycling ceases and the model maintains progesterone concentrations and describes fetal growth. A modeling analysis that varied milk production from 25 to 55 kg/d DMI from 18.8 to 27.3 kg DMI, gave a range of metabolic rate from 1090 to 1426 M/d and a range of IGFI from 86.4 to 106.4 ng/L). Increasing IFGI increased follicular growth], while increasing metabolic rate increased the degradation of estrogen and progesterone. Because most reproductive systems have negative and positive effects on each other, it is the interaction of these systems which provided an interesting pattern of change in follicular growth and steroid degradation. This model should be of use in testing hypotheses about effects of genetic selection and nutritional management in dairy cattle.

Key Words: systems biology, reproduction, nutrition

0501 Metabolic, paracellular permeability, and immune gene expression in ruminal epithelium during the transition period in dairy cattle. A. Minuti*[1], S. Alqarni[2], P. Cardoso[2], E. Trevisi[1], and J. J. Loor[2], [1]*Università Cattolica del Sacro Cuore, Piacenza, Italy,* [2]*University of Illinois, Urbana-Champaign, Urbana.*

The study was aimed to investigate the mRNA expression linked to systems involved in the metabolic, epithelial integrity, and immune function in ruminal epithelial tissue during the transition period in dairy cattle. Seven multiparous Holstein cows with a ruminal fistula were dried off at −50 d relative to the expected calving and fed a controlled-energy diet (NEL = 1.24 Mcal/kg of DM) until calving, and then a common lactation diet. Ruminal epithelial tissue was biopsied at -14, 10, and 28 d in milk (DIM). Extracted mRNA was used for profiling of 23 genes via quantitative real-time RT-PCR. The expression of genes was normalized using geometric mean of 3 internal control genes (CMTM6, ERC1, and MRPL39). Data were analyzed as a repeated measures study using the MIXED procedure of SAS (SAS Inst. Inc., Cary, NC). The epithelial integrity genes OCLN and TJP1 had a decrease ($P < 0.05$) of expression from -14 to 10 DIM. For genes involved in the immune function, TNF did not change significantly. In contrast, the expression of CD45 decreased ($P < 0.05$) from -14 to 10 DIM and the expression of TL2 and TLR4 decreased ($P < 0.01$) until 28 DIM compared with -14 DIM. The transporters SLC14A1, SLC16A1, and SLC16A3 increased expression during the transition period with highest ($P < 0.05$) values at 28 DIM. The ketogenic gene HMGCS2 had higher ($P < 0.05$) expression at 28 DIM vs. -14 and 14 DIM. Expression of PPARA, PPARD, and PPARG did not change during the transition period; while, the nuclear receptor RXRA decreased ($P < 0.01$)from -14 DIM to 28 DIM. Expression of the insulin receptor (INSR) was lower ($P < 0.05$) at 10 DIM vs. -14 and 28 DIM. Expression of TGFB1, involved in cell growth and proliferation, had the highest ($P < 0.05$)expression at 10 DIM; while, its receptor (TGFBR1) had higher ($P < 0.05$) expression at -14 DIM and subsequently decreased. Results suggest that along with other tissues the ruminal epithelium also experiences changes at the transcriptome level. These are likely important for a successful transition into lactation. The observed changes could be driven by both changes in feed composition and nutrient intake typical of this period, and to the metabolic and hormonal changes that take place in preparation to the time of calving and the onset of lactation.

Key Words: rumen, transition cow, transcriptomics

0502 Energy expenditure is lower in efficient compared with inefficient lactating dairy cattle.

K. DiGiacomo*[1], L. C. Marett[2], W. J. Wales[2], B. J. Hayes[3], F. R. Dunshea[1], and B. J. Leury[1], *[1]The University of Melbourne, Parkville, Australia, [2]The Department of Environment and Primary Industries, Victoria, Ellinbank, Australia, [3]The Department of Environment and Primary Industries, Bundoora, Australia.*

Measuring the energy expenditure (EE) of an animal, particularly while it is at pasture exhibiting natural behaviours, is of particular importance to improve management, breeding, and feeding practices. Recently, the estimation of EE based on heart rate (HR) has been explored. In cattle, this relationship appears to be more stable than in other nondomestic animals, likely due to the acclimation and low fear response of domestic, particularly dairy, cattle. Sixteen lactating, primiparous Holstein-Friesian cows previously classed as efficient (n = 8) or inefficient (n = 8) based on residual feed intake (RFI) were housed in open circuit respiration chambers for a period of 48 h. Animals were fed lucerne hay cubes ad libitum and recieved 6 kg DM crushed wheat grain (and minerals) at milking (total diet CP 18% and ME 10.5 MJ/kg DM). Real time measurements of methane, CO_2, and O_2 flux were obtained in the chamber and real time HR measurements obtained using a Polar Equine HR monitor fitted to the cows for the duration of the chamber measurement period. Production measures (e.g., intake, milk yield, and milk content), heart rates, and O_2 consumption were not different between the efficiency groups. Oxygen consumption per heart beat (HB), defined as O_2 pulse, was calculated for the first 24 h of the study. The O_2/HB over the entire 24 h there was a significant effect of efficiency group such that efficient cows consumed less (0.01029 g min^{-1} per HB, $P < 0.05$) O_2 per heartbeat than inefficient cows. The finding of a relationship between efficiency and O_2 pulse being present in lactating dairy cattle is novel. Taken together, the lower pulse O_2 in efficient animals without a variance in intake or production indicates that there are fundamental differences in maintenance energy consumption between inefficient and efficient groups. This finding supports the idea that a more efficient animal will deliver less O_2 per HB whilst maintaining a level of health and production similar to that of an inefficient animal.

Key Words: energy expenditure, efficiency, residual feed intake

0503 Supplementation of OmniGen-AF during the receiving period modulates the metabolic response to a lipopolysaccharide challenge in feedlot steers.

N. C. Burdick Sanchez*[1], J. O. Buntyn[2], J. A. Carroll[1], T. Wistuba[3], K. DeHaan[3], S. E. Sieren[4], S. J. Jones[4], and T. B. Schmidt[4], *[1]USDA-ARS, Livestock Issues Research Unit, Lubbock, TX, [2]University of Nebraska, Department of Animal Science, Lincoln, [3]Prince AgriProducts Inc., Quincy, IL, [4]University of Nebraska, Lincoln.*

The use of probiotic feed supplements to enhance animal health and growth are of great interest to the beef industry. Studies have demonstrated that some probiotic supplements may affect metabolism, and therefore influence an animal's response to an immune challenge. This study was designed to determine the effect of supplementing feedlot steers with OmniGen-AF (Prince Agri Products Inc., Quincy, IL) during the receiving period on the metabolic response to a lipopolysaccharide (LPS) challenge. Steers (n = 18; 270 ± 5 kg BW) were obtained and transported to the University of Nebraska Agricultural Research and Development Center feedlot. Upon arrival steers were processed and separated into 2 treatment groups (n = 9/treatment): 1 group was fed a standard receiving diet (Control, Cont) and the other group was fed the same receiving diet supplemented with OmniGen-AF at 4 g/45.4 kg BW/d for 29 d (OmniGen-AF). On d 27, steers were fitted with indwelling jugular cannulas and placed in individual stalls. On d 28, steers were challenged i.v. with LPS (0.5 µg/kg BW at 0 h), and blood samples were collected at 30-min intervals from -2 to 8 h and at 24 h postchallenge. Serum was isolated and stored at −80°C until analyzed for glucose, NEFA, and blood urea nitrogen (BUN) concentrations. Data were analyzed using the Mixed procedure of SAS (SAS Inst. Inc., Cary, NC) specific for repeated measures. Glucose concentrations were affected by treatment (P = 0.009) and time ($P < 0.001$). Glucose was greater in OmniGen-AF steers compared with Cont steers (76.4 ± 1.1 mg/dL vs. 72.4 ± 1.0 mg/dL). For NEFA concentrations, there was a treatment ($P < 0.001$) and time ($P < 0.001$) effect. Specifically, Cont (0.210 ± 0.007 mmol/L) steers had greater NEFA concentrations than OmniGen-AF steers (0.101 ± 0.010 mmol/L). There was a tendency (P = 0.07) for a treatment × time interaction such that NEFA concentrations were greater ($P \leq 0.03$) in Cont steers than OmniGen-AF steers from 3 to 8 h after LPS challenge. For BUN, there was a treatment ($P < 0.001$) effect such that concentrations were greater in Cont steers (12.4 ± 0.1 mg/dL) than OmniGen-AF supplemented steers (11.5 ± 0.1 mg/dL) throughout the study, and were not affected by time (P = 0.28). These data suggest that OmniGen-AF supplementation modulates the metabolic response to a LPS challenge and provides an indication that supplementation of feedlot steers with OmniGen-AF may prevent the breakdown of other substrates (e.g., protein and fat) for energy during an immune challenge.

Key Words: cattle, metabolism, OmniGen-AF

0504 Supplementation of *Saccharomyces cerevisiae* modulates the metabolic response to a lipopolysaccharide challenge in feedlot steers.

T. B. Schmidt*[1], J. O. Buntyn[2], N. C. Burdick Sanchez[3], E. Chevaux[4], K. Barling[5], S. E. Sieren[1], S. J. Jones[1], and J. A. Carroll[3], *[1]University of Nebraska, Lincoln, [2]University of Nebraska, Department of Animal Science, Lincoln, NE, [3]USDA-ARS, Livestock Issues Research Unit, Lubbock, TX, [4]Lallemand Animal Nutrition, Milwaukee, WI, [5]Lallemand Animal Nutrition, Iola, TX.*

Live yeast has the potential to serve as an alternative to the use of low-dose supplementation of antibiotics in cattle due to the ability to alter ruminant metabolism; which in turn may influence the immune response. Therefore, the objective of this study was to determine the metabolic response to a lipopolysaccharide (LPS) challenge in feedlot steers supplemented with *Saccharomyces cerevisiae CNCM I-1079* (SC). Steers (n = 18; 266 ± 4 kg BW) were processed and separated into 3 treatment groups (n = 6/treatment): (1) steers were fed a standard receiving diet and served as the control (Cont); (2) steers were fed the receiving diet supplemented with SC (Lallemand, Inc.) at 0.5 g·animal^{-1}·d^{-1} (SC-0.5); and (3) steers were fed the control diet supplemented with SC at 5.0 g·animal^{-1}·d^{-1} (SC-5.0) for 29 d. On d 27, steers were fitted with indwelling jugular cannulas and rectal temperature (RT) probes, and were placed in individual stalls. On d 28, steers were challenged i.v. with LPS (0.5 µg/kg BW at 0 h), and blood samples were collected at 30-min intervals from -2 to 8 h and at 24 h postchallenge. Serum was isolated and stored at −80°C until analyzed for glucose, NEFA, and blood urea nitrogen (BUN) concentrations. There was a treatment (P = 0.02) and time effect (P < 0.001) for glucose; SC-0.5 steers had greater glucose concentrations (77.8 ± 1.6 mg/dL) than Cont (71.5 ± 1.3 mg/dL) and SC-5.0 steers (71.6 ± 1.4 mg/dL). Glucose concentrations also increased (P < 0.001) over time in response to LPS challenge. Concentrations of NEFA were also affected by time (P < 0.001) but were not affected by treatment (P = 0.42). For all treatments, NEFA concentrations increased in response to LPS challenge. There was a treatment (P < 0.001) and a time (P < 0.001) effect for BUN concentrations; BUN concentrations were greater (P < 0.001) in SC-0.5 steers (14.5 ± 0.2 mg/dL) than Cont (12.8 ± 0.2 mg/dL) and SC-5.0 (12.8 ± 0.2 mg/dL) steers. For all 3 groups, BUN concentrations increased (P < 0.001) in response to LPS challenge. These data demonstrate that *S. cerevisiae* supplementation may alter the metabolic response to LPS challenge. Repartitioning of nutrients may help explain the variations in the acute phase response observed in cattle supplemented with *S. cerevisiae*. Data from this study suggest that *S. cerevisiae* products may be useful as alternatives to antibiotic use in feed to enhance cattle health.

Key Words: cattle, live yeast, metabolism

0505 Circulating amino acids and biomarkers of metabolism and inflammation during the peripartal period in cows with different liver functionality index.

Z. Zhou*[1], J. J. Loor[1], F. Piccioli-Capelli[2], G. E. Lobley[3], and E. Trevisi[2], *[1]University of Illinois, Urbana, IL, [2]Università Cattolica del Sacro Cuore, Piacenza, Italy, [3]Rowett Institute of Nutrition and Health, University of Aberdeen, Aberdeen, UK.*

Objectives were to profile AA and biomarkers of inflammation during the peripartal period. Eighteen multiparous cows were used from -21 through 56 d around parturition. Cows were monitored for health status, milk yield, and DM intake. Body weight and BCS were measured every week. Blood samples were obtained twice weekly or daily from -10 to 10 d. Cows were ranked retrospectively in tertiles according to the liver functionality index (LFI), which includes 3 liver biomarkers of hepatic function: albumin, cholesterol, and total bilirubin. The LFI measures the relevant changes in concentrations between 3 and 28 d, standardized with the optimal pattern of change for the 3 parameters obtained from healthy cows at the same stage of lactation. A high LFI (better liver function) is characterized by lower bilirubin and higher cholesterol and albumin, and the opposite is true for low LFI. Although DMI (16.8 kg/d) and BCS (2.45) did not differ (P > 0.05) due to LFI or the interaction, cows in the high (39.2 kg/d) and medium (34.8 kg/d) vs. low (30.8 kg/d) LFI had greater (P < 0.05) milk production. As expected, there was a significant interaction (P < 0.05) for the concentration of albumin, cholesterol, and bilirubin such that cows in low vs. high LFI had lower cholesterol and albumin but greater bilirubin namely after calving. There was no interaction or LFI effect (P > 0.05) for NEFA, hydroxybutyrate, and haptoglobin but concentrations increased (P < 0.05) after calving. The interaction (P = 0.06) effect observed for concentration of essential AA was due in part to greater values in high and medium LFI cows namely during d 7 through 14. A similar type of response resulted in a trend (P = 0.10) for an interaction in the concentration of branched-chain AA (BCAA). There was no LFI or interaction effect (P > 0.05) for concentration of Lys, which decreased (P < 0.05) markedly from -21 d to calving followed by a gradual increase to prepartal values by d 14. In contrast, concentration of Met decreased markedly between -21 d and calving but did not reach prepartal values until d 42. Results suggest some alterations in postpartal EAA and BCAA concentration such that cows with high vs. low LFI produce more milk and maintain greater concentrations of these AA.

0506 Peripheral leukocytic responses to ultraviolet radiation in prepubertal rabbits fed a turmeric-supplemented diet. V. A. Togun*, *Ladoke Akintola University of Technology, Ogbomoso, Nigeria*.

This study investigated the antioxidant/antiinflammatory effect of turmeric (*Curcuma longa*) to enhance developmental resilience in stress induced, UV irradiated (*R*) rabbits indexed by peripheral leukocytic responses. This study was conducted for a total of 85 d in 3 phased periods: 40 d preirradiation, 5 d irradiation, and 40 d postirradiation in 72 acclimatized prepubertal, unsexed rabbits of average body weight range of 600 g, randomly assigned to 6 groups of 12 rabbits each and treated as follows: Group 1 served as control; they were fed unsupplemented diet and forage (*Tridax procumbens*) basal diet (BD) for the entire study periods without any treatment. Group 2 animals were fed BD supplemented with 2% crude pulverized turmeric (T) during Periods 1, 2, and 3, but were not irradiated. Group 3 animals were fed unsupplemented BD at Periods 1, 2, and 3 and irradiated. Group 4 rabbits were fed supplemented BD during Periods 1 and 2 only, and irradiated. Group 5 animals were fed supplemented BD at Periods 1, 2, and 3 and irradiated. Group 6 animals were fed BD in Periods 1 and 2, and irradiated at Period 2, following which supplemented BD was served in Period 3. Blood was collected on d 86 from 00.09 h. Feed and water were available ad libitum. The experimental design was completely randomized block design. Data were analysed by ANOVA with graphic post-hoc test of significance. Evident from Table 0506 with data for all the periods, UV irradiation significantly ($P < 0.05$) suppressed WBC and absolute lymphocytic count. Turmeric supplementation significantly ameliorated these UV effects ($P < 0.05$).

Key Words: turmeric, leukocytic-response, ultraviolet radiation, rabbits

0507 Regulation of adipogenesis and key adipogenic gene expression by retinoic acid in 3T3–L1 preadipocytes. S. Ji*[1], M. Du[2], and R. A. Hill[1], *[1]University of Idaho, Moscow, [2]Washington State University, Pullman.*

Adipogenesis plays an important role in metabolic homeostasis and nutrient pathways, and is crucial for regulating body fat reserves and body weight of mammals. The transcriptional control of adipogenesis requires a sequential series of gene expression events and activation of a number of key signaling pathways. Retinoic acid is considered as a potent inhibitor of adipogenesis for decades, and understanding the mechanism of retinoic acid regulation of adipogenesis is useful for helping to control body fat and to manipulate meat quality in the beef industry. To investigate the function of retinoic acid in regulation of adipogenesis, adipocyte differentiation and key adipogenic gene expression were studied in 3T3-L1 preadipocytes. Lipid accumulation was measured by Oil Red O staining, and expression of key adipogenic genes was quantified using quantitative real-time PCR. Adipogenic responses to different concentrations of retinoic acid were determined on d 2, 4, 6, 8, and 10 after stimulation of adipogenesis with the traditional hormonal cocktail (dexamethasone, isobutyl-1-methylxanthine and insulin) in the absence or presence of retinoic acid. In response to high concentrations (10^{-6}, 10^{-7} M) of retinoic acid, lipid accumulation and the expression of PPARγ, C/EBPα, FABP4, and SCD-1 were inhibited through d 8, but on d 10, lipid accumulation and the expression levels of these genes rebounded to levels comparable with the control. Interestingly, the greatest effects of retinoic acid treatments were on expression of FABP4. However, expression of SREBP-1c was not affected. The lowest retinoic acid concentration (10^{-10}M) did not affect adipocyte differentiation or expression of adipogenic genes. These results indicate that retinoic acid inhibited adipogenesis via suppressing adipogenic specific genes, especially FABP4. Our data indicate that a deeper understanding of the roles of retinoic acid in regulating adipogenesis will be informed by further study of adipogenic specific gene promoter activity.

Key Words: adipogenesis, transcription factors, retinoic acid

0508 Cholesterol metabolism, transport, and hepatic regulation during negative energy balance in early and mid-lactation in dairy cows.

J. J. Gross*[1], E. C. Kessler[1], C. Albrecht[2], and R. M. Bruckmaier[1], *[1]Veterinary Physiology, Vetsuisse Faculty, University of Bern, Bern, Switzerland, [2]Institute of Biochemistry and Molecular Medicine, University of Bern, Bern, Switzerland.*

The negative energy balance (NEB) in early lactation has considerable effects on the cholesterol metabolism of dairy cows. The objective of this study was to investigate the response of plasma and milk lipids, enzyme activities, and hepatic mRNA expression of transcripts encoding for factors involved in cholesterol metabolism to a NEB in early and mid-lactation. Fifty multiparous Holstein dairy cows (25 control [C], 25 feed-restricted [R]) were studied from wk 1 postpartum (pp) until wk 17 pp, with an almost 50% feed-restriction from wk 14 to 17 pp. Blood samples, liver biopsies, and milk samples were taken in wk 1, 14, and 17 pp. Blood and milk lipid concentrations [triglycerides (TG), cholesterol, lipoproteins] and enzyme activities [phospholipid transfer protein (PLTP), lecithin-cholesterol acyltransferase (LCAT)] related to cholesterol homeostasis were analyzed. Hepatic gene expression of 3-hydroxy-3-methylglutaryl-coenzyme A (HMGC) synthase 1 (HMGCS1) and HMGC reductase (HMGCR), sterol regulatory element-binding factor (SREBF)-2, microsomal triglyceride transfer protein (MTTP), ATP-binding cassette transporter (ABC) A1, and ABCG1 were measured. While values were lower for cows in wk 1 pp, plasma concentrations of TG, cholesterol, VLDL-cholesterol (VLDL-C) and LDL-C increased in R cows from wk 14 to 17 pp compared with C cows. Whereas in wk 1 pp, PLTP activity was increased and LCAT activity was lower, activities of PLTP and LCAT did not differ between wk 14 and 17 pp in C and R cows. Cholesterol concentration in milk did not change from wk 14 to 17 pp, whereas cholesterol mass in milk was decreased in wk 17 pp for R cows and tended to be lower in R cows compared with C cows. On the contrary, cholesterol concentration and mass in milk were higher in wk 1 pp. SREBF-2, HMGCS1, HMGCR, MTTP, ABCA1, and-G1 showed no changes during the experiment. In contrast, during the NEB at the onset of lactation the expression of HMGCS1, HMGCR, SREBF-2, and ABCA1 were increased. In conclusion, increased plasma concentrations of TG, cholesterol, VLDL-C, and LDL-C during the feed restriction period suggest that in later stages of lactation the liver is able to enhance the export of generated TG as VLDL. The diminished milk cholesterol mass might represent a measure to save cholesterol for the constitution of VLDL.

Key Words: cholesterol metabolism, lipoprotein, dairy cow

PHYSIOLOGY AND ENDOCRINOLOGY: INTERRELATIONSHIPS BETWEEN ENVIRONMENTAL, METABOLIC, AND PHYSIOLOGICAL PROCESSES II

0509 Effects of calcium salts of soybean oil on factors that influence pregnancy establishment in *Bos indicus* beef cows. B. I. Cappellozza*[1], R. F. Cooke[1], T. Guarnieri Filho[1,2], I. Bueno[2], D. W. Bohnert[1], R. L. A. Cerri[3], and J. L. M. Vasconcelos[4], *[1]Oregon State University–EOARC Burns, Burns, [2]Faculdade de Medicina Veterinária e Zootecnia, UNESP–Univ. Estadual Paulista, Botucatu, Brazil, [3]Faculty of Land and Food Systems–University of British Columbia, Vancouver, Canada, [4]UNESP–FMVZ, Botucatu, Brazil*.

This experiment compared fatty acid (FA) concentrations in plasma, reproductive tissues, as well as hormones, and expression of genes associated with pregnancy establishment in beef cows supplemented or not with Ca salts of soybean oil (CSSO) beginning after timed AI. Ninety nonlactating multiparous Nellore (*Bos indicus*) cows were inseminated on d 0 of the experiment, and divided into 18 groups of 5 cows/group. Groups were randomly assigned to receive (as-fed basis) 100 g of protein-mineral mix + 100 g of ground corn per cow/d, in addition to (1) 100 g/cow daily of CSSO ($n = 9$), or (2) 100 g/cow daily of kaolin (CON; rumen-inert indigestible substance; $n = 9$). Groups were maintained in a single *Brachiaria brizantha* pasture with ad libitum access to forage. However, groups were segregated daily and offered treatments individually during the experiment (d 0 to 18). Blood samples were collected and transrectal ultrasonography was performed to verify ovulation and corpus luteum (CL) volume immediately before AI (d 0), on d 7, and 1 d 8. On d 19, 36 cows (18 cows/treatment, 2 cows/group) diagnosed without the presence of a CL on d 0, but with a CL > 0.3 cm^3 in volume on d 7 and 18, were slaughtered for collection of conceptus, uterine luminal flushing, and tissue samples from the CL and endometrium. Data were analyzed using the MIXED procedure of SAS (SAS Inst. Inc., Cary, NC) with group as experimental unit. Cows receiving CSSO had greater ($P \leq 0.08$) concentrations of linoleic and other ω-6 FA in plasma, endometrium, CL, and conceptus compared with CON. On d 7, CSSO-supplemented cows had greater plasma progesterone concentrations ($P = 0.02$) and CL volume ($P = 0.01$) compared with CON, whereas no treatment effects were detected ($P \geq 0.20$) for these parameters on d 18 (treatment × day interaction; $P < 0.01$). Cows receiving CSSO tended ($P = 0.09$) to have greater concentrations of IFNt in the uterine flushing media compared with CON. No treatment effects were detected ($P \geq 0.12$) for mRNA expression genes associated with pregnancy establishment in endometrial (cyclooxygenase-2 and oxytocin receptor), CL (steroidogenic enzymes), and conceptus (IFNt) samples. In summary, supplementing beef cows with 100 g of CSSO beginning after AI favored incorporation of ω-6 FA into their circulation, reproductive tissues, and conceptus, without impacting expression of genes associated with pregnancy establishment on d 19 of gestation.

Key Words: beef cows, calcium salts of soybean oil, pregnancy

0510 Metabolomics profiling of four biofluids from dairy cows fed different forages using gas chromatography–time of flight/mass spectrometry. H. Z. Sun*[1], B. Wang[1], D. M. Wang[1], J. K. Wang[1], L. L. Guan[2], and J. X. Liu[3], *[1]Institute of Dairy Science, Zhejiang University, Hangzhou, China, [2]Department of Agricultural, Food and Nutritional Science, University of Alberta, Edmonton, Canada, [3]Zhejiang University, Hangzhou, China*.

The quality of forage can significantly impact milk production and quality. This study aims to investigate the effect of type of forage on metabolites in biofluids of dairy cow and their potential role in lactation. Sixteen multiparous Holstein dairy cows were blocked based on days in milk (164 ± 27.5 d, mean ± SD) and milk yield (29.4 ± 2.16 kg, mean ± SD), and were randomly assigned into 1 of 2 treatments. Isonitrogenous diets with a ratio of forage-to-concentrate at 45:55 contained similar concentrate mixtures and 15% corn silage, with 2 different forage sources (DM basis): 23% alfalfa hay and 7% Chinese wild rye hay (AH); and 30% corn stover (CS). After a 65-d feeding, 4 biofluids (rumen fluid, milk, serum, and urine) were collected from all cows to characterize the metabolites using a novel metabolomics method based on gas chromatography–time of flight/mass spectrometry). A total of 165, 195, 218, and 156 metabolites were identified in rumen fluid, milk, serum, and urine, respectively. Among them, 29 metabolites were mutual in all 4 biofluids. The chromatograms among 4 biofluids were obviously different, with a clear discrimination between diets CS and AH. Principal component analysis yielded the separated clusters of metabolite profiles between diets AH and CS. Partial least squares discriminant analysis also showed segregation in the metabolites from 4 biofluids between 2 diets. There were 56, 8, 31, 31 metabolites in 4 biofluids, respectively, that differed significantly between diets AH and CS (VIP > 1 and $P < 0.05$). These metabolites were mainly involved in AA metabolism and carbohydrate metabolism. Among 56 dissimilar metabolites in the rumen, 90% was lower for diet CS than for AH, while 74% of 31 dissimilar urinary metabolic wastes was higher in CS. The cumulative explanation rate (R^2Y) of orthogonal to partial least squares discriminant analysis was 0.899, 0.967, 0.899, and 0.982, respectively, suggesting that biofluid metabolomics combining metabolic profiles with multivariate analysis can be used to investigate the cow complex metabolic alteration in response to different type of forages with successful metabolites models.

Key Words: biofluids, metabolomics, dairy cow

0511 Separation of proteins from the milk fat globule membrane with minimal losses. W. Holzmüller*, *Technische Universität München, Freising, Germany.*

Components of the milk fat globule membrane (MFGM) are reported to have functional properties. However, determination of the specific properties of individual MFGM components is hardly possible, since the MFGM is a complex 3-layered structure consisting of phospholipids and proteins. Therefore, to assess the MFGM proteins' functionalities, first an isolation of the MFGM from the bulk milk proteins is required. Second, single MFGM proteins must be separated from the phospholipid phase. The aim of this project was to compare established and novel isolation methods in terms of the capacity to obtain MFGM proteins at high yield. First, the method of washing the cream for several times was used. After each washing step the cream sample was churned and the buttermilk obtained was analyzed regarding MFGM proteins using SDS-PAGE. The intensities of the different proteins (XO/XDH, BTN PAS6/7) were compared with a nonwashed sample. Beside the removal of caseins and whey proteins it was found that a significant loss of MFGM proteins up to 90% occurs, which has been neglected in previous studies. Particle size measurements showed that the fat globules increased during the washing process. This is due to coalescence of the fat globules and consequently results in a loss of MFGM material including membrane proteins. Second, filtration experiments with buttermilk were done. Because of an overlap in size between the casein micelles and the MFGM fragments a pre-treatment of the buttermilk was necessary to realize an isolation of the MFGM. In this study, a new approach based on the coagulation of casein micelles by adding rennet was developed. The supernatant (buttermilk-sweet whey) obtained was used for a subsequent diafiltration to remove the residual whey proteins. All permeates and retentates of each diafiltration step were again analyzed for the remaining MFGM proteins, caseins, and whey proteins by SDS-PAGE to evaluate the isolation procedure. However, significantly higher amounts (~70%) of the total MFGM proteins were recovered when the newly developed MFGM isolation method was used in comparison with the washing method. Concluding, both separation methods are applicable to realize MFGM isolates, but a simultaneous loss of MFGM proteins is hardly avoidable. As far as we oversee the literature, this fact was not sufficiently considered in previous studies. Finally, the results of this work show that different MFGM proteins are enriched in the particular isolates depending on their location in the MFGM and the applied extraction method.

Key Words: milk fat globule membrane proteins

0512 Serotonin (5-HT) receptor expression in bovine apocrine sweat gland epithelial cells isolated from cow skin. S. Hamzaoui[1], J. L. Collier[2], and R. J. Collier*[2], [1]*Universitat Autònoma de Barcelona, Bellaterra, Spain,* [2]*University of Arizona, Tucson.*

Apocrine sweat glands in bovine skin are involved in thermoregulation. Human, horse, and sheep sweat gland epithelial cells have been isolated and grown in vitro. However, isolation of bovine sweat gland epithelial cells (BSGEC) has never been reported. Recent studies have demonstrated that serotonin (5-HT) is an important local regulator of lactational homeostasis and involution in bovine, mouse, and human mammary epithelial cells. We hypothesized that, since the mammary gland is a modified sweat gland, that 5-HT receptors may also be present in BSGEC. The present study was conducted to identify a method to isolate bovine sweat glands and culture apocrine BSGEC in vitro and evaluate the expression of 5-HT receptors (1B, 2A, 2B, 4, and 7) in bovine skin, intact apocrine sweat glands and BSGEC. Collagenase digestion, neutral red staining and mechanical shearing were used to identify and isolate the apocrine glands from skin. The isolated material was transferred to complete media (keratinocyte serum-free media, K-SFM), bovine pituitary extract (BPE), and human recombinant epidermal growth factor (EGF) + 2.5% FBS in a T25 flask with media film then incubated at 37°C for 24 h. After sweat glands adhered to the bottom, an additional 2 mL of complete media was added, and the media was changed every 3 d. Isolated apocrine sweat glands and BSGEC were immunostained for cytokeratin and fibroblast specific protein, indicating fibroblast-free cultures. We also determined the mRNA expression of bovine 5-HT receptor subtypes in bovine whole skin, sweat glands, and BSGEC. The mRNAs for 5 receptor isoforms (5-HT 1B, 2A, 2B, 4, and 7) were identified by conventional PCR. We identified isoforms 5HT 1B, 2A, 2B, 4, and 7 in whole skin; 1B, 2B, and 7 in isolated sweat glands and BSGEC. We report a method for the isolation of bovine apocrine sweat glands and suggest that keratinocyte medium supplemented with 2.5% FBS is effective and suitable for the culture of BSGEC. The presence of 5-HT receptors in BSGEC indicates that the serotonergic system is involved in regulation of BSGEC function.

Key Words: apocrine gland, serotonin 5-HT receptors, dairy cow

0513 Responses to an insulin challenge in dairy cows classed as efficient or inefficient based on residual feed intake during mid-lactation and the dry period. K. DiGiacomo*[1], E. Norris[1], L. C. Marett[2], W. J. Wales[2], B. J. Hayes[3], F. R. Dunshea[1], and B. J. Leury[1], *[1]The University of Melbourne, Parkville, Australia, [2]The Department of Environment and Primary Industries, Victoria, Ellinbank, Australia, [3]The Department of Environment and Primary Industries, Bundoora, Australia*.

Cows selected for milk yield are insulin resistant and readily mobilize lipid energy stores during lactation. Upon exposure to a stressor, insulin secretion from the pancreas is inhibited by epinephrine and consequently adds to the hyperglycemic responses to stress. Insulin-induced hypoglycemia is an indirect means of stimulating the hypothalamic-pituitary-adrenal (HPA) axis to release adrenocorticotropic hormone (ACTH) and subsequently cortisol. This experiment was designed to explore the nutrient partitioning and stress hormone responses to an insulin challenge in mid-lactating and dry cows classed as efficient or inefficient based on residual feed intake (RFI). Sixteen multiparous Holstein-Friesian cows (589 ± 37 kg) were selected based on RFI extremes (8 inefficient and 8 efficient). On 2 occasions, during mid-lactation (122 ± 23 d in milk) and the dry period (~38 d dry), an i.v. insulin challenge was conducted. Animals were housed in metabolism stalls and fed lucerne hay cubes ad libitum and recieved 6 kg DM crushed wheat grain (and minerals) per day at milking (18% CP and 10.5 MJ ME/kg DM) and had food removed 12 h before the challenge. The day before the challenge cows were fitted with interdwelling jugular catheters. Insulin (0.12 U/kg) was infused via the catheter and blood samples collected at regular intervals pre- and postinfusion. Isolated plasma was analysed for cortisol, GH, IGF-1, NEFA, and glucose concentrations. Overall, responses to the insulin challenge were more pronounced during mid-lactation compared with the dry period. Basal plasma IGF-1 concentrations were greater in inefficient compared with efficient cows during mid-lactation (11.2 vs. 15.9 ng/mL respectively, $P = 0.006$) but not the dry period ($P = 0.78$). Peak plasma cortisol concentrations were not influenced by efficiency group during either measurement periods. Plasma cortisol and NEFA concentrations were greater, and glucose concentrations lower, in mid-lactation compared with the dry period. This experiment demonstrated a stress (cortisol) response to the insulin-induced hypoglycemia, although this response did not vary with efficiency. The diminished responses to insulin during the dry period are likely due to the varied metabolic states of the animals at these 2 varied stages of production. The greater basal IGF-1 concentrations in inefficient animals may in part explain their inefficiency as IGF-1 mimics the actions of insulin and reduces circulating glucose concentrations, reducing the concentration of glucose available for use in mammary tissues.

Key Words: stress responses, efficiency, insulin

0514 Interactions between metabolic load and dairy cow welfare-related parameters in herbage-based feeding systems. R. S. Zbinden[1], J. J. Gross*[1], M. Falk[2], H. A. van Dorland[1], A. Münger[2], F. Dohme-Meier[2], and R. M. Bruckmaier[1], *[1]Veterinary Physiology, Vetsuisse Faculty University of Bern, Bern, Switzerland, [2]Agroscope, Institute for Livestock Sciences ILS, Posieux, Switzerland.*

In Switzerland, herbage feeding with only little input of concentrates plays an important role in milk production. The objective here was to investigate the effects of a solely herbage based diet on production, metabolic, endocrine and welfare-related parameters of dairy cows. Twenty-five multiparous Holstein dairy cows were divided into 2 groups according to their previous lactation yield (4679 to 10,808 kg): a control (C, $n = 13$) and a treatment group (nC, $n = 12$) from wk 3 antepartum until wk 8 postpartum. Within C and nC, the median of the preceding lactation yields (7752 kg) was used to split cows into a high (CH, nCH) and low yielding (CL, nCL) subgroup. While CH/CL received fresh cut herbage plus additional concentrate according to their estiamted energy and nutrient requirements, no concentrate was fed to nCH/nCL throughout the experiment. Milk yield and DMI were recorded daily. Blood samples were weekly and analyzed for IGF-1, glucose, NEFA, BHBA, and welfare-related parameters haptoglobin (Hp), serum amyloid A (SAA), β-endorphin (BE), and alkaline phosphatase (AP). Saliva samples were taken biweekly and analyzed for cortisol. Data were analyzed using mixed models. Throughout the study, CH had a higher milk yield (35.9 kg/d) compared with the other subgroups (27.2 to 31.7 kg/d, $P < 0.05$). Plasma glucose (3.51 vs. 3.72 mmol/L) and IGF-1 (66.0 vs. 78.9 ng/mL) concentrations were lower in nCH/nCL compared with CH/CL cows ($P < 0.05$). Plasma NEFA and BHBA concentrations were higher in nCH (1.1 and 1.6 mmol/L) compared with the other subgroups (0.5 and 0.6 mmol/L, $P < 0.05$). Saliva cortisol (0.60 vs. 0.68 ng/mL), SAA (0.60 vs. 0.87 µg/mL), Hp (728 vs. 909 U/L), BE (30.0 vs. 32.1 pg/mL), and AP (48.5 vs. 45.9 mg/mL) were not different among C and nC. In conclusion, in herbage dominated feeding systems without supplementary concentrate especially high yielding dairy cows experience a higher metabolic load during early lactation leading in turn to a reduced lactational performance compared with cows of a similar potential fed according to their needs. Low yielding dairy cows can perform well without concentrate supplementation. Interestingly, the commonly accepted welfare-related parameters cortisol, Hp, SAA, BE, and AP did not indicate a reduced animal welfare induced by metabolic stress.

Key Words: welfare, metabolism, herbage feeding, dairy cow

0515 Effects of repeated short-term feed restrictions and lipopolysaccharide-induced systemic inflammation on metabolism and performance in dairy cows. J. J. Gross*[1], E. Kalaitzakis[2], O. Wellnitz[1,2], H. Bollwein[2], and R. M. Bruckmaier[1], *[1]Veterinary Physiology, Vetsuisse Faculty, University of Bern, Bern, Switzerland, [2]Clinic of Reproductive Medicine, Vetsuisse Faculty, University of Zurich, Zurich, Switzerland.*

A negative energy balance (NEB) may occur later in lactation when feed supply and/or quality are insufficient. We investigated if responses of metabolism, performance and immune system to energy deficiency differ between lactational stages. Fourteen multiparous Holstein dairy cows were grouped according to their previous lactation yield in 2 groups: a control (CON) group and a restricted (RES) group. The trial lasted from wk 3 antepartum until wk 12 postpartum (pp). Cows (CON and RES) were fed with grass ad libitum plus additional concentrate throughout the study, except the RES group, which received only grass during 1-wk feed-restrictions in wk 2, 5, 8, and 11 pp. At the end of the first restriction period, lipopolysaccharide (LPS) from *Escherichia coli* was infused intravenously (0.5 μg/kg BW) to mimic an inflammatory status interacting with a different metabolic status. Dry matter intake and milk yield were recorded daily. Blood was obtained weekly throughout the study, daily during the restriction periods in wk 2, 5, 8, and 11 pp, and every 0.5 h during the day of systemic LPS challenge. Blood samples were analyzed for glucose, NEFA, BHBA, and IGF-1 concentrations. Data were analyzed using a mixed model including group and wk as fixed effects. During restriction periods, RES had an elevated grass DMI (0.3 to 4.2 kg/d) compared with CON. In-between restriction periods, DMI did not differ between RES and CON. Milk yield was lower for RES in wk 2, 5, 8, and 11 pp (ca. 5 kg/d) compared with CON and recovered between restriction periods. On the day of LPS challenge, milk yield in RES dropped more distinct than in CON (9.5 vs. 11.3 kg/d). CON cows recovered faster in milk yield after the LPS challenge. During wk 2 pp, plasma concentrations of glucose, NEFA, BHBA were not different between RES and CON, while IGF-1 was lower in RES (41.1 vs. 82.6 ng/mL). During the restriction periods in wk 5, 8, and 11, NEFA and BHBA concentrations were elevated in RES (up to 0.67 mmol/L NEFA and 0.74 mmol/L BHBA), while glucose and IGF-1 concentration were lower in RES compared with CON (3.77 vs. 4.03 mmol/L glucose, 68.8 vs. 98.4 ng/mL IGF-1 in wk 8). In conclusion, the experiment showed the changing priority of the lactating mammary gland during different stages of lactation. Performance, metabolic and endocrine changes became less with progress of lactation. Further analyses are in progress.

Key Words: feed-restriction, metabolism, grass feeding, dairy cow

0516 Effects of heat stress on pancreatic insulin content and β-cell distribution in growing pigs. M. Sanz Fernandez*[1], J. S. Johnson[1], M. Abuajamieh[1], S. K. Stoakes[1], S. M. Lei[1], R. P. Rhoads[2], and L. H. Baumgard[1], *[1]Iowa State University, Ames, [2]Virginia Tech, Blacksburg.*

Heat stress (HS) induces postabsorptive metabolism changes, independent of inadequate nutrient intake. Despite marked hypophagia, HS inexplicably increases plasma insulin kinetics in a variety of animal models, and we have previously demonstrated that the HS pigs included in this study had increased plasma C-peptide (10%; $P < 0.05$), an indicator of insulin secretion. Whether higher plasma insulin is due to increased pancreatic insulin production or secretion is unknown. Seventeen crossbred gilts (57 ± 5 kg BW) were subjected to 1 of 2 environmental treatments: (1) constant HS conditions (32°C, 23% relative humidity) and ad libitum feeding ($n = 7$), or (2) pair-feeding in thermoneutral conditions (20°C, 36% relative humidity; PFTN; $n = 10$) to eliminate the confounding effects of dissimilar feed intake. After 8 d of environmental exposure, pigs were sacrificed and the pancreas was immediately collected. Insulin content was determined after acid-ethanol protein extraction from frozen samples using a commercially available ELISA kit. Fixed samples were sectioned and stained for insulin using an indirect immunoperoxidase immunohistochemical technique. Heat stress tended to decrease (32%; $P = 0.08$) insulin stained area compared with PFTN conditions. In agreement, pancreatic insulin protein content was numerically reduced (39%; $P = 0.18$) in HS pigs. There were no differences ($P > 0.10$) in the quantity of β-cell groups, determined as the number of insulin positive cells clusters. However, when classifying β-cell groups by size, HS decreased (66%; $P < 0.01$) the percentage of larger β-cell clusters (diameter > 100 μm), while increasing (4%; $P \leq 0.01$) the percentage of smaller clusters (diameter < 50 μm). In conclusion, the similar amount of β-cell groups between treatments, coupled with the decrease in pancreatic insulin content in the HS pigs, indicates that HS-induced changes on plasma insulin concentration might be due to increased pancreatic insulin secretion, rather than production.

Key Words: heat stress, pig, insulin, pancreas

0517 Effects of protein supplementation frequency on metabolic responses associated with reproduction of beef cows. M. M. Reis*[1], R. F. Cooke[1], B. I. Cappellozza[1], R. Marques[1], T. Guarnieri Filho[1,2], G. A. Perry[3], and D. W. Bohnert[1], *[1]Oregon State University–EOARC Burns, Burns, [2]Faculdade de Medicina Veterinária e Zootecnia, UNESP–Univ. Estadual Paulista, Botucatu, Brazil, [3]South Dakota State University, Brookings.*

This experiment evaluated if frequency of protein supplementation impacts physiological responses associated with reproduction in beef cows. Fourteen nonpregnant, nonlactating Angus cows were ranked by parity and BW, and allocated to 3 groups. Groups were assigned to a 3 × 3 Latin square design, containing periods of 21 d and the following treatments: (1) daily supplementation of soybean meal (7D), (2) soybean meal supplementation 3 times/wk (3D), and (3) soybean meal supplementation once/wk (1D). Within each period (d 0 to 21), cows were assigned to an estrus synchronization protocol; 100 μg of GnRH + controlled internal device release (CIDR) containing progesterone (P4) on d 1, 25 mg of $PGF_{2\alpha}$ on d 8, CIDR removal plus 100 μg of GnRH on d 11. Straw was offered for ad libitum consumption. Soybean meal was individually supplemented at 1 kg/cow daily. Moreover, 3D were supplemented on d 0, 2, 4, 7, 9, 11, 14, 16, and 18, whereas 1D were supplemented on d 4, 11, and 18 of each period. Blood samples were collected on d 11 and 18 from 0 to 72 h relative to supplement feeding, and analyzed for plasma urea N (PUN). Samples collected from 0 to 12 h were analyzed for plasma glucose, insulin, and P4 (d 18 only) concentrations. Uterine flush fluid was collected 28 h after supplementation for pH measurement. Data were analyzed with the MIXED procedure of SAS (SAS Inst. Inc., Cary, NC) and cow as experimental unit. A treatment × hour interaction ($P < 0.01$) was detected for PUN, which peaked ($P < 0.01$) for 1D and 3D at 28 h after supplement feeding, whereas the same response was not detected in 7D. Moreover, PUN concentration at 28 h was greater ($P < 0.01$) for 1D compared with 3D and 7D (42.7, 34.4, and 25.7 mg/dL, respectively), and also greater ($P < 0.01$) for 3D compared with 7D. No treatment effects were detected ($P \geq 0.65$) for plasma glucose and P4 concentrations, whereas mean plasma insulin concentrations were greater ($P \leq 0.02$) in 7D and 3D compared with 1D (4.61, 4.76, and 3.74 μIU/mL, respectively). Uterine flushing pH tended ($P \leq 0.10$) to be greater for 1D compared with 3D and 7D (6.204, 6.130, and 6.140, respectively). In conclusion, reducing frequency of protein supplementation to once/week impacted plasma insulin, PUN, and uterine flushing pH, which are known to modulate reproduction of beef cows.

Key Words: beef cows, protein, physiology, reproduction

0518 A vaccine-induced acute-phase reaction increases plasma leptin concentrations in beef cattle. R. Marques*[1], R. F. Cooke[1], B. I. Cappellozza[1], T. Guarnieri Filho[1,2], M. M. Reis[1], D. H. Keisler[3], and D. W. Bohnert[1], *[1]Oregon State University–EOARC Burns, Burns, [2]Faculdade de Medicina Veterinária e Zootecnia, UNESP–Univ. Estadual Paulista, Botucatu, Brazil, [3]University of Missouri-Division of Animal Sciences, Columbia.*

The objective of this experiment was to evaluate if a vaccine-induced acute-phase reaction also results in increased plasma leptin concentration, which would explain a potential DMI decrease in vaccinated beef cattle. Twelve yearling Angus × Hereford calves (9 steers and 4 heifers) were ranked by sex and BW, and allocated to 2 groups (6 calves per group, 4 steers and 2 heifers). Groups were assigned to a crossover design containing 2 periods of 14 d, and the following treatments on d 0 of each period: (1) vaccination against *Mannheimia haemolytica* (VAC; One Shot; Pfizer Inc., New York, NY), or (2) saline-injected control (CON). Calves were maintained in individual pens, offered grass hay for ad libitum consumption, in addition to 1.3 kg/d (DM basis) of a corn-based supplement. During Period 1, hay and concentrate intake were evaluated daily. During Period 2, blood samples were collected before (0 h) and at 2, 4, 6, 8, 12, 16, 24, 36, 48, 60, 72, 96, 120, 144, 168, 240, and 336 h after treatment administration. All samples were analyzed for plasma haptoglobin concentration. Samples collected from 0 to 36 h were also analyzed for plasma cortisol, whereas samples collected from 0 to 96 h were analyzed for serum NEFA and plasma leptin concentrations. Values obtained at 0 h served as covariates within each respective analysis. Treatment × day interactions were detected ($P = 0.05$) for hay and total DMI, given that these parameters were reduced ($P \leq 0.02$) in VAC compared with CON on d 0 and 1. Mean plasma cortisol was greater ($P \leq 0.01$) in VAC compared with CON (39.8 vs. 26.3 ng/mL, respectively; SEM = 2.4). Treatment × hour interactions were detected ($P < 0.01$) for all other blood variables. Serum NEFA concentration was greater ($P \leq 0.03$) in VAC compared with CON at 16, 24, 48, and 72 h. Plasma haptoglobin concentration was greater in VAC compared with CON at 8 h, and from 16 to 120 h. Plasma leptin concentration was greater ($P \leq 0.05$) in VAC compared with CON beginning at 6 h relative to treatment administration. In conclusion, plasma leptin concentration was increased during a vaccine-induced acute-phase reaction, and may explain the decrease in DMI observed herein in vaccinated cattle.

Key Words: acute-phase reaction, feed intake, leptin, vaccination

0519 A prepartum diet supplemented with rolled sunflower seed increased calf weight, the incidence of dystocia, and colostrum immunoglobulin content in Holstein cows. R. Salehi*[1], M. G. Colazo[2], M. Oba[1], and D. J. Ambrose[2], *[1]University of Alberta, Edmonton, Canada, [2]Alberta Agriculture and Rural Development, Edmonton, Canada.*

Supplementing dietary fats during late gestation period has certain advantages, but its effects on the incidence of dystocia, calf weight and colostrum quality are sparsely reported. Our objective was to investigate whether prepartum diets supplemented with sunflower or canola seed will affect calf birth-weight, calving-ease and colostrum immunoglobulin content. Pregnant Holstein cows, blocked by BCS, were assigned to 1-of-3 prepartum diets supplemented with canola (n = 43, CAN; high oleic acid), sunflower (n = 46, SUN; high linoleic acid), or control (no oilseed, n = 43; CON) from 35 d (d 35) before expected calving date until parturition (d 0). The concentrate portion of CAN- and SUN-diets contained 0.99 kg rolled oilseeds (DM basis), providing 0.27 kg/d oleic or 0.31 kg/d linoleic acid. Feed intake was recorded daily from d -35 to d 0, and BCS was evaluated on d -35 and d 0. After parturition, colostrum samples (n = 13 per treatment) were collected at first milking and stored at -20°C until evaluating total fat, protein, fatty acid profile and IgG. Calves (n = 132) were weighed at birth. Colostrum immunoglobulin content was estimated using a Brix refractometer. Cows fed CON had greater ($P < 0.05$) mean DMI (15.3 ± 0.6 kg/d) than those fed SUN (13.3 ± 0.5) and CAN (13.5 ± 0.5) during prepartum. The BCS on d -35 did not differ among treatments, but cows fed SUN (3.5 ± 0.0) and CAN (3.5 ± 0.0) had higher BCS on d 0 than CON (3.4 ± 0.0). The difference in BCS between d -35 and 0 was greater in SUN (0.22 ± 0.02) than in CON (0.12 ± 0.02) but not CAN (0.18 ± 0.02). Total fat content of colostrum (%) was higher in CON (5.8 ± 0.5) compared with CAN (4.5 ± 0.4) and SUN (3.8 ± 0.4), whereas, total protein (%) was significantly higher in SUN (15.0 ± 0.6) than in CON (12.1 ± 0.8) and CAN (12.5 ± 0.8) fed cows. Mean colostrum immunoglobulin (brix%) was significantly higher in SUN (24.1 ± 0.9) than in CON (20.4 ± 1.0) and CAN (20.0 ± 1.0). Cows given SUN during prepartum delivered heavier (kg) calves (44.3 ± 0.9) than those fed CON (41.2 ± 0.8) or CAN (42.9 ± 0.8). Moreover, cows fed SUN (35%) during prepartum had a tendency to have higher incidence of dystocia at parturition than those fed CON (17%, P = 0.07) or CAN (18%, P = 0.08). In summary, cows fed supplemental oilseeds during late gestation consumed less DM than those fed a no oilseed control diet, but had greater BCS at parturition. Calf birth weight and the incidence of dystocia were higher in cows fed SUN; colostrum IgG and total protein content were also higher in cows fed SUN.

Key Words: colostrum, immunoglobulin, oilseed

0520 Effect of altering the dietary ratio of n-6 to n-3 fatty acids on luteolytic mechanism in dairy cows. L. F. Greco*[1], J. T. Neves Neto[2], A. Pedrico[2], F. S. Lima[2], R. S. Bisinotto[1], N. Martinez[1], E. S. Ribeiro[1], W. W. Thatcher[1], C. R. Staples[1], and J. E. P. Santos[1], *[1]Department of Animal Sciences, University of Florida, Gainesville, [2]University of Florida, Gainesville.*

Objectives were to evaluate the impacts of altering the ratio of dietary n-6 to n-3 fatty acids (FA) on timing of luteolysis, uterine production of prostaglandin $F_{2\alpha}$, and endometrial fatty acid profile and gene expression in dairy cows. Diets were supplemented (1.43% DM) with a mixture of Ca salts of fish oil, safflower oil and palm oil to create different ratios of n-6 to n-3 FA; 4, 5, and 6 parts of n-6 to 1 of n-3 FA (R4; R5; R6). Cows were blocked by milk production from 6 to 10 d in milk (DIM) and then assigned randomly to 1 of the 3 dietary treatments. Cows had the estrous cycles synchronized starting at 40 DIM. An indwelling catheter was inserted in the tail vessel on d 15 of the estrous cycle and blood was sampled every 2 h from estrous cycle d 16 to 23. Progesterone and 13,14,dihydro-15-keto-$PGF_{2\alpha}$ metabolite (PGFM) were measured in plasma. Cows had the estrous cycle resynchronized and endometrial tissue was collected for biopsy on d 8 of the cycle. Gene expression and FA profile were measured. Data were analyzed using MIXED procedure of SAS (SAS Inst. Inc., Cary, NC). Treatment did not influence the length of the estrous cycle or concentrations of progesterone in plasma. Basal PGFM concentrations did not differ (P = 0.66) among treatments. The number of PGFM pulses decreased (P = 0.05) as the ratio n-6 to n-3 FA increase, and they averaged 5.6, 4.3, and 3.8 pulses, for cows fed R4, R5, and R6, respectively. The area under the curve of the largest PGFM pulse increased as the ratio n-6 to n-3 increased (P = 0.02) and were 764, 958, and 1953 pg/h per mL, for cows fed R4, R5, and R6, respectively. The concentrations of arachidonic acid increased (R4 = 8.09, R5 = 10.35, and R6 = 11.04% of the identified FA; P = 0.01) and of eicosapentaenoic acid decreased linearly (R4 = 2.29, R5 = 1.90, and R6 = 1.83% of the identified FA; P = 0.03) in the endometrium by altering the ratio of n-6 to n-3 from R4 to R6. Of the genes evaluated, expression of the oxytocin receptor, estrogen receptor and steroidogenic acute regulatory protein linearly increased as the diet change from R4 to R6. Altering dietary ratio of n-6 to n-3 FA of lactating dairy cows influenced the pattern of prostaglandin synthesis, the FA profile, and gene expression of the endometrium, but did not influence the length of the estrous cycle.

Key Words: dairy cow; fatty acid; luteolysis

PHYSIOLOGY AND ENDOCRINOLOGY: NOVEL APPROACHES TO IMPROVING REPRODUCTIVE SUCCESS IN DOMESTIC ANIMALS

0521 Ovarian and endocrine responses and efficacy associated with three ovulation synchronization strategies (Heatsynch, Doublesynch, and Estradoublesynch) in Murrah buffaloes.

R. Mirmahmoudi*[1] and B. S. Prakash[2], [1]*Department of Animal Science, Faculty of Agriculture, University of Jiroft, Jiroft, Iran,* [2]*National Dairy Research Institute, Karnal, India*.

Experiments were conducted on 71 cycling and 37 anestrus buffalos to investigate; (a) the endocrine changes, timing of ovulation, and efficacy of Estradoublesynch ($PGF_{2\alpha}$ 0, GnRH 2, $PGF_{2\alpha}$ 9, Estradiol Benzoate; EB 10), Heatsynch (GnRH 0, $PGF_{2\alpha}$ 7, EB 8), and Doublesynch ($PGF_{2\alpha}$ 0, GnRH 2, $PGF_{2\alpha}$9, GnRH 11) protocols in cycling buffaloes, and (b) to compare the efficacy of Estradoublesynch, Heatsynch, and Doublesynch protocols for fertility improvement in cycling and anestrus buffaloes. Follicle size and ovulation rate were determined following all GnRH and EB treatments using transrectal ultrasonography at 2-h intervals. Plasma progesterone and total estrogen concentrations were determined in blood samples collected at daily intervals, beginning 2 d before onset of protocols until day of second ovulation detection. Plasma LH, total estrogen and progesterone concentrations were determined in blood samples collected at 30-min intervals post-GnRH and EB injections until detection of ovulation. The first ovulatory rates were significantly ($P < 0.05$) higher in Doublesynch (90%) and Estradoublesynch (83.3%) protocols than that in Heatsynch protocol (36.4%). The first LH Peak concentrations in Estradoublesynch (73.3 ± 9.2 ng/mL) and Doublesynch (99.8 ± 28.5 ng/mL) protocols were significantly ($P < 0.05$) higher than that of Heatsynch (55.3 ± 7.4 ng/mL) protocol. In both Estradoublesynch and Doublesynch protocols, the total estrogen concentration gradually increased from the day of GnRH administration coinciding with LH peak, and then gradually declined to the basal level until the time of ovulation detection. However, in Heatsynch protocol, the gradual increase in total estrogen concentration after GnRH was observed only in those buffaloes which responded to treatment with ovulation. In both Estradoublesynch and Heatsynch protocols, ovulatory follicles size increased from GnRH/EB injections until ovulation. The pregnancy rates after Estradoublesynch (62.2%) and Doublesynch (58.1%) protocols were significantly ($P < 0.05$) higher than that achieved after Heatsynch protocol (32.5%). Our observations demonstrated that the Estradoublesynch and Doublesynch protocols can be potentially used to obtained satisfactory pregnancy rates after TAI in both cycling and anestrus buffaloes.

Key Words: estradoublesynch, heatsynch, doublesynch

0522 Cholesterol-loaded cyclodextrin improves the post-thaw semen quality but not the fertility in Sahiwal bulls.

A. Sattar*[1], A. G. Tarin[1], N. Ahmad[1], K. Javed[2], M. Ahmad[1], A. Razzaq[1], K. Ahmad[3], and M. Younis[4], [1]*Department of Theriogenology, University of Veterinary and Animal Sciences, Lahore, Pakistan,* [2]*Department of Livestock Production, University of Veterinary and Animal Sciences, Lahore, Pakistan,* [3]*Livestock Experiment Station, Fazilpur, Rajanpur, Pakistan,* [4]*Semen Production Unit, Qadirabad, Sahiwal, Pakistan*.

Sahiwal cattle is the best dairy breed of Pakistan, whose pure-bred population is reduced to an extent where it can be declared as endangered. AI is a tested tool for genetic improvement and conservation. During cryopreservation, cholesterol is an important component in the regulation of membrane fluidity. The objective of the present study was to determine if addition of cholesterol in semen extender has a beneficial effect on its post-thaw semen quality and pregnancy rate in Sahiwal bulls. Experiment 1: Cholesterol was added to Tris-citric acid semen extender in the form of cholesterol-loaded cyclodextrin (CLC). Extended semen was incubated with CLC at room temperature for 15 min before the addition of egg yolk and glycerol. Five replicates of each bull ($n = 3$) were separately evaluated and further processed with at least 60% sperm motility. Semen samples were diluted at 37°C in extender containing either 1 mg (LOW), 2 mg (MEDIUM), 3 mg (HIGH) of CLC or without (CON) per mL containing 120 million spermatozoa. Post-thaw motility (PTM), live spermatozoa (LS), plasma membrane integrity (PMI), and normal apical ridge (NAR) were assessed using standard procedures. Mean PTM, LS, and NAR values were significantly ($P < 0.05$) higher in MEDIUM group (50.33 ± 1.50, 59.53 ± 2.32, and 65.13 ± 1.63%, respectively) as compared with CON and LOW groups, but did not differ ($P > 0.05$) with HIGH group. Mean PMI was significantly ($P < 0.05$) higher in MEDIUM group (60.73 ± 1.49%) as compared with CON, but did not differ ($P > 0.05$) with those of LOW and HIGH groups. Experiment 2: Semen doses from MEDIUM ($n = 94$) or CON ($n = 94$) were used for fertility trial ($n = 188$). Pregnancy rate was numerically higher (63%) in cows inseminated with semen of MEDIUM group as compared with CON (57%), but did not differ ($P > 0.05$). It is concluded that addition of cholesterol in MEDIUM concentration (2 mg CLC) to Sahiwal bull semen can improve post-thaw semen quality, but not fertility as compared with CON group.

Key Words: cholesterol-loaded cyclodextrin, Sahiwal bull, semen

0523 Effects of administration of prostaglandin $F_{2\alpha}$ at initiation of the 7-d CO-Synch + CIDR estrus synchronization protocol for replacement beef heifers. V. R. G. Mercadante*[1], L. E. Kozicki[2], F. M. Ciriaco[1], D. D. Henry[1], C. R. Dahlen[3], R. N. Funston[4], J. E. Larson[5], G. A. Perry[6], T. L. Steckler[7], and G. C. Lamb[1], *[1]University of Florida, Marianna, [2]Pontifical Catholic University (PUCPR), Curitiba, Brazil, [3]North Dakota State University, Fargo, ND, [4]University of Nebraska, North Platte, [5]Mississippi State University, Mississippi State, [6]South Dakota State University, Brookings, [7]University of Illinois, Simpson.*

We determined the effect of administration of $PGF_{2\alpha}$ at CIDR (controlled internal drug release device) insertion during the 7-d COSynch + CIDR ovulation synchronization protocol on subsequent pregnancy rates of replacement beef heifers. At 10 locations, heifers were synchronized with the 7-d CO-Synch + CIDR protocol (100 µg injection of GnRH at CIDR insertion [d -10] with 25 mg injection of $PGF_{2\alpha}$ at CIDR removal [d -3], followed by an injection of GnRH and fixed-time artificial insemination [TAI] 54 h later on d 0). Heifers were stratified by BCS before being assigned to 1 of 2 treatments: (1) CO-Synch + CIDR (n = 498); and (2) heifers received a 25 mg injection of PGF at CIDR insertion of the CO-Synch + CIDR protcol (PG-CO-Synch + CIDR; n = 501). Follicle dynamics and corpus luteum development were assessed on d -10 and -3, and pregnancy status determined on d 30 to 35. Blood was collected on d -20, -10, -3, and 0 to determine P4. Overall TAI pregnancy rates (54.0 ± 2.9% and 50.7 ± 2.9%, for CO-Synch + CIDR and PG-CO-Synch + CIDR, respectively) did not differ (P = 0.428) between treatments. A location effect (P < 0.001) existed with pregnancy rates being the greatest at the FL1 location (75.0 ± 8.1%) and the poorest at the MS1 location (28.6 ± 9.3%). Of the 521 heifers in which cyclic status was assessed 81% had attained puberty. No treatment × cyclic status interaction existed; however, pregnancy rates of heifers that had attained puberty (55.0 ± 2.5%) tended (P = 0.080) to be greater than those heifers that were prepubertal (44.2 ± 5.2%). A treatment × concentrations of P4 interaction existed where concentrations of P4 were greater (P < 0.001) for CO-Synch + CIDR (6.31 ± 0.40 ng/mL) than PG-CO-Synch + CIDR (4.63 ± 0.40 ng/mL) on d -3. Similarly, corpus luteum (CL) volume did not differ between treatments on d -10, but CL volume tended (P = 0.059) to be greater for CO-Synch + CIDR (2.24 ± 1.14 cm^3) than PG-CO-Synch + CIDR (1.47 ± 1.14 cm^3) on d -3. Diameter of the largest follicle on d -10 (10.7 ± 1.4 mm) and -3 (11.6 ± 1.4 mm) did not differ between treatments. We concluded that administration of $PGF_{2\alpha}$ at CIDR insertion of the CO-Synch + CIDR protocol failed to increase TAI pregnancy rates in replacement beef heifers, but decreased concentrations of P4 and tended to decrease CL volume at CIDR removal.

Key Words: ovulation synchronization, artificial insemination, beef heifer

0524 Modifications to Ovsynch improve fertility during resynchronization: Evaluation of presynchronization with GnRH 6 d before Ovsynch and addition of a second PGF treatment. P. D. Carvalho*[1], M. J. Fuenzalida[2], A. Ricci[2], M. Luchterhand[2], J. M. Mulcahy[2], R. V. Barletta[2], G. M. Baez[2], V. G. Santos[2], M. C. Amundson[2], J. N. Guenther[2], A. H. Sousa[2,3], M. C. Wiltbank[1], and P. M. Fricke[2], *[1]University of Wisconsin, Madison, [2]Department of Dairy Science, University of Wisconsin-Madison, Madison, [3]University of California Cooperative Extension, Tulare.*

Recent modifications to Ovsynch, such as presynchronization with GnRH and addition of a second PGF have, at times, appeared to improve synchronization and fertility to the timed AI protocol; however, combining these 2 methods may further optimize the hormonal environment. Lactating Holstein cows were randomly assigned to a 2x2 factorial design to compare main effects of presynchronization with GnRH (± GnRH) 6 d before beginning an Ovsynch protocol, and a second PGF injection (± PGF) administered 24 h after the first on P/AI. For first TAI, cows were presynchronized with 2 injections of PGF 14 d apart, and cows detected in estrus after the second PGF injection were inseminated and removed from the experiment. Nonpregnant cows were resynchronized using an Ovsynch protocol initiated 32 ± 3 d after AI. Blood samples collected from all cows at the first GnRH (G1), at the PGF, and at the last GnRH (G2) injections of the Ovsynch protocol were assayed for progesterone (P4) concentrations. At 32 d after TAI, pregnancies per AI (P/AI) was greatest for cows presynchronized with GnRH and receiving a second PGF injection, intermediate for cows receiving the second PGF injection only and for cows presynchronized with GnRH only, and least for controls [(39.6% (91/230), 35.6% (73/205), 31.8% (77/242), 30.3% (67/221), respectively; P = 0.18]. Interestingly, treatments affected P/AI only for resynchronized cows [41.0% (57/139), 32.8% (39/119), 27.9% (41/147), 24.6% (35/142), respectively; P = 0.02], but not for cows receiving first TAI [37.4% (34/91), 39.5% (34/86), 37.9% (36/95), 40.5% (32/79), respectively, P = 0.96]. Fewer (P < 0.01) cows presynchronized with GnRH had low (< 0.5 ng/mL) P4 at G1 compared with cows not presynchronized (12.8 vs. 24.8%), and P4 was greater (P = 0.05) at the PGF injection for cows presynchronized with GnRH (4.4 vs. 4.0 ng/mL). Surprisingly, differences in P4 at PGF were only detected for resynchronized cows (P = 0.09) and not for cows receiving first TAI (P = 0.23). Cows receiving the second PGF injection had less (P < 0.01) P4 at G2 compared with cows not receiving the second PGF injection (0.2 vs. 0.4 ng/mL). We conclude that presynchronization with GnRH 6 d before

beginning an Ovsynch protocol increased P4 at the PGF injection of an Ovsynch protocol, and a second PGF injection 24 h after the first decreased P4 at TAI resulting in more P/AI in resynchronized cows. Supported by Hatch project WIS01171.

Key Words: Ovsynch; resynchronization; fertility

0525 The effects of prenatal stress and postnatal temperament on age and body weight at first sperm, puberty, and sexual maturity in Brahman bulls. M. C. Roberts*[1], R. C. Vann[2], D. A. Neuendorff[1], B. P. Littlejohn[1], D. G. Riley[3], J. A. Carroll[4], T. H. Welsh, Jr.[5], and R. D. Randel[1], *[1]Texas A&M AgriLife Research, Overton, [2]MAFES–Brown Loam Experiment Station, Mississippi State University, Raymond, [3]Texas A&M AgriLife Research, College Station, [4]USDA-ARS, Livestock Issues Research Unit, Lubbock, TX, [5]Texas A&M University Department of Animal Science, College Station.*

The objectives of this study were to determine if prenatal stress (PNS) or postnatal temperament affect age and BW at first sperm, puberty, and sexual maturity. Based on temperament, pregnant Brahman cows were assigned to a control (n = 44; C) or transport group (n = 45; transportation stress for 2 h on 60, 80, 100, 120, and 140 ± 5d of gestation; PNS). At weaning, bulls (n = 25 C and n = 18 PNS) were selected for this study. Temperament was assessed at weaning using temperament score [TS; (PS + EV)/2], pen score (PS; 1 = calm and 5 = excitable), and exit velocity (EV = m/s). These TS were then converted into temperament classes of calm (TS = < 1.78, n = 26), intermediate (TS = 1.7 to 2.90, n = 9) and temperamental (TS = > 2.90, n = 8). Bulls were measured every 2 wk from 10 mo of age for BW, scrotal circumference (SC), and right and left testis length. Electroejaculation was used to collect semen when SC reached 24 cm. Semen was analyzed for sperm motility and concentration using a hemacytometer. Sexual maturation was characterized by first sperm (the first visible sperm in the ejaculate), puberty (50 × 10^6 sperm in the ejaculate), and sexual maturity (500 × 10^6 sperm in the ejaculate). Paired testes volume (PTV) was calculated as PTV = [0.0396125 × (average testes length) × (SC) ^{2}]. Dependent variables were analyzed using repeated measures, mixed linear models. Fixed effects included temperament class, treatment, and interaction effects. Random animal effects were across repeated days. Age at first sperm, puberty and sexual maturity were similar between C and PNS bulls (P = 0.47, 0.73, 0.99, respectively). Times between first sperm and puberty (P = 0.32) and puberty to sexual maturity (P = 0.92) were not affected by PNS. Temperamental bulls had a greater (P = 0.009) time (69.25 ± 11.45 d) from puberty to sexual maturity than calm (28.47 ± 7.53 d) or intermediate bulls (38.19 ± 9.95 d). BW at first sperm was greater for PNS (382.16 ± 11.29 kg) than C bulls (353.19 ± 10.55 kg). Scrotal circumference at first sperm was greater (P = 0.03) in temperamental (26.8 ± 0.7 cm) than calm (25.5 ± 0.5 cm) or intermediate (25.1 ± 0.6 cm) bulls. There was a tendency for temperamental bulls to have a greater PTV at first sperm (P = 0.06) and sexual maturity (P = 0.07) than calm or intermediate bulls. While PNS influenced BW, SC, and PTV at first sperm, ages at puberty or sexual maturity were not affected by PNS. Temperamental bulls had retarded sexual development between puberty and sexual maturity.

Key Words: prenatal stress, temperament, bull sexual maturity

0526 Equine chorionic gonadotropin improves follicular dynamics, estrus expression, ovulation, and pregnancy rate in controlled internal drug release device based estrus synchronization protocol in Nili-Ravi buffalo. M. I. Naveed, A. Husnain, U. Riaz, M. Hassan, A. Sattar*, and N. Ahmad, *Department of Theriogenology, University of Veterinary and Animal Sciences, Lahore, Pakistan.*

Reproduction of buffalo is hampered due to poor ovarian reserves, vague estrus signs, anestrus, prolonged postpartum and calving intervals, and decreased fertility. Synchronization of estrus and ovulation including CIDR (controlled internal drug release device) based protocols are well established in cows and are gaining popularity in buffaloes. However, these need modifications based on physiology of estrous cycle in buffaloes. The present study tested the hypothesis that if the addition of equine chorionic gonadotropin (eCG) to a CIDR based synchronization protocol improves ovarian follicular dynamics, estrus behavior, ovulation and pregnancy rate in Nili-Ravi buffalo. Lactating multiparous Nili-Ravi buffaloes (n = 88) received CIDR (1.38 g progesterone Pfizer Co, USA) device for 7 d and prostaglandin F2α (Dalmazine, cloprostenol, Fatro, Italy) on d 6. These buffaloes were randomly assigned to receive either saline (without eCG, n = 45) or equine chorionic gonadotropin 1000 IU (Chronogest PMSG, Intervet, Holland) i.m. (eCG, n = 43) concurrent with prostaglandin F2α treatment of the CIDR protocol (d 6). Fixed time, 2 inseminations were performed at 48 and 60 h after CIDR removal (d 7). Pregnancy was diagnosed 35 to 40 d post-AI using transrectal ultrasonography. The mean size of dominant follicle just before ovulation did not differ in eCG treated buffaloes compared with or without eCG (14.8 ± 0.3 vs.14.5 ± 0.5; P > 0.05). Mean growth rate of the ovulatory follicle was higher in the eCG group compared with without eCG (1.8 mm ± 0.0 vs.1.4 mm ± 0.1; P < 0.05). Mean interval from CIDR removal to ovulation was shorter in eCG-treated buffaloes compared to no eCG (70.9 ± 2.0 h vs. 77.5 ± 2.3 h; P < 0.05). The estrus response and intensity was greater in the eCG group than the group without eCG (100 vs. 91%; P < 0.05), (3.2 ± 0.1vs. 2.4 ± 0.1; P < 0.05), respectively. Similarly, ovulation and pregnancy rates were higher in the eCG group than those without eCG (82.9% [34/41] vs. 69.4% [26/37]; P > 0.05), (53.4% [23/43] vs. 24.4% [11/45]; P < 0.05), respectively. Therefore,

we conclude that addition of eCG before P4 device removal improves ovulatory follicle growth rate, estrus behavior, and pregnancy rate in FTAI program in buffalo. These data have strong implications in hastening buffalo reproduction.

Key Words: equine chorionic gonadotropin, fertility, buffalo

0527 Effects of prenatal transportation stress on endogenous and exogenously-induced luteinizing hormone secretion in sexually mature Brahman bulls. B. P. Littlejohn*[1,2], M. C. Roberts[1,2], M. N. Bedenbaugh[1], A. W. Lewis[2], D. A. Neuendorff[2], D. G. Riley[1,3], J. A. Carroll[4], R. C. Vann[5], M. Amstalden[1], T. H. Welsh, Jr.[1,3], and R. D. Randel[2], *[1]Texas A&M University Department of Animal Science, College Station, [2]Texas A&M AgriLife Research, Overton, [3]Texas A&M AgriLife Research, College Station, [4]USDA-ARS, Livestock Issues Research Unit, Lubbock, TX, [5]MAFES–Brown Loam Experiment Station, Mississippi State University, Raymond.*

The effect of prenatal transportation stress (PNS) on secretion of LH before and after GnRH stimulation in sexually mature Brahman bulls was studied in 12 control and 11 PNS bulls. Control bulls were derived from nontransported pregnant cows, and PNS bulls were derived from cows transported for a 2-h period at 60, 80, 100, 120, and 140 ± 5 d of gestation. Temperament of each bull was assessed at weaning by pen score (PS; 1 = calm and 5 = excitable), exit velocity (EV; m/sec) and temperament score [TS = (PS + EV)/2]. Bulls were electroejaculated every 2 wk beginning at a scrotal circumference of 24 cm through sexual maturity (i.e., 500,000,000 sperm/ejaculate). Within 7 to 21 d after reaching sexual maturity, bulls were fitted with jugular vein cannulas, and blood samples were collected at 15-min intervals for 6 h to determine the pattern of LH release. GnRH was then administered intravenously (10 ng/kg BW) and blood collection continued at 15-min intervals for an additional 8 h. Concentrations of LH in serum were determined by RIA. Amplitude of a detectable LH pulse, baseline concentration of LH, and area under the LH curve (AUC) were calculated for the 4-h period immediately preceding GnRH administration. Luteinizing hormone pulse incidence was evaluated using Pulse XP algorithm. The amplitude and height of the GnRH-induced LH release, AUC post-GnRH administration, and the duration of the GnRH-induced LH release were determined. Data were analyzed using a fixed effect model, with treatment and temperament classification included in the model. The occurrence of LH pulses during the pre-GnRH period was compared between treatment groups by chi-square analysis. More PNS bulls exhibited an LH pulse before GnRH injection (10 of 11; $P < 0.01$) than control bulls (3 of 12). No other characteristic associated with the release of LH during the pre-GnRH treatment evaluated in this study differed between groups ($P > 0.1$). All bulls responded similarly to exogenous GnRH, with the exception of the duration of the LH response which was greater ($P = 0.02$) in PNS bulls (268 ± 18 min) relative to control bulls (207 ± 16 min). Pattern of LH secretion before GnRH and duration of GnRH-induced LH release differed between PNS and control bulls. Stress during prenatal development may affect secretion of LH in sexually mature Brahman bulls.

Key Words: bulls, prenatal stress, luteinizing hormone

0528 Effects of artificial insemination and natural service breeding systems on calving characteristics and weaning weights of resultant progeny. P. L. Steichen[1], S. I. Klein[1], Q. Larson[1], K. M. Bischoff[2], V. R. G. Mercadante[3], G. C. Lamb[3], C. S. Schauer[4], B. W. Neville[5], and C. R. Dahlen*[1], *[1]North Dakota State University, Fargo, [2]University of Florida, NFREC, Marianna, [3]University of Florida, Marianna, [4]Hettinger Research Extension Center, Hettinger, ND, [5]North Dakota State University, Streeter.*

Angus crossbred females ($n = 1067$) were used to evaluate effects of 2 breeding systems on calving characteristics and weaning weight of progeny. In 2 yr, females were stratified by age and BCS, then assigned randomly to 1 of 2 breeding systems: (1) exposed to natural service bulls for duration of the breeding season (NS; $n = 541$), or (2) exposed to ovulation synchronization and a fixed-time AI (7-d CO-Synch + CIDR) on d 0, followed by exposure to natural service bulls for duration of the breeding season (TAI, $n = 535$). Bulls were introduced to all females on d 1 and both treatments were managed as a cohort in the same pastures. Calving date, calving ease (scale of 1 to 5; 1 = no assistance and 5 = caesarean), calf vigor (scale of 1 to 5; 1 = normal calf and 5 = stillbirth), and birth weights were recorded within 24 h of calf birth and weights were also collected from each calf at weaning. Binomial data were analyzed using Proc GLIMMIX of SAS (SAS Inst. Inc., Cary, NC), whereas continuous data were analyzed using Proc GLM. More ($P < 0.01$) TAI females (53.2%) gave birth in the first 21 d of the calving season compared with the NS treatment (41.3%). From d 22 to 42, more ($P < 0.01$) females in the NS treatment (32.3%) gave birth compared with females in the TAI treatment (21.6%). No differences ($P \geq 0.34$) existed between treatments in the proportion of females that calved after d 43 or failed to have a calf. Overall mean calving date for females in the TAI treatment (d 16.7 ± 0.05 d) was 7 d earlier ($P < 0.01$) than that of females in the NS treatment (d 23.6 ± 0.93). However, no differences ($P \geq 0.37$) were present between treatments in calving ease (1.13 ± 0.02) or calf vigor (1.13 ± 0.04). Calves from the TAI treatment (37.9 ± 0.32 kg) were lighter at birth compared with calves from the NS treatment (39.5 ± 0.35 kg). In contrast, calves from the TAI treatment (207.3 ± 1.51 kg) had greater ($P = 0.01$) weaning weights compared with calves from the NS treatment (202.4 ± 1.50 kg). Incorporation of TAI into beef cattle breeding systems resulted

in calves born earlier in the calving season and heavier calves at weaning compared with natural service breeding systems.

Key Words: artificial insemination, calving characteristics, natural service

0529 Impact of manipulation of progesterone concentrations during follicular development on ovulatory follicle growth and timed artificial insemination pregnancy rate in beef cows.

F. M. Abreu*[1], M. A. Coutinho da Silva[1], L. H. Cruppe[1], M. L. Mussard[1], B. R. Harstine[1], G. A. Bridges[2], T. W. Geary[3], and M. L. Day[1], *[1]The Ohio State University, Columbus, [2]University of Minnesota, Grand Rapids, [3]USDA ARS Fort Keogh, Miles City, MT.*

This experiment was conducted to investigate the role of decreased progesterone (P4) concentrations during follicular development on fertility in multiparous beef cows ($n = 228$; Angus × Simmental) from 3 locations ($n = 92$; $n = 63$; $n = 73$). Ovulation was presynchronized with the 5-d CO-Synch + CIDR (controlled internal drug release device) program with the day of the final GnRH designated as d −6. On d 0, all ovarian follicles were ablated. Cows were stratified by age and days postpartum within location, and assigned to receive either a previously used CIDR and two 25-mg PGF doses 8 h apart (low-P4; L; $n = 115$) or a new CIDR (high-P4; H; $n = 113$) on d 0. On d 5, CIDR were removed, two 25-mg PGF doses administered and estrus detection tail paint applied. Tail paint scoring (TPS; 1 = paint completely removed; 2 = paint partially removed; 3 = paint largely undisturbed and no evidence of mounting), timed-AI (TAI) and administration of 100 μg GnRH were performed on d 8. Blood samples for P4 analysis were collected on d 5. Ultrasonography was conducted on d 0, 5, and 8 to assess ovarian structures, and d 35 for pregnancy diagnosis. Cows without a CL on d 0 were removed from all analyses. Across locations, P4 concentrations on d 5 were greater ($P < 0.05$) in the H (4.91 ± 0.13 ng/mL) than L (0.99 ± 0.06 ng/mL); a treatment by location interaction ($P < 0.05$), predominantly due to elevated P4 concentrations in 1 location, was detected. Follicle diameter on d 5 was greater ($P < 0.05$) in the L (8.9 ± 0.2 mm) than H (7.4 ± 0.1 mm) treatment, but did not differ between treatments (12.0 ± 0.1 mm) at TAI. Hence, follicle growth from d 5 to 8 was greater ($P < 0.05$) in the H (1.5 ± 0.1 mm/d) than in the L (1.3 ± 0.1 mm/d) treatment. Distribution of TPS differed ($P < 0.05$) between treatments with a majority of cows in the H treatment with TPS 3 (57%) and a majority in the L treatment with TPS 1 (54%). Cows with TPS 1 or 2 had a greater ($P < 0.05$) PR than cows with a TPS 3. However, PR did not differ between the H (67.3%) and L (67.8%) treatments. In conclusion, decreased P4 resulted in an increased percentage of cows in estrus before TAI, but did not impact timed AI pregnancy rate in beef cows.

Key Words: progesterone, fertility, cows

0530 Reproductive performance of lactating dairy cows after resynchronization with ovsynch or a program aimed to maximize artificial insemination in estrus and fertility of timed artificial inseminations based on ovarian structures.

J. O. Giordano*[1], R. D. Watters[2], R. Wijma[1], and M. L. Stangaferro[1], *[1]Department of Animal Science, Cornell University, Ithaca, NY, [2]Quality Milk Production Services, Cornell University, Ithaca, NY.*

Our objective was to compare the reproductive performance of dairy cows after enrollment in a program that combined resynchronization with Ovsynch and AI in estrus based on activity (AIAct) vs. a program aimed to maximize AIAct and fertility of timed AI (TAI) services by assigning treatments according to the ovarian structures present at nonpregnancy diagnosis (NPD). One day after NPD by transrectal ultrasonography at 31 ± 3 d after AI, lactating cows were blocked by parity (primiparous vs. multiparous) and randomly assigned to: (1) Control (CON; $n = 469$): resynchronization with Ovsynch-56 (GnRH-7d-PGF-56h-GnRH-16h-TAI) at 32 ± 3 d after AI combined with AIAct or 2) Treatment (TRT; $n = 430$): cows with a corpus luteum (CL) ≥ 20 mm (TRT-CL) received a PGF injection and AIAct for 9 d. Cows with no CL or CL < 20 mm (TRT-NoCL) received a GnRH injection 2 d after enrollment. Cows in TRT-CL and TRT-NoCL not AIAct were enrolled in a 5d-Ovsynch+Progeterone protocol (GnRH + CIDR-5d-PGF + CIDRremoval-1d-PGF-32h-GnRH-16h-TAI) 9 and 7 d after the PGF or GnRH injection, respectively. The percentage of cows with a CL ≥ 20 mm at NPD was similar ($P = 0.79$) for CON (64.2%; 301/469) and TRT (63.3%; 272/430) whereas, it was greater ($P = 0.005$) for multiparous than primiparous cows (66.8 vs. 57.1%). Cows in CON (mean 9.5 d, median 10 d) were reinseminated at a faster rate ($P < 0.01$; HR 2.9 CI: 2.4 to 3.5) than cows in TRT (mean 13.2 d, median 17 d). Parity did not affect ($P = 0.76$) time to reinsemination. After enrollment, a greater ($P < 0.001$) percentage of cows received AIAct in TRT (29.8%) than CON (10.4%) whereas, a greater ($P < 0.001$) percentage of cows were AIAct in TRT-CL (38.6%) than TRT-NoCL (14.6%). Pregnancies per AI (P/AI) for cows AIAct were similar ($P = 0.65$) for CON (32.7%; 16/49) and TRT (28.8%; 36/125) and were not affected by parity ($P = 0.37$). Also, P/AI after TAI were similar ($P = 0.47$) for CON (27.9%; 113/405) and TRT (30.4%; 87/286) and were not affected by parity ($P = 0.55$). Pregnancy rate from 0 to 21 d after enrollment was similar ($P = 0.62$) for CON (28.4%; 129/454) and TRT (29.9%; 123/411). Thus, compared with a typical resynchronization program, a program aimed to maximize AIAct and fertility of TAI by assigning treatments according to ovarian structures; increased the percentage of cows AIAct and had similar pregnancy rate by 21 d after NPD, however, time to reinsemination was delayed which could be explained by the small percentage of cows inseminated on activity.

Key Words: resynchronization, estrous activity, dairy cow

PHYSIOLOGY AND ENDOCRINOLOGY: REPRODUCTIVE SUCCESS IN RUMINANTS: A COMPLEX INTERACTION BETWEEN ENDOCRINE, METABOLIC, AND ENVIRONMENTAL FACTORS

0531 Recent advances in the hypothalamic control of reproduction. I. Clarke*, *Monash University, Clayton, VIC 3800, Australia.*

Reproduction is driven by the GnRH cells of the brain, but the pulsatile secretion of GnRH into the hypophysial portal blood is controlled by kisspeptin cells. In the sheep, as in other species, the kisspeptin cells form 2 major populations in the brain, 1 in the arcuate nucleus and the other in the preoptic area. The former appear to mediate the negative feedback effects of sex steroids as well as being initiators of the *positive feedback* effect that elicits the GnRH surge to cause ovulation in the female. The latter facilitate the positive feedback effect. The arcuate nucleus population of kisspeptin cells also produce neurokinin B and dynorphin, leading to their designation as KNDY cells. Kisspeptin expression in the KNDY cells is reduced in the nonbreeding season, further reinforcing the fundamental role these cells play in control of reproduction. In addition, these KNDY cells appear to be involved in the response to altered bodyweight. This is achieved via the signalling of leptin to the KNDY cells either directly or indirectly—kisspeptin gene expression is lower in lean animals, but this can be reversed by administration of leptin. KNDY cells are interconnected to the cells of the arcuate nucleus that produce anorexigenic melanocortins and those that produce the orexigen, neuropeptide Y. This provides a bidirectional interface between metabolic circuits and reproductive circuits. Thus, melanocortins and neuropeptide Y may regulate reproduction independently or via control of kisspeptin cells, providing a way that metabolic function and reproduction are interlinked. Recent data provide strong evidence that KNDY cells are most likely to be the cells that drive the pulsatile secretion of GnRH. Thus, c-Fos labelling in KNDY cells is seen at the time of ram-induced LH secretion (proxy for GnRH pulses) in anestrous ewes. In addition, KNDY cells in brains of animals sampled within 30 min of an endogenous pulse of LH displayed increased c-Fos labelling, compared with cells from animals that were not experiencing an LH pulse at the time of brain collection. Most interestingly, the means by which KNDY cells cause GnRH secretion appears to be due to action on the GnRH terminals within the median eminence. Accordingly, direct application of kisspeptin to the median eminence in vitro causes GnRH secretion. This novel mechanism has forced a revision of the model for neuroendocrine control of reproduction.

