Two experiments were conducted to evaluate the effects of adding an exogenous fibrolytic enzyme (FE) on ruminal pH and fermentation, digestibility, and growth performance in feedlot beef cattle fed finishing diet containing wheat dried distillers grains with solubles (DDGS). In Exp. 1, four ruminally cannulated Angus heifers (averaged BW of 807 ± 93.9 kg) were used in a repeated 4 × 4 Latin square design. Treatments were: 1) control (CON; 10% barley silage and 90% barley grain-based concentrate); 2) WDG (CON diet substituting 30% wheat DDGS for barley grain); 3) WDGL (WDG diet supplementing with low FE; 1 mL FE/kg diet DM); and 4) WDGH (WDG diet supplementing with high FE; 2 mL FE/kg diet DM). Heifers were fed at restriction of 90% ad libitum twice daily. Digestibility in the total digestive tract was measured using Yb as external digesta marker. Statistical contrasts were generated to compare CON vs. WDG and the linear and quadratic effects of FE dosages (0, 1, and 2 mL FE/kg diet). Digestibility of DM was less ($P = 0.01$) with WDG (67%) than CON diet (71%). Increasing FE linearly ($P < 0.05$) increased starch digestibility from 88.7, 89.7 to 91.3% without affecting digestibility of other nutrients. Adding FE also reduced ($P = 0.03$) ruminal ammonia-N concentration from 13.6 to 10.1 m*M*. In Exp. 2, one hundred and sixty yearling steers (initial BW of 495 ± 37.9 kg) were fed 1 of 4 diets used in Exp. 1. Dry matter intake (10.9 kg/d), final BW (684 kg), and ADG (1.69 kg) did not differ between steers fed CON and WDG diets. However, steers fed WDG reduced ($P < 0.05$) G:F (150 vs. 160 g/kg DMI) and increased ($P < 0.01$) percentage of abscessed livers (49 vs. 15%) compared to steers fed CON. Increasing FE did not affect DMI, final BW, and ADG but tended ($P < 0.09$) to linearly improve G:F (150 to 157), and decreased ($P = 0.03$) incidence of abscessed livers (49 to 25%). Carcass traits were not affected by treatments. These results indicated that inclusion of wheat DDGS at 30% of the ration DM in finishing diets had adverse impacts on digestibility, feed efficiency and animal health. However, supplementing finishing diet containing wheat DDGS with FE potentially offset the negative effect of including wheat DDGS.

Key Words: feed efficiency, fibrolytic enzyme, finishing feedlot steers

1565 (M279) Effects of forage intake to minimize the risk of subacute ruminal acidosis on performance of feedlot finishing cattle. K. M. Koenig*[1], G. E. Chibisa[1], G. B. Penner[2], and K. A. Beauchemin[1], *[1]Agriculture and Agri-Food Canada, Lethbridge Research Centre, AB, [2]University of Saskatchewan, Saskatoon, Canada.*

Growing beef cattle in North America are typically fed high grain diets with a limited amount of forage to maximize productivity cost-effectively. Distillers grains (DG) are now commonly fed as part of the concentrate lowering the amount of fermentable starch in the diet and the potential risk of ruminal acidosis. The objectives of the study were to determine the effects of varying the concentration of forage in barley-based diets containing DG on feed intake, growth performance, and carcass traits of feedlot finishing cattle. A uniform group of 160 cross-bred beef steers was stratified according to initial BW (349.7 ± 22.3 kg) and randomly allocated to 20 pens (5 pens of 8 steers per treatment). The treatments were barley silage at 0, 4, 8, and 12% of diet DM. The remainder of the diet consisted of 80, 76, 72, and 68% barley grain for the 4 diets, respectively, 15% corn dried DG and solubles, and 5% supplement (with monensin at 28 mg/kg diet DM). The diets were fed as a total mixed ration for ad libitum intake (minimum of 5% orts) once per day. Cattle were weighed on 2 consecutive d at the start and end of the experiment and on 1 d every 3 wk throughout the experiment (124 d). The DMI of each pen was determined from feed offered daily and orts at the end of each 3-wk period. The ADG was determined from linear regression of BW over time. Data for DMI for each pen, and BW, ADG, G:F, and carcass traits for each animal were analyzed as a completely randomized design using a mixed linear model with diet as a fixed effect, pen replicate and diet × pen replicate as random effects (except for the model for DMI), and pen as the experimental unit. There was a trend ($P = 0.10$) towards a linear increase in DMI by steers with increasing percentage of barley silage. However, there was no effect ($P > 0.05$) of the barley silage treatments on final shrunk BW (612.7 ± 4.25 kg), ADG (1.86 ± 0.03 kg/d), and carcass traits. Feed efficiency linearly decreased ($P < 0.05$) with increasing percentage of barley silage. Increasing the proportion of barley silage in a barley grain-based diet with DG may reduce the incidence of subacute ruminal acidosis but feed conversion efficiency is reduced.

Key Words: finishing cattle, forage, growth performance

1566 (M280) Saliva production and short-chain fatty acid absorption in beef cattle fed a low- or high-forage diet. G. E. Chibisa*[1], K. A. Beauchemin[1], and G. B. Penner[2], *[1]Agriculture and Agri-Food Canada, Lethbridge Research Centre, AB, [2]University of Saskatchewan, Saskatoon, Canada*.

Based on past research, there are indications that a potential decrease in acid removal from the rumen via epithelial absorption during a bout of ruminal acidosis could possibly be compensated for by an increase in salivation. However, there is limited information on whether similar changes in the relative contributions of salivary bicarbonate and passive and/or facilitated absorption of short-chain fatty acids (SCFA) to pH regulation occur when dietary forage content is altered. Therefore, the objective of this study was to determine the effects of feeding a low- (LF) or high-forage (HF) diet on ruminal fermentation, salivation and SCFA absorption. Eight ruminally-cannulated cattle were used in a crossover design with 49 d periods. The treatments were barley silage at 30 (LF) or 70% (HF) of dietary dry matter (DM). The LF and HF diets contained 45.3 and 30.9% starch and 26.4 and 38.3% physically effective fiber (DM basis), respectively. On d 35, ruminal fluid was collected to determine SCFA concentration. Ruminal pH was continuously measured from d 29 to 35. Eating or resting salivation, was measured by collecting masticate (d 39 and 40) or saliva samples (d 42 and 43) at the cardia, respectively. On d 42 and 43, the temporarily isolated and washed reticulo-rumen technique was used to measure total, and chloride competitive (an indirect measure of protein-mediated transport), absorption of acetate, propionate and butyrate. Total ruminal SCFA concentration and osmolality were higher ($P < 0.02$) in cattle fed the LF compared to the HF diet. Additionally, feeding LF resulted in a longer ($P = 0.02$) duration (h/d) and a larger ($P = 0.05$) area (PH × h/d) that pH was below 5.5. Although there was no diet effect on total and chloride competitive absorption (mmol/h and %/h) of SCFA, eating salivation (mL/min) was lower ($P = 0.02$), whereas resting salivation (mL/min) tended to be lower ($P = 0.10$) in cattle fed a LF diet. The lower ruminal pH in cattle fed the LF compared to the HF diet could be attributed to the increase in SCFA production and decrease in salivation, which were not compensated for by an increase in SCFA absorption.

Key Words: dietary forage content, saliva production, short-chain fatty acid absorption

1567 (M281) Interactions between levels and source of energy supplementation in beef cattle.

J. R. R. Dórea[*1], L. R. Dell Agostinho Neto[1], V. N. Gouvea[2], D. A. Fleury[1], A. V. Pires[1], and F. A. P. Santos[3], *[1]University of Sao Paulo, Piracicaba, Brazil, [2]University of São Paulo–FMVZ/USP, Pirassununga, Brazil, [3]University of São Paulo, Piracicaba, Brazil.*

The objective of this trial was to evaluate the effect of two levels and two sources of energy on voluntary intake and ruminal parameters of Nellore steers grazing intensively managed tropical pasture during the rainy season. Treatments corresponded to two levels of supplementation (0.3 and 0.6% of BW, as fed) combined with two sources of energy concentrate (fine ground corn and pelleted citrus pulp). Eight 24-mo-old rumen-cannulated steers (356 kg BW ± 9.8) were assigned to two 4 × 4 Latin squares and allocated in 2 ha of *Brachiaria brizantha cv.* Marandu (palisadegrass), managed in a rotational grazing system. Chromium oxide was used as an indigestible marker. Concentration of purine derivatives in the urine was used to estimate microbial synthesis. Total DMI was not affected by treatments. Feeding 0.6% of BW of energy supplement decreased forage intake ($P < 0.05$) and increased ($P < 0.01$) digestible DMI. There was interaction ($P < 0.05$) for ruminal pH between source and level of supplementation, with lower pH for steers fed citrus pulp and for steers supplemented at 0.6% of BW. Energy supplementation at 0.6% BW decreased ruminal N-NH_3 ($P < 0.05$) due to greater microbial synthesis ($P < 0.05$), resulting in greater N retention. No differences between ground corn and citrus pulp were observed as an energy supplement for growth cattle. Feeding 0.6% BW of energy supplement is an effective to increase digestible dry matter intake in grazing cattle.

Key Words: energy source, forage intake, supplementation

1568 (M282) Digestibility and nitrogen efficiency of growing beef cattle fed diets containing different proportions of *Stylosanthes* Campo Grande and corn silages.

W. F. D. Souza[1], O. G. Pereira[*2], K. G. Ribeiro[2], S. A. Santos[1], S. C. Valadares Filho[3], V. P. Silva[2], and M. C. N. Agarussi[4], *[1]Universidade Federal da Bahia, Salvador, Brazil, [2]Universidade Federal Viçosa, Minas Gerais, Brazil, [3]Instituto Nacional de Ciência e Tecnologia–Ciência Animal, Viçosa, Minas Gerais, Brazil, [4]University of Delaware, Newark.*

The objectives of this study were to evaluate total, ruminal and intestinal digestibility of nutrients, ruminal pH, ruminal ammonia concentration and nitrogen efficiency in growing beef cattle fed diets with varying proportions of *Stylosanthes* Campo Grande silage (SSt) replacing corn silage (CS). Treatments consisted of diets with ratios of 0:100, 25:75, 50:50, 75:25 and 100:0% SSt:CS. Diets consisted of 50% silage and 50% concentrate, formulated to be isonitrogenous (12.5% CP, DM basis). Ten crossbred Holstein-Zebu bulls with an average initial weight of 272 ± 86 kg, distributed in two 5 × 5 Latin squares were used. The bulls were non-castrated and rumen and abomasum-fistulated. This trial lasted 90 d divided in five experimental periods. Each period lasted 18 d and was divided into 10 d for adaptation to the diets and 8 d to collect samples. Chromium oxide (Cr_2O_3) was used to determine the fecal excretion and abomasum flow of nutrients. All data were analyzed using the PROC MIXED in SAS (version 9.1). Rumen apparent digestibility of CP and the intestinal apparent digestibility of NFC increased linearly ($P < 0.05$), with the addition of SSt to the diet. Intestinal digestibility of DM showed a quadratic effect ($P < 0.05$). Nitrogen balance, urea excretion in urine and urea nitrogen in the blood plasma showed no effect in response ($P > 0.05$) to the inclusion of SSt in the diet. Ruminal pH values were not affected ($P > 0.05$) by proportion of SSt in the diet ($P > 0.05$), but ruminal pH was affected ($P < 0.05$) by the time of collection, for which a cubic model was fit to the data. There was an interaction effect ($P < 0.05$) between treatment and collection time for rumen ammonia nitrogen concentration. Based on the results obtained in this study, it

can be concluded that *Stylosanthes* Campo Grande silage can be used as a source of roughage in the diet of beef cattle during the growing phase at a proportion of 50% of dry matter in the total diet. *Sponsored by FAPEMIG, CNPq and INCT-CA*.

Key Words: ammonia nitrogen, legume silage, ruminal pH

1569 (M283) Influence of *Macleaya cordata* preparation on feedlot performance and carcass characteristics of finishing bulls. R. Barajas*[1], B. J. Cervantes[2], I. Rogge[3], A. Camacho[1], and L. R. Flores[1], *[1]FMVZ-Universidad Autónoma de Sinaloa, Culiacan, México, [2]Ganadera los Migueles, S.A. de C.V., Culiacan, México, [3]Phytobiotics Futterzusatzstoffe GmbH, Eltville, Germany.*

The *Macleaya cordata* is a plant of the *Papaveraceae* family that contains as active components alkaloids of the Benzo[c] Phenanthridine family sanguinarine and chelerythrine; and alkaloids of the protopin family as is protopine and allocryptopine. Their combined effects include mild antimicrobial activity, anti-inflammatory properties, and inhibition of amino acids degradation; those characteristics suggest that *Macleaya cordata* could modify rumen microbial activity and reflect it on feedlot cattle performance. Despite *Macleaya cordata* is used in Europe as feed additive for farm animals, its effects of on feedlot cattle performance are not well-documented. In this research, 80 bulls weighing 380 ± SE 2.41 kg (approximately 75% *Bos taurus* and 25% *Bos indicus* blood), were used in a 91-d feedlot experiment to evaluate the influence of *Macleaya cordata* preparation on feedlot performance and carcass characteristics of finishing bulls. Blocked by initial weight, in a complete randomized block design with a 2 × 2 factorial arrangement, bulls were assigned to treatments as follows: 1) A 89% concentrate corn-cotton seed meal finishing diet (Control); 2) Control plus daily 4 g of *Macleaya cordata* preparation delivering 20 mg of alkaloids (MC); 3) Control plus 40 mg of sodium monensin/kg of DM (MN); and 4) Control plus MC and MN (MM). Results were analyzed for ANOVA as a complete randomized block design with a factorial 2 × 2 arrangement. MC was offered as Sangrovit-RS (Phytobiotics, Germany) a standardized preparation of *Macleaya cordata*; and monensin was supplied as Rumensin 200 (Elanco Animal Health, IN). Zilpaterol hydrochloride (Zilmax; Merck Animal Health) was supplemented during latest finishing. Treatments had no effect ($P > 0.15$) on final weight, ADG, DMI, and hot carcass weight. The inclusion of *Macleaya cordata* tended to increase ($P = 0.10$) diet net energy for maintenance and gain (2.04 *vs.* 1.98 Mcal ENm/kg; and 1.38 *vs*. 1.33 Mcal ENg/kg). Supplementation with *Macleaya cordata* tended ($P = 0.09$) to improve DMI/hot carcass gain ratio (7.946 vs. 8.452 kg DMI/kg of carcass). The addition of MC tended ($P = 0.08$) to reduce KPH-fat (1.96 *vs.* 2.13%). Remainder carcass characteristics were not affected by treatments ($P > 0.15$). It is concluded that the supplementation of *Macleaya cordata* preparation may contribute to improve diet net energy use, feed carcass conversion, and decreases the amount of fat deposited around of kidney, pelvis and heart in finishing bulls.

Key Words: beef cattle, *Macleaya cordata*, sanguinarine

1570 (M284) Supply levels of multiple supplements for beef heifers on pasture during the dry season: ruminal pH and ammonia nitrogen. R. P. D. Silva*, J. T. Zervoudakis, L. K. Hatamoto-Zervoudakis, L. D. S. Cabral, A. J. Neto, J. Q. Soares, A. C. B. Melo, E. R. Donida, P. I. José, R. C. Soares, E. A. Teixeira, and A. J. Possamai, *Federal University of Mato Grosso, Cuiaba, Brazil.*

This research aimed to evaluate the effect of different levels of multiple supplements for beef heifers that were restricted grazing during the dry season on pH and ruminal ammonia nitrogen. Five Nellore heifers were used, with age and initial weights average of 20 mo and 344.0 kg, respectively. The pastures were divided into five paddocks of 0.25 ha each, consisting of *Brachiaria brizantha* cv. Marandu. The experiment was divided into 5 × 5 Latin square design, composed by five experimental periods of 20 d each and five animals. The strategy adopted was to provide multiple supplements (soybean hulls + ground corn grain + soybean meal + sunflower + urea and mineral mix) at levels of 2, 4, 6, and 8 kg/animal/d. The animals were fed in two fixed hours: 50% of the daily amount at 1000 h and 50% at 1500 h, the mineral mixture was offered ad libitum (control). For determination of pH and ammonia concentration in the rumen fluid samples were collected by gavage on the 19 and 20 d of each period, 2 h before supplementation (10 to 0 h time) and 2 h after supplementation of afternoon (15 to 2h time).The availability of total dry matter was 2.29 ton/ha. The strategies of supplementation promoted a reduction of ruminal pH ($P = 0.0343$) and increased the concentration of ruminal ammonia nitrogen (NH_3–N) ($P = 0.0004$) before providing supplements, and after the supplementation the NH3 expressed a quadratic effect ($P = 0.0023$). The values observed for ruminal pH varied from 6.44 to 6.78 before supplementation in the morning and from 6.43 to 6.79 two h after feeding the animals in the afternoon, not harming the ruminal microbiota. Providing high levels of multiple supplements increases the nutritional support for cattle on systems with low level and quality of pasture during the dry season.

Key Words: *Brachiaria brizantha*, replacement effect, rumen

1571 (M285) Comparison of commercially available lick tubs to daily by-product supplementation of calves grazing corn residue. M. Jones*, M. Jones, J.C. MacDonald, T.J. Klopfenstein, G.E. Erickson, A.K. Watson, *University of Nebraska–Lincoln, Lincoln.*

Corn residue is a forage source low in energy and crude protein to meet the needs of growing calves. Providing supplementation increases average daily gain of calves grazing corn residue. The objective of this trial was to compare the use of a commercially available lick tub to daily by-product supplementation of calves grazing corn residue. One hundred twenty five crossbred steers (240 kg ± 2.64) were backgrounded on irrigated corn residue for a 60-d grazing period at the University of Nebraska–Lincoln Agricultural Research and Development Center near Mead, NE. The trial was replicated over two consecutive years (n = 8). Each year, an irrigated corn residue field was divided into eight paddocks, with four replications receiving dried distillers grains (DGS) and four having continuous access to lick tubs. Calves on the DGS treatment received supplementation in a bunk at 1.36 kg/head per d. Stocking rate was calculated based on grain yield of the field at harvest multiplied by an estimated 3.64 kg forage consumed/bu, 85% grazing efficiency factor and number of hectares available for grazing. Data was analyzed using Proc Glimmix with year run as a random effect. Average daily gain (ADG) of steers receiving dried DGS was 0.62 kg/head per day in comparison to 0.38 kg/head per day for steers on the lick tub treatment ($P < 0.01$). Average supplement intake for cattle on the lick tub treatment was 0.76 kg/day on an OM basis compared to 1.28 kg/day for steers receiving dried DGS ($P < 0.01$). Since forage estimations were not taken, supplement efficiency was used to compare the change in gain to intake by dividing ADG by supplement intake. Supplement efficiency for the lick tubs and dried DGS treatments were 43 and 46% on a DM basis ($P < 0.01$) compared to 50 and 48% on an OM basis, respectively ($P = 0.64$). Lick tubs are a convenient method for providing supplementation to calves and on an OM basis, offer similar supplement efficiency when compared with daily by-product supplementation.

Key Words: corn residue, grazing, stocker cattle, supplementation

1572 (M286) Dry matter intake of supplemented cattle under grazing during the dry season. T. O. J. A. Lins*, R. R. Silva, F. B. Mendes, M. M. Lisboa, M. M. S. Pereira, G. Abreu Filho, S. O. Souza, and L. G. Silva, *Universidade Estadual do Sudoeste da Bahia, Itapetinga, Brazil.*

This study aimed to evaluate the dry matter daily intake of cattle supplemented on pasture during dry season. The experiment was conducted in southwest region of the state of Bahia, Brazil. The study was the growing phase of 36 crossbred steers (*Bos taurus* x *Bos indicus*) with initial body weight of 378 kg ± 7.5kg and median age of 14 mo. The animals were distributed in a completely randomized design, with four treatments and eight replicates and were managed in an experimental area formed by a *Brachiaria brizantha* cv. Marandu in a system of intermittent grazing. The supplement was formulated so that the same amount of crude protein (CP%) coming from the supplement was consumed daily by animals in the different treatments. Thus, the treatments were on basis of body weight of animals (% BW): T2, 0.2%BW with 50% CP, T4,0.4%BW with 25% CP; T6, 0.6%BW with16.67% CP, and T8, 0.8%BW with 12.5% CP. The statistical model used was: $Y_{ijk} = \mu + T_i + e_{ijk}$, where: Y_{ijk}- observed value; μ- overall constant; T_i- effect of treatment i and e_{ijk}– randomized error. There was no difference in the daily intake of total dry matter (tDMI) ($P > 0.05$) between treatments. There was a linear effect ($P < 0.05$) in dry matter intake of forage (fDMI), characterizing a substitutive effect. It is concluded that supplementation of steers in growing phase presents better results when used at low levels, although with a high protein content.

Key Words: weight gain, protein supplementation, continuous stocking, substitutive effect

Table 1572. Dry matter intake of supplemented cattle under grazing during the dry season and their respective regression equations and coefficients of determination (R2)

Varibles	Treatment (%BW) 0.2%	0.4%	0.6%	0.8%	Regression equations	R2

1573 (M287) Interaction between grazing management and energy supplementation on behavior of grazing beef cattle. L. R. Dell Agostinho Neto*[1], M. G. M. F. D. Santos[1], M. R. Lovaglio[2], D. F. A. Costa[2], J. R. R. Dórea[2], and F. A. P. Santos[2], [1]*University of Sao Paulo, Piracicaba, Brazil,* [2]*University of São Paulo, Piracicaba, Brazil.*

The objective of this study was to evaluate the effects of two grazing managements, based on canopy height, and two levels of energy supplementation on ingestive behavior of beef cattle grazing an intensively managed tropical grass. Treatments were two pre-grazing heights (25 cm and 35 cm) both managed with stubble height corresponding to 60% of the pre-grazing height (15 cm and 21 cm, respectively) combined with two levels of energy supplementation (0 and 0.6% BW of fine ground corn). Eight 36-mo-old cannulated Nellore steers (487 kg BW ± 6.96 kg) were assigned to two 4 × 4 Latin squares and allocated in 2 ha of *Brachiaria brizantha* pasture. Animals were monitored every 5 min during 24 h to evaluate the ingestive behavior, according to the activities: grazing, rumination and idle. Bite

Table 1573. Grazing time, rumination, idle and bite rate of beef cattle grazing tropical grass

	Management, cm		Supplementation, % of BW		P value			
Activities	25- 15	35- 21	0	0,6	M	S	M*S	SEM

[1] Minutes.
[2] Bite/minute

rate was also evaluated. Grazing time was not affected by the managements ($P > 0.05$), however decreased ($P < 0.05$) with the energy supplementation (72.5 min). Both, management and supplementation did not affect rumination and bite rate ($P > 0.05$). Time spent in idle was increased ($P < 0.05$) by energy supplementation (100.62 min). The managements based on 60% of the pre-grazing height did not affect DMI.

Key Words: supplementation, beef cattle, Marandu palisadegrass, ingestive behavior

1574 (M288) Supply levels of multiple supplements for beef heifers on pasture during the dry season: Intake and digestibility of nutrients. R. P. D. Silva*[1], J. T. Zervoudakis[1], L. K. Hatamoto-Zervoudakis[1], L. D. S. Cabral[1], E. Alexandrino[2], R. L. Galati[3], J. Q. Soares[1], A. C. B. Melo[1], E. R. Donida[1], P. I. José[1], A. J. Possamai[1], K. F. Cervelati[1], L. B. D. Freiria[1], and D. A. D. Faria[1], *[1]Federal University of Mato Grosso, Cuiaba, Brazil, [2]Federal University of Tocantins, Araguaína, Brazil, [3]Federal University of Mato Grosso, Cuiaba, Brazil.*

This research aimed to evaluate the effect of levels of multiple supplements for beef heifers that were restricted grazing during the dry season on intake and digestibility of nutrients. Five Nellore heifers were used, with age and initial weights average of 20 mo and 344.0 kg, respectively. The pastures were divided into five paddocks of 0.25 ha each, consisting of *Brachiaria brizantha* cv. Marandu. The experiment was divided into 5 × 5 Latin square design, composed by five experimental periods of 20 d each and five animals. The strategy adopted was to provide multiple supplements (soybean hulls + ground corn grain + soybean meal + sunflower + urea and mineral mix) at levels of 2, 4, 6, and 8 kg/animal/d. The animals were fed in two fixed hours: 50% of the daily amount at 1000 h and 50% at 1500 h, the mineral mixture was offered ad libitum (control). To estimate feed intake, chromium oxide was used as an external marker and indigestible NDF was used as an internal marker. The feces collections were made in 3 d in different collection times. The availability of total dry was 2.29 ton/ha. The intake dry matter, organic matter, crude protein (CP), non-fiber carbohydrates (NFC) and total digestible nutrients, and total apparent digestibility of dry matter, crude protein, total carbohydrates and NFC increased linearly ($P < 0.0001$) and the dry matter intake of forage decreased ($P < 0.0001$) with supplementation levels, it indicates that there was replacement effect. We conclude that providing supplement for grazing cattle in the dry season enhances the digestion of nutrients from forage.

Key Words: *Brachiaria brizantha*, replacement effect, nutrients intake

1575 (M289) Individual and additive value of conventional and non-conventional technologies in beef heifers housed and fed using a GrowSafe feeding system. A. R. Harding*[1], G. K. Jim[2], C. W. Booker[2], E. J. Behlke[2], S. L. Parr[2], S. J. Hannon[2], T. M. Greer[2], Z. D. Paddock[2], M. L. May[2], L. O. Burciaga-Robles[2], and C. R. Krehbiel[1], *[1]Oklahoma State University, [2]Feedlot Health Management Services, Ltd., Okotoks, AB, Canada.*

This study evaluated the effects of conventional and non-conventional production (NCP) technologies in feedlot cattle. A total of 384 yearling heifers (859 ± 77 lb.) were stratified by BW and randomly allocated to 1 of 8 treatments: NCP1: fibrolytic feed enzyme (Econase RDE; Sage Biosciences Inc., Edmonton, Alberta); NCP2: Oleobiotec Ruminant (Oleo; Laboratoires Phodé, Terssac, France); NCP3: CitriStim (ADM Alliance Nutrition Inc., Quincy, Illinois); NCP4: Oleo and CitriStim. All NCP systems received a non-medicated supplement. Blended production systems (BP) included: BP1: non -medicated supplement, Oleo, melengesterol acetate (MGA; Zoetis Canada, Kirkland, Québec), and Zilpaterol hydrochloride (Zilmax; Merck Animal Health, Intervet Canada Corp., Kirkland, Québec) for the last 20 d; BP2: medicated supplement containing Rumensin and Tylan (Elanco Animal Health, Guelph, Ontario), MGA, Oleo, and Zilmax for the last 20 d. Control groups included a negative control (NEG): non-medicated supplement; and conventional production (CP): medicated supplement containing Rumensin, Tylan, and MGA, and Zilmax for the last 20 d. Individuals were randomized within diet treatment to receive an implant (Revalor-200; Merck Animal Health), parasite control (Dectomax Pour-On Solution; Zoetis Canada), both, or neither. Heifers were fed for 123 d and DMI was recorded using GrowSafe feeding systems (GrowSafe Systems Ltd., Airdrie, Alberta). Data

were analyzed using the GLIMMIX procedure (SAS Institute Inc, Cary, North Carolina). Relative to the NEG group, BP2 and CP treatments had greater live and carcass adjusted ADG and improved live G:F ($P < 0.05$) and the BP1, BP2, and CP treatments had improved carcass adjusted G:F ($P < 0.001$). No differences ($P > 0.05$) were detected in carcass characteristics of NCP and BP groups compared to the NEG and CP groups. Implanted cattle had greater ADG and improved G:F vs. non-implanted cattle ($P < 0.001$) while no differences ($P > 0.05$) in feedlot performance or carcass characteristics were detected for parasiticide treatment. No interactions ($P > 0.05$) were identified between diet, implant status and/or parasiticide. These results indicate that conventional production systems improve beef heifer performance.