Key Words: gonadotropin-releasing hormone

0532 Influence of stress on male reproductive physiology. T. H. Welsh, Jr.*[1], N. H. Ing[1], and R. D. Randel[2], *[1]Texas A&M University, Department of Animal Science, College Station, [2]Texas A&M AgriLife Research, Overton.*

Environmental, physiological, psychological, and managerial stressors have been implicated as causes of reproductive disorders and decreased fertility in animals and humans. Herd reproductive efficiency and the stud industry depend on the sperm producing capabilities and libido of bulls and stallions. With respect to male reproductive physiology, the steroidogenic and spermatogenic functions of the testis can be negatively impacted by stress-induced secretion of endogenous glucocorticosteroids (GC) as well as by treatment with exogenous GC agonists. The testes' gametogenic function, a primary component of male fertility, is dependent on appropriate transmission, receipt, and processing of specific endocrine signals. The deleterious effects of stress on reproductive performance are presumably signaled by GC activation of the glucocorticoid receptor (*NR3C1*). Questions related to molecular mechanisms whereby stress affects specific components of the hypothalamic-pituitary-testicular (HPT) axis of male rodents, primates, cattle, sheep, pigs, horses, and other species have been pursued by the use of in vitro and in vivo methods. This paper will provide a targeted overview of potential impacts of stressors on the endocrine aspects of the HPT axis, with particular focus on direct testicular effects. Specific data to be presented are derived from studies of the influences of endogenous and exogenous GC on androgen biosynthesis and gene expression in testes of bulls and stallions. Chronic administration of a synthetic GC has been reported to increase the incidence of abnormal spermatozoa by direct action or perhaps by disruption of the endocrine or genetic mechanisms that support sperm production in bulls and stallions. Acute elevation of the systemic concentration of GC by pharmacologic methods or by mimicry of physiologic stress have inhibited testicular steroidogenesis and transiently decreased the systemic concentration of testosterone. The inhibitory action of endogenous GC concentrations on testicular steroidogenesis under stressed and nonstressed conditions indicates that activity of the hypothalamic-pituitary-adrenal axis may be of critical importance in establishment or maintenance of a functional HPT axis during prenatal, prepubertal, and postpubertal life. Homeostatic regulation of reproductive processes involves a physiological integration of the adrenal and testicular axes. The biologic and economic importance of deleterious influences of stress on male reproductive processes dictate a thorough evaluation of adrenal–testicular interrelationships in domestic livestock species.

Key Words: stress, steroidogenesis, spermatogenesis

0533 Mechanisms linking infection and innate immunity in the female genital tract with infertility in dairy cattle. I. M. Sheldon*, *Swansea University, Singleton Park, Swansea, UK.*

One of the most common endemic diseases of dairy cattle is bacterial infection of the uterus after parturition. These infections damage the endometrium lining the uterus, reduce the production of milk, and cause infertility. Uterine disease is caused by *Escherichia coli, Trueperella pyogenes*, anaerobic bacteria, and viruses. These microbes posses a range of virulence factors that caused inflammation and damage in the endometrium. Innate immunity is an ancient system of defence against microbes, dependent on host cellular pattern recognition receptors such as toll-like receptors (TLR), which bind pathogen-associated molecular patterns. Epithelial and stromal cells are the first line of defence against microbes in the endometrium, and they express the most TLR. Activation of TLR signalling leads to the secretion of chemokines, cytokines, and prostaglandins, which attract and activate neutrophils and macrophages to clear the microbes. Microbial factors and host intracellular pathways regulate the scaling of the innate immune response, and the severity of postpartum uterine disease. Uterine disease also compromises ovarian function, with impacts on the corpus luteum, and on ovarian follicle development from primordial to antral follicles. Whilst healthy ovarian follicles are devoid of immune cells, granulosa cells express TLR and have roles in innate immunity. Pathogen-associated molecular patterns perturb granulosa cell endocrine function, stimulate the secretion of inflammatory mediators from granulosa cells, and lead to damage of oocytes. In conclusion, the fundamental mechanisms of innate immunity and inflammation in the female genital tract of dairy cattle are important for animal health and fertility. *Work in the Sheldon laboratory is funded by the Biotechnology and Biological Sciences Research Council (BBSRC) in the UK*.

0534 Influences of heat stress and uterine diseases on reproduction of dairy cows. J. E. P. Santos*[1], E. S. Ribeiro[1], E. Karakayan[2], K. N. Galvão[3], and F. S. Lima[4], *[1]Department of Animal Sciences, University of Florida, Gainesville, [2]University of Florida, Gainesville, [3]Department of Large Animal Clinical Sciences, University of Florida, Gainesville, [4]Cornell University, Ithaca, NY.*

Dairy cows undergo hyperthermia during the summer months in most of the world, which causes a dramatic reduction in establishment and maintenance of pregnancy. Hyperthermia has numerous effects on cellular metabolism and function that help explain reductions in fertility, including altered period of follicle dominance, reduced steroidogenic capacity of follicular and luteal cells, altered endometrial activity, and impaired oocyte quality. This multitude of effects results in reduced fertilization and influences subsequent embryo development, which impairs maintenance of pregnancy. Data are scarce on the associations between season and risk of uterine diseases in dairy cattle, but recent epidemiological studies indicate that incidence of retained placenta and metritis increases during the hot season. Therefore, it is suggested that hyperthermia during late gestation suppress the uterine defensive mechanisms, or elevated temperature and humidity during the hot months alters the environment that predisposes to increased pathogen challenge that induces disease. Unfortunately, data from studies at the University of Florida indicate that reducing hyperthermia by cooling cows during the entire dry period in the summer do not seem to alleviate the negative impacts of heat stress on metritis. It is well described that both retained placenta and metritis are important risk factors for clinical and cytological endometritis, and the multitude of diseases that affect the uterus of the cow also suppress fertility. Heat stress, but also endometrial inflammation, as observed in cows with cytological endometritis, compromises endometrial function, which can alter the secretory activity of the endometrium and lead to inability to establish and maintain pregnancy. Infection of the endometrium with *Trueperella pyogenes*, and likely also by other uterine pathogens, damages the superficial and glandular epithelium and increases the expression of inflammatory genes, and presence of inflammation seem to disrupt embryo development. Cows that develop uterine diseases, either metritis or cytological endometritis, have reduced fertilization, compromised early embryo development, impaired d 15 conceptus elongation, and increased risk of pregnancy loss. The d 15 conceptus of cows with metritis have marked changes in gene expression, and hyperthermia (in vivo or in vitro) dramatically alters mRNA expression of early embryos, and these changes might explain the differences in maintenance of pregnancy in cows that suffer from uterine diseases or heat stress. Collectively, heat stress directly and negatively impacts reproduction while also increasing the risk of uterine diseases that further depress the establishment and maintenance of pregnancy in dairy cows.

Key Words: heat stress, reproduction physiology, endometritis

0535 Cellular and molecular mechanisms of heat stress related to bovine ovarian function. Z. Roth*, *The Hebrew University of Jerusalem, Rehovot, Israel*

In light of the intensive genetic selection for high milk production and the onset of global warming, the reduced fertility of lactating cows during the summer is expected to worsen in coming years. While not entirely clear, the mechanism of fertility reduction appears to be multifactorial in nature, including altered follicular development, depressed follicular dominance, and impaired steroidogenesis and gonadotropin secretion. Heat-induced perturbations in the physiology of

the follicle-enclosed oocyte have also been documented, expressed by impaired cleavage rate and reduced developmental competence. Oocyte alterations include increased polyunsaturated fatty acids in the membrane, reactive oxygen species, ceramide formation, caspase activity, and induction of apoptosis via the sphingomyelin and/or mitochondrial pathways. New insight into the cellular and molecular alterations have revealed heat-induced perturbations in both nuclear and cytoplasmic maturation events—meiosis resumption, metaphase-II plate formation, cytoskeleton rearrangement and translocation of cortical granules. Alterations in mitochondrial distribution (i.e., a low proportion of category-I oocytes) and mitochondrial function (low membrane potential) have been recently reported for oocytes collected during the summer. These were associated with impaired expression of both nuclear (*SDHD* and *ATP5B*) and mitochondrial (*ND2*, *CYTB*, *COXII*) genes which are crucial in the mitochondrial respiratory chain. In addition, season-induced alteration in maternal-mRNA storage was documented, expressed by reduced transcript levels (*C-MOS*, *GDF9*, *POU5F1*, and *GAPDH*) in MII-stage oocytes and embryos, before (2-, 4-, and 8-cell stages) and after (8- to 16-cell stage) embryonic genome activation. These findings clarify the association between cellular and molecular modifications and reduced developmental competence during the hot season. This knowledge is essential for developing new approaches to coping with this unsolved problem.

Key Words: heat stress, bovine ovarian function

PHYSIOLOGY AND ENDOCRINOLOGY: ADVANCES IN ESTROUS SYNCHRONIZATION

0536 Detrimental effect of long term progestin-based protocol on oocyte quality and embryonic development in indigenous goats. C. Navanukraw*[1], A. Kraisoon[2], J. Thammasiri[2], V. Khanthusaeng[2], and S. Navanukraw[2], *[1]Khon Kaen University, Khon Kaen, Thailand, [2]Department of Animal Science, Khon Kaen University, Khon Kaen, Thailand.*

Long-term progesterone treatments for estrus synchronization have been associated with a lesser fertility in ruminants. This experiment was conducted to determine the effects of short-term (7 d) and long-term (14 d) progestin based and pregnant mare serum gonadotropin (PMSG) administration on number of follicles, oocyte quality, and embryonic development in goats. Nulliparous Thai-native goats (n = 36) were randomly assigned into short-term and long-term protocols. Goats in the short-term protocol were inserted with intravaginal sponges containing 60 mg medroxyprogesterone acetate (MAP; Synchrogest esponjas, Spain) for 7 d. Goats in the second group were inserted with the same synthetic progesterone for 14 d. Multiple follicular development was induced by intramuscularly injections of 300 IU PMSG (Synchrogest PMSG, Spain) in both groups on d 6 or d 13 (1 d before sponge withdrawal). Ovariectomy was performed at 24 h after sponge removal to evaluate number of follicles and collect oocyte for in vitro fertilization (IVF). Oocyte quality was determined by morphology of cumulus oocyte complex before in vitro maturation (IVM) as healthy or nonhealthy oocyte. After IVF, embryo was evaluated during the 8-d culture as numbers of cleaved oocyte, morula, and blastocyst embryo. Total numbers of follicles and oocytes were similar for both treatments. Plasma progesterone concentrations were not different during MAP insertion period ($P > 0.05$). However, goats that received the short-term protocol had greater number of follicles 4 to 6 mm, number of healthy oocytes, number of cleaved oocytes, and number of morula embryos than goats received the long term protocol ($P < 0.01$). These data highlight the detrimental effect of long term progestin-based protocol on oocyte quality and embryonic development in goats.

Key Words: synthetic progesterone, oocyte quality, indigenous goat

0537 Exogenous insulin effect on reproductive traits during a Heatsynch protocol in dairy cows. C. C. Brauner*[1], M. E. Lima[1], D. A. Velasco Acosta[1], L. F. Mielke[1], V. O. Freitas[1], E. G. Xavier[2], A. Schneider[1], F. B. Del Pino[1], V. R. Rabassa[1], and M. Nunes Corrêa[1], *[1]Universidade Federal de Pelotas, Pelotas, Brazil, [2]Granjas 4 Irmãos, Rio Grande, Brazil*.

The objective of this study was to evaluate the effects of exogenous insulin administration on reproductive traits in a Heatsynch protocol in dairy cows. Thirty-three multiparous Holstein cows, in a body condition score of 2.5 (on a 5-point scale) reared in a grazing system in Southern Brazil were submitted to a Heatsynch protocol at 84 ± 14 d in milk with an average of 28.33 ± 1.4 kg/d milk. The protocol consisted of one 25 µg of GnRH analogue i.m. injection, and insertion of an intravaginal device with 1.9 g of progesterone (CIDR, controlled internal drug release device) on d 0. Seven days later (d 7) the CIDR insert was removed and cows were given 25 mg PGF2α i.m., followed by 1 mg of estradiol cypionate i.m. (ECP) injection at d 8. At CIDR removal (d7) cows were randomly divided into 2 groups: The insulin group (n = 14) was given 0.25 IU/kg s.c. human insulin, and the control group (n = 19) was subjected to the same synchronization protocol, but without insulin injection. On the same day, blood samples were collected from the coccygeal and serum samples were analyzed for insulin concentrations. From d 8 to 10, cows that demonstrated estrus signs were then inseminated 12 h after detection. Follicular diameter evaluations were performed by transrectal ultrasonography on d 7, 9, and 10 of the protocol. The measurement of the increase in size of the dominant follicle was considered to be preovulatory follicular growth. Data were analyzed using the GLM procedures of NCSS (2005). There was no insulin concentration difference (P = 0.61) between groups at CIDR removal, which were respectively 25.8 ± 2.4 and 27.5 ± 2.4 ng/mL for control and insulin. Insulin administration did not affect (P = 0.85) pre-ovulatory follicular growth, being 5.16 ± 0.5 mm and 5.28 ± 0.6 mm, for the insulin and control groups, respectively. The interval from CIDR removal to AI was similar between groups (P = 0.81), being 59.6 ± 3.4 and 60.8 ± 3.4 h, respectively, for insulin and control groups. Also, no insulin concentrations difference (P = 0.81) were found in cows showing estrus signs or not, 26.32 ± 2.5 and 27.23 ± 2.9 ng/mL, respectively. In conclusion, exogenous insulin injection has no effect on reproductive traits in a Heatsynch protocol in dairy cows.

Key Words: artificial insemination, efficiency, reproduction

0538 Effects of administration of prostaglandin $F_{2\alpha}$ at initiation of the 7-d CO-Synch+CIDR estrus synchronization protocol for suckled beef cows.

V. R. G. Mercadante*[1], L. E. Kozicki[2], F. M. Ciriaco[1], D. D. Henry[1], C. R. Dahlen[3], J. E. Larson[4], B. E. Voelz[4], D. J. Patterson[5], G. A. Perry[6], T. L. Steckler[7], J. S. Stevenson[8], and G. C. Lamb[1], *[1]University of Florida, Marianna, [2]Pontifical Catholic University (PUCPR), Curitiba, Brazil, [3]North Dakota State University, Fargo, [4]Mississippi State University, Mississippi State, [5]University of Missouri, Columbia, [6]South Dakota State University, Brookings, [7]University of Illinois, Simpson, [8]Kansas State University, Manhattan.*

We determined the effect of administration of prostaglandin $F_{2\alpha}$ ($PGF_{2\alpha}$) at CIDR (controlled internal drug release device) insertion during the 7-d CO-Synch+CIDR estrus synchronization protocol on subsequent pregnancy rates of suckled beef cows. At 13 locations, cows were ovulation synchronized with the 7-d CO-Synch + CIDR protocol (100 μg injection of GnRH at CIDR insertion [d -10] with 25 mg injection of $PGF_{2\alpha}$ at CIDR removal [d -3], followed by an injection of GnRH and fixed-time AI [TAI] on d 0). Cows were stratified by days postpartum, BCS, and parity, and assigned to 1 of 2 treatments: CO-Synch + CIDR (n = 819) and PG-CO-Synch + CIDR (a 25-mg injection of $PGF_{2\alpha}$ was administered at CIDR insertion of the CO-Synch + CIDR protocol; n = 827). Follicle dynamics and corpus luteum development were assessed on d -10 and -3, and pregnancy status determined on d 30 to 35. Blood was collected on d -20, -10, -3, and 0 to determine progesterone (P4). Overall TAI pregnancy rates (53.5 ± 1.9% and 50.4 ± 1.9%, for CO-Synch + CIDR and PG-CO-Synch + CIDR, respectively) did not differ (P = 0.802) between treatments. A location effect (P < 0.001) existed with pregnancy rates being the greatest at the KS2 location (67.2 ± 6.1%) and the poorest at the KS4 location (15.3 ± 5.3%). Of the 1217 cows in which cyclic status was assessed, 55% were determined to be cyclic; however, incidence of pregnancy was not associated with cyclic status or the treatment × cyclic status interaction. Concentrations of P4 were greater (P < 0.001) for CO-Synch + CIDR (4.1 ± 0.3 ng/mL) than PG-CO-Synch+CIDR (3.4 ± 0.3 ng/mL) on d -3, whereas diameter of largest follicle on d -3 tended (P = 0.094) to be greater for PG-CO-Synch + CIDR (13.4 ± 0.3 mm) than CO-Synch + CIDR (12.6 ± 0.3 mm). We concluded that administration of $PGF_{2\alpha}$ at CIDR insertion of the CO-Synch + CIDR protocol failed to increase TAI pregnancy rates in suckled beef cows, but at CIDR removal, decreased concentrations of P4 and tended to increase dominant follicle diameter.

Key Words: ovulation synchronization, artificial insemination, beef cow

0539 Split-time artificial insemination: Delayed insemination of nonestrous beef heifers in timed artificial insemination following the 14-d CIDR-PG protocol.

J. M. Thomas*[1], M. R. Ellersieck[1], S. E. Poock[2], M. F. Smith[1], and D. J. Patterson[1], *[1]University of Missouri, Columbia, [2]University of Missouri, College of Veterinary Medicine, Columbia.*

An experiment was designed to test the hypothesis that pregnancy rates in beef heifers after fixed-time artificial insemination (FTAI) may be improved by delaying insemination of those heifers that have not expressed estrus before the standard FTAI time. Estrus was synchronized for 931 heifers across 3 locations using the 14-d CIDR-PG protocol (CIDR insert [controlled internal drug release, 1.38 gm progesterone] on d 0 with removal of CIDR on d 14; 25 mg $PGF_{2\alpha}$ 16 d after CIDR removal on d 30; and 100 μg GnRH on d 33, 66 h after $PGF_{2\alpha}$). Estrous detection aids (Estrotect) were applied at $PGF_{2\alpha}$ on d 30, and expression of estrus was recorded at GnRH on d 33. Treatments were balanced across locations, and heifers within each location were randomly assigned to 1 of 2 treatments based on reproductive tract score (RTS) and weight: (1) FTAI (concurrent with GnRH, 66 h after $PGF_{2\alpha}$) regardless of estrous expression prior or (2) FTAI for heifers having expressed estrus, and delayed AI (20 h after GnRH) for heifers failing to express estrus. A significant effect of treatment was found on AI pregnancy rate, with heifers assigned to treatment 2 achieving a higher AI pregnancy rate than heifers assigned to treatment 1 (54 vs. 46%, P = 0.012). The observed increase in AI pregnancy rate is attributed to the delayed AI of nonestrous heifers in Treatment 2, as AI pregnancy rates for nonestrous heifers were significantly greater for Treatment 2 (49 vs. 34%, P = 0.024), while AI pregnancy rates of estrous heifers did not differ by treatment **(**P = 0.244**)**. In summary, FTAI pregnancy rates in heifers can be improved through a strategy of split-time AI at the standard time of 66 h after $PGF_{2\alpha}$ for heifers that have expressed estrus and delayed insemination at 20 h after GnRH for heifers that have not expressed estrus before the standard AI time in the 14-d CIDR-PG protocol.

Key Words: artificial insemination, estrus synchronization, beef heifer

0540 Split-time artificial insemination: Delayed insemination of nonestrous beef cows in timed artificial insemination following the 7-d CO-Synch + CIDR protocol.

J. M. Thomas*[1], M. R. Ellersieck[1], S. E. Poock[2], M. F. Smith[1], and D. J. Patterson[1], *[1]University of Missouri, Columbia, [2]University of Missouri, College of Veterinary Medicine, Columbia.*

An experiment was designed to test the hypothesis that pregnancy rates in postpartum beef cows after fixed-time artificial insemination (FTAI) may be improved by delaying insemination of those cows that have not expressed estrus before the

standard FTAI time. Estrus was synchronized for 951 mature, suckled cows across 9 locations using the 7-d CO-Synch + CIDR (controlled internal drug release device) protocol (100 μg GnRH + CIDR [1.38 gm progesterone] on d 0; 25 mg $PGF_{2\alpha}$ at CIDR removal on d 7; and 100 μg GnRH on d 10, 66 h after CIDR removal). Estrus detection aids (Estrotect) were applied at $PGF_{2\alpha}$ and CIDR removal on d 7, and estrous expression was recorded at GnRH on d 10. Treatments were equally represented across locations, and cows within each location were assigned to 1 of 2 treatments based on age, days postpartum (DPP), and body condition score (BCS): (1) FTAI (concurrent with GnRH, 66 h after $PGF_{2\alpha}$) regardless of estrous expression before GnRH, or (2) FTAI for cows having expressed estrus, and delayed AI (20 h after GnRH) for cows failing to express estrus. In both treatments, cows that expressed estrus before FTAI achieved higher pregnancy rates than cows that did not ($P < 0.0001$). However, no significant effect of treatment was found on AI pregnancy rate ($P = 0.757$). In summary, mature suckled beef cows may be successfully artificially inseminated using a strategy of split-time AI at the standard time of 66 h after $PGF_{2\alpha}$ for cows that have expressed estrus, and delayed insemination at 20 h after GnRH for cows that have not expressed estrus before the standard AI time in the 7-d CO-Synch + CIDR protocol. However, such a strategy does not appear to offer a significant improvement in pregnancy rates compared with a standard FTAI approach.

Key Words: artificial insemination, estrus synchronization, beef cow

---

0541 Effect of double ovulation on corpus luteum blood perfusion, peripheral progesterone, and hepatic steroid inactivating enzymes in dairy cattle.

B. E. Voelz*, C. G. Hart, G. F. Cline, C. O. Lemley, and J. E. Larson, *Mississippi State University, Mississippi State.*

Double ovulation is more common in Holstein cows than other dairy breeds. The effects of double ovulation on the corpus luteum (CL) and subsequent peripheral progesterone and clearance have not been examined. Thus, the objective of this experiment was to determine if induction of an accessory CL, via hCG, alters blood perfusion of CL, peripheral concentrations of progesterone, or hepatic steroid inactivating enzymes. Lactating, nonpregnant Holstein cows ($n = 19$) were synchronized using Ovsynch. Seven days postovulation, 8 cows received an injection of hCG (1000 IU, i.m.) while 11 cows received no treatment. Size of CL were measured and photos of blood perfusion of CL were recorded (d 10 to d 18) via Doppler ultrasonography and a blood sample was collected daily. Picture images were analyzed visually by 2 consistent technicians, averaged, and categorized (0 to 9 with 0 = no perfusion and 9 = complete perfusion). Pictures were also assessed using ImageJ software for integrated density of pixels. On d 13 postovulation, a liver biopsy was performed and hepatic steroid inactivating enzymes were analyzed. The MIXED procedure of SAS (SAS Inst. Inc., Cary, NC) was used with day as a repeated measure and cow as a random variable. LSMeans and pooled SEM are presented. Cows with 1 or 2 CL had similar ($P = 0.62$) peripheral concentrations of progesterone, 7.2 ± 0.7 and 7.7 ± 0.8 ng/mL, respectively. Compared with cows with 1 CL, cows with 2 CL had similar ($P > 0.80$) volume (7.3 ± 1.0 vs. 7.7 ± 1.2 cm^3) but greater ($P < 0.001$) total blood perfusion (3.8 ± 0.3 vs. 6.9 ± 0.3 visual score; 4403.7 ± 641.3 vs. 7781.8 ± 759.2 pixels). Both visual and pixel perfusion scores adjusted for CL volume (per cm^3 of luteal tissue) were greater ($P < 0.01$) in cows with 2 CL than 1 CL with a day × treatment interaction. Hepatic enzyme (cytochrome P450 1A, 3A, and 2C, aldo-keto reductase 1C, and uridine diphosphate-glucuronosyltransferase) activities were not different ($P > 0.23$) between treatment groups. Overall, the increased blood perfusion of CL in cows with 2 CL did not correspond to peripheral concentrations of progesterone or clearance as measured by hepatic enzyme activity, perhaps indicating that a double ovulation does not impact progesterone necessary to maintain pregnancy.

Key Words: blood perfusion, corpus luteum, progesterone

0542 A novel procedure using a gonadotropin-releasing hormone agonist to increase pregnancy rates in lactating dairy cattle.

A. Willmore*[1], C. Hammons[1], J. Peak[1], T. M. Nett[2], and T. L. Davis[1], [1]*University of Idaho, Moscow,* [2]*Colorado State University, Fort Collins.*

An earlier postovulatory increase in circulating progesterone (P4) concentration is associated with greater pregnancy success, likely through P4 alteration of the uterine environment conducive for embryo survival. We have shown that chronic administration of a gonadotropin-releasing hormone (GnRH) agonist (Deslorelin; 1 μg/kg BW^{-1} d^{-1}) beginning d 3 of the estrous cycle increases mean and basal secretion of luteinizing hormone, size of the corpus luteum (CL), and circulating P4 concentrations in beef heifers. The objectives of the present studies were to increase circulating P4 concentrations and pregnancy rates in lactating dairy cows with chronic administration of Deslorelin. Luteal volumes and P4 concentrations were analyzed using a mixed model procedure with repeated measures. Pregnancy rates were analyzed using a Chi Square Analysis. Data were considered different at $P < 0.05$. Deslorelin treatment for 12 d (d 3 to 15; d 0 = estrus) increased CL volumes in primiparous lactating dairy cows ($n = 4$) compared with untreated primiparous lactating dairy cows ($n = 6$). Circulating P4 concentrations were increased in cows treated with Deslorelin as compared with controls. In a small pilot pregnancy study, cows of various parity received Deslorelin treatment for 7 d (d 3 to 10) or 12 d (d 3 to 15) following estrous synchronization and timed AI (d = 0). Pregnancy rates were

50% greater in cows treated with Deslorelin 7 d (n = 10; P < 0.05) compared with controls (n = 10). No difference was observed in pregnancy rates for cows treated 12 d with Deslorelin (n = 10) compared with controls. In summary, chronic administration of Deslorelin altered luteal volume and increased circulating P4 concentrations in primiparous lactating cows only, albeit not during the early postovulatory critical period. Chronic administration of Deslorelin for 7 d increased pregnancy rates in cows although no differences in circulating P4 concentrations were observed. None of the animals in these experiments exhibited insufficient luteal function as defined by circulating P4 concentrations < 1 ng/mL; therefore, it is unlikely that the induced P4 concentrations by Deslorelin treatment resulted in increased pregnancy rates. These findings provide evidence that chronic administration of a GnRH agonist increases pregnancy rates in dairy cattle. The mechanism by which chronic administration of a GnRH agonist increases pregnancy rates is unknown, but could potentially be a direct effect of Deslorelin acting on the oviduct or uterine horn since GnRH receptors have been identified in bovine uterine tissue.

Key Words: dairy cow, gonadotropin-releasing hormone agonist, pregnancy rates

0543 Effect of an automated estrous detection system during a timed artificial insemination program on first postpartum artificial insemination.

T. A. Burnett*, A. M. L. Madureira, B. F. Silper, A. C. C. Fernandes, and R. L. A. Cerri, *Faculty of Land and Food Systems–University of British Columbia, Vancouver, Canada.*

The aim of this study was to compare 2 reproductive programs for first AI based on activity monitors and timed AI (TAI). Seven-hundred-and-seventy-four lactating Holstein cows from 2 commercial farms (Farm A, n = 322; Farm B, n = 452) were enrolled. Animals were presynchronized with 2 injections of PGF followed by an ovsynch protocol. Treatments were (1) TAI: all first inseminations performed by timed AI, and (2) ACT: first insemination based on estrous detection by activity monitors (Heatime, SCR Engineering, Israel) after the presynchronization, whereas the remaining noninseminated cows were enrolled onto the ovsynch protocol. All animals had their body condition score (BCS, scale 1 to 5), hock score (HS, scale 1 to 4), gait score (GS, scale1 to 4), and corpus luteum presence by ovarian ultrasonography recorded twice during presynchronization. Continuous data was analysed using ANOVA by PROC GLM whereas binomial data was analysed by logistic regression using PROC logistic of SAS (SAS Inst. Inc., Cary, NC). The ACT treatment had 52.3% of cows inseminated by estrous detection, whereas 90.3% of cows were bred by timed AI in the TAI treatment. Pregnancy per AI did not differ (P = 0.12), and was 30.0 and 34.5% for ACT and TAI, respectively. Overall, pregnancy per AI was similar in cows bred by estrous detection compared with the ovsynch protocol (29.5 vs. 31.8%; P = 0.38). Median days open was similar between treatments (P = 0.92). From all cows inseminated on estrus, only 30.9 and 36.3% were considered lame (GS > 2) and with a swollen hock (HS > 2), respectively. Fertility was affected by foot and leg conditions as animals that were classified as being lame, with a swollen hock, or both, had decreased pregnancy per AI compared with healthy animals (P < 0.01; 25.6 vs. 39.9%). The BCS did not affect the number of animals inseminated by estrous detection, but low BCS decreased pregnancy per AI (P < 0.01; 23.9 vs. 38.9%). The proportion of noncyclic cows during the presynchronization that were inseminated on estrus was 38.7% compared with 54.9% in cyclic animals (P = 0.05). In conclusion, pregnancy per AI did not differ between treatments; however, gait score, hock score, BCS and cyclic status highly impacted fertility and the number of animals detected in estrus. The use of activity monitors for automated estrous detection can be used strategically in a traditional reproductive program for first AI after calving.

Key Words: activity monitor, dairy cow, timed artificial insemination

0544 Effects of progesterone supplementation on reproductive responses in dairy cows subjected to timed artificial insemination programs: A meta-analysis.

R. S. Bisinotto*, N. Martinez, L. D. P. Sinedino, G. C. Gomes, L. F. Greco, W. W. Thatcher, and J. E. P. Santos, *Department of Animal Sciences, University of Florida, Gainesville.*

Objectives were to summarize the effects of progesterone supplementation during synchronization programs on pregnancy per AI (P/AI), and pregnancy loss in dairy cows through a meta-analysis. A systematic search for peer-reviewed manuscripts using Pubmed and ScienceDirect databases (Key Words: progesterone, dairy cow) yielded a total of 2384 results. Only controlled clinical trials were included (k = 16), in which lactating dairy cows were either assigned to receive a single intravaginal device containing progesterone or remained as untreated controls subjected to the same timed AI (TAI) protocol. Studies were classified on whether cows received the first AI postpartum or subsequent AI (first, 2+, mixed), if presynchronization was performed, and if cows were observed for estrus and allowed to be inseminated before TAI. A subset of studies with cows classified based on presence of CL at the initiation of the TAI protocol (k = 10) was used to assess the effects of progesterone supplementation according to CL status. First and second pregnancy diagnoses were performed on d 30 (27 to 150 d) and d 60 (41 to 150 d) after AI. Pregnancy loss was defined for cows that lost their pregnancies between d 30 and 60. Meta-analysis was conducted using the Metafor package for R. Study was considered random and moderator variables were included as fixed effects. Results were reported as adjusted relative risk (RR) and its 95% confidence interval. Pregnancy loss and P/AI were calculated from raw data.

Overall, progesterone supplementation increased ($P = 0.003$) P/AI on d 60 (RR = 1.19; 95%CI = 1.07–1.32; P/AI: 33.3 vs. 28.6%). Presynchronization of the estrous cycle and AI number did not impact the benefit from progesterone supplementation and accounted for 6.9 and 6.0% of the heterogeneity, respectively. Allowance for AI at detected estrus accounted for 47.4% of the heterogeneity and reduced ($P = 0.01$) the benefit from progesterone supplementation compared with TAI only (RR = 0.81; 95%CI = 0.68 to 0.95; P/AI supplemented vs. control: estrus-AI or TAI = 32.6 vs. 30.2%, TAI = 34.5 vs. 25.9%). Progesterone supplementation tended to reduce ($P = 0.09$) pregnancy loss (RR = 0.82; 95%CI = 0.66 to 1.02; pregnancy loss: 10.9 vs. 13.0%); all heterogeneity was explained by AI number as supplementation reduced pregnancy losses in cows receiving first postpartum AI (10.1 vs. 14.0%) but not subsequent AI (11.8 vs. 12.0%). Subgroup analyses depicted that the benefit of progesterone supplementation on P/AI at 60 d and pregnancy loss were not affected by CL status. In conclusion, progesterone supplementation improved fertility mainly in cows not detected in estrus during the TAI program.

Key Words: dairy cow, progesterone, meta-analysis

0545 Regimens of progesterone supplementation for lactating dairy cows according to the presence of corpora lutea at the initiation of the timed artificial insemination program. R. S. Bisinotto*, L. O. Castro, C. D. Narciso, N. Martinez, M. B. Pansani, L. D. P. Sinedino, P. E. Carneiro, N. S. van de Burgwal, H. M. Bosman, R. Daetz, W. W. Thatcher, and J. E. P. Santos, *Department of Animal Sciences, University of Florida, Gainesville.*

Objectives were to evaluate the effects of supplemental progesterone on fertility of dairy cows according to the presence of corpora lutea (CL) at the initiation of the Ovsynch-56 program (d-10 GnRH, d 3 $PGF_{2\alpha}$, h 16 GnRH, d 0 AI). Cows had their ovaries evaluated by ultrasonography (d 10) and those without CL were assigned randomly to receive 0 (NoCL; $n = 558$) or 2 intravaginal inserts containing progesterone (CIDR) from d 10 to d 3 (2CIDR; $n = 544$). Cows with CL on d 10 were matched by pen and used as positive controls (Diestrus; $n = 543$). The remaining cows bearing CL were assigned randomly to receive 0 (Control; $n = 388$) or 1 CIDR inserts (1CIDR; $n = 393$). Ovaries were scanned on d 3 for assessment of ovulation after the first GnRH and the presence of a newly formed CL. A subgroup of cows ($n = 365$) had their ovaries scanned on d 1 and d 1 for measurement of the ovulatory follicle and evaluation of the response to the second GnRH. Estrus was detected based on removal of tail chalk beginning on d -10. Pregnancy was evaluated 32 and 60 d after AI. Data were analyzed using the GLIMMIX procedure of SAS (SAS Inst. Inc., Cary, NC). A greater ($P < 0.01$) proportion of NoCL and 2CIDR cows had a new CL on d -3 compared with Diestrus (71.6, 68.7, 43.2%), whereas no difference was observed between Control and 1CIDR (51.2, 56.6%). Fewer ($P < 0.01$) NoCL and 2CIDR cows had CL on d -3 compared with Diestrus (71.6, 68.7, 88.0%) and no difference was observed between Control and 1CIDR (86.4, 87.6%). Progesterone supplementation reduced ($P = 0.05$) the proportion of cows without CL inseminated before timed AI for first postpartum AI (2CIDR = 10.9, NoCL = 17.7%), but not for subsequent AI (2CIDR = 19.0, NoCL = 17.5%) or cows with CL (1CIDR = 7.8, Control = 9.1%). Ovulation to the second GnRH was not affected by treatment and averaged 86.5%. The diameter of the ovulatory follicle tended to be reduced ($P = 0.07$) by progesterone supplementation in cows lacking CL (2CIDR = 17.0 ± 0.4, NoCL = 18.1 ± 0.4 mm), but not in those with CL (1CIDR = 17.5 ± 0.4, Control = 17.8 ± 0.4 mm). Pregnancy per AI was greater ($P \leq 0.08$) for 2CIDR compared with NoCL, and intermediate for Diestrus on d 32 (38.4, 32.7, 35.9%) and 60 (33.3, 28.3, 31.4%). This benefit was observed exclusively in cows not detected in estrus at AI. Progesterone supplementation reduced ($P = 0.05$) P/AI in 1CIDR compared with Control on d 32 (38.3, 45.7%) but not on d 60 after AI (33.4, 37.4%), which was associated with smaller ($P = 0.04$) pregnancy loss in the 1 CIDR group (4.0, 12.6%).

Key Words: anovulation, dairy cow, progesterone

0546 Effect of preovulatory concentration of estradiol and length of proestrus on pregnancy rate to timed-artificial insemination and embryo transfer in beef cows. L. H. Cruppe*[1], R. S. Cipriano[2], F. M. Abreu[1], M. L. Mussard[1], K. J. Wells[1], G. E. Fogle[1], B. R. Harstine[1], M. D. Utt[3], G. A. Bridges[4], and M. L. Day[1], *[1]The Ohio State University, Columbus, [2]UniSalesiano, Araçatuba, Brazil, [3]Select Sires Inc., Plain City, OH, [4]University of Minnesota, Grand Rapids.*

Postpartum beef cows ($n = 327$) were used to investigate the effect of preovulatory estradiol concentration (Pre-E2) and length of proestrus on timed-AI (TAI) and embryo transfer (ET) pregnancy rates. Ovulation was presynchronized with the 5-d CO-Synch + CIDR (controlled internal drug release device), follicle aspiration performed 6.5 d later (d −7 of experiment) and cows received 50 mg PGF2α on either d -3 (normal estradiol treatment; HiE), or on d -1.5 (deficient estradiol treatment; LoE). All cows received 100 μg GnRH on d 0, creating a proestrus of either 3 or 1.5 d. Ultrasonography was performed on d −7, 0, and 7 to confirm ovulation to pre-synchronization, ovulatory follicle diameter and corpus luteum (CL) formation after GnRH, respectively. Blood samples on d -3, -1.5 and 0 were used to determine Pre-E2. Blood samples on d -3, d 0, and d 7 were analyzed for progesterone to confirm presence of CL, its regression and formation of new CL, respectively. Cows in the HiE and LoE treatments were either TAI on d 0 or ET on d 7, resulting in 4 distinct combinations (HiE-AI, $n = 77$; HiE-ET, $n = 67$; LoE-AI, $n = 98$; LoE-ET,

$n = 85$) in a 2 × 2 factorial arrangement. Pregnancy diagnosis was performed on d 35. Ovulatory follicle diameter (11.9 ± 0.1 mm) and progesterone on d -3 (3.8 ± 0.1 ng/mL), d 0 (0.4 ± 0.0 ng/mL) and d 7 (2.6 ± 0.1 ng/mL) did not differ among treatments. As expected, Pre-E2 on d -3 was similar between HiE (4.5 ± 0.1 pg/mL) and LoE (4.5 ± 0.1 pg/mL). In contrast, Pre-E2 was greater ($P < 0.05$) in the HiE on d -1.5 and 0 (7.6 ± 0.2; 10.1 ± 0.3 pg/mL, respectively) compared with LoE (5.1 ± 0.2; 9.2 ± 0.2 pg/mL, respectively). Pregnancy rate was greater ($P < 0.05$) in the HiE treatment and AI group (HiE-AI, 68.8%; HiE-ET, 52.2%; LoE-AI, 46.9%; LoE-ET, 37.6%) compared with the LoE treatment and ET group, however no interaction treatment (HiE/LoE) and breeding technique (AI/ET) was detected for pregnancy rate. Reduced Pre-E2 was the primary outcome of shortened proestrus, which resulted in similar reductions in TAI (31.8%) and ET (28.0%) pregnancy rate; relative to that achieved in the Hi-E treatment. Based on the similarity of these responses, it is concluded that the primary impact of deficient Pre-E2 is to impair the ability of the uterus to sustain the embryo during early gestation.

Key Words: preovulatory estradiol, timed artificial insemination, embryo transfer

PRODUCTION, MANAGEMENT, AND THE ENVIRONMENT: INFLUENCE OF DIET AND MANAGEMENT PRACTICES ON ENVIRONMENTAL FOOTPRINT

0547 Effect of breed type and pasture type on methane emissions from weaned lambs offered fresh grasses. M. D. Fraser, H. R. Fleming, V. J. Theobald, and J. M. Moorby*, *Aberystwyth University, Aberystwyth, UK.*

To investigate the extent to which enteric methane emissions from growing lambs are explained by simple body weight and diet characteristics, a 2 × 2 Latin square changeover design experiment was performed using 2 sheep breed types and 2 fresh pasture types. Weaned lambs of 2 sheep breed types were used: Welsh Mountain (a small, hardy hill breed; mean LW = 27 ± 3.6 kg) and Mule × Texel (prime lamb; 35 ± 2.5 kg; n = 8 per breed). The lambs were zero-grazed on material cut from contrasting high (ryegrass) and low (permanent pasture) digestibility pastures and fed fresh. In each experimental period, ad libitum DMI was determined individually indoors following an adaptation period of 2 wk, and methane emissions were measured individually in open-circuit respiration chambers over a period of 3 d. Mean pasture composition, as fed, for ryegrass and permanent pasture respectively, was: DM, 21.9 and 21.9%; CP, 12.4 and 11.1% DM; NDF, 41.2 and 53.3% DM; GE, 17.3 and 17.1 MJ/kg DM. Although total daily methane emissions were lower for the Welsh Mountain lambs than for the Mule × Texel lambs (13 vs. 16 g/d respectively; SED = 1.0; $P < 0.05$) when offered fresh forage, the yield of methane per unit DMI was similar for the 2 breed types (16.4 vs. 17.7 g methane/kg DMI; SED = 0.79; NS). Total output of methane per day was higher when lambs were offered ryegrass compared with permanent pasture (16 vs. 13 g/d respectively; SED = 0.49; $P < 0.001$) which was likely driven by differences in DMI (986 vs. 732 g/d; SED = 22.4; $P < 0.001$). Methane emissions per unit DMI (16.4 vs. 17.7 g methane/kg DMI; SED = 0.37; $P < 0.01$) and proportion of GE intake excreted as methane (4.9 vs. 5.3%; SED = 0.11; $P < 0.01$) were both higher on the permanent pasture. No forage × breed type interactions were identified. The results indicate that forage type had a greater impact than breed type on methane emissions from growing weaned lambs. It can be concluded that, when calculating methane emissions for inventory purposes, it would be more important to know what feeds growing lambs are consuming than to know what breeds they are.

Key Words: lambs, grass, methane

0548 Effects of dietary nitrate supplementation on enteric methane and nitrous oxide emissions from beef cattle. C. J. Neumeier*[1], Q. Wang[1], A. R. Castillo[2], Y. Zhao[1], Y. Pan[1], and F. M. Mitloehner[1], *[1]University of California-Davis, Davis, [2]University of California Cooperative Extension, Merced.*

Feeding nitrate has been proposed as a means to reduce enteric greenhouse gas emissions from ruminants. Nitrate can compete with methanogens for hydrogen in the rumen and therefore reduce methane from eructation. However, increasing the nitrate concentration in the rumen could induce enteric nitrous oxide emissions, potentially nullifying the greenhouse gas reduction achieved from lowering methane emissions. The present study investigated the effects 2% nitrate (on DM basis) vs. an isonitrogenous concentration of urea supplemented to finishing steers on enteric methane and nitrous oxide emissions. Sixteen steers were allocated to nitrate and urea treatments in a randomized complete block design (n = 8). Eructated emissions were collected using head chambers for 12 h following the morning feeding. Methane was measured using the TEI 55C direct methane analyzer and nitrous oxide using the 46i nitrous oxide analyzer (both were Thermo Environmental Instruments, Franklin, MA). All data was analyzed using the Proc Mixed Model in SAS (SAS Inst. Inc., Cary, NC). The nitrate vs. urea treatment lowered methane production at measurement h 1 and 2 ($P < 0.01$), but did not lower overall methane production during the 12-h measurement period. The nitrate vs. urea treatment increased nitrous oxide production at h 1, 2, and 3 ($P < 0.05$) of measurement, and the overall 12-h measurement period ($P < 0.0001$). Nitrous oxide was detected in both treatments at each time point, with a sixfold increase in production in the nitrate (~600 mg/12 h) vs. urea treatment (~100 mg/12 h). Overall, combined greenhouse gas production expressed as carbon dioxide equivalents was similar between treatments. This study indicates that nitrate supplementation in finishing beef cattle is effective at reducing eructated methane in the time immediately following feeding, and might need to be supplemented at a higher concentration and/or more frequently to achieve more optimal methane reduction. Furthermore, this study suggests that cattle could be a source of the potent greenhouse gas nitrous oxide, which is further stimulated by nitrate supplementation. Additional research is necessary to evaluate more effective means of reducing methane with nitrate in finishing beef cattle and the production of nitrous oxide with and without supplementation of nitrate.

Key Words: greenhouse gas, hydrogen sink, ruminant

0549 Comparison of active flux and passive concentration measurements of methane emissions from cattle. P. Huhtanen*[1], E. H. Cabezas Garcia[1], S. R. Zimmerman[2], and P. R. Zimmerman[2], *[1]Swedish University of Agricultural Sciences, Umea, Sweden, [2]C-Lock Inc., Rapid City, SD*.

There are 2 new measurement techniques to measure emitted CH_4 and CO_2 from cattle in production systems, the passive concentration measurement method (PCM) and the active gas capture method (AGC). Both systems estimate cattle muzzle CH_4 and CO_2 emissions for short-term periods (3 to 15 min) while cattle visit a feeding station multiple times daily. The objective was to determine if the 2 techniques yielded comparable results under farm conditions. A GreenFeed (GF) system was used (C-Lock Inc., Rapid City, SD) that measures individual animal emissions over a feed trough. For AGC, an active airflow (2000 L/min) was induced around the animal's muzzle that attracted emissions into a air collection pipe where airflow and CH_4 and CO_2 concentrations were measured and the average flux was calculated for each visit. For PCM, a concentration sampling intake (at 1 l/min) was placed inside the feed trough, no active airflow was used, and the average CH_4 and CO_2concentrations for each visit were calculated. 32 Swedish Red dairy cows (BW 664 ± 72 kg, MY 30.2 ± 6.3 kg/d, and DMI 20.1 ± 2.8 kg/d) housed in a free-stall barn had an access to 2 separate GF units. The diets were fed ad libitum as TMR (60% forages, 40% concentrates on DM basis). The GF were configured for 10-d sampling periods using PCM and AGC repeated twice. The data was analyzed with linear mixed models using the MIXED procedure in SAS (SAS Inst. Inc., Cary, NC). Repeatability (R) was calculated as $R = \delta^2_{Animal}/(\delta^2_{Ánimal} + \delta^2_{Residual})$. The cows visited GF on average 2.85 ± 0.95 times per day. For CH_4, the between animal coefficient of variation (CV) was greater (11.0 vs. 17.6%) with PMC compared with AGC. Comparing CH_4 results for individual animals to determine if ranking was consistent between AGC and PCM, a weak correlation was found between CH_4 concentration with PCM and CH_4 flux with AGC:CH_4 Flux (g/d) = 363 ± 30.5 + 0.058 ± 0.0214 × CH_4 (ppm; R^2 = 0.13; RMSE = 52.1). For CH_4/CO_2 ratio, CV values were similar (6.4 and 6.6%) but averaged CH_4/CO_2 ratio was greater (P = 0.001) with PMC (0.107) compared with AGC (0.094). The repeatability for AGC and PCM were high (0.72 to 0.74). It is concluded that PCM methods are not sufficient for ranking animal's emissions on farms. Measuring concentration passively is not the same as measuring fluxes.

Key Words: methane, cattle, emissions

0550 Methane emission intensities by Holstein and Holstein × Jersey crossbreed lactating cows in two Brazilian grazing systems. A. Berndt, A. P. Lemes, L. A. Romero, T. C. Alves, A. M. Pedroso*, A. D. F. Pedroso, and P. P. A. Oliveira, *EMBRAPA, São Carlos, Brazil.*

The aim of this study was the evaluation of methane emissions from pure Holstein and half Jersey, half Holstein high-producing lactating cows grazing 2 different forages. The study was conducted at EMBRAPA's (Brazilian Agricultural Research Corporation) experimental station located in São Carlos city, in the Southeast region of Brazil. Treatments were a combination of 2 factors: 2 breeds (Holstein, HOL; and 1/2half Jersey half Holstein, JH) and 2 grazing systems (extensively grazed pastures with low stocking rate, ELS, or irrigated pastures under intensive management and high stocking rate, IHS). A total of 24 dairy cows were used (2 breeds × 2 grazing systems × 3 animals per paddock × 2 replicates), grouped according to age, stage of lactation, and level of milk production. Cows were kept on pasture and supplemented with minerals and concentrates in accordance with milk yield (1 kg of concentrate/3 kg of milk produced). The IHS pasture was rotationally managed and both IHS and ELS were managed under variable stocking rates ("put-and-take"). Forage production and animal performance variables were measured to determine environmental, technical, and economic assessments. Methane emission evaluation took place in May 2013 using the SF6 tracer technique. Each animal received 2 permeation tubes (average load of 1431.0 ± 76.2 mg of SF6 with an average emission rate of 1.74 ± 0.18 mg/d) 5 d before collection. Samples were collected every 24 h for 5 consecutive days. Gases were measured on a Shimadzu GC 2014. Data were analyzed using the MIXED procedure of SAS (SAS Inst. Inc., Cary, NC) and averages were compared using Tukey's test with significant differences at $P < 0.05$. No interactions were observed between breed and grazing system. Crossbred JH presented lower ($P < 0.05$) methane emission intensity than pure Holstein (11.26 ± 1.11 vs. 14.62 ± 1.11 gCH_4/L milk) regardless of grazing system. Crossbreed JH cows emitted less ($P < 0.05$) methane per day than pure HOL (275.1 ± 20.8 vs. 337.2 ± 20.8 gCH_4/d) and produced the same amount of milk (25.11 ± 1.11 vs. 23.76 ± 1.11 L/d). Efficiency of milk production can be a mitigation strategy when less methane is emitted per liter of milk.

Key Words: dairy cows, emission intensity, methane emission

0551 Comparison between the sulfur hexafluoride tracer technique and the portable automated head chamber system for measurements of enteric methane fluxes in mid-lactation holstein cows.

A. B. D. Pereira*[1], C. D. Dorich[1], A. F. Brito[1], R. K. Varner[1], and R. Martineau[2], *[1]University of New Hampshire, Durham, [2]Agriculture and Agri-Food Canada, Dairy and Swine Research and Development Centre, Sherbrooke, QC, Canada.*

The objective of this study was to evaluate the concordance correlation coefficient (CCC) and coefficient of variation (CV) of enteric methane flux (Q_{CH4}) between the sulfur hexafluoride tracer technique (SF_6) and the portable automated head chamber system (The GreenFeed [GF]; C-Lock Inc., Rapid City, SD). Eleven multiparous and 4 primiparous lactating Holstein cows housed in a tie-stall barn and averaging 176 ± 34 d in milk (DIM), 42.9 ± 6.8 kg of milk yield and 681 ± 48 kg of BW were blocked by DIM, parity, and DMI (as % of BW) and, within each block, randomly assigned to 1 of 2 treatments: ad libitum intake (AI) or restricted intake (RI) (90% DMI) according to a crossover design. Each experimental period lasted 22 d with 14 d for treatments adaptation and 8 d for data and samples collection. Diets contained (DM basis): 40% corn silage, 12% grass-legume haylage, and 48% concentrate. Five-minute measurements were taken from all animals with intervals of 12 h between the 2 daily samplings using the GF. Sampling points were advanced 2 h from 1 d to the next to yield 14 gas samplings/cow over 7 d to account for diurnal variation in Q_{CH4}. For the SF_6 method, sampling was done twice a day before milking times with canisters placed in 5 different locations inside the barn for measuring background gas concentration. Animal performance data were analyzed using the MIXED procedure of SAS (SAS Inst. Inc., Cary, NC) while the comparison between methods was done using the CCC. Data inclusion criteria were a minimum of 5 measurements per animal per period and Q_{CH4} ranging from 150 to 800 g/d. There was a significant difference in DMI between treatments (23.7 vs. 22.3 kg/d for AI and RI, respectively) but no difference was found for milk yield and Q_{CH4} when using the GF system (471 vs. 458 g/d for AI and RI, respectively) or the SF_6 technique (406 vs. 409 g/d for AI and RI, respectively). Between animal Q_{CH4} CV averaged 14.5% (GF) and 36.5% (SF_6); within animal Q_{CH4} CV averaged 17.8% (GF) and 36.2% (SF_6). The CCC was 0.15 on 225 comparisons of 2 daily data points with error terms of 10% (central tendency), 17% (regression), and 73% (disturbance). Current results suggest that the SF_6 technique was twice more variable and yielded lower Q_{CH4} compared with the GF system. Poor concordance between these 2 methodologies warrants further investigations.

Key Words: methane, sulfur hexafluoride tracer technique, GreenFeed

0552 Nitrogen use efficiency and carbon footprint by beef cattle limit-fed co-product feedstuffs.

W. B. Smith*[1], K. P. Coffey[2], R. T. Rhein[1], E. B. Kegley[1], D. Philipp[1], J. D. Caldwell[3], and A. N. Young[1], *[1]Department of Animal Science, University of Arkansas Division of Agriculture, Fayetteville, [2]University of Arkansas, Fayetteville, AR, [3]Department of Agriculture and Environmental Sciences, Lincoln University, Jefferson City, MO.*

In terms of energy density, the cost of importing hay is often not justified in years where adverse conditions limit local hay production. Coproduct feedstuffs could represent an alternative to feeding hay in these conditions. While the primary objective of our work was to determine if coproduct feedstuffs could be used to meet the energy demands for cows, also of interest was the N use efficiency of such a system, as well as the potential environmental impacts. Eight ruminally-fistulated cows (671 ± 32.0 kg BW) were stratified by BW and allocated randomly to 1 of 4 treatments in a 2-period study: (1) limit-fed soybean hulls (LSH), (2) limit-fed distillers' dried grains with solubles (LDG), (3) a limit-fed mixture of soybean hulls and distillers' dried grains with solubles (MIX), or (4) ad libitum mixed-grass hay (HAY; 10.6% CP, 71% NDF). Limit-fed diets were formulated to meet the ME requirements of an 11-mo postpartum mature beef cow. Diet amounts were increased over a 14-d period. Cows were then moved to indoor 3 × 4.3 m concrete pens fitted with rubber mats for a 14-d adaptation and 5-d total fecal collection period. Carbon footprint and emissions were predicted according to an IPCC (2006) model for cows housed on pasture. Excretion of total N, as well as percentage excreted in feces and urine, was not different ($P \geq 0.31$) among treatments. Concentration of ammonia-N in the urine was greater ($P = 0.02$), and concentration of urea-N tended to be greater ($P = 0.07$) from LDG than from other treatments. Both ammonia-N and urea-N, when expressed as a percentage of the total urinary N, were greater ($P \leq 0.04$) from LDG than other treatments. Predicted enteric CH_4, CH_4 from manure, direct loss of N_2O, as well as N_2O from volatilization and leaching were not different ($P \geq 0.12$) among treatments. Contribution of feedstuffs to total CO_2 load tended to be greatest ($P = 0.07$) from LDG and least from HAY, with MIX intermediate to LDG and LSH and LSH intermediate to MIX and HAY. However, total carbon footprint (kg CO_2 eq/d) was not different ($P = 0.55$) among treatments. Based on this information, coproduct feedstuffs may be used in lieu of hay to meet the energy requirements of cows without adverse effects on total N excretion or environmental impact.

Key Words: limit feeding, coproduct feedstuffs, carbon footprint

PRODUCTION, MANAGEMENT, AND THE ENVIRONMENT: **ANIMAL HEALTH: A RETROSPECTIVE LOOK**

0553 Antibiotic use in period 2005–2012 in dairy herds in the Netherlands, with outlook to some other countries. A. Kuipers*[1] and H. Wemmenhove[2], *[1]Expertise Centre for Farm Management and Knowledge Transfer, Wageningen UR, Wageningen, Netherlands, [2]Livestock Research, Wageningen UR, Lelystad, Netherlands.*

Use of antibiotics in animals has become part of the societal discussion. National goal was to reduce use by 50% in 2013 compared to 2009. A herd health and treatment plan have been introduced. From 2012 on 3/4 generation drugs (3/4GE) are only allowed in exceptional cases. To gain insight, antibiotic use and attitudes of farmers were examined on 94 farms during period 2005 through 2012. Number of Daily Dosages (NDD) indicates how many days per year an average cow in the herd is under treatment of antibiotics. NDD was on average 5.86 (SD 2.14). The NDD level was increasing in period 2005 through 2007, followed by a period of growing societal interest in animal antibiotic use resulting in a reduction in use in 2011 through 2012. On average, 68% of NDD was applied to the udder, dealing with mastitis (25%) and dry-cow therapy (43%). Drugs other than applied to udder health tended to decrease the most, while farmers were reluctant to lower use of dry-cow therapy tubes. Use of 3/4GE drugs minimized from 18% of NDD in period 2005 through 2010 to 1% in 2012. More use of penicillins and wide spectrum drugs took place. The drop in NDD use varied between three groups of farmers studied. The guided study groups reduced usage since 2007, the environmental group (not guided) had a significant drop in use in 2011 and the incidental group (not guided) in 2012. Reduction in use was modeled applying the Rogers diffusion of innovation theory. A logistic function fitted nicely to the adaptation process including the early adapters and late majority groups of farmers. Also farm and herd factors affecting antibiotics use were studied, practicing a step-wise regression procedure. Variation in total use and dry cow therapy were explained, respectively, for 39 and 46% by factors such as quota size, milk amount/cow, health status, cell count, and calving interval. A correlation of -0,55 between cell count and NDD was found. The "more successful and entrepreneurial " farmers, with a good relation to the veterinarian, tended to use somewhat more antibiotics than the other colleagues. They were also able to adapt more easily to the new conditions. The situation in some other countries is compared to the analysis above. Denmark, with a quite different focus on antibiotic use, is especially of interest in this respect.

Key Words: antibiotic use, dairy herds, farm factors

0554 Retrospective analysis of body energy content profiles of dairy cows with different production and metabolic diseases during the transition period. G. L. Smith*[1], M. G. Chagunda[1], C. J. Ashworth[2], and N. C. Friggens[3], *[1]Scottish Rural University College (SRUC), Edinburgh, UK, [2]The Roslin Institute, University of Edinburgh, UK, [3]Institut National de la Recherche Agronomique (INRA), Paris, France.*

Characteristics of body energy profiles for dairy cows with production and metabolic diseases during the transition period were studied. We used 542 cow-lactations from Holstein Friesians. Cows were from one of the four divergent production systems that were based on two feeding regimes (high forage and low forage) and two genetic lines (control and select). Control cows were of average UK genetic merit and select cows were of high genetic merit based on selection for fat and protein yield. Cows were milked three times daily, and stockmanship was similar across all systems. Live-weight of individual cows was recorded three times daily in lactation and weekly in the dry period. Body condition score (BCS) was recorded weekly using a 5-point scale. Health records were maintained throughout the study period. First, prevalence of disease within the first 4 wk after calving was determined as a proportion of cow lactations with disease relative to the total number of cow lactations per production system. Second, cow-lactations were categorized into disease-groups: retained placenta, metritis, metabolic, and healthy. The metabolic group comprised left displaced abomasum, ketosis, hypomagnesaemia, and hypocalcaemia. Body energy content in mega joules was calculated using the equation: EC = [(9.4 × body lipid weight) + (5.7 × body protein weight)] x 4.1868. Body lipid and protein weights were calculated using standard equations, which included live weight, BCS, and days pregnant. EC profiles covered the period between 6 wk pre-calving and 4 wk post-calving. Effects were determined using the GLM procedure of SAS. High genetic merit cows on a forage rich diet and average genetic merit cows fed a low forage diet had the highest prevalence of disease (30 and 25%, respectively). In the pre-calving period, healthy cows had an EC of 5878 ± 24 MJ which was significantly lower ($P < 0.01$) than those that had retained placenta (6384 ± 156 MJ) or metritis (6156 ± 46 MJ). Cows that developed metabolic diseases had significantly lower EC (5466 ± 216 MJ) than cows with retained placenta or metritis ($P < 0.01$). In the post- calving period, the metabolic disease group had significantly lower EC ($P < 0.001$) than all other disease groups. The study demonstrated that EC is an important lead indicator of production diseases in the transition period. Real-time tracking of EC could be used to rank individual cow risk of developing metabolic diseases.

Key Words: transition period, energy content, production disease

0555 Update on animal health concerns of recombinant bovine somatotropin (rbST): Meta-analysis of use in dairy cows. N. St. Pierre[1], G. A. Millikin[2], D. E. Bauman[3], R. J. Collier[*4], J. S. Hogan[5], J. K. Shearer[6], K. L. Smith[5], and W. W. Thatcher[7], *[1]The Ohio State University, Columbus, [2]Kansas State University, Manhattan, [3]Cornell University, Ithaca, NY, [4]The University of Arizona, Tucson, [5]The Ohio State University, Wooster, [6]Iowa State University, Ames, [7]Dep. of Animal Sciences, University of Florida, Gainesville.*

The commercial form of recombinant bovine somatotropin, sometribove zinc formulation (rbST-Zn), was approved by FDA as safe and has been successfully used by the U.S. dairy industry since 1994. However, a meta-analysis by an expert panel assembled at the request of Health Canada concluded that the commercial use of rbST would cause serious health and welfare problems. The present investigation utilized a series of meta-analyses to re-evaluate the efficiency and safety of rbST-Zn when used according to label. A total of 26 studies met the criteria: 1) published in peer-reviewed journals or reviewed by regulatory agencies, 2) used the rbST-Zn formulation (Posilac) available to U.S. producers, and 3) used according to label for dose (biweekly), treatment initiation (57–70 d postpartum), and administration method (subcutaneous injection). Meta-analysis results indicated that milk, fat, protein, and 3.5% fat-corrected milk yields were all increased ($P < 0.001$) by rbST-Zn (average of 4.00, 0.144, 0.137, and 4.04 kg/d, respectively), whereas milk concentrations of fat, protein, and lactose were unaltered ($P < 0.09$, 0.07, and 0.26, respectively). A 5.4% improvement in pregnancy proportion from rbST-Zn was detected for the first two breeding cycles after the voluntary wait period ($P < 0.01$). However, a 5.5% decrease ($P < 0.05$) in pregnancy proportion during the length of the trials was likely due to reduced estrous behavior. There was no effect of rbST-Zn on fetal loss, days open, services per conception, twinning, or cystic ovaries ($P < 0.65$, 0.96, 0.12, 0.68, and 0.43, respectively); on the odds of clinical mastitis or milk somatic cell count ($P < 0.12$ and 0.54, respectively); nor on rates of clinical lameness, lameness lesions, or traumatic lesions of the integumentary system (all $P < 0.99$). The rbST-Zn reduced body condition scores by 0.06 point (1 to 5 scale), a difference in body weight of about 3 kg ($P < 0.03$). No change to culling rate was associated with rbST-Zn ($P < 0.63$). Overall, the present meta-analysis demonstrates that rbST-Zn is effective and presents no unmanageable effects on health or welfare.

Key Words: bovine somatotropin, animal health, meta-analysis

0556 Trends in U.S. milk quality based on bulk-tank somatic cell counts. J. E. Lombard*, C. A. Kopral, and K. E. Bjork, *USDA:APHIS:VS: Center for Epidemiology and Animal Health, National Animal Health Monitoring System, Fort Collins, CO.*

The objective of this study was to evaluate changes in bulk-tank somatic cell counts (BTSCC) from 2000 to 2012. BTSCC data from four Federal Milk Marketing Orders (FMOs), representing about half of the milk marketed in the United States, were used to evaluate changes in BTSCCs. The four FMOs were: Mideast, Upper Midwest, Central and Southwest. Data were collected monthly and included herd identification, FMO, pounds of milk shipped, and official BTSCC. These data represent all milk shipped through the four FMOs, and conclusions apply only to this population of shipments. Because this study was a census, no estimates of sampling variability were calculated. A milk-weighted, 3-mo geometric mean BTSCC was calculated and summed for all herds in each FMO and for all herds. SAS software was used for all calculations. The Upper Midwest FMO accounted for approximately 45% of milk monitored on an annual basis. In 2012, 43.1 billion kg of milk from 309,343 shipments representing 28,274 producers were monitored. The milk-weighted mean BTSCC decreased from 296,000 cells/mL in 2000 to 194,000 cells/mL in 2012, while the producer-weighted mean BTSCC decreased from 320,000 to 230,000 cells/mL during the same period. The Mideast FMO had the lowest BTSCC for 11 of the 13 yr evaluated. Seasonal variations in BTSCC were consistent from 2000 to 2012, with the highest counts occurring in July through September. The U.S. BTSCC limit is 750,000 cells/mL; however, some countries that import dairy products from the United States have a limit of 400,000 cells/mL. From 2000 to 2012, the percentage of milk shipped from the four FMOs with BTSCCs of less than 400,000 cells/mL increased from 74.8 to 95.6%, while the percentage of shipments with counts less than 400,000 cells/mL increased from 65.0 to 87.4%. The percentage of producers from which all shipments counts were less than 400,000 cells/mL increased from 42.2 to 64.5%. BTSCCs in the United States have decreased approximately 35% since 2000. Many factors are likely responsible for these improvements in milk quality, e.g., producer motivation in the form of bonuses for providing quality milk, milk-quality regulations of countries that import U.S. dairy products, and an emphasis on improving milking procedures.

Key Words: BTSCC milk quality

0557 Somatic cell counts, mastitis infection prevalence, and mastitis pathogen distribution in compost bedded pack and sand freestall farms.

E. A. Eckelkamp*, J. L. Taraba, R. J. Harmon, K. A. Akers, and J. M. Bewley, *University of Kentucky, Lexington.*

The objective of this research was to describe the relationships among somatic cell counts (SCC), mastitis infection prevalence (MIP, percent of cows with SCS > 3.9), and mastitis pathogen distribution (MPD) in eight compost bedded pack (CB) and seven sand freestall (SF) farms in Kentucky from May 2013 to January 2014. The same observer evaluated cow hygiene scores (HYS, Cook and Reinemann, 2007) biweekly for 50 cows per herd. Throughout the study, producers collected aseptic milk samples from all quarters displaying clinical mastitis signs for bacteriological culturing. Test-day SCC and MIP were obtained from DHIA. The PROC MIXED of SAS (SAS Institute, Inc., Cary, NC) was used to assess fixed effects of barn type (BT), maximum ambient temperature (MT), and HYS on SCC and MIP. Stepwise backward elimination removed nonsignificant interactions ($P \geq 0.05$) with main effects remaining in the model regardless of significance. A χ^2 analysis was conducted using the FREQ procedure of SAS to determine MPD between BT. Maximum ambient temperature, BT, and MT × BT were significant predictors of MIP ($P < 0.05$). As MT increased, MIP increased more rapidly in CB than in SF ($P < 0.05$). Calculated MIP LSMeans(± SE) for CB and SF herds were 30.67 ± 3.02% and 25.33 ± 3.12%, respectively ($P < 0.05$). Hygiene score and BT × MT were significant predictors of SCC ($P < 0.05$). With increasing MT, herd SCC increased more rapidly in CB than in SF ($P < 0.05$). Somatic cell count LSMeans(± SE) for CB and SF were 255,700 ± 24,269 cells/mL and 223,520 ± 25,163 cells/mL, respectively ($P \geq 0.05$). Table 0557 summarizes MPD frequency by BT. Results of this study demonstrate potential challenges for managing mastitis in CBP.

Key Words: mastitis, sand freestall barn, compost bedded pack barn

Table 0557. Frequencies of pathogens isolated from clinical mastitis cases in compost bedded pack (CB) barns and sand freestall (SF) barns[1,2]

Pathogen isolated[1]	CB[2] (Total number of cases = 219) (Mean number of cows = 1208)	SF[2] (Total number of cases = 109) (Mean number of cows = 629)
Coagulase negative staphylococci	16 (7%)	4 (4%)
Environmental streptococci	32 (15%)	21 (19%)
Escherichia coli	63(29%)	19 (17%)
Gram-positive Bacillus species	4(2%)	1 (1%)
Staphylococcus aureus	7 (3%)	6 (6%)
Yeast species	5 (2%)	2 (2%)
Klebsiella species	4 (2%)	4 (4%)
Other gram-negative species	28 (13%)	14 (13%)
Other gram-positive species	6 (3%)	8 (7%)
No growth	32 (15%)	20 (18%)
Contaminated samples	20 (9%)	8 (7%)
Missing samples	2 (1%)	2 (2%)

[1] Number of pathogens isolated per species (percent of total samples per barn type).
[2] $\chi 2$ analysis indicated no significant differences for mastitis pathogen distribution between barn types ($P \geq 0.05$).

0558 Corn silage management practices on California dairies. J. M. Heguy*[1], D. Meyer[2], and N. Silva-del-Rio[3], *[1]UCCE Stanislaus and San Joaquin Counties, Modesto, CA, [2]Dep. of Animal Science, University of California–Davis, Davis, [3]VMTRC, University of California, Tulare, CA.*

The aim of this study was to describe current corn silage management practices on California¢s Central Valley dairies. In spring 2013, a forage management survey was mailed to dairy producers in California's San Joaquin Valley (n = 1100). Producers received an envelope containing an invitation letter, a double-sided two-page survey, and a pre-paid return envelope. Response rate was 14.5%. Median herd size was 1200 cows. Harvest date was decided solely by the dairy producer (53.3%) or by the producer with the assistance of the forage grower, the chopper, and/or the nutritionist (23.4%). When the dairy producer was not involved in setting a harvest date, the chopper (12.0%), the grower (7.3%), the nutritionist (0.7%), or the chopper and the grower (3.3%) were responsible for setting the harvest date. Most dairies (75.0%) estimated crop DM before harvest, mostly by visual analysis of the milk line. Only one dairy determined DM by shredding and drying plants before harvest. The number of choppers operating simultaneously was either one (35.9%), two (50.3%), three (11.1%), or four to five (2.7%). The most common chopper size was eight-row (67.3%), followed by six-row (17.7%), and 10-row (15.0%). One (68.8%), two (29.7%) or three (1.4%) tractors were used for packing the forage on the silage structure. Dairies (62%) weighed every load of fresh chopped corn delivered at the silage pit with a farm scale (58.9%), the custom harvester's mobile scale (23.2%), other certified scale (16.6%), or other methods (1.3%). Most dairies completed filling their largest silage structure in less than 3 d (48.5%) or in 4 to 7 d (30.9%). Thirty-two percent reported filling silage

structures with more than five different fields of harvested forage, comprised of one (36.8%) or two (40.6%) varieties. Dairies (68.8%) reported covering silage within 24 h, with all dairies covering silage structures within 72 h of completion. Daily covering of silage structures was reported from 19.6% of dairies. Dairies (51.0%) used a temporary cover during filling, with duration of filling ranging from 1 to 60 d on their largest corn silage structure. Dairies that did not use a temporary cover reported pile completion duration up to 15 d on their largest structure. Results from this survey study help us to identify critical control points for education and outreach activities to improve silage management practices at harvest, packing, and covering on California's Central Valley dairies.

Key Words: silage management, dairies, survey

PRODUCTION, MANAGEMENT, AND THE ENVIRONMENT: NUTRITION AND MANAGEMENT

0559 Zilpaterol hydrochloride repartitions chemical components of the empty body of Holstein steers.

T. J. McEvers*[1], N. D. May[1], L. A. J. Walter[1], J. P. Hutcheson[2], and T. E. Lawrence[1], *[1]West Texas A&M University, Canyon, TX, [2]Merck Animal Health, DeSoto, KS.*

A serial harvest from 254 to 534 d on feed (DOF) was conducted to quantify changes in growth and composition of calf-fed Holstein steers (n = 110, initial BW = 449.2 ± 19.9 kg). One-half were supplemented with the β-2 adrenergic agonist zilpaterol hydrochloride (ZH; 8.33 mg/kg 100% DM basis) with the remainder fed a control (CON) ration during the final 20 d followed by a 3 d withdrawal before harvest. Cattle were randomly allocated to dietary treatment and harvest endpoint (254, 282, 310, 338, 366, 394, 422, 450, 478, 506, and 534 DOF) in a 2 × 11 factorial randomized complete block experimental design conducted in the years 2012 and 2013. Cattle fed ZH had increased ($P \leq 0.03$) empty body weight (EBW; 17.8 kg), HCW (20.7 kg), dressed yield as a percentage of shrunk BW (DYSBW; 2.1%), dressed yield as a percentage of EBW (DYEBW; 1.3%), and empty body moisture (EBM; 1.3%) compared to CON steers regardless of DOF. Concurrently, cattle fed ZH had less ($P \leq 0.02$) digesta fill (6.1 kg) and empty body fat (EBF; 1.7%) compared to CON steers. Absolute weights of the empty body components including blood, hide, internal cavity components (ICC), and bone were not different ($P > 0.20$) for steers fed ZH or the CON diet. However, cattle fed ZH had increased ($P < 0.01$) carcass soft tissue (CST; 20.2 kg) compared to CON cattle. When comparing ZH and CON empty body components as a percentage of EBW, cattle fed ZH had less ($P \leq 0.02$) hide (0.3%), ICC (1.0%), and bone (0.5%). Furthermore, cattle fed ZH had more ($P < 0.01$) CST (1.7%) compared to CON steers with no difference ($P = 0.81$) in blood as a percentage of EBW. Comparing the chemical composition of the ICC, ZH steers had less ($P = 0.05$) protein (0.7%) with more ($P = 0.02$) ash (0.1%) compared to CON steers. Comparing the chemical composition of CST, cattle fed ZH had increased ($P = 0.02$) moisture (1.4%) with a concurrent reduction ($P < 0.01$) in fat content (2.0%) compared to CON cattle. This investigation proposes that the increase in dressed carcass yield observed in ZH supplemented cattle may best be explained by reductions in hide, fill, and ICC.

Key Words: beef, zilpaterol hydrochloride, composition

0560 Effect of organic grain supplementation on activity and rumination time of organic dairy cows.

L. S. Sjostrom*[1], B. J. Heins[2], M. I. Endres[3], R. D. Moon[4], and J. Paulson[5], *[1]University of Minnesota, West Central Research and Outreach Center, Morris, [2]University of Minnesota West Central Research and Outreach Center, Morris, [3]University of Minnesota, St. Paul, [4]University of Minnesota, St. Paul, [5]University of Minnesota, Hutchinson.*

Organic cows (n = 57) were used to evaluate activity and rumination time of cows fed three grain supplementation strategies during the grazing season. Cows were assigned to one of three replicate supplementation groups: 1) no corn grain supplementation (100% pasture, GRS, n = 19), 2) low corn grain (2.72 kg/head/day, LOW, n = 19), and 3) high corn grain (5.44 kg/head/day, HI, n = 19), and calved during two seasons at the University of Minnesota West Central Research and Outreach Center, Morris, from October to December 2012 and March to May 2013. Supplement (organic corn grain and minerals) was fed with a TMR of corn silage and alfalfa haylage, and at least 30% of diet DMI for LOW and HI cows consisted of organic pasture. Pasture and TMR intake were measured on a group basis, because cows were group fed. Activity and rumination time (daily and 2-h periods) were monitored electronically using HR-LD Tags (SCR Engineers Ltd., Netanya, Israel) for 125 d. Activity is reported in "activity units" from SCR DataFlow II software. The PROC HPMIXED of SAS was used for statistical analysis, and independent variables were season of calving (fall or spring), month of grazing (June to September), parity (1, 2, 3+), breed group, supplementation group and the interactions of month of grazing and supplementation group, breed group and supplementation group, and parity and supplementation group. Cow and replicate were random effects with repeated measures. The GRS (1138) cows had greater ($P < 0.05$) daily activity than HI (1001) cows but were similar to LOW (1019) cows. Daily activity was the greatest ($P < 0.05$) during July (1258) and least during September (819). Rumination was not different for the GRS (397 min/d), LOW (384), and HI (370) cows. Daily rumination was greater ($P < 0.05$) during September (402 min/d) compared to July (361). Daily activity increased rapidly from h 6:00 and 8:00 to h 16:00 and 18:00. From h 18:00 to 20:00, cows had a rapid decline in activity until h 6:00 the next day. All supplementation groups had the greatest rumination during h 2:00 and 4:00 and the least during h 10:00 and 12:00. In summary, GRS cows had greater activity but not greater daily rumination compared to LOW and HI supplemented cows. Monthly activity and rumination patterns of grazing organic cows may have been influenced by the weather and fly populations.

Key Words: activity, rumination, organic

0561 Effect of feeding kelp on growth and profitability of group-fed dairy calves in an organic production system. B. J. Heins*[1] and H. Chester-Jones[2], *[1]University of Minnesota West Central Research and Outreach Center, Morris, [2]University of Minnesota Southern Research and Outreach Center, Waseca.*

Heifer calves (n = 113) were used to evaluate the effect of feeding kelp on growth and economics of calves in an organic group management system. Calves were assigned to replicate feeding groups of 10 in super hutches by birth order during two seasons from September to December 2012 and March to May 2013 at the University of Minnesota West Central Research and Outreach Center, Morris. Calves in groups were the experimental unit. Breed groups of calves were: Holsteins (HO, n = 16) selected for high production; HO (n = 17) maintained at 1964 breed average level; crossbreds (n = 51) including combinations HO, Montbéliarde, and Swedish Red selected for high production; and crossbreds (n = 29) including combinations of HO, Jersey, Normande, and Swedish Red selected for robustness. Treatment groups were 1) control calf starter (CS; 18% CP as-fed; CON), 2) CS plus 56.7 g kelp/calf daily (Kelp2), and 3) CS plus 113.4 g kelp/calf daily (Kelp4). Calf groups were fed 1.5% DM solids of 13% total solids organic milk of birth weight once daily and then weaned at 60 d when the group consumption averaged 0.91 kg starter/calf daily. Body weight and hip height were recorded at birth, once/wk, at weaning, and at 90 d of age. Data were analyzed using PROC MIXED of SAS. Independent variables for analyses were the fixed effects of birth weight (co-variable), season of birth, breed group, treatment group, along with replicate as a random effect. Calf group ADG to weaning and weaning BW were 0.67, 82.9; 0.63, 79.4, and 0.61; 78.4 kg for CON, Kelp2, and Kelp4, respectively ($P < 0.10$). Hip heights at weaning were 93.8, 91.2, and 91.8 cm for CON, Kelp2, and Kelp4, respectively ($P < 0.05$). Daily gain to 90 d were 0.78, 0.74, and 0.68 kg for CON, Kelp2, and Kelp4 respectively, ($P < 0.05$). Total costs (grain, health, and organic milk) to 90 d of age for calf groups were $2,660.20 for CON, $2,711.39 for Kelp2, and $2,718.42 for Kelp4; however, the cost per kilogram of gain was significantly higher ($P < 0.05$) for the Kelp4 ($4.16) group compared to the CON ($3.69) group. In summary, calves fed a control calf starter had higher daily gains than calves fed high kelp calf starter rations. Feeding kelp in calf starter rations for organic dairy calves may not be economically justified.

Key Words: calf starters, organic production, kelp

0562 Reproductive performance of Barki ewes in Siwa Oasis as affected by including date seeds in the concentrate ration. E. B. Abdalla*, *Faculty of Agriculture, Ain Shams University, Cairo, Egypt.*

The present study investigated the effect of feeding date seeds on productive efficiency of Barki ewes in Siwa Oasis. Seventy-five adult Barki ewes (37.8 ± 0.63 kg) were divided into three equal groups: (G1) was kept as control (0.0% date seed), while the other two groups were fed on date seeds as a partial (50%, G2) or complete replacement (100%, G3) of the yellow corn in the concentrate diet. Animals were offered berseem *(Trifolium alexandrinum)* hay ad libitum and had access to fresh water twice a day. Estrus cyclicity and hormonal profiles during estrous cycle and pregnancy were determined. Reproductive parameters (number of services/conception, conception rate, lambing rate, average litter size, and mortality rate) were also recorded. Results indicated that date seeds contain estrogen-like compounds (β-sitosterol, stigmasterol and estradiol) with values of 0.01, 0.31, and 0.10 mg/kg, respectively. These levels did not affect estrus activity, since 90 and 80% of the ewes exhibited regular estrous cycle lengths with an overall mean of 17.3 ± 1.09 and 17.1 ± 0.86 d, respectively. Estradiol-17β (E_2) and progesterone (P_4) profiles either during estrous cycle or pregnancy were found to follow the normal pattern reported in the literature. Plasma (P_4) levels increased during pregnancy, especially during late pregnancy and decreased to the basal values during lactation, while plasma (E_2) levels were not significantly different among experimental groups. Date seeds, on the other hand, had improved all reproductive parameters studied as compared to the control group. Conception rate and lambing rate were found to be higher in both G2 (92 and 92%) and G3 (88 and 80%) as compared to the control group (76 and 72%), respectively. No abortions or stillbirths were found in the three groups. These results may confirm that date seeds have no estrogenic effects and could be used safely as a partial (50%) or complete replacer (100%) for the concentrate ration of ruminants, which in turn positively reflect on the Bedouins' income and animal health under desert conditions.

Key Words: date seeds, Barki ewes, estrus activity

0563 Impact of heifer development system on subsequent ADG and reproduction in two different breeding seasons. H. R. Nielson*[1], J. D. Harms[1], A. F. Summers[2], R. A. Vraspir[1], and R. N. Funston[1], *[1]University of Nebraska, West Central Research and Extension Center, North Platte, [2]University of Nebraska, Lincoln.*

The objective of this study was to determine the impact of heifer development system on subsequent growth and reproductive performance in two breeding seasons. In Exp. 1, over a 3-yr period, 196 May-born crossbred (5/8 Red Angus, 3/8 Continental) heifers were stratified by BW and randomly assigned to one of two post-weaning nutritional treatments (2 pastures·treatment^{-1}·yr^{-1}) beginning mid-January to mid-April. Heifers were offered ad libitum meadow hay (HAY) and 1.81 kg/d (29% CP, DM basis) supplement or allowed to graze meadow (MDW) and 0.45 kg/d supplement. Heifers were managed as a single herd before and following treatment. Heifers were synchronized with a single $PGF_{2\alpha}$ injection 5 d after

being placed with bulls for 45 d. Heifers on HAY treatment had greater ($P < 0.01$) ADG during the treatment period compared with MDW heifers (0.63 ± 0.01 kg/d vs. 0.33 ± 0.01 kg/d, respectively). However, heifers grazing meadow experienced a compensatory gain resulting in similar ($P \geq 0.12$) BW in June, July, and at pregnancy diagnosis. There was no difference ($P = 0.65$) in the proportion of heifers attaining puberty before the breeding season for HAY (62 ± 18%) and MDW (49 ± 18%) heifers. Pregnancy rates were similar ($P = 0.79$) between HAY vs. MDW treatments (69 ± 6% vs. 67 ± 6% respectively). In Exp. 2, 100 spring-born, crossbred (5/8 Red Angus, 3/8 Continental) heifers were, over 2 yr, stratified by BW and randomly assigned to HAY or MDW treatments. Similar to Exp. 1, HAY heifers had greater ($P < 0.01$) ADG during the treatment period than MDW heifers (0.80 ± 0.02 vs. 0.47 ± 0.02 kg/d). During the spring, HAY and MDW heifers had similar ($P = 0.14$) ADG, and BW was similar ($P \geq 0.17$) in May and September. Pubertal status before breeding was not affected by treatment ($P = 0.55$). Pregnancy rates were similar for HAY (88 ± 5%) and MDW (86 ± 5%, $P = 0.78$) heifers. Although ADG during the winter feeding period was greater for HAY heifers, BW was similar in the spring, summer, and at pregnancy diagnosis between treatments, suggesting a compensatory growth effect for MDW heifers. Similarly, there was no difference in pubertal status or pregnancy rate, indicating that a lower input winter management system is viable to maintain heifer pubertal status and pregnancy rates in two breeding seasons.

Key Words: beef heifers, development system, reproduction

0564 A comparison of serum metabolic profiles of dairy cows that maintained or lost body condition score 15 d before calving. M. R. Sheehy[*1,2], F. J. Mulligan[1], and A. G. Fahey[3], [1]*School of Veterinary Medicine, University College Dublin, Dublin, Ireland,* [2]*Devenish Nutrition Ltd, Belfast, Northern Ireland,* [3]*School of Agriculture and Food Science, University College Dublin, Ireland.*

Body condition score is an indirect measure of energy balance. Energy balance before calving may affect production and health in the following lactation. Energy restriction before calving has recently been advocated as a nutritional strategy that may result in BCS loss before calving. The objective of this study was to determine if loss of BCS 15 d before calving had an impact on the NEFA and calcium at wk -1 and wk 0 relative to calving and β-hydroxy butyrate (BHBA) and haptoglobin at wk 0 and wk +1 relative to calving from 93 Holstein-Friesian cows. On d -15 to d 0 relative to calving, BCS was assessed (1 = emaciated, 5 = obese). Cows were divided into two groups: those that did not lose BCS between d -15 and d 0 (MAINT, $n = 50$) and those that lost BCS from d -15 to d 0 (LOSS, $n = 43$). The fixed effects of BCS group, parity, wk and their interactions and a random effect of cow were analyzed for using PROC MIXED of SAS. Before calving LOSS cows tended to have higher NEFA concentrations than MAINT cows (0.88 ± 0.05 v 0.78 ± 0.04 mmol/L, $P = 0.10$) and a group by wk interaction was also found ($P < 0.01$), with an increase of 0.69 ± 0.09 mmol/L for LOSS and an increase of 0.59 ± 0.07 mmol/L for MAINT from wk -1 to 0. There was no difference in calcium concentrations between the LOSS and MAINT cows (2.21 ± 0.02 v 2.23 ± 0.02 mmol/L); however, a group by wk effect ($P < 0.01$) was found with a decrease from wk -1 to wk 0 of 0.32 ± 0.04 and 0.25 ± 0.03 mmol/L for LOSS and MAINT, respectively. After calving, LOSS cows were found to have higher concentrations of BHBA than MAINT cows (0.72 ± 0.04 v 0.57 ± 0.04 μmol/L, $P < 0.05$). A group by wk interaction ($P < 0.05$) was found for BHBA with an increase of 0.19 ± 0.07 μmol/L for LOSS and an increase of 0.02 ± 0.07 μmol/L for MAINT cows from wk 0 to 1. There was no difference found for haptoglobin between the LOSS and MAINT cows (115.41 ± 1.45 v. 114.71 ± 1.29 ng/mL, $P > 0.05$. In conclusion, LOSS cows tended to have significantly higher NEFA before calving and had a higher BHBA after calving with little effect on serum concentrations of calcium or haptoglobin.

Key Words: haptoglobin, NEFA, β-hydroxy butyrate

0565 Comparison of methods for isolation of miRNA from bovine milk whey. X. L. Jin[*1], H. Y. Liu[1], L. Liu[1], Z. H. Wei[1], and J. X. Liu[2], [1]*Institute of Dairy Science, Zhejiang University, Hangzhou, China,* [2]*Zhejiang University, Hangzhou, China.*

Milk miRNAs have great potential to utilize as noninvasive biomarkers for diagnosis or prognosis of diseases due to their high stability in the whey. More than 400 different miRNAs have been found in the mammalian milk. Some protocols have been established for isolation and quantification of miRNAs in whey, but the efficiency and effectiveness of these protocols are variable. The objective of the present study was to compare the methods for isolation of miRNAs from whey. Bovine milk samples were centrifuged and filtered to obtain the whey, 250 μL of which was lysed by Trizol LS. Total RNA was isolated from the whey RNA homogenate by two methods: 1) modified phenol based technique (alcohol precipitation with the addition of glycogen as carriers), and 2) column-based clean-up by miRNeasy Mini Kit. Yield and quality of total RNA isolated by these two methods were measured by NanoDrop ND-1000 spectrophotometer. Bioanalyzer 2100 instrument analysis using RNA6000 PicoKit was employed for precise detection of the RNA distribution-electropherogram of the microchip gel electrophoresis. The cycle thresholds of several endogenous miRNAs (bta-miR-141, bta-miR-148a, bta-miR-200c, and bta-miR-375) and a spike-in synthetic miRNA (cel-miR-39) were tested by RT-qPCR to compare their recovery efficiency between these two methods. Both methods could successfully isolate similar amount of small RNA (< 200nt)

from whey. Results of cycle thresholds of the endogenous miRNAs and spike-in cel-miR-39 indicated that the column-based cleanup method yielded approximately 10-fold miRNA than the alcohol precipitation. Nanodrop and bioanalyzer2100 based on RNA6000 PicoKit analysis could not reflect the real miRNA recovery efficiency of the whey. Whereas, spike-in control cel-miR-39 could be utilized as reliable and stable reference due to its perfect performance during the RT-qPCR. In summary, it is preferable to isolate miRNA from whey by combined phenol and column based approach.

Key Words: Isolation, miRNA, whey

PRODUCTION, MANAGEMENT, AND THE ENVIRONMENT: **ECONOMICS OF DIFFERENT MANAGEMENT PRACTICES**

0566 Effects of technology use in feedlot production systems on feedlot performance and carcass characteristics. *C. L. Maxwell[1], B. C. Bernhard[*1], C. F. O'Neill[1], B. K. Wilson[1], C. Hixon[1], C. Haviland[1], A. Grimes[1], M. S. Calvo-Lorenzo[1], D. L. VanOverbeke[1], G. G. Mafi[1], C. J. Richards[1], D. L. Step[1], B. P. Holland[2], and C. R. Krehbiel[1], [1]Oklahoma State University, Stillwater, [2]Merck Animal Health, DeSoto, KS.*

The objectives of this study were to examine the effects of conventional feedlot production systems with and without the use of a β-adrenergic agonist compared to a natural production program on feedlot performance and carcass characteristics. Natural crossbred beef steers (n = 336; initial BW = 379 ± 8 kg) were randomized to one of three treatments in a RCBD (14 steers/pen; 8 pens/treatment). Treatments consisted of a natural treatment (NAT), a conventional treatment (CONV), and a conventional treatment with a β-agonist (CONV-Z). The NAT cattle received no growth-promoting technologies. The CONV and CONV-Z cattle were implanted with 40 mg of estradiol and 200 mg of trenbolone acetate on d 0, and were fed 33 and 9 mg/kg of monensin and tylosin daily, respectively. The CONV-Z cattle were fed zilpaterol hydrochloride at 6.76 mg/kg (90% DM basis) for the last 20 DOF. There was no effect of treatment on DMI (P = 0.83); however, CONV-Z steers gained 3.8% faster (1.64 vs. 1.58 kg/d; P < 0.01) and were 5.3% more efficient (0.160 vs. 0.152; P < 0.01) than CONV steers, and CONV steers gained 32.8% faster (1.58 vs. 1.19 kg/d; P < 0.01) and were 26.7% more efficient (0.152 vs. 0.120; P < 0.01) than NAT steers. Hot-carcass weight was increased by 8 kg for CONV-Z steers compared to CONV steers (394 vs. 386 kg; P = 0.05) and 46 kg compared to NAT steers (394 vs. 348 kg; P < 0.01). Fat thickness was less for CONV-Z compared to CONV cattle (1.10 vs. 1.22 cm; P = 0.03), but not different from NAT (P > 0.05). Longissimus muscle area was increased by 3.6 cm^2 for CONV-Z steers compared to CONV steers (92.29 vs. 88.67 cm^2; P = 0.02) and 12.1 cm^2 for CONV-Z steers compared to NAT steers (92.29 vs. 80.16 cm^2; P < 0.01), resulting in a 17.9% unit reduction in USDA YG 3 for CONV-Z steers compared to NAT steers (30.70 vs. 48.61%; P < 0.05). There was no difference in marbling score for CONV steers compared to NAT steers (470 vs. 471; P = 0.99); however, CONV-Z steers had a lower marbling score compared to the other treatments (432; P < 0.01). The results of this experiment show that CONV-Z and CONV production results in a significant improvement in feedlot performance and USDA Yield Grade compared to NAT.

Key Words: conventional, beef cattle, natural

0567 The effects of technology use in feedlot production systems on the health status of finishing steers. B. C. Bernhard[*1], C. L. Maxwell[1], C. F. O'Neill[1], B. K. Wilson[1], C. G. Hixon[1], C. Haviland[1], A. Grimes[1], M. S. Calvo-Lorenzo[1], C. J. Richards[1], D. L. Step[1], B. P. Holland[2], and C. R. Krehbiel[1], *[1]Oklahoma State University, Stillwater, [2]Merck, Volga, SD.*

Crossbred steers (n = 336; initial BW = 379 ± 8 kg) were utilized in a RCBD (24 pens; 8 pens/treatment; 14 steers/pen) to determine the effects of technology use in feedlot production systems on animal health. Treatments consisted of an all-natural treatment (receiving no growth promoting technologies; NAT), a conventional treatment (implanted with 40 mg of estradiol and 200 mg of trenbolone acetate on d 0, and fed 33 and 9 mg/kg of monensin and tylosin daily, respectively; CONV), and a CONV treatment plus the addition of a β-adrenergic agonist (zilpaterol hydrochloride at 6.76 g/ton for the last 20 DOF with a 3–4 d withdrawal; CONV-Z). Steers were observed daily for signs of respiratory disease and lameness. Blood samples were collected from seven steers/pen every 28 d until d 112 and then every 10 d during the β-agonist feeding period to determine the hemogram. At harvest, livers were observed for abscesses, and lungs were palpated for abnormalities. Three steers died during the study, with necropsies indicating bloat (1-NAT; 1-CONV-Z before the zilpaterol feeding period; 1-CON-Z during the zilpaterol feeding period) as the cause of death, and no steers required treatment for respiratory disease. All blood analytes measured were within clinically normal concentrations throughout the experiment. Treatment had no effect on red blood cells, hematocrits, reticulocytes, or platelets (P > 0.34). There was a Treatment × Time interaction for total white blood cells (WBC; P < 0.01) with CONV and CONV-Z cattle having greater WBC counts than NAT cattle from d 28 (9.83 and 9.54 vs. 8.60 K/μL, respectively) through d 132 (10.83 and 11.25 vs. 9.83 K/μL, respectively; P < 0.03). There was a Treatment x Time interaction (P < 0.01) for neutrophils with CONV and CONV-Z cattle having greater neutrophil counts than NAT cattle from d 28 (2.57 and 2.47 vs. 1.99 K/μL, respectively) through d 132 (3.51 and 3.47 vs. 2.44 K/μL, respectively; P < 0.03). More monocytes were detected in the CONV and CONV-Z cattle compared to the NAT cattle (1.21 and 1.22 vs. 1.08 K/μL, respectively; P < 0.01). No differences in blood analytes were observed between CONV and CONV-Z during the zilpaterol feeding period (P > 0.25). There was no effect of treatment on liver abscesses (P = 0.74) or lung abnormalities (P > 0.09). Collectively, this experiment demonstrates that growth-promoting technologies did not affect overall health of finishing steers.

Key Words: β-adrenergic agonist, blood analytes, health status

0568 Survey of BQA cattle handling practices that occurred during processing feedlot cattle.

R. Woiwode* and T. Grandin, *Colorado State University, Fort Collins.*

The public is increasingly concerned with how animals in production agriculture are treated. The objective of this study was to ascertain feedlot performance in Beef Quality Assurance cattle handling categories. A survey was conducted to quantify prevalence of cattle handling practices that adhere to BQA guidelines. Data were collected at 28 feedlots ranging in size from 5000 to more than 100,000 head in Colorado, Kansas, and Nebraska. According to BQA guidelines, 100 cattle were observed during handling at every site except for two, where 90 and 78 head were observed due to lack of cattle. Data were collected on percentage of cattle moved with an electric prod, percentage that vocalized after capture in the squeeze chute before procedure, percentage of falls while exiting the squeeze chute, percentage stumbling while exiting, and percentage jumping and running on exit from the squeeze chute. Feedlots in this survey performed above BQA guidelines in the categories of electric prod use (5.5% vs. 10%); vocalization (1.4% vs. 5%), stumbles (6.7% vs. 10%), falls (0.8% vs. 2%), and cattle that jumped and ran from the squeeze chute (12.8% vs. 25%). The mean percentage of cattle moved with an electric prod was 5.5%, with a range of 0 to 45%; cattle that vocalized in the chute before procedure was a mean of 1.4% with a range of 0 to 5.1%. The mean percentage of cattle stumbling while exiting the squeeze chute was 6.7%, with a range of 0 to 28%; cattle falling was 0.5%, with a range of 0 to 2%. The mean percentage of cattle that jumped and ran out of the squeeze chute was 12.8%, with a range of 0.1 to 18%; cattle miscaught in the squeeze chute was 2%, with a range of 0 to 16.1%. Under BQA guidelines, there is zero tolerance for an improper catch that is not adjusted, and feedlots in this survey show some room for improvement, with a mean score of 2% vs. the BQA guideline of 0%. Of the improper catches, 60% were not adjusted. Round crowd pen handling systems were used at 25 yards, and three yards used Bud box handling systems. At one feedlot, a contract crew employee jerked out ear tags, resulting in some ear splits. Discussion with feedlot managers revealed increased awareness of the importance of moving small groups of cattle into the crowd pen and avoiding yelling.

Key Words: cattle handling, BQA guidelines, feedlots

0569 The effects of technology use in feedlot production systems on cattle behavior and mobility.

B. C. Bernhard*[1], C. L. Maxwell[1], C. F. O'Neill[1], B. K. Wilson[1], C. Haviland[1], A. Grimes[1], M. S. Calvo-Lorenzo[1], C. J. Richards[1], D. L. Step[1], B. P. Holland[2], C. R. Krehbiel[1], and C. G. Hixon[1], *[1]Oklahoma State University, Stillwater, [2]Merck, Volga, SD.*

Crossbred steers (n = 336; initial BW = 379 ± 8 kg) were utilized in a randomized complete block design (24 pens; 8 pens/treatment; 14 steers/pen) to determine the effects of technology use in feedlot production systems on animal behavior and mobility. Treatments consisted of an all-natural treatment (defined as cattle receiving no growth promoting technologies; NAT), a conventional treatment (implanted with 40 mg of estradiol and 200 mg of trenbolone acetate on d 0, and fed 33 and 9 mg/kg of monensin and tylosin daily, respectively; CONV), and a CONV treatment plus the addition of a β-adrenergic agonist (zilpaterol hydrochloride at 6.76 g/ton for the last 20 d on feed with a 3–4-d withdrawal; CONV-Z). Handling assistance, temperament, and exit scores at the chute and temperament in each home pen were collected every 28 d until d 112, and then every 10 d during the β-agonist feeding period. On the d of shipment, cattle mobility was scored before loading at the feedlot and while unloading at the abattoir. There was no effect of treatment on cattle requiring assistance to enter the squeeze chute (P = 0.35). There was a Treatment x Time interaction for chute temperament score (P = 0.03), with NAT cattle being more restless than CONV cattle at d 56 (2.24 vs. 1.98; P = 0.02) and CONV-Z cattle intermediary (2.14). Pen temperament was not affected by treatment (P = 0.14). Overall temperament score resulted in CONV-Z cattle being numerically calmer than NAT cattle (1.47 vs. 1.61; $P < 0.02$) and CONV cattle intermediary (1.57). Chute exit scores resulted in a Treatment x Time interaction ($P < 0.01$), with NAT cattle having a greater exit score than CONV and CONV-Z cattle (2.24 vs. 1.93 and 1.87; $P <$ 0.03) on d 132. There were no differences in exit velocity ($P >$ 0.37). Treatment displayed no effect on cattle mobility before loading or during unloading ($P \geq 0.14$), but numerically, cattle had a more difficult time moving at the abattoir than at the feedlot. The results of this experiment suggest that growth-promoting technologies have no negative effects on cattle mobility and could potentially improve cattle temperament at the end of the finishing period.

Key Words: behavior, β-adrenergic agonist, mobility

0570 Predicting dry matter intake by growing and finishing beef cattle: evaluation of current methods and equation development. U. Y. Anele*[1], E. M. Domby[2] and M. L. Galyean[3], [1]*Lethbridge Research Centre, Agriculture and Agri-Food Canada, AB,* [2]*Cargill Animal Nutrition, Amarillo, TX,* [3]*Texas Tech University, Lubbock.*

The NRC (1996) equation for predicting DMI by growing-finishing beef cattle, which is based on dietary NEm concentration and average $BW^{0.75}$, has been reported to over- and underpredict DMI depending on dietary and animal conditions. Our objectives were to: 1) develop more robust equations for predicting DMI from BW and dietary NEm concentration; and 2) evaluate the use of NE requirements and dietary NE concentrations to determine the DMI required (DMIR) by feedlot cattle. Two DMI prediction equations were developed from a literature data set that covered a wide range of dietary NEm concentrations, which represented treatment means from published experiments from 1980 to 2011. Predicted DMI from the two equations, which were based on NEm concentration and either the ending BW for a feeding period or the DMI per unit of average BW (End BW and DMI/BW, respectively), accounted for 61 and 58% of the variation in observed DMI, respectively, vs. 48% for the 1996 NRC equation. When validated with four independent data sets that included 7751 pen and individual observations of DMI by animals of varying BW and feeding periods of varying length, DMI predicted by the 1996 NRC equation, the End BW and DMI/BW equations, and the DMIR method accounted for 13.1 to 82.9% of the variation in observed DMI, with higher r^2 values for two feedlot pen data sets and lower values for pen and individual data sets that included animals on lower-energy, growing diets, as well as those in feedlot settings. The DMIR method yielded the greatest r^2 values and least prediction errors across the four data sets, but mean biases ($P < 0.01$) were evident for all the equations, ranging from as high as 1.01 kg for the DMIR method to -1.03 kg for the 1996 NRC equation. Negative linear bias was evident in virtually all cases, suggesting that prediction errors changed as DMI increased. Despite an expanded literature database for equation development, other than a trend for lower standard errors of prediction with the DMI/BW equation, the two new equations did not offer major advantages over the 1996 NRC equation when applied to the validation data sets. The DMIR method accounted for the greatest percentage of variation in observed DMI and had the least RMSE values in all data sets evaluated, indicating that this approach should be considered as a means of predicting DMI.

Key Words: beef cattle, dry matter intake prediction, feed intake

0571 Optimizing concurrently dairy farm profitability and environmental performance. D. Liang* and V. Cabrera, *University of Wisconsin, Madison.*

The objective of this analysis was to assess economic and environmental impacts of a dairy farm milk production using the Integrated Farm System Model (IFSM, version 4.0, University Park, PA). The IFSM was applied to integrate crop growth, feed storage, machinery usage, and herd management to simulate the highest possible milk production with the available on-farm resources and purchased feed. A representative Wisconsin dairy farm system was defined as a typical farm with 100 milking cows and 247 acres of cropland. Farm performance was then simulated using 25 yr of daily weather data (1986 to 2010). A sensitivity analysis was conducted by increasing the input target milk production starting at 9837 kg/cow per yr. The fat-protein-corrected milk production (FPCM) increased linearly as the target milk production was increased to 10,457 kg/cow per yr. Followed, the FPCM increased nonlinearly (at a decreasing rate) until the target milk production was increased to 10,980 kg/cow per yr. Thereafter, FPCM remained flat regardless of higher target milk production input. The per-kg FPCM net return ($/kg FPCM) showed a similar trend, increasing from $4.08 ± 2.32 to $6.20 ± 2.19, and then to $6.78 ± 2.18, respectively. Given the farm carbon footprint (kg CO_2eq/kg FPCM) as the result of dividing the net greenhouse gas emission (including methane, nitrous oxide, and carbon dioxide) by the FPCM, it decreased from 0.69 ± 0.04, to 0.67 ± 0.04, and then to 0.65 ± 0.04, respectively, as the FPCM and the net return increased. We concluded that increasing productivity using only farm available resources would elevate the net return and decrease carbon footprint at the same time. Further research is required to explore management strategies that determine increased productivity within farm-specific conditions.

Key Words: whole-farm simulation model, farm profit, greenhouse gas emission

Table 0571.

Input target milk production (kg/cow per yr)	Simulated actual milk production (kg/cow per yr)	Fat-protein-corrected milk production (FPCM; kg/cow per yr)	Net return per kg of FPCM (FPCM; $/kg FPCM)	Carbon footprint (kg CO2 eq/kg FPCM)
9834	9834 ± 0.00	9079 ± 0.00	4.80 ± 2.32	0.69 ± 0.04
10,457	10,455 ± 9.54	9652 ± 9.54	6.20 ± 2.19	0.67 ± 0.04
10,980	10,748 ± 96.82	9922 ± 89.54	6.78 ± 2.18	0.65 ± 0.04
11,457	10,746 ± 87.27	9921 ± 80.45	6.78 ± 2.15	0.65 ± 0.04

0572 Economics of transition cow management of dairy herds. G. M. Schuenemann[*1] and K. N. Galvão[2], *[1]Dep. of Veterinary Preventive Medicine, The Ohio State University, Columbus, [2]Dep. of Large Animal Clinical Sciences, University of Florida, Gainesville.*

It is common to observe large among-herd variation in culling risk within 60 DIM. The objective was to assess the effect of two culling risks within 60 DIM (6% vs. 12%) on the economic outcomes of dairy herds with the same reproductive performance using an individual cow-based model. For the simulation, two culling risks (6% vs. 12%) and two cow sale prices ($1.85 vs. $1.37 per kg) were compared using the same reproductive program and performance. Cows were enrolled in an Ovsynch (OVS) preceded by Presynch with two injections of PGF 14 d apart, and OVS for resynchronization of open cows at 32 d after AI. Also, cows undergo estrous detection (ED) and AI after first AI, and cows diagnosed open 32 d after AI are resynchronized using OVS. Cows were not inseminated after 365 DIM, and open cows were culled after 450 DIM. Culled cows were immediately replaced with primiparous cows. Herd was maintained at 1000 cows. Mortality was set at 6% and abortion at 11.3%. The dry period and VWP was 60 d. Conception rate to first service was set to 32% (decreased by 2.5% for every subsequent service), and ED was set to 60%. Accuracy of ED and compliance with each injection were set at 95%. Net daily value was calculated by subtracting the costs associated with replacement heifers ($1,600/heifer), feeding costs ($0.25/kg of lactating cow diet; $0.15/kg of dry cow diet), breeding costs ($0.15/cow/d for ED; $2.65/dose PGF; $2.4/dose GnRH; $0.25/injection administration), and other costs ($2.5/d) from the daily income with milk sales ($0.44/kg milk), cow sales ($1.85 or $1.37/kg live weight), and calf sales ($240/calf). Simulation was performed until steady state was reached (4000 d), then average daily values for the subsequent 1000 d were used to calculate profit ($/yr). According to the model (same herd size, synchronization program, reproductive performance, and feeding costs), the annual profit was $55,480 higher for herds with 6% compared to 12% culling risk within 60 DIM. When the cow sale price was $1.37/kg and replacement costs remain the same, the annual profit was $80,300 higher for herds with 6% compared to 12% culling risk within 60 DIM. Early removal of lactating cows from the milking herd affects the bottom line of dairy operations.

Key Words: culling risk, economics, dairy herds

0573 The impact of selected milking, feeding, and housing management systems on the profitability of Quebec dairy herds. H. A. Delgado[*1], R. I. Cue[2], A. Sewalem[3], R. Lacroix[4], D. Lefevre[4], E. Bouchard[5], D. Haine[5], and K. Wade[1], *[1]McGill University, Ste-Anne-de-Bellevue, QC, Canada, [2]McGill University, Dep. of Animal Science, Ste-Anne-de-Bellevue, QC, Canada, [3]Agriculture and Agri-food Canada AAFC, Guelph, ON, Canada, [4]Valacta, Ste-Anne-de-Bellevue, QC, Canada, [5]University of Montreal, Ste-Hyacinthe, QC, Canada.*

In Quebec, management of dairy herds is affected by various combinations of milking systems (milk line, milking parlor, or milking robot), housing systems (tie-stall or free-stall), and feeding systems (traditional feeding, automatic forage distribution, automatic concentrate distribution, computerized automatic concentrate distribution, automatic silage and concentrate distribution, and total mixed ration). The objective of this research was to determine if there were differences in the lifetime profitability of dairy cows, based on common Quebec management conditions, specifically with regard to their associated production and health costs. Grouping the three variables resulted in eight existing management combinations that contained data (e.g., milk line + tie-stall + total mixed ration). Health and production data for individual animals were provided by the Quebec Animal Health Files (DSA) and Quebec DHI (Valacta), respectively. Herds were required to have at least 12 calvings per year, resulting in a data set of 70 Holstein herds with both health and production data for the period 2000 though 2010, inclusive. Individual cumulative values by parity, as well as the last cumulative lifetime record, were computed for each animal. Four profitability measures were examined to account for different criteria, such as variable costs, opportunity costs, and discounted net present value, and mixed-model methodologies were used to test differences among those profitability measures for the different management combinations. Of the 70 herds, 58 used a milk line, seven used a milking parlor, and five used robotic milkers. There were significant differences among the management combinations for the four different profitability measures examined. Management groups associated with a milking parlor had the lowest estimated lifetime cumulative feed cost: $3,968 (± 73) vs. $4,297 (± 36) for milk lines and $4,057 (±86) for robotic milkers. They also had animals with an earlier age at first calving (1.1 mo earlier than those in groups with milk lines). Management groups with robotic milkers had the lowest lifetime cumulative health cost, explained in part by the lower average number of mastitis events per animal per parity: 0.12 (± 0.034) vs. 0.20 (± 0.028) for milking parlor groups and 0.23 (±0.020) for milk line groups. There were significant variations in profitability measures of milk-line groups that were attributable to feeding system. Variation in lifetime profitability of individual animals is, therefore, not

only explained by the obvious feed and health factors but also by the various management systems in which they occur.

Key Words: profitability, management, dairy cows

0574 Grazing alfalfa as an alternative to reduce production costs in intensive milk production systems.

F. A. Kuwahara[1], A. M. Pedroso[*2], G. B. Souza[3], and R. P. Ferreira[3], *[1]UNESP/FMVZ, Botucatu, Brazil, [2]EMBRAPA, São Carlos, Brazil, [3]EMBRAPA, Sao Carlos, Brazil.*

Intensively managed grass-based milk production systems in Brazil are highly dependent on concentrate supplementation of the milking cows to achieve high productivity levels. Depending on feed prices, the production costs can be very high, leading to low profitability. This study aimed to evaluate the use of grazing alfalfa (*Medicago sativa, sp*.) as an alternative to reduce concentrate inputs and reduce production costs. The trial was conducted at EMBRAPA's (Brazilian Agricultural Research Corporation) research station, located in Sao Carlos, SP, in the southeast region of Brazil. Thirty-six lactating dairy cows were used on a complete blocks design to evaluate the effect of allowing the cows to graze alfalfa for different periods on milk production, dry matter intake, and feed efficiency. Cows were allocated to four experimental treatments (A = control, no alfalfa grazing; B = access to alfalfa paddocks for 1 h; C = access to alfalfa paddocks for 2 h; D = access to alfalfa paddocks for 4 h) according to stage of lactation and milk production. All cows rotationally grazed tropical grass paddocks and were supplemented with different concentrate quantities (9.82, 9.32, 9.03, and 8.73 kg of DM daily for treatments A, B, C, and D, respectively) Cows on treatment A had no access to alfalfa, and cows on the other treatments had access to alfalfa paddocks for 1, 2 or 4 h immediately after the morning milking. Results are shown on Table 0574. Data were analyzed using PROC MIXED of SAS and averages were compared with Tukey test. Treatment differences were considered significant at $P < 0.05$. No effects were observed among treatments for any parameter analyzed. Based on the results, alfalfa grazing may be a good strategy to reduce production costs, depending on the prices of the concentrate supplements.

Key Words: milk production, grazing, alfalfa

Table 0574.

	Treatment A	Treatment B	Treatment C	Treatment D
DMI, kg/d	15.68	15.84	15.81	15.09
Milk, kg/d	23.86	23.28	23.41	24.21
FE, kg/kg	1.605	1.566	1.549	1.656

0575 Comparison of productivity and management practices on Dairy Herd Improvement Association (DHIA) and non-DHIA herds in the United States.

J. E. Lombard*, C. A. Kopral, M. A. Parke,r and C. A. Haley, *USDA:APHIS:VS: Center for Epidemiology and Animal Health, National Animal Health Monitoring System, Fort Collins, CO.*

The objective of this investigation was to compare productivity and management practices between DHIA and non-DHIA herds. Data for this comparison were collected as part of the National Animal Health Monitoring System¢s Dairy 2007 study, which surveyed 2194 randomly selected dairy herds in 17 top dairy states. The survey design was a stratified random sample, and all respondent data were statistically weighted to ensure that samples reflected the study population. Regression analyses were conducted and included multiple outcome variables of interest, herd size, region, and whether the operation participated in DHIA. *P*-values < 0.05 were considered significant. Almost half of herds in the study (46.0%) used DHIA for individual-animal recordkeeping. The average size for DHIA herds was 416 cows compared with 448 cows for non-DHIA herds. A higher percentage of herds in the east region (46.7%) were enrolled in DHIA compared with herds in the west region (37.3%). There were significant productivity differences between DHIA and non-DHIA herds. DHIA herds had a higher mean rolling herd average milk production than non-DHIA herds (9873 kg and 8521 kg, respectively) and a longer mean calving interval (13.6 and 13.0 mo, respectively). The percentage of DHIA herds that used bovine somatotropin was more than triple that of non-DHIA herds (23.8 and 7.8%, respectively). In addition, DHIA herds reported lower mortality rates for preweaned heifers than non-DHIA herds (8.3 and 9.5%, respectively). Best management practices, in general, were more widely adopted by DHIA herds than non-DHIA herds. A significantly higher percentage of DHIA herds were enrolled in quality assurance programs, used forage test results to balance rations, and fed a total mixed ration. Similarly, biosecurity practices were generally adopted by a significantly higher percentage of DHIA herds than non-DHIA herds. A lower percentage of DHIA herds than non-DHIA herds introduced new cattle to the operation during 2006 (36.9 and 40.9%, respectively). Brucellosis vaccinations were also administered on a higher percentage of DHIA herds than non -DHIA herds (51.7 and 33.0%, respectively). Common cow vaccinations (BVD, IBR, PI3, and BRSV) were administered on 87.9% of DHIA herds and 68.5% of non-DHIA herds. DHIA herds had higher milk production than non-DHIA herds, and a higher percentage of DHIA herds implemented best management practices compared with non-DHIA herds.

Key Words: DHIA, productivity, management, biosecurity

0576 Optimization of reproductive management programs using lift chart analysis and cost-sensitive evaluation of classification errors.
S. Shahinfar*[1], J. N. Guenther[1], D. Page[2], A. Samia- Kalantari[1], V. Cabrera[3], P. M. Fricke[1], and K. A. Weigel[3], *[1]Dep. of Dairy Science, University of Wisconsin–Madison, Madison, [2]Dep. of Biostatistics and Medical Informatics and Dep. of Computer Science, University of Wisconsin–Madison, Madison, [3]Unversity of Wisconsin–Madison, Madison.*

The common practice on most commercial dairy farms is to inseminate all cows that are eligible for breeding, while ignoring (or absorbing) the costs associated with semen and labor directed toward lowly fertile cows that are unlikely to conceive. Modern analytical methods, such as machine learning algorithms, can be applied to cow-specific explanatory variables for the purpose of computing the probabilities of success or failure associated with upcoming insemination events. Lift chart analysis can identify subsets of high fertility cows that are likely to conceive and are therefore appropriate targets for insemination (e.g., with conventional AI semen or expensive gender-enhanced semen), as well as subsets of low fertility cows that are unlikely to conceive and should therefore be passed over at that point in time. While such a strategy might be economically viable, the management, environmental, and financial conditions on one farm might differ widely from conditions on the next, and hence the reproductive management recommendations derived from such a tool may be suboptimal for specific farms. When coupled with cost-sensitive evaluation of misclassified and correctly classified insemination events, it can be potentially powerful tool for optimizing the reproductive management of individual farms. In the present study, lift chart analysis and cost-sensitive evaluation were applied to a data set consisting of 54,806 insemination events of primiparous Holstein cows (as experimental unit) on 26 Wisconsin farms, as well as a data set with 17,197 insemination events of primiparous Holstein cows on three Wisconsin farms, where the latter had more detailed information regarding health events of individual cows. In the first data set, the gains in profit associated with limiting inseminations to subsets of 79 to 97% of the most fertile eligible cows ranged from $0.44 to $2.18 per eligible cow, depending on days in milk at breeding and milk yield relative to contemporaries. In the second data set, the strategy of inseminating only a subset consisting of 59% of the most fertile cows conferred a gain in profit of $5.21 per eligible cow. These results suggest that, when used with a powerful classification algorithm, lift chart analysis and cost-sensitive evaluation of correctly classified and misclassified insemination events can enhance the performance and profitability of reproductive management programs on commercial dairy farms. Note: In machine learning methods, *P*-value is not a criteria of decision-making as it is in classic statistics.

Key Words: machine learning, reproductive management, cost-sensitive

0577 The cost of clinical mastitis in the first 30 d of lactation: an economic assessment tool.
E. Rollin*[1] and M. W. Overton[2], *[1]University Of Georgia College of Veterinary Medicine, Athens, [2]Elanco Animal Health– Dairy, Athens, GA*

Mastitis results in considerable economic losses for dairy producers and is most commonly diagnosed in early lactation. The objective of this study was to create a tool to estimate the predicted economic impact of clinical mastitis occurring during the first 30 d of lactation for a representative North American dairy. A deterministic partial budget model was created in spreadsheet software to estimate the projected direct and indirect costs per case of clinical mastitis occurring during the first 30 d of lactation in a typical dairy. The cost calculator was built by adapting published estimates from recent peer reviewed literature covering mastitis incidence, pathogen prevalence, recurrence risk, culling effects, reproductive effects, and milk production effects to estimate the value of projected future production, culling, death, and reproductive losses. Herd specific data including milk price, reproductive performance, lactational culling risk, diagnostic costs, treatment protocol costs, replacement costs, market cow prices, feed costs, labor costs, and veterinary costs are input to allow full customization of the projection model. The average case of clinical mastitis resulted in a net economic loss of $458, including $135 in direct costs and $323 in indirect costs. Direct costs included diagnostics ($3), therapeutics ($42), discarded milk ($20), veterinary service ($15), labor ($30), and death loss ($26). Indirect costs included future milk production loss ($135), future culling and replacement loss ($162), future reproductive loss ($21), and ongoing monitoring costs ($5). Accurate decision-making regarding mastitis control relies on understanding all of the economic impacts of clinical mastitis, especially the longer-term indirect costs that represent 71% of the total costs per case of mastitis. Future milk production loss represents 29% of total costs, and future culling and replacement loss represents 35% of the total costs of a case of clinical mastitis. In contrast to older estimates, these values represent the current dairy economic climate, including milk price ($0.48/kg), feed price ($0.286/kg DM), replacement costs ($2000), and use the latest estimates on the production and culling effects of clinical mastitis. This economic model is designed to be customizable for specific dairy producers and their herd characteristics to better aid them in developing mastitis control strategies.

Key Words: mastitis, economics, transition

PRODUCTION, MANAGEMENT, AND THE ENVIRONMENT: **EFFECTS OF TEMPERATURE ON PERFORMANCE**

0578 Urine metabolomics of heat-stressed dairy goats supplemented with soybean oil. A. Salama[*1,2], N. Nayan[3], A. Contreras-Jodar[1], S. Hamzaoui[1], and G. Caja[1], *[1]Group of Ruminant Research (G2R), Universitat Autonoma de Barcelona, Bellaterra, Barcelona, Spain, [2]Animal Production Research Institute, Dokki, Giza, Egypt, [3]Dep. of Animal Science, Faculty of Agriculture, University Putra Malaysia, Serdang.*

Biofluids assessment by ^{1}H nuclear magnetic resonance (NMR) spectroscopy would highlight the physiological mechanisms that may have occurred in goats when exposed to different management and environmental conditions. Our objective was to detect metabolomic changes in the urine of heat-stressed goats supplemented with soybean oil (SBO) for alleviating fat depression. Murciano-Granadina dairy goats (n = 8; 42.8 ± 1.3 kg BW) kept in metabolic cages were used in a replicated 4 × 4 Latin square design with 4 periods, 19 d each (14 d adaptation, 5 d for measurements). Goats were allocated to one of four treatments in a 2 × 2 factorial arrangement. Factors were no oil (C) or 4% SBO, and thermal neutral (TN; 15 to 20°C) or heat stress (HS; 12 h/d at 37°C and 12 h/d at 30°C) conditions, resulting in four treatments: TN-C, TN-SBO, HS-C, and HS-SBO. Urine samples were collected and analyzed with ^{1}H NMR spectroscopy for a qualitative metabolomic study. Principal component analysis (PCA) and partial least square–discriminant analysis (PLS-DA) were used to detect possible outliers and to identify possible metabolite markers of HS and SBO. The PLS-DA revealed that there were two separated clusters corresponding to TN (TN-C + TN-SBO) and HS (HS-C + HS-SBO) groups. Metabolites increased (P < 0.01) by HS were: hippurate, isoleucine, acetate, glutamate, glycine, and 3-hydroxybutyrate. On the other hand, L-phenylalanine and creatinine decreased (P < 0.01) by HS. Changes in those metabolites could be related to physiological responses to HS, including increased harmful gut microbiota activity (hippurate), increased catecholamine activity (conversion of L-phenylalanine to catecholamines), neurotransmitter inhibition (glycine), and decreased degradation of energy-related metabolites (acetate, isoleucine and glutamate). No significant regression model was found for the effects of SBO supplementation. We conclude that urine metabolomics could help in understanding the responses to heat stress and establishment of new alleviation strategies.

Key Words: heat stress, metabolomics, multivariate analysis

0579 Bovine core body and scrotal temperature measured using surgically implanted temperature-sensitive radio-transmitters, iButtons, and infrared thermography. A. Wallage[*1], J. B. Gaughan[1], A. Lisle[1], L. Beard[2], A. J. Cawdell-Smith[1], C. W. Collins[1], and S. Johnston[1], *[1]The University of Queensland, Gatton, Australia, [2]The University of Queensland, St Lucia, Australia.*

An ability to continuously and remotely monitor body (BT) and scrotal temperature (ST) without adverse or behavioral interference is fundamental to any study that investigates thermoregulation of the testis. Several methods for monitoring BT exist: loggers inserted into the rectum or vagina or placed in the ear close to the tympanic membrane, implantable radio-transmitters (RT), and rumen boluses. However, with all but RT and rumen boluses, data can only be collected for a few days. Previously, ST had only been measured via thermocouples for short durations (hours) or by manual scanning of microchips. This study compared the three most suitable technologies available for the coincident measurement of BT and ST: temperature sensitive RTs, data logging iButtons (IB), and infrared imaging (IRI). Bundles containing RT and IB were calibrated and surgically implanted in the abdominal muscle wall and scrotum of six bulls for between 29 and 49 d. IBs logged every 30 min, and RT pulse intervals were scanned every 15 min. Hourly IRI were taken of the body and scrotum of each bull for one 24 h period. Histology samples were obtained after castration at the conclusion of a series of heat-stress trials. IB were more reliable than the RT; all RT lost at least 11% of data, while 11 of the 12 IB had 100% data recovery. Pearson correlations between IB and RT were strong for both BT (r > 0.94, P < 0.001) and ST (r > 0.80, P < 0.001). Bland-Altman plots (limits of agreement) also showed stronger agreement with BT than ST, possibly due to the temperature gradient within the scrotum. The surgical procedure produced minor inflammation and hematoma in 2 animals immediately after the surgery. On castration, scar tissue was observed at all surgical sites but active spermatogenesis was evident in 10 of the 12 testicles. As all animals had been used in additional heat stress trials, it was impossible to determine the exact pathological effect of implant surgery. No significant correlation of IRI with either IB or RT existed, although sample size was small and, given that IRI measures surface temperature rather than BT, the usefulness of IRI is uncertain. IB provided a reliable, robust, and continuous BT and ST data set and can be successfully implanted in both the abdomen and scrotum of bovines.

Key Words: scrotal-temperature, iButton, radio-transmitter

0580 Rumen temperature of Brahman, Angus, and Charolais steers with and without access to shade. A. M. Lees*, J. B. Gaughan, M. L. Sullivan, J. C. Lees, and A. Lisle, *The University of Queensland, Gatton, Australia.*

Continuous measurement of body temperature (BT) is often difficult, and data collection is often restricted to short intervals. Remote assessment of BT through rumen boluses is a method of obtaining consistent BT over long periods of time without compromising animal comfort and potentially degrading carcass value. In this study, rumen temperature (T_{RUM}) of three cattle breeds, with and without access to shade, were assessed. Thirty-six steers (12 Angus, Charolais, and Brahman) with an initial BW of 318.5 ± 6.7 kg were used in a 180-d feedlot study with two treatments: un-shaded and shaded (3 m^2/animal; 90% solar block shade cloth). There were six steers (two/breed) per pen (162 m^2) and three pens/treatment. Ten-min T_{RUM} data were obtained over 130 d using rumen boluses. Individual T_{RUM} data were first converted to an hourly average, and then mean hourly T_{RUM} within breed x treatment were calculated. Rumen temperature was analyzed using a repeated measures model (PROC MIXED; SAS Inst. Inc. Cary, NC). The model analyzed the effect of breed ($P < 0.0001$), hour (h; $P < 0.0001$), breed x h ($P < 0.0001$), treatment x h ($P < 0.0001$), and breed x treatment x h ($P = 0.0036$). On average T_{RUM} of un-shaded Angus were greater ($P < 0.05$) than shaded and un-shaded Brahman's by 0.65 ± 0.05°C and 0.64 ± 0.05°C, respectively. Rumen temperature of shaded Angus were on average 0.46 ± 0.03°C ($P < 0.05$) lower than unshaded Angus between 1200 and 1600 h. Differences were observed between shaded and un-shaded Charolais between 1000 and 1700 h, with the shaded treatment on average 0.48 ± 0.02°C lower than unshaded. No h or treatment differences were detected between unshaded and shaded Brahman's, with a daily mean of 39.08 ± 0.08°C and 39.07 ± 0.08°C respectively, indicating that these animals may be utilizing breed specific behavioral and physiological mechanisms to regulate BT. These data suggest that providing feedlot cattle with shade during summer improves a non-heat-tolerant breed's ability to regulate BT. The relationship between rectal temperatures and T_{RUM} were also assessed ($r = 0.57$), with an average difference of 0.06 ± 0.06°C indicating that T_{RUM} is a robust measure of BT. Therefore, the assessment of an animal's thermal status can be undertaken through the remote assessment T_{RUM}.

Key Words: rumen temperature, body temperature, rectal temperature

0581 The effect of shade on vaginal temperature of cows housed outside under subtropical summer conditions. J. C. Lees*, J. B. Gaughan, A. M. Lees, and M. L. Sullivan, *The University of Queensland, Gatton, Australia.*

It is generally agreed that lactating dairy cows with access to shade have lower body temperatures than those without shade. The aim of this study was to determine the effect of shade on vaginal temperature (T_{VAG}) of cows housed outside in a sub-tropical environment. Holstein Friesian cows (n = 40) were paired based on milk yield and live-weight. Each pair was then allocated to either a shade (S) or a no shade (NS) treatment. Pairs were then randomly allocated to a T_{VAG} group (five pairs/group). Data were collected on one group per week, over 8 wk (two reps/group). A temperature logger was attached to a CIDR and inserted into the vagina for 5 d, logging every 10 min. Weather was monitored via an automated weather station (200 m from cows) and temperature humidity index [THI = 0.8 × ambient temperature + relative humidity x (ambient temperature – 14.3) + 46.3] was calculated using these data. Cows were milked twice daily at 0500 and 1500 h. Fans and sprinklers were used for 15 min before afternoon milking. Cows were placed within treatment from 0700 to 1445 h daily; fed a mixed ration twice daily, and turned out to improved pasture overnight. Averages for T_{VAG} and THI were obtained for each h over each 5-d period. Three data periods were examined: day (D), night (N), and evening (E); T_{VAG}_D and THI_D (0900 to 1500 h); T_{VAG}_N and THI_N (2200 to 0600 h); and T_{VAG}_E and THI_E (1700 to 2100 h). Pearsons correlations were performed on T_{VAG} against THI for each period. Overall, relationships were found between T_{VAG}_N and THI_N (r = -0.256; P = 0.041); T_{VAG}_D and THI_D (r = 0.34; P = 0.006); and T_{VAG}_D-N and THI_D-N (r = 0.61; $P < 0.000$) on the whole herd. Moderate correlations were determined for T_{VAG}_D-N and THI_D-N for S (r = 0.516; P = 0.003) and NS (r = 0.769; $P < 0.000$) cows. Shaded cows were better able to regulate T_{VAG} up to a THI of 76, after which T_{VAG} increased, whereas NS showed a positive, linear increase in T_{VAG} with increasing THI. It appears that S cows were better able to regulate body temperature than NS when THI_D-N was smaller than seven THI units. Above this point, the rate of increase in T_{VAG} against THI was greater in both treatments.

Key Words: vaginal temperature, shade, dairy cows

0582 Differences in panting score and shade usage between Brahman, Angus, and Charolais steers with and without access to shade during summer. J. B. Gaughan*, A. M. Lees, M. L. Sullivan, J. C. Lees, and N. B. Nquyen, *The University of Queensland, Gatton, Australia.*

The use of shade is largely a function of breed type and weather conditions. In this study the effect of breed on shade use and

subsequent respiratory response to heat load were evaluated. Thirty-six steers (12 each of Angus, Charolais, and Brahman; initial BW of 318.5 ± 6.7 kg) were used in an 81-d feedlot study with two treatments: no shade and shade (3 m^2/animal; 90% solar block shade cloth). There were six steers (two/breed) per pen (162 m^2) and three pens/treatment. Individual panting scores (PS) were obtained daily at 2-h intervals from 0600 to 1800 h. The PS system uses a seven-point score (0, 1, 2, 2.5, 3, 3.5, and 4) where PS0 indicates no thermal stress and PS4 indicates severe thermal stress (open mouth, tongue extended, rapid labored breathing). Individual PS were collated (breed and treatment), and mean panting scores (MPS) for each observation time (h) calculated. A MPS of 0.8 to 1.2 indicates high heat load, and if > 1.2 extreme heat load. Analysis of variance of MPS and shade usage was performed using repeated measures. The model analyzed the effect of breed, treatment, h, and all interactions. Angus used the shade in greater numbers ($P < 0.05$) at all times except 0600 h. For all breeds < 1% were under shade at 0600 h. For Angus maximum shade usage occurred at 1200 h (81.5%); for Charolais and Brahman maximum use occurred at 1400 h (39.4% and 24.6%, respectively). Mean PS was affected ($P < 0.05$) by treatment, treatment × h, breed, and breed × treatment. At 0600 h unshaded Angus had a greater ($P < 0.05$) MPS (1.06 ± 0.04) compared with unshaded Brahman (0.10 ± 0.02) and unshaded Charolais (0.90 ± 0.04). At 1400 h, when maximum MPS occurred, the values for unshaded (shaded in brackets) Angus, Charolais, and Brahman steers were 1.77 (1.52), 1.37 (1.31), and 0.78 (0.69), respectively. The percentage increase in MPS (0600 to 1400 h) of unshaded Brahmans was 87% ($P < 0.05$) (97% for shaded); for unshaded Angus the increase was 40% (47% for shaded), for Charolais it was 34% for unshaded and 41% for shaded. The MPS for shaded cattle suggests that the provision of shade allows cattle to improve thermoregulation. The greater percentage rise in MPS of Brahmans indicates that this breed does use increased respiratory dynamics in thermoregulation.

Key Words: panting, shade, cattle

0583 Correlation between mean panting score and temperature humidity index in lactating dairy cows in a sub-tropical summer. M. L. Sullivan*, J. B. Gaughan, N. Son, J. Lees, and A. M. Lees, *The University of Queensland, Gatton, Australia.*

Climate directly influences production and physiological responses of lactating dairy cows. Panting score (PS) can assist in determining the level of heat stress within a herd, but there is little research in this area for dairy cows. Forty lactating Holstein-Friesian cows were used in a 103-d study investigating the influence of summer conditions on animal response to heat load. The cows were managed within a partial mixed ration system and were milked twice daily (0530 h, 1400 h). The cows were observed twice daily [1000 h (AM); 1400 h (PM)] by the same observer. Individual PS were obtained once at each observation. Panting score system uses a seven-point score (0, 1, 2, 2.5, 3, 3.5, and 4), with PS0 = no thermal stress and PS4 = severe thermal stress (open mouth, tongue extended, rapid labored breathing). Individual PS were collated and converted into mean PS (MPS) for 40 cows at AM and PM. A MPS of 0.8 to 1.2 = high heat load, MPS > 1.2 = extreme heat load. In both instances milk production and reproduction are adversely affected. Ambient temperature (T_A) and relative humidity (RH) were obtained at 10-min intervals from an automated on-site weather station. THI was calculated from these data (THI = 0.8 × T_A) + [(RH/100) × (T_A - 14.4)] + 46.4). Mean PS were analyzed using repeated measures model. Correlations between MPS and THI at time of observation (0 h; AM/PM) and for 2- and 1-h lags were determined using Pearson correlation analysis. The MPS of cows (0 h) at PM (1.3 ± 0.05; extreme heat load) was greater ($P < 0.01$) than AM (1.1 ± 0.05; high heat load). Overall, MPS and THI were moderately correlated ($P < 0.001$) for 0-, 1-, and 2-h lags for AM and PM. For AM the best correlation between MPS and THI was $r^2 = 0.50$ for 1-h lag. For PM the best correlation between MPS and THI was $r^2 = 0.69$ for no lag (0 h). Elevated PS during AM may be an attempt to reduce heat load while there is a positive temperature gradient between the cow and the environment.

Key Words: panting, heat stress, temperature humidity index

0584 Correlation between milk production, days in milk, and temperature humidity index in lactating dairy cows in a sub-tropical summer. M. L. Sullivan*, J. B. Gaughan, N. Son, J. Lees, and A. M. Lees, *The University of Queensland, Gatton, Australia.*

Heat load is a significant factor that contributes to reductions in milk production in sub-tropical dairy cows. Forty lactating Holstein-Friesian cows were used in a 103-d study investigating the influence of summer conditions on animal responses. The cows were managed within a partial mixed ration system (70% total mixed ration and 30% pasture) and were milked twice daily at 0530 h and 1400 h. Individual milk production (MP) was recorded at each milking. Ambient temperature (T_A) and relative humidity (RH), were obtained at 10-min intervals from an automated on-site weather station, and temperature humidity index (THI) was calculated based on these data: (THI = 0.8 x T_A) + [(RH/100) x (T_A - 14.4)] + 46.4. Individual MP were collated and converted into mean MP for the 40 cows. Correlations between MP and mean THI for -1, -2, and -3-d lags were examined using Pearson correlation analysis. The mean MP over the duration of the study was 23.3 kg/cow.d^{-1} (range 18.9 to 28.3 kg/cow.d^{-1}), and DIM was < 50 d at the commencement of the study. The mean monthly THI for the duration of the study progressively increased: December, 71.0 ± 0.07 (range 51.5 to 84.7); January, 73.2 ± 0.07 (range 60.2 to 86.4); February, 74.1 ± 0.09 (range 59.7 to 87.1). Milk production was negatively correlated with THI ($P < 0.01$) for

1-, 2-, and 3-d lags. The correlation between MP for the 1-, 2-, and 3-d lags and THI on d 0 were -0.57, -0.55, and -0.53. Fluctuations in MP during summer are generally attributed to changes in THI, and this is supported by the current study. However, there was a negative correlation (r = -0.72, P < 0.001) between MP and DIM. During the study, increasing heat load corresponded with increasing DIM. Reductions in MP due to increasing DIM need to be accounted for so as not to confound the reductions in MP due to heat load. This study suggests that there is a strong negative correlation between the THI, MP, and DIM and that the effects are cumulative.

Key Words: heat stress, milk production, temperature humidity index

0585 Effects of metabolizable energy intake on tympanic temperature and ADG of steers finished in southern Chile during wintertime. R. A. Arias[*1], T. Brown-Brandl[2], and T. L. Mader[3], *[1]Universidad Católica de Temuco, Núcleo de Investigación en Producción Alimentaria, Temuco, Chile, [2]ARS-USDA, Clay Center, NE, [3]Mader Consulting, LLC, Gretna, NE.*

A total of 24 Angus x Hereford steers (BW = 479.8 ± 4.48) were used to assess the effect of ME intake (MEI) on ADG and tympanic temperature (TT) during the wintertime in southern Chile. The study was conducted at the experimental field of the UC Temuco and included a period of 21 d for adaptation to diet and facilities. Steers were randomly allocated in four pens (six/pen) equipped with a Calan Feeding System. Steers were sorted by BW, assigned to block (lighter or heavier), and then allocated into one of two treatments: T1 = 1.85x or T2 = 2.72 x MEI for maintenance. All steers were fed 1x/day with the same diet; treatments were applied by controlling DMI. Subsequently, five animals/treatment received a device to collect TT; those were retrieved 10 d later. Climatic data were obtained from a weather station located 5 km southeast from the research site. All data were analyzed under a complete randomized block experimental design (α = 0.05), and each steer was considered an experimental and observational unit. The steers fed with higher MEI showed higher TT than those fed with lesser MEI (P < 0.0001) through all days. In addition, both groups followed the same TT pattern throughout the TT collection period. This could be explained by changes in precipitations (PP) and wind speed (WS). The highest TT was observed in those days without PP and low WS. On the other hand, the lowest TT was observed when WS and PP were higher. Thus, in adult animals it appears that WS has an important role in the thermal balance during the wintertime. Similarly, steers fed with less MEI showed lesser TT when compared with those fed high MEI (P < 0.0001) through every hour of the day, even when both groups had theoretically enough energy to cover maintenance requirements. Following the same trend, observed ADG was higher (P = 0.0004) for those steers fed the high MEI compared with those fed the less MEI (0.54 vs. 0.17 ± 0.06 kg/d, respectively). This represents a performance of 3.18 times better for T2; however, MEI was only 1.47 times higher in this treatment. In conclusion, based on the data collected so far, it can be said that MEI has a direct effect on the TT and ADG of steers finished during the winter period in an open feedlot. In addition, both variables are directly affected by climatic conditions.

Key Words: tympanic temperature, thermal comfort, climate

0586 Conductive cooling as an alternative to cool down dairy cows. X. A. Ortiz[*1], J. F. Smith[1], F. Rojano[1], C. Y. Choi[2], J. Bruer[3], T. Steele[3], N. Schuring[4], J. D. Allen[5], and R. J. Collier[6], *[1]University of Arizona, Tucson, [2]University of Wisconsin-Madison, Madison, [3]Conco Technology Inc., Phoenix, AZ, [4]GEA Farm Technologies, Naperville, IL, [5]Northwest Missouri State, Maryville, [6]The University of Arizona, Tucson.*

The typical cooling system utilized to reduce heat stress in dairy operations requires high energy and/or water usage. With the steady increase in electricity costs and reduction of water availability and increase in water usage regulations, passive cooling systems need to be investigated as ways to cool cows and reduce the utilization of water and electricity. An experiment was designed to investigate the use of heat exchangers buried 25 cm below the surface as components in a conductive system for cooling cows. Six cows were housed in environmentally controlled rooms with tie-stall beds that were equipped with a heat exchanger and filled with 25 cm of either sand or dried manure. Beds were connected to supply and return lines and individually controlled. Two beds (one per each kind of bedding material) constituted a control group (water OFF), and the other four (two sand and two dried manure) used water at 7°C passing through the heat exchangers (water ON). The experiment was divided in two periods of 40 d, and each period involved three repetitions of three different climates (hot dry, thermo neutral, and hot humid). Sand bedding remained cooler than dried manure bedding in all environments and at all levels of cooling (water ON or OFF). Bed temperatures were lower and heat flux higher during the Sand ON bed treatment. We also detected a reduction in the core body temperatures (CBT), the respiration rates (RR), rectal temperatures, and skin temperatures of those cows heat-stressed during the Sand ON treatment. Dry matter intake and milk yield numerically increased during the Sand ON bed treatment for all climates. No major changes were observed in the lying time of cows or the composition of the milk produced. We concluded that use of heat exchangers is a viable alternative to systems that employ fans, misters, and the evaporative cooling methods to mitigate the effects of heat stress in dairy cows. Sand was a better bedding material to use in combination with heat exchangers. Additional research is needed to investigate alternative ways to increase the ex-

change of heat through conduction. Future studies should investigate the benefits of placing the heat exchanger closer to the skin surface and further reducing the water temperature through mechanical cooling.

Key Words: conductive cooling, heat stress and dairy cow

0587 Comparison of winter feeding systems for the evaluation of beef cow performance, reproductive efficiency, and system costs. D. Jose[*1], G. B. Penner[1], J. J. McKinnon[1], K. Larson[2], and B. Lardner[1,2], *[1]University of Saskatchewan, Saskatoon, Canada, [2]Western Beef Development Centre, Humboldt, SK, Canada.*

Extensive winter grazing has been proven as a successful strategy to reduce production and labor costs in a cow-calf operation without much adverse effects on animal health and performance. Two experiments were conducted during the winter of 2012–13, to evaluate three winter feeding systems: 1) field grazing standing whole plant corn (SC; TD*N* = 59.5%, CP = 7.8%), 2) field grazing swathed barley hay (SB; TD*N* = 66.2%, CP = 8.5%), and 3) barley hay bales fed in drylot pens (DL; TD*N* = 60.1%, CP = 12.7%). The specific objectives were to compare beef cow performance, reproductive efficiency, and system costs in experiment 1 (EXP 1), and ruminal pH parameters in experiment 2 (EXP 2). In EXP 1, dry pregnant Angus cows (n = 60, body weight (BW) = 651.2 ± 7 kg), stratified by body weight and days pregnant, were randomly allocated to one of three replicated (n = 2) winter grazing treatments for 77 d. Cow BW, body condition score (BCS), and rib and rump fats were measured at the start and end of the trial. Increases in rump fat were greater (P = 0.002) for SC cows compared to DL cows (1.90 mm vs. 0.55 mm, respectively). Calves born to cows on SC were heavier (P < 0.001) at birth compared to calves from SB cows (42 vs. 40 kg respectively). In EXP 2, nine cannulated beef heifers were cycled through the three winter systems concurrently within EXP 1 in a replicated 3 × 3 Latin square design for 63 d to evaluate effect of forage type on rumen pH. Results from EXP 2 indicated that SB heifers had the lowest (P < 0.003) mean, minimum, and maximum rumen pH and greatest duration and area under pH < 5.8 (P < 0.001) compared to heifers on SC and DL winter systems. Economic analysis revealed that total costs were greatest for the DL ($2.29/head/d) compared to SC ($1.78/head/d) and SB ($1.65/head/d) systems. Results suggest that both SC and SB systems are cost-effective alternatives to DL system and do not negatively affect cow body weight or reproductive performance in winter.

Key Words: winter grazing, corn grazing, swath grazing, reproductive performance

0588 Effect of two winter housing systems on production, body weight, somatic cell count, BCS, and dry matter intake of organic dairy cows. L. S. Sjostrom[*1], B. J. Heins[1], M. I. Endres[2], R. D. Moon[2], and U. S. Sorge[3], *[1]University of Minnesota, West Central Research and Outreach Center, Morris, [2]University of Minnesota, St. Paul, [3]University of Minnesota, Dep. of Veterinary Population Medicine, St. Paul.*

Organic cows (n = 83) were used to evaluate the effect of two winter housing systems (December 2012 to May 2013) on production, SCC, body weight, BCS, and DMI. Cows were assigned to one of two treatments (two replicates per group): 1) outdoor (straw pack, n = 42) or 2) indoor (compost-bedded pack barn, n = 41). There were 21 cows per replicate for the outdoor housing and 21 and 20 cows per replicate for the indoor housing. Cows calved during two seasons (March to May 2012 and September to December 2012) at the University of Minnesota West Central Research and Outreach Center, Morris, MN, organic dairy. Organic wheat straw was used as bedding for the two outdoor bedded packs, which were 12 m wide by 27 m long, and maintained by farm management to keep cows dry and absorb manure throughout the winter. The open-front compost-bedded pack barn (two pens in the barn) was bedded with organic-approved sawdust, and the bedding material was stirred twice per day with a small chisel plow. Cows were fed a TMR that included organic corn silage, alfalfa silage, corn, expelled soybean meal, vitamins, and minerals. Milk, fat, and protein production and SCC were recorded from monthly DHIA testing. Body weight and BCS were recorded bi-weekly as cows exited the milking parlor. The PROC MIXED of SAS was used for statistical analysis, and independent variables were fixed effects of season of calving (fall or spring), parity (1, 2, 3+), breed group, housing system, with replicate and cow nested within the interaction of housing system and season as a random effect. Energy-corrected milk and SCC was not different for the outdoor (15.5 kg/d, 206,000 mL) and indoor (16.1 kg/d, 357,000 mL) housing systems, respectively. In addition, outdoor and indoor housing systems were not different for body weight (523 vs. 538 kg) and BCS (3.15 vs. 3.08), respectively. Daily DMI was 17.8 kg/d for indoor cows and 17.6 kg/d for the outdoor cows (P = 0.47). Total bedding costs during the winter was $8,275 for the outdoor system and $9,248 for the indoor system. In summary, cows housed outdoors on straw-bedded packs did not differ from cows housed in an indoor compost-bedded pack barn for production and SCC, as well as body weight, BCS, or DMI.

Key Words: organic, outwintering, compost barn

RUMINANT NUTRITION I

0589 Feedlot performance and diet digestibility of feed efficiency-ranked beef steers fed corn or roughage-based diets and finished with corn or byproduct-based diets. J. R. Russell*[1], N. O. Minton[2], W. J. Sexten[2], M. S. Kerley[2], and S. L. Hansen[1], *[1]Iowa State University, Ames, [2]University of Missouri, Columbia.*

The objective was to determine effects of growing phase (GP) diet and feed efficiency (FE) ranking, as well as finishing phase (FP) diet, on beef steer diet digestibility and FP growth. At University of Missouri, 193 steers were fed whole-shell corn (GPC) or roughage-based (GPR) diets using GrowSafe individual feed intake system for 70 d and FE was determined. At Iowa State University, the 12 greatest (HFE) and 12 least (LFE) feed efficient steers from each GP diet (n = 48; 509 ± 7 kg) were blocked by GP diet and FE ranking into GrowSafe-equipped pens of six. Steers were fed 10 g titanium dioxide (TiO_2) daily in diets similar to GP diets for 14 d, followed by 2 d fecal collection to determine GP diet DM digestibility (GPdig). Steers were then transitioned to FP corn (FPC) or byproduct-based diets (FPB), receiving FP diets for 14 d before again being fed TiO_2 daily for 14 d followed by 2 d fecal collection to determine FP diet DM digestibility (FPdig). Data were analyzed using PROC MIXED of SAS. There was a tendency for greater (P = 0.07) GPdig in HFE versus LFE steers, and FPdig was greater (P < 0.05) for steers fed FPC versus FPB diets. There was no relationship between FPdig and finishing phase G:F. There was a positive correlation between G:F in GP and FP (R = 0.29; P < 0.05). A positive correlation between GPdig and FPdig (R = 0.31; P < 0.05) was driven by a strong positive correlation between GPdig and FPdig (R = 0.71, P < 0.05) in cattle grown and finished on corn diets. Compared to LFE, HFE steers had greater finishing phase G:F (P < 0.05) and tended to have greater FP final BW and ADG (P = 0.07), while DMI did not differ due to FE rank (P > 0.1). No differences in ADG, G:F, or DMI (P > 0.1) during FP were noted due to GP or FP diet effects. In this study, G:F during FP was positively related to growing phase FE ranking, and FP performance was greater in steers ranked as highly FE during GP. Differences in GPdig may help explain growing phase FE ranking. The strong correlation for diet digestibility in steers grown and finished on corn diets supports the assertion that cattle FE testing should likely be conducted using the diet most similar to the environment of interest.

Key Words: cattle, digestibility, feed efficiency

0590 Effects of processing of treated corn stover and distillers grains on intake and digestibility of feedlot diets. J. L. Harding*, M. L. Jolly, J. C. MacDonald, and G. E. Erickson, *University of Nebraska-Lincoln, Lincoln.*

Four ruminally fistulated steers were utilized in a 4 × 6 Latin rectangle design to evaluate the effects of replacing dry-rolled corn (DRC) with a pelleted feed containing treated corn stover and distillers grains (DGS). The control (CON) treatment contained 50.3% DRC, 40% DGS, 5% stalks, and 1.7% limestone. The first treatment (TRT 1) consisted of 27% DRC, 40% DGS, 25% treated stover pellet, and 5% stalks. The second treatment (TRT 2) contained 25.9% DRC, 40% DGS, 10% treated stover pellet, 10% DGS, 5% solubles, 5% stalks, and 1.1% limestone. Treatment 3 (TRT 3) contained 27% DRC, 40% DGS, 25% treated corn stover and distillers pellet, and 5% stalks. The diet for TRT 2 was formulated to be of similar energy value as the treated stover and distillers pellet in TRT 3. Pellets used in TRT 1 contained corn stover that had been processed differently compared to the pellets fed in TRT 3. All treatments contained 3% supplement. Data were analyzed using the PROC MIXED of SAS. There were no ($P \geq 0.15$) differences observed among the CON, TRT 1, TRT 2, or TRT 3 for DM (10.10, 7.45, 8.49, and 8.52 kg/d, respectively), OM (8.07 ± 2.15 kg/d), or NDF (2.71 ± 0.65 kg/d) intakes. Correspondingly, no differences ($P \geq 0.50$) were observed between the CON, TRT 1, TRT 2, or TRT 3 for DM (75.41 ± 5.21%), OM (78.59, 78.81, 77.40, and 79.98%, respectively), or NDF (62.35, 72.63, 68.35, and 68.11%, respectively) digestibilities. Proportions (mMol/100 mMol) of acetate (54.75 ± 0.72), propionate (26.71 ± 1.10), and butyrate (12.05 ± 0.72) were not different between the four treatments (P > 0.50). There was a difference (P < 0.05) in maximum ruminal pH recorded with the treatments having a maximum pH of 6.30 (CON), 6.66 (TRT 1), 6.29 (TRT 2), and 5.96 (TRT 3). There was a tendency (P = 0.09) for differences in average ruminal pH, with treatment differences following the same trend as seen in maximum pH. Differences in maximum pH were attributed to varying pH of the two pellet types. It was concluded that the DRC could be replaced with a pelleted stover and distillers in the finishing diet without altering total tract digestion.

Key Words: cattle, pellet, treated stover

0591 Effects of dietary glycerin inclusion at 0, 5, 10, and 15% of dry matter on energy metabolism and nutrient balance in finishing beef steers. *K. E. Hales*, A. P. Foote, T. Brown-Brandl, and H. C. Freetly, USDA-ARS-MARC, Clay Center, NE.*

Expansion of the biodiesel industry has increased the glycerin (GLY) supply. Glycerin is an energy-dense feed that

can be used in ruminant species; however, the energy value of GLY is not known. Therefore, the effects of GLY inclusion at 0, 5, 10, and 15% in dry-rolled corn (DRC)-based diets were evaluated in eight steers (BW = 503 kg) using a replicated Latin square design. Data were analyzed with the fixed effects of dietary treatment and period and random effects of square and steer within square were included in the model. Contrast statements were used to separate linear and quadratic effects of GLY inclusion. Diets were based on DRC and GLY replaced DRC at 0 (GLY-0), 5 (GLY-5), 10 (GLY-10), and 15% (GLY-15) of dietary dry matter. Dry matter intake decreased linearly ($P = 0.02$) as GLY increased in the diet. As a proportion of GE intake, fecal energy loss tended to decrease linearly ($P < 0.07$), and DE also tended to decrease linearly ($P = 0.07$) as dietary level of GLY increased. Urinary energy loss was not different ($P > 0.31$) as a proportion of GE as GLY increased in the diet. Methane energy loss as a proportion of GE intake tended to respond quadratically ($P = 0.10$) decreasing from 0 to 10% GLY inclusion and increasing thereafter. As a proportion of GE intake, heat production increased linearly ($P = 0.02$) as GLY increased in the diet Additionally, as a proportion of GE intake, retained energy (RE) tended to respond quadratically ($P = 0.07$) increasing from 0% to 10% GLY inclusion and decreasing thereafter. Total dry matter digestibility tended ($P < 0.01$) to respond quadratically. As a proportion of N intake, urinary and fecal N excretion increased linearly ($P < 0.04$) as GLY increased in the diet. Furthermore, g of N retained and N retained as a proportion of N intake both decreased linearly ($P < 0.02$) as GLY increased in the diet. Overall, RE tended to decrease as GLY increased in the diet in conjunction with a decrease in N retention. The increase in N excretion as GLY increased in the diet could indicate an increase in microbial N excretion caused by a shift from ruminal fermentation to post gastric fermentation. *USDA is an equal opportunity provider and employer.*

Key Words: cattle, energy metabolism, glycerin

0592 Intake and digestibility of diets without forage in Nellore and Angus young bulls. *M. M. Ladeira[*1], J. R. R. Carvalho[1], M. L. Chizzotti[2], D. R. Casagrande[1], P. D. Teixeira[1], M. C. L. Alves[1], R. A. Gomes[1], and L. A. Silveira[1], [1]Universidade Federal de Lavras, Lavras, Brazil, [2]Universidade Federal de Viçosa, Viçosa, Brazil.*

The objective was to evaluate intake and digestibility of nutrients in Nellore and Angus young bulls fed a corn silage/concentrate diet and a whole shell corn (WSC) diet without the use of forage. Thirty-six animals with average body weight of 381.2 ± 11.87 kg were used in a completely randomized design using a 2 × 2 factorial arrangement (two breeds and two diets). The corn silage/concentrate diet contained 30% silage and 70% of concentrate based on corn and soybean meal. The WSC diet had 85% whole shell corn and 15% of a pellet based on soybean meal and minerals. Both diets had 12.5% of crude protein and 2.88 Mcal/kg of ME. The animals were allocated in individual pens and fed during 81 d of experiment. However, the digestibility trial started at Day 65 with total collection of feces and orts for five consecutive days. Intake was measured daily. Data were analyzed using PROC GLM of SAS 9.3. Angus animals had greater nutrient intake (kg/d) due to their greater body weight, compared to Nellore (Table 0592). However, there weren't differences on dry matter (DM) and neutral detergent fiber (NDF) intake, when data were analyzed on live weight percentage. WSC diets decreased DMI on both breeds studied. Breeds affected digestibility of non-fiber carbohydrates (NFC) only when WSC diet was used, being greater in Angus animals. WSC diet had greater digestibility of NDF, less digestibility of NFC and a tendency to increase DM digestibility. In conclusion, Angus young bulls have more capacity to digest NFC than Nellore. *Funded by Fapemig, CNPq, CAPES and INCT-CA.*

0593 A survey of dry-rolled corn particle size and fecal starch in U.S. feedlots. E. Schwandt*, *Kansas State University, Manhattan, KS.*

Optimizing grain processing practices in cattle feeding operations is critical to maximize feed efficiency. A survey was conducted to evaluate dry-rolled corn (DRC) processing practices on particle size distribution and fecal starch in finishing cattle. Twenty-four feedlots across South Dakota, Minnesota, Iowa, Nebraska, Kansas, and Colorado participated in the study. Samples of dry-rolled corn, freshly voided feces, and the finishing diet were collected from each feedlot. Particle size distribution of dry-rolled corn samples was determined at the Kansas State University Feed Technology Innovation Center (Manhattan, KS) using a Tyler Ro-Tap Sieve Shaker. The average geometric mean particle size across all operations was 4.6 ± 0.87 mm with a range of 3.2 to 6.8 mm. Fecal starch content averaged 18.2 ± 6.84%; by-product inclusion level averaged 27.0 ± 14.26%; roughage inclusion level averaged 8.3 ± 1.82%; NDF levels averaged 18.7 ± 4.02% on a dry matter basis. Fecal starch values indicate the amount of undigested starch in the feces, which may be influenced by corn particle size. There may be an opportunity to increase the degree of grain processing in some feedlot operations to improve total tract starch utilization.

Key Words: feedlot, grain processing, fecal starch

0594 Effects of feeding zilpaterol hydrochloride on feedlot performance and carcass characteristics of Nellore bulls and steers. A. L. Brichi[1], C. F. Costa[1], A. Perdigao[1], M. A. Factori[1], I. C. Pereira[1], D. D. Estevam[1], R. S. Goulart[2], C. L. Martins[1], D. D. Millen[*3,4], and M. D. Arrigoni[1], *[1]São Paulo State University (UNESP), Botucatu campus, Botucatu, Brazil, [2]MSD Saúde Animal, Sao Paulo, Brazil, [3]Supported by São Paulo State Foundation (FAPESP), [4]São Paulo State University (UNESP), Dracena, Brazil.*

This study, conducted at the São Paulo State University feedlot, Botucatu Campus, Brazil, was designed to determine the effects of feeding zilpaterol hydrochloride (ZH) on feedlot performance and carcass traits of Nellore steers and yearling bulls. The experiment was designed as a completely randomized block with a 2x2 factorial arrangement of treatments. Thirty-six 22-mo-old Nellore steers and 36 22-mo-old Nellore yearling bulls (483.9 ± 26.0 kg) were allocated in 24 pens and fed one of two finishing diets containing either 0.0 mg or 7.50 mg of ZH per kilogram of diet DM, replicated six times (three animals/pen), for 20-d before slaughter with a 3-d withdrawal. The finishing diet contained: 70.0% high moisture corn grain, 15.0% sugarcane bagasse, 5.5% peanut meal, 4.0% cottonseed hulls, 3.0% supplement, 1.0% Coast cross hay, 0.8% urea, and 0.7% limestone (DM basis). Cattle were fed ad libitum twice daily for 112 d, and feed offerings and refusals were weighed daily. Cattle were weighed 20 d before slaughter and at the end of the study. A significant ($P < 0.01$) ZH main effect was observed, in which cattle fed ZH had greater final BW (518.6 vs. 510.3 kg) and ADG (1.73 vs. 1.31 kg), improved F:G ratio (5.55 vs. 7.55), heavier HCW (292.7 vs. 280.0 kg), and increased dressing percentage (56.6 vs. 55.1%). In addition, a significant ZH x sex interaction was observed ($P = 0.04$) for DMI, expressed in kg, in which steers not fed ZH had greater DMI than steers fed ZH (9.88 vs. 9.00 kg). However, yearling bulls not fed ZH presented similar DMI when compared to yearling bulls fed ZH (9.61 vs. 9.47 kg). Likewise, a significant ZH x sex interaction was observed ($P = 0.03$) for DMI, expressed as % of BW, in which steers not fed ZH had greater DMI than steers fed ZH (2.00 vs. 1.81%). However, yearling bulls not fed ZH presented similar DMI when compared to yearling bulls fed ZH (1.91 vs. 1.87%). Thus, feeding ZH improves the feedlot performance, as well as carcass traits of Nellore cattle regardless of sex.

Key Words: intake, sex, Zebu

0595 Effects of Next Enhance concentrations in finishing diets on performance and carcass characteristics of yearling feedlot cattle. *C. J. Bittner*[*1], G. E. Erickson[1], K. H. Jenkins[2], M. K. Luebbe[2], G. I. Zanton[3], and M. A. Andersen[3], [1]University of Nebraska-Lincoln, Lincoln, [2]University of Nebraska, Scottsbluff, NE, [3]Novus International, Inc., St. Charles, MO.*

A feedlot study evaluated the effects of Next Enhance 300 (NEXT) essential oil concentration in finishing diets on yearling steer performance and carcass characteristics. Crossbred yearling steers ($n = 288$; BW = 446 ± 23 kg) were utilized in a randomized block design experiment. Cattle were separated into three weight blocks (light, medium, and heavy), stratified by BW, and assigned randomly within strata to 36 pens. Pens were assigned randomly to one of four treatments with nine replications per treatment and eight steers per pen. Treatments consisted of feeding NEXT at concentrations of 0, 16.5, 33.1, and 49.6 mg/kg of diet DM. Light, medium, and heavy blocks consisted of 3, 4, and 2 replications, respectively. Monensin and tylosin were provided in all treatments at 360 and 90 mg/steer daily, respectively. Steers were fed a common basal diet consisting of 54% dry-rolled corn, 25% wet distillers grains plus solubles, 15% corn silage, and 6% supplement (DM basis). Steers in the medium and heavy blocks were fed for 98 d, while steers in the light block were fed for 118 d. Animal performance and carcass characteristics were

analyzed using the PROC MIXED of SAS with pen as the experimental unit. Increasing NEXT concentration in the diet had no effect on DMI, ADG, or G:F ($P > 0.59$; linear or quadratic). Hot carcass weight, fat thickness, and calculated yield grade were not affected ($P > 0.21$; linear or quadratic) by NEXT concentration. As NEXT concentration increased, LM area tended ($P = 0.06$) to decrease quadratically. Greatest LM area were observed when steers were fed 0 or 49.6 mg/kg NEXT, while feeding 33.1 mg/kg NEXT produced the smallest LM area. These data suggest that feeding increasing concentrations of NEXT had little impact on feedlot performance of large yearlings.

Key Words: beef cattle, essential oil, feedlot performance

0596 Effects of plane of nutrition during late gestation and weaning age on transcriptome profiles of Longissimus muscle in Simmental x Angus offspring. S. Moisa*, L. M. Shoup, D. W. Shike, and J. J. Loor, *University of Illinois, Urbana, IL.*

The aim of this study was to evaluate potential carryover effects of maternal diet during late gestation and effects of weaning age on the transcriptome profiles of Longissimus muscle of Angus x Simmental offspring. Pregnant cows blocked by breed were utilized in a 2 × 2 factorial design. Three months before the projected parturition date, cows were assigned to diets (low or medium plane of nutrition). Low plane of nutrition was achieved by grazing endophyte-infected tall fescue/red clover pastures with no supplement, while medium plane of nutrition was achieved by grazing endophyte-infected tall fescue/red clover pastures supplemented with 2.3 kg of dried distiller's grains with solubles and soyhulls. Steer calves were randomly assigned to early or normal weaning treatments within each gestational diet ($n = 20$). At 80 d postpartum, early-wean offspring (EW) were weaned, and received a high-energy finishing diet. At 186 d postpartum, normal-wean offspring (NW) were weaned and joined EW steers at the feedlot where they received the same diet. Longissimus muscle (LM) biopsies were harvested on 81, 187, and 354 d of age. A 45,220 bovine microarray (Agilent) was used for transcript profiling ($n = 5$ steers/group). Functional analysis was performed by means of the Dynamic Impact Approach (DIA). ANOVA statistical analysis (FDR < 0.05 and $P < 0.05$) revealed 8400 differentially expressed genes (DEG) due to time alone and 856 DEG due to treatment alone. Treatment × time affected 33 genes and no DEG were detected for time × treatment × diet. Within the 8400 DEG, the functional analysis revealed that nitrogen metabolism and drug metabolism were the canonical pathways with the highest impact, specially comparing 81 to 354 d of age ($P < 0.05$). For the 856 DEG due to treatment, fatty acid biosynthesis, pyruvate metabolism and insulin signaling pathways were the most–impacted when comparing EW to NW at different time points. Within the 33 DEG due to treatment × time fatty acid biosynthesis was the only impacted canonical pathway ($P < 0.05$). Moreover, initial analysis based on expression pattern (i.e., up- or downregulation) of the 33 DEG indicated most were activated. Results indicated a minor response of the offspring transcriptome to level of maternal plane of nutrition at least when applied during the last 90 d of pregnancy. Post-natal nutritional management, however, led to marked differences in transcriptomics particularly between the growing (81 to 187 d) and finishing phases (187 to 354 d).

Key Words: nutrigenomics, bioinformatics, nutrition

0597 Post-natal nutritional management alters transcription regulator gene networks in Longissimus muscle of Angus x Simmental offspring. S. Moisa*, L. M. Shoup, D. W. Shike and J. J. Loor, *University of Illinois, Urbana, IL*

The aim of this study was to evaluate potential carryover effects of the maternal diet during late gestation and also effects of weaning age on the transcription regulator (TR) gene networks in Longissimus muscle. Angus x Simmental beef cows blocked by breed were utilized in a 2 × 2 factorial design. Three months before the projected parturition date, cows were assigned to treatments (low or medium plane of nutrition). Low plane of nutrition was achieved by grazing endophyte-infected tall fescue/red clover pastures with no supplement, while medium plane of nutrition was achieved by grazing endophyte-infected tall fescue/red clover pastures supplemented with 2.3 kg of dried distiller's grains with solubles and soyhulls. Steer calves were randomly assigned to early- or normal-weaning groups ($n = 20$). At 80 d of age, early-wean offspring were weaned and received a high-energy finishing diet. At 186 d of age, normal-wean offspring were weaned and joined early-wean steers at the feedlot where they received the same diet. Steers were group-fed and intake recorded using the GrowSafe system. Longissimus muscle (LM) biopsies were harvested at 81, 187, and 354 d of age. A 45,220 bovine microarray (Agilent) was used for transcript profiling ($n = 5$ steers/group). Differentially-expressed TR, ligand-dependent nuclear receptors, and their networks with differentially-expressed genes (DEG) were mined using Ingenuity Pathways Analysis (FDR < 0.05 and $P < 0.05$). The statistical model included treatment, maternal diet, time and its interactions, as fixed effects, and steer as random effect. Among the 8400 DEG ($P < 0.05$) affected by the overall effect of time IPA analysis revealed 625 TR and ligand-dependent nuclear receptors (NR). TP53 was the TR with the highest network of target genes. Considering only the DEG due to treatment ($P < 0.05$), among 856 DEG the IPA analysis revealed that 78 were classified as TR and NR. TP53 was also the TR with

the highest network of target genes. In the separate analysis of genes affected by time and treatment ($P < 0.05$) TP53, MYC, HTT, and ERS1 were the TR with highest networks of DEG in both analyses. Results suggest that different plane of nutrition during the last 90 d before calving did not markedly affect the expression of transcription regulators or ligand-dependent nuclear receptors in the offspring's skeletal muscle transcriptome. However, post-natal nutritional management seems to affect TR and NR by activating their expression at growthing stage (i.e., 81 to 187 d) especially when early-weaned.

Key Words: gene networks, nutrigenomics, bioinformatics

0598 Effect of ractopamine hydrochloride and dietary protein content on performance and carcass traits of Nellore bulls.

N. R. B. Cônsolo[1], F. Rodriguez[1], M. O. Frasseto[1], R. A. P. Maciel[2], V. Rizzi[3], and L. F. P. Silva[*1], [1]University of Sao Paulo, Pirassununga, Brazil, [2]University of Sao Paulo, [3]Ouro Fino, Cravinhos, Brazil.*

The objective of this research was to evaluate the effects of ractopamine hydrochloride (RH) and dietary crude protein (CP) on performance and carcass traits of Nellore young bulls. Forty-eight Nellore bulls were grouped by BW, and randomly assigned to treatments in a 2x2 factorial arrangement of treatments. The factors were two levels of dietary CP (100 and 120% of MP requirement), and two levels of RH (0 and 300 mg/animal/d). Treated animal received RH for the final 35d before slaughter. Dry matter intake was measured and adjusted daily. The animals were weighed at intervals of 21 d, at the beginning of supplementation, after 18 d of supplementation and before slaughter. Feed efficiency was calculated from ADG and DMI. On d 113 hot carcass weights were recorded at slaughter. After 24 h of chilling, longissimus muscle area (LMA), and fat thickness were measured at the left half-carcass. The statistical analyses were conducted using SAS, version 9.1.2 for Windows. There was no effect of RH supplementation on final BW ($P = 0.26$). However, animals supplemented with RH had 19% greater ADG than control animals (1.51 vs. 1.27 kg/d, $P = 0.03$), this effect was not dependent on the level of CP in the diet ($P = 0.43$). Increasing dietary CP content above requirements had no effect on final BW, ADG or G:F ratio ($P > 0.05$). For DM intake, the RH x CP interaction was significant ($P = 0.01$), where RH supplementation had no effect on DMI at CP100 ($P = 0.12$) yet it reduced DMI at CP120 (1.95 vs. 1.81% BW for RH0 and RH300, respectively; $P = 0.03$). Addition of RH to the diet considerably improved G:F ratio, independently of the CP concentration of the diet (0.15 vs. 0.13, $P = 0.02$). Treatments had no effect on HCW or dressing percentage of the carcass ($P > 0.10$). There was a tendency ($P = 0.07$) for RH supplementation to increase LMA, independently of dietary CP levels (83.2 vs. 87.9 cm^2). Ractopamine did not alter fat thickness ($P = 0.29$); however, increasing dietary CP above requirements (CP120) decreased fat thickness (5.1 vs. 4.3 mm for CP100 and CP120, respectively). In conclusion, ractopamine supplementation increased gain, improved feed efficiency, and increased LMA even in intact Nellore young bulls.

Key Words: β-agonist, cattle, muscle growth

0599 Effect of 300 or 400 mg daily of ractopamine hydrochloride on growth performance and carcass characteristics of finishing steers during the last 14, 28, or 42 d.

C. J. Bittner*[1], D. B. Burken[1], G. E. Erickson[1], and N. A. Pyatt[2], [1]*University of Nebraska-Lincoln, Lincoln,* [2]*Elanco Animal Health, Greenfield, IN.*

Crossbred yearling steers ($n = 576$; BW = 408 ± 29 kg) were utilized in a randomized block design ($n = 4$ BW blocks) with a 3 × 3 factorial treatment design to study the effects of ractopamine hydrochloride (RAC) dosage and duration on growth performance. Factors included RAC feeding duration (14, 28, or 42 d before harvest) and RAC dosage (0, 300, and 400 mg/hd/d). During the treatment phase, RAC dose was top-dressed daily using fine-ground corn as the carrier. There were no significant duration x dosage interactions ($P > 0.07$) for growth performance or carcass characteristics; however, simple effects will be presented. Live final BW was not different ($P > 0.44$) for steers fed 0, 300, or 400 mg RAC for 14 d. At 28 d, steers fed RAC at 400 mg were significantly ($P < 0.01$) heavier than steers receiving 0 mg. There was a tendency at 28 d for increased live final BW for steers fed RAC at 300 mg ($P = 0.07$) compared to 0 mg and steers fed 400 mg of RAC compared to 300 mg ($P = 0.07$). Live final BW was greater ($P < 0.01$) for steers fed RAC for 42 d at 300 and 400 mg compared to cattle receiving 0 mg; however, live final BW was similar ($P = 0.57$) between 300 and 400 mg of RAC. Between treatments, DMI was similar ($P = 0.27$). Hot carcass weight was similar ($P = 0.33$) between yearlings fed 0 and 300 mg of RAC for 14 d, but tended to be greater ($P = 0.07$) for steers fed 400 mg of RAC compared to 0 mg. Hot carcass weight was greater ($P < 0.01$) for steers fed 300 and 400 mg of RAC compared to cattle fed 0 mg for 28 d. Carcasses from yearlings fed RAC for 42 d at 300 and 400 mg were heavier ($P < 0.01$) than 0 mg fed steers. Feeding 300 mg of RAC for 28 or 42 d increased live final BW by 7 and 13 kg, while feeding RAC at 400 mg resulted in 14 and 11 kg increases relative to control steers. Feeding 300 mg of RAC for 28 or 42 d would suggest 4.9 and 7.5 kg improvements in HCW, while feeding 400 mg of RAC would suggest 8.7 and 9.3 kg heavier carcasses compared to steers fed no RAC.

0600 Comparison of the total tract digestibility in feedlot cattle fed barley grain treated with lactic and citric acid. M. Nematpoor[*1], K. Rezayazdi[2], and M. Dehghan-Banadaky[1], *[1]University of Tehran, Karaj, Iran, [2]Dep. of Animal Science, Faculty of Agriculture, University of Tehran, Karaj, Iran.*

RUMINANT NUTRITION II

0601 Using a dynamic metabolic model to investigate differences in metabolic patterns among lactating animals. L. Oliveira[1], H. Kimball[2], J. P. McNamara[*2], and A. Fix[2], *[1]Sao Paulo State University, Brazil, [2]Washington State University, Pullman, WA.*

In dairy cattle, the metabolic flux in body tissues, primarily in visceral, muscle, and adipose tissues make up a large contribution to variations in efficiency among animals housed and fed alike. Metabolic processes are affected by genotype, phenotype, and intake; genotypic differences eventually result in variation in patterns of metabolism that have different metabolic efficiencies. In continued work with the objective of identifying the patterns of metabolic flux in the most efficient dairy cattle, an existing mechanistic metabolic model (Molly, UC Davis) was used to describe differences in energetic and nitrogen efficiency among cows fed and housed alike. Data were from 42 high producing cows fed an alfalfa/corn/SBM based TMR. Data on genetic merit and DMI were input into the model, and milk component output, changes in adipose tissue lipid metabolism; visceral and body protein and lipid, nitrogen were output. Each cow was simulated separately. There was a range in metabolic processes from 27% (maintenance costs) to 93% (MUN) (Table 0601). Tissue metabolism rates (lipogenesis, lipolysis) varied by 48 to 74%; indicating a wide range in potential to metabolize nutrients. The intricate range of patterns of nutrient metabolism underlay the 21% range in net energy efficiency (milk energy/ME intake). A systems approach and model can be used, eventually, to improve selection of cows to reduce the variation in energy efficiency. Integrating all the biological processes with data on genomics and transcriptomics using systems models will help reduce variation in energy efficiency.