Key Words: feedlot, cattle, technology

1576 (M290) Effect of pregnancy and feeding level on voluntary intake, digestion and microbial N production in Nellore cows. M. P. Gionbelli*[1,2], M. S. Duarte[2], S. C. Valadares Filho[1,2], E. Detmann[1,2], B. C. Silva[2], D. F. Sathler[2], T. R. Gionbelli[2], F. A. Villadiego[2], and L. H. Silva[2], *[1]Instituto Nacional de Ciência e Tecnologia–Ciência Animal, Viçosa, Minas Gerais, Brazil, [2]Universidade Federal de Viçosa, Minas Gerais, Brazil.*

The objective of this experiment was to evaluate the effects of pregnancy and feeding level on intake, digestibility and efficiency of microbial N production in Nellore cows. Forty-four multiparous Nellore cows (32 pregnant and 12 non-pregnant) with average initial body weight of 451 ± 10 kg were fed either HIGH (ad libitum) or LOW (restricted feeding 1.2 times maintenance according to the NRC) feeding level. The diet consisted of corn silage (85%), ground corn, soybean meal, urea and mineral mixture. The intake was controlled daily and the DMI was evaluated weekly. In vivo apparent total digestibility was estimated using indigestible NDF as an internal marker and microbial N synthesis was estimated using the technique of purine derivatives in urine. Fecal and urine samples were collected every 28 d. The voluntary feed intake reduced as the pregnancy advances in Nellore cows and can be calculated as DMI (kg/d) = (16– 0.0093 × days of pregnancy)/1000 × SBW, where SBW is shrunk body weight. The average DMI of LOW-fed cows corresponded to 102, 98, and 67% of the amount of energy necessary to attend the maintenance and pregnancy energy requirements suggested by NRC for a cow at 0, 135, and 270 d of pregnancy, respectively. However, LOW-fed cows had 0.26 kg/d of average shrunk body gain indicating that the nutrient energy requirements of Zebu cows are likely lower than those suggested by NRC. The interaction between the feeding level and days of pregnancy was significant ($P < 0.05$) for the digestibility of DM, OM, CP, ether extract (EE), NDF corrected for ash and protein (NDF_{ap}) and GE, and the values of TDN. In all these cases there was a reduction in digestibility with increasing gestation age in HIGH-fed cows, while digestibility of OM, CP, EE, NDF_{ap} and GE increased as function of days of pregnancy in LOW-fed cows. The reduction in the digestibility of neutral detergent fiber occurs faster than in dry matter digestibility. These data suggests that the reduction of the digestibility as pregnancy increases in ad libitum fed cows is caused by an increase in the rate of passage as compensation factor for the ruminal volume reduction. There were no direct effects of pregnancy on microbial N production in Nellore cows. *Funded by INCT-CA, CAPES, CNPq, and FAPEMIG.*

1577 (M291) Growth and feed intake of Nellore steers fed whole corn diets containing feed antibiotics. B. J. M. Lemos[1], F. G. F. Castro[2], B. P. C. Mendonça[2], A. L. Braga Netto[2], C. E. Dambros[1], D. B. Fernandes[2], V. R. M. Couto[1], and J. J. R. Fernandes*[1], *[1]Universidade Federal de Goiás, Goiânia, Brazil, [2]AgroCria, Goiânia, Brazil.*

The objective was to investigate the effects of feed antibiotics on growth and feed intake of feedlot steers fed whole corn diets. Ninety-eight Nellore steers (302 ± 47 kg of BW and 24 mo of age) were assigned to a randomized complete block design experiment with four blocks (based on initial BW) and five treatments (Mon30: monensin 30 ppm; Virg25: virginiamycin 25 ppm; Mon20+Virg25: monensin 20 ppm + virginiamycin 25 ppm; Fla40: flavomycin 40 ppm; Mon20+Fla20: monensin 20 ppm + flavomycin 20 ppm). Pen was the experimental unit. The experiment consisted of a 100-d period. All steers were fed ad libitum with TMR (88.2% DM, 12.5% CP, 71.5% TDN) with 85% whole grain corn and 15% pelleted protein concentrate on a DM basis. Animals were weighed after a 16-h fast on d 0 and 100 of the experimental period to determine the ADG and feed efficiency (G:F, g of BW gain/kg of feed). No effect ($P > 0.01$) was observed on growth and feed intake of Nellore steers fed whole corn diets containing feed antibiotics (Table 1577). Feed antibiotics tested had the same results. Feed antibiotics tested were able to maintain satisfactory performance in finishing beef cattle fed high-concentrate diets based on whole corn.

1578 (M292) Effects of volume weight, precision processing and processing index on in vitro ruminal fermentation of dry-rolled barley grain. U. Y. Anele*[1], B. Refat[1], M. L. Swift[2], Z. He[1], T. A. McAllister[1], and W. Yang[1], *[1]Lethbridge Research Centre, Agriculture and Agri-Food Canada, AB, [2]Alberta Agriculture and Rural Development, Lethbridge, Canada.*

A study using batch culture technique was conducted to evaluate the effects of volume weight (VW, g/L), precision processing (PP; sieving grains into large versus small kernels and rolling based on kernel size), and processing index (PI; VW after rolling/VW before rolling × 100%) on kinetics of gas production, dry matter degradability (DMD), molar proportions and total short chain fatty acids (SCFA) of dry rolled barley grain. The study was arranged in a 2 × 2 × 2 factorial design. Gas production and DMD were measured at 3, 6, 12, and 24 h of incubation using rumen fluid from three fistulated beef heifers fed 70% barley silage and 30% barley grain. We hypothesized that incorporating other factors with PI would help improve prediction of the feeding value of processed barley grain. Barley samples were collected monthly from 10 different feedlots in Southern Alberta for 1 yr. Samples were ranked according to their VW into low (< 600 g/L) and high (> 600 g/L), which were later subjected to PP (processed vs. control) before dry-rolled with extent of processing expressed as PI 75 or 85% ± 3. The dry-rolled samples used in the study were not subjected to further grinding. Precision processing x PI interactions ($P < 0.01$) were observed for asymptotic cumulative gas volume, rate, lag time and absolute initial gas produced during the first hour. In addition, a PP × VW interaction ($P < 0.05$) was noted for cumulative gas volume. There were strong interactions ($P < 0.01$) between PP, VW and PI for the b fraction (insoluble but degradable in the rumen) and effective degradability of the samples. Effective degradability coefficients ranged from 0.18 to 0.26. Greater degradability coefficients were noted for processed samples with lower PI. Only PI had an effect ($P < 0.05$) on the rate of DMD. Interactions ($P < 0.05$) between PP, VW and PI were noted for the isobutyric, butyric, isovaleric, valeric and caproic contents of the samples after 6 h of incubation. Total SCFA values ranged from 30.2 to 40.1 mmol/L. Apart from PP and PI interaction ($P < 0.05$) on C_2:C_3, no other interaction was observed after 24 h of incubation. Regression results showed that VW and PP was better in predicting rate of DMD than PI and this is consistent with our hypothesis.

Key Words: barley, beef cattle, degradability, prediction

1579 (M293) Total tract NDF digestion predicted using rumen in vitro measures is related to commercial dairy in vivo total tract nutrient digestion. J. P. Goeser*[1,2], and C. R. Heuer[1,2], *[1]Dep. of Dairy Science, University of Wisconsin–Madison, Madison, [2]Rock River Laboratory, Inc, Watertown, WI.*

Dairy diet in vivo total tract digestion estimates of OM and NDF have been correlated to animal performance and used in the field to assess opportunities for improvement. Measuring in vivo digestion on commercial farms however is time consuming and relatively costly. Our objective was to determine if total tract NDF digestion estimates predicted from rumen in vitro data (TTNDFD) were related to in vivo apparent total tract organic matter (OM) and carbohydrate digestion coefficients. Commercial dairy total mixed ration (TMR) samples ($n = 50$) submitted for in vivo digestion analysis (% of nutrient, using 120h iNDF as an internal marker) were further digested in duplicate for 24, 30, and 48 h using Combs-Goeser rumen in vitro techniques. Potentially digestible NDF (pdNDF, % of NDF) was estimated using 120-h NDFD measures and NDF K_d was calculated using log-linear transformed 24, 30, and 48 h uNDF residues. TTNDFD was predicted by $K_d/(K_d+K_p)$ and a K_p based on NDF passage. In vivo organic matter and carbohydrate digestion coefficients (OMD, NDFD, pdNDFD and starchD) were also determined. TMR nutrient content and in vivo digestion coefficient descriptive statistics were calculated. TTNDFD estimates were regressed on in vivo OMD, NDFD, pdNDFD, and StarchD using SAS JMP Pro v11.0 and residuals assessed for normality. The TTNDFD was significantly ($P < 0.01$) related to OMD, NDFD, and pdNDFD. The regression equation parameters are outlined in Table 1579. These data suggest further evaluation is warranted but demonstrate a significant relationship between TTNDFD predictions and in vivo total tract digestion measures. On commercial dairies, in vitro TTNDFD measures may help identify dairy nutritive opportunities.

1580 (M294) Influence of fibrolytic enzyme supplements on production performance of lactating buffaloes in early lactation.

T. A. Morsy*, and S. Kholif, *National Research Center, Cairo, Egypt.*

The use of biotechnology such as exogenous fibrolytic enzymes to enhance quality and digestibility of fibrous forage is a novel approach for delivering practical benefits to ruminant production systems. A study was conducted to evaluate the use of commercial exogenous enzymes as feed additives with lactating buffaloes on milk yield and composition. Twenty-one lactating buffaloes in early lactation had body weight on average (570 ± 15 kg) were divided into three groups (seven animals each) using complete random design. Animals were fed individually on basic diet total mixed rations (TMR; 60% forage: 40% concentrate, dry matter basis). Treatments were 1) no additives (control), 2) 40 g Tomoko/head/day (Tom), and 3) 40 g Veta-Zyme Plus/head/day (Vet). Animals were milked twice daily and milk production was recorded at every milking. Milk samples were obtained every two wk from each buffalo at all milkings to determine milk composition. The enzyme additive did not alter dry matter intake, but Milk yield, 4% Fat Corrected Milk, and Fat percent significantly increased with (Vet) treatment than all other treatments. However, total protein percent increased ($P < 0.05$) with (Vet) and (Tom) treatments than control. Regarding the milk fatty acids profile, it was found that the total unsaturated fatty acids and conjugated linolenic acid (CLA) were increased ($P = 0.08$) with (Vet) and (Tom) groups compared with control. Therefore, the addition of an exogenous fibrolytic enzyme additive to the diet of lactating buffaloes affected milk production as well as milk quality.

Key Words: fibrolytic enzyme, lactating buffaloes, milk yield and composition

1581 (M295) Effect of two exogenous fibrolytic enzyme preparations on rumen fermentation and in situ degradability kinetics in dairy cattle.

J. J. Romero*[1], E. G. Macias[2], Z. Ma[1], R. M. Martins[3], C. R. Staples[1], and A. T. Adesogan[1], *[1]Dep. of Animal Sciences, University of Florida, Gainesville, [2]Dep. de Zootecnia, Universidad Nacional Agraria La Molina, Lima, Peru, [3]Dep. de Zootecnia, Universidade Federal de Viçosa, Minas Gerais, Brazil.*

The objective was to compare effects of two *Trichoderma reesei* exogenous fibrolytic enzyme preparations (EFE) on the ruminal degradation and fermentation of a bermudagrass- and corn silage-based TMR. Endoglucanase and xylanase activities of a moderate xylanase (MIX) and xylanase-rich (XYL) EFE were 2087 and 2714 and 10,549 and 26,926 µmol/min per g, respectively. Both EFE improved milk production by lactating dairy cows in previous studies. Three ruminally-cannulated lactating Holstein cows (735 ± 8 kg; 159 ± 47 DIM) were assigned to Control (CON), MIX or XYL treatments in a 3 × 3 Latin square design with 23-d periods. The MIX and XYL EFE were added to the ration of the cows just before feeding at rates of 3.4 and 1 mL/kg of TMR DM, respectively. On d 18 of adaptation, ground (4 mm) samples of the TMR were weighed (5 g of DM) into in situ bags, treated with or without the EFE, and massaged to ensure thorough mixing. Exactly 24 h later, bags were placed in the rumens of the cows for 0, 4, 8, 16, 24, 48, and 72 h. All bags were removed simultaneously, washed, dried, and weighed. An exponential model was fitted to the DM degradation data. On d 23, ruminal fluid was collected from each cow just before feeding and every 2 h afterward for 10 h and analyzed for fermentation products and pH. The model used to analyze the fermentation data included effects of treatment, time, treatment by time interaction, period and the random effect of cow. A similar model without the time effect was used to analyze the in situ degradability data. Applying EFE had no effect ($P > 0.1$) on in situ degrad-

ability lag phase, washout fraction, potentially degradable fraction, undegradable fraction, or fractional degradation rate of DM. Also, EFE application did not affect ($P > 0.1$) ruminal pH or concentrations of ammonia-N, total VFA, acetate (A), propionate (P), butyrate, isobutyrate, isovalerate, valerate or the A:P ratio. Adding these EFE to a bermudagrass and corn silage- based TMR did not affect ruminal fermentation or in situ ruminal degradability under the conditions of this study.