0602 A dynamic, mechanistic model of metabolism in adipose tissue of lactating dairy cattle. J. P. McNamara[*1], K. Huber[2], and A. Kenez[2], *[1]Washington State University, Pullman, [2]University of Hannover, Germany.*

Research in dairy cattle biology has resulted in a large body of knowledge on nutrition and metabolism supporting and underlying milk production and efficiency. The adipose tissues are an essential part of the overall efficiency of dairy cattle. Therefore we constructed a dynamic, mechanistic model of control of metabolism in the adipose tissues of dairy cattle. The model describes the biochemical interconversion of glucose, acetate, glycerol, fatty acids, and triacylglycerols. Data from our own research and published references were used to set equation forms and parameter values. Metabolites are absorbed from blood, and fatty acids are activated to the Acyl CoEnzymeA counterparts. Fatty acids are partitioned to palmitic, stearic, oleic and linoleic acids. Enzymatically catalyzed reactions are explicitly described with parameters including maximal velocity and substrate sensitivity. Energetic stoichiometry is maintained by the balance of ATP utilizing and generating reactions. Changes in gene transcription or post-translational modification of enzyme activity control nutrient metabolism, including control by insulin and norepinephrine. The model behavior to availability of nutrients and insulin or norepinephrine is in agreement with published data. For example, triacylglycerol synthesis when glucose is low (1 mM) is 17.82 + 1.9 X ln (Fatty Acyl CoA); when glucose is high (5 mM) it is 44.96 + 5.67 ln (Fatty Acyl CoA). Triacylglycerol lipolysis is -13.28- 4.33 ln (Fatty Acyl CoA) when norepinephrine is low, and is- 22.14- 7.22 ln (Fatty Acyl CoA) when it is high (25% more than basal). This model can form a basis for more sophisticated integration of existing knowledge and future studies on metabolic efficiency of dairy cattle.

Key Words: adipose, metabolism, mechanistic model, lactation

0603 Total volatile fatty acid concentrations are unreliable estimates of treatment effects on in vivo ruminal fermentation. M. B. Hall[*1], T. D. Nennich[2], and P. H. Doane[3], *[1]U. S. Dairy Forage Research Center, USDA-ARS, Madison, WI, [2]Purdue University, West Lafayette, IN, [3]ADM Research, Decatur, IL.*

The sum of ruminal acetate, propionate, butyrate, and valerate concentrations ([VFA], m*M*) are used to assess impact of dietary treatments on pattern of carbohydrate fermentation, typically with intent to indirectly relate microbial products to nutrient supply to the cow. However, discrepancies in statistical results of treatment effects between [VFA] and VFA pool size (VFAmol) within one study suggested there were problems with this approach. We investigated relationships among [VFA], VFAmol, and rumen digesta liquid kg (LIQ) measured

2 h post-feeding using individual lactating cow data (175 observations) measured in seven separate feeding trials. Regression analyses were performed using mixed models with "trial" as a discrete random variable; dependent (Y) and independent (X) variables are in Table 0603. Correlations (*r*) are the mean of individual trial values. Across studies, [VFA] had a numerically smaller within-study coefficient of variation (13%) than did VFAmol (23%). Rumen liquid increased with VFAmol. Change in LIQ was likely a function of water flux in the rumen based on the osmotic gradient of rumen liquid and blood; VFAmol represents a large ruminal pool of solute. Rumen liquid and [VFA] were poorly correlated. Concentration of VFA increased with VFAmol. The ratio of [VFA]/VFAmol ranged from 9.0 to 24.1 and changed as a function of 1000/LIQ. The equation reflects the inherent relationship among the three variables, and that [VFA] at differing LIQ differ in their relationship to VFAmol. Mean within-trial LIQ was 73 kg (standard deviation = 11.2), with an average within-study range of 43 kg. Assumption of equivalent ruminal liquid volumes is incorrect. Occupying variable LIQ, [VFA] are not on the equivalent basis needed for comparison of treatments. Alternate approaches must be developed to appropriately use [VFA] to assess treatment effects.

Key Words: rumen, VFA, liquid

Table 0603. Relationships between rumen measures[1]

Y	X	Intercept (SE)	Slope (SE)	p-value of X	Average r
[VFA]	VFAmol	83.9 (5.1)	5.83 (0.38)	< 0.01	0.74
LIQ	VFAmol	32.8 (2.15)	3.68 (0.18)	< 0.01	0.83
[VFA]	LIQ	113 (10.9)	0.473 (0.124)	< 0.01	0.26

0604 Effects of diets differing in starch, fiber, and fatty acid concentrations on milk production and energy partitioning.

J. P. Boerman*, S. E. Burczynski, M. J. VandeHaar, and A. L. Lock, *Michigan State University, East Lansing, MI.*

Effects of feeding diets similar in energy composition, yet differing in starch, fiber, and fatty acid (FA) concentrations, on yield of milk and milk components and energy partitioning were evaluated in a crossover design experiment. Holstein cows (*n* = 32; 102 ± 22 DIM) were randomly assigned to treatment sequence. Treatments were a high starch diet containing 34% corn grain (mixture of dry ground and high moisture corn; HS) or a high FA diet containing 2.5% palmitic acid-enriched FA supplement (HF). Diets contained corn silage, alfalfa silage, and wheat straw as forage sources and contained 34 or 18% starch, 3.2 or 6.3% FA, and 26 or 34% NDF for HS and HF, respectively. Treatment periods were 28 d with the final 5 d used for data and sample collection. The statistical model included the random effect of cow and fixed effects of treatment and period. DMI was 27.4 and 26.9 kg/d for HS and HF, respectively ($P = 0.11$). Compared with HF, HS increased milk yield (47.1 vs. 45.8 kg/d; $P = 0.02$), milk protein concentration (3.07 vs. 2.93%; $P < 0.01$), and milk protein yield (1.44 vs. 1.34 kg/d; $P < 0.01$), did not alter ECM ($P = 0.47$), but reduced milk fat concentration (3.58 vs. 3.95% kg/d; $P < 0.01$), milk fat yield (1.68 vs. 1.81 kg/d; $P < 0.01$), and milk to feed ratio (ECM/DMI, 1.73 vs. 1.78; $P = 0.03$). HS increased the yield of de novo synthesized (< 16-carbon) milk FA (58 g/d; $P < 0.01$) and reduced the yield of 16-carbon milk FA (179 g/d; $P < 0.01$). Yield of preformed (> 16-carbon) milk FA was not affected ($P = 0.80$). HS increased plasma concentration of insulin by 27% ($P < 0.01$) but decreased triglycerides by 10% ($P < 0.01$) and NEFA by 28% ($P < 0.01$). Compared with HF, HS increased BW gain by 14 kg/28 d ($P < 0.01$), change in BCS by 0.25 pt/28 d ($P < 0.01$), and fat thickness over the rump by 0.79 mm/28 d and between the 12th and 13th rib by 0.23 mm/28 d (both $P = 0.04$). Calculated body energy gain as a fraction of NE_L use was greater for HS (10 vs. 3%; $P < 0.01$), whereas milk energy as a fraction of NE_L use was decreased for HS (68 vs. 74%; $P < 0.01$). We conclude that the two diets resulted in similar NE_L intake but the HS diet partitioned more energy toward body gain, whereas the HF diet partitioned more energy toward milk. A high fiber and FA diet might diminish the incidence of over conditioning in mid-lactation cows.

Key Words: starch concentration, fatty acid concentration, energy partitioning

0605 Propionic acid decreased meal size and feed intake compared with glycerol when infused abomasally in cows in the postpartum period.

L. B. Gualdron-Duarte* and M. S. Allen, *Michigan State University, East Lansing, MI.*

Our objective was to evaluate effects of propionic acid (P) and glycerol (G) on dry matter intake (DMI) and feeding behavior for cows in the immediate postpartum period. We hypothesized that propionic acid will decrease DMI and meal size compared to glycerol because of differences in their hepatic metabolism. Isoenergetic infusions of P or G were administered abomasally to eight ruminally cannulated multiparous Holstein cows (4.8 ± 2.3 DIM) in a double crossover design with four, 2-d infusion periods. Treatment sequences (P-G-P-G or G-P-G-P) were assigned alternately to cows based on date of parturition. Treatments were propionic acid (99.5%, 1.00 M) and glycerol (99.7%, 0.92 M) infused at 483 mL/h, which provided 4.26 Mcal/d. Feeding behavior was recorded by a computerized data acquisition system. Data were averaged within period, and period means were analyzed by analysis of variance; the model included the random effect of cow, the fixed effects of period and treatment, and interactions between treatment and period and between treatment and cow. No difference was detected for the amount of each treatment infused (11.6 L/d). Propionic acid decreased DMI

16.7% compared with glycerol (12.5 vs. 15.0 kg/d, $P = 0.04$) by decreasing meal size (1.04 vs. 1.18 kg DM, $P < 0.05$). No interaction was observed between treatment and period indicating a sustained treatment effect over time. Propionic acid tended to increase the time between meals 35 min (114 vs. 79 min, $P = 0.11$) but did not affect meal frequency (12.3 meals per d; $P = 0.48$) compared with glycerol. Propionic acid decreased the hunger ratio (meal size to time since the previous meal) by 25% compared with glycerol (20.3 vs. 27.1 g/min, $P = 0.05$) as well as the satiety ratio (meal size to time until the next meal) by 27% compared with glycerol (24.6 vs. 33.6 g/min, $P < 0.02$). Consistent with our hypothesis, propionic acid decreased meal size and DMI compared with glycerol possibly because of differences in their metabolism in the liver.

0606 Responses to starch infusion on milk synthesis in low yield lactating dairy cows. Y. Zou*, Z. Yang, Y. Guo, S. Li, and Z. J. Cao, *State Key Laboratory of Animal Nutrition, College of Animal Science and Technology, China Agricultural University, Beijing.*

The effect of starch infusion on production and metabolic parameters was investigated in low yield lactating cows from 86 d in lactation. Six Holstein cows fitted with permanent ruminal cannulas were arranged into two complete 3 × 3 Latin squares, infused a starch solution containing 800 g starch for 16 d. The three treatments were: 1) ruminal and abomasal infusion with water (Control); 2) ruminal infusion with cornstarch solution and abomasal infusion with water (Rumen); 3) ruminal infusion with water and abomasal infusion with cornstarch solution (Abomasum). There was no significant difference ($P > 0.05$) among the three treatments with low yield lactating cows in dry matter intake, body condition and milk yield, and milk component concentrations. However, cows receiving starch through rumen performed better than through abomasum directly during the glucose tolerance test procedure with higher area under the curve (AUC; $P = 0.08$) and shorter half-time ($t^{1/2}$; $P = 0.11$) of plasma insulin, therefore, it increased glucose disposal, which stated a lipid anabolism other than mobilization after energy supplementation. In conclusion, extra starch infusion at concentration of 800 g/d did not ameliorate energy supplies to mammary gland and improve the lactating performance as we expected but resulted in a tendency of shifting metabolic event toward the pathway of subcutaneous adipose accumulation at low yield lactating cows.

Key Words: starch infusion, lactation performance, glucose tolerance test

0607 The effect of starch digestibility of two corn silage varieties on lactation performance in dairy cows. E. E. Klingensmith*, L. Harthan, and M. D. Hanigan*, Virginia Polytechnic Institute and State University, Blacksburg.*

The objective of this study was to investigate the effect of storage on two corn silage varieties with varying amounts of floury and vitreous endosperm. Floury endosperm is expected to have faster rates of ruminal starch digestion at harvest, resulting in increased overall starch digestibility. However it is unclear if these differences persist during storage. Two multiparous, ruminally cannulated dry cows were used to assess ruminal degradability of starch in ensiled corn silage derived from a floury and vitreous varieties of corn. Cows were fed lactating high cow TMR twice daily ad libitum. Ruminal degradability characteristics were determined as described by NRC (2001). Approximately 10 g of dried and ground corn silage stored for 54 and 80 d sealed in duplicate polyester bags and suspended in the rumen in a large nylon mesh bag for 2, 4, 8, 12, 24, and 36 h. Samples were placed in the rumen in reverse order at varying times and removed simultaneously at the end

Table 0606. Effects of starch infusion with 800 g/d on performance, production and glucose tolerance test in lactation dairy cows

Items	Treatment			Pooled SEM	Contrast	
	Control	Rumen	Abomasum		Infusion	Site
Dry matter intake, kg/d	18.58	17.96	17.67	0.30	0.26	0.70
Body weight, kg	584.5	590.5	600.7	8.35	0.55	0.63
Body condition score	2.71	2.75	2.79	0.06	0.64	0.79
Backfat thickness, mm	17.50	19.33	19.87	0.61	0.37	0.83
Milk yield, kg/d	21.05	21.02	21.07	0.28	0.99	0.93
Milk fat, %	3.43	3.42	3.35	0.03	0.43	0.25
Milk protein, %	2.88	2.91	2.88	0.02	0.71	0.56

Basal concentration, μIU/mL	18.4	16.5	18.7	1.88	0.83	0.79
Peak concentration, μIU/mL	30.3	27.7	41.4	1.36	0.91	0.62
Clearance rate, %/min	3.64	2.59	5.83	0.65	0.90	0.83
Area under the curve, μIU × min/mL	347.8	333.8	374.5	17.59	0.81	0.08
$t^{1/2}$, min	19.1	26.7	13.6	3.14	0.97	0.11

of the experiment. A 0-h sample was immersed in 39°C water for 20 min. Residues were submitted to Agri Analysis for fiber and starch content determination. Starch disappearance was calculated as the difference between the original starch mass and the mass remaining after ruminal fermentation and expressed as a percentage of the original starch mass. The two varieties of corn silage did not differ for soluble starch (24.10 vs. 26.41%; $P = 0.99$), degradation rate (0.35 vs. 0.24%/hr; $P = 0.79$), slowly digestible starch (67.65 vs. 68.22%; $P = 1.00$), and resistant starch (8.24 vs. 5.36%; $P = 0.70$) after 54 d storage. There were also no differences after 80 d of storage for rapidly digestible starch (19.06 vs. 36.71%; $P = 0.28$), degradation rate (0.23 vs. 0.24 $P = 1.00$%/h), slowly digestible starch (78.49 vs. 59.11%; $P = 0.11$), and resistant starch (2.45 vs. 4.18%; $P = 0.90$). Thus, any differences amount corn varieties did not persist by 54 d of storage. References: (1) National Research Council. 2001. Nutrient Requirements of Dairy Cattle. Natl. Acad. Sci., Washington, DC.

Key Words: starch digestibility, corn silage

0608 Effects of calcium oxide treated corn stover as a partial replacement for corn silage, Chinese wildrye or concentrate on milk yield and composition of dairy cows. H. T. Shi*, S. L. Li, Z. J. Cao, and Y. Q. Wu, *State Key Laboratory of Animal Nutrition, College of Animal Science and Technology, China Agricultural University, Beijing.*

The utilization of corn stover was limited by its poor digestibility for ruminants. Studies showed that the nutritive value of corn stover can be improved by calcium oxide (CaO) treatment. The objective of this experiment was to determine the effect of replacing a portion of corn silage (CS), Chinese wildrye (CW), or concentrate (CT) in the diets with CaO-treated corn stover on milk yield and milk composition of dairy cows. Sixty-four Holstein cows in mid to late lactation were assigned to one of the four treatments in a randomized block design (16 cows/group): 1) control treatment (CON), diets included 15% Chinese wildrye, 25% corn silage, 10% alfalfa hay, and 50% concentrate; 2) replacing 15% Chinese wildrye with treated stover (RCW); 3) replacing 12.5% corn silage with treated stover (RCS); 4) replacing 7% concentrate with treated stover (RCT). Cows were offered the total mixed ration (TMR) thrice daily and the experiment was lasted for 90 d. The inclusion of treated stover in treatment diets as a substitute for CW, CS, and CT had no effects ($P > 0.05$) on lactose percentage, 4% fat-corrected milk yield, milk fat yield, and milk protein yield. Cows in RCW and RCT treatments had similar milk yield ($P > 0.05$) compared with that in CON treatment. Cows in CON treatment had higher ($P < 0.05$) milk protein percentage than that in other treatments. Cows in RCS treatment had higher ($P < 0.05$) milk yield and milk lactose yield than that in CON treatment. Milk fat percentage was decreased ($P > 0.05$) for the RCW treatment compared with the CON treatment. The CON treatment had higher ($P < 0.05$) total solids percentage and MUN concentration than other treatments. The RCS treatment had lower ($P < 0.05$) somatic cell count than other treatments. These results suggest that a portion of corn silage, Chinese wildrye, or concentrate can be replaced by CaO-treated corn stover without negative effects on 4% FCM, milk fat, milk protein, and milk lactose yields of dairy cows.

0609 Effects of dried sugar beet pulp as a replacement for corn silage on performance of dairy cows. G. R. Ghorbani*, N. Naderi, A. Sadeghism, and I. Sadrearhami, *Isfahan University of Technology, Isfahan, Iran.*

This study investigated the effects of feeding dried beet pulp (BP) as a replacement for corn silage (CS) on performance of dairy cows. Four multiparous (126 ± 13 d in milk) and four primiparous (121 ± 11 d in milk) Holstein cows were used in a replicated 4 × 4 Latin square design with four 21-d periods. Dry matter intake was not affected by treatments. Nonetheless,

[1]Treatments were four different ratios of corn silage to beet pulp: 100:0 (A), 50:50 (B), 25:75 (C), or 0:100 (D).
[2]Trt: treatment effect, L: linear effect, Q: quadratic effect.
[3]3.5% fat-corrected milk.

as corn silage was replaced with dried beet pulp, milk yield increased in a curvilinear manner (Table 0609), which led to a trend ($P = 0.058$) for increasing 3.5% yield quadratically. Milk fat percentage linearly decreased ($P = 0.004$) as corn silage was replaced with dried sugar beet pulp. However, milk protein percentage tended ($P = 0.062$) to increase linearly as corn silage was replaced with dried beet pulp. As beet pulp was increasingly substituted for corn silage milk urea nitrogen (MUN) was decreased linearly ($P < 0.001$). Replacing corn silage with dried sugar beet pulp tended ($P = 0.100$) to have an effect on DM digestibility, which led to a trend ($P = 0.113$) for OM digestibility. The results of this experiment indicate that replacing of dried sugar beet pulp for 75% of corn silage can increase actual milk, 3.5% FCM and protein yields and decrease MUN.

Key Words: corn silage, dried sugar beet pulp, dairy cows

0610 Effect of feeding different types of sugars on rumen fermentation and productivity of lactating dairy cows. X. Gao* and M. Oba, *University of Alberta, Edmonton, Canada.*

The objective of this study was to investigate the effect of feeding different types of sugar (sucrose or lactose) on rumen fermentation and milk production of lactating dairy cows. Our hypothesis was that sucrose diets have lower rumen pH and milk fat yield compared with diets supplement with lactose. Twenty-eight multiparous lactating Holstein cows (141 ± 50 DIM; 614 ± 53 kg of BW) including eight ruminally cannulated cows were used in this study. Cows were assigned to four dietary treatments in a 4 × 4 Latin square design. Two high sugar diets contained 27% starch and 9% sugar with sucrose (SUC) or lactose (LAC) as a supplemental sugar. In addition, high starch diet (STA) contained 32% starch and 4% sugar, and control diet (CON) contained 27% starch and 4% sugar. All diets were formulated to contain 17% crude protein. There was no significant difference in DMI between two high sugar diets, but it was higher for SUC than CON (27.8 vs. 26.2 kg/d; $P < 0.01$). In addition, both high sugar diets had higher DMI than STA diet (27.8 and 26.9 vs. 25.5 kg/d; $P < 0.01$). There was no difference in minimum rumen pH, duration and area of rumen pH < 5.8 among treatments, though LAC diet tended to have lower mean rumen pH than STA diet (6.17 vs. 6.32; $P = 0.08$). Milk yield and milk composition were not different between two high sugar diets, but STA diet had lower fat yield compared to CON, SUC, and LAC diets (1.26 vs. 1.36, 1.32 and 1.33 kg/d; $P < 0.01$). Milk CP yield tended to be higher for SUC diet than STA diet (1.32 vs. 1.26 kg/d; $P = 0.08$), and both high sugar diets had higher CP concentration than CON (3.51 and 3.50 vs. 3.46%; $P = 0.04$). However, all STA, SUC and LAC diets had lower MUN concentration compared with CON (13.2, 12.9 and 13.3 vs. 14.5 mg/dL; $P < 0.01$), which was probably due to more carbohydrate fermentation in the rumen for high-starch or high-sugar diets compared with CON diet, providing more energy for microbes to capture NH_3–N. These results suggested that feeding different type of sugar (sucrose or lactose) to lactating cows might not affect rumen fermentation and animal performance.

Key Words: sucrose, lactose, milk fat content

0611 Effects of alfalfa and cereal straw as a forage source on nutrient digestibility, rumen microbial protein synthesis, and lactation performance in lactating dairy cows. B. Wang*[1], S. Y. Mao[2], H. J. Yang[3], Y. M. Wu[1], J. K. Wang[1], S. L. Li[4], Z. M. Shen[2], and J. X. Liu[5], *[1]Institute of Dairy Science, Zhejiang University, Hangzhou, China, [2]Nanjing Agricultural University, China, [3]China Agricultural University, Beijing, [4]State Key Laboratory of Animal Nutrition, College of Animal Science and Technology, China Agricultural University, Beijing, [5]Zhejiang University, Hangzhou, China.*

This study was conducted to investigate nutrient digestibility, rumen microbial protein (MCP) synthesis, and lactation performance when alfalfa was replaced with cereal straw in the diet of lactating cows. Forty-five multiparous Holstein dairy cows were individually fed, blocked based on days in milk (164 ± 24.8 d) and milk yield (29.7 ± 4.7 kg), and randomly assigned into one of three treatments. Three isonitrogenous diets with a forage-to-concentrate ratio at 45:55 contained similar concentrate composed by ground corn grain, wheat bran, soybean meal, and cottonseed meal and 15% corn silage, with three forage sources (DM basis): 23% alfalfa hay and 7% Chinese wild rye hay (AH); 30% corn stover (CS); and 30% rice straw (RS). The trial lasted for 14 wk. The rumen MCP was estimated using purine derivatives and creatinine in urine, and metabolizable protein was the sum of the intestinally absorbable MCP plus intestinally absorbable dietary protein estimated by modified three-step procedure. Apparent nutrients digestibilities were measured with acid-insoluble ash as internal marker. The data of animal performance are summarized in Table 0611. Cows fed AH had higher MCP yield ($P < 0.05$) and metabolizable protein ($P < 0.01$) than those fed RS and CS, which may be attributed to the higher content of soluble carbohydrates in AH. Total volatile fatty acids concentration in ruminal fluid collected by an oral stomach tube was higher in AH than in CS and RS. Apparent digestibilities of nutrients were higher in AH than in CS and RS ($P < 0.05$). In summary, when cereal straw was used to replace alfalfa as a main forage source for lactating cows, the shortage of easily fermented energy may reduce the rumen MCP synthesis, resulting in lower milk protein yield, and lower nutrient digestibility may restrict milk production.

Key Words: forage source, lactation performance, ruminal microbial protein

Table 0611. Dietary composition and lactation performance in dairy cows

Item	Treatment			SEM	*P*-value
	AH	CS	RS		
Composition, % of DM					
Crude protein	16.7	16.2	16.0		
Neutral detergent fiber	31.1	36.3	36.9

0612 Feeding lactating dairy cattle long hay separate from the TMR can maintain DMI during incidents of low rumen pH.

A. D. Kmicikewycz* and A. J. Heinrichs, *Penn State University, University Park.*

The objective of this study was to investigate effects of orchardgrass hay (H) quality and feeding method on rumen pH and feed preference in lactating dairy cows. Eight rumen-cannulated Holstein cows (104 ± 34 DIM, 601 ± 116 kg, and parity of 2.38 ± 1.69; mean ± SD) were used in a replicated 4 × 4 Latin Square. Each period encompassed 21 d divided into five phases: adaptation, d 1 to 14, ad libitum TMR; baseline, d 15 to 17, ad libitum TMR; restricted feeding, d 18, cows fed for 75% of baseline DMI; challenge, d 19, 4 kg (as-fed) fine ground wheat mixed into the digesta of each cow via rumen cannula before feeding; and recovery, d 20 to 21, ad libitum TMR. Cows were assigned to squares by parity and randomly assigned to treatments. Treatments were: corn silage (CS) with coarse H TMR (CC), CS and fine H TMR (CF; both hays chopped and included in TMR), CS TMR with 5.2% supplemental long coarse H (TMR+C), and CS TMR with 5.2% supplemental long fine H (TMR+F; both hays fed separate from TMR). Coarse H was 8.6% CP and 67.1% NDF, fine H was 14.4% CP and 56.2% NDF. Animals were housed individually, milked 2x/d, and fed 1x/d for 10% refusal rate. Data was analyzed using PROC MIXED of SAS. Rumen challenge decreased weighted average rumen pH from 5.72 to 5.51. Cows fed TMR+C had higher rumen pH compared to CC and TMR+F on d 19. During d 20, cows fed H had higher rumen pH than cows fed supplemental long H. Cows fed supplemental long H had greater DMI during baseline and challenge d compared to TMR H treatments. Minimal differences among diets were found for TMR particle size selection during challenge d; however, cows had a greater preference for fine long H during recovery d. Milk production averaged 38.3 kg/d and did not differ among treatments. Fat, protein, and lactose yields were also not different among treatments. Milk fatty acid profile was altered by treatment. The TMR+C and CF treatments increased production of conjugated linoleic acid (CLA) *cis*-9, *trans*-11 ($P = 0.02$). Results of this study indicate that feeding TMR plus supplemental long H can maintain DMI during incidents of and recovery from periods of low ruminal pH.

Key Words: subacute ruminal acidosis, ruminal pH, particle size

RUMINANT NUTRITION III

0613 Performance of and digestion in calves fed conventional, moderate, and aggressive milk replacer programs. T. M. Hill*, J. D. Quigley, H. G. Bateman, II, J. M. Aldrich, and R. L. Schlotterbeck, *Provimi North America, Brookville, OH.*

Calves fed large amounts of milk replacer (MR) gain more BW pre-weaning than calves fed less MR; however, post-weaning growth may be reduced. Limited research suggests that impaired nutrient digestion may depress growth post-weaning. We compared growth and post-weaning digestion in 3-d old male Holstein calves fed one of three MR programs. Programs were Conventional (C, 0.45 kg/d of powder containing 21% CP, 21% fat (DM basis), fed for 42 d), Moderate (M, 0.68 kg/d of powder containing 27% CP, 17% fat (DM basis), fed for 42 d), and Aggressive (A, up to 0.91 kg/d of powder containing 27% CP, 17% fat, fed for 49 d). All calves were fed a 20% CP (DM basis) textured starter and water ad libitum for 56 d. The trial used 96 calves (initial BW = 41.4 ± 1.86 kg) received 5 wk apart in two replicates of 48 calves. During d 51 to 55, fecal samples were collected from five calves per treatment randomly selected from calves in the first replicate. Selected nutrients and acid insoluble ash (used as an internal marker) were analyzed in starter and feces to estimate nutrient digestibility. Data were analyzed as a randomized complete block design with replicate as block. Repeated measures analysis was performed on overall (0 to 56 d) data. Means were separated with a protected LSD test. Pen was the experimental unit. Calves fed C had lower ($P < 0.05$) average daily BW gain (0.35, 0.51, and 0.55 kg/day, respectively, for C, M, and A; SEM = 0.018), gain/feed (0.35, 0.49, and 0.48; SEM = 0.016), and change in hip width (3.3, 4.1, and 4.1 cm; SEM = 0.20) compared to other calves. Calves fed A had greater ($P < 0.05$) change in body condition score and lower ($P < 0.05$) starter intake compared to other calves. Digestibility of OM was 79, 78, and 68% and NDF digestibility was 54, 51, and 26% for calves fed C, M, and A, respectively, and were lower ($P < 0.05$) in calves fed A. Results are similar to previous published results in calves and suggest that depressed post-weaning digestion may be related to reduced starter intake and impaired rumen development.

Key Words: calves, milk replacer, digestion

0614 Performance of and digestion in calves fed two levels of milk replacer and functional ingredients. T. M. Hill*, J. D. Quigley, H. G. Bateman, II, J. M. Aldrich, and R. L. Schlotterbeck, *Provimi North America, Brookville, OH.*

We compared growth and post-weaning digestion using 48 male Holstein calves (initial BW = 42.6 ± 1.50 kg; initial age = 2 to 3 d) fed to 56 d. Calves were fed diets in a 2 × 2 factorial arrangement of feeding rate (Low [L], 0.68 kg/d of milk replacer (MR) powder and High [H], up to 1.36 kg/d of MR powder) and inclusion of a functional ingredient (without [NT-] or with [NT+] NeoTec5 g, Provimi North America, Brookville, OH). The MR contained 27% CP and 17% fat (DM basis) and was fed to weaning at 49 d. The NT+ treatment was administered in MR before weaning and in calf starter (CS) from weaning to d 56. All calves were fed NT- CS before weaning. The CS were textured (pellets, oats, corn) and contained 20% CP (DM basis). Starter and water were available for ad libitum consumption throughout the study. During d 51 to 55, fecal samples were collected from five calves per treatment selected at random. Selected nutrients and acid insoluble ash (as an internal marker) were analyzed in CS and feces to estimate digestibility. Data were analyzed as a completely randomized design with a factorial arrangement of MR rate (L/H) and NeoTec5 g (NT+/NT-) using a repeated measures ANOVA. Pen was the experimental unit. There were no interactions of main effects. Average daily BW gain (ADG), change in body condition score (BCS), and average fecal score from d 0 to 56 were greater ($P < 0.05$) in calves fed H vs. L. Calf ADG, hip height change, and BCS change were greater ($P < 0.05$) in calves fed NT+ vs. NT-. Intake of CS during the digestion period tended ($P < 0.10$) to be lower in calves fed H vs. L. Digestibility of DM, OM, NDF, and ADF was reduced by 7, 7, 65, and 58%, respectively, in calves fed H compared to L ($P < 0.05$). Feeding NT+ increased digestibility of DM, OM, NDF, and ADF by 4, 4, 65, and 74%, respectively ($P < 0.05$) compared to NT-. Feeding high rates of MR reduced ADG by 12% during the last 2 wk of the trial (0.58 vs. 0.65 kg/d for H and L, respectively), which was likely due to reduced intake and digestion of CS as calves transitioned from MR to CS. Feeding NeoTec5 g improved ADG, hip width change, and digestion of nutrients.

Key Words: calves, milk replacer, digestion

0615 The effect of solid feed diet on the oral and cross-sucking behavior of pre-weaned dairy calves. J. K. Margerison* and C. Hansen, *Massey University, Palmerston North, New Zealand.*

In the dairy industry calves are most frequently artificially reared in groups, which create a greater opportunity for solid feed consumption and cross-sucking behavior. This study aimed to compare the effect of differing solid feed diets on the pre- and post- weaning feed intake, growth rate and oral behav-

ior of calves reared artificially in groups. This experiment was a randomized block design with the treatments diets allocated at random, in blocks. The research was completed at Massey University's dairy calf unit No. 4 and involved 108 Friesian and Jersey x Friesian dairy calves that were allocated to one of three treatment diets: lower forage (LF) alfalfa total mixed ration (TMR); a higher forage alfalfa (HF) TMR; and perennial ryegrass hay along with a pelleted starter (HPS). Calves were reared in 36 groups of three calves per group and monitored until 12 wk of age. The data was transformed and analyzed using PROC MIXED GLM in SAS using diet as a fixed effect and calf as a random effect in the model. Data was presented as means with standard errors for each observation according to diet treatment. Calves fed HPS had the greatest dry matter intake [LF: 0.80 (0.012), HF: 0.95 (0.012), HPS: 1.70 (0.011) kg/DM/d], live weight at 40 d of age [LF: 60.3 (1.41), HF: 63.8 (1.41), HPS: 67.1 (1.38) kg] compared with TMRs. These calves also spent the most time eating [LF: 129.1 (0.14), HF: 163.7 (0.14), HPS: 154.1 (0.14) mins/d], and spent the least amount of time engaged in non-nutritive pen sucking [LF: 13.4 (0.16), HF: 11.2 (0.17), HPS: 10.3 (0.16) mins/d]. It was concluded that, while cross-sucking was not entirely eliminated, providing perennial ryegrass hay along with a pelleted starter resulted in the least non-nutritive sucking behavior, along with the greatest feed intake and growth rates compared with low and high forage alfalfa based total mixed rations.

Key Words: calves, growth, feed intake, behaviour, sucking

0616 Development of a modified accelerated milk replacer feeding program through 8 wk of age.

B. M. Strayer*[1], D. Ziegler[2], D. Schimek[3], B. Ziegler[3], H. Chester-Jones[2], J. L. Anderson[1], K. F. Kalscheur[1], and D. Casper[1], *[1]South Dakota State University, Brookings, [2]University of Minnesota Southern Research and Outreach Center, Waseca, [3]Hubbard Feeds Inc., Mankato, MN.*

Our previous studies have demonstrated that a modified accelerated milk replacer (MR) having a 24:20 crude protein (CP):fat concentration fed at higher feeding rates (FR) resulted in improved growth performance and gain/feed, but not linearly. The current study was to evaluate pre- (d 1 to 42) and post-weaning (d 43 to 56) calf performance when modified accelerated MR was fed at higher FR compared to a MR having similar or higher CP and lower fat concentrations. One-hundred thirty (1 to 6 d old) fed Holstein heifer calves (40.1 ± 0.76 kg) were blocked by birth date and randomly assigned to one of five treatments. Treatments of MR fed at 14.7% solids were: 1) Control (C): all milk 24:20 MR fed at 0.26 kg at 2x/d from d 1 to 35; 2) C+: C MR fed at 0.32 kg 2x/d from d 1 to 35; 3) LF: CP and low fat (24:16) MR fed at 0.32 kg 2x/d from d 1 to 35; 4) LF+: LF MR fed at 0.32 kg 2x/d from d 1 to 7 and at 0.39 kg from d 8 to 35; and 5) HP+: High CP:LF MR (26:16) fed at the rates of LF+. All MR were fed 1x/d from d 36 to weaning at d 42 with water and 18% CP texturized calf starter (CS) offered free choice from d 1 through 56. Calves fed C+ had greater ($P < 0.05$) ADG (0.71, 0.75, 0.70, 0.72, and 0.72 kg/d for C, C+, LF, LF+, and HP+, respectively) from d 1 to 56 compared to calves fed LF, with other treatments being intermediate. Calves fed C+, LF, and HP+ were similar, but taller at the hips ($P < 0.05$) than calves fed C and LF+ (98.1, 99.6, 99.8, 98.5, and 99.8 cm). However, calves fed C+ had greater hip widths on d 56 (22.3, 22.6, 21.7, 21.8, and 22.3 cm) and on d 84 (26.2, 26.5, 26.0, 26.2, 26.4 cm) than calves fed LF with other treatments similar. This study demonstrates that feeding a modified accelerated MR (24:20) at a moderate FR improves ADG and frame measurements compared to calves fed MR having similar or different CP and fat concentrations. The development of a modified accelerated feeding program optimized the protein energy ratio for the potential of producing a dairy heifer with a frame that is taller and wider without having a weaning slump.

Key Words: milk replacer, protein concentration, fat concentration.

0617 Amino acid supplementation of calf milk replacers containing bovine plasma protein.

S. Y. Morrison*[1], K. A. Myers[1], A. E. Volland[1], P. Cardoso[1], J. M. Campbell[2], and J. K. Drackley[1], *[1]University of Illinois, Urbana, [2]APC, Inc., Ankeny, IA.*

Plasma protein (PP) is an effective alternative protein source for young calves, but utilization at higher amounts may be limited by Ile and Thr content. We determined the effects of PP and supplemental AA in milk replacers (MR) on calf growth and health. Male Holstein calves (n = 104) were blocked by BW and randomly assigned to 1 of 5 MR formulated to contain 22% CP, 20% fat, and 2.0% Lys. Treatments (trt) were: all milk protein (A); 5% PP plus Met to equal trt A (B); 5% PP plus Met, Ile, and Thr to equal A (C); 10% PP plus Met to equal A (D); or 10% PP plus Met, Ile, and Thr to equal A (E). Treatments (12.5% solids) were fed twice daily at 10% of BW for d 1 to 2, 12% of BW for d 3 to 7, and 14% of BW for d 8 to 35, adjusted weekly. No starter was fed. Calves were housed in individual hutches bedded with straw and offered water ad libitum. Health data were recorded daily and growth measured weekly. Serum obtained on d 28 before and 4 h after feeding was analyzed for total protein (TP), urea nitrogen, albumin, and globulin. Data were analyzed using the MIXED and GLIMMIX procedures of SAS. Initial BW (41.9 ± 4.38 kg) and serum TP (5.7 ± 0.09 g/dL) were similar among groups. Intakes of DM, CP, ME, and Lys did not differ ($P > 0.35$) among trts. Average daily gain tended ($P = 0.08$) to be decreased by 10% PP (D), but not when AA were supplemented (E). Gain:DMI ($P = 0.10$) and gain:Lys intake ($P = 0.08$) tended to be lower for trt D. The Logistic model revealed that during the first 21 d, scours occurrence

was higher in trt A than trt D and E (odds ratio [OR] = 1.35, P = 0.07 and 1.61, P = 0.01, respectively), and trt C tended to be higher than trt E (OR = 1.41, P = 0.08). The chance of antibiotic treatment was greater in trt A than trt B, C, and E (OR = 3.55, P < 0.0001; 3.39, P = 0.0002; 2.48, P = 0.001) and lower in trt B and C than trt D (OR = 0.31, P = 0.0003; 0.32, P = 0.0006). Serum albumin was highest (P = 0.02) for trt B, and urea nitrogen tended (P = 0.10) to be higher for trt A; TP and globulin did not differ (P > 0.11). Inclusion of PP in MR improved health of young calves; when AA were balanced, growth and efficiency were similar to all milk protein.

Key Words: amino acid, plasma protein, milk replacer

0618 The use of highly digestible corn grain in calf starters when calves are fed an accelerated milk replacer.

D. Casper[*1], S. Srivastava[2], M.Kkirk[3], S. Harris[4], K. Koone[4] and B. M. Strayer[1], *[1]South Dakota State University, Brookings, [2]South Dakota University, Hyderabad, India, [3]Masters Choice, Anna, IL, [4]Masters Choice, Anna, IL.*

New corn hybrids have been developed by Masters Choice (MC) seeds that vary in energy density and starch digestibility. These MC hybrids have lower starch densities due to an altered starch structure, which allows for greater ruminal and intestinal starch digestion. Altered starch structure of these new hybrids results in reduced feed manufacturing (i.e., grinding). Thirty (1- to 3-d old) Holstein heifer calves (40.6 ± 1.72 kg) were randomly assigned to one of two calf starters to evaluate growth performance of Holstein heifer calves through 8 wk of age. Treatments were: 1) Control (C) starter: containing 40% (DM basis) conventional ground shelled corn and 2) MC starter: containing (40% DM basis) MC corn. Experimental calf starters were formulated to contain 24% CP (DM basis) and were fed for ad libitum consumption as a pellet starting on d 1. The study was conducted from April 25 through August 1, 2013. Body weights and body measurements were collected weekly. All calves were fed a 28% (CP):18% fat accelerated milk replacer 2x/d at the rate of 0.68 kg/d up to 10 d, 1.02 kg/d from 11 to 35 d, and fed 1x/d at 0.51 kg/d from 35 to 42 d. Data were analyzed as a completely random design using the PROC MIXED of SAS Version 9.3. Initial body weights (40.6 and 40.7 kg for C and MC, respectively) were similar (P > 0.10), while final body weights (64.5 and 66.7 kg) were numerically greater for calves fed the MC starter. Body weight gains (23.9 and 26.0 kg) and average daily gains (0.68 and 0.74 kg/d) were similar but numerically greater for calves fed MC starter. No significant differences were detected (P > 0.10) in frame parameters as measured by change in body length (12.3 and 11.4 cm), heart girth (8.7 and 9.3 cm), hip height (6.8 and 6.6 cm), and wither height (13.1 and 12.3 cm). While no significance improvements in growth rates were detected in this study, which was conducted during the early summer, but the MC starter resulted in a numerical increase in body weight gains and average daily gains.

Key Words: corn hybrids, calf starter, starch

0619 Intensive milk feeding in calves affects growth performance, metabolic and endocrine traits, but not rumen development.

H. M. Hammon[*1], J. Maciej[1], J. Gruse[1], E. Wirthgen[2], R. Zitnan[3], M. Piechotta[4], and A. Hoeflich[1], *[1]Leibniz Institute for Farm Animal Biology (FBN), Dummerstorf, Germany, [2]Ligandis GbR, Gülzow, Germany, [3]National Centre of Agriculture and Food Nitra, Kosice, Slovakia, [4]University of Veterinary Medicine, Hannover, Germany.*

Restricted milk feeding during the pre-weaning period is supposed to stimulate solid feed intake, but growth performance is insufficient in calves. The objective of the present study was to compare feed intake, growth performance, metabolic traits, and rumen development during the pre-weaning period in calves with different milk feeding levels. The hypothesis was tested that intensive milk feeding supports metabolic changes related to enhanced growth but does not impair solid feed intake and rumen development. Four d after birth, 28 Holstein × Charolais calves (male and female) were fed either 6 L milk replacer (MR; 125 g powder/L)/d for 8 wk (RES) or unlimited amounts of MR up to d 35 of life (AL) that was stepped down to 6 L/d afterward. Concentrates and hay were available ad libitum for both groups. Blood samples were taken weekly for determination of plasma concentrations of glucose, triglycerides, NEFA, BHBA, urea, insulin, IGF-I, and IGF binding proteins (IGFBP). Calves were slaughtered at d 60 ± 2 and rumen tissue samples were taken for measurements of papilla size. Data were analyzed by the MIXED Model of SAS with feeding, sex, time, and feeding × time interaction as fixed effects. MR intake increased (P < 0.001) in AL to 14.5 ± 0.4 L/d in wk 5 of life, but did not change in RES calves. Concentrate intake increased (P < 0.001) in both groups from wk 4 on, but did not differ between groups. Body weight and ADG were greater (P < 0.001) in AL than in RES calves. Plasma concentrations of triglycerides, glucose, insulin, and IGF-I were higher (P < 0.05) and concentrations of NEFA, urea, and IGFBP-2 and −4 were lower (P < 0.05) up to d 35 of life in AL than in RES calves. Plasma concentrations of BHBA tended to be higher (P < 0.1; mainly from d 21 to d 35 of life). Rumen empty weight and papillae length were not different, but papillae densities in atrium and ventral sac were greater (P < 0.05) in RES than in AL. Intensive milk feeding resulted in enhanced body growth and changes in metabolic and endocrine traits supporting anabolic metabolism in AL calves. Intensive milk feeding did not impair concentrate intake and slightly affected rumen papillae growth.

Key Words: calf, milk feeding, rumen development

0620 Fish oil supplementation on growth and health of pre-weaning dairy calves. R. Panivivat*[1], P. Sopannarat[1], and S. Sriwichai[2], [1]*Kasetsart University, Bangkok, Thailand,* [2]*Dairy Promotion and Organization of Thailand, Saraburi.*

The objective of this study was to study the effect of fish oil (energy source) for preweaning calves. Preweaning calves were more sensitive to environment and stress to sickness. Thirty-six male dairy calves fed with 0% (group 1), 2.5% (group 2), and 5% (group 3) of fish oil in milk replacer. All calves were assigned with randomized complete block design. The calves were placed into individual pen after birth randomly. Calves were fed with colostrum after birth until 3 d of age. Calves were fed calf starter and milk replacer from d 4 to d 42 of age. All calves fed with calf starter and water in different bucket set in the front of pen. Calves were fed 5 kg/h/d milk replacer 2x/day. All calves were weaned on d 42. Body weights were measured after birth and d 1, d 21, and d 42. Feed and milk replacer intake and fecal scores were measured daily after feeding in the morning. Blood samples were collected on d 1, d 21, and d 42 after morning feeding for 2 h for chemical analysis. Growth, health and neutrophils and lymphocytes (stress indices) were evaluated for 42 d. Average daily gain (131.6, 141.5, and 118.4 g/d for group 1, 2, and 3, respectively), feed intake, fecal score, and body cleanliness score of calves did not differ ($P > 0.05$) among treatments but feed intake was affected by week ($P < 0.0001$). Calf health was also affected by week ($P < 0.001$). Immunoglobulin G was higher on d 1 (40.1 mg/ml, $P < 0.05$). The ratio of neutrophils and lymphocytes (1.13, 0.46, and 0.26 for d 1, d 21, and d 42, respectively), glucose concentration (163.7, 115.1, and 104.1 mg/dl for d 1, d 21, and d 42, respectively) decreased when calf was older ($P < 0.001$). Growth and health performance of calves fed with three levels of fish oil did not differ ($P > 0.05$). At 3 wk of age, immunoglobulin G of calves was increased as calf fed 2.5% fish oil supplemented in milk replacer.

Key Words: fish oil, dairy calf, health

0621 The effects of corn silage inclusion in pre-weaned calf diets. S. I. Kehoe*[1], S. L. Retz[1], T. J. Pogreba[1], K. Dill-McFarland[2], and G. Suen[2], [1]*University of Wisconsin–River Falls, River Falls,* [2]*University of Wisconsin–Madison, Madison.*

The objective was to evaluate the effects of corn silage inclusion in starter feed provided to calves after birth through weaning. Thirty-six heifer calves and nine bull calves were reared at the U.S. Dairy Forage Research farm, where they were individually housed in hutches. All treatments were fed pasteurized milk with either all calf starter (C), 60% calf starter and 40% corn silage (CC), or all corn silage (CS). Feed intake and health scores were recorded daily. Every other week, calves were sampled for weight, withers and hip height, heart girth, serum protein, hematocrit, blood urea nitrogen, glucose, and β-hydroxybutyrate. Nine bull calves were sacrificed 1 wk post-weaning at 8 wk of age. Rumen and intestinal tissue were collected and preserved with formalin for later analysis. One intestinal tissue sample was taken at consistent lengths from the duodenum, jejunum, ileum, and colon; from each tissue sample, three blocks were cut and 24 tissue slides were stained from each block for measurement. Three rumen samples were taken from four areas within the rumen and 12 random papillae per sample were measured for length and width. Daily and biweekly measurements were analyzed using a repeated measures analysis of the PROC MIXED and intestinal and ruminal measurements were analyzed using the General Linear Model procedure of SAS 8.3 (2010). Initial growth measurements were used as covariates for growth analysis and significance was found at $P < 0.05$. Feed intake was not different between treatments; however, there was a treatment by week interaction ($P < 0.0001$). Least squares means of rumen papillae lengths were different (9.3, 7.5, and 3.9 ± 0.3 mm for treatments C, CC, and CS, respectively; $P < 0.05$). Jejunal villi lengths tended to be different (97.65, 105.61, and 89.57 ± 5.8 μm for treatments C, CC, and CS, respectively; $P = 0.12$), and crypt depths were different (46.10, 48.58, and 38.69 ± 2.8 μm for treatments C, CC, and CS, respectively; $P = 0.03$). Treatments did not differ for weight ($P < 0.15$), heart girth ($P < 0.4$), hip height ($P < 0.7$), withers height ($P < 0.15$), serum protein ($P < 0.8$), and hematocrit values ($P < 0.6$). This data indicates the inclusion of corn silage to starter feed does not affect growth and overall feed intake but may affect weekly feed consumption. Solely feeding corn silage as starter feed stunted the growth of the rumen papillae and reduced crypt depths indicating reduced absorption and efficiency. Future milk production will be monitored.

Key Words: calves, corn silage, calf starter feed

0622 Growth performance and health of dairy calves fed with *Schizochytrium* sp. R. Panivivat* and K. Taboonpong, *Kasetsart University, Bangkok, Thailand.*

Thirty-six dairy calves were studied on *Schizochytrium* sp. supplementation affecting on growth performance and health. Repeated measurement in completely randomized design was assigned. Treatment had three groups (12 calves per group). Group 1 was control (fresh milk added with lactobacillus). Group 2 was control plus 3 g/h/d of *Schizochytrium* sp. supplementation. Group 3 was control plus 6 g/h/d of *Schizochytrium* sp. supplementation. After birth, calf was placed in individual pen. Each calf fed colostrum immediately until 3 d of age. On d 4, all calves were fed ad libitum of calf starter and water separated bucket in the front of individual pen. Calves were also fed fresh milk 5 kg/h/d, 2 times a day from d 4 to 42 of age. Feed intake, fecal fluidity score and calves cleanliness score were recorded daily. Initial body weight, d 7, d 21, and final body weight were measured. On d 1, d 21, and d 42 fresh

blood analyzed for neutrophil:lymphocyte ratio (N:L ratio; stress indicator), serum immunoglobulin G (IgG), serum glucose, serum urea-nitrogen (SUN) were collected. Feed intake (778.8, 763.3, and 758.3 g for group 1, 2, and 3, respectively) and average daily gain (ADG 552.5, 552.1, and 557.1 g/d for group 1, 2, and 3, respectively) did not differ ($P > 0.05$). However, feed conversion ratio (FCR; 1.40 for group 3) had lower than others (1.49 and 1.83 for group 1and 2; $P = 0.060$). Serum IgG (37.7, 38.6, and 37.6 mg/ml for group 1, 2, and 3, respectively), serum glucose (159.1, 171.9, and 179.4 mg/dl for group 1, 2, and 3, respectively) and SUN (9.6, 10.17, and 9.6 mg/dl for group 1, 2, and 3, respectively) did not differ ($P > 0.05$). The percentage of white blood cells count and N:L ratio (0.2, 0.17, and 0.16 for group 1, 2, and 3, respectively) also did not differ ($P > 0.05$). However, on d 1, serum IgG and serum glucose were the highest in three groups. Overall blood N:L ratio decreased when calf was older ($P < 0.05$).

Key Words: *Schizochytrium* sp., dairy calf, health

0623 Growth performance, health, and immunocompetence of preweaning dairy calves fed with stevioside.

R. Panivivat[*1], C. Boonkaewwan[1], and S. Sriwichai[2], [1]*Kasetsart University, Bangkok, Thailand,* [2]*Dairy Promotion and Organization of Thailand, Saraburi.*

The objective of this study was to study the effect of stevioside (medical herbs) supplementation on growth and health of preweaning calves. The preweaning calves were more sensitive to sickness because of lower immunoglobulin and more stress after birth. Thirty-six dairy calves fed with 0, 150, and 300 mg/kg of stevioside supplemented in calf starter. All calves were assigned with randomized complete block design. The calves were placed into individual pen after birth randomly. Calves were fed colostrum after birth until 3 d of age. Calves were fed calf starter and milk from d 4 to d 42 of age. Calves were fed 5 kg/h/d milk, 2x/d. All calves were fed with calf starter and water in different bucket set in the front of pen. Growth, health, and stress indices were evaluated for 42 d. Average daily gain (367.8, 348.5, and 315.5 g/d for group 1, 2, and 3, respectively), feed intake, fecal score, and body cleanliness score of calves did not differ ($P > 0.05$) among treatments, but feed intake was affected by week ($P < 0.05$). Calf health was also affected by week ($P < 0.05$). Immunoglobulin G was greater ($P < 0.05$) when calf was older. The ratio of neutrophils and lymphocytes (stress indices), serum glucose, and butyrate concentration decreased ($P < 0.05$), while immunoglobulin G increased ($P < 0.05$) when calf was older. The concentration of α-1 acid glycoprotein (AGP) and TNF-α did not differ ($P > 0.05$) among treatments. Growth and health performance of calves fed with three levels of stevioside did not differ ($P > 0.05$). At 3 wk of age, immunoglobulin G of calves increased ($P < 0.05$) as 150 mg/kg stevioside was supplemented in calf starter.

Key Words: stevioside, dairy calf, health

0624 An evaluation of a calf-side betahydroxybutyrate test in dairy calves fed a high plane of nutrition and weaned at six versus 8 wk of age.

H. E. Brown[*1], E. C. Eckert[1], M. A. Steele[2], T. J. DeVries[1], and K. E. Leslie[1], [1]*University of Guelph, Guelph, ON, Canada,* [2]*Nutreco Canada Agresearch, Guelph, ON.*

Recent research suggests that circulating betahydroxybutyrate (BHBA) levels may be a meaningful indicator of grain intake and rumen development in pre-ruminant calves. As such, BHBA levels may be a surrogate measure of rumen function to assure minimal weaning stress during the transition from liquid to solid feed. The Precision Xtra test for BHBA in whole blood has been validated in lactating dairy cows. The objective of this study was to validate the Precision Xtra test against a gold standard laboratory method in calves at weaning, and to determine preliminary associations between circulating BHBA levels and amount of solid feed intake in dairy calves fed higher planes of nutrition and weaned at 6 vs. 8 wk of age. A total of 20 Holstein female calves were randomly assigned at birth to be weaned at 6 wk ($n = 10$) or 8 wk ($n = 10$). Milk replacer (mixed at 150 g/L) was offered at 1.2 kg/calf/d in two meals until a 1-wk step down, where meals were reduced by 50% 1 wk before weaning. Measurements included daily starter, chopped straw, and water intake, as well as weekly blood BHBA, until 70 d of life. Whole blood BHBA was determined by the Precision Xtra test at calf-side. In addition, serum was separated from a clotted sample, frozen, and stored until laboratory analysis was performed. Data were plotted, and Spearman correlation coefficients between the Precision Xtra and laboratory BHBA levels were determined. Using an arbitrary level of BHBA to indicate meaningful rumen function, the sensitivity and specificity of the Precision Xtra test were calculated. Finally, the correlation between BHBA levels and solid feed intake was determined. The correlation coefficient between Precision Xtra and laboratory BHBA was high ($r = 0.95$; $P < 0.05$). Using a cut-off level of ≥ 250 μmol/L BHBA on the laboratory test, the sensitivity and specificity of the Precision Xtra test were 91% and 93%, respectively. These test characteristics were even higher, when the assessment was restricted to calves weaned at 8 wk (100% and 94%, respectively). The correlation between BHBA results and solid feed intake was also high ($r = 0.90$; $P < 0.05$). These results indicate that the Precision Xtra whole blood BHBA test conducted at calf-side is a highly accurate test and shows some promise for use in the decision-making process of determining appropriate weaning age.

Key Words: calves, weaning, betahydroxybutyrate

RUMINANT NUTRITION: SYMPOSIUM: THE RUMEN MICROBIOME AND NUTRITIONAL HEALTH AND PRODUCTION

0625 [Withdrawn]

0626 The microbiome and health. *G. B. Penner*[*1], *E. Khafipour*[2], *J. C. Plaizier*[2], *and L. L. Guan*[3], *[1]University of Saskatchewan, Saskatoon, Canada, [2]Dep. of Animal Science, University of Manitoba, Winnipeg, Canada, [3]Dep. of Agricultural, Food and Nutritional Science, University of Alberta, Edmonton, Canada.*

The linkage among the microbial community and health outcomes in monogastric species has been well documented along with demonstrated evidence for species-dependent health consequences. While a symbiotic relationship between the microbial inhabitants and the ruminant host has been accepted from the perspective of feed digestion, the mechanisms for host-regulation of the microbial community is not well understood and the influence of individual microbial species on health outcomes has been poorly defined. Major challenges include understanding the structure of the digesta associated and epimural populations and how these populations change across the gastrointestinal tract. Current research efforts are examining the establishment of the microbiome in newborn calves to gain an improved understanding of the colonization process. It is currently accepted that the dominant phyla within the microbiome consist of firmicutes, bacteroidetes, and proteobacteria and that these remain relatively stable for most of a healthy cow's life. However, variations in the composition, proportion, and functional properties of the rumen and intestinal microbiomes exist among individuals. To help understand the relationship between the microbiome and animal health, ruminal acidosis induction protocols have developed and proven to be an excellent model. In fact, it has been demonstrated that changes in the microbial community structure, specifically and increase in *Escherichia coli*, can be related to the systemic immune response induced by ruminal acidosis. However, it is still not clear whether the translocation of antigens induced by ruminal acidosis occurs in the reticulo-rumen or more distally in the gastrointestinal tract. The latter is especially important given the large changes in epithelial barrier function and marked changes in the concentration of lipopolysaccharide across the gastrointestinal tract. An in depth understanding of both the microbiome and host gastrointestinal physiology is key to addressing this challenging area.

Key Words: gastrointestinal tract, health, microbiome

0627 Use of genomics and transcriptomics to identify strategies to lower ruminal methanogenesis. T. A. McAllister[*1], L. L. Guan[2], G. Henderson[3], G. Attwood[3], and P. H. Janssen[3], *[1]Agriculture and Agri-Food Canada, Lethbridge, AB, [2]University of Alberta, Edmonton, Canada, [3]AgResearch Limited, Grasslands Research Centre, Palmerston North, New Zealand.*

Globally, methane emissions account for 40 to 45% of greenhouse gas emissions (GHG) from ruminant livestock, with more than 90% of these emissions arising from enteric fermentation. Reduction of carbon dioxide to methane is critical for efficient ruminal fermentation, as it prevents the accumulation of reducing equivalents in the rumen. Methanogens exist in a symbiotic relationship with rumen protozoa, fungi and within biofilms associated with feed and the rumen wall. Genomics and transcriptomics are playing an increasingly important role in defining the ecology of ruminal methanogenesis and identifying avenues for its mitigation. Genomic approaches have provided information on changes in abundances as well as the species composition of the methanogen community among ruminants that vary naturally in their methane emissions, their feed efficiency and response to methane mitigators. Sequencing the genomes of rumen methanogens has provided insight into surface proteins that may prove useful in the development of vaccines and allowed assembly of biochemical pathways for use in chemogenomic approaches to lowering ruminal methane emissions. Metagenomics and metatranscriptomic analysis of entire rumen microbial communities are providing new perspectives on how methanogens interact with other members of this ecosystem and how these relationships may be altered to reduce methanogenesis. Identification of community members that produce anti-methanogen agents that either inhibit or kill methanogens could lead to the identification of new mitigation approaches. Discovery of lytic archaeophage that specifically lyse methanogens is one such example. Efforts in using genomic data to alter methanogenesis have been hampered by a lack of sequence information that is specific to the microbial community of the rumen. Programs such as the Hungate 1000 and the Global Rumen Census are increasing the breadth and depth of our understanding of global ruminal microbial communities, steps that are key to using these tools to further define the science of ruminal methanogenesis.

Key Words: ruminal methanogenesis, genomics, transcriptomics

0628 Increasing condensed corn distillers solubles alters the rumen microbiome of beef cattle.

J. C. McCann*[1], S. A. Alqarni[1], J. R. Segers[2], D. W. Shike[1], and J. J. Loor[1], *[1]University of Illinois, Urbana, [2]University of Georgia, Tifton.*

Five ruminally fistulated steers were used in a 5 × 5 Latin square design to determine the effects of increasing dietary fat from corn distillers solubles (CDS) on the rumen microbiome. Treatments included a corn-based control (CON), and four levels of CDS (0, 10, 19, and 27%) in a coproduct-based (corn gluten feed and soybean hulls) diet. Fat concentrations were formulated to 3, 5, 7, and 9%, respectively, for diets containing CDS, and all steers were fed to ad libitum intake once daily. After 18 d of adaptation to the diet, ruminal samples were collected 3 h post-feeding and separated into solid and liquid fractions. Bacterial DNA was extracted from the solid fraction after physical homogenization. Real-time quantitative PCR was used to determine dietary effects on the relative abundance of culturable bacterial species. Orthogonal contrasts were used to compare diets formulated to similar fat concentrations (CON and 10% CDS), determine linear, quadratic, and cubic effects of CDS inclusion, and compare CON with all CDS treatments. Of the evaluated species, *Selenomonas ruminantium* was the most prevalent at 0.5 to 1.9% relative abundance. Moreover, *Selenomonas ruminantium* increased with greater CDS inclusion ($P < 0.001$). *Anaerovibrio lipolytica* was affected by treatment ($P < 0.001$); steers fed 0% CDS had eight-fold greater relative abundance than any other treatment. A quadratic effect was observed for *Butyrivibrio proteoclasticus,* with the greatest relative abundance at 0 and 27% CDS and the lowest at 19% CDS. *Butyrivibrio proteoclasticus* was also greater in steers fed 10% CDS compared with CON. *Eubacterium ruminantium* was not affected by treatment but was the second most abundant species evaluated (0.03 to 0.1%). *Fibrobacter succinogenes* was affected by treatment ($P = 0.005$) with a marked decrease for steers fed 19 and 27% CDS, yet relative abundance remained similar for steers fed CON and 10% CDS. *Prevotella bryantii* had a cubic response ($P = 0.005$) to CDS inclusion with the greatest relative abundance for steers fed 10% CDS, followed by the lowest abundance for steers fed 19% CDS. *Megasphaera elsdenii* was affected by treatment ($P < 0.001$); the lowest relative abundance was observed for steers fed CON compared with CDS diets ($P < 0.001$), and the greatest relative abundance was observed for steers fed 19% CDS. Results suggest the rumen microbiome is impacted by substantial changes in dietary CDS.

Key Words: microbiome, distillers solubles, dietary fat

0629 The microbiome composition of the hindgut is altered following weaning in dairy calves: impact of different weaning strategies.

S. C. Li*[1], M. A. Steele[2], P. Azevedo[1], M. Carson[2], J. C. Plaizier[1], H. Derakhshani[1], and E. Khafipour[1,3], *[1]Dep. of Animal Science, University of Manitoba, Winnipeg, Canada, [2]Nutreco Canada Agresearch, Guelph, ON, [3]Dep. of Medical Microbiology and Infectious Diseases, Winnipeg, MB, Canada.*

Composition of calf intestinal microbiota has immediate and long-term effects on health and productivity of the animal. Weaning stress may alter the colonization process due to dietary shifts and environmental factors. The objective of this study was to examine the effects of different weaning strategies on fecal microbiota of dairy calves. Twenty-four male and 20 female Holstein dairy calves were blocked according to gender and birth weight and randomly assigned into a step-down weaning (SW) or an abrupt weaning (AW) treatment at birth. Calves had free access to water and starter intake throughout the experiment and 9 L/d of milk until d 36 of life and weaned on d 49 of life. Calves in SW group were weaned gradually by reducing milk intake from 9 to 4.5 L/d from d 37 to d 48 while the AW calves were abruptly weaned on d 49 by reducing milk intake from 9 to 0 L/d. Fecal samples were collected on d 36 (pre-weaning) and on d 54 (post-weaning) of life. DNA was extracted and V4 region of 16S rRNA gene was amplified and subjected to paired-end Illumina sequencing. The output paired-end reads were merged using PANDASeq assembler and analyzed using QIIME. The resulted operational taxonomic units (OTUs) were aligned to Greengenes database. Alpha-diversity of bacterial community was calculated using different richness estimators. Differences in β-diversity of microbiota across treatments and time points were tested using PERMANOVA. Diversity of fecal microbiota was low before weaning but increased significantly post-wean indicating new species benefited from dietary change. However, different weaning strategies did not affect α and β-diversity measures. Before weaning, firmicutes (49.2%) and bacteroidetes (42.2%), proteobacteria (3.8%), tenericutes (1.7%), and actinobacteria (1.5%) were predominant phyla. Another 16 phyla were present at low abundance, each less than 1% of population. After weaning, the percentage of firmucutes and actinobacteria decreased to 42% and 0.4%, while proteobacteria, and tenericutes increased to 5.6% and 3.9%, respectively. Different weaning strategies did not affect fecal bacterial population at the phylum level. In total, 415 core OTUs, defined as OTUs shared amongst 50% or more of the calves, were different between pre- and post-wean. However, none of the core OTUs was affected by weaning strategies. Data showed fecal microbiota of dairy calves was undergoing a drastic change and became more diversified during the weaning process. However, weaning strategies had no substantial effect.

Key Words: calves, fecal microbiota, weaning

0630 Effects of different dry period managements on rumen microbiome composition. H. Khazanehei*[1], S. Li[1], J. C. Plaizier[1], and E. Khafipour[2], [1]*Dep. of Animal Science, University of Manitoba, Winnipeg, Canada,* [2]*Dep. of Medical Microbiology and Infectious Diseases, Winnipeg, MB, Canada.*

The effects of two different dry period managements on rumen bacterial population were examined during pre- and postpartum periods. Twenty-four Holstein dairy cows were paired according to their expected calving date and randomly assigned to one of the two treatments. Treatments included a 60-d dry period (60-d trt) with separate far-off and close-up diets and a 40-d dry period (40-d trt) during which only the close-up diet was fed. The far-off diet contained 1.28 Mcal/kg NE_l, 14.7% CP, and 50% NDF on a DM basis. The close-up diet contained 1.43 Mcal/kg NE_l, 14.6% CP, and 38% NDF. A common lactation diet was fed to all cows after calving, which contained 1.69 Mcal/kg, 17.6% CP, and 31% NDF. The forage portion of ration consisted of timothy hay, barley, and corn silage, and the concentration portion consisted of soybean, canola, barle, and wheat. Rumen fluid was sampled using stomach tube at wk -2, -1, +1, +2 and +7, relative to calving. DNA was extracted, normalized and used for amplification of the V4 region of bacterial 16S rRNA and subjected to Illumina sequencing. The QIIME pipeline was used for downstream data analyzing. After removing all chimeric reads, sequences were assigned to operational taxonomic units and aligned to Greengenes database. The α- and β-diversity of rumen microbiota were calculated using Chao1 and Unifrac distance matrices, respectively. PERMANOVA procedure was used to compare differences in bacterial communities between treatments and sampling time points. Partial least square discriminant analysis (PLS-DA) of SIMCA was performed to identify taxa associated with each treatment and time point. PERMANOVA analysis revealed significant differences in rumen bacterial composition between pre- and postpartum in the 60-d trt ($P < 0.01$); however, no difference was observed between pre- and postpartum in the 40-d trt ($P < 0.2$). At the genus level, *Bulleidia*, *Coprococcus* and *Ruminococcus* increased in 40-d trt compared with 60-d trt prepartum ($P < 0.05$). After calving, *Olsenella* increased and *Coprococcus*, *Bifidobacterium* and *Treponema* decreased ($P < 0.05$) in the 40-d trt compared with the 60-d trt. At the phylum level, no significant difference was observed between treatments prepartum ($P < 0.9$). However, after calving, spirochaetes and chloroflexi populations decreased ($P < 0.05$) while proteobacteria and firmicutes increased ($P < 0.05$) in 40-d trt compared with 60-d trt. Differences between treatments, at the phylum and genus levels during pre- and postpartum were likely due to longer consumption of close-up diet in the 40-d trt compared to the 60-trt.

Key Words: dairy cow, dry period management, rumen microbiome, illumina sequencing

RUMINANT NUTRITION IV

0631 Effect of sunflower seed or sunflower oil as diet supplement on milk production, milk composition, and milk fatty acid profile in lactating goats.
T. A. Morsy*[1], S. Kholif[1], O. Matloup[1], and A. Abu Elella[2], [1]*National Research Center, Cairo, Egypt,* [2]*Animal Production Research Institute, Agriculture Research Center, Cairo, Egypt.*

Seeds are natural source of fats and proteins in dairy animal feed, which contains unsaturated fatty acids. Some of these seeds, especially sunflower seed contain about 40% oil and the oils are protected in the seeds as long as has not been crushed. Given the importance of some of these seeds and oils to improve the performance of the animals and his reproductive activity and also increase the percentage of unsaturated fatty acids in milk specialty conjugated linolenic acid (CLA) which is of great importance to human health. Therefore, in this study we try to investigate the effect of a diet supplemented with sunflower seed or sunflower oil on milk production and composition and also milk fatty acids profile in dairy goats. Fifteen lactating Damascus goats were used in this experiment, starting by the first week of lactation stage through a 90-d period. Goats divided into three aged groups and assigned at random to receive one of three dietary treatments, five animals each, using complete randomized block design. The treatments were 1) control, 2) control +50 g/head/day sunflower seed, and 3) control +20 mL/head/day sunflower oil. Control ration consisted of concentrate feed mixture (CFM):bersem clover (50:50 dry matter bases). Milk was sampled every 2 wk during the experimental period for chemical analysis. Results indicated that experimental additives, especially sunflower oil had significantly increased ($P < 0.05$) milk yield, fat, and lactose contents compared with the control; however, urea nitrogen milk was decreased ($P > 0.05$) by treatments compared to the control. The experimental additives were increased ($P < 0.05$) unsaturated fatty acids in milk specially [C18:2 *trans*-10, *cis*-12] and conjugated linoleic acids (CLA). Moreover all additives increased ($P > 0.05$) C18:3N3 and C18:3N6 (omega 3 and omega6) compared with control. In conclusion, adding either whole sunflower seed or sunflower oil to lactating goats ration had beneficial effects on milk yield and milk composition and so enhance healthy fatty acids (CLA and omega 3) contents in milk, without detrimental effects on animal performance.

Key Words: lactating goats, sunflower, milk composition

0632 The relationship between human daily requirements of CLA, the potential enrichment of milk through cow's nutrition, and daily human consumption.
A. Siurana* and S. Calsamiglia, *Animal Nutrition and Welfare Service, Dep. of Animal and Food Sciences, Universitat Autònoma de Barcelona, Bellaterra, Spain.*

Interest in functional foods has increased in recent years, being the enrichment of milk with conjugated linoleic acid (CLA) one of the targeted products. The objectives of this research were: a) to identify the source of human daily recommendations (literature search), b) to determine the effect of feeding strategies on CLA concentration in milk (meta-analysis), and c) to determine current average human intake of CLA and the expected improvement if milk and milk products were consumed in a CLA enriched form (literature search). The most commonly reported intake recommendations for human are 0.8 g/d (from 0.6 to 3.0 g/d). All recommendations have been extrapolated from animal models and the few human studies reported contradictory results. We selected published papers ($n = 69$) where dairy cows were fed different fats and the milk fat content and fatty acid (FA) profile were reported. Treatments were categorized by source (vegetable oils, fish oils or the combination) and method of processing (raw, processed or extruded seeds, and oils). Data were analyzed using meta-analysis techniques. The combination of fish and vegetable oils resulted in the greatest increase (0.61 vs. 1.34 g CLA/100 g FA; $P = 0.01$), but milk fat content decreased (3.61 vs. 3.12%; $P = 0.01$). Linseed increased CLA proportion (0.61 vs. 0.90 g CLA/100 g FA; $P = 0.01$) without affecting milk fat content. The best processing methods to enriched milk with CLA were extruded seeds (0.57 vs. 1.11 g CLA/100 g FA; $P = 0.01$) and oils (0.57 vs. 1.10 g CLA/100 g FA; $P = 0.01$), but extruded seeds decreased milk yield (30.4 vs. 28.9 kg/d; $P = 0.01$) and oils decreased milk fat content (3.61 vs. 3.31%; $P = 0.01$). Considering the changes in CLA and milk fat content, supplementation with fish oils together with vegetable oils would be the best strategy (118% increase). The estimated current average human consumption in Europe, the United States, and Canada is 0.21 g/d, ranging from 0.06 g/d in Portugal to 0.40 g/d in Germany, well below the requirements. If we assume an increase content of 118% in CLA in milk and milk products, average human consumption would increase from 0.21 to 0.46 g/day. Although there is sufficient data on feeding strategies to increase CLA content in milk, human requirements have not been well-established and, based on current recommendations, they are unattainable even if all milk and milk products were consumed as CLA enriched products.

Key Words: conjugated linoleic acid (CLA), dairy products, human requirements

0633 Tolerance study of rumen protected conjugated linoleic acid on dairy cows during the transition and early lactation period. Z. H. Wei*[1], J. S. Shen[1], J. X. Liu[2], Y. J. Zhang[3], and Y. Jiang[3], *[1]Institute of Dairy Science, Zhejiang University, Hangzhou, China, [2]Zhejiang University, Hangzhou, China, [3]BASF (China) Company Ltd., Shanghai, China.*

The objective of the current study was to investigate the effects of dietary addition of rumen protected conjugated linoleic acids (CLA) on lactation performance and blood biochemical and hematological parameters of dairy cows during transition and early lactation period, and to evaluate the acute toxicity when it was added with the 10-fold of the recommended level. Twenty-seven perinatal Holstein cows were selected based on their parity and milk production of previous lactation and assigned to one of three treatments according to a randomized complete block design: 1) basic diet added with no extra CLA (control), 2) 50 g/d of CLA per head (recommended level), and 3) 500 g/d of CLA per head (10-fold of the recommended level). The CLA used in this trial contained 12.0% of cis-9, trans-11 and 11.9% of trans-10, cis-12 CLA isomer. The experiment started 3 wk before expected calving day and finished at 8 wk after calving. Milk yield was recorded, and milk samples were collected to analyze milk composition weekly. The blood samples were collected on d 21 and 10 prepartum and d 1 and week 1, 2, 4, and 8 postpartum to analyze the blood biochemical and redox parameters. An aliquot of blood samples collected on d 21 prepartum and 8 wk postpartum were used for hematological analysis. Addition of CLA did not exert significant effects on dry matter intake, milk yield, content and yield of milk protein and lactose, and somatic cell count ($P > 0.10$). Compared with control and recommended dose group, CLA addition at 500 g/d significantly reduced content and yield of milk fat, milk urine nitrogen, and total solids content ($P < 0.01$). No significant differences were observed in hematological parameters including red blood cell count, hematocrit, hemoglobin, white blood cell count, and its differential count and percentage, platelet count among groups ($P > 0.10$). Addition of CLA significantly decreased plasma levels of non-esterified fatty acids ($P < 0.05$), which is beneficial for alleviating negative energy balance status of dairy cows. The CLA also tended to improve the total antioxidant capacity ($P = 0.09$). There were no significant differences in plasma glucose, total protein, albumin, globulin-to-albumin ratio, creatinine, alanine transaminase, aspartate aminotransferase, and alkaline phosphatase among the three groups ($P > 0.10$). These results indicated that there is no adverse effects of CLA addition on dairy cows' health even at a 10-fold of recommended dose.

Key Words: conjugated linoleic acids, dairy cows, tolerance

0634 Effect of different dietary fat supplements on milk odd and branched chain fatty acids in dairy cows. E. Baumann*, P. Y. Chouinard, Y. Lebeuf, and R. Gervais, *Université Laval, Québec, Canada.*

The odd and branched chain fatty acid (OBCFA) profile of milk has emerged as an interesting, noninvasive option for evaluating rumen function. These fatty acids (FA) are synthesized by different ruminal microbe populations, absorbed in the intestine, and taken up by the mammary gland to be incorporated in milk fat. Lipid supplementation in lactating cows could affect different steps in these processes, as dietary FA have been reported to inhibit (step i) microbial growth, and (step ii) de novo microbial FA synthesis in the rumen, and to increase (step iii) the uptake preformed FA from dietary origin by mammary gland. Such phenomena could reduce synthesis and secretion of OBCFA, and thereby, when cows receive high fat diets, interfere with previously established relationships between these milk FA. To assess the influence of dietary lipids on milk OBCFA, eight Holstein cows (101 ± 11 DIM) were used in a double 4 × 4 Latin-square design with 14-d periods. Treatments were infusion of: CTL) fat-free emulsion in the rumen; SBR) 450 g emulsified unsaturated FA (soybean oil) in the rumen (putative effects on steps i, ii and iii); EBR) 450 g emulsified saturated FA (EnergyBooster) in the rumen (putative effects on steps ii and iii); and EBA) 450 g emulsified saturated FA in the abomasum (putative effects on step iii). Contrasts compared CTL to SBR, SBR to EBR, and EBR to EBA. The results indicate that dietary lipids do affect expression of various milk OBCFA; these effects would need to be considered in the development of models aiming to predict rumen parameters based on milk OBCFA.

0635 Feeding incremental levels of ground flaxseed increased n-3 fatty acids and conjugated linoleic acids in organically-managed jersey cows.

A. F. Brito[1], J. Kraft*[2], T. L. Resende[3], A. B. D. Pereira[1], K. J. Soder[4], D. H. Woitschach[5], and R. B. Reis[3], *[1]University of New Hampshire, Durham, [2]Dep. of Animal Science, University of Vermont, Burlington, [3]Universidade Federal de Minas Gerais, Belo Horizonte, Brazil, [4]USDA–Agricultural Research Service, University Park, PA, [5]Universidade Federal de Viçosa, Brazil.*

We reported previously that feeding incremental levels of ground flaxseed (GFLAX) linearly reduced DMI, milk production, and contents and yields of milk components. Flaxseed is a high-energy oilseed rich in α-linolenic acid. It is well established the impact of flaxseed on changing milk fatty acids (FA) profile but there is limited research about the effects of GFLAX on milk FA composition, particularly in cows fed high-forage diets. In a recent needs assessment of research and educational needs of the organic dairy industry in the Northeast 84% of respondents indicated the development of value-added dairy products as one of the most pressing areas for dairy research (Pereira et al., 2013 JDS 96:7340–7348), thus justifying additional studies with flaxseed. Twenty organically managed Jersey cows (425 ± 37 kg of BW and 111 ± 62 DIM) in the beginning of the study were blocked by milk yield and parity and randomly assigned to treatment sequences in five replicated 4 × 4 Latin squares to investigate the effects of incremental levels of GFLAX (0, 5, 10, or 15% diet DM) on milk FA composition. All cows were fed TMR containing (% of diet DM): 55% alfalfa-grass baleage, 8% grass hay, and 37% concentrate; soybean meal (from 6 to 2% of diet DM) and corn meal (from 27 to 16% of diet DM) were replaced with GFLAX (from 0 to 15% of diet DM), while roasted soybean (2% of diet DM) was maintained constant across treatments. Diets were isonitrogenous (mean = 18.3% CP), but crude fat increased from 3.8 to 7.4% when replacing soybean meal and corn meal with GFLAX. Milk concentration (% of total milk FA) of total n-3 FA (0.74 to 1.42%), *t*C18:1 (1.35 to 2.63%), *c*9, *t*11 CLA (0.47 to 0.87%), total CLA (0.55 to 1.08%), total monounsaturated FA (21.9 to 34.3%), and total polyunsaturated FA (2.87 to 4.72%) increased linearly in response to increasing levels of GFLAX. Conversely, milk concentrations of n-6 FA (1.78 to 1.49%) and total saturated FA (72.7 to 58.1%), and the n-6 to n-3 ratio (2.42 to 1.06) declined linearly with increasing levels of GFLAX. Quadratic effects were observed for total n-3 FA, *t*C18:1, *c*9, *t*11 CLA, total CLA, and the n-6 to n-3 ratio. It can be concluded that GFLAX is an effective supplement to enrich milk with bioactive FA of potential health benefits for humans.

Key Words: flaxseed, organic dairy cows, milk fatty acids

0636 Lactational responses to palmitic acid supplementation when substituted for soyhulls or corn grain.

C. L. Preseault, J. P. Boerman, and A. L. Lock*, *Michigan State University, East Lansing.*

Effects of a palmitic acid-enriched fat supplement (PA; 87% C16:0) when replacing soyhulls or corn grain on feed intake and metabolic and production responses of dairy cows were evaluated. Twenty-four Holstein cows (185 ± 70 DIM) were randomly assigned to treatment sequence in a 3 × 3 Latin square design. Treatments were a control diet (CON; no added PA), 1.5% added PA with soyhulls replaced (PA-SH), or 1.5% added PA with corn grain replaced (PA-CG). Treatment periods were 21 d, with the final 5 d used for sample and data collection. The study was conducted from June through August 2013 when temperature-humidity index in the barn averaged 70.5 ± 5.7°F. The corn silage and alfalfa silage-based diets contained 20.0% forage NDF and 16.8% CP. The statistical model included the random effect of cow and fixed effects of period and treatment; preplanned contrasts evaluated the effect of PA treatments (CON vs. 1/2[PA-SH+PA-CG]) and the effect of PA-SH vs. PA-CG. The PA treatments increased milk fat concentration (3.55, 3.65, and 3.71%; $P < 0.01$) and yield (1.38, 1.49, and 1.42 kg/d; $P < 0.05$) for CON, PA-SH, and PA-CG, respectively. Compared with CON, there was no effect of PA treatments on DMI, milk yield, milk protein yield, or ECM ($P > 0.18$). However, compared with PA-CG the PA-SH treatment increased DMI 1.35 kg/d, milk yield 2.38 kg/d, milk protein yield 0.08 kg/d, and ECM 2.26 kg/d ($P < 0.05$). The PA treatments increased feed efficiency (ECM/DMI), 1.46, 1.51, and 1.50 for CON, PA-SH, and PA-CG, respectively ($P < 0.05$). Compared with CON, PA treatments increased the yield of 16-carbon milk FA by 83 g/d ($P < 0.01$) but did not affect the yield of de novo ($P = 0.38$) or preformed ($P = 0.71$) milk FA. There was a trend for increased yield of de novo (21 g/d; $P = 0.07$) and preformed (27 g/d; $P = 0.10$) milk FA for PA-SH vs. PA-CG. The PA treatments did not alter BW ($P = 0.42$) or BCS ($P = 0.99$); however, PA-SH increased BW 9.5 kg vs. PA-CG ($P < 0.05$). There was no effect of PA treatments on plasma concentrations of glucose ($P = 0.92$) or insulin ($P = 0.57$), whereas PA treatments increased NEFA (99.5, 110, and 109 uEq/L for CON, PA-SH, and PA-CG, respectively; $P < 0.01$). Treatment had no effect on rectal temperature or respiration rate ($P > 0.46$). Results demonstrate that a PA-enriched fat supplement increased milk fat concentration and yield and feed efficiency. Responses were greater when PA replaced soyhulls rather than corn grain.

Key Words: fat supplementation, milk fat, palmitic acid

0637 Interaction between culture pH and corn oil concentration on NDF digestibility and biohydrogenation of unsaturated fatty acids in batch culture. Y. Sun*, M. S. Allen, and A. L. Lock, *Michigan State University, East Lansing.*

Effects of culture pH and corn oil (CO) concentration on NDF digestibility (NDFD) and biohydrogenation (BH) of unsaturated fatty acids (FA) in batch culture were evaluated in a 2 × 3 factorial design. Cultures (4/treatment/time point) included alfalfa hay plus increasing concentrations of CO (0, 1, 2% DM) incubated at culture pH 5.8 or 6.2 for 0, 6, 12, 18, and 24 h. Effects of culture pH, CO, time, and their interactions were determined. Increasing CO in cultures increased total FA concentration which averaged 2.19, 3.36, and 4.54% DM for 0, 1, 2% CO, respectively ($P < 0.001$). Culture pH did not affect total FA concentration ($P = 0.29$). Main effects of treatments (culture pH and CO concentration) across time were significant for the response variables of interest despite significant ($P < 0.10$) interactions (both two-way and three-way interactions) for these variables. Lower culture pH reduced NDFD across CO treatments and time (11.6 vs. 21.6%; $P < 0.001$), whereas increasing CO increased NDFD across pH treatments and time (14.2, 16.9, and 18.8%; $P < 0.001$); NDFD increased over time for all treatments ($P < 0.001$). Addition of CO increased the concentration of *cis*-9, *cis*-12 18:2 across pH treatments and time (7.88, 17.4, 23.0 g/100 g FA; $P < 0.001$) and higher culture pH reduced its concentration across CO treatments and time (13.8 vs. 18.4 g/100 g FA; $P < 0.001$). Lower culture pH reduced BH extent for *cis*-9, *cis*-12 18:2 (34.4 vs. 53.0%; $P < 0.001$), which increased with time ($P < 0.001$) and was affected to a lesser extent by increasing CO (43.0, 45.3, and 42.7%; $P < 0.001$ quadratic). Lower culture pH and increasing CO reduced the concentration of 18:0 (20.1 vs. 24.9 g/100 g FA and 28.7, 21.7, and 17.1 g/100 g FA, respectively; $P < 0.001$). Lower culture pH increased the concentration of *trans*-10 18:1 (1.04 vs. 0.73 g/100 g FA; $P < 0.001$) and reduced the concentration of *trans*-11 18:1 (4.73 vs. 6.11 g/100 g FA; $P < 0.001$) across CO treatments and time. Increasing CO increased the concentration of *trans*-10 18:1 (0.72, 0.92, and 1.03 g/100 g FA; $P < 0.001$) and *trans*-11 18:1 (3.46, 5.85, and 6.95 g/100 g FA; $P < 0.001$) across pH treatments and time. In conclusion, higher culture pH increased NDFD, BH of *cis*-9, *cis*-12 18:2, and formation of *trans*-11 18:1. Increasing the inclusion of CO increased the formation of BH intermediates as well as NDFD (unexpectedly). Treatments interacted with each other and with time for all variables of interest, particularly formation of *trans*-10 and *trans*-11 18:1.

Key Words: batch culture, biohydrogenation, digestibility

0638 Feed intake and production responses of lactating dairy cows when commercially available fat supplements are included in diets: a meta-analysis. J. P. Boerman* and A. L. Lock, *Michigan State University, East Lansing.*

This analysis was performed to evaluate the effects of commercially available fat supplements on DMI and production responses of lactating dairy cows. Available data were collected from 133 peer-reviewed publications; of which 88 met our selection criteria, comprising 159 treatment comparisons. Calcium-salts of palm fatty acid distillate (PFAD; $n = 73$), saturated prilled fats (PRILLS; $n = 37$), and tallow ($n = 49$) supplemented at $\leq$ 3% diet DM were compared to nonfat supplemented diets used as controls. Analysis was performed using Comprehensive Meta Analysis v2 software to calculate the effect size as the mean difference in least square means between control and fat supplemented treatments using a random effects model. Treatment comparisons were obtained from either randomized design ($n = 99$) or crossover/Latin square design experiments ($n = 60$). There were no differences in the overall effect of fat supplementation between randomized design and crossover/Latin square design experiments for any production parameter (all $P > 0.46$). Therefore, all types of experimental design were analyzed together. Fat supplementation reduced DMI compared to control (0.30 kg/d, $P < 0.01$). However, the response was dependent on fat type; PFAD and tallow reduced DMI (0.58 and 0.44 kg/d, $P < 0.01$ and $P = 0.06$, respectively), while PRILLS had no effect ($P = 0.71$). Fat supplementation increased milk yield by 1.05 kg/d ($P < 0.01$), with differences in the magnitude of response for PFAD (1.20 kg/d, $P < 0.01$), PRILLS (1.19 kg/d, $P < 0.01$), and tallow (0.70 kg/d, $P < 0.01$). Fat supplementation increased milk fat yield by 0.04 kg/d ($P < 0.01$) with increases of 0.05 and 0.06 kg/d for PFAD and PRILLS, respectively (both $P < 0.01$) with no effect of tallow ($P = 0.72$) compared to control. There was no overall effect of fat supplementation on milk fat concentration ($P = 0.84$), although compared with control, tallow reduced milk fat by 0.08% units ($P = 0.01$), PFAD had no effect ($P = 0.25$), and PRILLS increased milk fat by 0.08% units ($P = 0.05$). Milk protein yield was unaffected by PFAD and tallow (both $P > 0.31$) and increased by 0.03 kg/d by PRILLS ($P < 0.01$) resulting in an overall increase by fat supplementation of 0.01 kg/d ($P < 0.01$). Milk protein concentration was reduced by all fat supplements ($P < 0.01$ for PFAD and tallow; $P = 0.04$ for PRILLS) for an overall reduction in milk protein concentration of 0.05% units ($P < 0.01$). In conclusion, fat supplementation has the potential to reduce DMI and increase the yield of milk and milk components. However, consideration should be given to the type of fat, as production responses were highly variable across fat supplements.