Key Words: dairy cattle, enzyme, rumen kinetics

1582 (M296) Proteomic analysis of compositional differences between exogenous fibrolytic enzyme preparations that were effective or ineffective at improving forage digestibility. J. J. Romero*[1], Z. Ma[1], C. Silva-Sanchez[2], and A. T. Adesogan[1], [1]*Dep. of Animal Sciences, University of Florida, Gainesville,* [2]*Proteomics, ICBR, University of Florida, Gainesville.*

The objective was to use novel proteomic tools to identify differences in proportions of key enzymes and auxiliary proteins involved in hemicellulose and lignocellulose degradation between effective and ineffective exogenous fibrolytic enzyme preparations (EFE). We recently examined effects of applying 12 EFE from three companies on in vitro NDF digestibility (NDFD) of bermudagrass haylage (BH). The most- (2A) and second most- (11C) effective EFE were from *Trichoderma reesei* and they increased the NDFD of BH from 35.6 (Control) to 40.4 and 40.0%, respectively. The least effective EFE (9C) was from *T. reesei* and *Aspergillus* spp. and the NDFD of BH treated with this EFE was 36.2% (SEM = 0.55). The relative ratios of proteins in either 11C to 2A or 9C to 2A were analyzed in triplicate using quantitative proteomics. Specifically, EFE were analyzed with isobaric tags for relative and absolute quantitation coupled with liquid chromatography-mass spectrometry (iTRAQ LC-MS/MS). The identification and analysis of proteins were performed using ProteinPilot software version 4.5. Proteins were identified using the National Center for Biotechnology Information database for *T. reesei* and *Aspergillus* spp. The unused score threshold was set to > 1.3 (equivalent to 95% confidence or better). The Student's *t* test was used to measure the significance of the relative ratio of the proteins. The degrees of freedom were the number of distinct peptides within the protein evaluated minus 1. Quantitation was based on at least three unique peptides for each protein. The 2A EFE had 10 times more endoglucanase III, 17 times more acetylxylan esterase with Cellulose Binding Module 1, 33 times more xylanase III, 25 times more β-xylosidase, 7.69 times more polysaccharide monooxygenase with Cellulose Binding Module 1, and 3 times more swollenin compared to 9C. Relative to 11C, 2A had 14.3 times more xylanase III, 14.3 times more β-xylosidase, 7.7 times more endoglucanase III, and 1.9 times more polysaccharide monooxygenase. Therefore, the efficacy of the EFE at increasing NDFD was reflected by the relative proportions of novel xylanolytic and cellulolytic enzymes and auxiliary proteins that they contained.

Key Words: proteomics, enzyme, digestibility

1583 (M297) Effects of ensiling, exogenous protease addition and inoculation on ruminal in vitro starch digestibility in rehydrated corn. L. F. Ferraretto*, S. M. Fredin, R. D. Shaver, and P. C. Hoffman, *University of Wisconsin, Madison.*

Three experiments were simultaneously performed to evaluate the impact of: 1) rehydration and ensiling of dry ground corn on starch digestibility; 2) exogenous protease addition to rehydrated unensiled and ensiled corn on starch digestibility; and 3) exogenous protease addition or inoculation on fermentation profile and starch digestibility of rehydrated ensiled corn. To achieve these objectives, seven treatments ($n = 3$) were performed: dry ground corn (DRY), DRY + water addition to achieve DM content of 70% (WAT), WAT + exogenous protease addition (WATP), WAT ensiled for 30 d (ENS), WATP ensiled for 30 d (ENSP), ENS + inoculation (ENSI) and ENSP + inoculation (ENSPI). Vacuum-sealed bags were used for ensiled treatments. Exogenous protease (DSM Nutritional Products, Basel, Switzerland/Novozymes, Bagsvaerd, Denmark) was added at a rate of 1825 mg of protease per kg of corn DM. The recommended dose (4.5 g per ton of rehydrated corn) of a microbial inoculant containing lactic acid bacteria (1×10^9 CFU/g; Silo Charger "D", NU-AG Bosko, Inc., Oskaloosa, IA) was applied to inoculant treatments. Experiment 1 compared DRY, WAT and ENS in a completely randomized designed. Data were analyzed using Proc Mixed of SAS with treatment as a Fixed effect. Experiment 2 compared WAT and ENS without or with exogenous protease addition (WATP and ENSP, respectively) in a completely randomized designed in a 2×2 factorial arrangements of treatments. Data were analyzed using Proc Mixed of SAS with ensiling, protease addition and their interaction as Fixed effects. Experiment 3 compared the effects of exogenous protease addition and inoculation in ENS corn (ENS, ENSP, ENSI, and ENSPI). In experiment 1, starch digestibility was greater for ENS (64.9%) than DRY and WAT (51.7% on average). In experiment 2, ensiling and exogenous protease addition increased ($P < 0.05$) starch digestibility, but exogenous protease addition was more effective in ENS than WAT (6.4 vs. 2.6% units increase). In experiment 3, starch digestibility was increased by the addition of protease ($P = 0.02$) but not inoculant ($P = 0.38$). Inoculation resulted in lower ($P < 0.05$) pH, acetate, propionate and ethanol concentrations, but greater lactate ($P = 0.001$) and total acid ($P = 0.09$) concentrations. Ensiling and protease addition increased starch digestibility in rehydrated corn.

Key Words: ensiling, protease, starch digestibility

1584 (M298) Forage type and exogenous fibrolytic enzyme application rate effects on the digestibility of dairy cattle forages. J. J. Romero[1], Z. Ma[*1], E. G. Macias[2], D. H. Garbuio[3], and A. T. Adesogan[1], *[1]Dep. of Animal Sciences, University of Florida, Gainesville, [2]Dep. de Zootecnia, Universidad Nacional Agraria La Molina, Lima, Peru, [3]Universidade Estadual Paulista, São Paulo, Brazil.*

The objective was to examine the effects of applying two *Trichoderma reesei* exogenous fibrolytic enzyme products (EFE) at different application rates on the in vitro DM (DMD) and NDF (NDFD) digestibility of bermudagrass silage, a 50:50 alfalfa-orchardgrass hay mixture and corn silage. Treatments were a Xylanase-rich EFE (XYL), a 25:75 mixture of XYL and a cellulase EFE (MIX), and an untreated Control. Endoglucanase and xylanase activities of MIX and XYL were 2087 and 2714 and 10,549 and 26,926 μmol/min per g, respectively. The EFE were diluted in water and applied in quadruplicate to the substrate at 0, 0.5, 1, 4, and 8 μL of EFE/g of DM. The suspensions were incubated at 25°C for 24 h before addition of buffered-rumen fluid (39°C) and further incubation for 24 h in two runs. Rumen fluid was obtained from three lactating dairy cows fed TMR containing all of the tested forages. Data were analyzed as a completely randomized design with a 2 × 5 × 3 factorial treatment arrangement. The optimal dose was defined as the application rate with the highest digestibility that was higher ($P < 0.05$) than lower doses. Optimal doses of XYL and MIX for improving bermudagrass silage DMD were 0.5 (58.2 vs. 55.2%) and 1 (58.4 vs. 55.2%) μl/g, and those for increasing NDFD were 4 (39.7 vs. 32.9%) and 0.5 (36.7 vs. 32.9%) μl/g, respectively. For alfalfa/orchardgrass hay, respective optimal doses for DMD were 1 (68.8 vs. 66.0%) and 0.5 (68.7 vs. 66.0%) μl/g and those for NDFD were 1 (29.6 vs. 22.9%) and 0.5 (27.2 vs. 22.9%) μl/g, respectively. For corn silage, the respective optimal doses for DMD were both 1 μl/g (62.8 and 64.1 vs. 60.7%) and for NDFD they were both 4 μl/g (25.5 and 25.3 vs. 16.3%). Both XYL and MIX increased the in vitro DMD and NDFD of bermudagrass silage, alfalfa/orchardgrass hay and corn silage. Optimal application rates for improving DMD and NDFD differed across substrates for each EFE. The XYL and MIX EFE increased milk production by dairy cows when applied 1 and 3.4 μl/g of TMR DM, respectively in a subsequent trial.

Key Words: forage, enzyme, dose

1585 (M299) A meta-analysis on the effect of fibrolytic enzyme treatment of dairy cow diets. K. G. Arriola[*1], A. T. Adesogan[1], and M. C. Giurcanu[2], *[1]University of Florida, Dep. of Animal Sciences, Gainesville, [2]University of Florida, Dep. of Statistics, Gainesville.*

The objective of this study was to use a meta-analysis approach to summarize the results of experiments that investigated effects of exogenous fibrolytic enzymes (EFE) treatment of diets on the performance of dairy cows. The study evaluated data from 20 studies and 30 experiments. Treatments were classified based on predominant enzyme activities listed by the authors, which included: Cellulase (C)-Xylanase (X) (C-X), Amylase (A), Cellulase-Xylanase-Amylase (C-X-A), Cellulase-Glucose oxidase-Lactobacillus (C-GO-Lac), C-GO-Lac-Amylase (C-GO-Lac-A), Ferulic acid esterase (FAE), Cellulase-FAE (C-FAE), Xylanase-Endoglucanase-Exoglucanase (X-En-Ex), Endoglucanase-Xylanase (En-X), Exogenous proteolytic enzyme (EPE). Data were analyzed with an analysis of covariance model that included effects of study, the EFE type x application rate effect, and the application method (EFE application to the TMR, concentrate or forage). Data were weighted using the inverse of the variance of each study. Among EFE, A increased DMI ($P = 0.029$); C-X increased ($P < 0.05$) DMI, milk yield, lactose yield and NDFD; C-X-A increased ($P < 0.05$) DMI, milk protein yield, DMD, and NDFD; and En-X and EPE increased ($P < 0.05$) only milk protein concentration and milk lactose yield, respectively. Tendencies ($P < 0.1$) were detected for FAE to increase DMI, for En-X to increase feed efficiency (FCM/DMI) and for EPE to increase DMD. Therefore, C-X and En-X were the only EFE that increased milk yield and feed efficiency, respectively. A unit increase in the rates of application of C-X and En-X increased milk yield ($P = 0.017$) and feed efficiency ($P = 0.057$) by 0.19 and 0.18 units, respectively. Applying EFE to the forage increased DMD ($P = 0.003$), whereas application to the concentrate or TMR increased milk lactose yield ($P < 0.001$). Effects of EFE on the performance of lactating dairy cows were equivocal and they depended on the EFE type x rate interaction and the method of application.

Key Words: fibrolytic enzymes, cellulase, xylanase

1586 (M300) Effects of forage particle size and corn oil supplementation related to milk fat depression in dairy cows consuming reduced-fat corn dried distillers grains with solubles. H. A. Ramirez Ramirez* and P. J. Kononoff, *University of Nebraska, Lincoln.*

Four ruminally cannulated Holstein cows averaging (± SD) 116 ± 18 DIM and 686 ± 52 kg of BW were used in a 4 × 4 Latin square with a 2 × 2 factorial arrangement of treatments to test the effects of forage particle size and dietary concentration of

corn oil on milk fat depression (MFD). Cows were housed in individual stalls, milked twice daily and fed once daily to allow ad libitum access to feed. In each 28-d period each cow was offered one of four TMR that differed in forage particle size by inclusion of grass hay (LONG) or grass hay pellets (SHORT) and 0 or 2% corn oil (OIL). Chewing activity was monitored visually every 5 min for 24 h on d 25. Total rumen evacuation was performed on d 27 and 28 of each period to determine rumen kinetics. Dietary treatments were: 0% oil + short particle size (OIL0+SHORT); 0% oil + long particle size (OIL0+LONG); 2% oil + short particle size (OIL2+SHORT); and 2% oil + long particle size (OIL2+LONG). Dry matter intake and milk yield were not affected by treatment averaging 26.5 ± 0.90 kg/d and 32.8 ± 3.25 kg/d, respectively. There was a decrease ($P < 0.01$) in 3.5% FCM due to oil inclusion resulting in 34.6 and 26.6 ± 2.6 kg/d for 0 and 2% oil diets. An oil × size interaction ($P = 0.03$) resulted in 2.26, 3.02, 3.62 and 3.62 ± 0.23% milk fat for OIL2+SHORT, OIL2+LONG, OIL0+SHORT and OIL0+LONG. Fat yield was reduced ($P < 0.01$) from 1.22 to 0.81 ± 0.09 kg/d with 2% oil diets. An oil × size interaction ($P < 0.01$) affected yield of *trans*-10, *cis*-12 conjugated linoleic acid (CLA) resulting in 0.35 g/d for OIL2+SHORT and 0.11 g/d for OIL2+LONG. Long particles increased ($P = 0.02$) eating time from 169 to 198 ± 15 min/d, rumination time ($P < 0.01$) from 400 to 504 ± 35 min/d and reduced ($P = 0.02$) rate of passage of DM from 3.38 to 2.89 ± 0.42%/h. These results demonstrate that dietary manipulations that modify rumen kinetics also impact milk fat production in dairy cows consuming TMR supplemented with corn oil, the effects of corn oil on MFD were less severe when cows consumed long particle size.

Key Words: rumen kinetics, biohydrogenation, chewing activity

---

1587 (M301) Impact of forage inclusion rate in a dry total mixed ration on the behavior and growth of growing dairy cattle. M. J. Groen[1,2], M. A. Steele[3], and T. J. DeVries[*1], *[1]University of Guelph, Kemptville, ON, Canada, [2]Wageningen University, Netherlands, [3]Nutreco Canada, Guelph, ON.*

The objective of this study was to determine the impact of forage inclusion rate in a dry TMR on behavior and growth of young dairy cattle. Ten Holstein bull calves (90.5 ± 2.4 d of age, weighing 136.0 ± 12.3 kg) were assigned to one of two treatments, a TMR containing (DM basis) either: 1) 85% concentrate and 15% chopped straw for 10 wk (wk 1 to 10); or 2) 85% concentrate and 15% chopped straw for 5 wk (wk 1 to 5), then 70% concentrate and 30% chopped straw for 5 wk (wk 6 to 10). After 10 wk, all animals were transitioned to a TMR containing (DM basis) 42.3% corn silage and 57.7% haylage for 2 wk (wk 11 to 12). DMI was recorded daily and BW was recorded 2x/wk. Feeding behavior was scored from digital video recordings 3 d/wk. Samples of TMR and orts were taken for particle separation 3 d/wk. Sorting was calculated as: actual intake of each particle fraction expressed as a % of its predicted intake. Data were averaged by week and analyzed in a repeated measures mixed effect model. DMI (5.5 ± 3.3 kg/d), ADG (1.7 ± 0.1 kg/d), feed efficiency (3.5 ± 1.4 kg DM/kg gain), and eating time (151.9 ± 8.8 min/d) were similar between treatments during wk 1 to 5. Calves on the 70% diet ate less DM (5.5 vs. 7.4 kg/d; SE = 0.4; $P = 0.006$), grew slower (1.3 vs. 1.6 kg/d; SE = 0.08; $P = 0.02$), sorted more against long forage particles (62.8 vs. 103.8%; SE = 6.3; $P = 0.01$), and spent a greater duration of time feeding (194.9 vs. 102.6 min/d; SE = 12.5; $P = 0.001$) during wk 6 to 10. A treatment × hour interaction ($P < 0.001$) in the analysis of feeding patterns indicated that this difference in feeding time occurred only during the first 8 h after feed delivery. Despite no differences in DMI (5.2 kg/d) or ADG (1.1 kg/d) in wk 11–12, there was a carryover effect on behavior. In wk 11 to 12, a treatment × hour interaction was detected ($P = 0.03$); calves previously fed the 70% diet continued to spend more time feeding immediately after feed delivery. Interestingly, during wk 11 to 12 those calves did not sort for or against long particles (103.6%), while the calves previously-fed the 85% ration sorted for (107.0%) those particles. These results show that feeding a dry TMR to weaned calves can promote high growth rates and efficiency. Further, altering forage content of such a TMR may have an impact on the expression and persistence of feeding behavior patterns.

Key Words: feeding behavior, forage concentration, straw

1588 (M302) Assessment of feeding high moisture corn grain with different qualities of alfalfa hay in high-forage lactation dairy diets. A. W. Kelley, K. Neal, A. J. Young, and J. S. Eun*, *Utah State University, Logan.*

This experiment was performed to test a hypothesis that quality of alfalfa hay (AH) would affect nutritive benefits of feeding high moisture corn (HMC) due to their associative effects on nutrient utilization efficiency. Eight multiparous lactating Holstein cows were used; four were surgically fitted with ruminal cannula. Days-in-milk averaged 184 ± 10.7 at the start of the experiment. The experiment was performed in a duplicate 4 × 4 Latin square design. Within each square, cows were randomly assigned to a sequence of 4 diets during each of the four 21-d periods (14 d of treatment adaptation and 7 d of data collection and sampling). A 2 × 2 factorial arrangement was used; fair quality AH (FAH; 39.6% NDF and 17.9% CP) or high quality AH (HAH; 33.6% NDF and 21.9% CP) was combined with steam-flaked corn (SFC) or HMC to form four treatments: FAH with SFC, FAH with HMC, HAH with SFC, and HAH with HMC. The AH was fed at 32% DM, whereas HMC was included at 17% DM. Quality of AH did not affect DMI, whereas feeding HMC decreased DMI ($P =$

0.04) regardless of quality of AH. While digestibility of DM increased by cows fed with HAH compared to those fed with FAH (70.1 vs. 67.6%; $P = 0.05$), NDF digestibility increased by feeding HMC (67.6 vs. 58.4%; $P = 0.03$) but not quality of AH. Starch digestibility decreased by feeding HMC with FAH (85.7 vs. 95.0%) but not with HAH, resulting an interaction between quality of AH and type of corn grain (CG; $P = 0.02$). Feeding different qualities of AH did not affect milk yield; however, feeding HMC numerically decreased milk yield in FAH diet, but increased milk yield in HAH (30.4 vs. 29.6 kg/d), causing an AH × CG interaction ($P = 0.05$). Efficiency of milk yield/DMI was improved due to feeding HMC regardless of quality of AH ($P = 0.05$). In addition, dietary N utilization for milk N tended to increase by feeding HMC ($P = 0.07$), but it was not influenced by quality of AH. Overall results in this experiment indicate that feeding HMC in high-forage diets improved feed efficiency as well as N utilization efficiency regardless of quality of AH.

Key Words: alfalfa hay, feed efficiency, high moisture corn

1589 (M303) Replacing corn with soyhulls for late-lactation cows fed high-forage diets. V. R. Moreira*[1], L. K. Zeringue[2], C. Leonardi[3], D. Schilling[2], and M. E. McCormick[2], *[1]Louisiana State University AgCenter School of Animal Sciences, Franklinton, [2]Louisiana State University AgCenter, Franklinton, [3]Louisiana State University, HSC– School of Public Health– Biostatistics, New Orleans.*

The objective was to evaluate performance of 48 late-lactation multiparous Holstein cows (27.6 ± 5.90 kg milk/d, 280 ± 79 DIM) fed rations gradually substituting ground corn (C) with soyhull pellets (SH). Treatments contained 17.4% of dietary DM as C, no SH (C100:SH0); 11.6% C, 5.8% SH (C67:SH33); 5.8% C, 11.6% SH (C33:SH67), and no C, 17.4% SH (C0:SH100). Other dietary ingredients remained similar in all treatments: bermudagrass hay (6.3%, diet DM), corn silage (56%), soybean meal (15.3%), urea (0.5%), calcium carbonate (0.5%), mineral (2.5%), salt (0.5%), and yeast (1%). Fixed ingredients except forages were premixed weekly. Treatments were mixed and offered once daily as TMR. Refusals were weighed and removed before next day feeding. Cows were randomly assigned to treatments for 7 wk following a 2-wk standardization period. Intake and milk yield were recorded daily. Milk samples were collected from one 48-h collection period (2 milkings/d) during pretrial and three collection periods during trial. Milk samples were analyzed for fat, protein, SNF, MUN and SCC. Body weights and body condition scores were recorded at the beginning and end of the experimental period. Two cows were removed before the end of the study because of mastitis (treatments C100:SH0 and C0:SH100). Means were analyzed using PROC MIXEDs (SAS, version 9.3) for main effects of treatment and contrasts were set to test for linear, quadratic and cubic effects of levels of soyhulls substitution for corn. Treatment diets contained 56.5% ± 0.2% DM, 17.0% ± 0.2% CP, 0.91% ± 0.04% Ca, and 0.39% ± 0.02% P as analyzed (average ± standard deviation), and 1.48 Mcal/kg DM as estimated with NRC (2001). Dry matter intake was not affected by treatments (means = 20.8 kg/cow/d; SEM = 0.81), ranging from 19.6 kg for cows fed C67:SH33 to 22.3 kg for those fed C100:SH0. Milk yield averaged 23 kg/cow/d (SEM = 1.55 kg/cow/d) and was not significantly different. Milk fat (3.9%), milk protein (3.3%) and MUNs (18 mg/L) did not differ statistically. There was no evidence supporting better NPN utilization for either feedstuff. Regardless of treatment, cows gained 0.5 kg body weight/d during the study, but body condition score changes in nearly 49 d of study were negligible, averaging 0.04 unit. This study suggests that soyhull pellets can replace corn in late-lactation cows' diets without significantly affect animal performance.

Key Words: ground corn, soyhull pellets, dairy cows

1590 (M304) Effects of different dietary forage sources on milk performance and amino acid profile in early lactating dairy cows. X. Q. Zhou[1,2], D. P. Bu[1], Y. D. Zhang[1], M. Zhao[1], P. Sun[1], and J. Q. Wang*[1], *[1]State Key Laboratory of Animal Nutrition, Institute of Animal Science, Chinese Academy of Agricultural Sciences, Beijing, China, [2]Northeast Agricultural University, Harbin, China.*

The objective of this study was to evaluate the effects of different dietary forage sources on performance and milk amino acid profile in early lactation dairy cows. Thirty-two Chinese lactating Holstein cows with similar DIM (55 ± 15 d) and milk yield (31.4 ± 3.49kg/d) were randomly assigned to two groups and fed total mixed ration (TMR) using automatic feeding system. Diets contained similar concentrate mixtures with the same forage-to-concentrate ratio of 36:64 [dry matter (DM) basis]. Different forage sources were then added: 17.30% alfalfa hay and 18.77% corn silage (MF); 36.07% corn straw (CS).Experiment lasted for 90 d, including first 14 d dietary adaption. Animal health condition, milk yield, amount of feed offered and refused for individual cows were recorded every day in experimental period. Milk samples of each cow on 91 d were collected to analysis milk composition and amino acid profile in milk protein. MF group had increased daily DMI(21.35 vs. 17.43 kg/d, $P < 0.01$), milk yield (30.45 vs. 23.12 kg/d, $P < 0.01$), milk protein content (3.66 vs. 3.32%, $P < 0.01$), milk protein yield(1.11 vs. 0.75 kg/d, $P < 0.01$), milk fat yield (1.36 vs. 1.01 kg/d, $P < 0.01$) and milk lactose yield (1.47 vs. 1.13 kg/d, $P < 0.01$) compared with CS group. The content of Thr (3.79 vs. 3.71 g/100 g AA, $P < 0.01$), Ser (4.48 vs. 3.36, $P = 0.03$), Met (3.50 vs. 3.38, $P = 0.02$), Lys (7.71 vs. 7.55, $P < 0.01$) and Arg (3.35 vs. 3.31, $P = 0.02$) in milk protein were elevated significantly in MF group while the two kinds of BCAA (Leu 11.72 vs. 11.88, $P = 0.02$ and

Val 5.98 vs. 6.09, $P < 0.01$) showed an opposite trend. Otherwise, the concentrations of amino acids in milk were greater ($P < 0.01$) in response to MF group compared with CS group. But no difference was observed in content of milk fat and milk lactose between two treatments ($P > 0.05$).

Key Words: forage, milk performance, amino acid

1591 (M305) The partial replacement of corn silage by sugarcane silage plus crude glycerin and the effect of sensory feed additives for dairy cows.

O. F. Zacaroni*[1], F. F. Cardoso[1], A. C. S. Melo[1], R. F. Lima[1], R. A. N. Pereira[2,3], and M. N. Pereira[1,2], *[1]Universidade Federal de Lavras, Lavras, Brazil, [2]Better Nature Research Center, Ijaci, Brazil, [3]Empresa de Pesquisa Agropecuaria de Minas Gerais, Lavras, Brazil.*

Crude glycerin may compensate for the energy loss during the ensiling of sugarcane. The partial replacement of corn silage (CS) with an iso-NDF amount of sugarcane silage plus crude glycerin (SG), added or not of sensory feed additives (SA), was evaluated. Thirty-two Holsteins (182 DIM) were individually fed a standardization diet for 2 wk and a treatment for 44 d. The main statistical model contained covariate, block, forage, additive, interaction, time, and its two and three term interactions. Treatments were (% of DM): CS (30.2%) or CS (15%), sugarcane silage (10%), and crude glycerin (3.3%); with or without SA (Luctarom SFS-R 3386-Z and 1353-Z. Lucta, Spain) added to corn and then to forages in the mixer. Diets also contained 9.2% sorghum silage, 4.4% Tifton hay, and 24.5 ± 0.5 forage NDF. SA reduced milk yield in CS (32.2 vs. 31.1 kg/d) and increased in SG (30.3 vs. 31.7 kg/d) ($P < 0.01$ interaction); yields of lactose and solids followed the same trend ($P < 0.05$). SG increased DMI (22.6 *vs.* 21.9 kg/d, $P < 0.01$), while there was a trend for decreased DMI in response to SA (22.5 vs. 22.0 kg/d, $P = 0.07$). The ratio of milk to DMI had a greater positive response to SA in SG (1.34 vs. 1.43) than in CS (1.44 vs. 1.46) ($P = 0.03$ interaction). SG increased the contents of fat ($P = 0.01$) and protein ($P = 0.08$), improving milk solids ($P = 0.03$). There was no effect on feed sorting from 0700 to 1300 h ($P > 0.38$). From 1400 to 1900 h, SG induced selection in favor of particles > 19mm ($P = 0.05$), and, when added to CS, SA induced the rejection of 8- to 19-mm particles and consumption of < 8-mm particles, but had no effect when added to SG ($P < 0.01$ interaction). The intake rate from 0700 to 1300 h was faster in SG ($P < 0.01$), and it tended to be slower when SA was added to CS ($P = 0.05$ interaction). Plasma glucose content was reduced by SA in CS and increased in SG ($P = 0.01$ interaction). PUN did not respond to treatments ($P > 0.39$). There was a trend for reduced plasma γ-glutamyl transferase on SG ($P = 0.09$). Chewing activity was similar across treatments ($P > 0.49$), as well as the daily excretion of urinary allantoin ($P > 0.11$), ruminal fluid pH ($P > 0.24$), and protozoa count ($P > 0.48$). Total tract apparent digestibility was not determined by treatments ($P > 0.39$) neither the intake of digestible OM ($P > 0.72$). The partial replacement of CS by SG plus SA was a plausible alternative for feeding dairy cows.

Key Words: glycerin, sugarcane silage, sorting

1592 (M306) Relative excretion of nitrogen from alfalfa silage, corn silage, corn grain and soybean meal in urine and feces by lactating dairy cows.