Key Words: fat supplementation, meta-analysis, production response

0639 Effect of dietary fat source on milk production and milk composition in early lactation cows in a continuous trial design. G. Ma[*1], J. H. Harrison[2], E. Block[3], and L. VanWieringen[4], *[1]Washington State University, Pullman, [2]Washington State University, Puyallup, [3]Church and Dwight Animal Nutrition, Ewing, NJ, [4]Washington State University, Sunnyside.*

This study was designed to look at two dietary fat sources (Megalac and Palmit 80) when fed at amounts to deliver fatty acids at ~ 0.22 kg/d. Twenty-four multiparous dairy cows in early lactation (average DIM = 68) were used to compare the temporal relationship of DMI, milk production, milk composition, body weight, and BCS. Cows were fed individually via Calan headgates. Data from wk 1 to 2 was averaged and used as a covariate period, and cows were fed Megalac as the only source of supplemental fatty acids. During wk 3 to 12, 12 cows were fed the Megalac diet at 1.15% DM, and 12 cows were fed the Palmit 80 diet at 0.93% DM. Milk production was obtained 2x/d and 1x/wk an AM-PM composite of milk was obtained from each cow and analyzed for composition. Data were analyzed with PROC MIXED of SAS with repeated measurements using a model that included treatment, week, treatment x week. There was no treatment x week interaction ($P > 0.1$). The covariant played a significant role in the adjustment ($P < 0.05$). In this study, there was no significant difference between sources of supplemental fat on milk production, 39.2 vs. 40.0 kg; DMI, 29.2 vs. 29.1 kg; milk fat %, 4.3 vs. 4.3%; milk protein %, 2.91 vs. 2.98% ($P < 0.09$); milk fat yield, 1.65 vs. 1.74 kg; BCS, 2.81 vs. 2.80; BW, 668 vs. 677 kg; or BW change, 11.7 vs. 9.5 kg (Megalac vs. palmit 80, $P > 0.1$). Milk protein yield was greater 1.13 vs. 1.19 kg ($P = 0.002$) when cows consumed Palmit 80. A previously reported trial of similar design (J. Dairy Sci. 96 (Suppl.E):Abstr. W29) showed higher production by cows fed Megalac vs. Palmit 80. In that trial, cows were earlier in DIM at the start of the study. A hypothesis is that cows at different stages of lactation use individual fatty acids differently due to metabolic status.

Key Words: milk fat, dietary fat, fatty acids

0640 Farm survey: Milk fatty acid composition measured by mid-infrared. D. M. Barbano[*1,2], C. Melilli[1,2], and T. R. Overton[3], *[1]Cornell University, Ithaca, NY, [2]Northeast Dairy Foods Research Center, Ithaca, NY, [3]Cornell University, Dep. of Animal Science, Ithaca, NY.*

Our objectives were: 1) measure fatty acid (FA) composition of individual herd milks using new chemometric models for mid-infrared (IR) milk analysis and 2) determine if there were correlations between milk FA composition and bulk tank milk fat and protein tests. Bulk tank milks from 430 farms were tested multiple times per month for 14 mo by mid-IR (Lactoscope FTA, Delta Instruments) for fat, protein, and FA composition. The IR instrument could test about 100 samples per hour. Data were organized in two groups: Jersey and Holstein. A variety of individual FA and groups of FA were measured. Validation of IR FA results was done by GLC. The key FA parameter that was positively correlated with bulk milk fat and protein concentration was de novo FA (g/100 g milk). Structural parameters of FA chain length (carbon number) and total unsaturation (double bonds/FA) were negatively correlated with fat and protein (g/100 g milk). This was true for both Jersey and Holstein. When de novo FA (relative % of FA) were higher, fat test was higher for both Jersey and Holstein. As de novo FA (g/100 g milk) increased, fat (g/100 g milk) increased ($P < 0.001$) at a much faster rate (i.e., higher slope) than when preformed FA (g/100 g milk) increased (slope 2.28 vs. 1.29) for Jersey and (slope 2.16 vs. 1.22) for Holstein, for de novo vs. preformed, respectively. As the proportion of de novo increased (and fat percent increased), the measured FA chain length and double bonds per FA decreased ($P < 0.001$). True protein (g/100 g milk) increased as de novo FA (g/100 g milk) increased. We hypothesize that feeding and farm management practices influenced de novo FA production and milk fat and protein (g/100 g milk). A group of 20 Jersey and 20 Holstein farms of interest that had a wide range of de novo FA (g/100 g fat) were selected for a more in-depth field study, in the next year, to determine if there are cost effective feeding and management practices that can be used to increase fat and protein tests. During the 14-m period of our study, the 10 Holstein and 10 Jersey low de novo herds averaged 3.62 and 3.97% fat and 2.99 and 3.15% true protein, while the 10 high de novo Holstein and Jersey herds averaged 3.92 and 4.80% fat and 3.09 and 3.62% true protein, respectively.

Key Words: mid-infared milk analysis, de novo fatty acids, fat and protein concentration

0641 The effects of high rates protected fat in rations of high yielding dairy cows on production efficiency and digestibility. U. Moallem[*1], E. Frank[1,2], M. Zachut[1], L. Livshitz[1], and A. Arieli[2], *[1]Institute of Animal Science, Volcani Center, Bet Dagan, Israel, [2]Faculty of Agriculture, Hebrew University, Rehovot, Israel.*

Due to the rise in grain price, there is an increased use of fat in rations of dairy cows in Israel; however, the effects of high rates have never been examined in the Israeli rations. Therefore, the objectives were to determine the effects of increasing rate of calcium soap of fatty acids (CSFA) on yields, efficiency and digestibility. Forty-two multiparous dairy cows were divided into three treatment groups according to milk, parity and days in milk (DIM), and fed diets containing: (i) low fat (LF), 4.7% ether extracts (EE; 1.7% CSFA); (ii) moderate fat (MF), 5.8% EE (2.8% CSFA), and (iii) high fat (HF), 6.8% EE (3.9% CSFA). The diets were isonitrogenous (16.5%), but energy content was 1.8 in the HF compared to

1.78 Mcal/kg DM in the LF and MF diets. Rumen samples were taken three times in 1 d (2 h pre-feeding, at feeding, and 2 h post-feeding) for pH and rumen measurements. The data were analyzed using the PROC MIXED model of SAS and the model included parity, DIM, and related covariate data. No differences were observed in milk and FCM (4%) yields or fat and lactose percentages and yields among groups. A trend of decreased protein percentage in milk with increasing EE content in diet was observed ($P < 0.08$), and higher protein yields were observed in LF and MF than in HF. No differences were observed in dry matter intake (DMI) or energy intake among groups. Efficiency of converting DMI to milk was also similar, but conversion of DMI into FCM (4%) was higher in MF and HF than in LF. Rumen pH was higher in MF and HF than in LF, with no differences in rumen ammonia concentrations. Total VFA concentration in rumen was higher in LF than in MF and HF groups, and apparent digestibility of DM and organic matter (OM) was higher in the LF than in both other groups. In conclusion, although apparent digestibility of DM and OM was lower in MF and HF, no detrimental effects of high rate of CSFA supplementation (up to 3.9% of the diet) on milk yields and efficiency were observed.

Key Words: CSFA, digestibility, efficiency

0642 Long chain fatty acids alter expression of genes involved in lipid metabolism in goat mammary epithelial cells partly through PPARγ.

W. Zhao[*1,2], M. Bionaz[3], J. Luo[1], A. Hosseini[4], P. Dovc[5], and J. J. Loor[2], *[1]Northwest A & F University, Yangling, China, [2]University of Illinois, Urbana, [3]Dep. of Animal and Rangeland Sciences, Oregon State University, Corvallis, [4]University of Bonn, Germany, [5]University of Ljubljana, Domzale, Slovenia.*

Data from dairy cows and goats indicate a prominent role of PPARγ in regulating milk fat synthesis (MFS). The PPARγ binds and is activated by long-chain fatty acids (LCFA), hence is amenable for fine-tuning MFS. Previous data in MacT cells indicated an agonistic capacity of saturated LCFA but also the potential of LCFA to act through alternative transcriptional regulators. To determine the specificity of LCFA in modulating PPARγ in goats, triplicate cultures of primary mammary cells from Saanen goats cultivated in lactogenic medium were cultured for 24 h with 50 μM of the specific PPARγ activator rosiglitazone (ROSI) or the specific PPARγ inhibitor GW9662 (GW), 100 μM of several LCFA (16:0, 18:0, t10,c12-CLA, DHA, and EPA), and a combination of GW with each of LCFA (for a total of 12 treatments excluding controls). Expression of 28 genes involved in MFS plus three internal control genes was measured using qPCR. Data were log-transformed and statistically analyzed using the GLM of SAS. The multiple comparisons were corrected using Tukey's test and significance set at $P < 0.05$. The cells treated with GW alone allowed uncovering that a minimum activation of PPARγ is essential for the expression of LPIN1, PPARG, LXRA, LPL, ACSL1, FABP3, and FABP4. The combination of the data from GW and ROSI treatments allowed identification of SCD, FADS1, NR1H3, SREBF1, INSIG1, LPL, FABP3, and FABP4 as strong PPARγ target genes. The 16:0 and 18:0 had the strongest effect on most of the measured genes and stronger than ROSI. Among the unsaturated LCFA, the CLA had the strongest effect in decreasing expression of FASN, FADS1, LPIN1, SREBF1, SREBF2, INSIG1, RXRA, NCOR1, and FABP3. The combination with GW diminished but did not completely eliminate the effect of saturated LCFA and interacted in a complex manner with the effect of unsaturated LCFA. The expression of AGPAT6, PLIN2, and CD36 increased in all treatments compared with control. The expression of NR1H3 solely responded to ROSI and GW but not to LCFA. Results allowed pinpointing true PPARγ target genes in goat mammary cells, and confirmed that saturated LCFA are potent PPARγ agonists in ruminants but that they act also through alternative transcriptional factors. Data established the lipid-depressing effect of unsaturated LCFA, particularly CLA. A complex mechanism for LCFA in regulating expression of lipid-related genes in goat mammary cells was uncovered.

Key Words: nuclear receptors, milk fat synthesis, nutrigenomics

RUMINANT NUTRITION V

0643 Methane emissions from lactating and dry dairy cows fed diets differing in forage source and NDF concentration. *K. J. Hammond*, D. J. Humphries, L. A. Crompton, P. Kirton, C. Green, and C. K. Reynolds, University of Reading, UK.*

Methane emission factors are lacking from different livestock species in various production states fed varying diets. The objectives of the present study were to measure effects of physiological state, silage type, and supplemental NDF on DMI, DM digestibility (DMD), and methane emissions of lactating and dry dairy cows using two 4 × 4 Latin squares (5-wk periods) with four lactating (114 DIM ± SEM 3.30; square 1) or four dry and non-pregnant (square 2) ruminally cannulated Holstein dairy cows. Measurements included DMI and DMD during wk 4, and methane production (respiration chambers) in wk 5. Four isonitrogenous treatment diets were fed as total mixed rations (TMR) with 50% silage (DM basis) offered ad libitum to lactating cows and at 1.2 × maintenance ME to dry cows. Silage was comprised of either 25:75 (MS) or 75:25 (GS) grass silage:maize silage on a DM basis, without or with additional NDF from chopped straw and soy hulls (+ 47 g NDF/kg TMR DM). Data for each square were analyzed using mixed models for fixed effects of silage, NDF, and their interaction, and random effects of cow and period. Data from each square were combined to test the effect of physiological state. Lactating cows fed MS had a greater DMI ($P < 0.02$; 21.1 kg/d) and methane production ($P < 0.10$; 484 g/d) and lower methane yield ($P < 0.02$; 22.8 g/kg DMI) than when fed GS (17.7, 440, and 24.9, respectively), however there was no effect of silage type on DMD. Added NDF increased methane yield for lactating cows fed MS (22.8 vs. 23.7 g/kg DMI), but not GS (silage by NDF interaction, $P < 0.02$). Except for DMI, which was higher ($P < 0.03$) for MS compared to GS diets (12.9 vs. 10.6 kg/d), diet did not affect methane production or yield or DMD for dry cows. Compared to dry cows, lactating cows had greater DMI (19.7 vs. 11.0 kg/d; $P < 0.02$), higher DMD (749 vs. 725 g/kg; $P < 0.01$), and lower methane yield (24.0 vs. 28.0 g/kg DMI; $P < 0.03$). The difference in methane yield between lactating and dry cows may be due to differences in DMI and rumen function, including digesta dynamics such as rumen outflow and retention time. Such differences may also explain why silage type affected methane yield in lactating cows, but not dry cows.

Key Words: methane, dairy cows, forage NDF

0644 Effects of cysteamine on ruminal fermentation parameters and methane production of water buffalo by in vitro gas production method. C. Zou[*1], Y. L. Huang[2], X. Liang[2], S. J. Wei[2], B. Lin[2], C. J. Yang[2], and X. W. Liang[2], *[1]Buffalo Research Institute, The Chinese Academy of Agricultural Sciences, Nanning, China, [2]Buffalo Research Institute, Chinese Academy of Agricultural Sciences, Nanning, China.*

In our previous studies, supplement cysteamine (Cs) could increase the conjugated linoleic acids content in water buffalo milk, but we do not know whether Cs could reduce the methane production. Thus, the aim of this present study was to evaluate the effect of Cs on ruminal fermentation parameters and methane production of water buffalo by in vitro gas production method. In vitro fermentations were conducted in 180-mL serum bottles with a reading pressure in vitro gas production system. The oven-dried subtrate (187.50 mg maize grain, 56.25 mg soybean meal, 196.88 mg elephant grass, 140.63 mg brewers grains, and 168.75 mg cassava pulps, DM basis) was weighted with three replicates into 90-mL buffer medium. The ratio of concentrate to forage of substrate was 32.5:67.5. Cs was supplemented in concentrate at levels of 0, 0.2, 0.4, 0.6, 0.8, and 1.0% (dry matter basis), respectively. The water buffalo rumen contents obtained were mixed and strained through four layers of cheesecloth into a flask under CO_2 in the water bath at 39°C. The pressure and methane production were measured at 6, 12, and 24 h. At the end of the incubation (24 h), the incubation fluids were sampled and samples were stored at -20°C for an analysis of NH_3–N concentration and VFA composition. There were no significant differences for NH_3–N concentration (6.40, 6.53, 6.43, 7.07, 7.24, and 6.30 mg/dL for the levels of 0, 0.2, 0.4, 0.6, 0.8, and 1.0% Cs supplement, $P = 0.652$) and acetate (20.91, 20.95, 20.86, 20.44, 21.22, and 19.42 mmol/L, $P = 0.702$), propionate (7.06, 7.08, 6.71, 6.44, 6.71, 6.20 mmol/L, $P = 0.436$), total VFA (32.77, 32.81, 31.56, 30.98, 31.85, and 29.20 mmol/L, $P = 0.499$), and acetate/propionate (2.97, 2.97, 3.11, 3.17, 3.16, and 3.13, $P = 0.086$) among each treatments. Methane production at 6 h (0.14, 0.13, 0.10, 0.10, 0.08, and 0.09 mmol/L, $P = 0.03$), 12 h (0.37, 0.36, 0.25, 0.28, 0.26, and 0.28 mmol/L, $P < 0.0001$), 24 h (0.61, 0.61, 0.49, 0.54, 0.51, and 0.58 mmol/L, $P = 0.004$) were decreased with an increasing level of Cs. Butyrate content (4.80, 4.79, 3.99, 4.09, 3.92, and 3.59 mmol/L, $P = 0.037$) at 24 h were decreased with an increasing level of Cs. The results of in vitro gas production method indicate that Cs can promote rument microbe fermentation, but decrease methane production of water buffalo when supplemental level of Cs is 0.8%.

Key Words*:* cysteamine, methane emission, water buffalo

0645 Effect of lowered pH and increased passage rate on methane and volatile fatty acid production from continuous culture. B. A. Wenner*[1], F. Batistel[2], J. D. Souza[3], T. J. Hackmann[4], and J. L. Firkins[1], *[1]The Ohio State University, Columbus, [2]University of São Paulo, Piracicaba, Brazil, [3]University of Sao Paulo, Piracicaba, Brazil, [4]University of Florida, Gainesville.*

The present study was conducted as a 2 × 2 factorial treatment arrangement in a Latin square design using continuous culture fermenters (n = 4). Treatments were control pH (CpH; 6.3 to 6.9) or low pH (LpH; 5.8 to 6.4) factorialized with solids passage rates (k_p) of either low (Lk_p; 2.5%/h) or high (Hk_p; 5.0%/h); total dilution by buffer was constant at 7.0%/h. Fermenters were fed once daily (40 g DM; a 50:50 concentrate:forage diet) and periods lasted 10 d with 3 d of sample collection. The main effect of LpH decreased (P < 0.001) aqueous hydrogen compared with CpH by 3.82 μM, but there was no effect of k_p (P > 0.10). The main effect of LpH decreased headspace hydrogen (H_2(g); escaped from culture) by 60.1 mmol/L×d, and an interaction over time (P < 0.001) was explained by H_2(g) being greater for CpH/Hk_p than for LpH (both k_p) from 5 to 24 h post-feeding, and CpH/Lk_p being greater than LpH (both k_p) from 6 to 24 h post-feeding. Further, H_2(g) was greater (P < 0.05) with CpH/Hk_p compared with CpH/Lk_p from 15 to 24 h post-feeding. There was no main effect (P > 0.10) of pH on methane production, but the main effect of Hk_p tended (P = 0.08) to decrease methane production compared with Lk_p by 880 mmol/L×d. A treatment × time interaction (P < 0.01) was explained in that CpH/Lk_p had the greatest (P < 0.05) methane production from 11 to 23 h post-feeding, whereas LpH/Lk_p was not different (P > 0.05) from CpH/Lk_p at 24 h post-feeding. Acetate molar percentage was 61.8, 59.6, 58.2, and 54.7% for CpH/Lk_p, CpH/Hk_p, LpH/Lk_p and LpH/Hk_p, respectively. Both the main effects of LpH and Hk_p decreased acetate molar percentage (P = 0.01) compared with CpH and Lk_p, respectively. Propionate molar percentage was 22.5, 24.4, 23.9, and 26.2% for CpH/Lk_p, CpH/Hk_p, LpH/Lk_p and LpH/Hk_p, respectively. The main effect of LpH increased (P = 0.02) propionate molar percentage, decreasing (P = 0.002) A:P ratio from 2.61 to 2.34 compared with CpH. The main effect of Hk_p increased (P = 0.006) propionate molar percentage, decreasing (P = 0.002) A:P ratio from 2.62 to 2.34 compared with Lk_p. There were no effects on butyrate molar percentage or total VFA production (P > 0.10). The results indicate increasing $k_p$and decreasing pH decreased A:P ratio independent of the current diet.

Key Words: hydrogen, methane, volatile fatty acids

0646 Effects of encapsulated nitrate on nitrogen utilization and enteric methane emissions in beef cattle. C. Lee*[1], R. C. Araujo[2,3], K. M. Koenig[4], and K. A. Beauchemin[1], *[1]Lethbridge Research Centre, Agriculture and Agri-Food Canada, AB, Canada, [2]GRASP Ind. & Com. LTDA, Curitiba, Brazil, [3]EW|Nutrition GMBH, Visbek, Germany, [4]Agriculture and Agri-Food Canada, Lethbridge Research Centre, AB, Canada.*

Effects of encapsulated slow-release nitrate (EN; GRASP Ind. & Com. LTDA, Paraná, Brazil) on nitrogen (N) utilization and enteric methane emissions in beef cattle were investigated. Eight ruminally cannulated beef heifers (452 ± 21 kg BW) were used in a replicated 4 × 4 Latin square design. The basal diet (55:45 forage:concentrate ratio) included encapsulated urea [EU; 1.2% of dietary DM; Prote-N; GRASP Ind. & Com LTDA] for the control diet. The EN replaced a portion of EU and limestone with 1, 2, or 3% EN (0.8, 1.5, and 2.3% nitrate) in dietary DM. The diets (iso-nitrogenous; 12.7% CP) were fed once daily ad libitum. Each period consisted of 21 d of adaptation in a stepwise manner followed by 14 d of sampling (total collection for 4 d and enteric methane measurements in environmental chambers for 3 d). Dry matter intake tended to decrease (10.4 to 10.1 kg/d; P = 0.06) slightly with increases in EN, but body weight was not affected. Enteric methane emissions and intensity were linearly reduced (183 to 145 g/d and 21.3 to 17.4 g/kg DMI; P < 0.001) with increasing dietary EN where a treatment × hour interaction was observed (P < 0.001). Methane emissions with greater treatment effects occurred 0 to 12 h after feeding when cows consumed 87% of total feed offered. Nitrogen intake was not affected by EN. Plasma urea-N was linearly decreased (12.5 to 10.9 mg/dl; P < 0.001) with increasing dietary EN. Urinary N excretion tended to linearly decrease (100.2 to 86.5 g/d; P = 0.056) and the proportion of N intake was linearly reduced (46.1 to 39.2%; P = 0.03) with increasing dietary EN. Urinary urea-N excretion and the proportion of N intake were linearly decreased (75.9 to 56.2 g/d, P = 0.019 and 35.2 to 25.4%, P = 0.015, respectively) with increasing EN level. Fecal N excretion was not affected by EN. As a consequence, total N excretion and the proportion of N intake were linearly decreased (P = 0.047 and P = 0.001, respectively) with increasing dietary EN. In conclusion, supplementary nitrate in a protected form lowered enteric methane emissions in a dose–response manner. Urinary N excretion was reduced for heifers fed EN compared with EU, due to lower urea-N excretion in urine. The study demonstrates that feeding EN as a N source is environmentally beneficial compared with EU in beef cattle.

Key Words: encapsulated nitrate, enteric methane emissions, nitrogen utilization

0647 Correspondence between in vitro and in vivo rumen methane production obtained with different starch sources and starch levels. B. Hatew[*1], J. W. Cone[1], W. F. Pellikaan[1], S. C. Podesta[1], W. H. Hendriks[1], A. Bannink[2], and J. Dijkstra[1], *[1]Animal Nutrition Group, Wageningen University, Netherlands, [2]Wageningen UR Livestock Research, Wageningen University and Research Centre, Lelystad, Netherlands.*

To investigate the relationship between in vitro and in vivo methane (CH_4) production measured simultaneously, 16 rumen-cannulated lactating dairy cows were assigned to four blocks with a 2 × 2 factorial arrangement of treatments. The treatments were based on concentrates formulated to contain starch varying in source (slowly fermentable (S) vs. rapidly fermentable (*R*); native vs. gelatinized corn grain) and level of starch (low (L) vs. high (H); 270 vs. 530 g/kg of concentrate DM). The grass silage to concentrate ratio of the total diet was 60:40 (DM basis). After 12 d of adaptation, the cows were housed in respiration chambers for 5 d to measure CH_4 production, replicated in four periods. In each period rumen fluid was obtained from each of four donor cows adapted to one of the four different diets for about 16 d. Gas production (GP) and CH_4 was measured (in duplicate per period) for each substrate from the same diet as fed to individual donor cow using automated GP system with CH_4 measured at distinct time points. Rumen fermentable organic matter (OM) in concentrates was determined by in situ technique and in grass silage estimated by NIRS analysis. In vitro CH_4 production (24 h) was lower with R than with S starch (42.9 vs. 49.5 mL/g of incubated OM; $P = 0.004$), and higher with L than with H (49.8 vs. 42.6 mL/g of incubated OM; $P = 0.002$). In vivo, an increased rate of fermentation, but not increased level of starch, resulted in a lower CH_4 production per unit rumen fermentable OM (55.6 *vs*. 61.1 L/kg of fermentable OM; $P = 0.007$). Across the diets tested, in vitro CH_4 correlated well with in vivo CH_4 production expressed per unit fermented OM ($R^2 = 0.54$; $P = 0.040$), but not with in vivo CH_4 production expressed per unit ingested OM ($R^2 = 0.04$; $P = 0.878$). These results indicate the complexity of rumen fermentation conditions needs to be considered to predict in vivo CH_4 production from in vitro measurements. In conclusion, in vitro CH_4 production was only indicative of the trend of in vivo rumen CH_4 production from different combinations of source and level of starch when in vivo CH_4production was expressed per unit rumen fermented OM, but not when expressed per unit ingested OM.

Key Words: methane, in vitro, in vivo

0648 The potential benefit of corn dried distillers' grain (co)products (DDG) in the mitigation of methane production in cattle: an in vivo analysis. M. A. Fonseca[*1], L. F. L. Cavalcanti[2], J. G. L. Regadas Filho[3], T. R. Callaway[4], G. E. Carstens[1], T. A. Wickersham[1], and L. O. Tedeschi[1], *[1]Texas A&M University, College Station, [2]Universidade Federal de Minas Gerais, Belo Horizonte, Brazil, [3]Universidade Federal de Vicosa, Vicosa, Brazil, [4]USDA-ARS, College Station, Texas.*

Our preliminary in vitro study indicated that feeding high-fat diets may decrease methane (CH_4) production by cattle. The objective of this study was to determine the impact of different levels of DDG on the digestibility of OM and the production of CH_4using two open-circuit respiration chambers at the Nutrition and Physiology Center, Texas A&M University, College Station, Texas. The respiration chambers monitored the inflow and outflow of CO_2, O_2 (fuel cell oxygen, FC-1B; Sable Systems, Henderson, NV), CH_4, and water vapor continuously, and all calculations were corrected for the standard temperature and pressure of the air mass flowing through the chambers (FLOWKIT 500H; Sable Systems, Henderson, NV). Relative humidity was measured and used to calculate the dew point and water vapor pressure. Gases measurements were performed using a flow-through system (RH-100). Air from each source (chambers A and B, and baseline) were sampled every 4 min. The diets were formulated to have same level of ME (Mcal/kg) and to contain 0, 20, or 40% of DDG (DM basis). Animals were adapted to the experimental diets for 7 d outside the chambers and then brought in for a 48-h period for consecutive gas exchange measurement. The intake was restricted to 2% of BW and fed twice daily. Six Angus steers were allocated in an incomplete Latin rectangle design (two animals/diet for three periods). The R software (R Core Team, Vienna, Austria) and PROC MIXED of SAS (SAS Inst., Cary, NC) were used to analyze the data using a repeated measure design. Diets were assumed to be fixed factors, and periods and animals were random factors. The analysis of CH_4 emissions (L/d) corrected for a 24-h period and the CH_4 adjusted to BW (L/kg/d) had significant ($P = 0.0081$) linear and nonlinear decay patterns between CH_4 emissions and levels of DDG. Although the 20 and 40% DDG levels (DM basis) did not differ in reducing CH_4 emissions ($P = 0.16$), the linear relationship showed that for each percentage unit increase in DDG (DM basis) in the diet, a decrease ($P = 0.0027$) of 0.005 L/kg of BW/d of CH_4 emissions was observed. We concluded that 20% of DDG (DM basis) is sufficient to promote a significant reduction in CH_4 emission by cattle receiving DDG.

Key Words: abatement, greenhouse gas, respirometry

0649 Effects of including viginiamycin in feedlot diets containing monensin under commercial conditions in Mexico. M. Gorocica*[1], A. Gonzalez-Asif[2], and S. C. Loerch[3], [1]*Phibro Animal Health, Merida, Mexico,* [2]*SuKarne Agroindustrial, Culiacan, Mexico,* [3]*The Ohio State University, Wooster.*

A trial was undertaken to determine the effects of supplemental virginiamycin (VM) in combination with monensin (Mon) on finishing cattle performance. The trial was conducted in a large commercial feedlot in central Mexico. Upon arrival, 4874 crossbred bulls (LBW = 267.7 ± 21.32 kg) were dewormed, vaccinated against respiratory and clostridial pathogens and implanted with an estrogenic implant. At processing, cattle were randomly allotted to 84 pens with approximately 58 animals/pen. Two dietary supplement treatments were randomly allotted to the 84 pens: a corn-soybean based concentrate diet containing 400 mg/hd/d of Mon (MON), and the MON diet supplemented with 200 mg/hd/d of VM (MON+VM). Cattle were gradually adapted to their final diet (14% protein, 1.56 Mcal NEg/kg) over a 21–28 d period. When cattle were 60 DOF, they were reimplanted with a Trenbolone acetate implant (200 mg TBA + 20 mg Estradiol benzoate). Zilpaterol chlorhydrate was provided to all cattle at 0.15 mg/kg BW for 28 d and was withdrawn 3 d before harvest. Cattle in all pens were harvested after 130 DOF. At harvest, HCW were recorded. Data were analyzed using the PROC MIXED of SAS for a complete randomized design. Pen was used as the experimental unit. At reimplant, MON+VM cattle had greater ADG and G:F (both, $P < 0.01$) than MON (1.83 and 0.208 vs. 1.78 and 0.189, respectively). Hot carcass yield was greater ($P < 0.01$) in MON+VM cattle than MON (62.9 vs. 62.1% respectively). Total ADG and G:F were improved by 5% (both $P < 0.01$) when VM was included in the ration (MON+VM: 1.74 and 0.186 vs. MON: 1.67 and 0.177 for ADG and G:F respectively). Hot carcass weight was 5.2 kg greater ($P < 0.01$) in MON+VM than in MON cattle (306.0 vs. 300.8 respectively). Virginiamycin inclusion to feedlot diets containing Mon improved feedlot performance and carcass weight.

Key Words: virginiamycin, feedlot,

0650 Effects of extracts of *Perilla frutescens* (seeds) on in vitro rumen fermentation, methanogenesis, and microbial population. M. Liu*[1], J. X. Liu[2], and J. K. Wang[1], [1]*Institute of Dairy Science, Zhejiang University, Hangzhou, China,* [2]*Zhejiang University, Hangzhou, China.*

Seeds of *Perilla frutescens* are rich in linolenic and linoleic acid. An in vitro incubation was performed to investigate the effects of extracts from *Perilla frutescens* seeds on rumen fermentation, methanogenesis, and microbial population. Five-hundred milligrams of substrate (mixture of Chinese wild rye and corn meals at 70:30, w/w) were incubated in 120-mL serum bottles. The fermentation medium was 5 mL of sheep rumen fluid and 45 mL of buffer medium. The seeds of *Perilla frutescens* were extracted by 70% ethanol. To accurately add 20 mg of extracts, the freeze-dried extracts were dissolved into dimethyl sulfoxide (DMSO) to a concentration of 40 mg/ml, and then 500 mL of the DMSO solution was added to the incubation system. In the control, 500μL of DMSO was used without extracts. After 24 h of incubation at 39°C, rumen fermentation parameters were measured and absolute abundance of total bacteria, protozoa, fungi, and methanogens were quantified using real-time PCR based on the 16S, 18S rDNA and *mcr*A gene, respectively. Total volatile fatty acids and ammonia nitrogen concentrations were not affected ($P > 0.05$) by extracts, while methane production was decreased by 63.6% ($P < 0.01$), from 0.723 to 0.263 mmol/g DM substrate. Addition of extracts induced a dramatic shift in the population of rumen microbota (Table 0650), indicating the decreased protozoa (99.5%, $P < 0.01$) and fungi numbers (99.5%, $P < 0.01$) and reduced methanogens (62.2%, $P < 0.01$). These data indicate that ethanol extracts from seeds of *Perilla frutescens* have potential to reduce rumen methanogenesis by inhibiting protozoa and activity of methanogens without adversely affecting rumen fermentation.

Key Words: methanogenesis, *Perilla frutescens*, rumen fermentation

Table 0650. Effects of extracts of *Perilla frutescens* (seeds) on microbial population (copies/g centrifuged fermentation mixtures)

	Control	Extracts	SEM	*P*-value
Total bacteria ($\times 10^{11}$)	7.12	6.81	0.472	> 0.05
Protozoa ($\times 10^{7}$)	666.9	3.4	98.7	< 0.01
Fungi ($\times 10^{5}$)	1684.3	8.3	239.5	< 0.01

0651 Effect of tannin or inoculum as silage additives on silage quality and rumen fermentation kinetics. V. J. Taha*[1], J. A. Huntington[1], R. G. Wilkinson[1], and D. A. Davies[2], [1]*Harper Adams University, Newport, UK,* [2]*Silage Solutions, Aberystwyth, UK.*

Tannin has the ability to bind with different compounds including protein and carbohydrate to form complex undegradable compounds. Tannin-protein complexes form in the rumen (pH 6–7) and disassociate in the abomasum (pH < 3.5) enhancing duodenal supply of dietary protein. The in vitro gas production technique can be used to predict rumen fermentation kinetics. The effect of additional tannin (hydrolyzable, chestnut) and a bacterial inoculant as additives at ensiling on final silage quality and in vitro rumen fermentation kinetics were investigated. Whole crop grass, pea, and bean forages were harvested on July 14, 2011, and ensiled in triplicate in experimental silos (25kg). Before ensiling, each forage was treated with one of four additives: 40 g/kg fresh weight (FW) tannin (HT), 20 g/kg FW tannin (LT), an inoculant (*L. plan-*

tarum) 10^6 colony-forming units/g FW (In), or untreated (C). A standard volume of water (1 mL/kg FW) was applied to all treatments. Silos were opened after 100 d and subsamples stored (-20°C) before analysis for: pH, NH_3–N, DM, NDF, CP, and water soluble DM component (WS). Rumen fluid was collected from four mature wethers (fitted with permanent rumen cannula) fed straw plus concentrates (80:20 DM basis) with ad libitum access to water. Gas production (in vitro) was measured as described by Theodorou et al. (1994; J. Feed Sci. Tech. 48:185–197) and results fitted to an exponential decay curve (SigmaPlot12). Duplicate samples were incubated for 72 h with four experimental periods. The experiment was analyzed as 3 × 4 factorial design using Genstat 15 (VSN International, UK). The addition of tannin significantly reduced NH_3–N compared to control silages (41.60, 48.76, 55.66 and 60.01 g/kg total N for HT, LT, In, and C respectively, SED = 1.976, $P < 0.001$). Moreover, both tannin levels reduced the WS compared to In and C (197.2, 235.4, 258.5, and 263.7 g/kgDM for HT, LT, In, and C, SED = 8.154 $P < 0.001$). There was no significant effect ($P > 0.05$) on other proximate analysis. Effect of additive on rumen fermentation kinetics for mean silages showed that additional tannin reduced the total gas pressure (300.3, 329.6, 370.1, and 375.1 kPa for HT, LT, In, and C, respectively, SED = 26.32, $P < 0.05$) and the rate of fermentation (0.034, 0.037, 0.039, and 0.043, SED = 0.0046, $P < 0.05$) for HT, LT, In, and C, respectively. Addition of tannin at ensiling reduced crop protein degradation in silo and reduced rumen fermentation potentially increasing the supply of UDP to the small intestine.

Key Words: tannin, silage, gas production

0652 Improving the performance of dairy cattle with a xylanase-rich exogenous enzyme preparation. J. J. Romero*[1], E. G. Macias[2], Z. Ma[1], R. M. Martins[3], B. Y. Coy[1], F. M. Silva[4], D. H. Garbuio[4], I. A. Brody[1], C. L. Curry[1], K. J. Mills[1], M. G. Zenobi[1], C. R. Staples[1], and A. T. Adesogan[1], *[1]Dep. of Animal Sciences, University of Florida, Gainesville, [2]Dep. de Zootecnia, Universidad Nacional Agraria La Molina, Lima, Peru, [3]Dep. de Zootecnia, Universidade Federal de Viçosa, Minas Gerais, Brazil, [4]Universidade Estadual Paulista, São Paulo, Brazil.*

The objective was to compare effects of two *Trichoderma reesei* exogenous fibrolytic enzyme preparations (EFE) on the performance of lactating dairy cattle fed a bermudagrass- and corn silage-based TMR. The first EFE (MIX) had increased the efficiency of feed utilization by lactating dairy cows in a previous study and the second xylanase-rich EFE (XYL) was the best of 18 EFE candidates at improving in vitro NDFD and rumen-like fermentation of bermudagrass haylage. Endoglucanase and xylanase activities of MIX and XYL were 2087 and 2714 and 10,549 and 26,926 µmol/min per g, respectively. Sixty-six lactating Holstein dairy cows in early lactation (588 ± 75 kg; 21 ± 5 DIM) were grouped by previous milk production and parity and randomly assigned to control (CON), XYL, or MIX treatments. The XYL and MIX EFE were added to the diet just before feeding at rates of 1 and 3.4 mL/kg of TMR DM, respectively. Cows were fed experimental diets for 70 d after they were fed a common diet for an 11-d covariate period. The statistical model included effects of enzyme, parity, week and their interactions, as well as covariate milk production or DMI. The random effect was cow nested within treatment and parity. Body weight and condition score were not affected by treatment. Compared to CON, application of XYL increased ($P < 0.05$) intake (kg/d) of DM (28.6 vs. 27.4), OM (26.7 vs. 25.5), and CP (4.7 vs. 4.5), but MIX did not. Cows fed XYL had greater milk yield (kg/d) during wk 3 (41.2 vs. 39.8; $P < 0.10$), 6 (41.9 vs. 40.1; $P < 0.05$), and 7 (42.1 vs. 40.4; $P < 0.05$), as did those fed MIX during wk 6 (41.5 vs. 40.1; $P < 0.10$), 8 (41.8 vs. 40.0; $P < 0.05$), and 9 (40.9 vs. 39.5; $P < 0.10$). Cows fed XYL tended ($P < 0.10$) to produce more (kg/d) FCM (41.8 vs. 40.7) and fat yield (1.48 vs. 1.44) than those fed CON. Feeding with the EFE increased milk production by dairy cows.

Key Words: dairy cattle, enzyme, TMR

0653 Effects of feeding chitosan on nutrient digestibility in beef heifers. D. D. Henry*, F. M. Ciriaco, V. R. G. Mercadante, T. Schulmeister, D. Demeterco, A. Marin, G. C. Lamb, and N. DiLorenzo, *University of Florida, Marianna.*

The objective of this study was to determine whether adding the biopolymer chitosan would increase efficiency of beef heifers by improving apparent total tract nutrient digestibility of a low quality diet. Twenty-four crossbred heifers (318 ± 35 kg) were used in a randomized block design replicated in two experimental periods. Heifers were stratified by weight and randomly assigned to 12 pens (two heifers/pen), and pens were randomly assigned to one of six treatments in a 2 × 3 factorial arrangement. Factors included diet [a high concentrate (85% concentrate; HC), and a low concentrate (36% concentrate; LC)], and chitosan inclusion level (0.0, 0.5, and 1.0% of dietary DM). Heifers were housed in the University of Florida–Feed Efficiency Facility in Marianna, FL, where diets were offered ad libitum and individual intake was recorded by a GrowSafe system. Feed and fecal samples were collected for four consecutive days to determine apparent total tract digestibility of DM, OM, CP, NDF, and ADF using indigestible NDF (iNDF) as an internal digestibility marker. Feed samples were collected once a day, and fecal samples were collected by rectal grab twice daily (0700 h and 1500 h). Feed and fecal samples were pooled within pen and heifer, respectively. Concentrations of iNDF in feed and feces were determined by in vitro incubations conducted using a 4:1 buffer to ruminal fluid ratio for 288 h. Data were analyzed using PROC MIXED of SAS with heifer as the experimental unit, including the fixed effects of

diet and chitosan inclusion level, and the random effect of period. Orthogonal polynomial contrasts were conducted to determine linear and quadratic effects of chitosan inclusion level on nutrient digestibility. There was a diet × chitosan interaction for digestibility of DM ($P = 0.05$) and OM ($P = 0.04$). Inclusion of chitosan in LC at up to 1% diet DM linearly increased ($P < 0.05$) digestibility of DM and OM as compared to control (40.3 vs. 33.2%, and 41.1 vs. 34.5% for DM and OM digestibility, respectively). No differences ($P > 0.10$) were found for digestibility of CP, NDF, or ADF. In conclusion, adding 1% chitosan to low concentrate diets increased apparent total tract digestibility of DM and OM by 21 and 19%, respectively.

Key Words: beef, chitosan, digestibility

0654 Effect of *Saccharomyces cerevisiae* fermentation product (XP) on energetic efficiency of diet fed to high producing dairy cows during the hot season.

U. Moallem*, L. Livshitz, and M. Zachut, *Institute of Animal Science, Volcani Center, Bet Dagan, Israel.*

The objective was to test whether *Saccharomyces cerevisiae* fermentation product (XP, Diamond V, Cedar Rapids, IA) could compensate for lower energy density in diets by increasing digestive efficiency. Forty-two multiparous Israeli-Holstein dairy cows were divided into two treatment groups according to milk production, parity, DIM and BW. Treatments consisted of: 1) control, a common Israeli diet containing 1.78 Mcal NE_L/kg DM; 2) XP, a diet contained 1.75 Mcal NE_L/kg DM and supplemented with 50 g XP/cow/day. Diets were isonitrogenous and consisted of the same ingredients. The study was conducted for 14 wk during the typical hot season. Milk yield, DMI, rumination time, and lying time were recorded daily, and milk components were measured weekly. Rumen and blood samples were taken at the 12th wk of the study: -2, 0, 2, and 4 h relative to feeding time for rumen pH, VFA and ammonia, and plasma glucose and urea. Data were analyzed using the PROC MIXED model of SAS. Milk yields tended to be higher ($P < 0.1$) in control than in XP group, and FCM (4%) yields and milk components percentages and yields were similar between treatments. No treatment effect was observed for daily rumination and resting time. The energy intake was lower (48.9 and 50.5 Mcal/d, respectively; $P < 0.05$), and DMI tended to be lower ($P < 0.1$) in cows supplemented with XP than in control cows. Energy in milk per energy consumed tended to be higher ($P < 0.1$) in cows supplemented with XP, and resulted in similar feed efficiency (milk, ECM, or FCM/DMI). Plasma glucose concentrations were higher in cows supplemented with XP than in control cows (66.2 and 63.8 mg/dL, respectively; $P < 0.05$). Plasma urea concentrations were 15% lower ($P < 0.001$), and rumen ammonia concentrations were also lower in cows supplemented with XP than in control cows (125.8 and 157.2 μg/ml, respectively; $P < 0.001$). Rumen pH was higher in cows supplemented with XP than in the control group (6.76 and 6.57, respectively; $P < 0.05$). Rumen propionic, butyric, and total VFA concentrations were higher ($P < 0.05$) in control cows than cows supplemented with XP, whereas the acetic/propionic ratio tended to be higher ($P < 0.1$) in cows supplemented with XP. In conclusion, supplementation of 50 g XP/d to dairy cows fed a lower energy diet increased energy availability, potentially through improved ruminal nitrogen metabolism and increased supply of glucose for milk production.

Key Words: energetic efficiency, XP, nitrogen metabolism

RUMINANT NUTRITION VI

0655 Effect of rumen-protected lysine supplementation of corn-protein based diets fed to lactating dairy cows. N. E. Lobos*[1], G. A. Broderick[2], and M. A. Wattiaux[3], *[1]Dep. of Dairy Science, University of Wisconsin–Madison, Madison, [2]Broderick Nutrition & Research, LLC, Madison, WI, [3]University of Wisconsin–Madison, Madison.*

This trial tested whether rumen-protected Lys (RPL) supplementation would improve the nutritive value of RUP from corn protein. Thirty-two lactating Holstein cows were blocked by DIM and parity into eight squares of four cows in replicated 4 × 4 Latin squares. Treatments were all supplemental CP from: 1) Soy [67% expeller soybean meal (ESBM) plus 33% solvent soybean meal (SSBM)]; 2) Soy/Corn [33% ESBM, 17% SSBM, 25% corn gluten meal (CGM) plus 25% distillers dried grains plus solubles (DDGS)]; 3) Corn (50% CGM plus 50% DDGS); or 4) Corn/RPL [diet 3 top-dressed with RPL (125 g Ajipro/d, an estimated 20 g absorbed Lys/d)]. Diets contained (DM basis) 22% alfalfa silage, 43% corn silage, 18% ground high moisture and dry corn, 2.4% mineral-vitamin premix, 1.5–3.9% soyhulls, 15% CP, 30–32% NDF, and, as predicted by NRC (2001), equal RDP, RUP and metabolizable protein. Cows within squares were randomly assigned to treatment sequences and fed diets for 4-wk periods before switching; data from the last 2 wk were analyzed using the PROC MIXED of SAS. The Table 0655 reports LS-means. Intake was highest on diet 1, intermediate on diets 2 and 3, and lowest on diet 4; BW change was highest on diet 3, intermediate on diets 1 and 2 and lowest on diet 4. Intakes and BW changes were reflected by differences in Milk/DMI, which were highest on diets 2 and 4 and lowest on diet 3. Milk yield was lower on diet 3 than on diets 1, 2, and 4, and protein yield was highest on diets 1 and 2, intermediate on diet 4, and lowest on diet 3. These results indicated that dilution of soybean meal RUP with that from corn protein did not reduce milk yield and adding RPL to the corn-protein based diet increased milk and protein yields.

Key Words: soybean meal, corn gluten meal, corn distillers dried grains, rumen-protected Lys

0656 Effects of a rumen protected lysine (AjiPro-L) supplementation on peripartum disease, reproduction, and lactational performance of dairy cows. J. E. Nocek*[1], A. Haruno[2], M. Miura[2], T. Takagi[2], I. Shinzato[3], and T. Fujieda[2], *[1]Spruce Haven Farm and Research Center, Auburn, NY, [2]Ajinomoto Co., Inc.,, Tokyo, Japan, [3]Ajinomoto Heartland, Inc., Chicago, IL*

We used 108 multiparous cows to examine the effects of feeding AjiPro-L (Ajinomoto Co., Inc., Tokyo) 21 d pre- through 21 d postpartum and then withdrawal. Cows were assigned to one of four pre/postpartum regimens: a) Control:Control (C/C), b) 100 g AjiPro-L:Control (A/C), c) Control:150 g AjiPro-L (C/A), and d) 100 g AjiPro-L:150 g AjiPro-L (A/A). All cows started their treatment regime 21 d before expected calving date through 21 d postpartum (phase 1). Upon completion of the 21 d postpartum period, all cows were moved to a common group and fed the same diet without AjiPro-L (phase 2, 21–63 DIM). Individual DMI and milk yield were measured daily, and milk components weekly throughout both phases. Body weights, BCS, health incidence were recorded. During phase 1, DMI was not affected in the prepartum period by AjiPro-L inclusion. Postpartum, cows on A/C consumed more ($P = 0.05$) DM than C/C and C/A, with A/A cow not being different. Milk yield was highest ($P = 0.04$) for cows receiving A/A compared to C/C, with other treatments not being different. Milk fat yield was higher ($P = 0.04$) for cows supplemented with A/A compared to C/C and C/A, but not different from A/C. Cows receiving the C/A had higher milk protein percentage than A/C and A/A and not different from C/C. Milk fat percentage and milk protein yields were not affected by treatment regimens. During phase 2, no differences in body weight, BCS or milk yields were observed. Milk fat yield was higher ($P = 0.05$) for A/C and A/A cows compared to C/A with C/C not being different. Milk protein percentage was higher ($P = 0.02$) for C/A cows than those on C/C or A/A regime, with A/C not being different. Cows on A/C had higher ($P = 0.05$) milk fat percentage than C/C and C/A, not being different than A/A. Cows on A/C exhibited lower incidences of displaced abomasum and ketosis than other regimens. These results suggest that AjiPro-L supplementation both pre- and postpartum generally resulted in the most consistently positive production performance immediate postpartum than other regimens. It was also suggested that feeding AjiPro-L only prepartum had some specific effects on postpartum health status and production performance.

Key Words: lysine, milk production, transition period

0657 Effect of strategic ration balancing with use of Prolak and USA-Lysine on the efficiency of milk protein production and environmental impact. J. H. Harrison[1], J. Jarrett[2], Y. Chen[*3], L. VanWieringen[4], B. Chalupa[5], F. Sun[3], P. Ndegwa[3], D. Wilks[6], and H. S. Joo[3], *[1]Washington State University, Puyallup, [2]Prince Agri, Quincy, IL, [3]Washington State University, Pullman, [4]Washington State University, Sunnyside, [5]University of Pennsylvania, New Bolton Center, [6]EPL Feeds, Dixie, WA.*

The objective of this study was to evaluate the effect of a diet supplemented with a high quality protein and rumen protected lysine source on the efficiency of milk production and environmental impact in a commercial dairy herd. The general herd diet was reformulated with the Agricultural Model and Training System model and use of Prolak and USA-lysine. The control and treated diet had similar dietary CP concentration (17.7% vs. 17.6%). Cows were completely randomized to two groups with 163 cows each pen and milked three times per day. The groups had similar average days in milk (135 vs. 135) and parities (2.99 vs. 2.84) before initiation of the trial. Respective diets were fed in a 40 d switch back design trial with two periods. Milk weight (all three milkings), and milk (sample from one of three milkings) and manure samples were obtained at the end of second and third weeks of each period for analysis. Cows fed the two diets had similar pen DMI (24.2 vs. 24.1 kg/d), but the reformulated diet supported more milk yield (43.0 vs. 44.9 ± 0.15 kg/d), milk protein yield (1.27 vs. 1.33 ± 0.01 kg/d), milk fat yield (1.51 vs. 1.57 ± 0.01 kg/d), and increased ratio of milk true protein to total protein intake (29.4 vs. 31.2%) and ratio of total milk protein to total protein intake (34.3 vs. 36.5%). The concentration of MUN was higher when cows were fed reformulated diet (16.5 vs. 18.7 mg/dl). Cows fed the reformulated diet consumed 2.6% less N, but produced 4.7% more milk N, and excreted 6.2% more predicted urinary N and 24% less calculated fecal N. Manure from cows fed the reformulated diet had lower ammonia (NH3) flux (145 vs. 130 mg*h^{-1}*m^{-2}). This study illustrates that diets supplemented with high quality protein could improve efficiency of milk production and N utilization, and reduce the environmental impact.

Key Words: protected lysine, bypass protein, milk production

0658 Effect of strategic ration balancing with use of Prolak and MetaboLys on the efficiency of milk protein production and environmental impact. P. Ndegwa[1], J. H. Harrison[2], D. Wilks[3], L. VanWieringen[4], Y. Chen[*1], W. Chalupa[5], F. Sun[1], and H. S. Joo[1], *[1]Washington State University, Pullman, [2]Washington State University, Puyallup, [3]EPL Feeds, Dixie, WA, [4]Washington State University, Sunnyside, [5]University of Pennsylvania, New Bolton Center.*

The objective of this study was to evaluate the effect of reduced dietary CP concentration on efficiency of N utilization and environmental impact in a commercial dairy herd. The general herd diet was reformulated with the Agricultural Modeling and Training System model and use of Prolak and MetaboLys. Reformulation reduced the dietary CP concentration (17.4 vs. 15.9%) and resulted in a DCAD of 31.3 vs. 21.2 mEq/100 g DM. Cows were completely randomized to two groups with 155 cows each and milked three times per day, and the two groups had the same average days in milk (DIM = 149) before initiation of the study. Respective diets were fed in a 40-d switch back design trial with two periods. Milk weight, milk, and manure samples were obtained at the end of the second and third week of each period. The manure samples were incubated in closed chambers for 19 d to measure ammonia (NH3) flux. Average pen DMI was similar (25.1 vs. 25.3 kg/d). The reformulated diet supported 0.6 kg less milk production (44.3 vs. 43.7 ± 0.16kg/d), less milk protein yield (1.27 vs. 1.25 ± 0.01kg/d) and the same amount of fat yield (1.48 vs. 1.46 ± 0.01kg/d), but increased the ratio of true protein/total CP intake (28.4 vs. 30.6%) and milk CP/total CP intake (33.3 vs. 38.6%). The concentration of MUN was lower for cows fed the reformulated diet (13.4 vs. 11.56 mg/dl). When the cows were fed reformulated diet, they consumed 9% less N, produced 1% less milk N, but excreted 14% less predicted urinary N and 15.4% less calculated fecal N. The manures from the reformulated diet had a lower NH3 flux (147 vs. 137mg*h^{-1}*m^{-2}). This study illustrated that the lower N diet could improve the efficiency of N utilization and reduced the environmental impact, but may influence the milk production.

Key Words: milk protein, lysine, rumen undegradable protein

0659 Evaluation of diets formulated with soybean-based products, blood meal, or rumen-protected lysine to meet MP lysine demands of lactating dairy cows. W. D. Weich[*1], K. F. Kalscheur[1], K. J. Herrick[2], and F. R. Valdez[2], *[1]South Dakota State University, Brookings, [2]Kemin Industries, Inc., Des Moines, IA.*

Objectives were to determine if production of early to mid-lactation dairy cows was maintained when fed diets formulated to be similar in grams of metabolizable protein (MP) lysine and methionine but lower in CP. Diets were formulated using: 1) soy-based protein (positive control; PC, 17.7% CP,

204 g/d MP-lys), 2) blood meal and soy-based protein (BM; 16.4% CP, 203 g/d MP-lys), or 3) rumen-protected lysine and soy-based protein (RPL; 16.2% CP, 205 g/d MP-lys). Diets formulated to desired MP lysine (204 g/d) were compared with a negative control diet lower in MP lysine (LL; 16.2% CP, 193 g/d MP-lys) created by removing dietary RPL. Diets were formulated using AMTS (Version 3.4.7.1). Sixteen Holstein cows blocked by parity (12 multiparous) and production were assigned one of four treatments arranged in a 4 × 4 Latin square design with 28-d periods. The model included: treatment, square, treatment × square, and period. Treatments were prepared as four separate concentrate mixes that were combined with common amounts of corn silage (36% of diet DM) and alfalfa hay (19%) among diets. Milk production was similar ($P > 0.10$), comparing BM and RPL with PC or LL, but tended ($P = 0.06$) to be greater for BM over RPL. Cows fed BM and RPL had lower ($P = 0.04$) DMI than LL; however, ECM was sustained which led to an increase in feed efficiency comparing BM and RPL with LL. Performance of lower CP diets, BM, and RPL, were similar to PC, but performance from LL suggests that MP supply was sufficient across treatments.

Key Words: amino acid, lysine, metabolizable protein

Table 0659.

Item	Treatment				SEM	Contrast[1]

0660 The plasma free amino acid dose response technique: A proposed approach for determining lysine bioavailability of ruminally protected lysine products.

N. L. Whitehouse*[1], A. F. Brito[1], and C. G. Schwab[2], *[1]University of New Hampshire, Durham, [2]Schwab Consulting, LLC, Boscobel, WI.*

While most companies provide estimates of lysine (Lys) bioavailability for their products, values are often obtained with different techniques, and there are little to no data comparing efficacy and cost-effectiveness of different products. Our objective is to propose that the plasma free amino acid (AA) dose–response technique be accepted as the standardized method for evaluating rumen protected Lys (RP-Lys) products, because its animal-derived estimates of bioavailability are obtained under conditions similar to commercial use. Bioavailability estimates are calculated by dividing the slope of the regression line relating changes in plasma Lys to increased feeding of RP-Lys divided by the slope of the Lys infusion regression line. Eleven dose–response Latin square trials using 66 lactating, ruminally cannulated multiparous Holstein cows (d in milk = 60 through 315; milk yield = 25 to 62 kg/d at the start of the study) were conducted. Abomasally infused and fed amounts of Lys ranged from 0 to 84 g/d and periods from 4 to 21 d. The RP-Lys products were mixed with 1 kg of total mixed ration, placed in tubs, and fed 30 min before each of the three daily feedings. Product not consumed within 20 min was delivered via the ruminal cannula. Diets were formulated (NRC, 2001) to be adequate in metabolizable protein-Met but varied in predicted metabolizable protein-Lys (5.04–6.81%). One to four blood samples were taken from the tail vein for 1 to 3 d in each period. Basal plasma Lys concentrations ranged from 2.14 to 5.62% of total AA without infusions, from 2.33 to 5.67% of total AA for fed RP-Lys, and from 2.94 to 8.62% of total AA with infusions. Results corroborate previous research that showed a positive linear relationship between both infused and fed RP-Lys and plasma Lys concentrations. Regression analysis (by trial and cow) indicated the two factors that most affected the magnitude of the response slopes, and hence the technique's precision, were the cows basal level of plasma Lys (i.e., intercept, the lower the better) and the cows plasma Lys response to infused Lys (measured by the magnitude of their response to the highest level of infused Lys). Stage of lactation and milk production did not affect plasma Lys response. It is concluded that the plasma free AA dose response technique is sensitive to increasing amounts of absorbed Lys and therefore is an appropriate technique for evaluating RP-Lys supplements.

Key Words: technique, bioavailability, lysine

0661 Effects of maternal nutrition and rumen-protected arginine supplementation on pregnant and non-pregnant ewe and postnatal lamb serum amino acids.

J. L. Peine*[1], G. Jia[1], M. Kapphahn[1], S. T. O'Rourke[1], A. M. Meyer[2], L. P. Reynolds[1], and J. S. Caton[1], *[1]North Dakota State University, Fargo, [2]Div. of Animal Sciences, University of Missouri, Columbia, MO.*

Our hypothesis was that rumen-protected arginine supplementation would increase levels of serum amino acids in both non-pregnant and pregnant ewes and their offspring, and thereby help overcome negative effects of nutrient restriction during the last two-thirds of gestation. To test this hypothesis, two studies were conducted with Rambouillet ewes penned individually in a temperature-controlled facility: Study 1 was a dose titration study to determine the most effective dose of rumen-protected arginine, and Study 2 tested our hypothesis in pregnant ewes and their lambs. Study 1 used non-pregnant primiparous ewes ($n = 60$) randomly assigned to one of four treatments: a control group receiving no supplement (0), and groups receiving 90mg/kg BW (90), 180mg/kg BW (180), or 360mg/kg BW of rumen-protected

arginine supplement (360). After 15 d of supplementation, ewes receiving 180 had greater serum ornithine ($P = 0.05$) and arginine ($P = 0.05$), and tended to have greater aspartate ($P = 0.08$) than ewes receiving 90, and 180 were similar to 360 fed ewes ($P \geq 0.55$). In Study 2, multiparous ewes ($n = 32$) were allocated to trhee treatments at 54 ± 3.9 d of gestation: 100% of requirements (control, CON), 60% of control (restricted, RES), or RES plus a 180 mg/kg BW rumen-protected arginine supplement once daily (RES-ARG). Ewes were maintained on treatments through parturition, when lambs were removed from dams and reared independently. At 128 d of gestation, CON ewes weighed more ($P \leq 0.001$) than RES and RES-ARG ewes, and had greater ($P \leq 0.001$) BCS. In addition, serum ornithine, citrulline, aspartate, arginine, and methionine were greater ($P \leq 0.03$) in CON than RES and RES-ARG ewes, suggesting that arginine supplementation could not overcome differences in nutritional plane. Lambs from CON ewes had greater ($P = 0.03$) birth weights than RES, with lambs from RES-ARG ewes being intermediate and similar in weight to other treatments ($P \geq 0.08$). At birth, lambs from RES-ARG ewes had greater serum arginine ($P = 0.04$) and lysine ($P = 0.04$) than those from RES ewes, suggesting effects on amino acid transport from dam to fetus. These results support our hypothesis that maternal rumen-protected arginine supplementation could increase serum levels of amino acids in offspring. Additionally, arginine supplementation of dams may be able to increase fetal circulating arginine without altering maternal circulating arginine.

Key Words: arginine, amino acids, developmental programming

0662 Intestinal digestibility of amino acids in fluid- and particle-associated rumen bacteria determined using a precision-fed cecectomized rooster bioassay.

A. C. Fonseca[1], S. M. Fredin[*1], L. F. Ferraretto[1], P. L. Utterback[2], C. M. Parsons[2], and R. D. Shaver[1], *[1]Univeristy of Wisconsin, Madison, [2]University of Illinois at Urbana-Champaign, Urbana.*

Microbial protein represents the majority of metabolizable protein absorbed by ruminant animals. Enhanced understanding of the AA digestibility of rumen microbes will improve estimates of metabolizable protein. The objective of this experiment was to determine the digestibility of AA in fluid- (FAB) and particle-associated bacteria (PAB) using the precision-fed cecectomized rooster bioassay. Bacteria were isolated from four ruminally cannulated lactating Holstein cows fed an 89% forage diet (DM basis). Samples of FAB and PAB were fed to nine cecectomized roosters to determine standardized digestibility of AA. Data were analyzed using PROC MIXED (SAS, 2004). Bacterial N composition (average = 8.3%) was similar to previous literature values. Total AA digestibility was (mean ± SE) 76.8 ± 2.4 and 75.5 ± 2.2% for FAB and PAB, respectively. Amino acid digestibility did not differ between FAB and PAB ($P > 0.05$). There were differences in essential (EAA) and non-essential AA digestibility within bacterial type when compared with mean essential or non-essential AA digestibility values ($P < 0.05$). Arginine, His, and Met were greater than the mean EAA digestibility in FAB, whereas Trp and Val were lower. Arginine and Lys were greater than the mean EAA digestibility in PAB, whereas Phe and Val were lower. Compared with previous literature and relative to NRC (2001) estimates of AA digestibility in microbes, the precision-fed cecectomized rooster assay is an acceptable in vivo model to determine AA digestibility of rumen bacteria.

Key Words: amino acid, digestibility, rumen bacteria

0663 Performance by holstein steers offered hay and supplement with or without added methionine.

A. L. Bax[*1], J. D. Caldwell[1], L. S. Wilbers[1], B. C. Shanks[1], T. Hampton[2], S. E. Bettis[2], Y. Liang[2], and G. I. Zanton[2], *[1]Dept. of Agriculture and Environmental Sciences, Lincoln University, Jefferson City, MO, [2]Novus International, Inc., St. Charles, MO.*

Recently, amino acid supplementation by forage-fed cattle has been examined in greater detail. Methionine can restrict productivity of many ruminant animals, chiefly because microbial protein, the main source of metabolizable protein in forage-based ruminant diets, is most limiting in methionine. The objective of this study was to evaluate steer performance when offered hay and a supplement with or without added methionine as MFP (MFP). On Oct. 24, 2013, a total of 90 (230 ± 2.2 kg body weight) Holstein steers were stratified by body weight within five blocks and were allocated randomly to one of two treatments: 1) control supplement (C; 15 replications) or control supplement plus MFP (15 replications). Each replication had access to a 0.4-ha pasture with limited forage available for grazing and were offered ad libitum access to medium quality hay, water, and shelter. A soybean hull and wheat middling based, pelleted supplement was offered daily at 0.5% of body weight for each replication; in addition the supplement contained minerals, and vitamins. Treatment was provided at 1.17% of supplement DM resulting in an average intake of approximately 15 g/d of MFP. Hay offered did not differ ($P = 0.62$) across treatments. Initial, d 14, and d 28 body weights did not differ ($P \geq 0.11$) across treatments, but d 42 and d 56 body weights were greater ($P \leq 0.05$) from pastures receiving MFP compared with C. Average daily gain and gain at d 14 did not differ ($P \geq 0.27$) across treatments. However, d 28 ADG and gain tended ($P \leq 0.07$) to be greater from MFP compared with C and were greater ($P \leq 0.03$) at d 42 and d 56 from MFP compared with C. Through 56 d, steers in pastures offered MFP gained 5.0 ± 2.1 kg/hd more ($P < 0.03$) body weight than steers fed C. It is concluded that, when steers were offered medium quality hay, providing a supplement that contained MFP showed improved body weights, ADG, and total gain through the backgrounding phase.

Key Words: methionine, backgrounding, steers

0664 Effects of feeding slow release NPN and microbial fermentation extracts on lactation performance of high-producing dairy cows. F. Díaz-Royón[*1], A. D. Garcia[1], K. F. Kalscheur[2], and K. Mjoun[3], *[1]Dairy Science Dep., South Dakota State University, Brookings, [2]South Dakota State University, Brookings, [3]Alltech, Brookings, SD.*

The objective of this study was to examine the effects of partial substitution of soybean meal with a product containing slow release NPN and microbial fermentation extracts [(OPT); Optimase Alltech Inc., Nicholasville, KY)] in diets with two forage concentrations. Sixteen lactating Holstein dairy cows (four primiparous and 12 multiparous) were randomly assigned to a 4 × 4 Latin square in a 2 × 2 factorial. High and low forage diets contained respectively 61% (HF) and 46% forage (LF), with (O) and without OPT (NO). Forage consisted of 75% corn silage and 25% alfalfa hay (DM basis). Experimental diets containing OPT (125 g/cow/day) were designed to partially replace soybean meal 48 (0.625 kg) with forage fiber [corn silage (0.225 kg) and alfalfa hay (0.075 kg)] and non-forage fiber [soybean hulls (0.200 kg)]. Feeding cows HF versus LF reduced DMI, milk, ECM, protein %, and protein yield, but increased fat % (Table 0664, $P < 0.05$). Feeding OPT decreased ($P = 0.033$) DMI 1.05 kg/d compared to diets without OPT. Milk yield decreased ($P = 0.046$) slightly with OPT inclusion; however, 4%FCM and ECM were not affected. Feeding OPT did not affect milk fat percentage and yield, lactose percentage, and total solids percentage and yield. Milk protein yield decreased ($P = 0.013$) 3.5% in cows fed OPT. OPT fed both in HF and LF diets as a partial replacement to soybean meal resulted in similar lactation performance (4% FCM and ECM) and feed efficiency despite a decrease in DMI and milk yield.

0665 Concentration of soluble non-ammonia nitrogen and related transporter expression in non-mesenteric gastrointestines of dairy cows. Y. M. Xie[1], Q. B. Xu[*1], Y. M. Wu[1], and J. X. Liu[2], *[1]Institute of Dairy Science, Zhejiang University, Hangzhou, China, [2]Zhejiang University, Hangzhou, China.*

Dietary protein is gradually degraded from peptide-bound amino acids (PBAA) into free amino acids (FAA) and ultimately into ammonia by the rumen microbes. Both PBAA and FAA are milk protein precursor, and the rumen and small intestines are the main sites where milk protein precursor is produced and absorbed. This work was designed to investigate the concentrations of PBAA, FAA and soluble protein and the expression of peptide transporter (PepT-1) and amino acid transporters in the rumen, omasum, and duodenum of dairy cows. The digesta and tissues were collected from six healthy Holstein dairy cows (BW = 643 ± 67.4 kg and milk yield = 13.4 ± 2.05 kg/d) immediately after the animals were slaughtered. The FAA was assessed by amino acid (AA) analyzer, PBAA was by quantification of AA before and after acid-hydrolysis by 6M HCl, and soluble protein was by bicinchoninic acid. Concentrations of FAA, PBAA, and soluble protein are shown in Table 0665. Concentration of all portions of non-ammonia nitrogen was the highest in the duodenum. The PBAA was the largest component of soluble non-ammonia nitrogen in all the digesta from rumen, omasum, and duodenum, indicating that peptides may be the main form absorbed in these sites. Abundance of PepT-1 mRNA was consistent with the concentrations of PBAA from rumen to duodenum. Expression of all genes was greater in the duodenum than in the rumen and omasum, suggesting that the duodenum is the major nonmesenteric site where peptides are transported and absorbed.

Key Words: gastrointestine; milk protein precursor; peptide-bound amino acids

0666 Role of proton-coupled oligopeptide transporter 1 in small peptide absorption in the bovine forestomach. Q. B. Xu*[1], Y. M. Wu[1], H. Y. Liu[1], and J. X. Liu[2], [1]*Institute of Dairy Science, Zhejiang University, Hangzhou, China,* [2]*Zhejiang University, Hangzhou, China.*

In this work, transepithelial transport of glycylsarcosine (Gly-Sar) in bovine forestomach cells was determined to investigate the role of proton-coupled oligopeptide transporter 1 (PEPT1) in small peptide absorption. Primary cultured omasal epithelial cell (OEC) and rumen epithelial cell (REC) monolayers derived from newborn Chinese Holstein male calves were grown in transwell set-up. The transepithelial electrical resistance of transwell model reached plateau after a week, and that of OEC monolayers was higher than that of REC monolayers (2468 ± 216 vs. 1918 ± 33 $\Omega \cdot cm^2$). Fluorescein sodium was used to measure the permeability of monolayers. After 150 min, transmittances of fluorescein sodium across OEC and REC monolayers were 0.63 and 0.19%, respectively, whereas that of control (blank filter) was 12.0%. The monolayers were then used for incubation with various concentrations of Gly-Sar in apical side at various pH values or at 37°C and 4°C for various times. In addition, mRNA of PEPT1 was detected in OECs and RECs. The cells were also incubated in absence or presence of 0.5 mM diethylpyrocarbonate, an inhibitor of PEPT1. Transportation of Gly-Sar was dependent on concentration, incubation time, temperature and pH value. Accumulation of Gly-Sar in basolateral side (pH 7.4) increased with the increasing level of Gly-Sar and reached a plateau at 5 mM. Transportation of Gly-Sar by OEC monolayers was higher at 37°C compared to 4°C ($P < 0.05$), with an optimal pH of 6.0 to 6.5, and inhibited by diethylpyrocarbonate. In addition, accumulation of Gly-Sar in basolateral side of OEC monolayers was greater than that of REC ($P < 0.05$), indicating that the OECs have greater ability to transport Gly-Sar than RECs. In summary, the PEPT1 plays an important role in small peptide absorption in bovine forestomachs.

Key Words: bovine forestomach epithelial cells, oligopeptide transporter 1, transport

RUMINANT NUTRITION VII

0667 Effect of reduced energy density of close-up diet on ruminal fermentation parameters in multiparous Holstein cows. W. M. Huang*, A. Simayi, A. Yasheng, Z. H. Wu, Z. J. Cao, and S. L. Li, *State Key Laboratory of Animal Nutrition, College of Animal Science and Technology, China Agricultural University, Beijing.*

The objective of this study was to determine the effect of reduced energy density of close-up diet on ruminal fermentation parameters in multiparous Holstein cows. Fourteen dry cows were utilized in a randomized block design. Cows were blocked by their milk production in the first 3 mo of the previous parity, BW, and expected calving date and assigned randomly into one of three energy levels (6.8, 6.2, 5.4 MJ of NE_L/kg; 14.0% CP) diets to meet 100% (100NRC; n = 4), 90% (90NRC; n = 5), 80% (80NRC; n = 5) of the NRC (2001) dietary NE_L recommendation, respectively, from 21 d before expected day of calving. After parturition, all cows were fed the same lactation diet to 28 d in milk (DIM). Intake of DM (DMI) of individual cows was determined every day. Ruminal fluid was obtained at 1030 h on -21, -14, −7, 1, 3, 5, 7, 14, 21, and 28 d relative to parturition, and at 0830, 1030, 1230, 1430, 1630, and 1830 h on 7 DIM, at 0930, 1130, 1330, 1530, 1730, and 1930 h on 8 DIM. Data were analyzed by SPSS with repeated measures procedure. The reduced energy density diet decreased the average DMI prepartum ($P < 0.05$) and tended to increase the DMI postpartum ($P = 0.08$). The average ruminal pH of the 80NRC group was higher prepartum (6.88, 6.35, 6.44; $P < 0.05$) and lower (6.05, 6.21, 6.30; $P < 0.05$) during the first 4 wk of lactation compared with 90NRC and 100NRC groups. The 80NRC group had three sampling points of pH below 5.6 on 7 and 8 DIM, none for 90NRC and 100NRC groups. The reduced energy density diet depressed the average ruminal concentration of propionate (16.7, 17.9, 19.6 mmol/L; $P = 0.04$), tended to decrease butyrate (7.4, 9.4, 10.4 mmol/L; $P = 0.06$) prepartum, and increased the average concentration of total VFA (112.6, 95.8, 92.0 mmol/L; $P < 0.001$) and decreased the ratio of acetate to propionate (2.4, 2.3, 2.7; $P = 0.03$) during the first 4 wk of lactation. In conclusion, the cows fed reduced energy density diet prepartum had higher VFA concentration for energy metabolism but were more susceptible to subacute ruminal acidosis postpartum.

0668 Prepartum dietary energy strategies for Holstein dairy cows: Effects on markers of negative energy balance and performance. S. Mann*[1], F. A. Leal Yepes[2], T. R. Overton[2], J. J. Wakshlag[3], and D. V. Nydam[1], *[1]Cornell University, Dep. of Population Medicine and Diagnostic Sciences, Ithaca, NY, [2]Cornell University, Depar. of Animal Science, Ithaca, NY, [3]Cornell University, Dep. of Clinical Sciences, Ithaca, NY.*

Study objectives were to compare different dry cow nutritional strategies and their influence on peripartal concentrations of β-hydroxybutyrate (BHBA) and nonesterified fatty acids (NEFA) as analytes related to negative energy balance and periparturient dry matter intake (DMI) and milk yield. Cows (n = 84) were dried off 57 d before expected calving and assigned to one of three diets: a controlled-energy diet (L) that was formulated to meet, but not greatly exceed, energy requirements for the entire dry period; a step-up approach (I) in which animals received diet L for the first 4 wk of the dry period and after that a diet supplying 125% of energy requirements until calving; and a higher energy diet (H) formulated to contain 150% of requirements for the entire dry period. Data measured over time were subjected to repeated measures ANOVA using PROC MIXED with treatment, time and parity as fixed effects (Table 0668). Energy content was 1.28, 1.35, and 1.42 Mcal NEl/kg DM for the L, I, and H diets, respectively. Animals fed L had lower concentrations of BHBA during both the prepartum and postpartum periods than cows fed H. Concentration of NEFA in cows fed L was higher prepartum compared with the

other two treatments, while being lower in cows fed L or I compared with H postpartum. Yields of milk and energy-corrected milk (ECM) were not different among treatments. Although sample size was not sufficient to study health outcomes, results suggest positive effects on metabolic health by feeding a controlled energy diet during the dry period.

0669 Hepatic acetyl CoA concentration decreases following feeding in early-postpartum but not in late-lactation dairy cows. P. Piantoni*, C. M. Ylioja, and M. S. Allen, *Michigan State University, East Lansing.*

The relationship between hepatic acetyl CoA concentration (Ac-CoA) and dry matter intake (DMI) was determined using 28 multiparous Holstein cows. Fourteen were early-postpartum (PP; 12.6 ± 3.8 DIM), and 14 were late-lactation cows (LL; 271 ± 29.6 DIM). Cows were fed once daily, and DMI was determined for the first 4 h after feeding. Liver and blood samples were collected before feeding and 4 h after feeding. Feed intake over the 4-h period ranged from 3.2 to 9.6 kg DM and did not differ by stage of lactation. Before feeding, Ac-CoA was greater ($P < 0.0001$) for PP (mean: 36.0; range: 12.7 to 56.1 nmol/g) compared with LL (mean: 14.1; range: 7.7 to 19.4 nmol/g), and tended to decrease over the 4 h after feeding for PP only ($P < 0.10$). The range of change in Ac-CoA over the 4-h period was wide for both PP (-24.3 to 10.4 nmol/g) and LL (−5.7 to 16.1 nmol/g), and was negatively related to DMI at 4 h for PP ($P < 0.01$), but not for LL. The reduction in plasma NEFA concentration over the 4-h period was greater for PP than LL (−684 vs. −52 μEq/L; $P < 0.0001$), and was greater for PP ($P < 0.05$) and tended to be greater for LL ($P < 0.10$) as DMI at 4 h increased. Greater reductions in Ac-CoA were related to higher DMI during the first 4 h after feeding in PP ($P < 0.01$), which is contrary to our expectation if oxidation of Ac-CoA increased hepatic energy charge. However, hepatic energy charge is dependent on the relative rates of production and utilization of high-energy phosphate bonds and the rate of utilization might have been greater for cows with higher DMI. Alternatively, increased DMI over the first 4 h after feeding might have been from decreased oxidation of Ac-CoA during meals if the greater reduction in plasma NEFA concentration reduced Ac-CoA production by β-oxidation. Consistent with this is that the change in Ac-CoA was positively related to the reduction in plasma NEFA concentration for PP ($P < 0.05$). Besides oxidation, the pool of Ac-CoA is decreased by ketogenesis and hydrolysis and export as acetate. Further research is required to determine the fate of Ac-CoA within the timeframe of meals and the effects of feeding on energy charge in hepatic tissue.

Key Words: acetyl CoA, metabolic control of intake, postpartum

0670 Overconditioned prepartum cows exhibit a greater magnitude of insulin resistance and mobilize more NEFA earlier compared with lean cows. J. E. Rico*[1] and J. W. McFadden[1,2], *[1]West Virginia University, Morgantown, [2]Johns Hopkins University, Baltimore, MD.*

Overconditioned transition cows are at greater risk of developing metabolic disease compared with lean cows. Severity of metabolic disease can be augmented by the magnitude of insulin resistance. Our objective was to identify the onset of insulin resistance in overconditioned prepartum cows to delineate the progression of the disease for future predictive biomarker discovery. Multiparous Holstein cows were allocated into two treatment groups according to their BCS at d −30 prepartum: lean (LEAN; BCS < 3.25; $n = 21$) or overconditioned (OVER; BCS > 3.75, $n = 26$). Diets were formulated to meet nutrient recommendations. Blood samples were collected at d −45, −30, −15 and −7, relative to expected calving, and at d 1 and 4 postpartum. Plasma glucose, NEFA, insulin, and BHBA concentrations were measured, and the Revised Quantitative Insulin Sensitivity Check Index (RQUICKI) was calculated as an insulin sensitivity indicator. The statistical model included the random effect of cow and the fixed effects of BCS and time (relative to calving). BCS was different for LEAN and OVER at d -30 postpartum (3.04 ± 0.042 vs. 3.91 ± 0.038; $P < 0.001$). With the exception of glucose, plasma variables were affected by time ($P < 0.001$). NEFA (mM) were higher for OVER relative to LEAN at d −45, −30, −15, and −7 (+54%, $P < 0.01$; +40%, $P < 0.05$; +116%, $P < 0.001$; and +91%, $P < 0.001$, respectively) and tended to be higher at d 1 (+31%, $P = 0.07$). Insulin (μU/ml) was higher in OVER relative to LEAN at d −15 (+37%; $P < 0.05$). RQUICKI was lower for OVER relative to LEAN at d −30, -15, and −7 (−10%, $P < 0.05$; −18%, $P < 0.001$; and −9%, $P < 0.01$, respectively), and tended to be lower at d −45 and d 1 for OVER relative to LEAN (−8 and −7%, respectively, $P = 0.08$). BCS affected NEFA and RQUICKI (+44% and −9%, respectively, OVER relative to LEAN; $P < 0.001$). Glucose and BHBA were not affected by BCS. Relative to LEAN, OVER showed a negative change in BCS from d -30 to d −7 (0.13 vs. −0.10 units, $P < 0.01$). BCS had no effects on BW or milk yield. Somatic cell score was higher in OVER at d 10 (+18%, $P = 0.025$). Overconditioned cows experienced a greater magnitude of insulin resistance and mobilized more NEFA earlier compared with lean cows. Early detection of pre-onset insulin resistance in overconditioned dairy cows is needed to develop interventions aimed at reducing excessive NEFA mobilization and associated metabolic disorders.

Key Words: insulin resistance, overconditioned, transition cow

0671 Identifying biomarkers for pre-onset insulin resistance using mass spectrometry-based metabolomics: Plasma ceramides are elevated in overconditioned transition dairy cows.

J. E. Rico[1] and J. W. McFadden[*1,2], *[1]West Virginia University, Morgantown, [2]Johns Hopkins University, Baltimore, MD.*

Metabolomics is a systems biology analytical approach used to study disease phenotypes, an established field in biomedicine that is emerging in the dairy sciences. Parallel with transcriptome and proteome, the comprehensive set of small molecules in biological systems constitutes its metabolome. Because no single analytical methodology is suited to identify all metabolites, a combination of untargeted and targeted methods (measurement of any molecule that ionizes within a specific mass range, and measurement of specific metabolites, respectively) are employed using gas chromatography (GC) or liquid chromatography (LC), coupled with mass spectrometry (MS). Metabolome screening provides the opportunity to discover molecules (biomarkers) that are associated with disease progression. Similar to overweight monogastrics, overconditioned transition dairy cows experience greater insulin resistance compared with lean cows. Since insulin resistance accelerates NEFA mobilization, overconditioned dairy cattle are at greater risk of developing postpartum disease. Therefore, our objective was to screen the bovine metabolome using GC/MS and LC/MS technologies in search for metabolic phenotypes associated with decreased insulin sensitivity. Our data set included multiparous Holstein cows grouped according to BCS at d -30 prepartum: lean (BCS < 3.0; n = 10; LEAN) or overconditioned (BCS > 4.0, n = 11; OVER), with blood samples collected at d −45, −30, −15 and −7, relative to expected calving, and at d 4 postpartum. For untargeted detection, derivatized plasma methanol extracts were analyzed using GC/MS. For targeted analysis, plasma chloroform-methanol extracts were analyzed by LC/MS. Following normalization, log transformation, and median-scaling, data were analyzed using ANOVA and cluster analysis. Non-parametric spearman's correlations were used to evaluate the associations between NEFA and insulin sensitivity to ceramides. Relative to LEAN, OVER had reduced insulin sensitivity and greater NEFA mobilization at d −30, −15 and −7 prepartum (P < 0.05). GC/MS and LC/MS analysis detected lactate, urea, glycerol, amino acids, citrate, mono- and disaccharides, saturated and unsaturated free FA, uric acid, vitamin E, nonesterified cholesterol, ceramides, hexylceramides, and others. Of interest, relative to LEAN, OVER had elevated ceramides at d −15, −7, and 4 (e.g., C20:0-ceramide; P < 0.05), and mono- and dihexylceramides at d4 (P < 0.05). Multiple ceramides were positively associated with NEFA, and negatively associated with insulin sensitivity (e.g., C22:0-, C24:0-, C24:1-, and C26:0-ceramide; P < 0.05). Currently used markers (e.g., NEFA and BHBA) have limited predictive power for pre-onset insulin resistance, as they are delayed indications of metabolic stress. Metabolomics may improve our ability to predict prepartum cows at risk of developing greater insulin resistance.

Key Words: insulin resistance, metabolomics, transition cow

0672 Effects of yeast product supplementation on production, feeding behavior, and metabolism in transition dairy cows.

K. Yuan[*1], T. Liang[2], M. Muckey[1], L. Mendonca[1], L. Hulbert[1], L. Mamedova[1], C. C. Elrod[3], and B. Bradford[1], *[1]Kansas State University, Manhattan, [2]GM Powertrain, Pontiac, MI, [3]Vi-COR, Inc., Mason City, IA.*

The objective of this study was to assess the effects of supplementing a yeast product derived from *Saccharomyces cerevisiae* on production, feeding behavior, and metabolism in transition cows. Forty multiparous Holstein cows were blocked by expected calving date and randomly assigned within block to one of four treatments (n = 10) from 21 d before expected calving to 42 d postpartum. Rations were top-dressed with yeast culture plus enzymatically hydrolyzed yeast (Celmanax, Vi-COR, Mason City, IA) at the rate of 0, 30, 60, or 90 g/d throughout the experiment. Dry matter and water intake, feeding behavior, and milk production were monitored. Plasma collected on −21, −7, 1, 4, 7, 14, 21, and 35 d relative to calving was analyzed for glucose, β-hydroxybutyrate, nonesterified fatty acids (NEFA), and haptoglobin. Data were analyzed using mixed models with repeated measures over time. Pre- or postpartum DMI and water intake did not differ (P > 0.10) among treatments. There were quadratic dose effects (P < 0.05) for prepartum feeding behavior, reflecting decreased meal size, meal length, and intermeal interval, and increased meal frequency for cows received 30 and 60 g/d of yeast products. Postpartum feeding behavior was unaffected (P > 0.10) by treatments. Milk yields were not affected (P > 0.10; 45.3, 42.6, 47.8, and 46.7 kg/d for 0, 30, 60, and 90 g/d, respectively) by treatments. Tendencies toward increased ($0.05 < P \leq 0.10$) percentages of milk fat, protein, and lactose were detected for cows receiving yeast. A treatment × wk interaction (P < 0.01) was observed for somatic cell linear score (SCS), reflecting a quadratic dose effect on SCS in wk 1 (P = 0.03; 2.34, 2.85, 1.47, and 4.05 ± 0.57 units for 0, 30, 60, and 90 g/d, respectively). Yeast product increased (P < 0.01) plasma β-hydroxybutyrate and tended to decrease (quadratic P = 0.06) glucose, but did not affect NEFA or haptoglobin. Yeast product supplementation during the transition period did not affect milk production, but may modulate feeding behavior, mammary gland health, and metabolism.

Key Words: production and metabolism, transition cow, yeast

0673 Milk production performance of autumn-calving Holstein Friesian cows managed under flat-rate or feed-to-yield concentrate feeding systems.

D. C. Lawrence[*1,2], E. Kennedy[2], M. O'Donovan[2], T. M. Boland[3], A. Lawless[4], and J. Patton[5], *[1]School of Agriculture and Food Science, University College Dublin, Belfield, Ireland, [2]Teagasc, Animal and Grassland Research and Innovation Center, Moorepark, Fermoy, County Cork, Ireland, [3]School of Agriculture and Food Science, University College Dublin, Ireland, [4]Teagasc, Johnstown Castle, Co. Wexford, Ireland, [5]Teagasc, Grange, Dunsaney, County Meath, Ireland.*

This experiment was conducted to examine the effects of two feeding systems, on milk production, body condition score and feed inputs of autumn-calving cows. Autumn-calving Holstein Friesian cows (n = 84) were blocked pre-partum according to parity, body condition score, genetic merit for milk production and assigned to one of two postpartum concentrate feeding systems; feed to budget (FTB) or feed to yield (FTY); FTB cows were allocated concentrate at a flat rate, and FTY were allocated concentrate based on individual milk production. Both feeding systems were offered 14.5 kg forage DM/cow/day during the winter housing period containing grass silage and maize silage (in the ratio 2:1) plus 3.0 kg DM of concentrate. Cows on the FTB treatment received a further 3.95 kg DM of concentrate in the milking parlor; cows on the FTY treatment received 0.43 kg DM of concentrate in the milking parlor per kg of milk (based on the previous weeks mean milk production) exceeding a base milk yield 23.0 kg/cow/day. Cows were turned out to pasture on February 10. During the main grazing period (March-September) pre-grazing herbage mass was 1300 to 1500 kg DM/ha (above 4 cm), and was grazed to a residual of < 100kg DM/ha (target 4.0 cm). Where pasture supply was adequate, the FTY group was offered 0.43 kg DM concentrate per kg milk, exceeding a base yield of 25.0 kg/day as described previously. When pasture supply was below the demand, additional concentrate (plus silage if required) was allocated at a flat-rate to both treatments. Data were analyzed using a mixed model procedure in SAS v9.3 which included a repeated measure for week of experiment. Concentrate feeding system had no significant effect on milk yield, milk solids production or mean BCS during the indoor period or at grazing. In total the FTY treatment was fed 250 kg DM/cow less concentrate that the FTB ($P < 0.001$). The ratio of concentrate fed per kg of milk output was lower for FTY which indicates improved efficiency of milk production from forage.

Key Words: feed to yield, pasture, autumn calving

0674 Does concentrate allocation pattern affect the milk production of autumn calving cows at high and low feeding levels?

D. C. Lawrence[*1,2], M. O'Donovan[3], T. M. Boland[4], E. Lewis[3], and E. Kennedy[3], *[1]Teagasc, Animal and Grassland Research and Innovation Center, Moorepark, Fermoy, County Cork, Ireland, [2]School of Agriculture and Food Science, University College Dublin, Belfield, Ireland, [3]Teagasc, Moorepark, Fermoy, County Cork, Ireland, [4]School of Agriculture and Food Science, University College Dublin, Ireland.*

The objective of this experiment was to examine the effects of concentrate allocation pattern at two concentrate feeding levels, on feed intake, milk yield, and milk composition of autumn calving cows offered a base forage mix of grass silage and maize silage. The study used a randomized block design with a 2 × 2 factorial arrangement of treatments and was performed over an 11-wk period in 2011 and 2012. The treatment factors were flat (F) or variable (V) concentrate allocation pattern, at high (7.0 kg DM/cow per day (Hi)) or low (4.0 kg DM/cow per day (Lo)) concentrate feeding level. Cows (n = 108) were blocked in groups of four based on calving date, parity and the milk yield, body weight and BCS of weeks three and four of lactation. Within each treatment cows were sub-grouped as high, medium, and low milk yield based on pre-experimental milk data. The HiV cows received 8.7, 7.0, or 5.3 kg DM of concentrate/cow per day in the high, medium and low subgroups, respectively. The LoV cows received 5.3, 4.0, or 2.7 kg DM of concentrate/cow per day in the high, medium and low subgroups, respectively. Flat rate treatments received 7.0 kg DM (HiF) or 4.0 kg DM (LoF) of concentrate/cow per day. Concentrate was allocated in the base diet; 2 kg and 2.4 kg DM for Hi and Lo, respectively, and the remaining amount was allocated in the parlor. All cows remained on a fixed level of concentrate for the duration of the experiment. Data were analyzed using a mixed model procedure in SAS v9.3, which included a repeated measure for week of experiment. Cows on the Hi treatment had 2.9 kg higher total DM intake ($P < 0.001$), and 0.5 kg reduction in base feed DM intake ($P < 0.05$), compared to animals on the Lo treatment, which had a total DM intake of 15.8 kg DM and a base feed intake of 14.2 kg DM. Each additional 1 kg concentrate DM intake above the Lo treatment, resulted in a 0.43 kg increase in milk yield ($P < 0.001$) which was 25.1 kg and 23.8 kg on Hi and Lo, respectively. There was no allocation pattern by feeding level interactions for milk yield, milk composition or dry matter intake. Allocating concentrate at a variable rate had no effect on milk yield or DM intake, when compared to allocating concentrate at a flat rate.

Key Words: feed-to-yield, flat-rate: Holstein Friesian

0675 Characterization of rumen microbial community composition of buffalo fed diets varying in forage:concentrate ratio. B. Lin[*1,2], C. Zou[1], F. Cox[2], G. Henderson[2], P. H. Janssen[2], X. Liang[1], and G. Attwood[2], [1]*Buffalo Research Institute, The Chinese Academy of Agricultural Sciences, Nanning, China,* [2]*AgResearch Limited, Grasslands Research Centre, Palmerston North, New Zealand.*

Murrah and Nili-Ravi are two widely used dairy water buffalo breeds in Asian countries. In this study, we investigated the diversity of ruminal microbes in six Murrah and six Nili-Ravi water buffalos maintained in China. The buffalos were separated into two groups; each group contained three Murrah and three Nili-Ravi buffalos, and two different diets (with forage to concentrate ratios of 3.2 or 1.6) were fed to the two groups. After feeding the diets for 15 d, ruminal fluid was sampled by stomach tube before the morning feeding. The bacterial and archaeal 16S rRNA genes and the ciliate protozoal 18S rRNA genes from the 12 rumen samples were sequenced by multiplex 454 Titanium pyrosequencing, and the sequence data was analyzed using QIIME 2.0 software. Our results showed that at the phylum level, Bacteroidetes was the predominant bacterial group, accounting for 42% to 72% of total bacteria, followed by Firmicutes, Fibrobacter and Proteobacteria. At the genus level, *Prevotella* dominated, accounting for 22 to 58% of total bacteria, followed by *Fibrobacter*, *Paludibacter* and *Ruminococcus*. While there were differences between the bacterial community compositions of different animals, there was no obvious correlation of bacterial community composition, at the phylum or genus level, with the diets or with buffalo breeds. For the archaea, *Methanobrevibacter*-related organisms were the dominant group, accounting for around 80% of the total, followed by *Methanoplasmatales* (RCC, 15%) and *Methanosphaera* (3%). Similar to the bacterial community, there was no clear correlation of the archaea community profile with diet or buffalo breed. The ciliate protozoal communities differed between the samples analyzed, although *Entodinium* was the most abundant group of ciliates in every sample, accounting for more than 40% of total protozoa. The second largest ciliate group varied in different samples with *Isotricha*, *Polyplastron* or *Dasytricha* the dominant genera after *Entodinium*. In summary, the predominant genera observed in the bacterial, archaeal and ciliate protozoal communities in rumen samples of Murrah and Nili-Ravi buffalo were *Prevotella*, *Methanobrevibacter* and *Entodinium,*, respectively. Overall, the buffalo rumen microbial communities varied greatly between individual animals, regardless of the diet composition or the buffalo breed used in this study.

Key Words: buffalo, rumen, microbial community, forage to concentrate ratio

0676 Bacterial diversity associated with different primer pairs on different diets in the rumen microbiome of Kankrej cattle. D. W. Pitta[*1], N. Indugu[2], S. Kumar[1], K. B. Prajapathi[3], A. K. Patel[4], N. Parmar[4], A. B. Patel[4], B. Reddy[4], and C. Joshi[4], [1]*University of Pennsylvania, Kennett Square,* [2]*University of Pennsylvania, Kennett Square,* [3]*Sardharkrushinagar Dantiwada Agricultural University, India,* [4]*Anand Agriculture University, India.*

A comprehensive analysis of the bacterial diversity in the rumen of Kankrej cattle was investigated in this study. Two groups of four animals were assigned to two diets of Dry and Green roughage, respectively. In each dietary group, four animals (replicates) were group fed one of three dietary treatments for 6 wk each; dietary treatments were K1 (50% concentrate, 50% dry/green roughage), K2 (25% concentrate, 75% dry/green roughage), and K3 (100% dry/green roughage). The rumen samples were collected at the end of 6 wk period and separated to solid and liquid fractions. The genomic DNA was extracted from each sample and PCR-amplified for V1-V3, V4-V5, and V6-V8 hypervariable regions, sequenced on 454 Roche platform and analyzed for bacterial diversity using QIIME. A total of 600, 851 pyrotags were analyzed in this study. Differences in community composition were based on UniFrac distance metric calculated by primer, diet, treatment, fraction, and animal and analyzed by Permanova test. Different primers had a significant ($P < 0.001$) effect on community compositions. There was no difference between diets but the inclusion of concentrate had an effect on community composition ($P < 0.01$). Also community compositions between fiber and liquid fractions were different ($P < 0.01$). Phylogenetic analysis revealed significant differences in the rumen microbiome mediated by primer ($P < 0.001$). In primer pair 1 associated bacterial communities, the predominant phyla were *Bacteroidetes* and *Firmicutes* which together constituted > 90% of abundance. These two phyla were influenced by dietary treatment ($P < 0.001$) and fraction ($P < 0.05$). Among communities associated with primer pairs 2 and 3, *Firmicutes* was predominant and contributed up to 90% of the fiber fraction. Dietary treatment had an influence on the abundance of B*acteroidetes* ($P < 0.001$) and *Firmicutes* ($P < 0.001$) with K1 showing higher ($P < 0.001$) *Bacteroidetes* while K2 and K3 treatments had higher ($P < 0.001$) abundance of *Firmicutes*. Other bacterial phyla such as *Proteobacteria* and *Fibrobacter* together contributed up to 6% of the bacterial abundance that was influenced by dietary treatment ($P < 0.001$) and fraction ($P < 0.001$) across all three primer pairs. The identified repertoire of bacterial populations was dependent on the primer pair, as targeting the V1-V3 region resulted in greater diversity profiles of the rumen microbiome in this study. Within each primer pair, there were no differences between dry and green roughages. However, inclusion

of concentrate in the diet altered the community composition with noticeable shifts at the phylum level.

Key Words: rumen microbiome, Kankrej cattle, QIIME, concentrate, roughage

0677 Development of rumen microbiota in dairy calves: Impact of weaning and different weaning strategies.

S. C. Li*[1], M. A. Steele[2], P. Azevedo[1], M. Carson[2], J. C. Plaizier[1], H. Derakhshani[1], and E. Khafipour[1,3], *[1]Dep. of Animal Science, University of Manitoba, Winnipeg, Canada, [2]Nutreco Canada Agresearch, Guelph, ON, Canada, [3]Dep. of Medical Microbiology and Infectious Diseases, Winnipeg, MB, Canada.*

Weaning stress affects the establishment of rumen bacterial community in dairy calves, which is important for rumen development and future rumen physiology. This study examined the effects of different weaning strategies on the microbial composition of rumen in 24 male and 20 female Holstein dairy calves. Calves were blocked according to gender and birth weight, and randomly assigned to a step-down weaning (SW) or an abrupt weaning (AW) treatment. All calves had free access to water and starter intake throughout the experiment and 9 L/d of milk until d 36 of life and weaned on d 49 of life. Calves in SW group were weaned gradually by reducing milk intake from 9 to 4.5 L/d from d 37 to d 48 while the AW calves were abruptly weaned on d 49 by reducing milk intake from 9 to 0 L/d. Rumen fluid was sampled on d 36 (pre-weaning) and on d 54 (post-weaning) of life. DNA was extracted and V4 region of 16S rRNA gene was amplified and subjected to paired-end Illumina sequencing. The output paired-end reads were merged using PANDASeq assembler and analyzed using QIIME. The resulted operational taxonomic units were aligned to Greengenes database. Alpha-diversity of bacterial community was calculated using different richness estimators. Differences in β-diversity of microbiota across treatments and time points were tested using Permutational ANOVA. Alpha-diversity of microbiota declined post-weaning, indicating a compositional heterogeneity reduction in rumen population. Beta-diversity of microbiota differed ($P < 0.05$) between pre- and post-weaning. Different weaning strategies did not affect α and β-diversities. Predominant phyla before weaning included *Bacteroidetes* (66%), *Firmicutes* (19%) and *Proteobacteria* (11%). Another 18 phyla were present at low abundance; each below 1% of population. In post-weaned calves, *Bacteroidetes* was reduced (44%) while *Firmicutes* and *Proteobacteria* increased. However, a smaller increase in *Firmicutes* and a greater increase in *Proteobacteria* were observed after weaning in SW compared to AW calves (28% vs. 38%, and 22% vs.17%, respectively). Eighty-two out of 348 identified bacterial genera were different between pre- and post-weaned calves across AW and SW treatments, which accounted for 50% of sequences. The impact of weaning strategy was observed on several genera, including but not limited to, several members of *Alphaproteobacteria*, RF32, *Alcaligenaceae*, and *Helicobacter*. Data provided novel information on the profile of rumen microbiota associated with weaning and weaning strategy that can be used as biomarkers in future studies.

Key Words: calves, weaning, rumen microbiota

0678 The potential benefit of corn dried distillers' grain (co)products (DDG) in the mitigation of methane production in cattle: An in vitro analysis.

M. A. Fonseca*[1], D. K. A. Silva[2], H. D. Naumann[3], T. R. Callaway[4], and L. O. Tedeschi[1], *[1]Texas A&M University, College Station, [2]Federal Rural University of Pernambuco, Garanhuns, Brazil, [3]University of Missouri, Columbia, [4]USDA-ARS, College Station, TX.*

The objective of this work was to determine the impact of different levels of DDG on the digestibility of OM and the production of methane (CH_4) using an in vitro technique. Nine diets were formulated with Bermuda grass hay, ground corn, and alfalfa hay mixed with DDG (0, 10, 20, 30, 40, 50, 60, 80, and 100% of diet DM). These nine diets and alfalfa hay alone (laboratory control) were ground (1 mm), and incubated with rumen fluid (from grazing cows) and media. Blanks (rumen fluid and media only) were used to adjust the CH_4 production. Three replicates and four incubation times (3, 6, 24, and 48 h) were investigated in the bottle's headspace using a syringe for collection. Because these diets had different amounts of potentially fermentable substrate, adjusted CH_4 was computed as CH_4 concentration divided by the amounts of NDF (CH_4NDF, mM/g NDF), NFC (CH_4NFC, mM/g NFC), fermentable carbohydrate (FCHO = CHOA + CHOB1 + CHOB2) (CH_4FCHO, mM/g FCHO), OM (OM = 100– Ash) (CH_4OM, mM/g OM), and fermentable OM (FOM = OM– Ash– EE) (CH_4FOM, mM/g FOM) in the diet sample. The PROC MIXED of SAS (SAS Inst., Cary, NC) was used to analyze the data assuming a repeated measure design. Diets and incubation times were assumed as fixed factors and replicate within diet as random factor. Except for CH_4FCHO and CH_4NFC, diet effect was significant ($P < 0.001$) for all other adjusted CH_4 concentrations, suggesting that FCHO and NFC may not explain differences in CH_4 concentration. Regarding incubation time and its interaction with diet, all adjusted CH_4 concentration were highly significant ($P < 0.001$). There was a tendency to decrease CH_4 concentration as the DDG level increased, but the level of DDG in the diet had to be greater than 50% to yield significant reduction in the adjusted CH_4 concentration, CH_4FOM and CH_4OM (CH_4 per unit of OM) when the fat content was greater than 7.39% DM. Significant linear regressions for adjusted CH_4 concentration ($CH_4 = 14.5 - 0.667 \times$ Fat; $r^2 = 0.64$, RMSE = 1.48 mM, $n = 46$) and CH_4FOM (CH_4FOM $= 83.8 - 3.35 \times$ Fat; $r^2 = 0.53$, RMSE = 9.30 mM/% FOM, $n = 46$) on fat content of the diets were observed. These in vitro results suggested that under normal ru-

minal fermentation CH_4concentration will decrease as dietary fat increases if ruminal retention time is between 24 and 48 h.

Key Words: abatement, greenhouse gas, ruminant

0679 Use of avian antibodies against lipopolysaccharides to improve gastrointestinal function in early lactation dairy cows. L. Ibarbia[*1], F. Cunha[1], K. N. Galvão[1], F. Maunsell[1], A. Donovan[1], and N. DiLorenzo[2], *[1]Dep. of Large Animal Clinical Sciences; University of Florida, Gainesville, [2]University of Florida, Marianna.*

Subacute ruminal acidosis (SARA) has been associated with decreased milk production in early lactation dairy cows. During SARA, increased lipopolysaccharides (LPS) are released in the rumen from the breakdown of gram negative bacteria, increasing LPS concentrations and potential translocation to blood. Presence of LPS in the blood stream leads to activation of the acute phase response in peripheral blood, which in turn leads to a reduced DMI and milk production. An avian-derived anti LPS polyclonal antibody preparation (PAP-LPS) was developed (Camas Inc., LeCenter, MN) to use as a feed additive in dairy cattle. Our objective was to evaluate the effectiveness of PAP-LPS in decreasing the intensity of the inflammatory response and increasing milk yield on early lactation dairy cows. Primiparous (Pr; n = 174) and multiparous (Mu, n = 226) Holstein cows from one herd were randomly allocated to one of three treatments: 1) PAP-LPS (n = 55 Pr and n = 70 Mu), 2) Placebo (n = 66 Pr and 77 Mu), and 3) Control (n = 53 Pr and 79 Mu). Cows on PAP-LPS received a dose of 3 g/d of PAP-LPS via oral drench in a water suspension, while Placebo received the same dose of a PAP-LPS inactivated by an acid-shock treatment. Control cows did not receive any treatment. The PAP-LPS and Placebo treatments were administered from d 0 (calving) until 14 DIM. Milk production was recorded from d 0 to d 98 and weekly averages were used in a repeated measures analysis using the PROC MIXED of SAS and a first-order autoregressive covariate structure. The model included the fixed effects of treatment, parity and treatment x parity interactions. Feeding PAP-LPS increased (P = 0.04) total milk production on the first 98 DIM when compared with Control (3881 and 3769 kg, respectively), while only tended to increase it (P = 0.07) when compared to placebo (3785 kg). A week x treatment interaction was observed (P = 0.088) for weekly average milk production. Weekly average milk production was greater (P < 0.05) for PAP-LPS vs. Control on weeks 3, 4, and 10. On week 6, cows fed PAP-LPS had greater (P < 0.05) milk production (44.9 kg/d) when compared with both Control (43.1 kg/d) and Placebo (43.1 kg/d). In conclusion, feeding PAP-LPS increased milk production in early lactation dairy cows, likely due to a reduced inflammatory response during diet transition.

Key Words: dairy cows, LPS, avian antibodies

0680 Large-subunit rDNA based differentiation of anaerobic rumen fungi using restriction fragment length polymorphism. D. Sumit[1,2,3], S. Kumar[*2,4], D. W. Pitta[4], J. Edwards[1], T. Callaghan[1], G. Grifith[1], P. Mudgil[2], and A. Puniya[2], *[1]Aberystwyth University, Aberystwyth, UK, [2]National Dairy Research Institute, Karnal, India, [3]Agharkar Research Institute, Pune, India, [4]University of Pennsylvania, Kennett Square.*

The contribution of rumen anaerobic fungi to animal production systems is substantial despite their lower numbers in the rumen. Utilizing both cultivation-based and advanced genomic tools, several reports have described the repertoire of ligno-cellulolytic enzymes secreted by these fungi. However, characterization of anaerobic rumen fungi is a tedious process with difficulties in isolation methods, their pleomorphic nature and lack of appropriate targeted genetic markers to understand fungal diversity. Previously, we have identified a new marker, D1/D2 domain of 28S rDNA of LSU (large-subunit; LSU) region which provided a better resolution in species differentiation of genus *Orpinomyces* than internal transcribed spacer (ITS) region, a preferred genetic marker for most fungal diversity studies. In the current study, we applied the same D1/D2 marker to assess species level distribution of several fungal lineages. For this, nearly 100 isolates of known lineages (*Orpinomyces*, *Neocallimastix*, *Anaeromyces*, *Piromyces*, *Caecomyces*, *Cyllamyces*) and unknown anaerobic fungi were cultivated from the rumen of different herbivorous animals. The isolates were extracted for their genomic DNA using modified method of Cetyl tri-methyl ammonium bromide (CTAB) and also MoBio genomic DNA extraction kit. The genomic DNA samples were PCR-amplified for D1/D2 regions of LSU (≈ 780 bp) using NL1 and NL4 primers. The amplified PCR products were purified, sequenced and characterized for phylogeny. Based on the phylogenetic analysis, representative sequences from identified fungal lineages were further subjected to in silico restriction digestion that led to the identification of two restriction enzymes, *Alu*I (recognition sequence, AG▼CT) and *Hinf*I (recognition sequence, G▼ANT C). About 34 selected sequences were co-digested by these two restriction enzymes using Restriction Fragment Length Polymorphism (RFLP) assay. The RFLP analysis of electrophoretic runs revealed distinct riboprints for individual fungal lineages that were identified in this study. Sequences annotated to similar fungal lineages showed comparable riboprints, which confirmed that targeting D1/D2 region of the LSU gave repeatable results. Our study summarized that RFLP-based differentiation of fungal lineages was better accomplished when D1/D2 region of the LSU was used as a genetic marker.

Key Words: rumen, anaerobic fungi, LSU, PCR-RFLP, co-digestion

0681 Responses in rumen microbiomes of *Bos taurus* and *Bos indicus* steers fed rice straw and supplemented protein. E. A. Latham[*1], J. C. McCann[2], K. Weldon[1], T. A. Wickersham[1], J. Coverdale[1], and W. E. Pinchak[3], *[1]Texas A&M University, College Station, [2]University of Illinois, Urbana, [3]Texas A&M AgriLife Research, Vernon.*

Bos indicus typically perform better than *Bos taurus* when consuming a low-quality diet; however, the response to supplementation is generally greater in *Bos taurus*. The underlying mechanisms supporting these responses have not been elucidated. Characterization of differences in rumen bacterial populations and their role in the two subspecies may provide insight. Five cannulated Angus and Brahman steers were used in concurrent 5 × 5 Latin squares with repeated measures. Animals were offered ad libitum access to rice straw (4.7% CP). Treatments consisted of an unsupplemented control and two levels (50 and 120 mg N/kg BW) of isonitrogenous supplements (30% CP), either high (H; 74%) or low (L, 26%) in UIP. Rumen sample were collected at 0 and 4 h post-feeding, separated into liquid and solid fractions and frozen immediately in liquid N. Rumen bacterial taxa were sequenced utilizing a Roche 454 platform based on the 16s rRNA gene. At 97% sequence similarity, 97,826 OTUs were identified, which included 21 phyla, 108 families, and 255 genera. Each taxa was analyzed using PROC MIXED with period and animal as random effects. The top seven phyla accounted for > 98% of observed abundance. Six phyla differed as a function of fraction, time, and fraction × time interaction ($P < 0.05$). *Bacteroidetes* (65%) and *Firmiucutes* (28%) were dominant phyla, both tended to differ as a function of subspecies × treatment and treatment ($P < 0.06$). The top 14 families accounted for > 93% observed abundance. Unlike phyla, families were influenced more by subspecies and treatments than fraction ($P < 0.05$). *Prevotellaceae* (> 42%), *Ruminococcaceae* (> 13%), *Sphingobacteriaceae* (> 8%), and *Lachnospiraceae* (> 7%) were the dominant families. Genus abundance also varied as a complex function of subspecies, time and various associated interactions with treatment and fraction ($P < 0.05$). Twenty genera were present at > 0.8% average abundance and accounted for over 85% of total observed abundance. Dominant genera were *Prevotella* (29.5%), unknown *Prevotellaceae* (11%), unknown *Ruminococcaceae* (8.5%) and unknown *Sphingobacteriaceae* (7%). Overall bacterial community diversity was greater than expected because rice hay is recalcitrant to bacterial digestion. Similarly, consistent differences in family and genus taxa between *B. indicus* and *B. taurus* suggest important roles the symbiotic rumen microbiome may have in the capacity of *B. indicus* to utilize low-quality forage over a range of supplement types and levels.

Key Words: cattle, microbiome, supplementation

0682 Effects of dietary fat source and monensin on methane to carbon dioxide ratio, VFA profile, and performance of finishing steers. A. C. Pesta[*1], A. K. Watson[1], R. G. Bondurant[1], S. C. Fernando[2], and G. E. Erickson[1], *[1]University of Nebraska-Lincoln, Lincoln, [2]University of Nebraska, Lincoln.*

A finishing study was conducted to evaluate effects of supplemental fat type and presence or absence of monensin on methane to carbon dioxide ratio (CH_4:CO_2), ruminal VFA profile, and performance of finishing steers. Steers ($n = 60$, initial BW = 414 ± 16 kg) were individually fed for 125 d using Calan gates. Steers were stratified by initial BW and assigned randomly to one of six treatments. Four diets were designed to compare fat source: CON (corn-based diet with no added fat), MDGS (50% modified distillers grains plus solubles added), OIL (3% corn oil added), and TAL (3% tallow added). Added fat diets were formulated to provide 6.5% total dietary fat. An additional two treatments were added to factorialize presence or absence of monensin (375 mg daily) with CON or MDGS diets. At time of feeding, exhaled breath samples were collected from each animal at weekly intervals throughout the study using a custom built automated gas collection system and were analyzed for CH_4 and CO_2, using gas chromatography. Carbon dioxide was used as an internal marker and CH_4:CO_2 was used to quantify the effects of diet on methane emission. Rumen fluid collected via esophageal tubing on d 55, before feeding, was analyzed for VFA profile. Treatment differences were evaluated using pre-planned contrasts. No diet × monensin interaction was observed ($P = 0.19$). The CH_4:CO_2 for cattle fed MDGS was greater ($P = 0.03$) than CON, 0.057 compared to 0.050, respectively. No effect ($P = 0.56$) of monensin inclusion on CH_4:CO_2 was observed. Differences in CH_4:CO_2 observed may be due to composition of dietary fat, as steers fed MDGS had greater CH_4:CO_2 than those fed TAL or CON ($P < 0.03$), while those consuming OIL were intermediate. No differences were observed ($P = 0.45$) for ruminal acetate to propionate ratio (A:P) due to fat type or presence of monensin, as A:P of all diets fell between 1.08 and 1.40. Finishing performance was also unaffected as no differences in DMI ($P = 0.48$), ADG ($P = 0.37$), or G:F ($P = 0.78$) were observed. Composition of the finishing diet, particularly source of added fat does impact CH_4:CO_2.

Key Words: distillers grains, fat, methane

RUMINANT NUTRITION IX

0683 Effects of supplemental zinc, copper, and manganese concentration and source on performance and carcass characteristics of feedlot steers. E. Caldera*[1], J. J. Wagner[1], K. Sellins[1], T. E. Engle[1], S. B. Laudert[2], and J. Spears[3], [1]*Colorado State University, Fort Collins,* [2]*Micronutrients, Indianapolis, IN,* [3]*North Carolina State University, Raliegh.*

Four-hundred cross-bred steers (initial BW 335 ± 9.6 kg) were utilized to investigate the effects of supplemental Zn, Cu, and Mn concentration and source on performance and carcass characteristics of feedlot steers fed a high concentrate steam flaked corn-based finishing diet for 159 d and zilpaterol hydrochloride for the last 21 d before slaughter (5-d withdrawal). The experimental design was a randomized complete block design. Steers were blocked by weight and randomly assigned within block to one of the five treatments (eight pens/treatment; 10 hd/pen). Treatments consisted of: 1) 90 mg of Zn/kg DM from $ZnSO_4$; 17.5 mg of Cu/kg DM from $CuSO_4$; 48 mg of Mn/kg DM from $MnSO_4$; 2) 30 mg of Zn/kg DM from Zn hydroxychloride; 10 mg of Cu/kg DM from basic Cu chloride; 20 mg of Mn/kg DM from Mn hydroxychloride; 3) 45 mg of Zn/kg DM from hydroxychloride; 12.5 mg of Cu/kg DM basic Cu chloride; 29.5 mg of Mn/kg DM from Mn hydroxychloride; 4) 60 mg of Zn/kg DM from Zn hydroxychloride; 15 mg of Cu/kg DM from basic Cu chloride; 39 mg of Mn/kg DM from Mn hydroxychloride; and 5) 90 mg of Zn/kg DM from Zn hydroxychloride; 17.5 mg of Cu/kg DM from basic Cu chloride; 48 mg of Mn/kg DM from Mn hydroxychloride. Steers were individually weighed on d -1, 0, 55, 112, and pen-weighed two consecutive days at the termination of the experiment. Steers were transported to a commercial abattoir, slaughtered, and individual carcass data and liver samples were collected. Initial pen BW was used as a covariate in the statistical analysis and significance was determined at $P \leq 0.05$. No differences were observed for final body weight ($P > 0.42$). Overall ADG, DMI, and feed efficiency were similar across treatments. Hot carcass weight, dressing percentage, yield grade, LMA, adjusted fat thickness, KPH, and marbling score were similar across treatments. Concentrations of Zn, Cu, and Mn in livers and blood samples collected on d 112 and at harvest were similar across treatments. These data indicate that under the conditions of this experiment, supplemental Zn, Cu, and Mn concentration and source had no impact on performance and carcass characteristics in feedlot steers.

Key Words: cattle, feedlot, trace mineral

0684 Decreasing dietary calcium to potentiate changes in beef tenderness with zilpaterol hydrochloride supplementation. C. L. Van Bibber-Krueger*, K. A. Miller, and J. S. Drouillard, *Kansas State University, Manhattan.*

Dietary calcium concentrations were manipulated during supplementation of zilpaterol hydrochloride (ZH) to evaluate impact on feedlot performance, carcass characteristics, and beef tenderness using 96 heifers (BW 392 kg ± 3.2). We hypothesized that temporary depletion followed by repletion of dietary calcium before harvest would increase intracellular calcium concentrations, thus stimulating postmortem activity of calcium-dependent proteases. Heifers were stratified by initial BW and randomly assigned, within strata (block), to treatments consisting of a finishing diet in which calcium was added in the form of limestone (+Ca) and a diet in which the limestone had been removed (-Ca) during ZH supplementation. Cattle were fed a common diet before ZH supplementation, and 24 d before slaughter ZH was added to the diet with and without the supplemental calcium. Calcium content of the diets during ZH supplementation was 0.74% or 0.19% (diet DM) for +Ca and-Ca, respectively. Zilpaterol hydrochloride was fed for 21 d, then removed from the diet 3 d before harvest. The final 3 d before harvest, limestone was added back into the-CA diet at 0.74% of diet DM. Heifers were housed in concrete surfaced pens with eight animals per pen (six pens per treatment). At the end of the finishing phase, animals were weighed and shipped to an abattoir in Holcomb, KS. Severity of liver abscesses and HCW were collected the day of harvest, and after a 48-h chill USDA yield and quality grades, KPH, LM area, 12th rib fat thickness were determined and boneless loin section was collected for Warner-Bratzler shear force determination. Removal of calcium did not affect Warner-Bratzler shear force values ($P = 0.64$). In addition, ADG, DMI, final BW and feed efficiency were unaffected by treatment ($P > 0.05$). Carcass measurements also were unaffected by the decrease in dietary calcium ($P > 0.05$). In conclusion, temporary depletion of dietary calcium did not alter beef tenderness, live animal performance, or carcass measurements.

Key Words: calcium, zilpaterol hydrochloride, beef tenderness

0685 Optimizing phosphorus utilization by dairy cows. J. C. Plaizier*, K. H. Ominski, and E. J. McGeough, *University of Manitoba, Winnipeg, Canada.*

A survey was conducted on 10 dairy farms in Manitoba to quantify factors that affect the utilization of phosphorus (P) by lactating cows. Farms were visited once to collect samples and data, including days in milk (DIM), milk yields (MY), parities (PAR), body condition scores (BCS), and body weights from 30 Holstein cows in different stages of lactation. Feeds were analyzed for crude protein (CP), fat (FAT), ash (ASH), NDF,

starch (STARCH), P (DIETP) and acid insoluble ash (AIA). Feces were collected from the rectum and analyzed for P (FECALP) and AIA. Composite milk samples were analyzed for fat (MFAT), protein (MPROT), and P (MILKP). The apparent digestibilities of P (ADCP) of cows were determined using AIA as a marker. Dry matter intake was estimated using the equation of NRC(2001). The P utilization efficiencies (PEFF) of cows were determined as the ratio between the output of P in milk and the P intake. Descriptive statistics (Table 0685) show the considerable variation of parameters among cows. Examination of dietary and fecal P concentrations and measures of P utilization suggested that approximately half of the cows received more P than required. Linear regression models were developed between dependent variables (FECALP, PEFF, ADCP) and independent diet and cow variables. Independent variables with a significance level greater than 0.25 were stepwise removed.

Regression models were:

$$ADCP = -152.9 + 1.00 \times PAR - 2.06 \times MFAT + 2.22 \times CP + 3.63 \times FAT + 1.18 \times ASH + 2.52 \times NDF + 114.06 \times DIETP \ (R^2 = 0.39)$$

$$PEFF = 45.91 - 0.45 \times PAR - 0.04 \times DIM + 0.34 \times MY - 2.64 \times MFAT + 313.80 \times PMILK - 82.37 \times DIETP \ (R^2 = 0.79)$$

$$FECALP = 1.21 + 0.0005 \times DIM + 0.03 \times CP - 0.10 \times FAT + 0.06 \times ASH - 0.01 \times STARCH - 0.04 \times NDF \ (R^2 = 0.25)$$

Correlations among independent variables, including PDIET and other dietary variables, complicated assessing relationships between variables. The models show the complexity of factors that determine the efficiency of P for milk production, and generally suggest that this efficiency decreases in later stages of lactation when and milk yield decreases and diets are formulated accordingly.

Key Words: phosphorus, efficiency, dairy

0686 Effect of supplementary copper source on copper status in growing beef heifers offered a diet naturally high in copper antagonists. S. J. Whelan[1], T. M. Boland[1], V. P. Gath[2], J. C. Jacquier[1], and K. M. Pierce[*1], *[1]School of Agriculture and Food Science, University College Dublin, Ireland, [2]School of Veterinary Medicine, University College Dublin, Belfield, Ireland.*

The bioavailability of Cu sources fed to ruminant animals has been the subject of many research articles due to its essentiality in bodily processes and the complexities between Cu and other minerals such as Mo, S, and Fe, rendering Cu unavailable to the animal. As many of these complexes occur within the rumen, an attractive method of improving Cu bioavailability is to offer Cu sources which bypass the rumen digestive process and are subsequently digested and absorbed in the abomasum and small intestine, respectively. This experiment evaluated the effect of three Cu sources on animal Cu status where diets naturally high in antagonists are fed. Sixty beef heifers (*Bos taurus*) were used in a randomized block design based on liver Cu content and offered one of four dietary treatments (n = 15). These were: Control (Con), $CuSO_4$, Bioplex (Bio), and a novel Cu complex (NCu). The Con contained 20 mg Cu/kg DM whereas the other diets contained 54 mg Cu/kg DM. Animals were offered their basal diet of grass silage and concentrate (minerals: Fe, Cu, Mo, and S at 703, 17, 5, and 1400 mg/kg DM). Treatments were fed individually on a daily basis while blood sampling and weights were taken on a weekly basis with a liver biopsy harvested at the beginning (d −7) and end (d 56) of the trial. There was no effect of treatment on live weight (404 kg, P = 0.77). However, animals offered NCu gained more weight (+ 0.18 ± 0.11 kg/d, P = 0.03) than those offered Con. Similarly, liver Cu at d 56 was higher (+132.5 ± 25 mg/kg DM, $P < 0.01$) for animals offered NCu than those offered Con; animals offered Bio and $CuSO_4$ were not different from other treatments. Plasma Cu levels were in the normal biological range for cattle and were lower in Bio supplemented animals compared to other groups (-0.16 ± 0.03 mg/L, $P < 0.01$). Similarly, caeruloplasmin was within the normal range for cattle but was higher for animals offered $CuSO_4$ than those offered Bio (+3.41 ± 0.85 U/ml, $P < 0.01$). These results suggest that animals offered Con may have mobilized liver Cu to maintain Cu homeostasis in the blood as measured by caeruloplasmin and plasma Cu. The NCu complex gave the highest liver Cu concentration and weight gain, demonstrating the role of rumen protection of Cu in improving Cu bioavailability and animal performance.

Key Words: copper

0687 Evaluation of liver mitochondrial oxygen consumption of lactating Holstein dairy cows supplemented with Cobalt, Copper, Manganese and Zinc in organic and inorganic forms. G. Acetoze*[1], J. Champagne[2], J. J. Ramsey[3], A. M. Gehman[4], K. A. Dawson[5], and H. A. Rossow[6], *[1]University of California–Davis, Tulare, [2]VMTRC–UC Davis, Tulare, [3]University of California–Davis, Davis, [4]Alltech, Inc., Nicholasville, KY, [5]Center for Animal Nutrigenomics and Applied Animal Nutrition, Alltech, Nicholasville, KY, [6]VMTRC, University of California, Tulare.*

Production of reactive oxygen species (ROS) at mitochondrial level may cause membrane damage impacting energetic efficiency by yielding less ATP. The objective of this study was to evaluate the impact of different concentrations of organic and inorganic forms of Co, Cu, Mn, and Zn (Bioplex Co, Cu, Mn, and Zn; Alltech, Inc.) on liver mitochondrial respiration of lactating dairy cows at a commercial dairy. Fifty lactating Holstein dairy cows (70 DIM) were randomly assigned to five treatments: Control, Organic75, Organic100, Organic125, Inorganics ($CuSO_4.5H_2O$, $MnSO_4.H_2O$, and ZnSO4.H_2O supplemented at the same amount as Organic100) (Table 0687). Minerals were supplemented on top of control diet to individual cows daily with an oral solution of the mineral for 28 d (24 d for adaptation and 4 d of sample collection). On the last day of treatment, 1 g of liver tissue was biopsied to measure O_2 consumption in isolated mitochondria. Statistical analysis was performed in R (version 2.15.1) using ANOVA. State 3 respiration (maximum ATP stimulated respiration), State 4 respiration (maximum leak-dependent respiration), and respiratory control ratio (RCR = State 3/State 4) did not differ among treatments ($P = 0.72$, $P = 0.38$, and $P = 0.76$, respectively), which may be related to high variation in mitochondrial respiration among cows. Numerically, Organic100, 75, and inorganics had the greatest oxygen consumption for ATP production and the greatest rates of oxygen consumption during proton leak dependent respiration. If only considering oxygen consumption results, greater mitochondrial efficiencies would be expected for cows with less oxygen consumption during State 4 and greater oxygen consumption during State 3 respiration. In the present study, supplementation of Co, Cu, Mn, and Zn in Organic125 and control cows had the least oxygen consumption during State 4 respiration, however data on individual cow's feed intake may change these results. Concentration of minerals for Organic125 could be acting as antioxidants by decreasing the incidence of ROS and protecting mitochondria from oxidative damage. Limiting oxidative damage by feeding greater concentrations of antioxidants may prevent mitochondrial membrane damage increasing the efficiency of ATP production and potential increase on milk production and feed efficiency.

Key Words: dairy, mitochondria, minerals

Table 0687. Amount of minerals supplemented on top of control diet for each treatment

	Control	Organic75	Organic100	Organic125	Inorganics
			(mg/d)		
Co	2.96	14.70	19.60	24.50	19.60
Mn	354.00	125.07	166.76	208.45	166.76
Cu	472.00	215.07	286.76	358.45	286.76
Zn	1409.00	375.88	501.18	626.48	501.18

0688 Cobalt-lactate inclusion in a high forage total mixed ration fed to late lactation dairy cows. J. P. Pretz*[1], H. T. Purvis[2], D. Davis[2], B. Trautman[2], J. L. Anderson[1], K. F. Kalscheur[1], and D. Casper[1], *[1]South Dakota State University, Brookings, [2]Ralco Nutrition, Marshall, MN.*

Cobalt-lactate is a highly soluble source of Co in the rumen. Prior research evaluating higher Co feeding rates has been shown to increase ruminal fiber digestion. Feeding high forage rations to late lactation dairy cows to improve income over feed cost could potentially benefit from feeding higher ruminal soluble Co rates to enhance ruminal fiber digestion and nutrient digestibility. Twenty-four late-lactation (238 ± 68.8 DIM and 36.5 ± 5.4 kg milk) Holstein dairy cows (10 primiparous and 14 multiparous), were blocked by milk yield, DIM, and parity and randomly assigned to one of two treatments. Treatments included: 1) CONTROL diet containing cobalt carbonate fed at 58 mg/cow/d, and 2) TEST diet being the same basal diet but including an additional 5 g/cow/d of a 1% Co-lactate product (Co-Max) to increase levels of cobalt by 50 mg/cow/d. Rations were 70% forage and 30% of the respective experimental grain mix on a DM basis with the forage blend consisting of 60% alfalfa baleage and 40% corn silage (DM basis). Cows were fed the CONTROL ration during the covariate period of 7 d followed by 4 wk of data collection when CONTROL and TEST diets were fed. Milk production (26.2 and 25.8 kg/d for CONTROL and TEST, respectively throughout results) was similar ($P = 0.72$). Dry matter intakes (22.9 and 23.1 kg/d) were similar ($P = 0.8$). Concentration of milk fat (4.13 and 4.13%), milk protein (3.53 and 3.40%), and lactose (4.68 and 4.71%) were similar ($P = 0.98$, $P = 0.21$, and $P = 0.66$, respectively). Body weights (684 and 673 kg) were not different ($P = 0.11$). Feeding additional Co as cobalt-lactate did not influence milk production, milk composition, dry matter intake, or body weight for lactating dairy cows fed a high forage ration.

Key Words: dairy cattle, cobalt-lactate, high-forage diet

0689 Supplemental trace minerals (Zn, Cu, and Mn) as sulfates, organic amino acid complexes, or hydroxy trace mineral sources for shipping-stressed calves. A. W. Ryan*[1], E. B. Kegley[1], J. Hawley[1], J. A. Hornsby[1], J. L. Reynolds[1], and S. B. Laudert[2], [1]*Dep. of Animal Science, University of Arkansas Div. of Agriculture, Fayetteville,* [2]*Micronutrients, Indianapolis, IN.*

The objective of this study was to evaluate the effect of trace mineral supplementation from sulfate, organic amino acid complexes, or hydroxy sources on growth performance, morbidity and immune response to bovine viral diarrhea (BVD) vaccination in newly received stocker cattle. Crossbreed calves (n = 350; average BW = 240 ± 1 kg) were obtained from regional livestock auctions. Within each arrival set (block, n = 4), calves were stratified by BW and sex, and allocated into one of eight pens (10 to 12 calves/pen). Pens were assigned randomly to one of three treatments consisting of supplemental Zn (360 mg/d), Cu (125 mg/d), and Mn (200 mg/d) from sulfate (n = 2 pens/block), organic complexes (Availa4, Zinpro Corp., Eden Prairie, MN; n = 3 pens/block), or hydroxy (IntelliBond, Micronutrients, Indianapolis, IN; n = 3 pens/block) trace mineral sources fed over a 42- (block 4) to 45-d (blocks 1, 2, 3) backgrounding period. Cattle were observed daily for signs of morbidity from bovine respiratory disease (BRD) and treated according to a preplanned protocol if rectal temperature exceeded 40°C. Serum samples for BVD antibody titer analysis were obtained on d -1, 14, 28, and final day from the calves in 2 blocks (n = 175). Data were analyzed using the PROC MIXED of SAS with treatment as a fixed effect, block as a random effect, and pen as the experimental unit. When dead (n = 1) and chronic (n = 6) calves were removed from the dataset, final BW did not differ among treatments (280 ± 4 vs. 283 ± 3 vs. 280 ± 3 kg for sulfate, organic complexes, and hydroxy, respectively; P > 0.55) or ADG (0.94 ± 0.05 vs. 0.99 ± 0.04 vs. 0.93 ± 0.04 kg for sulfate, organic complexes, and hydroxy, respectively; P = 0.51). For all calves, dietary treatments had no effect on the number treated once (P = 0.93), twice (P = 0.71), or three times (P = 0.53) for BRD, or on the number of calves classified as chronic (P = 0.55). Trace mineral source had no effect (P = 0.78) on average medical cost per calf. Antibody titer response to BVD vaccination was not affected by trace mineral source (treatment × day, P = 1.00). Based on results from this experiment, source of trace mineral supplementation did not affect total weight gain, ADG, morbidity, medical costs, or antibody titer response to BVD vaccination during the receiving phase in shipping stressed calves.

Key Words: beef cattle, trace mineral

0690 Effect of inorganic or organic selenium supplementation during gestation and lactation on cow and pre-weaning calf performance. C. R. Muegge*[1], K. M. Brennan[2], R. P. Lemenager[1], and J. P. Schoonmaker[1], [1]*Purdue University, West Lafayette, IN,* [2]*Alltech Inc., Nicholasville, KY.*

Angus x Simmental cows (n = 48, BW = 594 kg, BCS = 5.26, Age = 2.7), pregnant with male fetuses, were used to determine the effect of selenium (Se) source during the last 80 d of gestation and first 105 d of lactation on cow and calf performance. At 203 d in gestation, cows were allotted to one of three treatments based on body weight, breed composition, and calf sire: no Selenium, organic Se, or inorganic Se. Diets contained corn silage, corn stover, haylage, dried distiller grains solubles, and mineral and were formulated to contain 10.4% CP and 0.90 Mcal/kg NEg during gestation and 12.1% CP and 1.01 Mcal/kg NEg during lactation. Diets were fed daily as a total mixed ration and none, 0.30 mg/kg Se as sodium selenite, or 0.30 mg/kg Se as Sel-Plex were top-dressed daily. Treatment diets were fed through 105 d post-partum (DPP). At 105 DPP cow-calf pairs were commingled until weaning at 210 DPP. At 68 DPP milk production was calculated using the weigh-suckle-weigh procedure, and a milk sample was collected to determine composition. Cow weight and BCS and calf birth weight did not differ at the beginning of the trial ($P \geq 0.55$). Cow BW and BCS ($P \geq 0.85$) did not differ between treatments at any time point during the study. Milk production, milk fat %, and total solids % ($P \geq .38$) did not differ among treatments. Milk protein % tended to increase in the inorganic Se diet compared to organic Se diet (P = 0.07) and milk lactose % tended to be greatest in the organic Se cows (P = 0.10). Conception to AI and overall pregnancy rates did not differ between the diets ($P \geq 0.39$). Calf weights and ADG did not differ for the 105 d experimental period ($P \geq 0.77$) or for the entire pre-weaning period ($P \geq 0.33$). In conclusion, dietary Se source did not affect cow performance, milk production, or reproductive ability. Organic Se decreased milk protein and increased milk lactose, but did not alter pre-weaning performance of the progeny.

Key Words: beef, cow/calf, selenium

0691 Effects of calf age at weaning on cow and calf performance and feed utilization in an intensive production system. J. M. Warner*[1], K. H. Jenkins[2], R. J. Rasby[1], M. K. Luebbe[2], G. E. Erickson[1], and T. J. Klopfenstein[1], [1]*University of Nebraska, Lincoln,* [2]*University of Nebraska, Scottsbluff.*

A 2-yr experiment compared the feed utilization of producing a weaned calf to 205 d of age between early and normal weaning in an intensive beef cow-calf production system. Multiparous, crossbred (Red Angus x Red Poll x Tarentaise x South Devon x Devon), lactating beef cows (n = 163) with

summer-born calves at side were blocked by prebreeding BW (H, M, L), stratified by calf age and assigned randomly to one of four treatments within strata. The experiment was a randomized complete block design with a 2 × 2 factorial arrangement of treatments with three replications (pens) per treatment per year (total $n = 24$). Treatment factors were: 1) location: eastern (ARDC) or western (PHREC) Nebraska, and 2) calf age at weaning: 91 ± 18 (EW) or 203 ± 16 (NW) d of age. Regardless of location, EW cows and calves and NW pairs were fed a common diet (60:40 distillers grains:crop residue [yr 1]; 40:40:20 corn silage:distillers grains:crop residue [yr 2], DM basis) from the time of early to normal weaning. EW cows were limit-fed (6.9 kg DM/cow daily), while EW calves were offered ad libitum access to feed (4.0 kg DM/calf daily). NW pairs were limit-fed the equivalent amount of DM consumed by EW cows and calves (10.8 kg/pair daily). All cattle were managed in earthen feedlot pens, with pen serving as the experimental unit. By design, BW and BCS at early weaning were similar ($P \geq 0.27$) between EW and NW cows. At normal weaning time, EW cows had greater BW than NW cows, and BW change from early to normal weaning was 17 kg greater ($P \leq 0.01$). Cow BCS at normal weaning time was not impacted ($P = 0.42$) by weaning management. Likewise, calf age at weaning had no impact on BCS change. As intended, calf BW at the time of early weaning was not different, but remained similar ($P = 0.38$) at normal weaning time. NW and EW calves gained 0.85 and 0.82 kg daily, respectively. Similar feed energy intake resulted in comparable performance between weaning regimens. These data indicate early weaning has minimal effect on reducing the feed energy needed to maintain a cow-calf pair. Thus, decisions regarding early weaning should be made on the basis of management rather than feed efficiency.

Key Words: cow, efficiency, weaning

0692 Can treatments of barley grain with lactic and citric acid improve performance of male calves?

K. Rezayazdi[*1], M. Nematpoor[2], and M. Dehghan Banadaky[1], [1]*Dep. of Animal Science, Faculty of Agriculture, University of Tehran, Karaj, Iran,* [2]*University of Tehran, Karaj, Iran.*

Thirty Holstein male calves with an initial body weight 308 ± 22 Kg were used in a completely randomized design with 3 treatments and 10 replicates in each treatment for 100 d. Rolled barley grain steeped in an equal quantity (i.e., in a ratio of 1: 1, wt/vol) of either tap water alone, 0.5% lactic acid solution, or 1% citric acid solution was added to rations. Therefore, dietary treatments included: 1) control (with rolled barley), 2) rolled barley treated with citric acid, and 3) rolled barley treated with lactic acid. The rations were formulated according NRC beef (1996) guidelines. Calves were housed in tie stalls and fed individually. Dry matter intake was measured daily, and weight gain was measured every 4 wk. All of data were analyzed with PROC MIXED of SAS. Final body weight differed across treatments ($P < 0.05$) being 424, 439, and 442 kg to the treatment 1, 2, and 3, respectively. Average daily gain was greater in treatment 2 and 3 vs. 1 ($P < 0.05$, 1.30, 1.48, and 1.50 kg/d, respectively). Dry matter intake was not different among treatments. Gain-to-feed ratio increased due to lactic or citric acid treatment compared with control ($P < 0.05$; 0.162, 0.167, and 0.144, respectively). Overall, feeding feedlot cattle with rolled barley grain treated with lactic or citric acid improved growth performance of calves.

Key Words: barley treated with acid, feedlot cattle, performance

0693 Starter crude protein concentrations on growth and intake of dairy calves.

S. A. McCullough[1], B. Houin[2], and T. D. Nennich[*1], [1]*Purdue University, West Lafayette, IN,* [2]*Homestead Dairy, Plymouth, IN.*

The objective of this study was to determine the effects of starter CP levels on growth, intake, feed efficiency, and plasma urea nitrogen (PUN) concentrations of dairy calves on a commercial dairy. In this randomized complete block design, 120 Holstein heifers (BW = 40.3 ± 4.9 kg) were blocked by birth date. Heifers were assigned to starter CP levels of 18, 20, 22, or 24% (as fed). Calves were fed whole milk and allowed ad libitum access to starter. All calves were fed milk 3x/day and received 5.7 L/d for 14 d, 6.7 L/d from d 15 to 21, and 7.6 L/d from d 22 to 1 wk before weaning when calves were reduced to 1.9 L once/d. Calves were weighed at birth and measured every 3 wk for BW, hip height, heart girth circumference (HGC), and hip width. Blood samples were taken at wk 12 and analyzed for PUN. Data were analyzed as repeated measures using the PROC PROC MIXED of SAS. At 12 wk, BW was greater ($P < 0.01$) for 24% compared to 18% calves (106.9 and 101.4 kg, respectively) with 20% and 22% (103.7 and 104.1 kg, respectively) being similar to all treatments. Overall average daily gain (ADG) for 20% and 22% (0.74 and 0.75 kg/d, respectively) were similar to 18 and 24%, but 18 and 24% (0.72 and 0.78 kg/d, respectively) were different ($P < 0.05$). Starter intake over the study was similar among treatments at 0.80, 0.83, 0.87, and 0.91 kg/d for 18, 20, 22, and 24%, respectively ($P > 0.23$). Overall feed efficiency was similar ($P > 0.45$) among treatments at 1.78, 1.83, 1.92, and 2.0 kg DM intake/kg gain, respectively. Hip height and HGC were similar among treatments ($P > 0.55$), but hip widths at 12 wk were greater for 22 and 24% ($P < 0.05$). As CP levels increased from 18 to 24%, PUN concentrations increased among treatments (11.8, 13.1, 15.2, and 16.4 mg/dL, respectively; $P < 0.001$). Feeding calves increasing levels of CP in starter did not result in differences in skeletal growth, feed efficiency, or overall starter intake. At 12 wk, feeding calves 24% CP starter resulted in greater BW than feeding 18% CP, but was similar to feeding 20 or 22% CP starter. Feeding 18, 20, or 22% CP starter resulted in similar ADG.

Key Words: dairy calves, starter, protein

0694 Influence of dietary carbohydrate fractions on growth and development of prepubertal dairy heifers. T. S. Dennis*, J. E. Tower, A. M. Mosiman, and T. D. Nennich, *Purdue University, West Lafayette, IN.*

The objective of this study was to evaluate the effects of altering dietary non-fiber carbohydrates (NFC) on heifer growth, dry matter intake (DMI), feed efficiency, and blood and rumen metabolites. Ninety Holstein heifers (145.3 ± 25.4 kg, 144 ± 26 d of age) were randomly allocated by body weight (BW) to one of 15 pens. Pens were randomly assigned to dietary treatments of high NFC (HNFC; 40.7% of diet DM), low NFC (LNFC; 31.4% of diet DM) and low NFC plus fat (LNFC+; 31.9% of diet DM). Diets were formulated to be isonitrogenous, with lower calculated ME for LNFC compared with HNFC and LNFC+. Heifers were fed diets for 112 d, and forage:concentrate ratios were increased from 35:65 to 60:40 on d 57 of the study. Body weights were taken every 2 wk, and hip and withers heights, body condition score (BCS), heart girth, hip width, and blood samples were collected monthly. Rumen fluid was collected esophageally 6 h after feeding from 10 heifers/treatment (two heifers/pen) to determine pH and volatile fatty acids (VFA) monthly. Data were analyzed as repeated measures using PROC MIXED of SAS with pen as the experimental unit. Feeding LNFC+ resulted in heifers that were 4.8 kg ($P < 0.10$) and 8.8 kg heavier ($P < 0.01$) at the end of the study compared with HNFC and LNFC, respectively. Average daily gains ($P < 0.01$) and feed efficiency ($P < 0.10$) were greatest for LNFC+ from d 0 to 56; however, no treatment differences were observed from d 57 to 112. Intake as a percent of BW was greatest for HNFC (3.3%) compared with LNFC (3.1%) and LNFC+ (3.1%) throughout the study ($P < 0.01$). Heifers fed LNFC+ were taller at the hip and withers than heifers fed HNFC ($P < 0.05$) and LNFC ($P < 0.01$) on d 112. Additionally, feeding LNFC+ resulted in greater BCS compared to LNFC ($P < 0.01$), but not HNFC ($P > 0.10$). Rumen pH was lower for HNFC from d 0 to 56 ($P < 0.05$), but similar among treatments at d 84 and 112. Proportions of acetate and butyrate were least and greatest, respectively ($P < 0.01$), for HNFC from d 57 to 112. Unexpectedly, increasing dietary NFC did not improve growth compared to lower NFC diets despite increased DMI, indicating that energy availability may have greater impacts on growth than dietary carbohydrates.

Key Words: heifer, carbohydrates, growth

RUMINANT NUTRITION: THE GLEN BRODERICK SYMPOSIUM – IMPROVING NITROGEN UTILIZATION IN DAIRY COWS

0695 Opening remarks and overall impact of Dr. Glen Broderick on research around the world.
A. Faciola*, *University of Nevada, Reno, NV.*

Dr. Glen Broderick has been an ADSA member since 1968. Glen has been an ad hoc reviewer for JDS since 1975 and is currently a collaborator with the USDA-ARS and emeritus professor at UW-Madison. Glen received his B.S., M.S., and Ph.D. degrees from UW–Madison. Glen served as an assistant and associate professor of animal science at Texas A&M University from 1972 to 1980. In 1981, he returned to Madison to work at the USDFRC and was appointed as professor of dairy science at UW–Madison. His research focused on protein nutrition of the lactating cow, with emphasis on enhancing utilization of feed nitrogen for milk production and reducing nitrogen excretion. This work involved developing strategies to minimize dietary CP without losing milk or protein yield, identifying factors influencing microbial protein synthesis in the rumen, and perfecting methodologies for quantifying ruminal protein degradation both in vivo and in vitro. Glen's research has generated more than 135 peer-reviewed publications, of which over 100 are in JDS and JAS alone. Glen's major contributions to dairy science include: 1) understanding ruminal microbial metabolism utilizing isotope marker techniques, 2) improvements of in vitro methodologies for assessing ruminal microbial growth and ruminal protein degradation, 3) in vivo quantification of ruminal nitrogen metabolism, and 4) improving overall nitrogen utilization and reducing the environmental impact of milk production. According to the Web of Science, Glen's research articles have been cited more than 4580 times, with an average of at least 105 citations per year. According to the same source, Glen's most cited article is Broderick and Kang. 1980. J. Dairy Sci. 63: 64–75, which has been cited over 600 times. Moreover, in addition to teaching and mentoring of graduate students at UW–Madison and other universities around the world, he has served on the editorial boards of several journals, including JDS, JAS (1981–1993), and Animal Feed Science & Technology (1999–2013), among others. Glen presented a number of invited papers at meetings in more than 25 different countries and mentored over 50 graduate students, postdocs, and visiting scientists. He did sabbaticals at the Rowett Research Institute (1985–1986) in Aberdeen, Scotland, and the Swedish Agricultural University in Uppsala (1997–1998 and 2013). Glen was named a "highly-cited researcher" by the Web of Knowledge in 2005 and received the Nutrition Research Award of the American Feed Industry Association presented by the American Dairy Science Association (1997).

Key Words: dairy cow nutrition

0696 Conundrums of protein and peptide metabolism in the rumen.
R. J. Wallace*, *Rowett Institute of Nutrition and Health, Aberdeen, UK.*

Nitrogen retention in ruminants is inefficient due to rumen microbial activity. Protein in forages is particularly vulnerable, because a high proportion of forage carbohydrate comprises cellulose or hemicellulose, which are slowly degraded, in contrast to the soluble protein, which degrades rapidly. The release of energy-yielding sugars, which enables ruminant microbes to trap the forage protein N, therefore does not match the availability of amino acids, which are degraded excessively, leading to high N emissions by the animal. Protein supplements are almost as vulnerable. The problem with supplements is that they tend to be variable in their degradation rate; thus, diet formulation relies on knowledge of their rate of degradation in the rumen. How to assess protein degradation and the chemistry and microbiology of the process have long been interests of Glen Broderick. It was therefore natural that Glen might want to spend time at the Rowett Research Institute, where Bob Orskov and I shared this interest. Malt whiskies and old Scottish castles also had their part to play! Bob was a committed advocate of the nylon-bag method, a technique that Glen abhorred. I sat on the fence on that one. It might seem like a trivial thing to do, to develop a method to assess the rate and extent of protein degradation. Many have tried to develop in vitro incubations that enable the determination of those characteristics, soon finding that something simple, like the release of ammonia, was vastly in error. Protein supplements are not comprised entirely of protein, indeed starchy carbohydrate even exceeds protein in some supplements. Thus, an enzyme system is fraught with difficulty. The physical form of the supplement is an issue: to grind or not to grind? Furthermore, when ruminal digesta is used as an inoculum for protein degradation assays hydrolyses in vitro, microbes mop up the released amino acids and ammonia as they ferment the carbohydrate. Glen and his colleagues devised an in vitro system that overcame these problems and at the same time revealed some fundamental properties of ruminal protein metabolism. Peptides as an intermediate of the proteolysis cascade were a contentious topic when Glen first arrived on Scottish shores. He and I had great fun in establishing the sequence characteristics that dictate microbial degradation rates of peptides— particularly the importance of the N-terminal amino acids and whether the peptide was basic or acidic.

Key Words: proteolysis, peptide metabolism, rumen

0697 Dr. Glen Broderick's contributions to in vivo quantification of ruminal nitrogen metabolism using the omasal sampling technique. P. Huhtanen*, *Swedish University of Agricultural Sciences (SLU), Umea, Sweden.*

Dr. Glen Broderick has made a significant contribution to improve understanding of protein and amino acid nutrition of dairy cows with the aim of improving overall nitrogen utilization and reducing the environmental impact of milk production. Development of in vitro method to determine ruminal protein degradability was one of his main contributions at earlier stages of career. More recently, he has focused on studying ruminal N metabolism in lactating dairy cows, with the main emphasis in optimizing the efficiency of microbial N synthesis. In these studies Dr. Broderick and his PhD students have applied and developed omasal sampling technique. The method is now widely replaced more invasive duodenal sampling technique, but it also allows studying ruminal N metabolism in more detail as sampling takes places before hydrolysis in the abomasum and endogenous contribution is less. Applying omasal sampling technique Dr. Brodrick demonstrated that the flow of soluble NAN fractions has an important contribution to feed N flow from the rumen. Soluble feed amino acid (AA) flow accounted approximately 10% of omasal total AA flow indicating substantial escape of dietary soluble AA from ruminal degradation. This calls into question the use of in situ estimations of protein degradation to predict RUP flow. Oligopeptides had the greatest contribution of soluble feed AA flow. The study investigating gradual replacement of solvent extracted soybean meal (SBM) with lignosulfonate-treated SBM concluded that NRC (2001) overestimated the supply of RUP from treated SBM. The other important conclusion from this study was decreased microbial protein synthesis with increased proportion of RUP in dietary protein. Consistently with this, replacement of solvent extracted SBM with urea and lignosulfonate-treated SBM decreased NAN and microbial N flow at the omasum demonstrating that microbial protein synthesis is stimulated by true protein RDP compared with NPN. Comparison of red clover and alfalfa silages supported the conclusions from previous studies; increased RUP supply from red clover was counteracted by reduced microbial protein synthesis. Meta-analysis of the data from omasal sampling studies indicated usually smaller residual variance of digesta flow estimates compared with studies applying duodenal sampling, probably reflecting more the marker system applied to estimate digesta flow than sampling site per se. The results suggested that the NRC (2001) system underestimates microbial N flow and overestimates the supply of RUP. The contributions Dr. Broderick emphasize the need for re-evaluation of the feed protein systems.

Key Words: Dr. Broderick, omasal sampling, dairy cow

0698 Glen Broderick's contributions to improving in vitro methodologies for assessing ruminal microbial growth and ruminal protein degradation. P. Udén*, *Swedish University of Agricultural Sciences, Uppsala, Sweden.*

Dr. Broderick has supervised numerous graduate students during his career, been a very active contributor to scientific meetings throughout the world, and also published 126 full papers in refereed journals (Web of Knowledge, Jan. 16, 2014) of which 28 have "in vitro" in the title. The most cited (707) paper of them is so far Broderick and Kang (J. Dairy Sci. 63:64–75, 1980), describing an automated method to analyze ruminal ammonia and amino acids. This method was essential for enabling use of the inhibited in vitro (IIV) system, previously developed by Broderick (J. Nutr. 108:181–190, 1978), to measure release of ammonia and amino acids. He subsequently compared the IIV method with solubility estimates (Broderick and Craig, J. Nutr. 110:2381–89, 1980) and against in sacco estimates (Broderick et al., J. Anim. Sci. 66:1739–45, 1988). In sacco rates were only 36% of those of IIV due to an immediate loss of more rapidly degradable protein in soluble and fine particle forms. This, however, did not prevent adoption of the in sacco method as a standard method for protein evaluation, at least in Europe. The theory of the IIV method is elegant: to inhibit microbial protein synthesis without affecting protein hydrolysis and to estimate degradation as the sum of microbial extra- and intracellular metabolism. The latter feature is attractive as casein data from Broderick and Craig (J. Dairy Sci. 72:2540–48,1989) suggested that uptake of amino acids and peptides is too slow to be ignored. So far, this methodological feature is only shared with the gas-in vitro method of Raab et al., Br. J. Nutr. 50:569–82, 1983). However, the use of inhibitors has limited the use of long incubation times ($> \sim 4$ h) due to a concomitant loss of microbial activity. Nevertheless, the IIV method seems to give biologically sensible degradation rates for sufficiently rapidly degrading proteins. Dr. Broderick has also been involved in developing a 15N based in vitro method to estimate microbial growth (Hristov and Broderick, J. Dairy Sci. 79:1627–37, 1994). An important finding of this study was that microbial protein synthesis is positively related to protein degradation which implies a compensatory effect of low-escape proteins by an increased supply of microbial amino acids to the duodenum.

Key Words: in vitro, protein, dairy cow

0699 Dr. Glen Broderick's contributions to protein and amino acid nutrition of the dairy cow. A. N. Hristov*, *Dep. of Animal Science, The Pennsylvania State University, University Park.*

Dr. Broderick's interest in amino acid (AA) nutrition of the dairy cow started as early as the 1970s, stemming from his

M.S. and Ph.D. studies at the University of Wisconsin under the supervision of the late Dr. Larry Satter. In these early experiments, Dr. Broderick demonstrated that abomasal infusion of casein plus Met in cows fed a 16% crude protein diet increased milk protein content and yield. In his thesis work, Dr. Broderick utilized the concept that an essential AA will not accumulate in plasma, if it is limiting, but will start to accumulate once demands for it in the tissues are met. Using this approach, he concluded that Met, Val, and Lys were most likely limiting AA for milk production in dairy cows. Dr. Broderick's interest in Met continued throughout his career resulting in a number of key publications on production responses to rumen-protected Met (RPMet) products. These experiments demonstrated that, under some circumstances, supplemental RPMet may alleviate the negative impact of decreased dietary protein on milk production and composition with the additional benefit of drastically reducing N excretion in urine and manure. His protein and AA research branched into investigating sources of rumen-undegraded protein (RUP) for the high-producing dairy cow. Early experiments in this challenging area showed increased milk production with roasted soybeans compared with solvent-extracted soybean meal. By comparing forages in the basal diet, it was concluded that resistant protein sources may have a greater value with diets containing alfalfa silage than corn silage-based diets. Working at the U.S. Dairy Forage Research Center, Dr. Broderick's research was focused exclusively on the nutritional aspects of feeding forages, specifically alfalfa, to dairy cows. A series of studies was conducted to assess the feeding value of alfalfa silage vs. hay, with or without preservatives, and the benefit of protein supplementation of alfalfa silage-based diets. This work confirmed that alfalfa silage-based diets may benefit from RUP supplementation and identified the effectiveness of various protein feeds as RUP sources supplying limiting AA postruminally. Other forages, including tanniferous plants, were also investigated as dairy feeds. Research on urea vs. true protein sources established maximum urea supplementation levels. Studies on the interaction of fat and RUP challenged the concept that fat-supplemented diets would benefit from RUP supplementation. These numerous contributions have made Dr. Broderick one of the world's foremost experts in protein nutrition of the dairy cow.

Key Words: Glen Broderick, amino acid, dairy cow

0700 Exploring milk urea-N excretion as a nutritional and environmental management tool for the dairy industry. M. A. Wattiaux* and P. M. Crump, *University of Wisconsin–Madison, Madison.*

In controlled experiments, concentration of urea-N in milk, commonly referred to as milk urea-N (MUN), has been highly correlated with dietary CP level, N use efficiency (NUE, milk-N/intake-N) and urinary urea-N excretion (UUNE). However, under field conditions, variations due to non-nutritional factors (e.g., sampling type, frequency of milking, milk production) and lack of information about N intake the day of DHI testing have lessened the value of MUN as a management tool. This study explored the use of milk urea-N excretion (MUNE) as a UUNE predictor, and the use of MUNE per unit of milk protein yield (PY) as an indicator of NUE. Using DHI (AgSource-CRI) records from 2005 to 2013, we determined the association between PY and MUN or MUNE (calculated as MUN x milk production, regardless of sampling type). Then, we studied the relationship between MUNE/PY and NUE, and between MUNE and UUNE with data of a 128-cow nutritional study. Finally, we compared the MUNE/PY of DHI herds to the values obtained from the nutritional study. Regression analysis of approximately 1.5 million test-day MUN records of 529 DHI herds indicated no linear ($P = 0.08$) relationship between PY and herd-level MUN, but the relationship between PY (g/d) and MUNE (mg/d) was described as: PY = 0.173 + 4.19xMUNE ($r^2 = 0.995$, $P < 0.001$) for PY in the range of 600 to 1300 g/d. In the nutritional study, MUNE was calculated as average morning and evening MUN weighted by milk production at each milking. The relationship between UUNE and MUNE was described as: UUNE (g/d) = 26.8xMUNE ($r^2 = 0.991$, $P < 0.001$) for UUNE in the range of 40 to 125 g/d. Furthermore, MUNE/PY increased from (mean ± SE) 1.1 ± 0.3, to 2.2 ± 0.3, 3.6 ± 0.5, and 4.3 ± 0.3 mg/g as NUE decreased linearly ($P < 0.01$) when mid- to late-lactation cows were fed diets of 11.8, 13.1, 14.6, and 16.2% CP (DM basis), respectively. In the DHI database, however, MUNE/PY averaged 4.6 ± 0.01 mg/g, but ranged from 2.5 to 6.7 mg/g for the 47 herds for which MUNE could be calculated as in the nutritional study. In conclusion, MUNE may be used as a reliable predictor of UUNE and indicator of NUE. Comparing MUNE/PY of the nutritional study to MUNE/PY of selected Wisconsin dairy herds suggested that producers could feed cows to increase NUE and lower UUNE simultaneously across a wide range of PY. Additional research is needed to ascertain the usefulness of MUNE and MUNE/PY as management tools.

Key Words: protein nutrition, nitrogen, environment.

RUMINANT NUTRITION X

0701 Evaluation of 2013 survey of beef producers in Nebraska. M. Jones*, *University of Nebraska–Lincoln, Lincoln.*

Methane is a type of greenhouse gas (GHG) that can capture heat in the atmosphere 21 times more efficiently than carbon dioxide, illustrating its potency as a GHG. Enteric fermentation by ruminants is a known contributor to methane production. A survey was sent to 3391 Nebraska cattle producers with a 19% response rate. The objective of the survey was to evaluate producer opinions regarding beef cattle, climate, and their interaction to direct extension education at reducing GHG emissions in intensive and extensive beef systems. Data were analyzed using the chi-squared method in SPSS. Before accounting for size and type of operation, overall findings were not significant even though numerical differences were evident for many questions. When asked whether they agree or disagree with the statement "methane production impacts cattle performance," 48.1% of all respondents neither agreed nor disagreed. Almost half (45.6%) disagreed with the statement "cattle diet influences methane production." The majority of respondents believed cattle had a positive impact on the environment and reported their confidence in methane production as "not very confident" or "somewhat confident" (34.9 and 45.1%, respectively). After accounting for size and type of operation, significant variables were found using a 99% confidence interval. Feedlots of all sizes tended to agree they were likely to adopt practices that would improve animal performance ($\chi^2 = 45.8$). Veterinarians tended to neither agree nor disagree with methane production being a concern to the environment ($\chi^2 = 22.0$). Producers who obtain livestock production information from the government and other sources tended to agree that cattle diet influences methane production ($\chi^2 = 29.0$). An open-ended question was included in the survey, and responses contained themes on how methane production by cattle was a minor issue, cattle impact on the environment outweighs any negative effects by methane production, and an acknowledgement of a lack of knowledge on the subject. While survey analysis has shown differences among groups for many of the questions, there does not appear to be one specific target group in need of outreach activities. Therefore, extension outreach efforts should focus on current management practices that improve profitability of the operation while also including information about how to reduce methane production in intensive and extensive systems.

Key Words: greenhouse gases, methane, beef cattle, education

0702 Meta-analysis of concentrate supplement effects on voluntary intake in high and low quality pastures. J. R. R. Dórea and F. A. P. Santos*, *University of Sao Paulo, Piracicaba, Brazil.*

The objective was to evaluate the effects of level of supplementation and forage quality on forage and total dry matter intake (DMI). Individually intakes from 1153 beef animals reported in 45 articles published from 1974 to 2011 were compiled. Forage was classified as high quality (more than 9% of CP) and low (less than 9% of CP). A meta-analysis approach was used according to St. Pierre (2001). For high quality pastures forage DMI decreased linearly as the supplementation level increased (-0.651% BW for energy 1% BW supplementation level) ($P < 0.05$). However, total DMI increased linearly ($P < 0.05$) as supplementation level increased (0.348% BW for energy 1% BW supplementation). On the other hand, for low quality pastures forage DMI was increased up to 0.25% BW supplementation level and it was decreased ($P < 0.05$) with high levels of supplementation. Total DMI was increased linearly ($P < 0.05$). The positive effect of supplementation fed up to 0.25% BW on low quality forage intake is due to the high CP content of these supplements supplying RDP to microbes. The negative effect of supplementation on forage DMI occurs when doses are greater than 0.25% BW, and energy is included in the supplement.

Key Words: pasture, protein, supplementation

Table 0702. Best-fit equations for simple regression of response to concentrate supplementation on voluntary intake in different pastures quality

Pasture quality	Variable	Intercept	SE	Slope β1	SE	β2	SE	β3	SE	r^2	RMSE
High	TI	2.35	0.15	0.348	0.242	–	–	–	–	0.66	0.462
	FI	2.35	0.15	-0.651	0.242	–	–	–	–	0.35	0.465
Low	TI	1.70	0.13	0.900	0.122	–	–	–	–	0.65	0.338
	FI	1.63	0.14	1.732	0.789	−5.281	2.670	3.384	2.126	0.30	0.372

FI = forage intake, TI = total intake, SE = standard error, RMSE = root means square error.

0703 Determining the preference and in situ digestibility of a microalgae co-product for beef cattle. M. L. Van Emon*, S. L. Hansen, and D. D. Loy, *Iowa State University, Ames.*

Two experiments were conducted to determine preference (Exp. 1) and in situ digestibility (Exp. 2) of dried, mechanically de-oiled, milled microalgae co-product (ALG) in beef steers. In both experiments, three ruminally cannulated steers (998 ± 103 kg BW) and four treatments were utilized: 1) dry rolled corn-based diet (CON), 2) 15% ALG as a DM replacement of corn (ALG15), 3) 30% ALG (ALG30), and 4) 45% ALG (ALG45). Exp. 1 was performed in a 3 × 6 Latin square design with six 5-d periods and six paired diet combinations. Steers were fed the CON diet for 3 d. On d 4, each steer was offered two diets, placed in either side of a bunk divider in-tubs. Steer diet preference was determined based on DM disappearance for the 4-h immediately post-feeding. On d 5, paired diets were again offered to each steer, on the opposite side of the divider. Exp. 2 was conducted in a 3 × 4 unbalanced Latin square design with three diets fed each period and four 14-d periods. Steers were limit-fed at 2% of BW and adapted to diets for 12 d. On d 13, Dacron bags containing samples of dried and ground corn, soyhulls, or ALG were incubated in the rumen for 6, 12, 24, or 36 h to determine DM disappearance. Data were analyzed using Glimmix and PROC MIXED of SAS for Exp. 1 and 2, respectively. In Exp. 1, the proportion of total DM consumed by steers during the 4-h period was affected ($P = 0.01$) by the paired diet combination. Intake of ALG45 was lesser ($P \leq 0.008$) when offered in combination with the ALG15 or ALG30 diets, but not when offered with CON ($P = 0.76$). No other paired diet combinations altered ($P \geq 0.23$) DMI. In Exp. 2, inclusion of ALG in the diet did not affect ($P \geq 0.12$) rate of, or overall digestibility of, corn, soyhulls, or ALG (71.5 ± 0.83% DM disappearance for ALG at 24 h). Additionally, DMI was linearly decreased ($P = 0.05$) as ALG increased in the diet due to lesser intake ($P = 0.05$) by ALG45 compared with CON, while ALG15 and ALG30 did not differ from CON ($P \geq 0.19$). In summary, steers readily consumed the microalgae co-product but preferred concentrations of less than 45% of diet DM under the conditions of these experiments.

Key Words: beef, digestibility, microalgae

0704 Digestibility of traditional and adding cellulosic ethanol wet distillers grains in finishing lambs. E. L. Lundy*, M. L. Van Emon, D. D. Loy, and S. L. Hansen, *Iowa State University, Ames.*

The feeding value of further processed distillers grains is unclear. A new, secondary fermentation process for converting corn kernel fiber into cellulosic ethanol, including a pretreatment with cellulosic enzymes, yeast, and heat, results in a novel wet distillers grain (WDG) called Adding Cellulosic Ethanol WDG (A-WDG). The study objective was to evaluate the impact of increasing inclusion of WDG from traditional WDG (T-WDG) or A-WDG on nutrient digestibility in lambs. Ten wethers (34.1 ± 0.74 kg) were used in a replicated 5 × 5 Latin square with 15-d periods, including 10-d of diet adaptation and 5-d of fecal and urine collection. Lambs received one of five diets per period: a corn-based control containing 7.5% each of T-WDG and A-WDG (CON), and 30% and 45% inclusion of T-WDG (30T-WDG or 45T-WDG) or A-WDG (30A-WDG or 45A-WDG) on a DM basis. Data were analyzed using PROC MIXED. Dry matter intake (DMI) was not affected ($P \geq 0.25$) by concentration of T-WDG. However, DMI was quadratically affected ($P = 0.02$) by increased concentration of A-WDG, due to lesser DMI by lambs fed 30A-WDG. Digestibility of DM tended to decrease quadratically ($P = 0.09$) in lambs fed T-WDG diets (80.6, 80.0, and 77.4%, SEM 0.57 for CON, 30 and 45T-WDG, respectively). Digestibility of DM linearly decreased ($P < 0.01$) as A-WDG inclusion in the diet increased (78.3 and 75.3%, for 30 and 45A-WDG, respectively). Diet NDF concentration linearly increased ($P < 0.01$) with increasing inclusions of A-WDG (24.6, 31.0, and 33.6%, SEM 0.83 for CON, 30A-WDG, and 45A-WDG, respectively). Diet NDF concentration quadratically increased ($P = 0.03$) with increasing inclusions of T-WDG (26.9 and 32.2%, for 30T-WDG, 45T-WDG, respectively). Digestibility of NDF and ADF did not differ ($P \geq 0.25$) with increased inclusion of A-WDG in the diet. A linear increase in NDF and ADF digestibility was observed with increased inclusion of T-WDG ($P < 0.05$; 50.8, 51.8, and 55.1%, SEM 1.04 for NDF digestibility, and 50.2, 51.8, and 57.2%, SEM 1.74 for ADF digestibility of CON, 30T-WDG, and 45T-WDG, respectively). In this study, WDG from a novel, secondary fermentation process appeared to be an effective substitute for corn in finishing diets, with similar fiber digestibility and a slight decrease in DM digestibility as inclusions increased. With traditional WDG, fiber digestion was linearly improved with increasing inclusions and DM digestibility was decreased only at the highest inclusion.

Key Words: cellulosic ethanol, digestibility, wet distillers grains

0705 Effect of sugarcane fiber digestibility and mode of conservation on intake and ruminal short chain fatty acids of growing steers. *D*. Sousa[*1], B. Mesquita[1], J. Diniz-Magalhes[1], F. Rodriguez[2], I. Bueno[1], and L. F. P. Silva[2], *[1]University of São Paulo, Pirassununga, Brazil, [2]University of Sao Paulo, Pirassununga, Brazil.*

Effect of sugarcane stalk fiber digestibility (NDFD) and method of conservation on intake and ruminal short chain fatty acids (SCFA) was evaluated. Eight ruminally cannulated steers (275 ± 20 kg BW) were used in a duplicated 4 × 4 Latin square design with a 2 × 2 factorial arrangement of treatments. Two sugarcane genotypes with differing stalk

NDFD were used: IAC86–2480 with higher NDFD (33.7% 30h-NDF digestibility), and SP91–1049 with lower NDFD (29.6% 30h-NDF digestibility). Treatment diets contained 40% sugarcane (DM basis) as sole roughage source given as freshly-chopped or as silage. All diets were formulated with 14.8 CP to provide daily gain of 1.2 kg/d. Animals were housed individually in tie-stalls with free access to water, and fed ad libitum allowing 10% orts. Periods lasted for 14 d, with 10 d for adaptation and 4 d for sample collection. Dry matter intake was determined on d 10, 11, and 12, and rumen fluid samples were collected at six times: 0, 1, 3, 6, 9, and 12 h after feeding on d 14. Samples were taken from three areas of the rumen, filtered through a 1-mm nylon mesh, and centrifuged at 6500×g for 15 min. A 2-mL subsample of the supernatant was taken, mixed with 0.4 mL of formic acid for SCFA determination by gas chromatography. Main effects of sugarcane genotype (GEN), method of conservation (CONS), and their interaction were tested by PROC MIXED. Feeding sugarcane with higher NDFD increased DM intake (5.6 vs. 4.5 ± 0.5 kg/d, $P = 0.01$), however the interaction GEN x CONS was significant ($P = 0.01$). The effect of greater NDFD on DMI was only significant when feeding sugarcane as silage ($P < 0.01$), having no effect on DMI when sugarcane was fresh ($P = 0.53$). Total concentration of SCFA was higher for fresh sugarcane compared with silage (114 vs. 99 ± 12 mM, $P = 0.05$). Conserving sugarcane as silage resulted in greater acetate proportion in the rumen, when compared with fresh sugarcane (58.7 vs. 55.8 ± 1.6% of total SCFA, $P = 0.01$). Proportion of propionate was also effect by conservation method, with greater proportion for diets with fresh sugarcane than sugarcane silage (24.2 vs. 20.6 ± 1.6% of total SCFA, $P = 0.01$). There was no effect of GEN of SCFA in the rumen. Increased in vitro NDFD improved intake, but only when given as silage. Feeding sugarcane ensiled decreased total SCFA and propionate proportion and increased acetate proportion.

Key Words: sugarcane silage, cattle, NDF digestibility, short chain fatty acids.

0706 Evaluation of a mixture of crude glycerol and molasses as an energy supplement for beef cattle consuming bermudagrass hay.

F. M. Ciriaco*, D. D. Henry, V. R. G. Mercadante, T. Schulmeister, G. C. Lamb, and N. DiLorenzo, *University of Florida, Marianna.*

The objective of this study was to evaluate the effects of a crude glycerol:molasses supplement on forage digestibility and cattle performance. Twenty-four Angus crossbred heifers (380 ± 31 kg) were used in the study. On d 0, heifers were weighed after 16-h feed withdrawal, stratified, blocked by initial BW (2 blocks: lightest and heaviest), and randomly assigned to one of four treatments: 0.00, 0.45, 1.36, and 2.27 kg/d of a 50:50 liquid mixture of crude glycerol:molasses. Heifers were housed in individual pens for 28 d and had ad libitum access to ground Tifton 85 bermudagrass hay (13.0% CP, 56% TDN, DM basis). Individual intake of hay was monitored using a GrowSafe feed intake monitoring system. The liquid supplement was weighed and offered daily to each individual animal. Any unconsumed amount of supplement was weighed and recorded. Feed (hay and liquid) and fecal samples were collected starting on d 22 and d 23, respectively, for four consecutive days to determine apparent total tract digestibility of DM, OM, CP, NDF, and ADF. Fecal samples were collected twice daily at 0800 h and 1600 h from the ground, inside the pen, immediately after the animal defecated. Feed and fecal samples were pooled within heifer and indigestible NDF (iNDF) was used as an internal indigestible marker. Concentrations of iNDF in feed and feces were determined by in vitro incubations conducted for 288 h. Data were analyzed as a generalized randomized block design using heifer as the experimental unit and the model included the fixed effects of treatment, and the random effect of block. Orthogonal polynomial contrasts were conducted to determine the effects of supplementation level on animal performance or nutrient digestibility. There was a linear effect ($P \leq 0.05$) of liquid feed supplementation level on ADG, total DMI, and G:F measured using hay DMI only. No effect on G:F ($P = 0.70$) was observed using total DMI (hay plus supplement). The ADG was 1.31, 1.37, 1.39, and 1.56 kg for 0, 0.45, 1.36, and 2.27 kg/d, respectively. Apparent total tract digestibility of DM, OM, NDF, and ADF increased linearly ($P \leq 0.05$), while that of CP decreased linearly ($P = 0.01$) as the level of supplementation increased. The inclusion of up to 2.27 kg/d of a mixture of crude glycerol:molasses supplement may favor forage fiber digestion, improving performance of beef cattle.

Key Words: crude glycerol, molasses, forage digestibility

0707 The effects of dietary energy density and intake restriction on apparent maintenance energy requirements of beef cows.

L. A. Trubenbach*, T. A. Wickersham, and J. E. Sawyer, *Texas A&M University, College Station.*

Intensification of cow calf systems may offer a mechanism to increase land use efficiency of beef production. To determine effects of dietary energy density and intake restriction on energy requirements of beef cows, 32 crossbred cows were individually fed using Calan gates. Cows were fed either a high energy density (H; 1.54 Mcal NEm/kg) or low energy density (L; 1.08 Mcal NEm/kg) diet at each of two levels of intake to achieve 80 or 120% of maintenance energy requirements as predicted by the NRC model. Cows were blocked by BW and treatments were applied in a 2 × 2 factorial to yield four treatment combinations (H80, H120, L80 and L120). After initial treatment application (d −7), cows were weighed daily for 7 d to detect measurable fill change. To accommodate initial fill differences, BW gain was measured from d

−4 to d 42. On days −7 and 42, 12th rib fat thickness was measured via ultrasound. Equations from the NRC model were utilized to calculate heat energy (HE) for individuals. All responses were analyzed as a randomized block design with a factorial treatment arrangement. No energy density by intake level interactions were observed for any response ($P > 0.14$). While there was a difference ($P < 0.01$) in initial body weight between energy density groups due to differential fill loss before d −4, neither diet energy density ($P = 0.09$) nor intake restriction ($P = 0.13$) affected change in BW over the 46-d observation period. Similarly, change in rib fat was not affected by diet energy density ($P = 0.48$) or intake restriction ($P = 0.24$). Cows fed H had 11.6% lower ($P < 0.01$) HEd^{-1} and 9.9% lower maintenance requirements (daily HE/kg $BW^{0.75}$; $P < 0.01$) than cows consuming L. Cows fed 80 had 28.7% lower ($P < 0.01$) HEd^{-1} and 29.1% lower maintenance requirements ($P < 0.01$) compared to cows fed 120. When predicted NEm requirements were based on the equation: 0.077Mcal NEm per $BW^{0.75}$, apparent maintenance requirement deviations were greater (more negative) in both H ($P < 0.01$) and 80 ($P < 0.01$). These results suggest that the additive effects of increasing diet energy density and restricting intake reduce apparent maintenance requirements of beef cows. Substantial gains in efficiency of maintaining beef cows in intensive systems can be achieved by limit feeding an energy dense ration.

Key Words: cow energy requirements

0708 Comparison of the effects of pectin and starch on the rumen fermentation, growth performance, and microbial populations in sheep. J. Liu*[1], M. Liu[1], and J. X. Liu[2], *[1]Institute of Dairy Science, Zhejiang University, Hangzhou, China, [2]Zhejiang University, Hangzhou, China.*

Supply of available energy is important for microbial synthesis in the rumen. Pectin and starch are two primary sources of soluble carbohydrates, but remarkably different in digestion and fermentation characteristics. This study was conducted to compare the effects of pectin and starch on rumen metabolism, growth performance, and microbial populations in sheep. Forty-five male sheep (40.2 ± 3.16 kg) were divided into five groups of nine animals each according to body weight, with three pens of three sheep in each group, and then assigned to five dietary treatments with supplementation of 0, 2.5, and 5% pectin or corn starch, respectively, to a basal diet consisted of corn stover and concentrate mixture (50:50, DM basis). The trial lasted 5 wk, and feeds offered and refused were recorded for two consecutive days every week. Body weights were measured at the beginning and end of the feeding trial for two consecutive days. At the end of the trial, two-thirds of experimental sheep were slaughtered before morning feeding to collect samples of rumen contents. Dry matter intake was increased quadratically or decreased linearly with the increasing level of pectin or starch, respectively. Increasing level of pectin led to a linear increase ($P < 0.01$) in microbial protein synthesis and daily weight gain, with highest values at 5% pectin among all treatments ($P < 0.01$). Total volatile fatty acids concentration in the rumen was linearly increased ($P < 0.01$) by inclusion of either pectin or starch, but the ratio of acetate to propionate was not affected. Abundances of *Treponema* genus and *Treponema saccharophilum* quantified by real-time PCR were positively stimulated ($P < 0.01$) only by pectin, suggesting their specific role on pectin digestion. On the contrary, abundances of typical rumen amylolytic bacteria such as *Succinivibrio dextrinosolvens*, *Ruminobacter amylophilus*, *Succnimonas amylolytica* were higher ($P < 0.05$) when starch was supplemented. Both pectin and starch increased ($P < 0.01$) the population of *Treponema bryantii*. Increasing the level of pectin led to a linear decrease ($P < 0.01$) of the rumen lipolytic bacterium *Anaerovi briolipolytica*, whereas starch stimulated the growth of the species. Because *A. lipolytica* cannot utilize starch but lactate as substrate, the growth of *A. lipolytica*in starch treatments may be attributed to the lactate accumulation. A better understanding of microbial populations that accompany dietary differences will expand our knowledge of ecological importance of bacteria in the rumen and may further lead to beneficial strategies to improve ruminant production performance.