M. J. Powell[1], T. Barros[2], M. A. C. Danes[2], M. J. Aguerre*[2], and M. A. Wattiaux[2], *[1]USDA–Agricultural Research Service, U.S. Dairy Forage Research Center, Madison, WI, [2]University of Wisconsin–Madison, Madison.*

The main objective of this trial is to determine the partitioning of nitrogen (N) from different feed ingredients in milk, feces and urine. This abstract focuses on relative excretion of N in feces and urine. Twelve multiparous late lactation Holstein cows (means ± SD; 264 ± 18 DIM) were fed a pretreatment TMR once a day for 11 d containing (DM basis) 35.5, 28.6, 20.3, 12.9 and 2.6% of corn silage (CS), alfalfa silage (AS), corn grain (CG), soybean meal (SBM) and a mineral and vitamin premix, respectively. On d 12, cows were grouped by milk yield and randomly assigned to one of four dietary treatments corresponding to each feed ingredient at natural abundance of ^{15}N being replaced by its homologue ingredient enriched with ^{15}N (except for CS treatment for which only 75% of the unlabeled CS was replaced by ^{15}N enriched CS). After 4 d feeding the ^{15}N-enriched TMR's, cows were fed the pretreatment non-enriched TMR during d 16 to 19. Total fecal and urinary collection was conducted on each cow every 6 h during d 12 to 19. Feed intake and lactation performance were also measured from d 12 to 19. Data were analyzed as a complete randomized design with treatment as a fixed effect and cow as a random effect. Corn silage and CG had the highest ^{15}N enrichment (atom % ^{15}N of 1.857 and 2.040, respectively) whereas AS and SBM had the lowest (atom % ^{15}N of 0.730 and 1.385, respectively) due to ^{15}N dilution by the atmospherically-fixed N by these legumes. Feeding ^{15}N-enriched ingredients had no effects on DMI (23.2 ± 2.4 kg/d, $P = 0.39$), milk yield (26.1 ± 5.2 kg/d, $P = 0.85$), N intake (601 ± 61 g/d, $P = 0.41$), protein yield (0.89 ± 18 kg/d, $P = 0.80$) and N use efficiency (milk N/N intake; 0.23 ± 0.05, $P = 0.86$). Cumulative ^{15}N recovery (% of total ^{15}N fed) in feces between d 12 and 19 was similar ($P = 0.61$) between AS and CS treatments (29.8 vs. 28.2%), which were greater ($P < 0.05$) than CG (21.5%) and SBM treatments (12.5%). Although not significantly different ($P = 0.12$), greater cumulative ^{15}N recovery (%) in urine was measured in AS (27%), it was intermediate in CS and CG (21.6 and 19.4%, respectively) treatments, and smallest in the SBM (17.0%) treatment. Results from this study suggested that AS and CS contributed most to fecal N excretion and AS contributed most to urinary N excretion.

Key Words: N partitioning, N use efficiency, ^{15}N

1593 (M307) A sensory additive improves performance of dairy cows under heat stress. F. Bargo*[1], S. Muñoz[2], M. Candelas[2], J. Vargas[1], and I. Ipharraguerre[1], [1]*Lucta S.A., Barcelona, Spain,* [2]*Nuplem, Durango, México.*

Five hundred seventy Holstein dairy cows (280 primiparous and 290 multiparous; 194 DIM and 34.4 kg/d milk) from the commercial dairy farm El Trébol (Durango, México) were used to evaluate the effect of a sensory additive (ProEfficient, Lucta S.A.) on dry matter intake, milk production, and feed conversion efficiency under heat stress conditions in a completely randomized design. Cows were grouped by parity (primiparous vs. multiparous) in four free-stall pens and randomly assigned to two treatments: control TMR or the same TMR supplemented with 30 g/d of ProEfficient (PE). The TMR (52:48 concentrate: forage; 18.2% CP, 29.1% NDF, 42.1% NFC) was offered twice daily and PE was top-dressed at each feeding during 34 d starting on June 25ᵗafter 2 wk of adaptation. Daily dry matter intake of each pen and individual milk yield (Alpro, De Laval) were measured. Data were analyzed by ANOVA with a mixed model with repeated measures using the PROC PROC MIXED of SAS (1999) where pen nested within treatment was considered as random effect. During the experimental period, maximum and minimum temperatures averaged 38.9 and 20.4°C, respectively. Dry matter intake increased 1.2 kg/d (23.6 vs. 24.8 kg/d; $P < 0.05$) with the inclusion of the PE additive. Cows fed the TMR with PE produced 2 kg/d more of milk (35.2 vs. 33.2 kg/d; $P < 0.05$) with similar feed conversion efficiency (1.42 kg milk/kg DMI; $P > 0.05$). Based on previous findings from studies with PE, the milk response to this additive could have been related to changes in ingestive behavior (meal size and frequency) and/or positive modulation of hormonal signals associated with the control of feed intake (e.g., ghrelin). Feeding a sensory additive under heat stress conditions increased dry matter intake and milk production of dairy cows fed a TMR.

Key Words: sensory additive, heat stress, intake and milk production

1594 (M308) Performance and health of calves pre- and post weaning fed milk replacers with supplements for heat abatement in the summer months. H. Chester-Jones*, *University of Minnesota Southern Research, and Outreach Center, Waseca.*

Two studies were conducted in the summer of 2012 and 2013 to evaluate pre- (d 1 to 42) and post-weaning (d 43 to 56) calf performance and health when fed milk replacers (MR) with supplements to aid in heat abatement. Calves were fed a non-medicated 20% fat:20% CP MR at 0.284 kg in 1.99 L water (12.5% solids) 2x/d for the first 35 d and 1x/d from d 36 to weaning at 42 d. From d 1 to 14, 1:1 neomycin:oxytetracycline was added to the MR solution to provide 22 mg/kg BW daily. Calf starter (CS; 18% CP) and water were fed free choice d 1 to 56. In study 1, 51 (2- to 4-d-old) individually fed Holstein heifer calves (38.5 ± 0.96 kg) were assigned to MR supplements as follows: SA1 = none; SA2 = B-complex vitamin premix fed at 1.42 g/calf daily and SA3 = betaine fed at 5 g/calf daily. There were no treatment differences in pre- and post-weaning ADG or total hip height (HH) gain which averaged 0.64 kg and 9.63 cm, respectively. There was a trend ($P < 0.10$) for increased 56-d CS intake when calves were fed the SA2 or SA3 compared to SA1 MR (0.81 vs. 0.72 kg DM/d). There were no differences in BW gain, total DMI, gain/feed or scouring days across treatments. Calves fed SA2 had higher ($P < 0.05$) daily health treatment costs vs. SA1 calves but were not different from SA3 calves ($P = 0.07$). In study 2, 75 (2- to 4-d-old) individually fed Holstein heifer calves (39.4 ± 0.65 kg) were assigned to MR supplements SB1, none; SB2, B-complex vitamin premix fed as in study 1 and SB3, B-complex vitamins as in SB2 plus an electrolyte mix fed at 28 g/calf daily. There were no treatment differences in ADG and HH gain (0.68 kg and 10.85 cm, respectively over the 56-d study). Pre-weaning gain/feed was higher ($P < 0.05$) for SB3 compared to SB1 or SB2 calves. There were no differences in health parameters. A heat index of 90 or more occurred on 34 d in 2012 and 26 d in 2013 studies, respectively. Under the conditions of these studies, heat abatement supplements added to MR did not consistently enhance calf performance.

Key Words: milk replacers, heat abatement supplements, performance

1595 (M309) Performance and health of calves pre- and post weaning fed milk replacers with supplements for heat abatement in the summer months. D. Schimek*[1], B. Ziegler[1], D. Ziegler[2], H. Chester-Jones[2], and M. Raeth-Knight[3], [1]*Hubbard Feeds Inc., Mankato, MN,* [2]*University of Minnesota Southern Research and Outreach Center, Waseca,* [3]*University of Minnesota, St. Paul.*

Two studies were conducted in the summer of 2012 and 2013 to evaluate pre- (d 1 to 42) and post-weaning (d 43 to 56) calf performance and health when fed milk replacers (MR) with supplements to aid in heat abatement. Calves were fed a non- medicated 20% fat:20% CP MR at 0.284 kg in 1.99 L water (12.5% solids) 2x/d for the first 35 d and 1x/d from d 36 to weaning at 42 d. From d 1 to 14, 1:1 neomycin:oxytetracycline was added to the MR solution to provide 22 mg/kg BW daily. Calf starter (CS; 18% CP) and water were fed free choice d 1 to 56. In study 1, 51 (2- to 4-d-old) individually fed Holstein heifer calves (38.5 ± 0.96 kg) were assigned to MR supplements as follows: SA1 = none; SA2 = B-complex vitamin premix fed at 1.42 g/calf daily and SA3 = betaine fed at 5 g/calf daily. There were no treatment differences in pre- and post-weaning ADG or total hip height (HH) gain which averaged 0.64 kg and 9.63 cm, respectively. There was a trend (*P*

< 0.10) for increased 56-d CS intake when calves were fed the SA2 or SA3 compared to SA1 MR (0.81 vs. 0.72 kg DM/d). There were no differences in BW gain, total DMI, gain/feed or scouring days across treatments. Calves fed SA2 had higher ($P < 0.05$) daily health treatment costs vs. SA1 calves but were not different from SA3 calves ($P = 0.07$). In study 2, 75 (2- to 4-d-old) individually fed Holstein heifer calves (39.4 ± 0.65 kg) were assigned to MR supplements SB1, none; SB2, B-complex vitamin premix fed as in study 1 and SB3, B-complex vitamins as in SB2 plus an electrolyte mix fed at 28 g/calf daily. There were no treatment differences in ADG and HH gain (0.68 kg and 10.85 cm, respectively over the 56-d study). Pre-weaning gain/feed was higher ($P < 0.05$) for SB3 compared to SB1 or SB2 calves. There were no differences in health parameters. A heat index of 90 or more occurred on 34 d in 2012 and 26 d in 2013 studies, respectively. Under the conditions of these studies, heat abatement supplements added to MR did not consistently enhance calf performance.

Key Words: milk replacers, supplements, performance

1596 (M310) Effect of supplementing heat stressed dairy cows with electrolytes on milk yield, composition, and blood metabolites. C. J. Cabrera*, S. H. Ward, and A. J. Geiger, *Mississippi State University, Starkville.*

The objective of this study was to determine the effect of supplementing electrolytes from -21 to 30 DIM to heat stressed cows on DMI, MY, and blood metabolites. A total of 104 Holstein and Jersey, cows and heifers, were utilized between August–September 2012 and August–November 2013. Before calving, all cows and heifers were fed ryegrass baleage in the morning and TMR in the evening (CON) or the same base ration plus 270 g of electrolyte (E+, Bovine Bluelite, TechMix, Inc; MN) providing balanced electrolytes (0.55% Ca; 0.30% P; 9.60% NaCl; 8.25% K; 0.14% Mg). Post-calving, CON cows were fed standard TMR and E+ cows received the same TMR plus 270 g of Bovine Bluelite. DMI, MY, rectal temperature, and respiration rate were monitored daily; while blood metabolites, body weight, condition score and frame (withers height, hip height, and heart girth) were measured weekly. Orts and feedstuffs were sampled weekly and subjected to proximate analysis. Milk samples were taken weekly and analyzed for fat, protein, solids, lactose content, and SCS. Blood samples were taken via jugular venipuncture, further analyzed for pH, HCO3, tCO2, pCO2, Anion Gap, Na^+, K+, and Cl^-, using an onsite IDEXX Blood Gas Analyzer, and for hematocrit utilizing a micro centrifuge. DMI was not different among treatments, however, during 2013 dry cows consumed more than in 2012 (8.33 vs. 7.09 kg/d; $P < 0.0001$). Cows fed E+ had lower MY than CON cows (29.64 vs. 34.99 kg/d; $P = 0.0042$). Holstein cows averaged greater MY than Jerseys (36.45 vs. 28.18 kg/d; $P < 0.0001$) but despite this expected breed effect, MY for CON and E+ cows only differed between Holsteins (40.90 vs. 32.00 kg/d, respectively; $P < 0.0001$), not between Jerseys (29.08 vs. 27.29 kg/d, respectively; $P = 0.6084$). Milk composition was not affected, however, E+ cows had increased fat content ($P < 0.001$) weekly for the first 4 wk, whereas CON cows decreased ($P < 0.001$) until wk 2. Respiration rate (57.12 vs. 55.30 bpm; $P = 0.1197$) and rectal temperature (38.7 vs. 38.7°C, respectively; $P = 0.9853$) were not influenced by treatment, but Holstein cows had greater respiration rates than Jerseys (58.63 vs. 53.78 bpm, respectively; $P < 0.0001$). No differences were observed in blood metabolites, nor in body weight change and condition score, except for withers height which was greater for CON cows (133.40 vs. 130.75 cm, respectively; $P = 0.0170$). Electrolyte supplementation did not increase MY, nor affect any of the other measured variables in the present study.

Key Words: dairy, electrolyte, transition

1597 (M311) Average daily gain among calves fed a high plane of milk replacer during the pre-weaning period is not associated with improved reproductive efficiency or lactational performance in Holstein heifers. M. D. Sellers*, C. R. Nightingale, and M. A. Ballou, *Texas Tech University, Dep. of Animal and Food Sciences, Lubbock.*

The objective was to determine if increased ADG while on a high plane of nutrition during the pre-weaning period is associated with improved reproductive efficiency as a heifer and improved reproductive efficiency or lactational performance as a primiparous cow. Seventy-two Holstein calves from a single herd in western Texas (2 ± 1 d old) were fed a high plane of nutrition (28/20 milk replacer fed at 756 g/d DM and 1010 g/d DM for the first wk and wk 2 through 6, respectively, with ad libitum access to calf starter grain during the pre-weaning period. Weaning was initiated at wk 7 with the removal of PM milk replacer feeding and was completed when starter intake was 800 g/d DM after d 53. Daily milk replacer and starter intakes were recorded, and ADG was calculated for the pre-weaning period (wks 1 to 7). All calves were returned to the dairy of origination 3 mo after weaning and were managed according to their standard procedures. Reproductive efficiency as a heifer, as well as first lactation reproductive efficiency and milk production were collected from DairyComp305 records. All descriptive data will be reported as [0, 25, 50, 75, and 100 percentile]. The pre-weaning ADG was [0.144, 0.491, 0.560, 0.636, and 0.827 kg/d]. There was no relationship between pre-weaning ADG and age at first calving [647, 672, 685, 721, and 776 d; $P = 0.14$]. Reproductive performance as a primiparous cow was not affected by pre-weaning ADG, as no relationship was observed for average days open [61, 83, 104, 173, 298 d; $P = 0.14$. In addition, there was no relationship between pre-weaning ADG and first lactation production metrics of peak milk [28.2, 35.9, 39.1, 41.8, and 50 kg; $P = 0.15$] and estimated 305 d mature

equivalent [8191, 10827, 11914, 13407, 16073 kg; $P = 0.32$]. Additional research is needed to evaluate the relationship between post-weaning heifer nutrition and health statuses and subsequent reproductive and lactational performance.