Key Words: soluble carbohydrate, microbial protein synthesis, bacterial populations

0709 Effect of dietary starch at similar energy intake during backgrounding on subsequent finishing performance and carcass characteristics in beef cattle: a meta-analysis. *P. A. Lancaster*, C. R. Krehbiel, and G. W. Horn, Oklahoma State University, Stillwater.*

Intramuscular fat is reported to utilize glucose for fatty acid synthesis rather than acetate, but inconsistent results have been reported on the effect of dietary starch on marbling in beef cattle. The objective of this study was to use meta-analysis methods to determine the effect of dietary starch during backgrounding on subsequent finishing performance and carcass characteristics in beef cattle. Following a literature search, 14 studies were identified where diets differing in grain inclusion level were fed to normal-weaned steers such that energy intake was controlled for similar ADG. All treatments within a study were fed the same finishing diet. Treatments within study were classified as low, medium, or high starch based on grain inclusion level of the diet. This resulted in subdividing the dataset to analyze comparisons of high (HI1) vs. medium (MED) starch (9 studies) and high (HI2) vs. low (LOW) starch (seven studies); not enough studies had a medium vs. low starch comparison. Data were analyzed using a linear mixed model (PROC MIXED of SAS) that included diet as a fixed effect and intercept as a random effect with the unstructured option and study as the subject. Least square means

were computed using the inverse of the squared standard error for the dependent variable as a weighting factor. The mean grain inclusion level, calculated NEg concentration, and growing phase ADG were 79.4 and 45.2% of DM, 1.42 and 1.02 Mcal/kg DM, and 1.07 and 1.12 kg/d for HI1 and MED, respectively, and were 72.8 and 16.4% of DM, 1.42 and 1.03 Mcal/kg DM, and 1.30 and 1.26 kg/d for HI2 and LOW, respectively. Growth rate, DMI, and G:F were similar ($P > 0.05$) between HI1 and MED and HI2 and LOW. Likewise, HCW, LM area, and 12th–rib fat thickness were similar ($P > 0.05$) between HI1 and MED and HI2 and LOW. Marbling score was similar ($P > 0.05$) between HI1 and MED (427 and 436 ± 17; 400 = Small[00]) and HI2 and LOW (443 and 434 ± 19). These data indicate that dietary starch inclusion level at similar energy intake during the growing phase does not impact subsequent finishing performance or carcass characteristics.

Key Words: backgrounding, dietary starch, marbling

0710 Evaluation of MegaFerm Fiber to enhance ruminal fermentation and nutrient digestibility of a total mixed ration using an in vitro gas production measurement system. D. Casper*[1], I. P. Acharya[1], and D. Miller[2], [1]*South Dakota State University, Brookings,* [2]*Miller-Casper Life Sciences, Brookings, SD.*

The addition of specific feed additives to a total mixed ration (TMR) has the potential to enhance the rate and/or extent of ruminal fermentation and nutrient digestibility. MegaFerm Fiber (MFF) is a unique blend of nutritional technologies that enhances the ruminal fermentation and nutrient digestion of a TMR fed to lactating dairy cows. A standard TMR consisting of alfalfa haylage, corn silage, and a grain mix was dried at 55°C and ground through an ultracentrifuge mill having a 1.0-mm screen. One g of ground TMR was placed in a 50 µm dacron bag, heat sealed, and then placed in a 500 mL Ankom Gas Fermentation Bottle (GFB) to measure rate of gas production and digestion. Treatments were: Control (C) and MFF fed at 3 rates to equate to a feeding rate of 5, 10, and 15 g/cow/d. Each treatment was replicated six times as individual GFB. Rumen fluid was collected from a ruminally cannulated lactating dairy cows fed the same TMR. The rumen fluid was strained through four layers of cheesecloth and 20 mL were added with 200 mL of buffer to each GFB. Bottles were incubated in a circulating water bath at 39°C and gas measurements were collected every 5 min for 30 h. At the completion of 30 h fermentations, Dacron bags were removed and dried to calculate dry matter disappearance and then analyzed for NDF concentrations to calculate NDF digestibility. The rate of gas production was linearly improved ($P < 0.07$) with the addition of MFF to the C TMR (8.0, 8.2, 9.0, and 8.6%/h for C, and MFF at 5, 10, and 15 g/cow/d, respectively). The extent of digested dry matter (76.8, 76.7, 75.8, and 75.2%) was similar ($P > 0.09$) for all treatments. The pH at 30 h was similar for all treatments (6.45, 6.45, 6.46, and 6.49). The pH decline from 0 to 30 h was similar for all treatments (-0.069, -0.073, -0.097, and -0.089 pH units). This study demonstrated that MFF can enhance the rate of digestion by increasing the rate of gas production, but the extent of nutrient digestibility was not affected. The enhanced rate of nutrient digestibility could possibility enhance the milk production of lactating dairy cows

Key Words: gas production, nutrient digestibility, MegaFerm Fiber

0711 Application of fecal NIRS profiling to predict diet characteristics and voluntary intake in beef cattle. J. R. Johnson*[1], G. E. Carstens[1], S. D. Prince[2], K. H. Ominski[3], K. M. Wittenberg[3], M. Undi[3], J. A. Basarab[4], T. D. Forbes[5], A. N. Hafla[6], and D. R. Tolleson[7], [1]*Texas A&M University, College Station,* [2]*Texas A&M AgriLife Research, Temple,* [3]*University of Manitoba, Winnipeg, Canada,* [4]*Alberta Agriculture and Rural Development, Lacombe, Canada,* [5]*Texas A&M Agrilife Research, Uvalde,* [6]*USDA–Agricultural Research Service, University Park, PA,* [7]*University of Arizona, Camp Verde.*

Objectives of this study were to evaluate the use of fecal near-infrared reflectance spectroscopy (fecal NIRS) to predict dietary characteristics and voluntary DMI in beef cattle. Fecal samples and phenotype data were collected from 11 growing cattle trials for which intake was measured individually (Calan-gate or GrowSafe systems), and residual feed intake (RFI) calculated. For each trial, animals were fed diets containing at least 70% roughages (1.9 to 2.7 Mcal ME/kg DM), and composite fecal samples were analyzed using a Foss NIRS 6500 monochromator. Modified partial least squares approach was used to develop calibration equations to predict CP, NDF, and DMI using fecal NIRS spectra as independent variables, and CP, NDF, or DMI as dependent variables. Calibration accuracies (SE calibration; SEC and R^2 of calibration; R^2_c) were 0.61 and 0.90 for prediction of CP, 2.35 and 0.85 for NDF, and 11.3 and 0.76 for DMI. Validation of equations was accomplished by cross-validation and evaluated using SE cross-validation (SECV) and R^2 of cross-validation (R^2_{cv}). Validation accuracies (SECV and R^2_{cv}) for prediction of CP and NDF were acceptable and in agreement with previous studies, further indicating that fecal NIRS is a capable tool for predicting dietary CP and NDF. Validation accuracy for prediction of DMI was less accurate than for prediction of dietary CP and NDF. However, the results were comparable to those reported for the prediction of individual-animal intake by fecal NIRS and n-alkane methods in previous studies. Additionally, the fecal NIRS prediction equation for DMI in this study was able to predict individual-animal DMI for the evaluation of divergent RFI groups. Across studies, low RFI animals consumed 12% less ($P < 0.01$) than high RFI animals based on observed intakes (107.8 vs. 122.4 ± 2.2 g/BW$^{0.75}$), and 10% less ($P <$

0.01) based on fecal NIRS predicted intakes (108.9 vs. 120.9 ± 2.13 g/BW$^{0.75}$). Results from this study indicate that fecal NIRS profiling may be useful in predicting animal variance in diet characteristics and DMI.

0712 A comparison between propylene glycol and a multiple component drench on energetic variables in early lactating Holstein cows.

M. Abuajamieh*[1], S. K. Stoakes[1], M. V. Sans-Fernandez[1], J. S. Johnson[1], P. J. Gorden[1], D. M. McKilligan[2], and L. H. Baumgard[1], [1]*Iowa State University, Ames,* [2]*TechMix LLC, Stewart, MN.*

Gluconeogenic precursors are therapeutically administered to treat ketosis in early lactation dairy cows and frequently provided as a standard management practice on all fresh cows. Study objectives were to compare and contrast a multiple component drench (MCD) containing glycerol, propylene glycol, calcium propionate, and water to propylene glycol (PG) on circulating glucose, insulin, NEFA, and β-HBA. Lactating Holstein dairy cows (n = 24, 11.6 ± 1 DIM; parity 1 to 7) were utilized in a replicated experimental design. Cows were randomly assigned to receive one of four treatments: 1) control (300 mL water), 2) 300 mL of PG (Propylene Glycol USP/EP, Dow Chemical Company, Midland MI), 3) 300 mL (M-MCD; TechMix, Stewart MN), and 4) 360 mL (H-MCD; TechMix, Stewart MN). The PG and H-MCD treatments were designed to provide a similar amount of gluconeogenic precursors. Cows were fasted for 4 h and then received a rumen drench of their respective treatment at 0800 h. All products were administered using an orogastric tube to assure successful rumen delivery and chased with 100 mL of warm water. Blood samples were collected via a jugular catheter at -15, 0, 15, 30, 60, 90, 120, and 150 min relative to treatment administration. Metabolite and hormone responses were calculated as area under the curve (AUC) by linear trapezoidal summation between time coordinates after subtracting their respective baseline values. Compared to controls, PG, M-MCD, and H-MCD all increased ($P < 0.01$) circulating glucose following the drench, but the glucose AUC did not differ between treatments. The insulin response peaked at +30 min in the PG, M-MCD, and H-MCD; the overall response was similar amongst treatments. Compared to controls, PG, M-MCD, and H-MCD all markedly decreased ($P < 0.05$) NEFA (42% at +120 min) and NEFA nadir occurred 60 min following treatment administration. Compared to controls, all three treatments decreased β-HBA, but PG tended ($P < 0.09$) to decrease ketones more than M-MCD and H-MCD. In summary, although variable, all three gluconeogenic precursor treatments influenced energetic variables, and thus the MCD product appears to be a viable strategy to manage energetic deficits in early lactation.

Key Words: dairy cow, propylene glycol, multiple component drench

0713 A comparative analysis of metabolomics and transcriptomics from prepartal liver of cows developing ketosis postpartum and healthy cows supplemented with Smartamine M and MetaSmart during the transition period.

K. Shahzad*[1], J. S. Osorio[1], D. N. Luchini[2], and J. J. Loor[1], [1]*University of Illinois, Urbana-Champaign, Urbana,* [2]*Adisseo S.A.S., Alpharetta, GA.*

Cows overfed energy during the dry period are most susceptible to developing ketosis postpartum. Supplementation with Smartamine M (SM) and MetaSmart (MS) during the transition period improves postpartal dry matter intake and resulted in fewer cases of clinical ketosis postpartum. Metabolomics (GC–MS, LC-MS; Metabolon Inc.) and transcriptomics (45K-whole-transcriptome microarray; Agilent) analyses were performed in liver tissue harvested at -10 d relative to parturition from cows that were healthy on 7 d postpartum or were diagnosed with clinical ketosis (K, n = 8). From -21 d to calving all cows consumed a higher-energy diet without (developed K) or with SM (n = 8) and MS (n = 8) (clinically healthy). From 313 identified biochemical compounds, metabolomics analysis ($P \leq 0.10$) revealed 34 or 33 affected in the comparison of K vs. SM or K vs. MS. Comparing profiles in K vs. SM revealed 13 compounds up-regulated and 21 downregulated. Among the up-regulated compounds most belong to bile acid, fatty acid, branched-chain amino acid, and arginine and proline metabolism. Among the downregulated compounds, there were several lysolipids and di-carboxylic acids along with components of pentose, purine, and sphingolipid metabolism. Citrate was markedly lower in liver of K vs. SM. In the comparison of K vs. MS, seven compounds were up-regulated and 26 were downregulated. The up-regulated compounds are intermediates of glycolysis/gluconeogenesis/pyruvate, histidine, glycine/serine/threonine, and fatty acid metabolism. Among downregulated compounds, seven were lysolipids, but also citrate, squalene, several pentoses, and purines were affected. Analysis of transcriptomics data resulted in 834 or 1261 differentially expressed genes (DEG, $P \leq 0.05$) in K vs. SM or K vs. MS. Bioinformatics analysis using the Dynamic Impact Approach (DIA) revealed a strong activation in K vs. MS of Notch, Hedgehog, and TGF-β signaling pathways along with "steroid biogenesis." In contrast, "synthesis and degradation of ketone bodies" was markedly inhibited. The pathway response in K vs. SM was less pronounced in part due to the fewer number of DEG. For example, the Hedgehog signaling pathway was highly impacted but moderately activated; whereas, the "renin-angiotensin system" was the most impacted and markedly inhibited. Preliminary data analysis suggests that supplemental MS and SM elicit distinct metabolomics and transcriptomics responses in liver before calving. Cows developing K postpartum also had a distinct molecular phenotype compared with those supplemented with methionine. The functional relevance of these differences remains to be determined.

Key Words: ketosis, transition cows, metabolomics

0714 The effect of subacute ruminal acidosis on milk fat synthesis and relative expression of key lipogenic enzyme genes in liver tissue in dairy cows. Y. Guo[*1,2], S. L. Li[1], Z. J. Cao[1], X. Xu[1], and Y. Zou[1], [1]*State Key Laboratory of Animal Nutrition, College of Animal Science and Technology, China Agricultural University, Beijing,* [2]*Shijiazhuang Academy of Agriculture and Forestry Science, Shijiazhuang, China.*

The aims of this study were to: 1) determine the variation of performance and relative expression of lipid anabolism related genes in liver tissue triggered by induced subacute ruminal acidosis (SARA), and 2) evaluate the ability of pelleted beet pulp (BP) as a substitute for ground corn to alleviate SARA. Eight mid-lactation Holstein cows were fed four diets during four successive 17-d periods: 1) total mixed ration (TMR) containing 0% finely ground wheat (FGW) (W0), 2) TMR containing 10% FGW (W10), 3) TMR containing 20% FGW (W20), and 4) TMR containing 10% BP as a replacement for 10% ground corn (BP10). The SARA induction protocol reduced the mean ruminal pH from 6.37 to 5.94 ($P < 0.01$), and the minimum ruminal pH decreased from 5.99 to 5.41 from baseline to challenge period. Mean ruminal pH increased from 5.94 to 6.05, and minimum pH increased from 5.41 to 5.63, when BP was substituted for corn. Dry matter intake and milk yield were not affected by the dietary treatments; however, milk fat percentage and yield were reduced ($P < 0.01$) in the W20 and BP10 treatments than the W0 treatment. Cows fed the W20 diet had a lower ($P < 0.01$) plasma concentration of triglyceride and total cholesterol, and a higher ($P < 0.01$) plasma concentration of glucose and insulin than cows fed the W0 diet. Liver tissue relative expression of acetyl-CoA carboxylase α (ACACA) ($P = 0.03$), FA synthase (FASN) ($P = 0.05$), sterol-response element binding protein 1 (SREBF1) ($P < 0.01$) was increased in cows fed the W20 diet, but there were no significant differences among the W10, W20, and BP10 diets. Our results indicate that the SARA could decrease of milk fat synthesis and increase of relative expression of lipid synthesis key genes in liver tissue. The substitution of pelleted BP for ground corn in a high-concentrate diet could reduce the risk of SARA in dairy cows.

Key Words: subacute ruminal acidosis, milk fat, key lipogenic enzyme

0715 Effect of 2-hydroxy-4-(methylthio)butanoate (HMTBa) on risk of diet-induced milk fat depression. M. Baldin[*1], J. Y. Ying[1], G. I. Zanton[2], and K. J. Harvatine[1], [1]*Penn State University, University Park,* [2]*Novus International, Inc., St. Charles, MO.*

Dietary polyunsaturated fatty acids (FA) and diet fermentability are key risk factors for diet-induced milk fat depression (MFD). A role for HMTBa in increased milk fat yield has been proposed, but the interaction of HMTBa and dietary risk factors for MFD have not been investigated. The objective was to evaluate the effect of HMTBa (ALIMET feed supplement, Novus International, Inc., St. Charles, MO) on milk fat synthesis when feeding diets with increasing risk for MFD. Thirty multiparous Holstein cows [227 ± 88 DIM, producing 38 ± 17 kg milk/d (Mean ± SD)] were used in a randomized block design. Treatments were control (corn carrier) and HMTBa (HMTBa fed at 0.1% of the diet DM provided with a corn carrier). The experiment was 70 d and included a 14-d covariate period followed by three phases that fed diets with increasing risk of MFD. During the low-risk phase (28 d) the base diet was balanced to 33.5% NDF and had no exogenous oil, during the moderate-risk phase (14 d) the diet was balanced to 31% NDF and contained 0.75% soybean oil, and during the high-risk phase (14 d) the diet was balanced to 28.5% NDF and contained 1.5% soybean oil. Milk yield, DMI, and BW were measured daily. Milk was sampled every 7 d and analyzed for fat and protein concentration. Data were analyzed using PROC MIXED with repeated measures and the effect of treatment was tested at each time point. There was no overall effect of treatment or treatment by time interaction for DMI, BW, milk yield, and milk protein concentration and yield. A treatment by time interaction was observed for milk fat concentration ($P = 0.02$) and yield ($P = 0.01$). HMTBa increased milk fat percent during the high-risk phase on d 63 (2.83 vs. 3.55, $P < 0.0001$) and d 70 (2.91 vs. 3.43%, $P = 0.005$) and increased milk fat yield on d 63 (821 vs. 1093 g/d, $P = 0.002$) and d 70 (771 vs. 951 g/d, $P = 0.018$). In conclusion, HMTBa increased milk fat yield when cows were fed a diet with a high risk of diet-induced MFD.

Key Words: HMTBa, milk fat depression

0716 Time-course of changes in select ruminal microbes during induction and recovery from diet-induced milk fat depression in dairy cows. D. E. Rico*, S. H. Preston, and K. J. Harvatine, *Penn State University, University Park.*

Diet-induced milk fat depression (MFD) results from bioactive fatty acids produced in the rumen during altered biohydrogenation, and changes in the rumen microbial population are commonly proposed as a key factor in development of the condition. An experiment was conducted to characterize the changes in select rumen microbes during induction and recovery from diet-induced MFD. Eight ruminally cannulated cows were used in repeated design and fed a low fiber, high PUFA diet (Induction; 29.5% NDF and 3.7% PUFA; DM basis) for a period of 21 d, and then switched to a high fiber, low PUFA diet (Recovery; 36.9% NDF and 1.1% PUFA) for 21 d. The control was the high fiber, low PUFA diet. We have previously reported decreased milk fat yield by d 7 and near maximal MFD by d 13 during induction, and a progressive increase in milk fat yield with full recovery by d 15. Ruminal digesta samples were collected 8 h after feeding on Days 0, 4,

8, 12, and 20, and select ruminal microbes were quantified by Real-time PCR. Data were analyzed by PROC MIXED with the repeated statement and treatments compared at each time point. Treatment by time interactions were observed for most taxa ($P < 0.05$). *Megasphaera eldesnii* and *S. ruminantium* (lactate using bacteria) increased progressively > 170% until d 12 of induction and decreased progressively during recovery. *Streptococcus bovis* (amilolytic bacteria) peaked at 350% higher than control on d 4 of induction ($P < 0.01$) and rapidly decreased during recovery. *Prevotella bryantii* (amilolytic bacteria) decreased 66% from d 8 to 20 of induction compared with the control and increased to control levels by d 12 of recovery. *Ruminococcus albus* (fibrolytic bacteria) and *P. ruminicola* (fibrolytic bacteria) were nearly constant during induction and recovery. However, *F. succinogenes* (fibrolytic bacteria) decreased 97% compared to control by d 4 of induction and increased progressively to an equal extent during recovery. The *Butyrivibrio/Pseudobutyrivibrio* group (*t*11–18:1 producer) decreased progressively during induction and increased during recovery, whereas the *Butyrivibrio hungatei* group (*t*11–18:1 producer) was not affected by treatment. Both ciliate protozoa and total fungi decreased progressively by > 90% during induction and increased during recovery. Rapid adaptation of most of the observed microbes occurred during both induction and recovery from diet-induced MFD, and the time-course of adaptation matches the time-course of changes in biohydrogenation intermediates and inhibition of milk fat.

Key Words: dairy cows, milk fat depression, ruminal microbes.

0717 The effect of length of adaptation to a high-grain diet and acidosis challenge and recovery on rumen papillae mRNA expression of genes relating to barrier function, inflammation, and short-chain fatty acid transport in beef heifers.

K. M. Wood*[1], T. Schwaiger[1], J. C. Plaizier[2], K. A. Beauchemin[3], and G. B. Penner[1], *[1]University of Saskatchewan, Saskatoon, Canada, [2]University of Manitoba, Winnipeg, Canada, [3]Lethbridge Research Centre, Agriculture and Agri-Food Canada, Lethbridge, AB, Canada.*

Ruminal acidosis induced by high-grain diets can have serious negative effects on animal health and performance. The objective of this study was to investigate if the duration that ruminally cannulated beef heifers were fed a high-grain diet influences mRNA expression of genes relating to barrier function, immune response and short-chain fatty acid (SCFA) absorption in rumen papillae. Heifers were assigned to one of four blocks and randomly allocated to be long adapted (LA; 34 d; $n = 8$) or short adapted (SA; 8 d; $n = 8$) from a backgrounding diet to a high-grain (81% barley) finishing diet before inducing ruminal acidosis. Ruminal acidosis was induced by restricting DMI to 50% for 24 h followed by an intra-ruminal dose of barley grain (10% of DMI). Rumen papillae from the ventral sac were collected and stored in RNA later during the baseline period (BASE; 6 d of before challenge), 24 h after challenge (Recovery1; REC1), and 8 d after challenge (REC2). Total mRNA was isolated from papillae using TriZol and quantitative real-time PCR was conducted to quantify relative expression of genes relating to gut barrier function (zonula occluden 1, claudin 1, and occuldin), immune response (TNF-α, Toll-like receptor 4;TLR4), and intracellular pH regulation and SCFA metabolism (Na^+/H^+ exchanger 1 and 3, monocarboxylate transporter 1 and 4; MCT1 and 4 respectively, and 3-hydroxy-3-methylglutaryl-CoA synthase 1 and 2; HMGS 1 and 2 respectively). Expression of mRNA were normalized for expression of GAPDH and β-actin and expressed as normalized relative fold-change. Data were analyzed using PROC MIXED in SAS and mean separation conducted using Tukey post-hoc separation test. Dietary treatment ($P \geq 0.19$) and the treatment × period interaction ($P \geq 0.06$) did not influence mRNA expression of genes of interest. Total mRNA expression was affected by period ($P \leq 0.03$) for TLR4, ZO1, claudin, occludin, MCT1 and MCT4. In general, REC1 showed least expression and expression during REC2 returned to values similar (TLR4, claudin 1, and occludin) or intermediate (ZO1, MCT1, and MCT4) to BASE. These results indicate that length of dietary adaptation used in our study was not sufficient to differentially influence the expression of mRNA for key genes influencing barrier function, immune response and SCFA transport following an acidosis challenge. However exposure to ruminal acidosis generally reduced mRNA expression with values returning to baseline conditions within 8 d.

Key Words: barrier function, cattle, immune response, rumen acidosis, short-chain fatty acids

0718 Induction of subacute ruminal acidosis affects the rumen microbiome.

J. C. McCann*, S. A. Alqarni, S. Luan, P. Cardoso, and J. J. Loor, *University of Illinois, Urbana.*

Subacute ruminal acidosis (SARA) negatively impacts the dairy industry by decreasing milk production, efficiency of milk production, and increasing culling rate and death loss. Six lactating Holstein cows were used in a replicated 2 × 2 Latin square design to determine the effects of SARA induction on the rumen microbiome. Experimental periods were 10 d with d 1 through 3 for ad libitum intake of control diet, followed by 50% feed restriction on d 4, and ad libitum access on d 5 of the control diet (control) or control diet + 4.6 kg of a 50:50 wheat/barley pellet (challenge). Ruminal samples were collected on d 1 and 6 of each period before morning feeding and separated into liquid and solid fractions. Bacterial DNA was extracted from the solid fraction after physical homogenization. Real-time quantitative PCR was used to determine SARA challenge effects on culturable bacterial species. *Butyrivibrio proteoclasticus* was observed in the greatest rela-

tive abundance of the evaluated species (0.4 to 0.2%) with a treatment × day effect ($P < 0.01$). For the control treatment, *Butyrivibrio proteoclasticus* increased ($P = 0.04$) from d 1 to d 6, but there was a tendency to decrease ($P = 0.08$) for the challenge treatment from d 1 to d 6. *Anaerovibrio lipolytica* remained stable during the challenge treatment; however, relative abundance increased ($P < 0.01$) decidedly on control d 6. A primary cellulolytic species, *Fibrobacter succinogenes*, was decreased ($P < 0.02$) from d 1 to d 6 of the control and challenge treatment. While *Selenomonas ruminantium* and *Eubacterium ruminantium* decreased ($P \leq 0.03$) from d 1 to d 6 of the challenge treatment, both species were unaffected by control treatment. Relative abundance of *Prevotella bryantii* increased ($P < 0.01$) on d 6 of the challenge treatment, but no effects of the control treatment were observed. Similarly, the lactate-utilizing species, *Megasphaera elsdenii*, had a tendency to increase ($P < 0.06$) on d 6 of the challenge treatment, yet populations remained stable during the control treatment. Overall, results indicate the challenge treatment caused greater shifts within the rumen microbiome and are likely linked to the onset of SARA.

Key Words: acidosis, SARA, microbiome

0719 Effects of feeding a negative DCAD diet prepartum for varied lengths of time on serum metabolites and performance.

Z. Wu*[1], J. K. Bernard[1], K. P. Zanzalari[2], and J. D. Chapman[3], *[1]University of Georgia, Tifton, [2]Prince Agri Products, Inc., Franklin, IN, [3]Prince Agri Products, Inc., Quincy, IL.*

Forty-five multiparous Holstein cows and 15 springing heifers were used in a completely randomized design trial to determine the effect of length of feeding a negative DCAD diet prepartum on serum metabolites, DMI, milk yield and composition. After training to eat through Calan doors, cows within parity were assigned randomly to negative DCAD diets for 3 (3WPC), 4 (4WPC) or 6 wk (WPC) before predicted calving. Actual days cows were fed negative DCAD diets were 19.2 ± 4.1, 27.9 ± 3.1, and 41.5 ± 4.1d for 3WPC, 4WPC, and 6WPC, respectively. All cows were fed a diet formulated for late gestation (14.6% CP, 42.3% NDF, 20.5% starch, 7.1% ash, and 0.97% Ca) supplemented with Animate (Prince Agri Products, Inc., Quincy, IL) with a resulting DCAD (Na + K– Cl–S) of -21.02 mEq/100 g DM. After calving, cows were fed a diet formulated for early lactation (18.0% CP, 36.4% NDF, 24.2% starch, 8.1% ash, and 0.94% Ca) for the following 6 wk with a DCAD of 20.55 mEq/100 g DM. Urine pH was not different ($P > 0.10$) among treatments before calving and averaged 6.36. No differences ($P > 0.10$) were observed in prepartum DMI which averaged 11.4, 11.5 and 11.7 kg/d for 3WPC, 4WPC, and 6WPC, respectively. Prepartum serum total protein ($P = 0.03$), albumin ($P = 0.01$), Ca ($P = 0.02$), and anion gap ($P < 0.01$) were within normal limits, but decreased linearly with the increasing time cows were fed a negative DCAD diet. No differences were observed in serum metabolite concentrations on the day of calving. After calving, serum total protein ($P = 0.04$) and globulin ($P = 0.02$) increased linearly with the increasing time cows were fed a negative DCAD diet. No differences were observed in postpartum DMI, milk yield, or concentration of fat or protein among treatments: 19.1, 40.6, 4.30, and 2.80; 19.6, 41.5, 4.50, and 2.90; and 18.6 kg/d, 41.0 kg/d, 4.30% and 2.73% for 3WPC, 4WPC, and 6WPC, respectively. Results of this trial indicate that extending the length of time cows are fed a negative DCAD diet does not negatively affect serum metabolites or resulting performance.

Key Words: DCAD, serum metabolites, milk yield, milk composition

---

0720 Effect of pre-calving dietary cation anion difference on milk production: A meta-analysis.

I. J. Lean[1], R. Rodney[1], P. J. DeGaris[2], D. M. McNeill[3], and E. Block*[4], *[1]SBScibus, Camden, Australia, [2]Tarwin Veterinary Group, Leongatha, Australia, [3]University of Queensland, Gatton, Australia, [4]Church and Dwight Animal Nutrition, Ewing, NJ.*

The effects of dietary cation anion difference (DCAD) of pre-calving diets on milk production. A total of 15 studies and 34 comparisons were identified and analyzed (Stata 13.0 Statacorp, Texas) using a random effects model. A weighted mean difference between treated and control was also calculated. Meta-regression analysis evaluated whether parity of the cattle, difference in DCAD between treatment and the control diet and estimated energy density, crude protein, crude fat, neutral detergent fiber, non-fiber carbohydrates, DCAD, calcium, magnesium, phosphorus, potassium, and content of the control diet influenced responses. The average ± SE days of exposure to transition diets was 29 ± 3, and the DCAD of controls and treated cows was 232 ± 37 and -27 ± 33 meq/Kg, respectively. Only the parity of the cow ($P = 0.003$) and NDF of the control diet ($P = 0.02$) influenced responses with milk production increased in cows ($P = 0.0001$) and lowered in heifers ($P = 0.027$). The effect size (ES) for milk production of studies in cows was positive (0.629 95% CI 0.292 to 0.965). Estimated responses in milk or fat corrected milk over 65 ± 14 d of lactation were 1.153 (95% CI 0.335 to 1.971) L per day. In heifers, milk production responses were ES of -1.211 (95% CI -2.288 to -0.135) and the weighted mean difference was -1.482 (95% confidence interval -1.872 to -1.093) L per day. The I^2 was 77.1 for cows and 87.2 for heifers, indicating very considerable variability in responses. The effect size response was lower with higher NDF diets. The lower response to DCAD in high NDF studies may indicate a role for ruminal outputs to influence acid-base status. Critically, other sources of variation, as indicated by the high I^2, were not identified, despite the large number of covariates tested. Reference: Lean IJ, DeGaris PJ, McNeil DM, Block

0721 Evaluation of choline metabolites in milk as potential biomarkers for choline absorption in the lactating dairy cow. V. M. Artegoitia*[1], C. L. Girard[2], H. Lapierre[2], S. R. Campagna[1], F. Harte[1], and M. J. de Veth[1,3], *[1]University of Tennessee, Knoxville, [2]Agriculture & Agri-Food Canada, Sherbrooke, QC, [3]Balchem Corporation, New Hampton, NY.*

Choline is an essential nutrient for growth and performance of production animals, and an established symptom of choline deficiency in periparturient cattle is fatty liver. Dietary choline is extensively degraded in the rumen, and although rumen-protected choline (RPC) has been found to reduce the extent of hepatic fat infiltration, no biomarkers have been established to assess the efficacy of RPC supplements in dairy cows. Secretion of total choline in milk could be a potential biomarker; however, choline is secreted in milk in many metabolic forms and some specific metabolites in milk may be more closely associated with choline absorption than total choline secretion. The objective of this study was to evaluate secretion of choline metabolites in milk as potential biomarkers of choline absorption. Five lactating Holstein cows (237 ± 17 DIM) were used in a 5 × 5 Latin square design, with 5-d treatment periods and a 2-d interval between periods. Treatments were 1) control (0 g/d choline), 2) RPC- low dose (RPC-L), 3) RPC-high dose (RPC-H), 4) abomasal infusion (ABO)– low dose (ABO-L), 5) ABO– high dose (ABO-H). The low and high doses of RPC (Reashure, Balchem Corp.) and ABO each supplied 12.5 and 25 g choline/d, respectively. Milk samples from d 5 were analyzed for acetylcholine (AC), betaine (Bet), free choline (Cho), glycerophosphocholine, lysophosphocholine, phosphatidylcholine, phosphocholine (PC), and sphingomyelin, using liquid chromatography-tandem mass spectrometry. Although total choline secretion in milk was not affected by ABO, Cho and Bet secretion increased ($P < 0.01$) in a dose dependent manner with ABO by 74% and 171%, respectively, with ABO-L and 146% and 278%, respectively, with ABO-H. The amounts of Cho and Bet secreted in milk increased from 0.54 to 0.94 and 1.33 g/d and from 0.14 to 0.38 and 0.53 g/d, respectively for the low and high doses. Increases in the yields of AC and PC were also observed ($P = 0.04$), although only with ABO-H. The other metabolites were not changed by ABO ($P > 0.12$), nor were any changes observed in secretion of individual choline metabolites with RPC. Multiple regression indicated the changes in milk PC and Bet secretion could be explained to a large degree by the ABO dose of choline ($P = 0.01$; $R^2 = 0.72$). The results of this study suggest that some choline metabolites may be more sensitive biomarkers than total choline for absorption of supplemental choline.

Key Words: choline, bioavailability, dairy cow

0722 Association of plasma ghrelin concentrations with feed intake in beef cattle. A. P. Foote*, K. E. Hales, C. A. Lents, and H. C. Freetly, *USDA-ARS, U.S. Meat Animal Research Center, Clay Center, NE.*

Active ghrelin is an acylated peptide produced in the gastrointestinal tract of animals that is thought to stimulate appetite. Cattle used in this experiment were sired by bulls representing five breeds in the United States, including Hereford, Angus, Limousin, Charolais, and Gelbvieh. Steers ($n = 128$) and heifers ($n = 133$) were fed a finishing diet and individual intake was recorded for 84 d. Blood samples were collected via jugular puncture at 113 d on feed. Active ghrelin was protected by acidifying the blood plasma and adding a protease inhibitor. Active ghrelin was quantified using a commercial RIA specific for the acylated form of ghrelin. The mixed model procedure of SAS was utilized to determine factors influencing active ghrelin levels. Fixed effects included sex, sire breed, dam breed, total dry matter intake (TDMI), and BW at time of blood collection. Sire nested within sire breed was included as a random effect. A mixed model was also used to determine if concentrations of active ghrelin could be used to predict TDMI. Fixed effects included concentrations of active ghrelin, sire breed, dam breed, sex, BW, and sire nested within sire breed was included as a random effect. Concentrations of active ghrelin were positively associated with TDMI ($P = 0.012$) when sex and breed effects were accounted for in the model. Regardless of breed, heifers had lower TDMI than steers ($P = 0.012$) but tended to have greater concentrations of active ghrelin ($P = 0.099$). Gelbvieh-sired cattle had the greatest concentrations of active ghrelin and Angus, Limousin, and Charolais had the lowest concentrations while concentrations of ghrelin in Hereford-sired cattle were intermediate ($P = 0.003$). Angus-sired cattle had the highest TDMI, while Limousin-, Charolais-, and Gelbvieh-sired cattle had the lowest TDMI with Hereford cattle intermediate ($P < 0.001$). Modeling the data showed that active ghrelin concentrations had a positive association with TDMI; however, both the sex and sire breed effects indicate that cattle with lower intakes (e.g., heifers and Gelbvieh-sired cattle) tend to have greater concentrations of active ghrelin than cattle with higher intakes. Data indicate there is a genetic effect on active ghrelin levels that may affect the association with intake. *USDA is an equal opportunity provider and employer.* *Funded in part by NIFA Grant 2011–68004–30214 through the National Program for Genetic Improvement of Feed Efficiency in Beef Cattle.*

0723 Effects of ruminal dose of sucrose, lactose, and starch on ruminal fermentation and expression of genes in ruminal epithelial cells. M. Oba*, J. Mewis, and Z. Zhu, *University of Alberta, Edmonton, Canada.*

The objective was to evaluate effects of ruminal dose of sucrose (SUC), lactose (LAC) and cornstarch (STA) on ruminal fermentation and expression of genes in ruminal epithelial cells. Six ruminally cannulated non-lactating non-pregnant Holstein cows (BW = 725 ± 69.6 kg) were fed a diet containing whole crop barley silage and dry ground corn (dietary NDF and CP contents: 41.8 and 13.2% at DM basis, respectively), and assigned to treatments in a 3 × 3 Latin square design with 7-d periods; 1 d for data and sample collection followed by a 6-d washout period. Treatment was a pulse-dose of SUC, LAC, and STA (3.0, 3.0, and 2.85 kg DM, respectively, to provide similar amount of hexose across the treatments) through the rumen cannulas. All treatments were given with alfalfa silage (1.75 kg DM) to prevent acute rumen acidosis. Rumen pH was continuously monitored, and rumen fluid was sampled at 0, 30, 60, 90, 120, 150, and 180 min after the dose. In addition, ruminal papillae were sampled from the ventral sac at 180 min after the dose. Ruminal dose of SUC and LAC, compared with STA, increased ($P < 0.05$) ruminal total VFA concentration and molar proportion of butyrate since 60 min after the dose, and expression of genes for sodium hydrogen exchanger 1 and 2, and ATPase-1 in ruminal epithelial cells. Ruminal dose of SUC, compared with LAC and STA, decreased ($P < 0.05$) rumen pH since 120 min after the dose and molar proportion of acetate in ruminal fluid from 60 to 150 min after the dose, and increased ($P < 0.05$) molar proportion of propionate in ruminal fluid from 60 to 150 min, and expression of genes involved in butyrate metabolism (3-hydroxy-3-methylglutaryl-Coenzyme A synthase 1) and anion exchange across ruminal apical cell membrane (putative anion transporter 1). These results suggest that replacing dietary starch with sugar may affect ruminal fermentation, and metabolism regulating intracellular pH and fermentation acid absorption in ruminal epithelial cells, and that these effects can be greater for SUC than LAC.

Key Words: sucrose, lactose, starch

SMALL RUMINANT

0724 Rumen microbial species associated with feed efficiency in sheep fed a forage-based diet.
K. M. Cammack*[1], M. Ellison[2], G. C. Conant[3], W. R. Lamberson[3], R. Cockrum[4], and K. J. Austin[1], *[1]Dep. of Animal Science, University of Wyoming, Laramie, [2]University of Wyoming, Laramie, [3]University of Missouri, Columbia, MO, [4]Virginia Polytechnic Institute and State University, Blacksburg.*

The rumen microbial ecosystem plays a dominant role in fermentation of consumed feeds in ruminant livestock and therefore influences the efficiency of feed utilization. Determination of rumen microbial species important to feed efficiency may ultimately lead to development of technologies to aid producers in selecting more efficient seedstock. Our objective was to identify rumen microbial species associated with variation in feed efficiency in lambs fed a forage-based diet. Briefly, growing wethers (initial BW = 51.5 ± 1.7 kg; n = 38) of Rambouillet, Suffolk, and Hampshire breed backgrounds were administered a forage-based pelleted diet and individual feed intake was collected using a GrowSafe system over a 7-wk period. Residual feed intake (RFI) was estimated for each lamb and subsequently used to rank lambs for feed efficiency. The most efficient (low-RFI; n = 4) and the least efficient (high-RFI; n = 4) lambs were selected for sequencing of DNA isolated from respective rumen fluid samples. Pair-end reads were filtered, quality trimmed and compared with a database of known 16S rDNA genes. Operational taxonomic units (OTU) were defined as sequence clusters with ≥ 97% identity. Abundance of 28 OTUs differed (P < 0.05) with feed efficiency status, with the majority (n = 18) of these being *Prevotella* species. Of particular interest were *Ruminococcus flavefaciens* and *Ruminococcus albus*, two predominant rumen fibrolytic bacterial species involved in cellulose digestion. Unexpectedly, these two bacteria were in greater (P < 0.001) abundance in high-RFI lambs (3.2-fold greater for *R. flavefaciens*; 1.5-fold greater for *R. albus*). This may be due to differences in diet quality and form (i.e., pelleted), as previous studies have indicated that changes in abundance of such fibrolytic species can be associated with diet differences. Data from this study suggest that rumen microbial populations differ with feed efficiency status; however, certain species may be prone to variations in diet quality and presentation.

Key Words: feed efficiency, microbes, rumen, sheep

0725 Rationing late gestation ewes using a net energy or metabolisable energy rationing system: Impacts on ewe and lamb performance.
F. Campion*, F. McGovern, A. G. Fahey, and T. M. Boland, *School of Agriculture and Food Science, University College Dublin, Ireland.*

Ewe body reserves, colostrum, and milk production, lamb birth weight, lamb vigour and lamb survival are influenced by late gestation nutrition. Net energy (NE) rationing systems are purported to more accurately define the requirements of the animal relative to metabolisable energy (ME) systems. The objective of this study was to investigate the effect of rationing ewes to ME or NE during late gestation on ewe and lamb performance. Twenty-six twin-bearing ewes (n = 13) were rationed to either 100% of ME (MER) or 100% of NE requirements (NER) for the final 5 wk of gestation. Ewes were rationed on an individual basis and offered a grass silage diet supplemented with concentrate to 100% of requirements. Ewe live weight and body condition score (BCS) were recorded at Day 85 of gestation, parturition, 5 wk postpartum and weaning (14 wk postpartum). Colostrum production was measured at 1, 10, and 18 h postpartum along with lamb colostrum intake. Lamb live weights were collected at birth, weekly during the first 7 wk postpartum and fortnightly from 9 wk postpartum to slaughter. Lamb growth rate was calculated by regression of live weight on time. Carcass weight was obtained at slaughter and kill-out percentage calculated. Statistical analysis was performed using generalised least square means in SAS v9.4. Energy intake expressed as both NE and ME was lower for the MER ewes (P < 0.01). Live weight loss of MER ewes during the same period was higher (P < 0.05) reflecting their lower energy intake. No difference was observed in ewe live weight loss from parturition to weaning (P > 0.05). Ewe BCS did not differ between treatments throughout the study (P > 0.05). Total colostrum production to 18 h postpartum tended to be greater for NER ewes (P < 0.1). This difference was not mirrored in lamb colostrum intake to 18 h postpartum (P > 0.05) indicating both treatments produced sufficient colostrum to meet requirements. Lamb live weight, growth rate, carcass weight, and kill-out percentage did not differ between treatments (P > 0.05). This uniformity in postnatal performance appears to have resulted from increased body reserve mobilization by the MER ewes, thus countering potential negative effects of the reduced energy intake. For ewes in the correct BCS in late gestation, either the NE or ME rationing system used in this study are appropriate for dietary formulation.

Key Words: energy postpartum performance

0726 Determining growth performance implications on meat goat kids fed soybean hull or corn-based pelleted diets. A. C. Vesco*, C. K. Jones, L. C. Grimes, T. H. Fountain, B. R. Faris, and A. K. Sexten, *Kansas State University, Manhattan.*

The meat goat industry is rapidly expanding, yet there is limited knowledge on feeding kids to market weight, providing opportunities for research in this area. This study investigates the option of an alternative energy source to corn for a growing kid ration. Eighty-four Boer × Spanish kids (30 kg; 8 mo) were used in a randomized complete block design to determine the effects of a soybean hull based diet on growth performance and blood serum mineral composition. Kids were blocked by sex and randomly assigned to one of two treatments: 1) corn and soybean meal based pellet (Corn) or 2) soybean hull and soybean meal based pellet (Soyhull). Kids were allowed a 10-d pen and diet adaptation period. Feed was delivered once daily at 0600 with daily intake adjustments to maintain ad libitum intake of pellets and brome hay for 70 d. There were 7 pens per treatment with six head per pen; sex was divided equally between treatments. Weights for all kids were recorded every 2 wk. Pellet and hay grab samples were collected daily, composited by 2-wk period, oven-dried, and ground to be analyzed for DM, Ash, N, NDF, and ADF. Blood samples were taken on d 0, d 28, and d 70, and serum was analyzed for levels of Na, K, Cl, Ca, P, and Mg. Initial body weight was similar ($P = 0.24$) between treatments. Body weights remained similar ($P \geq 0.12$) between treatments for each weigh date for the entire 70-d feeding period. Overall gain and ADG were likewise not different ($P \geq 0.18$) between treatments. Kids consuming the Soyhull diet had greater ($P \leq 0.001$) DMI throughout the study compared to kids consuming the Corn diet. Overall DMI averaged 1.37 $kg \cdot hd^{-1} \cdot d^{-1}$ vs. 1.06 $kg \cdot hd^{-1} \cdot d^{-1}$ for the kids consuming the Soyhull and Corn diets, respectively. No differences ($P \geq 0.44$) were observed for blood serum mineral composition between treatments. Based on these results soybean hulls are a viable alternative feed source to corn for growing meat goats when protein requirements are met.

Key Words: meat goat, soybean hulls, mineral

0727 Early supplementation of alfalfa to starter diets improves the pre- and post-weaning performance of lambs. B. Yang*[1], B. He[1], S. S. Wang[1], J. X. Liu[2], and J. K. Wang[1], [1]*Institute of Dairy Science, Zhejiang University, Hangzhou, China,* [2]*Zhejiang University, Hangzhou, China.*

The objective of this study was to determine the effects of alfalfa supplementation to starter diets of artificial reared lambs on pre- and posting performance. Twelve Hu lambs at the age of 10 d, with an initial body weight of 3.87 ± 0.564 (SD) kg, were randomly divided into two equal groups and allocated to two dietary treatments: cereal feeding (CF, milk replacer, and pelleted starter) and forage feeding (FF, milk replacer, pelleted starter, and alfalfa). All animals were fed the same milk replacer at 880 mL/d on d 1, and milk replacer was then reduced at a rate of 30 mL/d until d 24. The lambs were then fed at 180 mL milk replacer per day from d 24 to 28 (weaning). During this period, the pelleted starter (16.8% NDF) was offered to all animals, but alfalfa (38.6% NDF) was only to group FF ad libitum. After weaning, the animals were offered with 300 g/d cereal powder (21.5% NDF) and had free access to alfalfa. Feed offered and refused, and body weights were recorded for two consecutive days at 0800 every week during the 4-wk feeding trial after weaning. On d 57, blood samples were obtained to determine serum concentration of glucose and β-hydroxybutyrate. After slaughtered, rumen pH and weight of carcass and forestomachs were determined immediately. Average alfalfa intake was 118 g/d before weaning, and 345 and 289 g/d ($P = 0.365$) for FF and CF after weaning, respectively. Starter intake was not affected by early supplementation of alfalfa ($P = 0.195$), but intake of cereal powder tended to be higher in FF group than in CF (258 vs. 209 g/d, $P = 0.051$). Average daily gain was 69% ($P = 0.001$) and 12% ($P = 0.006$) higher in FF than that in CF before and after weaning, respectively. Forage feeding before weaning resulted in higher carcass weight compared to cereal feeding (5.76 vs. 4.57 kg, $P = 0.005$). No significant difference was observed in abomasum and reticulum weight between CF and FF ($P > 0.05$), but rumen weight tended to be higher in FF than in CF (292 vs. 247 g, $P = 0.059$), and omasum weight increased by 24% ($P < 0.05$) in FF than in CF. Differences in rumen pH and serum concentration of glucose and β-hydroxybutyrate were not observed between two treatments ($P > 0.05$). From the present study, it is inferred that supplementation of alfalfa in starter diets is beneficial to growth performance and forestomach development in weaned lambs.

Key Words: alfalfa, lamb, starter

0728 Performance and reproductive measurements of Katahdin ewes and fall-calving Angus cows grazing stockpiled toxic tall fescue under a mixed or sequential grazing scheme: 2-yr summary. R. E. Daugherty Jr.*, J. D. Caldwell, B. C. Shanks, C. L. Boeckmann, C. A. DeOrnellis, and A. L. Bax, *Dep. of Agriculture and Environmental Sciences, Lincoln University, Jefferson City, MO.*

Multi-species grazing has several potential advantages and ultimately may improve performance for one or both species. With renewed interest in multi-species grazing, there is value in evaluating mixed versus sequential grazing schemes. However, there has been little research evaluating hair sheep and cattle grazing stockpiled toxic tall fescue (E+) either mixed or sequentially. Our objectives were to determine performance and reproductive measurements of Katahdin ewes and fall-

calving Angus cows grazing stockpiled E+ under a mixed or sequential grazing scheme. Katahdin ewes (n = 81; 27 ± 3.6 kg initial BW; 3 ± 0.07 initial BCS) and fall-calving Angus cows (n = 40; 471 ± 23.5 kg initial BW; 6 ± 0.6 initial BCS) were stratified by BW and age within species and were allocated randomly to one of four groups representing two treatments: 1) mixed grazing (four replications) or 2) sequential grazing (four replications). In the sequential grazing treatment, cows always followed ewes. Each group had access to a 0.68-ha paddock and were rotated based on available forage. A total of 8.16 ha were grazed over 40 d for all groups. Initial weight and BCS from ewes and cows did not differ ($P \geq 0.83$) across treatments. Average daily gain, total gain, end weight, and end BCS from ewes and cows did not differ ($P \geq 0.35$) across treatments. Cow pregnancy rate, calf birth date, and calf birth weight did not differ ($P \geq 0.56$) across treatments. Calf start weight, end weight, average daily gain, and total gain did not differ ($P \geq 0.26$) across treatments. Ewe pregnancy rate, lamb birth date, and lamb counts did not differ ($P \geq 0.11$) across treatments. A treatment × sex interaction tendency (P = 0.06) was detected for lamb birth weight and a treatment × sex interaction (P = 0.01) was detected for lamb weaning weight. Mixed grazing ram lambs tended to be heavier at birth compared with mixed grazing ewe lambs, and mixed grazing ram lambs were heavier compared with sequentially grazed ram lambs at weaning. Therefore, utilizing sequential grazing with Katahdin ewes and fall-calving Angus cows may not increase performance or reproductive measurements; thus, managing a multi-species, sequential grazing regime relative to mixed grazing may not be warranted.

Key Words: fescue, mixed grazing, sequential grazing

0729 Reducing dietary cation-anion difference increased gastrointestinal calcium binding proteins-D9k expression level of transition goats for plasma calcium absorption. W. X. Wu* and Y. Yang, *College of Animal Science, Guizhou University, Guiyang, China.*

The mechanism to explain why reducing dietary cation-anion difference (DCAD, mEq/kg DM) could prevent hypocalcemia in transition dairy cows remains unclear. Calcium binding protein-9 kDa (CaBP-D9k) was the main biological factor highly associated with Ca absorption in the gastrointestinal tract (GIT; rumen, reticulum, omasum, abomasum, jejunum, ileum, colon, cecum, and rectum). This study was conducted to clarify the mechanism by investigating the influence of varying DCAD level on CaBP-D9k expression level in GIT and plasma Ca concentration of transition goats, which had similar anatomy and metabolic process relative to dairy cows. Twenty-seven transition goats were randomly allocated to one of three treatments and were fed one of three diets with varying DCAD levels: +300 (HD), +150 (CON), and −50 (LD), respectively. Goats were bled on d 10 before lambing, d 0 for lambing, and d 3 after lambing to determine plasma ions contents; and were slaughtered to detect the CaBP-D9k expression level, respectively. Dry matter intake was unaffected by DCAD treatments ($P > 0.05$). Urine pH was reduced with decreasing DCAD level ($P < 0.05$). The LD diet level induced higher plasma Cl^- and Ca^{2+} concentrations relative to CON and HD diets ($P < 0.05$). Greater CaBP-D9k mRNA expression level was observed in whole GIT of LD-fed goats except for ileum, cecum, and rectum compared with goats in two other groups ($P < 0.05$). Moreover, feeding LD diet moderated the decline of CaBP-D9k mRNA expression level in abomasum, jejunum, and colon after lambing ($P < 0.05$). In conclusion, reducing DCAD could up-regulate CaBP-D9k expression level in stomach, proximal intestine and colon, which was accompanied with higher plasma Ca concentration for transition goats. This result would be the possible mechanism of low DCAD enhancing blood Ca homeostasis during periparturient period to prevent hypocalcemia of transition dairy animals.

Key Words: dietary cation-anion difference, calcium binding protein-9 kDa, transition goats

0730 Hematological and serum chemical profiles in lambs fed sericea lespedeza. M. Acharya*[1], J. M. Burke[2], J. E. Miller[3], T. H. Terrill[4], E. Smyth[1], G. Huff[5], E. B. Kegley[6], K. P. Coffey[1], and C. F. Rosenkrans[1], *[1]University of Arkansas, Fayetteville, [2]USDA-ARS, Booneville, AR, [3]Louisiana State University, Baton Rouge, [4]Fort Valley State University, Fort Valley, GA, [5]USDA, Agriculture Research Service, Fayetteville, AR, [6]Dep. of Animal Science, University of Arkansas Division of Agriculture, Fayetteville.*

Sericea lespedeza (SL) is plant-grazed or fed to small ruminants for parasite control. Condensed tannins in SL may lead to unintended consequences such as changes in production. The objective was to determine the effect of SL with or without molybdenum supplementation on changes in BW, hematology, and serum chemistry in lambs. Thirty Katahdin or Katahdin × Romanov lambs weaned in May (84 ± 1.5 d of age; 27 ± 1.1kg) were blocked by BW, breed, and parasite resistance, and assigned randomly to be fed 900 g of 75% alfalfa pellets (CON; n = 10) or 75% SL pellets (n = 20) for 104 d. Supplements were isonitrogenous, ioscaloric, and similar in trace mineral concentrations. Within the SL group, half of the lambs were administered ~ 70 mg/Lamb of sodium molybdate daily to ameliorate a reduction in serum molybdenum (SL+MO) observed previously. Lamb BW was obtained and blood collected every 14 d to determine hematological and serum chemical profiles. Data were analyzed using a mixed model with repeated measures. Mean packed cell volume, number of platelets, lymphocytes, monocytes, eosinophils, and hemoglobin were similar among diets ($P > 0.10$). White blood cell count ($P < 0.05$) and number of neutrophils ($P < 0.001$) were greater in CON than SL lambs.

Red blood cell count was greater in CON and SL+MO than SL lambs ($P < 0.03$). However, mean corpuscular volume ($P < 0.08$) and corpuscular hemoglobin ($P < 0.06$) tended to be greater in SL than CON lambs ($P < 0.08$). Serum concentrations of albumin ($P < 0.001$) and aspartate aminotransferase ($P < 0.003$) were lower in SL than CON lambs. Serum concentrations of creatinine were greater for CON and SL+MO than SL lambs ($P < 0.04$), and total protein was greater in CON and SL than SL+MO lambs ($P < 0.001$). Serum concentrations of uric acid were similar among diets ($P > 0.10$). There was a treatment × time interaction for BUN in that values were greater in CON lambs between d 14 and 42 than SL fed lambs, and otherwise similar ($P < 0.001$). Lambs BW was similar among diets ($P = 0.11$). Since most hematological and serum chemical profiles were within a normal range, any changes in animal health or production associated with condensed tannins in SL observed in previous studies likely were not related to these variables examined.

Key Words: hematology, lambs, molybdenum, sericea lespedeza

0731 Comparison of white blood cell phagocytic efficiency in two genotypes of Katahdin sheep.

S. Azarpajouh*, T. Wuliji, and A. L. Bax, *Dep.of Agriculture and Environmental Sciences, Lincoln University, Jefferson City, MO*

The production and deployment of phagocytic cells are central functions of the hematopoietic system. Neutrophils, the most abundant type of white blood cells in mammals, are an essential part of the innate immunity. The objective of this study is to compare the phagocytic efficiency of neutrophils in two genotypes of footrot resistant and susceptible Katahdin sheep. Fourteen Katahdin ewes, seven in each of high resistant footrot gene markers (HR) and low resistance (LR) were selected and blood sampled, weekly for 8 wk. Blood samples were collected in vacutainer tubes (2 × 10 mL) contained EDTA. Blood smears were made on glass slides to determine the percentage of neutrophils in whole blood. Neutrophils were isolated using a Percoll gradient technique, and stained with 0.8 mM Trypan Blue to determine the percentage of viable cells. Subsequently, 1 mL of freshly isolated neutrophils was inoculated with 1 mL of Lactobacillus casei (2×10^7/mL) in PBS and incubated with rotation at 37°C for three time periods at 20 min, 40 min and 1 h. Control samples were incubated in PBS with neutrophils alone to account for bacterial growth during the assay. At specific intervals of 20, 40, and 60 min the number of surviving bacteria in the supernatant (extracellular) was determined by culture plate colony counting to estimate the phagocytic efficiency of the neutrophils. The data were analyzed by using mixed model procedures of SAS and $P < 0.05$ was considered as significant. The average viability of extracted neutrophils was 95% in each individual specimen at inoculation. The percentage of neutrophils in whole blood was not significantly different ($P = 0.57$) in HR vs. LR genotypes. There were no significant differences ($P = 0.63$) among the numbers of bacterial colonies after addition of neutrophil and incubation periods in HR vs. LR genotypes. The number of bacterial colonies significantly decreased after 20, 40, and 60 min of incubation ($P < 0.001$). The interaction of time and gene marker groups was not significant ($P = 0.23$). No bacterial colony growth was observed in control samples. There is no difference in phagocytic efficiency of the white blood cells in footrot resistant and susceptible genotypes of Katahdin sheep.

Key Words: neutrophil, phagocytic efficiency, sheep

0732 Short-term effects of divergent selection for parasite resistance in F_1 Kiko × Boer doe progeny.

C. L. Thomas*[1,2], B. C. Shanks[1], J. D. Caldwell[1], L. S. Wilbers[1], K. L. Basinger[1], B. Weaber[3], and W. R. Lamberson[2], *[1]Dep. of Agriculture and Environmental Sciences, Lincoln University, Jefferson City, MO, [2]University of Missouri, Columbia, [3]Kansas State University, Manhattan.*

Future prospects of the goat industry appear optimistic as demand for goat meat has consistently overwhelmed domestic supply in recent years. However, parasitism is arguably the most serious economic restriction limiting goat production in the United States. One approach to combat internal parasites is utilizing the host animal's natural immunity in a selection program to increase the level of parasite resistance in a herd. The objective of this study was to evaluate the short-term effects of divergent selection for parasite resistance in F_1 Kiko × Boer doe progeny. First generation Kiko × Boer progeny ($n = 41$) from two lines of does selected for high resistance to internal parasites (HL; $n = 22$) or low resistance to internal parasites (LL; $n = 19$) were compared. Fecal egg counts (FEC), FAMACHA scores (FAM), and packed cell volumes (PCV) were measured at weaning, 28 d post-weaning, pre-breeding, during breeding, and at end of breeding. No differences ($P \geq 0.12$) were found between HL and LL for FEC, FAM, or PCV at all measurement times except for PCV at 28 d post-weaning, which tended ($P = 0.09$) to be higher for HL vs. LL. Consequently, number of times dewormed and survival rates were similar ($P \geq 0.19$) between lines. Reproductive rate, litter size, kidding date, and F_2 kid birth weight did not differ ($P \geq 0.23$) across lines. A sex effect ($P \leq 0.04$) was detected, with males weighing more vs. female kids. Correlations between FEC and FAM were significant ($P < 0.05$) and positive for LL ($R = 0.26$), but were insignificant ($P = 0.74$) for HL; correlations between FEC and PCV were significant ($P < 0.01$) and negative for LL ($R = -0.30$), but were insignificant ($P = 0.25$) for HL; correlations between FAM and PCV were significant ($P < 0.001$) and negative for LL ($R = -0.46$) and tended to be significant ($P = 0.10$) and negative for HL ($R = -0.16$). Short-term effects of divergent selection for parasite resistance re-

sulted in minimal differences in parasitism, survival rate, and reproductive performance. Associations between indicators of parasitism were moderate in some cases, but varied by doe line. This research is part of an ongoing long-term selection project for parasite resistance.

Key Words: divergent selection, F_1 Kiko × Boer, parasite resistance

0733 Milk production and characteristics of lactation curve in dairy sheep and their crosses in Mexico.

J. C. Angeles Hernandez*[1], D. A. Solis Guzman[2], M. Gonzalez Ronquillo[3], A. H. Ramirez Perez[4], and S. Angeles campos[2], *[1]Universidad Nacional Autonoma de México, México City, [2]Universidad Nacional Autonoma de México, México City, [3]Universidad Autonoma del Estado de México, Toluca, [4]Universidad Nacional Autonoma de México, Mexico City.*

The use of appropriate genotypes for milk production in dairy sheep herds allows maximizing the use of natural resources, obtain adequate milk yields and promotes their economic viability. The aim of this study was analyze the milk yield and the characteristics of the lactation curve of sheep of local breeds, dairy breeds and their crosses. Lactation records used were obtained from dairy herd located in Mexico. We used 863 weekly milk records of sheep of six genotypes: 12 East Friesian (EF), 12 Native (Nt), 6 EF1/2Native1/2 (EF50Nt50), 16 EF3/4Native1/4 (EF75Nt25), 15 Suffolk1/2Native1/2 (SF50Nt50), and 8 Corriedale sheep. Sheep were milked mechanically, and milk production was recording weekly from the fourth day after lambing; the first 60 d of lactation, sheep were milked once a day with a partial weaning, lambs were separated from sheep during the night and milked in the morning (0800). At d 60 post-lambing, full weaning was complete, and sheep began to be milked twice daily (0800 and 1800). For analysis of the lactation curve and their parameters, we used the Wood (WD) model: $Y_t = at^b e^{ct}$. Where Y is the milk production at time *t,* and *a, b,* and *c* are the parameters describing the curve shape, these were estimated individually for each lactation using a nonlinear regression. Using WD model, we calculated total milk yield observed (TMY^{obs}) and adjusted to 180 d (TMY^{180}), peak yield (PY), peak time (PT), and persistence (Per). Genotype influenced significantly ($P < 0.05$) in the TMY^{obs} and TMY^{180}, where EF50Nt50 sheep had the best performance. With respect to parameters of WD model, differences between genotypes were observed only in the parameter *b,* being higher ($P < 0.05$) in SF50Nt50, EF50Nt50, and EF sheep. PY was higher ($P < 0.05$) in sheep EF50Nt50, also PY showing a positive correlation with TMY ($r = 0.582$) and negative with Per ($r = -0.176$). PT was positively correlated ($P < 0.01$) with TMY^{180} and Per ($r = 0.479$ and 0.525 respectively). There was a positive effect on the TMY^{obs}, TMY^{180} and shape of the lactation curve in EF50Nt50 sheep. EF and EF75Nt25 sheep showed lower TMY compared with EF50Nt50, who show the best productive performance, which may be associated with better adaptation to the agroclimatic conditions and the lower adaptation to the environmental conditions of animals with a higher proportion of EF genes. The crossing EF50Nt50 is a viable option in dairy sheep herds with similar climatic conditions to those of the present study.

Key Words: dairy sheep, crossbreeding

0734 Goats of Arkansas and Missouri: A production survey.

K. F. Cole*[1], B. M. Onyango[1], J. A. Pennington[2], C. A. Clifford-Rathert[3], C. Hoegeman[1], and E. L. Walker[1], *[1]Missouri State University, Springfield, [2]Lincoln University, Jefferson City, MO, [3]Dep. of Agriculture and Environmental Sciences, Lincoln University, Jefferson City, MO.*

A survey of goat producers in Arkansas and Missouri was conducted to assess the current state of the goat industry. Production data from 206 producers (response rate of 21%) were examined to determine areas needed for education, future research, and outreach activities. An introductory email was sent to 1087 producers before the survey followed by reminder email sent after the survey was delivered. Undeliverable and inapplicable targets were removed from the original listing. Producer addresses and emails were obtained from registry organizations and extension personnel. The survey was conducted primarily as Web-based via email through Survey Monkey with a hard-copy option. Survey questions focused on farm characteristics, farm management protocols, product marketing, informational sources, and personal demographics. Of the 206 responding farms, 30.6% were from Arkansas and 69.4% from Missouri, with 24.7% raising both meat and dairy, 41.8% raising only dairy, and 33.5% only meat goats. An estimated 57% of producers were between the ages of 41 and 60. Respondents reported a source of income (58.9%) and personal consumption (54.3%) as major incentives to raise goats. Over 94.3% of respondents use anthelmintics as a part of their deworming program, whereas 38.3% use culling and animal selection. Years of experience influenced deworming strategies ($P \leq 0.05$). Educational attainment ($P \leq 0.05$) also influenced producer willingness to use services provided by extension and university personnel. Producers with less than 5 yr of experience use other goat producers ($P \leq 0.05$) for information; whereas, producers between 61 and 70 and 71 and 80 are more likely ($P \leq 0.05$) to use group meetings as an informational sources. Dairy goat producers are less likely to use farm visits ($P \leq 0.05$), farm field days ($P \leq 0.05$), group meetings ($P \leq 0.05$), and university/extension staff ($P \leq 0.05$) as informational sources than meat goat producers. Dairy producers are also more likely ($P \leq 0.05$) to use the internet as a source of information and consider food safety regulations a limiting factor in selling their products ($P \leq 0.05$). Based on our results, producers need to lower their reliance

on anthelmintics to reduce internal parasite resistance and rely more on more sustainable production practices. Understanding how age, education level, years involved, and farm type influence the type of resources used to gain further knowledge of new practices and informational sources could allow the development of education programs more suited for the population. Awareness of current production practices will assist educators, extension, and industry collaborators in conducting appropriate educational programming.

Key Words: goats, survey, production

SMALL RUMINANT: SUSTAINABLE SMALL RUMINANT PRODUCTION STRATEGIES TO MEET GLOBAL DEMANDS

0735 Pasture development and sustainable grazing management.

S. P. Hart*, *American Institute for Goat Research, Langston University, Langston, OK.*

Because grazed forage is the cheapest source of nutrients for small ruminants, grazing systems should be planned around maximizing use of grazed forages and minimizing that of hay and purchased feedstuffs. From 4 wk before parturition until weaning, the doe or ewe will consume 60% of the nutrients required in a year; therefore, it is important to provide as much nutrition as possible during this time from grazed forages. This may be accomplished by adjusting the lambing/kidding season and/or utilizing appropriate forage species that provide grazing during this period. Soil type (series), fertility, and rainfall (amount and distribution) are major determinants of forage production. A soil survey and soil test determine limitations in selection of forage species. Local/state level expertise is very important for planning a forage production system. Planting new forage species is expensive, although no-till drills reduce the cost. However, it can be cost-effective to establish forages that provide grazing during critical periods, such as cool-season forages for kidding/Lambing or warm-season forages for summer grazing. Overseeding forages, especially cool-season legumes and grasses, can be quite cost-effective. Forage plant structure (bunch vs. sod forming) and tannin-containing plants can facilitate control of internal parasites. Control of internal parasites is often a more important factor in pasture management than maximizing forage production. Inclusion and/or maintenance of woody species in the goats' grazing system is beneficial. Woody species may be leguminous, provide high quality forage, tolerate drought, and enable animals to graze away from the soil, reducing parasite challenge. Nonetheless, the inclusion of woody species in grazing systems is limited by lack of information. Rotational grazing is important for the control of internal parasites, uniform utilization of available forages, weed control, and pasture persistence. Timely provision of supplements such as minerals and/or protein can increase intake and digestibility of available forage, mitigating need for additional supplementation. Fencing costs can be a major constraint of small ruminant pasture management, but electric fencing may be a cost-effective solution. Shade is necessary in humid areas, and a windbreak is necessary during cold weather to reduce stress in grazing animals. A well-planned water distribution system will facilitate a rotational grazing program. Predator control is essential for an effective small ruminant grazing program. An appropriate forage management plan will reduce internal parasite problems and costs of production, thereby improving profitability of the small ruminant enterprise.

Key Words: pasture management, grazing system, internal parasite

0736 Internal parasite anthelmintic resistance and control.

J. E. Miller*, *Louisiana State University, Baton Rouge.*

Gastrointestinal nematodes are major pathogens of small ruminants, and control has relied almost exclusively on the frequent use of anthelmintics. Nematodes, especially *Haemonchus contortus*, have developed resistance to all approved anthelmintics. *H. Contortus* is a problem in warm/wet environments like the southeastern United States (year-round) and is now a seasonal (summer) problem in the rest of United States. For the past 50+-plus years, recommended control strategies maximized benefits of treatment and ignored resistance issues. Resistance is the ability of nematodes to survive treatments that are generally effective at the recommended dose. Treatment eliminates those whose genotype renders them susceptible and those that are resistant survive and pass on their "resistant" genes. Resistant nematodes accumulate and finally treatment failure occurs. For anthelmintics to remain effective, refugia must be preserved. Refugia is the proportion of the population that is not selected by drug treatment and provides a pool of susceptible genes to dilute resistant genes in that population. Targeted selective treatment is a concept based on the unequal distribution of nematodes in the animal population. A small proportion of animals in a population harbor most of the nematodes and are responsible for most of the egg output and thus pasture contamination. Targeting only those animals for treatment will provide refugia in the untreated animals. Monitoring with FAMACHA and/or fecal egg counts are proven concepts to identify those animals needing treatment. Once identified, smart use of anthelmintics and incorporating alternative control measures into an integrated control program are essential for sustainability.

Key Words: small ruminant nematodes, anthelmintic resistance, control

0737 Genetic selection for enhanced production efficiency.

D. F. Waldron*, *Texas A&M AgriLife Research, San Angelo.*

The objective of this presentation is to cover issues related to using genetic selection to enhance production efficiency of small ruminants. Efficiency of production is a function of outputs and inputs. Meat and fiber production are the most economically important outputs. Outputs may be expressed as a function of number of breeding animals, amount of feed utilized, amount of land area, amount of time or labor required, or some other input factor. Genetic means of improving production efficiency should start with selection of the proper breed(s) for the production environment. Sheep and goat production can be thought of as a means of harvesting and con-

verting forage or grains to meat and fiber. Small ruminants can be productive in a variety of environmental conditions. The efficient breed(s) is one that fits the environment. Clarifying selection objectives is an important first step in developing a selection program. Selection for traits that have high heritability and can be measured early in life can yield results in a short period of time. Improvement in traits that can only be measured later in life and/or have a lower heritability take longer to yield results. An effective selection program must be adopted by enough breeders to have an impact on the larger population. The segmented nature of the meat and fiber industries does not lend itself to efficient communication of economic incentives for improvements in production. Breeders and producers may not realize the importance of traits that are crucial at the processing stage. Improvement in information flow via economic incentives will provide breeders with the information needed to set breeding goals. Improved knowledge of relative importance of traits, in all segments of the industry, will lead to design of more effective selection programs. Designing an effective selection program requires knowledge of genetic and phenotypic relationships among traits and relative economic values of output traits. Selection programs must also account for substantial changes in relative values of input traits.

Key Words: sheep, goats, genetics

0738 Efficiency of small ruminant reproductive management. M. Knights*, *West Virginia University, Morgantown.*

Productivity of the female small ruminant is below its true potential in part due to suboptimal reproductive performance. Lifetime reproductive performance of the ewe is influenced by age at first lambing, frequency of lambing and prolificacy. Replacement females comprise 20 to 30% of the breeding flock but their pregnancy rates, embryonic survival and prolificacy are lower than that of their adult flock mates, which reduces overall reproductive efficiency. Strong correlations exist between weight at first breeding and variables contributing to lambing rate. A positive correlation also has been reported between fertility and genetic potential for growth of the ewe lamb. These findings indicate that fertility of replacements can be improved through nutritional management and selection without delaying the age at first breeding. Additionally, pre-treatment with progestogen and gonadotropins enhances fertility and should be integrated in management of replacements. Seasonality of reproduction restricts lambing to once per year in temperate latitudes. Frequency of lambing can be accelerated by increasing the proportion of females bred out -of-season through light management, selection and breeding, and the use of the male effect in combination with pre-treatment with progestogens. These approaches are less effective in fall-born ewe lambs and lactating ewes, but genetic selection may improve fertility in these categories. Development of efficient, low-cost weaning systems, and approaches that increase the fertility of the lactating ewe during seasonal anestrous are needed to increase lifetime reproductive performance. Maintaining an appropriate ratio of parous to non-parous breeding females, synchronization of estrus, and pregnancy diagnosis will increase the proportion of ewes lambing and assist in controlling the timing of births to facilitate accelerated lambing programs. Wide variation in ovulation rate and prolificacy exists between and within breeds and across parity, and, lower prolificacy is observed in ewe lambs and ewes bred out-of-season. Optimum prolificacy can be achieved through a combination of selection and breeding, nutritional management and by maintaining an appropriate parity distribution in the breeding flock. Pharmacological treatments, including use of gonadotrophic hormones and immunization against protein and steroid hormones can increase prolificacy, but the response is limited by increasing prenatal losses as ovulation rate is increased. Cost effectiveness of such treatments needs to be evaluated further. In conclusion, our current understanding of reproduction provides an opportunity to make incremental changes to age at first lambing, pregnancy rate, frequency of lambing and prolificacy and thereby increase lifetime reproductive performance of the ewe.

Key Words: reproductive efficiency, small ruminants

0739 Managerial steps to alleviate the effects of heat stress, water deprivation, and low pasture quality in small ruminants. P. Y. Aad*[1] and S. Abi Saab[2], [1]*Notre Dame University, Zouk Mosbeh, Lebanon,* [2]*Lebanese University, Faculty of Agricultural Sciences, Dekwaneh, Lebanon.*

Global environmental challenges as depicted by increased ambient temperature by 0.7°C, decreased rainfall, and unpredictable weather patterns are associated with global warming. Such changes are translated by an increase in heat stress amplitude and duration, less water, and more solar radiation, resulting in slower pasture growth, higher soil erosion, and overgrazing. Therefore, small ruminants will be exposed to more days outside thermal neutral zone, less available water, and poorer pasture quality. Unfortunately, in most parts of the world threatened by global warming, small ruminants are managed extensively and walk long distances for pastures and water access. Heat stress in sheep and goat is associated with both lower feed intake and performance. Intensive small ruminant production could benefit from highly digestible and denser energy diets as supplemented by fats or isoflavonoids, and temperate water with modulated salt content. Moreover, in extensively managed animals, proper pasture rotation to prevent overgrazing, and the use of mixed pasture such as legume and grass could provide proper feeding under heat stress conditions. Furthermore, traveled distance modulation, timing of sheering, shade, ventilation and sprinkles provide good management to alleviate solar radiation intensity and heat stress and additionally improve follicular and semen quality

and prevent early embryonic loss. Breeding strategies and the usage of locally adapted breeds should be promoted alongside planned breeding for animals with lower environmental impact. Small ruminants, when properly managed, have the potential to be good energy converters and could provide a viable solution for food security in a globally warming world.

Key Words: heat stress, gobal warming, small ruminant management

0740 Global demand for small ruminant products.

G. W. Williams* and D. Anderson, *Texas A&M University, College Station.*

A dynamic world market continues to evolve for the products of small ruminants. Small ruminants, for this paper, are restricted to sheep and goats. While we may focus on lamb and sheep meat, other products including goat meat, wool, mohair, and cashmere remain important. Several factors are at work in today's global market for small ruminant products. As usual, they are the classic factors that affect the demand for any product: the product's own price, consumer incomes, the prices of competing goods, and changing tastes and preferences. Fueled by growth of the Chinese economy and incomes, Chinese sheep meat imports have surged in recent years. In 2012, China overtook France as the world's largest importer of sheep meat by volume. China imports primarily lower value cuts so that the average value of the Chinese sheep meat imports is lower than that of Northern European and U.S. markets. Nevertheless, the average value of Chinese sheep meat imports is growing. A better picture of the changing market requires a look at supply as well as demand factors impacting the market. Global sheep flock numbers remain just below the 2007 peak of about 1.1 billion head, although some growth in flocks did begin to occur again in 2011. China has the world's largest flock at 139 million head. Global sheep meat production has grown by 20% over the last decade, however, due to increases in productivity. The major meat exporting countries of Australia and New Zealand are in the top 10 ranking by flock size. Production in those countries has been hampered by drought, volatile prices, and the profitable economics of competing enterprises like dairy and milk production. U.S. sheep meat production has declined by 35% over the last decade. Although decreased global wool production has led to higher prices in recent years, those prices have been tempered by the effects of the worldwide recession on demand. The demand for relatively high priced fibers has struggled during the recession and economic recovery. Overall, the global market for small ruminant market continues to evolve. Trade flows between countries are changing as incomes rise and production patterns shift.

Key Words: sheepmeat, wool, China

SWINE SPECIES: MINI-SYMPOSIUM: OPPORTUNITIES AND CHALLENGES WITH THE USE OF CARBOHYDRASE AND PROTEASE ENZYMES IN SWINE FORMULATIONS

0741 Opportunities and challenges with the use of carbohydrase and protease enzymes in swine formulations.

R. T. Zijlstra[*1], T. A. Woyengo[1], Z. Nasir[1], and E. Beltranena[1,2], *[1]University of Alberta, Edmonton, Canada, [2]Alberta Agriculture and Rural Development, Edmonton, Canada.*

Co-products from crops processed for the food, biofuel, or bio-industry are attractive feed ingredients to manage feed costs per unit of gain in pigs. Compared with crops from which they are derived, alternative feed ingredients may contain more anti-nutritional factors such as phytate, fiber, and indigestible proteins that may limit nutrient digestibility. Together with feed processing technologies and advanced feed quality evaluation techniques, supplemental feed enzymes are important parts of a strategy to mitigate the risks associated with high dietary inclusion of co-products and reduce feed cost per unit of gain. Supplementation of feed enzymes to cereal-based diets has been studied. Recently, feed enzyme technology has been applied to co-products. Among feed enzymes, phytase inclusion has one of the most consistent effects on increased nutrient digestibility, especially for P. For fiber-degrading enzymes (carbohydrases) and proteases, some important considerations are: 1) the substrate for the enzyme must be the main limitation for digestibility of the nutrient of interest, 2) processing technology may affect the content and functional characteristics of fiber in the co-product, and 3) age and thus gut development may affect responses to enzyme supplementation. Generally, carbohydrases increase energy digestibility, but their effects on AA and P digestibility are variable depending on trial conditions. Protease enzymes appear to have less consistent effects on nutrient digestibility in grower pigs. Due to the alterations made in nutrient flow through the intestinal tract, supplemental enzymes may also alter nutrient availability to intestinal microbes, and hence alter microbial populations. Thus apart from opportunities, a major challenge for using carbohydrases and proteases is to obtain effects as consistent as observed for phytase. If solved, application of enzyme technology combined with modern feed processing and feed quality evaluation technologies may then provide the pig with additional energy, AA, and P resulting in cost-effective, predictable growth performance and carcass quality.

0742 Betaine supplementation in maternal diet modulates the epigenetic regulation of hepatic gluconeogenic genes in neonatal piglets.

D. Cai*, Y. Jia, H. Song, S. Sui, J. Lu, Z. Jiang, and R. Zhao, *Nanjing Agricultural University, China.*

Maternal gestational nutrition provides a critical window in which neonates are predisposed to metabolic syndrome in adult life. Betaine as a methyl-donor nutrient is critical for fetal development and it donates methyl donors for DNA and protein methylation through methionine metabolism, which is critical for the epigenetic regulation of gene expression. However, direct evidence regarding the effects of betaine supplementation in maternal diet during gestation on hepatic gluconeogenic genes in neonatal offspring are lacking. In this study, gestational sows were fed control or betaine-supplemented diets (0.3% w/w) throughout the pregnancy, and we are aiming to elucidate if maternal dietary betaine affects offspring hepatic gluconeogenic genes through epigenetic mechanisms. Neonatal piglets born to betaine-supplemented sows had significantly higher serum and hepatic betaine contents ($P < 0.05$), together with significantly enhanced expression of methionine metabolic enzymes ($P < 0.05$) in the liver. Interestingly, significantly higher serum concentrations of lactic acid ($P < 0.05$) and glucogenic amino acids, including serine ($P < 0.05$), glutamate ($P < 0.05$), methionine ($P < 0.05$) and histidine ($P < 0.05$) were detected in betaine-exposed piglets, which coincided with higher hepatic glycogen content ($P < 0.05$) and greater protein expression of gluconeogenic enzymes, pyruvate carboxylase (PC) ($P < 0.05$), cytoplasmic phosphoenolpyruvate carboxykinase (PEPCK1) ($P < 0.05$), mitochondrional phosphoenolpyruvate carboxykinase (PEPCK2) ($P < 0.05$) and fructose-1, 6-bisphosphatase (FBP1) ($P < 0.05$). Moreover, maternal betaine significantly changed the methylation status of both CpGs and histones on the promoter of gluconeogenic genes. The decreased *PEPCK1* mRNA was associated with DNA hypermethylation ($P < 0.05$) and increased repression histone mark H3K27me3 ($P < 0.05$), while the up-regulated *PEPCK2* and *FBP1* mRNA was associated with DNA hypomethylation ($P < 0.05$) and increased activation histone mark H3K4me3 ($P < 0.05$). Furthermore, hepatic expression of miRNAs predicted to target *PC* and *PEPCK1* was also affected by maternal betaine supplementation. Two out of seven miRNAs targeting *PC* and 6 out of 7 miRNAs targeting *PEPCK1* were detected to be dramatically suppressed ($P < 0.05$) in the liver of betaine-exposed piglets. Our results provide the first evidence that maternal betaine supplementation affects hepatic gluconeogenic genes expression in newborn piglets through enhanced hepatic methionine metabolism and epigenetic regulations which involve DNA and histone methylations, as well as miRNAs-mediated post-transcriptional mechanism.

Key Words: betaine, epigenetic regulation, gluconeogenic genes expression

0743 Rearing system affects the efficiency of oleic acid deposition in Duroc x Iberian pigs.

D. Solà-Oriol[1], S. López-Vergé*[1], E. Varella[2], A. C. Barroeta, and J. Gasa[1], *[1]Animal Nutrition and Welfare Service, Dep. of Animal and Food Sciences, Universitat Autònoma de Barcelona, Bellaterra, Spain, [2]Tecnología & Vitaminas, S.L., Alforja, Spain.*

The aim of the study was to evaluate the impact of the rearing system (intensive 2.5 m^2/pig vs. semi-extensive 30 m^2/pig) used during the growing-finishing period on PUFA deposition by using an oleic enriched diet during the finishing period. The Iberian pig regulations require a minimum of 51% of oleic acid in fat (10 cm from the caudal basis) at slaughter to be considered for cured ham. Therefore, the effect of the rearing system on the time spend to reach the oleic acid proportion was also evaluated. A total of 16 barrows (Duroc x Iberian) were selected at 90 kg of BW ($n = 8$ per system) and offered the same growing and finishing diets. A diet based on barley–wheat–oats and soybean–sunflower meal to contain 14.7 MJ/kg ME; 5.7 g/kg Lys; 60.9 g/kg ether extract and 34.3 g/kg oleic acid was fed for the finishing period. Back fat samples were collected from each pig on Days 0, 14, 28, 62, and 85 (slaughter) of the finishing period. Back fat samples were collected by an automatic cut/extraction system with a needle (8 mm Ø), and fatty acid profile was analyzed by the direct transesterification method and the percentage of oleic acid content calculated. The deposition response of the oleic acid was fitted by linear regression using the REG procedure of SAS. The comparison of slopes and times were analyzed with ANOVA by using the GLM procedure of SAS. The oleic acid deposition response for the semi-extensive reared pigs was y = 46.6 + 0.054(t) ($R^2 = 0.84$), while for the intensive reared pigs was y = 47.5 + 0.071(t) ($R^2 = 0.83$). Higher efficiency for oleic acid deposition was observed for the animals reared in the intensive system ($P = 0.013$). Therefore, a reduction of the days spent to reach the required level of oleic acid (51%) was observed for the animals reared in the intensive system than those reared in a semi-extensive system (49.0 vs. 80.4 d SEM = 5.24; $P = 0.003$). However, although higher efficiency on oleic acid and PUFA deposition was observed for the animals reared in the intensive system, the higher subcutaneous and inter-muscular but not intramuscular (marbling) fat content of the semi-extensive reared pigs has to be taken into account. It is concluded that the rearing system has a high impact on the efficiency of oleic acid deposition.

Key Words: Iberian, oleic acid, rearing system

0744 Effects of sugar beet pulp on reproductive performance of gestation sows. Z. Cheng*, D. Hou, Y. Chen, H. Zhang, B. Wang, Y. Wang, S. Bai, H. Lei, S. Jiang, and W. Jin, *Animal Nutrition & Feed Center, COFCO Nutrition and Health Institute, Beijing, China.*

Sugar beet pulp is widely used as feed ingredient in dairy feeds. However, its use in sow feeds may benefit sows because of its high level of fiber. The purpose of the study was to investigate the use of sugar beet pulp to see if there is any benefits for gestation sows fed sugar beet pulp. One hundred gestation sows were divided into three treatments with 33, 34, and 33 sows per treatment, they were fed diets containing 0, 7.5, or 15% of sugar beet pulp at breeding, respectively, for 3 mo. The diets contained the same calculated levels of crude protein and digestible energy. On d 91, they were fed the same lactating sow diets for another 25 d until farrowing. Total number of pigs born were 12.48 ± 2.44, 12.28 ± 2.21, and 13.24 ± 2.26 for sows fed diets containing 0, 7.5, or 15% of sugar beet pulp, respectively. Total pigs born live weight were 17.66 ± 2.87 kg, 17.86 ± 3.82 kg, and 18.45 ± 2.98 kg, for sows fed diets containing 0, 7.5, or 15% of sugar beet pulp, respectively. There were no significant differences in total pigs born and total pigs born live weight among all treatments ($P = 0.063$). Total number of pigs born alive were 11.76 ± 2.23, 12.00 ± 2.08, and 13.05 ± 2.40, for sows fed diets containing 0, 7.5, or 15% of sugar beet pulp, respectively; total number of pigs born alive were significantly increased ($P < 0.032$) by supplementing 15% sugar beet pulp into gestation sow diets as compared to control sow diets.

Key Words: sugar beet pulp, gestation sows, reproductive performance

0745 Utilizing meta-analyses to generate prediction equations for pork carcass back, belly, and jowl fat iodine value. C. B. Paulk*[1], J. R. Bergstrom[2], M. D. Tokach[1], S. S. Dritz[1], D. D. Burnett[1], J. M. DeRouchey[1], R. D. Goodband[1], J. L. Nelssen[1], and J. M. Gonzalez[1], *[1]Kansas State University, Manhattan, [2]DSM Nutritional Products, Inc., Parsippany, NJ.*

Iodine value (IV) is a measure of unsaturated fatty acids and is currently the industry standard for assessing pork fat quality. The objective of this meta-analysis was to use data from existing literature to generate equations to predict back, belly, and jowl fat IV of finishing pigs. The final database resulted in 24 papers with 169 observations for backfat IV, 21 papers with 124 observations for belly fat IV, and 29 papers with 197 observations for jowl fat IV. Some observations (back $n = 36$, belly $n = 37$, and jowl $n = 45$) changed dietary fatty acid composition during the experiment (i.e., switching from higher to lower or lower to higher iodine value product diet), where initial diets (I) were defined as those fed before the change in diet composition and final diets (F) were defined as those fed after the change in diet composition. The predictor variables tested were divided into five groups: 1) diet fat composition (dietary percent C16:1, C18:1, C18:2, C18:3, EFA, and unsaturated fatty acids, and iodine value product) for both I and F diets; 2) duration of feeding of the I and F diets; 3) ME or NE content of the I and F diet; 4) performance criteria (initial BW, final BW, ADG, ADFI, and G:F); and 5) carcass criteria (HCW and backfat thickness). PROC MIXED (SAS institute, Inc., Cary, NC) was used to develop regression equations, and experiment within paper was included as a random effect. Statistical significance for including terms in the models was determined at $P < 0.10$. Evaluation of models with significant terms was then conducted based on the Bayesian Information Criterion (BIC), where the lowest BIC were preferred. Optimum equations to predict back (BIC = 739), belly (BIC = 558), and jowl (BIC = 758) fat IV were: backfat IV = 84.83 + (6.87 × I EFA) − (3.90 × F EFA) − (0.12 × I d) − (1.30 × F d) − (0.11 × I EFA × F d) + (0.048 × F EFA × I d) + (0.12 × F EFA × F d) − (0.0060 × F NE) + (0.0005 × F NE × F d) − (0.26 × backfat depth); belly fat IV = 106.16 + (6.21 × I EFA) − (1.50 × F d) − (0.11 × I EFA × F d) − (0.012 × I NE) + (0.00069 × I NE × F d) − (0.18 × HCW) − (0.25 × BF); and jowl fat IV = 85.50 + (1.08 × I EFA) + (0.87 × F EFA) − (0.014 × I d) − (0.050 × F d) + (0.038 × I EFA × I d) + (0.054 × F EFA × F d) − (0.0066 × I NE) + (0.071 × I BW) − (2.19 × ADFI) − (0.29 × backfat depth). These regression equations may be used to predict the back, belly, and jowl fat IV of finishing pigs fed different diets.

Key Words: Iodine value, meta-analysis, pork quality

0746 The effects of copper source (copper sulfate or methionine hydroxy analogue chelate; Mintrex) on growth performance, carcass characteristics, and barn cleaning time in finishing pigs. K. F. Coble*[1], J. M. DeRouchey[1], M. D. Tokach[1], S. S. Dritz[1], B. Lawrence[2], J. Escobar[2], J. C. Woodworth[1], R. D. Goodband[1], and N. Boettger[2], *[1]Kansas State University, Manhattan, [2]Novus International, St. Charles, MO.*

Copper source and feeding duration on growth performance, carcass characteristics, and pen wash time were determined using 1196 pigs (initially 25.7 kg BW) in a 111-d study. Pigs were allotted to one of six dietary treatments, based on initial pen weight in a randomized incomplete block design with 26 pigs/pen and seven to eight pens/treatment. A negative control diet was supplemented with 17 ppm Cu from the basal trace mineral. Remaining diets were formulated by supplementing the negative control with 50 ppm Cu from $CuSO_4$ or Mintrex, or 125 ppm Cu from $CuSO_4$. The 50 ppm Cu as CuSO4 diet was fed for 111 d. The 50 ppm Mintrex and 125 ppm CuSO4 diets were fed for either 42 or 111 d. Diets were formulated 0.05% below the estimated standardized ileal digestible Lys

Table 0746. Copper source, level and duration for finishing pigs

Cu source		$CuSO_4$	Mintrex Cu	$CuSO_4$	Mintrex Cu	$CuSO_4$		
Added Cu, ppm		50	50	125	50	125		Treatment,
Duration, d	0–111	0–111	0–42	0–42	0–111	0 -111	SE	$P <$
d 111 BW, kg	122.7	124.6	124.3	122.5	125.3	125.0	1.33	0.16
ADG, kg	0.890	0.907	0.901	0.883	0.909	0.901	0.008	0.12
ADFI, kg	2.25[c]	2.33[a]	2.26[bc]	2.25[c]	2.30[abc]	2.31[ab]	0.027	0.02
G:F	0.397[ab]	0.389[c]	0.399[a]	0.393[abcc]	0.396[abc]	0.390[bc]	0.003	0.04
HCW, kg	89.0	89.3	88.9	89.4	89.7	90.2	0.92	0.71

[1] Means within row with different superscripts differ, $P < 0.05$.

requirement. Average daily gain was not affected ($P > 0.12$). Pigs fed either 50 or 125 ppm of Cu from $CuSO_4$ from d 0–111 had greater ADFI ($P < 0.02$) than pigs fed the control or diet with 50 ppm of added Cu from Mintrex from d 0–42. Feed efficiency was poorer ($P < 0.04$) for pigs fed either 50 or 125 ppm of added Cu from $CuSO_4$ fed throughout compared with those fed 50 ppm of Cu from Mintrex from d 0 to 42. There were no differences in final BW, HCW, or pen wash time. In summary, pigs fed 50 ppm of Cu from Mintrex for the first 42 d of the finishing period had improved G:F compared with pigs fed 50 or 125 ppm of Cu from $CuSO_4$ for the complete finishing period; however, G:F for those pigs was not improved when compared to those not fed added Cu.

Key Words: finishing pig, copper, wash time

0747 Immunocastration affects testicular mass, serum concentrations of testosterone, and average daily gain of boars. D. Lugar*[1], S. Clark[2], S. Callahan[1], L. Wittish[1], and M. Estienne[3], *[1]Virginia Tech, Blacksburg, [2]Virginia–Maryland Regional College of Veterinary Medicine, Blacksburg, VA, [3]Virginia Tech, Suffolk.*

The objective of this study was to determine the effects of an immunological castration product (Improvest, Zoetis) on reproductive steroid hormones, reproductive organs, and growth. A total of 72 Landrace x Yorkshire boars (69 d of age, 22.76 ± 4.64 kg BW) were used in two successive replications. This study was a randomized design with three treatment groups: single injection (SI) of Improvest at 10 wk of age, double injection (DI) of Improvest at 10 and 15 wk of age, and intact controls (no Improvest; CNT) (n = 24 per group). At wk 10, 15, 20, and 25, blood was collected and serum harvested to evaluate testosterone concentrations via RIA, and BW were determined. At wk 25, 18 pigs (n = 6 per group) were sacrificed and testicles were removed, weighed, and measured for length, width, and circumference. Statistical analysis was performed using JMP Pro 10. Testosterone concentrations at wk 20 and 25 were less ($P < 0.0001$ and $P = 0.0003$, respectively) for DI (0.065 ng/mL and 1.178 ng/mL, respectively) compared to SI (1.589 ng/mL and 6.372 ng/mL, respectively) and CNT (1.356 ng/mL and 5.920 ng/mL, respectively). Testosterone concentration for wk 10 and 15 were similar ($P = 0.5332$ and $P = 0.7875$, respectively) among the three treatments. Body weights were greater ($P = 0.017$) for DI compared to CNT at wk 25 (122.0 kg and 117.6 kg, respectively), while SI (120.1 kg) was not different ($P = 0.398$) from DI and tended ($P = 0.119$) to be greater than CNT. The ADG from birth to the initiation of the treatments (10 wk of age) was not different ($P = 0.7631$) among treatments; ADG from 10 to 25 wk of age was greater ($P = 0.0093$) for DI compared to CNT and there was a tendency ($P = 0.067$) toward a greater ADG for SI compared to CNT. Both left and right testicle length, width, and circumference were less ($P < 0.0001$) for DI compared to SI and CNT. Testicle wt (g/kg BW) was less ($P < 0.0001$) for both the left and right testicles for DI compared to SI and CNT. The results of the current study indicate that immunological castration has a major impact on ADG and that a single injection tended to cause a greater ADG when compared to intact males

Key Words: boars, immunocastration, swine

0748 New perspectives to the enterotoxigenic *E. coli* F4 infection model in weanling piglets in relation to the susceptibility genotypes and bacterial shedding. P. J. Roubos*, R. H. G. M. Litjens, J. W. Resink, and Y. M. Han, *Nutreco Research & Development, Boxmeer, Netherlands.*

Post-weaning diarrhea caused by enterotoxigenic *E. coli* (ETEC) is a major problem in weaner piglets. Responses of individual animals to ETEC infection are very different and show high varieties in animal experiments with ETEC infection. The aim of this study was to optimize the ETEC F4ac infection model in piglets by combining the genotype susceptibility with performance and bacterial shedding.

Before weaning 120 male piglets (individual housed) were tested for susceptibility or resistance towards ETEC O149:F4ac by a DNA marker based test. After weaning (27 ± 2-d-of-age) the piglets were orally infected with 5 mL of an inoculum suspension (containing $1.5*10^8$ CFU/ml ETEC F4ac in a 2.5% sucrose solution) at d 7, 8, and 9 after weaning. Fecal bacterial shedding was determined at d 7 (before challenge), 10, and 13 by spreading on CBA plates. Hemo-

lytic colonies were confirmed by an agglutination test with an ETEC F4ac specific antiserum. In the first week after challenge all (n = 4) homozygote sensitive (SS) animals died. During the same period, feed efficiency (FE) was significant lower ($P < 0.001$) in heterozygote sensitive (RS)-animals (FE = 0.67; n = 61) compared with the homozygote resistant (RR) animals (FE = 0.8; n = 55). After this week the animals started to recover and the feed efficiency differences became less. Diarrhea incidence was significantly different ($P < 0.001$) between genotypes SS (91%) compared to RS (67%) and RR animals (47%) in the first week after challenge. Furthermore while ETEC was hardly detected in the fecal material of the RR animals, they were found in most of the RS animals and in all SS animals (see Table 0748). In conclusion, susceptible animals (RS and SS) compared to resistant animals (RR) animals showed poorer feed efficiency, higher diarrheal incidence and higher numbers of ETEC fecal shedding in the first week after challenge. The DNA marker based test can be used to select animals that are susceptible for ETEC for inclusion in the ETEC infection model.

SYMPOSIUM: PROCEDURES AND METHODOLOGY FOR DETERMINING STANDARD ILEAL DIGESTIBILITY (SID) AMINO ACID DIGESTIBILITY AND ENERGY OF FEEDSTUFFS

0749 Procedures and methodology for determining standard ileal digestibility (SID) amino acid digestibility of feedstuffs. H. H. Stein*, *University of Illinois at Urbana-Champaign, Urbana.*

Since results of the first digestibility experiments with animals and humans were published more than 250 yr ago, it has been known that not all nutrients that are ingested by an animal are absorbed. The early work with AA digestibility was based on determining apparent total tract digestibility of AA in individual feed ingredients using rats or chickens as models. It was soon recognized that to avoid the contribution of microbial protein to AA output, AA digestibility is more correctly determined as ileal digestibility. The first procedure to collect digesta from the distal ileum, the reentrant ileal cannula, was described in 1962 and in 1974 the first description of the intestinal T-cannula was published. With this technique, it became possible to collect fluids from the distal ileum and by subtracting the ileal output of AA from the intake of AA it is possible to calculate the ileal digestibility of individual AA. In addition to dietary AA that enter the intestinal tract, there is also a contribution of endogenous AA that are secreted in the form of mucins, enzymes, bile acids, etc., and because of the contribution of endogenous AA to the ileal output, digestibility values that are calculated by subtracting the ileal output of AA from the intake are called apparent ileal digestibility (AID) values. The practical consequence of the endogenous contribution of AA is that values for AID that are measured in individual feed ingredients often are not additive in mixed diets. The endogenous AA may be divided into AA that are non-specific to the diets, also called basal endogenous AA, and AA that are secreted in response to the diet that is being fed. Basal endogenous AA and are not needed for calculation of digestibility values that characterize specific feed ingredients and may be determined after feeding a protein-free diet. By disregarding the basal endogenous losses in the calculation, values for standardized ileal digestibility (SID) are calculated. This concept was first proposed in 1995 and later publications documented that values for SID of AA are additive in mixed diets when fed to pigs. Because practical diet formulation relies on the assumption that values for AA digestibility in individual ingredients are additive in mixed diets, diets are most correctly formulated based on values for SID of AA.

Key Words: amino acids, ileal digestibility, pigs

0750 Procedures and methodology for determining the net energy content of feedstuffs. C. M. Nyachoti*, *University of Manitoba, Winnipeg, Canada.*

Feed is the single most expensive input in commercial pork production and a large portion of the cost associated with feed is related to supplying energy. Thus, there have been concerted efforts to develop methods and systems for evaluating the energy content of feed. In this regard, the net energy (NE) system, which takes into account the metabolic utilization of energy, has been proposed as a superior system for characterizing the energy value of feeds. Furthermore, the NE system allows for a more effective use of high fiber feedstuffs and may lead to reductions in feed cost. Various procedures and methods have been used to determine NE in feeds and feedstuffs, the most common ones being the comparative slaughter (CS) and indirect calorimetry (IC) methods. Each of these methods has its advantages and disadvantages. For instance, although the CS method is regarded as the gold method, it is labor-intensive and requires a large number of animals. The IC method requires fewer animals, takes a relatively short period of time and can be used for repeated measurement of energy balance, but it also requires sophisticated and often expensive equipment for the required gaseous exchange measurements. Nonetheless, the IC method is the most commonly used method for determining the NE content in swine feed and feedstuffs and require accurate estimation of energy lost as heat and the energy required for maintenance. These estimates, which are influenced by several factors including physiological status and activity level, have direct impact on the NE estimates obtained, and therefore it is critical that these are accurately determined. For routine estimation of NE content, however, prediction equations based on chemical composition measurements of feeds and feedstuffs have been suggested, although questions of acceptability for such equations still exists. In this presentation, the procedures and methods for estimation of NE in feeds and feedstuffs and considerations for design of experimental diet will be discussed. Results of recent studies comparing determined and predicted NE values will be highlighted.

Key Words: net energy, methodologies, feeds, feedstuffs, pigs

0751 Procedures for determining digestible and metabolizable energy contents of feedstuffs. O. Adeola*, *Department of Animal Sciences, Purdue University, West Lafayette, IN.*

A pig derives energy for cellular processes by oxidation of carbohydrates, amino acids, and fatty acids contained in feeds, and thus the resulting energy is equal to the sum of the energy produced from oxidation of these feed nutrients. The utilization of energy in a feed for pigs may be determined by total collection method in which pigs are fed test diet over a period of time and then feces and urine are collected for

subsequent chemical analysis. Depending on the collected energy-containing components (feces and urine), either apparent digestible (DE) or metabolizable energy (ME) can be determined. Total quantitative collection of feces and urine from pigs fed the diet or ingredient is achieved by placing pigs in metabolism cages with feed intake and feces and urine output commonly determined over a 5-d period that is preceded by an adaptation period of 5 to 10 d. Ensuring that the feces collected originate from the feed provided during the 5-d collection period requires a marker that is added to the feed at the beginning and end of the collection period to signal the start and end of feces collection, respectively. Urine collection during the period when feces are collected starts and ends at the time of marker addition to the feed at the beginning and end of the collection period. The difference between the gross energy (GE) in the feed and that in the feces is DE. Subtracting the GE in urine from the DE of the diet gives ME. For most pig feed, the ME is between 92 and 98% of the DE.

Key Words: digestible energy, feed, metabolizable energy, pig

0752 Apparent and standardized ileal amino acids digestibility for different protein feedstuffs fed at two dietary protein levels for growing pigs.
A. O. Adebiyi[1], D. Ragland[2], L. Adeola[2], and O. A. Olukosi[*1], *[1]Scotland's Rural College, Ayr, UK, [2]Purdue University, West Lafayette, IN.*

This study determined the apparent and standardized ileal amino acids digestibility (AID or SID) for growing pigs fed three protein feedstuffs with different fiber types at two dietary crude protein (CP) levels. Twenty boars (Yorkshire × Landrace) with 35 kg body weight and fitted with a simple T-cannula at the distal ileum were used. The treatments were three protein feedstuffs [soybean meal (SBM), canola meal (CM) or corn distillers dried grains with solubles, (cDDGS)] and two dietary CP levels (18 or 14%). Eighteen pigs were allocated to the experimental diets using a replicated 6 × 2 Youden square design. In each of the two experimental periods, two pigs were offered a nitrogen free diet to determine basal endogenous amino acid flow. Digesta was collected for 2 d after 5 d of adaptation. Reducing dietary CP level by 4% did not affect AID of DM and AA or SID of AA. Except for Met, Trp, Cys and Pro, AID for all the other AA were greater ($P < 0.05$) in the SBM diet compared with the CM diet. Apparent ileal digestibility for Gly and Asp was greater ($P < 0.05$) for the SBM diet compared with the DDGS diet. The AID for Ile, Leu, Phe, Val, Ala, Tyr and Asp was greater ($P < 0.05$) in the DDGS diet compared with the CM diet. There was protein feedstuff × protein level interaction ($P < 0.05$) for AID of Lys because in the diets with 18% CP, the AID of Lys was greater ($P < 0.05$) in the SBM and cDDGS diets compared with the CM diet, whereas the AID of Lys was not different among the protein feedstuffs in diets with 14% CP. Standardized digestibility was greater ($P < 0.05$) in the SBM diet compared with the CM diet for all AA except Trp and Pro, whereas the SID of Gly and Asp were greater ($P < 0.05$) in the SBM diet compared with the cDDGS diet. Standardized digestibility for Ile, Leu, Val, Ala, Tyr and Asp were greater in the cDDGS diet compared with the CM diet. It was concluded that differences in AA digestibility observed for the pigs were related to differences in chemical, including fiber, profiles of the protein feedstuffs used but independent of dietary CP level.

Key Words: amino acids, protein feedstuff, protein level

0753 Effects of high levels of nicotinic acid on growth, carcass traits, and meat quality of finishing pigs.
J. R. Flohr[*1], J. M. DeRouchey[1], J. C. Woodworth[1], M. D. Tokach[1], S. S. Dritz[1], R. D. Goodband[1], T. A. Houser[1], C. A. Fedler[2], and K. J. Prusa[2], *[1]Kansas State University, Manhattan, KS, [2]Iowa State University, Ames, IA*

A total of 1232 pigs (PIC 337 × 1050; initially 27.0 ± 0.51 kg) were used in a 98-d study to determine the influence of high doses of added nicotinic acid (NA) on growth, carcass traits, and meat quality of finishing pigs during the summer months. Average daily high, mean, and low temperatures were 27.5, 23.9, and 20.5°C, respectively. There were 28 pigs per pen and 11 replications per treatment. Four dietary treatments were made by adding 0, 350, 700, or 1050 mg/kg NA (Lonza, Allendale, NJ) to a corn-soybean meal basal diet that contained 30 mg/kg of added NA. Diets were fed in four phases with the same NA concentrations in each phase. On d 98 of the study, two pigs per pen (one barrow and one gilt) were transported to a commercial abattoir. Carcass traits and pH decline (45 min, 3, and 21 h) were measured at the abattoir. Afterward, a 40-cm segment of boneless LM was used to determine purge loss and ultimate pH following a 10-d aging period. Then 2.5-cm boneless chops were cut and used to measure subjective color and marbling, objective color (L*, a*, b*), 24-h drip loss, and NA concentration. Overall (d 0 to 98), increasing NA had no effect on ADG or G:F; however, ADFI tended ($P = 0.07$) to increase. Carcass traits were not influenced by NA. Forty-five min and 21 h pH were decreased with increasing NA ($P < 0.01$), but ultimate pH was not different. Purge loss, drip loss, and NA concentrations were not influenced by treatment. The a* and b* were increased ($P < 0.05$) with increasing NA; however, subjective color scores were not different among treatments. Overall, high doses of NA had little influence on growth, carcass traits, and meat quality of finishing pigs raised in a commercial setting.

Key Words: finishing pigs, niacin, nicotinic acid

Table 0753. Effects of added dietary NA on growth and meat quality of finishing pigs

	Dietary NA, mg/kg					Probability, $P <$

0754 Effects of sugar beet pulp and expansion on performances of lactating sows and nursery piglets. Z. Cheng*, D. Yuan, D. Hou, Y. Chen, H. Zhang, Y. Wang, W. Jin, B. Wang, H. Lei, Q. Li, S. Jiang, S. Bai, and Z. Zhang, *Animal Nutrition & Feed Center, COFCO Nutrition and Health Institute, Beijing, China.*

Ninety-six PIC lactating sows were divided into six treatments with 16 sows per treatment. They were fed diets containing 0, 5, or 10% of sugar beet pulp for 21 d. Three treatment diets were pelleted, and the other three diets were expanded and then pelleted. The diets contained the same calculated levels of CP and DE, sows were fed three times daily. On d 21, piglets were weaned and performances of lactating sows and nursery piglets were recorded. Results indicated that total weaning weight of piglets per litter and average daily weight gain of piglets were 50.47 ± 6.14 kg/Litter and 201.70 ± 30.17 g/piglet; 51.07 ± 11.04 kg/Litter and 189.04 ± 45.89 g/piglet; and 53.43 ± 12.31 kg/Litter and 207.27 ± 41.79 g/piglet for sows fed diets containing 0, 5, or 10% of pelleted sugar beet pulp, respectively; and total weaning weight of piglets per litter and average daily weight gain of piglets were 62.19 ± 12.56 kg/Litter and 222.38 ± 36.75 g/piglet; 47.97 ± 10.63 kg/Litter and 198.13 ± 47.15 g/piglet; and 53.75 ± 7.35 kg/Litter and 193.81 ± 36.30 g/piglet for sows fed diets containing 0, 5, or 10% of expanded and then pelleted sugar beet pulp, respectively. Results also indicated that expansion has significant effects on sow feed intake, total weaning weight of piglets per litter and average daily weight gain of piglets ($P < 0.05$), feed intake was 3.26 ± 0.90 kg/d and 4.77 ± 0.71 kg/d, for sows fed pelleted and expanded diets, respectively; total weaning weight of piglets per litter was 50.47 ± 6.14 kg/Litter and 62.19 ± 12.56 kg/Litter for sows fed pelleted and expanded diets, respectively; and average daily gain of piglets was 201.70 ± 30.17 g/d and 222.38 ± 36.75 g/d for sows fed pelleted and expanded diets, respectively. There were no internations between sugar beet pulp and diet forms ($P > 0.05$).

Key Words: sugar beet pulp, pellet, expansion, lactation sows, piglets

0755 The evaluation of narasin in grow-finish swine diets. L. Greiner[1], R. Barrett[1], A. Graham[*1], and J. Connor[2], *[1]Carthage Innovative Swine Solutions, Carthage, IL, [2]Carthage Veterinary Service, Ltd, Carthage, IL.*

A total of 1180 pigs were placed on study at approximately 27.0 ± 2.6 kg in a wean-to-finish barn to determine if feeding narasin improves feed conversion and average daily gain during the grow-finish period. Pigs were sorted by gender, with the lower 10% being sorted off and the rest gate-cut into a total of 48 test pens. Pens were randomly allocated to one of three treatments: control, narasin included at 15 ppm (S1), or narasin included at 20 ppm (S2). Treatments were randomly assigned within a block. Narasin was fed from d 0 to d 63. Diets consisted of 20% dried distillers grain with solubles (DDGS) from d 0 to 42, 20% DDGS from d 42 to 63, and then 0% DDGS from d 63 to market. Diets met or exceeded NRC (2012) recommendations. Pen weights and feed intake information were collected at each diet phase change to allow for calculation of ADFI and G:F by period. Data that were collected and analyzed included: wean-to-finish mortality (non-value pigs), full value pigs, non-full value pigs/culls (sub-standards at weaning and culls sold to secondary market), finishing ADG (pens), finishing ADFI (pens), G:F (pens), and days to 90 kg HCW. Data were analyzed as an incomplete block design using PROC MIXED, and starting average pig weight was used as a covariate. Data were reported as LSMEANS. The feeding of narasin resulted in no differences in ADG, ADFI, or G:F from d 0 to 21 of the study, regardless of inclusion rate. However, feeding narasin at both 15 and 20 ppm inclusion improved G:F from d 21 to 42 (0.431, 0.443 and 0.440, respectively; $P < 0.003$). Narasin inclusion improved G:F from d 0 to 63 (0.428, 0.435, 0.434, respectively; $P < 0.01$). Once narasin was removed from the diet at d 63 (approximately 89 kg BW), there were no differences in performance. After the removal of narasin from the diet, there were no further improvements or residual impacts on growth performance. Overall, from d 0 to 63, the feeding of narasin at either 15 or 20 ppm improved G:F when compared to control-fed pigs.

Key Words: grow-finish, narasin, pigs

0756 Replacement value of maize offal in diets of weaned pigs supplemented with chicken offal meal. A. O. K. Adesehinwa[*1], E. O. Akinfala[2], and O. O. Adeleye[3], *[1]Institute of Agricultural Research & Training, Obafemi Awolowo University, Ibadan, Nigeria, [2]Dep. of Animal Sciences, Obafemi Awolowo University, Ile-Ife, Nigeria, [3]Federal University of Agriculture, Abeokuta, Nigeria.*

Young pigs have been reported in earlier studies to utilize up to 13.66% maize offal (MO) (a by-product of maize milling consisting mainly of the aleurone layer and some adulterants of germs and endosperm), as replacement for 25% maize in a 54.62% maize-based diet supplemented with chicken offal meal (COM) (ground dried poultry processing by-product comprising heads, viscera, feathers, beaks, etc.) but not 50% replacement of maize with 27.26% MO. Seventy-two weanling pigs (8.84 ± 0.2 kg body weight) were therefore randomly allotted to six dietary treatments of 0, 13.66, 16.34, 19.03, 21.70, and 24.39% MO representing 0, 25, 30, 35, 40, and 45% replacements of maize in 53.34% maize-based diet (containing 20% crude protein) enriched with COM to determine the replacement value of MO for maize in a complete randomized design. There were three pigs per pen and four replicate pens per treatment group. Weekly record of feed intakes and weight gains were taken for the 56-d trial period.

Two pigs/replicate were randomly selected and bled at the first and last weeks of the trial to determine the serum total proteins, albumin, globulin, creatinine, urea, cholesterol, and glucose. All statistical data were subjected to ANOVA, and, where statistical significance were observed, the means were compared using the Duncan's multiple range test (SAS). The results indicated that the increasing levels of MO resulted in increased levels of crude fibre (5.83, 6.57, 6.83, 7.05, 7.27, and 7.38%) and decreased levels of predicted metabolizable energy (ME) contents of the diets (3531.01, 3459.51, 3447.60, 3416.08, 3410.05, and 3372.47 Kcal ME/kg), while the dry matter intake (0.85, 0.84, 0.80, 0.82, 0.87, and 0.85 kg) was not ($P > 0.05$) affected for the 0, 25, 30, 35, 40, and 45% MO levels, respectively. The diets and the constituent nutrients were efficiently utilized in terms of G:F (0.56, 0.54, 0.58, 0.54, 0.56, and 0.54), ME intake per gain (6361.82, 6277.67, 5991.78, 6382.28, 6067.30, and 6199.02 Kcal ME) to support comparable ($P > 0.05$) gains (0.47, 0.49, 0.48, 0.47, 0.51, and 0.48 kg), though slight variations were observed with the ME intake. The performance of pigs fed up to 45% MO replacement of maize were comparable ($P > 0.05$) to those fed the maize-based control diet.

Key Words: maize offal, weaned pigs, non-conventional feedstuff

0757 The effects of standardized ileal digestible lysine level with or without tribasic copper chloride on growth performance, carcass characteristics, and fat quality in finishing pigs. K. F. Coble*[1], S. S. Dritz[1], J. L. Usry[2], J. E. Nemechek[1], M. D. Tokach[1], J. M. DeRouchey[1], R. D. Goodband[1], J. C. Woodworth[1], and G. M. Hill[3], *[1]Kansas State University, Manhattan, [2]Micronutrients, Social Circle, GA, [3]Michigan State University, East Lansing.*

A total of 1248 pigs (initially 28.9 kg BW) were used in a 120-d study to determine the effects of added tribasic copper chloride (TBCC; IntelliBond C; Micronutrients, Indianapolis, IN) and increasing standardized ileal digestible Lys on growth performance, carcass characteristics, liver Cu concentration, and carcass fat quality in finishing pigs. Pens of pigs were allotted to one of six dietary treatments, balanced on average pen weight in a randomized complete block design with 26 pigs per pen and eight replications per treatment. Treatments were arranged in a 3 × 2 factorial with main effects of SID Lys (85, 92.5, and 100% of the estimated requirement) and added Cu (0 or 150 ppm) from TBCC. All diets were corn-soybean meal-based with 30% distiller's dried grains with solubles, 15% bakery meal and 17 ppm Cu from $CuSO_4$ provided from the trace mineral premix. There were no TBCC × SID Lys interactions observed for growth performance or liver Cu concentrations. Increasing SID Lys increased ($P < 0.01$) ADG, G:F and final BW (Table 0757). Pigs fed 150 ppm TBCC tended ($P < 0.10$) to have increased ADG, G:F and final BW. Liver Cu concentrations were greater ($P < 0.01$) in pigs fed TBCC and tended to decrease (quadratic; $P < 0.09$) as SID Lys increased. In pigs fed TBCC, jowl fat iodine value (IV) calculated from the fatty acid analysis of all three fat layers, increased with increasing SID Lys but not in pigs fed diets without TBCC (Lys × TBCC interaction; $P < 0.03$). In summary, SID Lys did not influence the response to TBCC is this experiment.

Key Words: finishing pig, copper, lysine, iodine value

0758 Effects of hard red winter wheat particle size on finishing pig growth performance and caloric efficiency. J. A. De Jong*, J. M. DeRouchey, M. D. Tokach, R. D. Goodband, and S. S. Dritz, *Kansas State University, Manhattan.*

A total of 288 pigs (43.8 kg BW) were used in an 83-d trial to determine the effects of hard red winter wheat particle size on finishing pig growth performance and caloric efficiency. Caloric efficiency (CE) was calculated using the ingredient energy values from NRC (2012) ME and INRA (2004) NE. Pigs were allotted to one of three dietary treatments with six pens/treatment and eight pigs/pen. The same wheat–soybean meal-based diets were used for all treatments. Diets were fed in mash form. The three dietary treatments included hammer-mill ground wheat to particle sizes of) 728, 579, and 326 µm, respectively. From d 0 to 40, decreasing wheat particle size decreased (linear; $P < 0.03$) ADFI (2.29, 2.24, 2.20 kg), but improved (quadratic; $P < 0.01$) G:F (0.400, 0.413, 0.409) and

Table 0757. Dietary SID Lys level with or without tribasic copper chloride in finishing pigs

	TBCC, ppm						Probability, $P <$ [1]		
	0			150				SID Lys

[1]SEM were 1.52, 0.007, 0.032, 0.004, 3.3, and 0.801 for d 120 BW, ADG, ADFI, G:F, liver Cu, and jowl IV, respectively.
[2]Linear TBCC × Lys interaction ($P < 0.03$).

CE (7.89, 7.65, 7.72 Mcal ME/kg) and (5.84, 5.66, 5.71 Mcal NE/kg) basis, with no change ($P > 0.24$) in ADG (0.92, 0.93, 0.90 kg/d). From d 40 to 83, decreasing wheat particle size increased (quadratic; $P < 0.01$) ADG (0.92, 0.90, 0.95 kg/d), and improved (linear; $P < 0.01$) G:F (0.319, 0.322, 0.336) and CE (9.92, 9.83, 9.44 Mcal ME/kg and 7.45, 7.38, 7.08 Mcal NE/kg), with no change ($P > 0.23$) in ADFI (2.87, 2.80, 2.84). Overall from d 0 to 83, reducing wheat particle size improved (linear; $P < 0.01$) G:F and CE on both an ME and NE basis, with no difference in ADG or ADFI. Fine grinding wheat was detrimental to feed intake in early finishing but improved ADG in late finishing and G:F for both periods and overall.

Key Words: finishing pig, particle size, wheat

0759 The effects of dietary zinc oxide and chlortetracycline on nursery pig growth performance.

J. A. Feldpausch*, J. A. De Jong, M. D. Tokach, S. S. Dritz, J. C. Woodworth, R. G. Amachawadi, H. M. Scott, J. L. Nelssen, and R. D. Goodband, *Kansas State University, Manhattan.*

A total of 240 weaned pigs (PIC 1050; initially 6.08 ± 0.60 kg) were used in a 47-d study to compare the effects of added Zn from ZnO, alone or in combination with a low or high dose of chlortetracycline (CTC) on nursery pig growth performance. Pigs were allotted to pens at weaning (d 0) and fed a common starter diet with no antimicrobial for 5 d before the start of the experiment. On d 5, pens of five pigs were allotted to one of six dietary treatments, balanced on average pen weight in a randomized complete block design with eight replications per treatment. Dietary treatments were arranged in a 2 × 3 factorial with main effects of added ZnO (0 vs. 2500 ppm of Zn) and CTC (0, 55, or 441 mg/kg feed). Pigs were fed experimental diets from d 5 to 26 after weaning followed by a common corn-soybean meal-based diet without antimicrobial from d 26 to 47. Pigs on the 55 mg/kg treatment received CTC continuously from d 5 to 26; however, to comply with FDA guidelines, CTC was removed from the diets of pigs fed 441 mg/kg CTC on d 15, then added again from d 16 to 26. All diets contained at least 110 ppm of Zn from ZnO in the trace mineral premix. No ZnO × CTC interactions were observed. Pigs fed added ZnO had increased ($P = 0.001$) ADG, ADFI, and BW during the treatment period but decreased G:F ($P = 0.025$) from d 26 to 47 when a common diet was fed. Overall (d 5 to 47), pigs fed added ZnO had increased ($P < 0.05$) ADG and ADFI. Pigs fed CTC had increased (linear, $P < 0.05$) ADG, ADFI, and BW during the treatment period. Overall, pigs fed CTC tended to have increased (linear, $P < 0.10$) ADG and ADFI, but G:F tended (quadratic, $P = 0.070$) to increase then decrease as CTC increased. In summary, ZnO and CTC increased ADG and ADFI but had a minimal effect on feed efficiency.

Key Words: nursery pig, zinc, chlortetracycline

0760 Efficacy of Biomin BBSH 797 to biotransform deoxynivalenol to the metabolite de-epoxy-deoxynivalenol in serum of pigs.

S. Schaumberger*[1] and U. Hofstetter[2], [1]*BIOMIN Holding GmbH, Herzogenburg, Austria,* [2]*Biomin Holding GmbH, Herzogenburg, Austria.*

The mycotoxin deoxynivalenol (DON) and its metabolites are important biomarkers to demonstrate the efficacy of DON deactivating products in vivo. The aim of this study was to prove the capability of Biomin BBSH 797 to detoxify DON to the metabolite de-epoxy-deoxynivalenol (DOM-1) in the gastrointestinal tract of pigs. Therefore, DON and DOM-1 were measured in the serum of pigs. A total of 124 weaned piglets (mixed sex, approx. 28 d) were adapted for 2 wk. After adaption, 24 animals were randomly assigned to three experimental groups, according to weight, gender and overall condition. Control group received no DON and no BBSH 797. The second group only received 2 µg/kg of naturally DON contaminated wheat and the third group received two µg/kg DON and 1.7 × 10^8 cfu BBSH 797/kg feed. During the experimental phase, piglets were fed restrictively twice a day. Serum samples of all animals in all groups were taken on four consecutive days. Sample 1 (blank serum sample) was taken before feeding the experimental diets. All other serum samples were taken 1.5, 4, 10, and 24 h after feeding the experimental diets. Serum samples were analysed for DON and DOM-1 concentrations by LC/MS-MS method. There were no significant differences in blank serum samples between the three groups. Due to the presence of DON in the standard diet, small amounts of DON and DOM-1 produced by the native intestinal flora were also found in the blank samples. On d 3 of the trial, DON concentration 1.5 h after feeding was more than four times higher in serum of the DON group compared to the control and the DON+BBSH group ($P = 0.02$). DOM-1 concentrations in serum (d 3, 1.5 h) were

highest in the DON+BBSH group and differed significantly ($P = 0.00$) from the control as well as the DON group. To conclude, biomarker analysis of pig serum samples revealed a significant reduction of DON concentration and a simultaneously significant increase of the metabolite DOM-1 in Biomin BBSH 797 treated animals. These results demonstrate the efficacy of Biomin BBSH 797 to detoxify DON in vivo.

Key Words: Biomin BBSH, deoxynivalenol, biotransformation

0761 The effect of superdosing phytase on inositol and phytate concentration in the gastrointestinal tract and its effect on pig performance. P. Wilcock[1], C. L. Bradley*[1], J. J. Chewning[2], and C. L. Walk[1], [1]*AB Vista Feed Ingredients, Marlborough, UK,* [2]*Swine Research Services, Inc., Springdale, AR.*

Dietary phytate has been shown to be detrimental to piglet performance and the use of superdosing levels of phytase can improve performance through phytate destruction rather than phosphorus provision. This extra phosphoric effect of superdosing phytase has not been widely tested in older pigs and therefore this trial was conducted to determine if increasing phytase (Quantum Blue) levels would improve performance in grower pigs (22.8 to 56.5 kg). In addition, inositol and phytate (IP6) levels were measured in the stomach and duodenum to determine if these were correlated to phytase dose and performance. Pigs ($n = 300$) were allocated to one of five treatments (five pigs per pen and 12 replicate pens per treatment): T1, commercial diet formulated to meet the pigs nutrient requirements, except AVP and Ca were reduced 0.15% and 0.16% (equivalent of 500 FTU/kg phytase matrix), respectively; T2 was T1 with the addition of 500 FTU/kg phytase to target an AVP (0.32%) and Ca (0.71%) adequate diet; T3, T4 and T5 were T1 with, 1000, 1500, and 2000 FTU/kg phytase, respectively. All pigs were fed a two-phase feed program (0 to 21 d and 21 to 35 d) with gain, feed intake and FCR determined for the complete feeding period. At 35 d, six pigs per treatment of average BW were selected, penned individually and fed twice per day with the same treatment feed as previously fed. At 42 d each pig was fed 1.5 kg for 30 min, and after an additional 60 min pigs were slaughtered and stomach and duodenum contents were removed for phytate and inositol analyses. There was a linear increase in ADG ($P < 0.01$) and ADFI ($P < 0.01$) and a linear improvement in FCR ($P < 0.01$) as phytase dose increased. There was a linear increase in inositol ($P < 0.01$) in the stomach/duodenum and a quadratic ($P < 0.01$) decrease in IP6 with increasing levels of dietary phytase. There is a good relationship between gastrointestinal phytate breakdown ($R^2 = 0.95$), inositol production ($R^2 = 0.93$), and FCR improvement. In conclusion supplementing grower diets with dietary phytase to doses exceeding commercial levels (> 500 FTU/kg) linearly improved performance (T1, 51.8 kg; T2, 54.5 kg; T3, 55.1 kg; T4, 55.7 kg; T5, 56.5 kg) and feed conversion (T1, 2.07; T2, 1.95; T3, 1.94; T4, 1.89; T5, 1.88) which may be linked to IP6 breakdown and inositol production in the gastrointestinal tract.

Key Words: phytase, phytate pig

TEACHING: UNDERGRADUATE AND GRADUATE EDUCATION

0762 The effects of learning communities and pro-active advising on performance of first semester students.

S. L. Schaake*, A. K. Sexten, T. L. Douthit, D. A. Nichols, J. M. Kouba, D. W. Moser, B. W. Schurle, and M. R. Hay McCammant, *Kansas State University, Manhattan.*

Learning communities in higher education are not new, but they have received increased attention as universities look to enrich student learning. The objective of this study was to determine if students are more engaged and perform better academically when in an environment designed to foster stronger relationships with faculty advisors, course instructors, and peer students. First semester pre-veterinary freshmen at Kansas State University with ACT scores ranging from 21 to 28 (n = 122) were assigned to one of four treatment groups: 1) pro-active advising, learning community, and advisor as instructor; 2) learning community only; 3) pro-active advising only; 4) no intervention beyond standard advising. Students who were pro-actively advised were requested to meet with their faculty advisors a minimum of five times. Learning community students were enrolled in four common courses (eight credit hours). Students were monitored for academic performance, attendance in courses and advisor meetings. Additionally, students were required to complete a survey at the end of their first semester. Pro-actively advised students had a greater (P = 0.01) first semester grade point average (GPA) than students who were not pro-actively advised. Participation in the learning community alone or in addition to pro-active advising did not affect first semester GPA. Students whose faculty advisor was also one of their classroom instructors had a greater first semester GPA (P = 0.05) than students with an advisor they did not have as a classroom instructor. Grades for the Principles of Animal Science course, enrollment n = 147, were greater for students in treatment groups 1, 2, and 3 compared to students without intervention. There were no differences in course attendance between treatment groups. Treatment group 1 reported attending more (P < 0.0001) advisor meetings than students in treatment group 3. Treatment group 2 reported attending a similar number of advisor meetings to students in treatment group 4. More friendships (P < 0.0001) among peers were reported among students in treatment group 1 than any of the other treatment groups. Engagement of students with faculty and their peers seems to be greater when students participated in both the learning community and pro-active advising compared to students who only engaged in one or none of these activities. Increased engagement in the classroom and academic advising may be the reason for improved academic performance.

Key Words: learning community, pro-active advising, student performance

0763 Changes in the perceptions of students involved in a traditional meat science course.

M. J. Anderson*, J. L. Lucia, K. J. Stutts, M. M. Beverly, and S. F. Kelley, *Sam Houston State University, Huntsville, TX.*

Many students have an interest in their food, but the idea of participating in or observing the slaughter and fabrication processes concerns them. However, the effect of participating in slaughter and fabrication on the perceptions of students taking a meat science course is relatively unknown. The objective of this study was to evaluate changes in student perceptions concerning fabrication and slaughter practices after participating in a traditional meat science course and laboratory. Students were surveyed at the beginning and end of the meat science course at SHSU. Survey questions centered on students' perceptions of sanitation during slaughter and fabrication, U.S. slaughter practices, and the students' current and desired level of knowledge about food production. All questions were measured using a 15-cm line scale with the lowest numerical value representing the most negative perception and the greatest numerical value representing the most positive perception. Averages of the paired pre- and post-course surveys were analyzed using the TTest procedure in SAS. When asked how sanitary the processes of slaughter and fabrication were, the responses in the post-course survey were greater (P < 0.01) for both questions. Results of the post-course survey indicated that students believed they were significantly more knowledgeable about the meat products that they consume compared to before taking the course. However, no differences (P = 0.29) were detected in the overall level of knowledge that students desired to gain about their food products. After taking the course, students had a more positive (P < 0.01) outlook toward slaughter practices in the United States. When asked which in step of slaughter that beef cattle go from being an animal to a product, no differences (P = 0.52) were detected between the pre- and post-course surveys. These results indicate that involving students in slaughter and fabrication did not change students' interest in the meat industry or their perceptions on when an animal becomes a product. However, it improved their overall perceptions of the meat industry and their overall level of knowledge, leading us to the conclusion that participating in and observing slaughter and fabrication continues to be a valuable teaching instrument despite student concerns.

Key Words: meat science, fabrication, slaughter

0764 Student and evaluator perceptions of an oral equine "speed selling" exercise. J. S. McCann*, *Virginia Tech, Blacksburg.*

Evaluation skills taught in animal science curriculums often serve as foundation education for judging competitors that may be required to deliver oral reasons. The formality and structure of the oral reasons may be a deterrent to some students' enrollment. Thus, a class of 43 students in an equine conformation and biomechanics class were required to apply their knowledge in two oral "speed selling" exercises for a grade. Students were required to select an outstanding horse with photos and/or video and construct a maximum 90-sec presentation designed to sell the horse on its merits. A panel of evaluators familiar with oral reasons volunteered to score students on a scale range from 1 to 5 for eye contact, voice strength, confidence, terminology, and analysis depth. Students were required to present twice for the first exercise and had the option to present two or three times for the second exercise (top two scores recorded). Class average grade recorded for the first exercise was 41.6 ± 4.7 points, while an improvement was evident when compared to the average 46 ± 2.8 points for the second exercise. To prepare, 70% of the students searched through a minimum of four to 10 horses (Internet sales or farm sites) to find a suitable horse. Most students (81%) elected to practice their oral presentation more than three times, either alone or in front of others. Nervousness decreased from the first exercise (84% either agreed or strongly agreed they were nervous) to 56% on the second exercise. All but three students felt the 90-sec time frame was appropriate for the exercise, and 77% felt the exercise enhanced their verbal skills, a value similar to the 77% who felt they ultimately spoke more like a horseman. When asked if the exercise should be included in future classes, 86% responded positively. Among the volunteer evaluators, 67% were comfortable with scoring within three students. Most evaluators (83%) preferred a 60-sec review time with the student to explain the scores given and agreed the exercise was worth their time. Among the traits scored, evaluators indicated confidence was the trait most important in earning a higher score. Oral speed selling scores were attained for the entire class within a 45-min time frame, and the positive reception to the exercise from students and evaluators has ensured the future implementation of the exercise.

0765 Efficacy of *i*CEV incorporation into a general animal science undergraduate classroom. R. J. Rathmann* and R. A. Ritz, *Texas Tech University, Lubbock.*

The purpose of this study was to evaluate the effectiveness of utilizing online media technology (*i*CEV; CEV Multimedia, Ltd., Lubbock, TX) as opposed to a traditional textbook to enhance learning in a general animal science undergraduate course. *i*CEV is an online media library of over 40,000 edited minutes of content specific to courses taught in agriculture and especially disciplines in animal science. A customized playlist was created which was linked to the instructors' syllabus online. The playlist allowed students to easily identify and view the segments required by the instructor before attending lecture in the classroom. The instructor administered accountability quizzes at the beginning of the lecture period to ensure that students viewed the material. The objective was to efficiently enhance learning through visual exposure to industries and experts across disciplines in animal science to engage students at a deeper level. The instructor developed a 16-item instrument to survey students after completion of the course. A convenient sample of students (n = 37) were asked to indicate their level of agreement with each statement by using a four point Likert-type scale (strongly agree, agree, disagree, strongly disagree). Participation of subjects was voluntary and data was collected in confidentiality. Descriptive statistics were generated with SPSS (IBM SPSS, Chicago, IL; 20.0 software). Twenty percent of the respondents indicated they spent less than an hour weekly viewing *i*CEV, 52.5% spent one to 2 h, 25% spent two to 3 h, and 2.5% spent more than 3 h. Of the respondents, a total of 83.3% strongly agreed or agreed that viewing *i*CEV increased their interest in the animal science field of study and a total of 94.4% strongly agreed or agreed that viewing *i*CEV increased their awareness of career paths. Seventy-five percent of the respondents either strongly agreed or agreed that they preferred learning from online media compared to learning from a textbook. A total of 94.6% of the respondents indicated that they either strongly agreed or agreed that utilizing online media for course reference materials increased learning. Collectively, it would appear that incorporation of *i*CEV in replacement of a traditional textbook in an undergraduate general animal science course was preferred by students to stimulate the learning process.

Key Words: online multimedia, *i*CEV, teaching

0766 Impact of the male on meat production: A case scenario in swine. J. J. Parrish* and J. L. Susko-Parrish, *University of Wisconsin, Madison.*

To target global competencies in animal sciences, a case scenario exploring climate impacts on swine production was developed. Case scenarios differ from case studies in that the former are guided explorations around a topic, while the later are more open ended. The project had three major objectives: 1) development of technical skills related to understanding male physiology, semen collection, analyzing data, and processing semen for artificial insemination; 2) learning outcomes related to impact of climate on male reproduction, solutions to climate impact on boars, understanding how decisions related to boar management impact society differently in the United States and Philippines, relationship of theory to real world in male reproduction, and role of infrastructure in

livestock production; and 3) general goals of global awareness or competency, issues in global agriculture, critical thinking to solve real world problems, understand issues that would place the United States in a more favorable position to compete in global agriculture. The case scenario can be found at: http://www.ansci.wisc.edu/jjp1/pig_case/html/firstjob.html and involves a student graduating and being hired by a swine production facility in the Philippines as the boar stud manager. Student teams worked through interactive and Web-based scenarios to achieve the objectives. The case scenario replaced two lab periods in a general reproductive physiology course that is a core component of the animal science major. Several written documents (3), analysis of data (3), and class discussions were required of students. A survey was used to evaluate the project with the scoring system being on a 1-to-5 scale, with 1 being not successful, 3 being somewhat important, and 5 being very successful (n = 82), and data is presented as the mean ± sem. The attainments of six technical skills were individually evaluated, but overall the average was 4.08 ± 0.04. The six learning outcomes were also individually evaluated and were very high overall, with an average score of 4.43 ± 0.03. There were four general goals individually evaluated, but overall results were high, with an average score of 4.03 ± 0.06. A Wordle approach was used to examine the usage of words within an assignment to describe the role of the swine industry in the Philippines for a company newsletter. Students were able to demonstrate relationships between, meat, the male, meeting demand, a commercial setting and quality. Overall, the project succeeded in achieving the objectives and demonstrates how international content can be incorporated into core classes within animal sciences.

Key Words: boar, international, climate

0767 Incorporating writing-intensive assignments in an animal science production course.

S. J. Trojan*[1], C. Meyers[2] and N. Hudson[2], *[1]Texas Tech University, Dep. of Animal and Food Sciences, Lubbock, [2]Texas Tech University, Lubbock.*

Writing skills are pivotal for effective communication and are not well-developed among a majority of college students, particularly students in the field of animal science. At a southwestern university, upper-level undergraduate animal science production classes are required to be writing-intensive. In an effort to improve writing skills and as a component of course writing requirements, weekly in-class writing assignments based on prompts related to the week's lecture material were integrated into a dual-listed feedyard management course. Assignments represented 25% of the student's grade and were evaluated using a rubric for individualized feedback. To assess effectiveness of this assignment, students completed a pre-test and post-test to gauge writing apprehension. An instrument was also completed at the end of the semester for student reflection. Total course enrollment was 40; seven graduate students and 27 undergraduate students completed all assessments. A paired t test was used to analyze writing apprehension; after completing writing assignments, students indicated they were better able to express ideas through writing (P < 0.05); were more confident in expressing ideas clearly through writing (P < 0.05); stated that writing helps them think more thoroughly through concepts (P = 0.06); and felt more confident in their ability to write (P < 0.05). The majority of students (56%) indicated the writing assignments helped them to better understand the course material; felt the writing assignments allowed them to be more comfortable with the material (53%); and thought the assignments were useful and relevant (63%). The reflection instrument also revealed that writing assignments helped students learn to organize their thoughts better (57%), and that the individualized feedback for each assignment was adequate to help students to make improvements in their writing approach (67%). Based on the feedback received, this assignment will be used again, but with more detail provided throughout class on the writing process.

Key Words: animal science, production course, writing

0768 Improved student achievement through gamification and the flipped classroom.

C. J. Mortensen* and A. M. Nicholson, *University of Florida, Gainesville.*

Emerging teaching strategies for educating informational-age students include gamification and the flipped classroom. Use of game design elements in non-game contexts are thought to not only make the classroom more enjoyable for students, but also assist them in mastering knowledge. Game design elements can also potentially increase critical thinking skills based on gaming elements utilized. The flipped classroom as a pedagogy is defined as students viewing asynchronous lectures on their own and participating in learning activities during scheduled meeting times. For this experiment, students enrolled in an Introduction to Equine Science course were instructed in a flipped classroom learning environment and participated in weekly educational games over the course of a 16-wk semester. Students were administered the Cornell Critical Thinking Test (CCTT: Level X) on the first and last day of the semester. Students' exam scores and overall course grades were compared to the previous three course offerings taught in traditional lecture format. Finally, students were asked to evaluate their experiences based on a 5-point Likert scale: 1 (strongly disagree), 2 (disagree), 3 (neutral), 4 (agree), and 5 (strongly agree). For CCTT, students' scores (n = 67) increased mean 50.5 ± 0.76 from the pretest to a 55.8 ± 0.78 for the post-test (P < 0.001). When given similar exams, students' scores increased a mean 5.6% ± 1.1 for Exam 1 (P < 0.001), a mean 4.8% ± 0.9 for Exam 2 (P < 0.01), and a mean 3.8% ± 1.1 for Exam 3 (P < 0.05) compared to the previous 3 yr (n = 166). Overall course grades improved 4.0% ± 1.1 (P < 0.05) compared to the previous three class grades. Students

(n = 55), when asked to evaluate their experience, ranked the "flipped classroom has been enjoyable" as mean 4.5 ± 0.09, "flipped classroom is an effective teaching strategy" as mean 4.25 ± 0.08, "I would prefer to watch lectures online and do learning activities in class" as 4.43 ± 0.12, "in-class activities are a wise use of class time" as 4.43 ± 0.08, "this course encourages independent, creative and critical thinking" as 4.45 ± 0.09, and "I would recommend this course to a friend" as 4.67 ± 0.07. Gamification was viewed as an excellent teaching tool, particularly as review before an exam. Overall, the flipped classroom as a teaching strategy led to greater student critical thinking, achievement, and satisfaction.

Key Words: flipped, gamification, critical thinking

0769 Impact of student engagement activities on student performance on a short assessment.

O. N. Genther* and S. L. Hansen, *Iowa State University, Ames.*

Cooperative learning techniques such as Turn To Your Partner (TTYP) offer opportunities to engage an entire classroom while encouraging learners to think more deeply about a topic. A question is formulated to promote deeper understanding of a lecture concept. Students are challenged to think about the question multiple times—individually, with a partner, and during classroom discussion where individuals are randomly held accountable for thinking. To assess the value of this activity on achievement in a challenging senior-level animal science class, 47 students were enrolled in a blinded study comparing the number of TTYP activities in a class period (0, 1 or 2) with student performance on a short five-point quiz at the beginning of the following lecture period. The experiment was conducted twice during the semester, with each treatment (0, 1, or 2 TTYP) conducted during the first exam period (P1) and again during the second exam period (P2). Only scores from students that were in attendance during both experimental and assessment lectures were included in analysis (n = 35 to 42 students). Data were analyzed using the PROC MIXED of SAS, with the fixed effects of period and number of TTYP, and the random effect of student. There was a tendency for a TTYP × period interaction (P = 0.08) where during P1, 2 TTYP scores (3.47 ± 0.177) were greater (P = 0.004) than 0 TTYP scores (2.81 ± 0.183), and tended to be greater (P = 0.07) than 1 TTYP scores (3.05 ± 0.192). Scores between 0 TTYP and 1 TTYP did not differ (P = 0.30). However, during P2 there were no differences (P > 0.33) between scores for 0, 1, or 2 TTYP, (3.43 ± 0.187, 3.20 ± 0.191, and 3.38 ± 0.185, respectively). After the use of TTYP during P1, scores improved, possibly because material in this period is biochemistry-based and typically less interesting to students. However, by P2 the students may be more interested in the material and have a better understanding of expectations, such that TTYP number did not impact overall performance. This experiment suggests that utilizing simple techniques to engage learners during lecture may be beneficial to encourage participation early during the semester, as well as promote thinking during presentation of difficult material. Student evaluations at the end of the semester were overwhelmingly positive in response to both the TTYP exercises and the quiz assessments.

Key Words: student, cooperative learning, engagement

0770 The impact of implementing interactive exam review strategies on student satisfaction and exam scores.

D. T. Masser, J. M. Falk, and A. Ahmadzadeh*, *University of Idaho, Moscow.*

Interactive teaching increases students' satisfaction and performance in college courses. These strategies require time and effort from the instructor. Due to student personality differences, there is no guarantee that students are satisfied with the teaching methods of the instructor. The objective was to investigate the impacts and relationship between student personalities, the type of course review strategy on exam scores, and student satisfaction. The population consisted of 53 students enrolled in the spring 2013 Animal Reproduction and Breeding course at the University of Idaho. The Real Colors Personality Indicator (RCPI) was administered to assess and describe students' personality. For Exam 1, students were assigned randomly to one of the two review session methods: quiz bowl (QB) question-answer or lecture review (LR), with both methods facilitated by the course instructor. The groups were then switched for Exam 2. For the final exam, students chose the review method session or attended both. After attending review sessions, student satisfaction of the review type was measured using a researcher-created, (scale of 1 to 4). Data from the RCPI, satisfaction questionnaires, and exam scores were analyzed using the Statistical Package for the Social Sciences. The class was 80% animal science majors. Overall, students were more satisfied with the QB review method (M = 3.24, SD = 0.74; M = 3.52, 0.45) than the LR review method (M = 2.50, SD = 0.35; M = 2.64, 0.32) for both Exam 1 and 2, respectively. Data also revealed that students who attended the QB review session scored greater on Exam 1 (M = 79.5, SD = 13.6) than the group of students who attended LR (M = 71.6, SD = 13.0) or did not attended review session (M = 62.4, SD = 14.7). For the final exam, students attending both review methods had a greater score than those who did not attend any review sessions. When exam scores of the four personality groups were compared, students with a green personality scored the highest on all three exams. Green personalities tend to be logical intellectuals who are curious and irritated by drill and routine. It appears that interactive review sessions improve student information retention. It is recommended that college professors provide review sessions and perhaps incorporate interactive review strategies, like quiz bowl. By improving teaching methods, and awareness of student personality differences, improvements can be made in student's course performance and satisfaction.

Key Words: learning styles, review strategies, teaching

0771 Integrating teaching and extension: Swine production. H. M. Zaleski*, *University of Hawaii at Manoa, Honolulu.*

Swine Production is a senior capstone course in which students integrate concepts learned in courses such as nutrition, genetics and reproduction and apply them to practical swine production. Most animal science students at the University of Hawaii at Manoa are urban students interested in veterinary medicine, with little knowledge of or interest in swine production. The departmental learning objectives include applying principles to livestock production, but having students engage in learning this material is a challenge. The extension specialist teaching the course tried a new approach in fall 2013, integrating instruction and extension. Instead of traditional classroom instruction and written reports, teams of three students were sent out to work with cooperating farmers. Each team described their farm using a list of required information on general farm description, breeding program, feeding program, housing, waste management, health program, production management, and economics. The farms were carefully selected to represent different management approaches including varying use of local food waste and agricultural byproducts in the swine rations and different types of housing and waste management. The teams presented the results of farm visits and farmer interviews in class presentations and written reports, which were revised before being submitted in final form to both the instructor and the farmer. The course was designated as developing both oral and written communication skills. Course evaluations indicated that 78% of the students felt that the farm visits and interactions with the farmers were the most valuable part of the course, and 44% mentioned hands-on laboratories (artificial insemination and baby pig processing), while others mentioned constructive feedback, small class size, having to think, oral presentations, and writing. Student journals indicated a strong rapport with and a very positive view of the farmers and farm practices. The farmers changed some of their practices based on student recommendations, most notably adjusting feeding according to condition score. Student grades were equal to or better than in more traditional learning environments. The new structure had some challenges. Students were required to sign liability waivers and confidentiality agreements. Students had to use their own cars and to find times when all team members were available for farm visits. The relative contributions of the team members to the group reports were evaluated by all members of each team. Students indicated that the amount of work justified four rather than three credits for the course.

Key Words: swine production, undergraduate teaching, extension

0772 Teaching companion animal management: Perspective from a livestock nutritionist. J. L. Wahrmund*, *Texas A&M University–Commerce, Commerce.*

Many students enrolling in animal science programs aspire to attend veterinary school and find there are few courses in their course catalogs focused on their primary interest, companion animals. Institutions have recognized this demand, and some have created companion animal management courses to help satisfy students' wants and needs. However, few institutions employ animal science professors specializing in companion animals. At Texas A&M University–Commerce, there are two animal science professors, both of whom specialize in beef cattle. One was tasked with teaching companion animal management, and this abstract outlines the approach utilized to effectively develop and deliver this course. The course was taught online during the summer with an enrollment of 17. At the beginning of the course, students were asked to identify which species most interested them, other than dogs and cats, and which topics they were most eager to learn. Species interests included rabbits (n = 5), reptiles (n = 4), fish (n = 3), ferrets (n = 2), chinchillas (n = 1), and birds (n = 1), with one student indicating interest in all species. Topics of greatest interest included nutrition (n = 12), health (n = 11), anatomy (n = 4), and reproduction (n = 3). Other topics covered in addition to these included breeds, behavior, training, showing, geriatrics, business management, careers, and managing unwanted animals. All topics covered were presented with dogs and cats as the primary models. Other species were presented in specific lectures for that species and covered basics of nutrition, reproduction, health, and housing. The textbook *Companion Animals: Their Biology, Care, Health, and Management* by Campbell and Campbell was used as the primary guide for presentation of information. Other sources of information were obtained from the American Veterinary Medical Association, the American Kennel Club, and the Cat Fanciers' Association, to name a few. At the end of the course, students were asked to indicate their favorite and least favorite aspects of the course. Generally, students enjoyed learning about a wide variety of species and disliked that the course was offered during a short summer session online, which eliminated possibilities of hands-on learning. Student course evaluations were unanimously positive. Instructors teaching management courses outside their species of expertise can employ numerous resources. Allowing students to provide input regarding topics to be covered can help provide rewarding educational experiences for both students and the instructors.

Key Words: companion animals, teaching, undergraduate education

0773 A comparative veterinary course for pre-veterinary students. *A. P. Fidler*, University of Arkansas, Fayetteville.*

Students entering veterinary school are expected to adapt to a new learning environment and begin retaining volumes of information very quickly. These students arrive with learning strategies developed during their undergraduate studies, which may not prove adequate for the speed and volume of learning required in veterinary school, and some subject areas might be quite foreign depending on the students' academic background. Problems resulting from unfamiliar material being met with deficient learning strategies often become evident in first-year anatomy courses. To address this issue, a Comparative Veterinary Anatomy course has been developed at the University of Arkansas for junior and senior pre-veterinary students. The objectives of this course are to familiarize students with anatomical structures of domestic animals, as well as to develop critical learning strategies for success in future scientific careers, graduate programs, and professional school. The course utilizes didactic lectures, illustrative reference materials, and hands-on laboratory experiences with live animals, preserved specimens, and fresh cadavers. Course topics are reinforced by examinations requiring identification of anatomical structures in illustrations as well as on specimens. The course objectives, modes of instruction, and student evaluation are meant to closely resemble a first-year veterinary curriculum's anatomy course to prepare students to succeed in such a course. In the two semesters the course has been offered, it has reached maximum capacity at 20 students. A survey was administered following the conclusion of the first semester asking students to describe the most valuable learning experiences during and outside of class. Nineteen of 20 students responded (95.0%). Eighty percent (80.0%) of respondents indicated that laboratory time spent examining live, preserved, and fresh dead specimens was the most valuable learning experience during class time. Sixty percent (60.0%) of respondents indicated that reviewing and/or recreating illustrations from the textbook was the most valuable learning experience outside of class.

Key Words: veterinary, anatomy

TRIENNIAL LACTATION SYMPOSIUM

0774 Utilizing 'omic' techniques to understand energy balance in the lactating dairy cow.
J. R. Roche*[1], C. V. Phyn[1], T. M. Grala[2], C. G. Walker[2], M. A. Crookenden[2], S. Meier[1], J. K. Kay[1], and J. J. Loor[3], *[1]DairyNZ, Hamilton, New Zealand, [2]DairyNZ, Auckland, New Zealand, [3]University of Illinois, Urbana.*

Nutrigenomics describes how the amount and/or type of feed an animal receives, relative to its genetic and physiological requirements, affects its molecular phenotype, thus changing production, energy balance, reproduction, and health. For example, Holstein-Friesian cows (HF) bred almost exclusively for milk production have a more prolonged and severe negative energy balance in early lactation than HF cows bred on an index that includes traits related to longevity and health. This is due, in part, to a greater uncoupling of the somatotropic axis and the level and duration of this uncoupling can be influenced by diet. In addition, the decline in reproductive success in recent decades has been associated with the increased negative energy balance associated with genetic selection for milk production. However, differences in the endometrial transcriptome indicate that genetic selection for milk production is also associated with a failure to recognize pregnancy as well as inadequate suppression of the local immune system and nourishment of the embryo, which are not necessarily related to energy balance. Nonetheless, some of the genes involved are epigenetically regulated and could be altered by nutrition. Factors that influence energy balance, such as nutrition and milking frequency, have different effects on the metabolism of the mammary gland, liver, and adipose tissue. For example, although once-daily milking and greater feeding levels improve energy balance, once-daily milking lowers milk production through reduced secretory cell activity and number, whereas, greater feeding levels increase milk production through the provision of more nutrients. These effects are independent and at least partially additive; if both strategies are used, the outcome is a combination of the two. Experimental results indicate that the molecular changes underpinning these effects can persist beyond the period of treatment. Less frequent milking results in an earlier recoupling of the somatotropic axis post-partum and adipose accretion, physiological changes that are also influenced by energy balance, but are dependent on feed type as well as availability. A greater understanding of the effects of nutrition on the molecular phenotype is required to optimize cow management for productivity and welfare.

Key Words: nutrigenomics, energy balance, reproductive failure, genotype

0775 Systems biology of regulatory mechanisms of nutrient metabolism in lactation.
J. P. McNamara*, *Washington State University, Pullman.*

The role of the dairy cow is to help provide high-quality protein and other nutrients for humans. We must select and manage cows with the goal of reaching the greatest possible efficiency for any given environment. We have increased efficiency tremendously over the years, yet the variation in productive and reproductive efficiency among animals is still quite large. In part this is because of a lack of full integration of genetic, nutritional, and reproductive biology both in research and management decisions. However, integration across these disciplines is increasing as biological research findings show more specific control points at which genetics, nutrition, and reproduction interact. An ordered systems biology approach that focuses on why and how cells regulate nutrient use and on how and why organs interact by endocrine and neurocrine mechanisms will speed improvements in efficiency. Nutrient metabolism is controlled by a number of factors, including type and amount of intake, stage of lactation, and amount of milk production, through a complex system of neurocrine and endocrine regulation. In turn, nutrient metabolism in the brain, liver, splanchnic organs, and muscle directly affect the efficiency of the animal. The metabolic efficiency of the mammary gland runs at its thermodynamic maximum unless there is a physiological disease or a massively imbalanced ration. The variation in efficiency of animals is a result of variations in metabolism in non-mammary tissues; including nutrient metabolism in the liver, protein turnover in the muscle, and lipid turnover in the adipose tissue. These metabolic paths are allotted to maintenance costs in practical application. Thus, using a systems biology modeling approach, we can design experiments specifically to integrate our knowledge on tissue metabolism, food intake, milk production and overall efficiency. Data from genomic studies, transcriptional arrays, endocrine and neural signals, tissue metabolism and animal level experiments can be integrated to clearly indicate which are the controlling factors. This approach can help focus our research to make faster and large advances in efficiency and show directly how this can be applied on the farms.

Key Words: systems biology, lactation, metabolism

0776 Insights provided by nutrigenomics into the effect of diet on metabolism and milk production.
K. J. Harvatine*, *Pennsylvania State University, University Park.*

The impact of diet on metabolism and milk production has been well-appreciated by dairy nutritionist for many years. Nutrigenomics has provided tools and experimental approaches critical to identifying the functional mechanism of nutrients. First, nutrigenomics has led to the discovery of basic mechanisms using cell culture and rodent models that provide strong candidate

mechanisms for testing in the cow. Second, the application of nutrigenomics approaches in the cow has provided direct insight into novel mechanisms of the cow. The presentation will focus on the application of nutrigenomics to understanding diet-induced milk fat depression and dietary regulation of the circadian rhythm of the mammary gland. Milk fat depression is caused by specific intermediates of ruminal biohydrogenation of polyunsaturated fatty acids and is a clear example of nutritional regulation of metabolism. Advances in lipid analysis and chemistry allowed identification of the bioactive conjugated linoleic acid isomers, but nutrigenomic approaches were key to identification of mechanism. Specifically, microarray analysis identified candidate systems and transgenic approaches have allowed demonstration of the functional mechanism. Nutrient intake also entrains the daily rhythm of metabolism through regulation of a transcriptionally regulated biological clock. Although the exact nutrient is not clear, nutritional entrainment of the mammary gland clock has been demonstrated. Understanding the mechanisms of bioactive nutrients has allowed development of targeted nutritional strategies and has great future potential as an experimental approach.

Key Words: nutrigenomics, milk fat depression, gene expression

---

0777 Nutrigenomics in dairy cows. *M. Bionaz*[*1] *and J. J. Loor*[2], [1]*Oregon State University, Corvallis,* [2]*University of Illinois, Urbana.*

Nutrigenomics is defined as the study of the genome-wide influences of nutrition altering the expression and/or structure of an individual's genetic makeup. Nutrigenomics can be performed in a reductionist way, with the intent to dissect the nutritional effect on a limited part of the genome (e.g., expression of few genes) or using a systems biology approach, where a holistic view of the nutritional effect on the genome is studied. Nutrigenomics in dairy cows is a relatively new area of research. Among all nutritional factors able to affect cell biology by changing gene expression, dietary energy, fatty acids, and amino acids have the strongest potential. The level of dietary energy has a powerful and broad transcriptomics effect. This was evidenced by data generated in liver and adipose tissue, especially in peripartal dairy cows. Profound nutrigenomics effects of amino acids are emerging, particularly during the process of milk protein synthesis. The most powerful nutrigenomics dietary components are fatty acids, particularly long-chain fatty acids (LCFA). In relation to dairy production, the effect of trans10,cis12-conjugated linoleic acid on depressing milk fat synthesis via effects on few well-studied enzymes was among the first and likely the best-known nutrigenomics example tied to LCFA. The LCFA can affect expression of genes primarily because of their capacity to modulate activity of specific transcriptional factors. Among those the most sensitive to LCFA and best studied are the peroxisome proliferator-activated receptors (PPARs). Emerging data support a role of PPARs in ruminant physiology and metabolism, including the regulation of milk fat synthesis. In addition, at least in vitro, there is a strong agonistic effect of LCFA, particularly the saturated fatty acids, in activating PPARs in ruminants. The capacity of LCFA to modulate PPARs (and likely other transcriptional factors such as LXR) offers the possibility to fine-tune the biology of dairy animals, including milk synthesis. The emerging data on PPARs in ruminants allowed proposing a dynamic model where activation of PPARs in several major tissues at distinct physiological stages could improve the adaptation of dairy cows to lactation. We are at the frontier of the nutrigenomics era in ruminants and initial data strongly indicate that this scientific branch can play a critical role in future strategies to feed dairy cattle. Outputs from nutrigenomics research can help improve efficiency of high-producing dairy cows and modifying milk quality for an ever-growing number of consumers demanding "healthy" food.

Key Words: nutrigenomics, dairy cow, transcription factors

0778 Systems biology and the role of nutrition in coordinating adaptations to lactation. J. J. Loor[*1] and M. Bionaz[2], [1]*University of Illinois, Urbana,* [2]*Oregon State University, Corvallis.*

The advent of genome- and metabolome-enabled technologies (e.g., microarrays, RNA-sequencing) constituted a setback to the use of reductionism in livestock research. Those tools along with bioinformatics were essential for the advent of modern systems biology. Systems biology is a field of study widely-used in model organisms (e.g., rodents, yeast) to enhance understanding of the complex biological interactions occurring within cells and tissues at the gene, protein, and metabolite level. Application of systems biology concepts is ideal for the study of interactions between nutrition and physiological state with tissue and cell metabolism and function during key life stages of mammalian organisms, including the transition from pregnancy to lactation (i.e., the peripartal period). Within that framework, the use of a single time point to study NutriPhysioGenomics is reductive and insufficient to capture the dynamism of biological adaptations; therefore, implementation of time-course experiments must be undertaken. Modern bioinformatics tools complement the ever-increasing ability to generate large molecular and metabolite datasets. The Dynamic Impact Approach (DIA) was conceived to help interpret in a more biologically relevant manner the longitudinal physiological adaptations to lactation occurring simultaneously in several tissues such as liver, adipose, and mammary. This tool along with gene and transcriptional factor (TF) network analyses using software suites, such as the popular Ingenuity Pathway AnalysisÒ, are ideally suited for understanding high-throughput datasets. Results utilizing our own and publicly available datasets demonstrate that the DIA is robust for physiological systems analysis of complex transcriptome datasets within a tissue or among tissues. Simultaneous visualization of the complex inter-tissue adapta-

tions to physiological state and nutrition can be discerned. An example of this approach using liver, mammary, and adipose tissue during late-pregnancy and early lactation is presented. Furthermore, we present examples of new knowledge generated through the application of functional analyses and gene network tools on transcriptome and metabolome datasets encompassing nutritional management of dairy cattle, e.g., plane of dietary energy prepartum or the supplementation of amino acids or long-chain fatty acids. Overall, we demonstrate that the integrative approach across and within tissues provides a more holistic understanding of the complex dynamic physiological adaptations during lactation. The longitudinal analyses of functional and TF networks within adipose and liver in response to nutrition may prove useful for fine-tuning nutritional management of dairy cattle. An important goal during this process is to uncover key molecular players involved in the tissue's adaptations to physiological state or nutrition.

Key Words: bioinformatics, nutritional science, omics

0779 Nutrient partitioning during intramammary inflammation: A key to severity of mastitis and risk of subsequent disease? K. M. Moyes*, *Dep. of Animal and Avian Sciences, University of Maryland, College Park.*

In early lactation, susceptibility to disease is greatest, impacting cow health, productivity, and leading to economic losses. Mastitis is the most economically costly disease to the dairy industry and is most frequent at this time. Glucose and amino acids (especially glutamine) are the primary fuels used by leukocytes in other species and are essential substrates for optimal leukocyte function, but have not been elucidated in bovine leukocytes. Yet, because these substrates are in high demand to support milk synthesis in early lactation, their supply to leukocytes may be compromised. Production-related metabolic diseases during early lactation, such as ketosis and hepatic lipidosis, can also adversely affect health and productivity. Risk of subsequent disease for cows during mastitis is unknown. During an inflammatory response, increases in circulating non-esterified fatty acids and glucose during an IMI in dairy cows have been reported. Previous work indicates that hepatic expression of key genes associated with gluconeogenesis (e.g., PCK1 and G6PC), ketogenesis (e.g., HMGCS2) and fatty acid metabolism (e.g., SREBF1 and PPARA) are downregulated after intramammary infection (IMI). These results suggest a potential link between mastitis and the risk of subsequent metabolic disease for dairy cows during lactation. This presentation will discuss the complex relationships between metabolism and immune function, and how these immunometabolic interactions relate to susceptibility to mastitis and increase the risk of subsequent disease during early lactation. New strategies to prevent or control mastitis development and reduce the risk of subsequent disease during early lactation will also be discussed.

0780 Nutritional effects on immunology and inflammation in dairy cattle. E. Trevisi*, P. Grossi, and A. Minuti, *Università Cattolica del Sacro Cuore, Piacenza, Italy.*

Optimal health is of paramount importance for an acceptable life of farm animals, mainly during the pivotal phases of their life cycle, such as parturition and weaning. Nutrition is one of the most important players of the health status and can influence onset of clinical diseases or mild malaise (subclinical diseases). A large portion of the host resistance to infection involves the immune system and, mainly at the gastro-intestinal level, represents a crucial site of the body for the relationship among nutrients, microbes and host. Balanced diets guarantee that nutrient requirements are met and simultaneously can: 1) counteract the survival of infectious pathogens in the gastro-intestinal tract (as occurs with diets too high in fermentable carbohydrates), 2) prevent damage of the gut epithelium, 3) improve the host resistance to the pathogens, and 4) reduce tissue damage due to metabolic disorders associated with deficiencies (e.g., ketosis, liver lipidosis) and excesses (e.g., milk fever, obesity) of nutrients. A wide variety of nutritional compounds (e.g., macro and micronutrients, secondary metabolites of plants) are involved in aspects of immuno-regulation, but mechanisms are only partly known. The physiological conditions of the animals also play a relevant role in the regulatory effects of the nutrients on immune and metabolic systems. In dairy cows, the transition period represents the most vulnerable physiological life stage, in which the nutrition can influence the immune and inflammatory responses. The tremendous physiologic changes taking place during this period make the diagnosis of the nutritional-management causes challenging. Nevertheless, the immune-metabolic profiling appears as a valuable tool in the management of health of transition dairy cows, particularly for direct diagnosis of sub-clinical diseases (metabolic and infectious). Recently, growing evidence suggests that inflammation around calving is responsible for reduced performance and is associated with decreased production, efficiency and fertility. In particular, composite indices based on multiple variables associated with inflammation (e.g., Liver Functionality Index) are promising for use as an aid in the diagnosis and correction of management and nutritional problems on dairy farms. Nutritional improvements in the periparturient period not only reduce the frequency of inflammatory events, but also minimize their intensity and duration. In particular, some nutrients and compounds (e.g., omega-3 fatty acids, Conjugated Linoleic Acid, methionine, plant extracts) have demonstrated to improve the immune function and the inflammatory response around calving, underscoring a need for further studies of the interactions between nutrition, immunity and inflammatory response.

WORKSHOPS: **CRAFTING USAID'S LIVESTOCK RESEARCH AGENDA– ANIMAL SCIENCE PRIORITIES UNDER FEED THE FUTURE**

0781 Feed the Future research strategy and USAID's global livestock investments. S. Moon Chapotin* and J. Turk, *U.S. Agency for International Development, Washington, DC.*

This presentation will outline major program areas under the Feed the Future research strategy, which encompasses global investments in aquaculture, poultry, and livestock production systems. It will summarize recent and current livestock research and value chain investments by USAID. USAID is currently conducting priority setting for livestock value chain research aimed at informing future investments. This presentation will also describe how stakeholders can provide input and advice about the research priorities as well as the role of U.S. universities and colleges in USAID-supported research activities.

Key Words: USAID, livestock research, value chain

0782 Nutritional value of animal source foods. L. Iannoti*, *Institute for Public Health, Washington University, St. Louis, MO.*

Animal source foods (ASF) reinforce household food security. One of the most difficult and least accounted values of livestock is their nutritional value. From the early 1970s to the 1990s, meat and milk consumption in developing countries grew by more than twice the rate in developed countries. On a global basis, foods of animal (including fish) origin provide about 17% of the energy and more than 35% of the dietary protein for humans. Most importantly, the biological value of protein in animal source foods is about 1.4 times that of foods from plants and animal proteins are 20 to 30% more digestible than plant proteins (96 to 98% vs. 65 to 70%). In rural areas of developing countries, diets of children are primarily crop-based and often deficient in vitamin A, vitamin B-12, riboflavin, calcium, iron and zinc— vitamins and minerals that are essential for human health and are more bio-available in animal source foods. Vitamin A in its usable form and vitamin B-12, for example, critical for the normal functioning of the brain and nervous system, are present only in animal-source foods. Iron is more easily absorbed by humans from meat than from vegetables, zinc has a role in the metabolism of RNA and DNA, riboflavin plays a key role in energy metabolism, calcium is an essential nutrient for cell physiology and bone mineralization, and iron is necessary for hemoglobin and myoglobin production.

0783 Research needs for inclusive livestock markets in developing countries. J. Yazman*, *U.S. Agency for International Development, Washington, DC.*

The global population is predicted to reach 9.6 billion by 2050. Nearly all of future population growth will be in urban areas, with some 50% of the developing world's population living in more than 425 cities with 1 million residents or more. Urban families in developing countries, with higher average incomes, generally consume diets higher in animal-source foods (ASF) than rural families. ASFs in developing countries reach consumers through various market value chains, often with weak enforcement of public health regulation. Disease hazards and risks inherent in traditional ASF food marketing systems are not well-understood. These challenges, along with complex trade pathways, will make traceability by developing world livestock producers difficult and prevent engagement in the growing global trade in ASFs. Increasingly consumers across the globe are linking their food choices to environmental and social equity attributes and, specifically with respect to ASFs, assurance of humane treatment of animals at farm level through to harvest. End market intermediaries often enforce private standards that associate their ASFs with a range of best management practices or adhere to accepted global standards. USAID's Feed the Future Initiative seeks to link smallholder and pastoralist livestock producers to increasing local, regional and global ASF demand. Research supported by Feed the Future will enable increased competitiveness and market linkage through new technologies and improved management practices of herds and flocks that incorporate environmental standards, reduce greenhouse gas generation, and eliminate health hazards and risks all along ASF value chains.

0784 The indispensable role of mixed small holder systems in global food and nutritional security. J. Smith*, *International Livestock Research Institute, Washington, DC.*

By the time global population stabilizes at around 10 million in the 2050, about 60% more food will be needed than is produced now, and about 75% of that must come from intensification as the agriculture land frontier has been largely reached. In this quest to produce much more food sustainably, small holder mixed crop livestock systems, where more than half of the food in the developing world is currently produced, will play a critical role. Studies by ILRI (2009) show that globally these mixed systems produce about 50% of the cereals, and 60% and 70% of the meat and milk, respectively. Once connected to markets, small holder mixed systems respond rapidly to the application of new interventions— both technical and institutional. It is such mixed systems that are expected to undergo the greatest transition (growth/intensification) in

the coming decades, transforming to more market-oriented systems and at the same time presenting a major opportunity to ensure that the transition is positive not only for food security but for livelihoods, economies, people's health, and the environment. Because of increasing natural resource scarcity and the effect of increasing climate variability, meeting global food and nutritional security will be extremely challenging, but the transformation of mixed crop livestock systems also offers an enormous opportunity for poverty reduction and rural transformation through stronger participation of small holders in the global food economy.

0785 Africa livestock futures and one health.
D. Carroll*, *U.S. Agency for International Development, Washington, DC.*

The current trend of a rapid increase in the demand for animal products in Africa is not yet matched by a similar trend of increased production. The increase in demand will grow in the next three decades— at least. There will be efforts to produce more animal products to fulfill the demand. At the same time, livestock are critical to people's nutrition, food security, livelihoods and resilience in many parts of Africa. There would be widespread benefits if marginal farmers were to be able to respond to (and profit from) the increased demand. An unmanaged increase in production, as witnessed in Asia between 1960 and 2000, could bring adverse consequences, including pressure on natural resources such as water and land, increased greenhouse gas emissions, and increased threats of zoonotic diseases. If animal-derived pathogens are readily transmissible between humans and cause illnesses with high fatality rates, serious outbreaks— or even pandemics— will occur. This session will examine work underway to assess options for livestock futures in Africa based on plausible assumptions of growth through 2050 of 1) consumption of animal origin foods, 2) production of livestock and products (i.e., both demand and supply sides), 3) possible consequences and risks of the different scenarios, and 4) policy options that could, if applied, reduce or mitigate the potential adverse consequences of each scenario.

0786 The role of new technologies in increasing livestock production.
D. Nkrumah*, *Bill and Melinda Gates Foundation, Seattle, WA.*

In the next 30 yr, the world's population is projected to grow by nearly 2 billion and will become more urbanized, with a more skilled workforce. The good news is that global prosperity and affluence will increase. The challenge is that food supply will need to more than double to meet the increasing demand. Specifically, the demand for animal-sourced foods needs to more than double to meet the demands of the newly affluent. With fewer and fewer people engaged in agriculture, and for the sake of the planet, animal production growth cannot continue to come from the deployment of more animals and land. Some have argued that current organic systems may be for the rich and curious and could not produce enough food to feed the world in the future. Past technologies that allowed us to advance productivity may not be enough to bring about future intensification, especially for small holders who live in areas that require attention to climatic adaptability and disease resiliency. Instead, changes in total factor productivity needs to occur through significant changes in current techniques. To transform current near-subsistence small holder production systems, we need technological innovation to drive the needed sustainable productivity increases. We require collaborative global research teams to come up with new ways of developing and adapting modern concepts in biotechnology to create the next-generation of animal genetics, health, and livestock nutrition systems. These technologies will then have to be deployed affordably through context-relevant mobile communication and digital platforms to increase accessibility.

0787 (M001) Characterization of serotonin (5-HT) and glucose patterns and their hepatic receptor profiles during the transition period in dairy cows.

M. Olsen*, J. Laporta, A. P. Prichard, S. A. E. Moore, B. P. Schnell, S. R. Weaver, C. R. Cronick, and L. L. Hernandez, *University of Wisconsin–Madison, Madison.*

The liver is crucial for metabolism and partitioning of nutrients to the mammary gland during lactation. Recent evidence suggests that non-neuronal serotonin (5-HT) participates in glucose metabolism, but little is known regarding 5-HT actions in the liver during the transition period in dairy cattle. Our objective was to explore glucose and 5-HT circulating patterns and to characterize the 5-HT and glucose receptor profiles in the liver during the transition from pregnancy to lactation in dairy cows. Multiparous pregnant Holstein cows (n = 6, avg. lactation = 3.5) were utilized to collect daily blood samples from 7-d pre-calving (−7 d) through 7d post-calving (+7 d), and liver biopsies were performed at −7 d, +1 d and +7 d. Total RNA was extracted and cDNA was synthetized to measure mRNA expression of 5-HT receptors (HTR, isoforms 1A, 1B, 1D, 1F, 2A, 2B, 2C, 5A, and 7) and glucose transporters (SGLT-1, Glut-1, -2, −5, −8, −9, and 10) by RT-PCR. Glucose concentrations decreased pre-calving (−7 to -1 d, 72 vs. 57 ± 3.5 mg/dl, P = 0.045), increased post-calving (+1 and +3 d, 74 ± 4.1 mg/dl, P = 0.008), decreasing again and reaching lowest concentrations at +7 d (50.2 ± 1.7 mg/dl, P = 0.0012). Serum 5-HT concentrations decreased abruptly pre-calving (−7 to −5 d, 916 vs. 90 ± 35 ng/ml, P = 0.001), remained low until +3d (160 ± 35 ng/ml, average for -3, -1, and +1 d), and increased again at +5 and +7 d (355 ± 27, average for +5 and +7 d). Hepatic mRNA expression of HTR-1D, -2D, and −7 were decreased, while HTR-2A was increased at +1 d compared to −7 d (P < 0.045). Only HTR-1F increased 2.5-fold at +7 d, compared to both −7 and +1 d (P < 0.048). HTR-4 mRNA expression was undetectable at +7 d, and HTR-2C was undetectable at +1 d. HTR-5A was not expressed at all in the liver. Hepatic expression of Glut-2, Glut-5, and SGLT1 were decreased on both +1 d and +7 compared to −7 d, while Glut-1 was increased twofold at +7 d compared to −7 d (P < 0.04). These results indicate that 5-HT can potentially play a role in liver glucose homeostasis during the transition period in dairy cows, possibly through the modulation of specific receptors. Additional research is needed to further explore the functional role of these HTRs in the liver during the transition from pregnancy to lactation.