Key Words: calf, lactation performance, plane of nutrition

1598 (M312) Ruminal in situ DM and starch digestion descriptive statistics of corn silage and high moisture corn. C. R. Heuer*[1,2], J. P. Goeser[1,2], and R. D. Shaver[3], *[1]Dep. of Dairy Science, University of Wisconsin–Madison, Madison, [2]Rock River Laboratory, Inc, Watertown, WI, [3]University of Wisconsin, Madison.*

Starch comprises 20 to 35% of dry matter (DM) in diets for lactating dairy cows. Ruminal starch digestibility is highly variable across and within feed types. Our objective was to determine ruminal in situ starch digestibility (StarchD) for corn silage (CS; $n = 52$) and high moisture corn (HMSC; $n = 41$) samples. Samples were dried at 50°C in a forced air oven for 48 h and ground to pass through a 1-mm Udy Mill screen for DM and starch analysis, or a 6-mm Wiley Mill screen for ruminal in situ analysis. Rumen in situ samples were weighed with 3 g per bag in an Ankom 5x10-cm bag (50µm pore size) in triplicate. Bags were soaked in warm water before incubation. One bag was placed in three different ruminally-cannulated lactating dairy cows consuming a 58% forage diet with a 50:50 ratio of corn silage to legume (DM basis). Samples were incubated for 3 and 7 h; all bags were removed simultaneously. Following incubation the bags were rinsed until effluent was clear. Bags were dried at 50°C for 24 h and weighed to determine the DM digestibility (DMD). Residue samples were composited and ground to pass a 1-mm Udy Mill screen. Starch content was then determined according to a modified M.B. Hall 2008 procedure using an YSI2700 (YSI Life Sciences On-Line Biochemistry Analyzer), to determine glucose after samples were enzymatically digested, instead of theglucose oxidase–peroxidase procedure. StarchD was calculated as the difference in grams of starch remaining in the residue, relative to the grams of starch in the sample. DMD and StarchD descriptive statistics were analyzed using SAS JMPv10 and are presented in Table 1598. Ruminal in situ StarchD was highly variable for HMSC and CS.

Key Words: rumen, starch, digestion

Table 1598. Rumen in situ 3 and 7-h descriptive statistics of DMD and StarchD

Type	Hour	Mean	St.dev.	Min.	Max.	C.V
Dry Matter Digestion (%)						
HMSC	3	40.3	16.6	19.0	82.5	41.2

1599 (M313) Response of rumen fermentation to urease inhibitor using dual-flow rumen simulation system. P. P. Wang[1], D. Jin[1], J. Q. Wang*[2], D. P. Bu[2], and S. Zhao[1], *[1]State Key Laboratory of Animal Science, Institute of Animal Science, Chinese Academy of Agricultural Science, Beijing, China, [2]State Key Laboratory of Animal Nutrition, Institute of Animal Science, Chinese Academy of Agricultural Sciences, Beijng, China.*

The objective of this study was to investigate urea degradation using a novel dual-flow rumen simulation system. Eight fermentation vessels (1 L) were allotted to a 2 × 2 factorial arrangement of treatments with urea supplemented at 0 or 0.5% dry matter intake (DMI), and urease inhibitor equivalent to 0 or 450 mg/kg DMI. A total of 40 g of DM with urea were fed in two equal portions daily, while the urease inhibitor, contained approximately 98% (w/w) acetohydroxamic acid (AHA), was added in the artificial saliva infused into the vessels twice daily. The experimental period consisted of 6 d for adaptation and 3 d for sampling. On each sampling Day 15 mL fermentation fluids were obtained from each fermentation vessel by syringes at 0, 2, 4, 6, 8, and 10 h, respectively. Temperature (39°C), liquid, and solid dilution rates (8%/h and 200 mL/d, respectively) were maintained through the whole process. Both protozoa numbers and dry matter disappearance (DMD) ($P = 0.62$ for urea; $P = 0.47$ for AHA) from each fermentation vessel were not affected by urea or AHA supplementation. Urea supplementation significantly ($P < 0.01$) increased pH and ammonia-nitrogen (NH_3–N) concentration, and AHA addition increased ($P = 0.03$) urea-N concentration. There was no interaction between urea and AHA. The pH reached the peak value at 2 h with urea supplementation only, and the pH began to reduce at 4 h with both urea and AHA addition. NH_3–N concentration arrived at maximum at 2 h with urea and/or AHA supplementations, but it sharply ($P < 0.05$) decreased at 4 h with urea supplementation and at 6 h with both urea and AHA addition. Urea-N concentration of treatment with urea and AHA supplementation was sustainably higher than other

treatments until 6 h. It was concluded that AHA inhibited urea degradation but had no effect on ammonia formation.

Key Words: dual-flow rumen simulation system, fermentation, urease inhibitor

1600 (M314) Effects of four ruminant feed additives on in vitro ruminal fermentation kinetic gas production and degradability. J. Li[1,2], J. Q. Wang[1], P. Sun[1], F. D. Li[2], and D. P. Bu[*1], *[1]State Key Laboratory of Animal Nutrition, Institute of Animal Science, Chinese Academy of Agricultural Sciences, Beijing, China, [2]College of Animal Science and Technology, Gansu Agricultural University, Lanzhou, China.*

This experiment was designed to investigate the effects of four ruminant feed additives, *Bacillus subtilis*, *procreatin* (major ingredient was high-enriched live yeast), *Aspergillus oryzae* culture and fibrase (major ingredient was *Aspergillus oryzae, Aspergillus niger* and lactic acid yeast) on gas production (GP) kinetics of different doses of 0(control), 1.0, 2.0, 4.0mg/kg diet (DM), respectively. Ruminal fluid was collected approximately 2 h before feeding from three lactating Holstein dairy cows (BW = 558 ± 10 kg, DIM = 153 ± 16d) fed total mixed ration (C:F = 40:60) and mixed with McDougall's phosphate buffer (v/v = 1:2). 500mg diet substrates, which were consistent with the donor cows, were incubated with diluted buffered rumen fluids (75ml) for 72 h at 39°C. The batch completed in 2 experimental runs, and 4 fermentations per treatment were arranged in each run. All bottles were connected to gas channel inlets of Automated Trace Gas Recording System for Microbial Fermentation (AGRS, Beijing, China). Data on the cumulative gas production were fitted to a model: GP_t (ml/g DM) = $A/(1+(C/t)^B)$. Where GP_t was the cumulative gas production (ml/g DM) at t incubation time (h), A was the asymptotic gas production (ml/g DM), B was a sharpness parameter determining the shape of the curve and C was the time (h) at which half of A is reached. A, B and C were calculated by the nonlinear procedure of SAS. There was no difference of C in all treatments ($P > 0.05$). Regarding to *Bacillus subtilis*, the GP_{72} ($P = 0.08$), A ($P = 0.09$) tended to linearly decrease with increase of adding levels, while B tended to increase ($P = 0.06$). For procreatin, the GP_{72} ($P = 0.06$) tended to quadratically increase and A quadratically increased ($P < 0.05$), however, the doses did not affect B ($P > 0.05$). The addition of *Aspergillus oryzae* linearly increased the GP_{72} ($P < 0.01$) and A ($P < 0.01$) and had a tendency for B ($P = 0.09$). The GP_{72} ($P < 0.05$) and A ($P < 0.05$) linearly increased with the rise of fibrase addition levels and no difference in B. In vivo digestibility of animal feeds was estimated by measuring in vitro GP of feed samples incubated in ruminal fluid buffered. The results suggested that *Aspergillus oryzae* and fibrase addition could increase the extent and rate of feed degradation while *Bacillus subtilis* and procreatin addition had slightly effects.

Key Words: feed additives, gas production, in vitro

1601 (M315) Comparison of omasal and reticular sampling methods on ruminal nutrient outflow and digestion in lactating dairy cows. S. M. Fredin[*1], L. F. Ferraretto[1], M. S. Akins[2], and R. D. Shaver[1], *[1]University of Wisconsin, Madison, [2]University of Wisconsin, Platteville.*

An experiment was conducted to compare omasal and reticular sampling methods on ruminal nutrient outflow and digestion in lactating dairy cows fed normal- or reduced-starch diets. Eight ruminally-cannulated multiparous Holstein cows (96 ± 8 DIM at trial initiation) were randomly assigned to a 2 × 2 factorial arrangement of treatments in a replicated 4 × 4 Latin square design with 21-d periods. Treatments were finely (F; mean particle size = 552 μm) and coarsely (C; 1270 μm) ground dry shelled corn in normal (NS) and reduced (RS) starch diets fed as TMR. The NS and RS diets contained 27 and 18% starch (DM basis), respectively, by partially replacing corn grain with soy hulls. Continuous infusion of flow markers Cr-EDTA and YbCl began on d 15. Spot samples of omasal digesta were collected four times daily every 2 h on d 18 to 20, with a 6-h interval between sampling days to represent a 24-h feeding cycle. A 250-mL digesta sample was taken from the reticulum immediately after omasal digesta collection. Indigestible NDF, determined after a 288-h ruminal in situ incubation, was used as a large particle marker and digesta samples were reconstituted using the triple-marker system. Data was analyzed using Proc Mixed of SAS. Dry matter intake was 23.2 ± 1.6 kg/d across all treatments ($P > 0.43$). Marker concentrations were greater in omasal samples compared with reticular samples ($P < 0.001$), resulting in increased ($P < 0.001$) estimates of apparent ruminal digestibility of NDF (39.1 vs. 37.8%), and starch (83.5 vs. 78.9%) for omasal sampling. Outflow of starch from the rumen was greater ($P < 0.01$) for reticular sampling (1.0 vs. 0.8 kg/d), however outflow of NDF was similar ($P = 0.82$) between sampling methods (4.1 kg/d). Ruminal NDF digestibility was greater ($P < 0.001$) for RS compared to NS for omasal samples (43.4 vs. 34.9%, respectively). Unexpectedly, the diets containing C resulted in greater ruminal starch digestibility ($P = 0.02$) compared with F for omasal (85.0 vs. 82.2%, for C and F, respectively) or reticular samples (81.4 vs. 76.5%, for C and F, respectively). Although differences for ruminal nutrient digestibility estimates between sampling methods were observed, they were relatively minor. Therefore, reticular sampling appears to be an acceptable method to estimate ruminal nutrient outflow and digestibility.

Key Words: dairy cow, omasal sampling, reticular sampling

1602 (M316) Validation of a new approach to estimate total tract fiber digestibility from in vitro NDFD values. F. Lopes*[1], K. Ruh[1], D. K. Combs[2], L. F. Ferraretto[1], S. M. Fredin[1], C. Arndt[1], R. D. Shaver[1], and L. E. Armentano[1], *[1]University of Wisconsin, Madison, [2]Dep. of Dairy Science University of Wisconsin, Madison.*

The objective was to validate an in vitro model to predict the total tract fiber digestibility (TTNDFD) in dairy cattle. Nineteen diets from six different trials conducted at University of Wisconsin–Madison were analyzed for fiber digestibility using the in vitro standardized model (Goeser and Combs, 2009). Forages varied amongst diets (corn, alfalfa, tall-fescue and meadow fescue and wheat straw silages) and nutrient composition (NDF ranges from 22.5 to 32.1%, CP 15.8 to 18.9% and NFC 38.0 to 51.0%). Total NDF digestibility observed from the in vivo trials was calculated using indigestible NDF or lignin as marker analyzed in fecal, diet and orts samples. The in vitro TTNDFD model predicts total tract fiber digestibility from the rate of pdNDF degradation (kd, ranges from 1.5 to 4.8%/h), the rate of passage of pdNDF (kp, ranges from 2.5 to 2.8%/h) and the proportion of total NDF that is potentially digestible. The kd is calculated from in vitro NDFD measurements taken at 24, 30, and 48 h of incubation using first order kinetics model with an indigestible fraction (Mertens, 1993). Passage of potentially digestible fiber is predicted from a regression model (Krizsan et al., 2010) for iNDF which is adjusted to account for the selective retention of pdNDF (Lund et al., 2006). The pool of indigestible fiber was estimated from 240 h in vitro NDF residues. Data were analyzed using SAS procedure of logistic regression. The coefficient of determination (R^2) was used to measure the proportion of variation explained by the model. The range of in vivo TTNDFD was 26.3 to 55.6% compared to 33.8 to 52.8% for predicted in vitro TTNDFD. The relationship between predicted in vitro TTNDFD and in vivo TTNDFD was TTNDFD in vivo = −5.7531 + 1.1561 TTNDFD in vitro predicted with R^2 of 61.6%, Root-MSE of 4.3% and P-value of < 0.001. The in vitro test of diets from six different trials demonstrated that TTNDFD model can provide important insights into fiber utilization by dairy cattle that could be used in the field. The TTNDFD value can also be used as a stand-alone value to index forages, as already shown in other publications from our lab. The ability to predict total tract fiber digestibility from a model based on in vitro NDF degradation and incorporate this information into rations could improve our ability to optimize forage utilization and milk production.

Key Words: iNDF, fiber, digestibility

1603 The effects of supplementation with a blend of capsicum, cinnamaldehyde, and eugenol on milk production performance of dairy cows. R. Blanck*[1], K. Vecht[1], C. Oguey[2], and E. Wall[2], *[1]Bar-Magen, Emek Hefer, Israel, [2]Pancosma, Geneva, Switzerland.*

Essential oils are naturally-occurring chemicals in plants, and many of these molecules have been reported to influence production efficiency of dairy and beef animals. Previously, it was reported that a blend of capsicum, cinnamaldehyde, and eugenol increases feed efficiency of beef steers. Our objective was to determine if that same additive (EO; Xtract®-7065, Pancosma) would influence the milk production performance of lactating dairy cows during the summer months in Israel. In two consecutive field trials, Holstein dairy cows were assigned to no additive or supplementation with EO (1 g/d; n = 30 cows/treatment in trial one, 70 cows/treatment in trial two; n = 2 pens/treatment) for 4 mo. The EO was blended with ground corn meal and top-dressed; control cows received corn meal without EO. Dry matter intake (DMI) per pen was calculated daily and individual cow milk production, milk composition, and somatic cell count (SCC) were recorded monthly. Data were subjected to analysis of variance with repeated measures using pen as the experimental unit and trial as a random variable. Cow activity was monitored in the first trial using a pedometer (Afimilk, Isreal), and rumination minutes per day were measured in the second trial (SCR, Israel). Those data were analyzed using analysis of variance with repeated measures and cow as the experimental unit. Milk production was increased in EO cows (39.4 vs. 42.0 kg/d; $P < 0.01$) with no effect of EO on DMI (22.6 vs. 22.5 kg/d; $P > 0.70$). Consequently, there was an improvement in feed efficiency of EO cows (milk/DMI = 1.74 vs. 1.89; $P < 0.001$). There was no effect of EO on milk composition ($P > 0.50$), but there was an increase in energy-corrected milk with EO (40.1 vs. 42.2 kg/d; $P < 0.01$). In addition, there was a decrease in SCC of EO cows (306.1 vs. 242.4 cells*1000/ml; $P < 0.05$). In trial one, there was a decrease in activity of EO cows (165 vs. 137 steps/d; $P < 0.001$); however, in trial two, there was no effect of treatment on rumination time (425 vs 436 min/d; $P = 0.30$). We conclude that a blend of capsicum, cinnamaldehyde, and eugenol can increase milk production and feed efficiency of lactating dairy cows. Additional experiments are needed to confirm these observations and to understand the mechanism underlying the response of dairy cows to EO.

Key Words: essential oil, feed additive, phytonutrient

1604 (M318) Stochastic analysis of the effects of variation in corn silage composition on the supply of metabolizable energy and protein in lactating dairy cows. J. Ferguson*, Z. Wu[1], D. T. Galligan, L. Baker, and N. Thomsen, *University of Pennsylvania, Kennett Square.*

The UPENN Ration Balancer, based on CPMDairy and CNCPS 5.1 with modifications, was used to construct a stochastic model to evaluate the influence of variation in corn silage (CSG) composition on the supply of ME and MP and their allowable milk production. Proximate analysis of CSG samples (n = 514) from 63 PA farms defined the mean and range in nutrient composition (CP, soluble protein (SP), NPN as a percent of SP, NDF, starch, sugars, water soluble fiber, silage acids, fat, and ash) and NDF degradation rate (Kd) for model inputs. A diet was formulated using mean CSG nutrient content and Kd to meet the ME and MP requirements for a cow (675 kg BW) producing 45.0 kg/d milk with 3.7% fat and 3.1% true protein and a DMI of 24.1 kg/d with the following ingredients (% DM): CSG (41.54), alfalfa haylage (6.22), grass silage (8.30), corn grain (21.98), soybean meal (12.64), Soy Pass (5.51), Energy Booster (0.62), blood meal (1.02), minerals and vitamins (2.12), and an amino acid supplement (0.06). The basal diet composition was as follows (% DM): CP 17.7, NDF 29.0, starch 30.1, sugars 3.4, water soluble fiber 5.3, silage acids 4.2, fat 3.9, and ash 6.5. The mean, SD and nutrient correlation matrix of CSG composition was used to construct an @Risk model (Palisade Corporation, NJ) to exam the influence of stochastic variation in nutrient composition of CSG on ME and MP supply. Five thousand simulations were run varying CSG composition and consequently TMR composition. The influence of CSG nutrient content variation on ME and MP allowable milk was as follows: Lignin content of CSG had the major influence on both ME and MP supply followed by NDF kd and NDF and starch. Lignin and NDF digestion should be included in forage analysis of CSG.

Key Words: corn silage, production, nutrient content

Table 1604.

Nutrient (%DM)	CSG Content			Range in Allowable Milk, kg/d (in rank)			
	Mean	Min.	Man.	ME		MP

1605 (M319) Extruded soybean meal increases feed intake and milk production in dairy cows. T. Frederick*[1], F. Giallongo[1], J. Oh[1], H. Weeks[1], A. N. Hristov[1], D. M. Kniffen[1], and R. A. Fabin[2], *[1]Dep. of Animal Science, Pennsylvania State University, University Park, [2]Fabin Bros. Farms, Indiana, PA.*

Extruded soybean meal (ESBM) has higher fat content and lower ruminal protein degradability than solvent-extracted soybean meal (SSBM), but information on its nutritive value for dairy cows is limited. A replicated 3 × 3 Latin square design trial with nine Holstein cows (*P*arity, 3.1 lactations; DIM and BW at the beginning of the trial, 161 ± 21 d and 637 ± 20.3 kg, respectively) and 28-d experimental periods was conducted to evaluate the effect of ESBM processed at two extruder temperatures, 149°C (LTM) and 171°C (HTM), on milk production and composition and blood plasma amino acid profile in dairy cows. The control diet contained 13% SSBM [53.8% crude protein (CP) with 71.4% ruminal degradability and 1.8% ether extract (EE)], which was replaced with equivalent amount (DM basis) of LTM (46.8% CP, 59.8% degradability, 10.0% EE) or HTM (46.9% CP, 41.1% degradability, 10.9% EE) ESBM in the two experimental diets (LTM and HTM, respectively). Other ingredients in the diets were (DM basis): 40% corn silage, 20% alfalfa haylage, 5% grass hay, 9% ground corn grain, 5% cottonseed hulls, 5% molasses, salt, urea (LTM and HTM diets only), and mineral-vitamin premix. The diets had 16% CP and met or exceeded the NE_L and metabolizable protein requirements of the cows (NRC, 2001). Both LTM and HTM tended to increase (P = 0.06) DMI compared with the control diet (28.3, 28.2, and 26.8 kg/d, respectively). This resulted in increased ($P < 0.001$) milk yield for both ESBM diets: 40.2 and 40.8 vs. 37.5 kg/d, respectively. Milk fat (3.38 to 3.60%) and milk true protein (2.86 to 2.95%) contents and milk fat yield were not affected by treatment. Milk protein yield tended to be increased (on average by 60 g/d; P = 0.09) by the ESBM diets. Plasma urea N and MUN were increased ($P < 0.03$) 18 and 13%, respectively, by the ESBM diets compared with the control. Blood plasma concentrations of His, Leu, and Val were increased ($P \leq 0.03$) by HTM compared with the control and LTM. Concentration of plasma Met was decreased (P = 0.05) and that of carnosine was increased (P = 0.02) by the ESBM diets compared with the control. This study demonstrated that replacement of SSBM with ESBM in the diet of lactating dairy cows increased feed intake, which resulted in increased milk yield, and increased milk protein yield.

Key Words: solvent-extracted soybean meal, extruded soybean meal, dairy cow

1606 (M320) Effect of inclusion of canola meal or wheat dried distillers grains with solubles on ruminal fermentation, omasal nutrient flow, and production performance in lactating Holstein dairy cows fed two levels of forage: concentrate. M. E. Walpole, G. E. Chibisa, and T. Mutsvangwa*, *University of Saskatchewan, Saskatoon, Canada.*

Canola meal (CM) and wheat distillers grains with solubles (W-DDGS) are high quality protein sources for lactating dairy cows, which are readily available for use in western Canada and parts of the U.S.A. When comparing the amino acid profile of CM and W-DDGS, CM generally has higher levels of lysine; however, ruminal degradability of CM is lower than that of W-DDGS. It is generally accepted that increasing ruminally-available N while increasing dietary ruminally-fermentable energy (e.g., by altering the forage:concentrate [F:C] ratio) can improve the rate of microbial protein synthesis in the rumen. Therefore, the objective of the current study was to examine the effects of differing F:C levels (45:55 vs. 55:45) when the main source of dietary protein was either CM or W-DDGS on milk production and composition, ruminal pH, and omasal nutrient flow. Eight lactating dairy cows (100 ± 58 DIM) were used in a replicated 4 × 4 Latin square design with 28-d periods (20 d adaptation + 8 d measurements) and a 2 × 2 factorial arrangement of dietary treatments. Four cows in one Latin square were ruminally-cannulated for measurements of ruminal fermentation and omasal nutrient flow. Diets were isonitrogenous (15.5% CP). Interactions between dietary source of protein x F:C ratio were not significant. Dietary treatment had no effect on DM intake ($P > 0.05$). Source of protein had no effect on milk yield and composition ($P > 0.05$); however, cows fed diets with the low F:C ratio tended to have higher milk ($P = 0.06$) and milk protein yields ($P = 0.07$), but had a lower milk fat content ($P = 0.04$) and milk urea nitrogen ($P = 0.02$) compared to those fed the high F:C ratio. Milk fat yield was unaffected by dietary F:C ratio ($P > 0.05$). Ruminal ammonia and mean pH were unaffected by dietary treatment ($P > 0.05$). Omasal DM flow was not affected by dietary treatment ($P > 0.05$). Apparent ruminal DM digestibility was numerically greater in cows fed the diet with the low F:C ratio when compared to those fed the high F:C ratio ($P = 0.11$). Total N intake, and omasal N flow were unaffected by dietary treatment ($P > 0.05$). In conclusion, both CM and W-DDGS are suitable protein sources when lactating dairy cows are fed diets varying in F:C ratio.

Key Words: canola meal, milk production, wheat dried distillers grains with solubles

1607 (M321) Analysis of dipeptidyl peptidase IV from microbial metagenomic library in the rumen of dairy cow. J. W. Zhao*[1], J. Q. Wang[2], S. G. Zhao[2], and D. P. Bu[2], [1]*College of Animal Science and Technology of Inner Mongolia University for the Nationalities, Tongliao, China,* [2]*State Key Laboratory of Animal Nutrition, Institute of Animal Science, Chinese Academy of Agricultural Sciences, Beijing, China.*

The study for sequence characteristics and enzymatic properties of dipeptidyl peptidases IV (DPP-IV), which is the key enzyme of oligopeptide degradation, will contribute to searching for it inhibit targets, reduce the dipeptide generating speed, and then decrease ammonia generation, thereby improve nitrogen efficiency. The DPP-IV gene of DP7 clone which could reduce the dipeptide activity of crude enzyme from microbial metagenomic library in the rumen of dairy cow was studied. Two primers were designed using DPP-IV gene (GenBank: JX466878) from DP7 clone, and plasmid of DP7 clone was direct sequenced. The structural feature of DPP-IV gene was analyzed by bioinformatics method and DPP-IV gene was expressed in BL21 competent cell. The DPP-IV gene expression sequence was obtained from PCR amplification of DP7 clones using sequence expression primer, and the target protein of DPP-IV was acquired by prokaryotic expression and purification. The analysis of DPP-IV gene sequence showed it had one open reading frame with 2298 bp length (756 amino acid residue) containing the characteristic catalytic domain GWSFGG found in all known DPP-IVs and the conserved region DWVYEEE. The results of BLASTP analysis showed the highest similarity of sequences derived from *Pontibacter sp* DPP-IV (46% identity), followed by *Sphingobacterium sp* (46%), *Solitalea canadensis* (46%), *Marinilabilia sp* (45%) and *Cecembia lonarensis* (45%). DPP-IV gene of DP7 had the identification of the catalytic triad (Ser-633, Asp-708 and His-740), and an inserted amino acid sequence from 422 to 445 compared with other organisms. The results demonstrated DPP-IV gene obtained from DP7 was a new sequence of DPP-IV. The molecular weight of target protein was consistent with the predicted molecular weight (78 kDa) indicating that the enzymatic properties of DPP-IV could proceed with further study.

Key Words: dipeptidyl peptidases IV, gene expression, sequence analysis

1608 (M322) Modification of the feeding behavior of dairy cows through live yeast supplementation. T. J. DeVries*[1] and E. Chevaux[2], [1]*University of Guelph, Kemptville, ON, Canada,* [2]*Lallemand Animal Nutrition, Milwaukee, WI*

The objective of this study was to determine if the feeding behavior of lactating dairy cows can be modified through live yeast supplementation. Twelve lactating Holstein dairy cows (2 primiparous and 10 multiparous) were individually

exposed to each of two treatment diets (over 35-d periods) in a replicated crossover design. Treatment diets were: 1) control TMR, and 2) control TMR plus $1x10^{10}$ cfu/head/d live yeast (*Saccharomyces cerevisiae* CNCM I-1077; Levucell SC20; Lallemand Animal Nutrition, Montreal, QC, Canada). Milk production, feeding, and rumination behavior were electronically monitored for each animal for the last 7 d of each treatment period. Milk samples were collected for the last 6 d of each period for milk component analysis. Data were analyzed in a general linear mixed model. DMI (28.3 kg/d), eating time (229.3 min/d) and rate (0.14 kg DM/min) were similar between treatments. With yeast supplementation, meal criteria were shorter (20.0 vs. 25.8 min; SE = 2.3; $P = 0.04$), translating into cows tending to have more meals (9.0 vs. 7.8 meals/d; SE = 0.6; $P = 0.07$), which tended to be smaller in size (3.4 vs. 3.8 kg/meal; SE = 0.2; $P = 0.09$). Meal length (33.9 min) was similar between treatments. Yeast supplemented cows also tended to ruminate longer (570.3 vs. 544.9 min/d; SE = 13.2; $P = 0.08$). Milk yield (45.8 kg/d) and efficiency of production (1.64 kg milk/kg DMI) were similar between treatments. There was a tendency for higher milk fat % (3.71 vs. 3.55%; SE = 0.08; $P = 0.09$) and yield (1.70 vs. 1.63 kg/d; SE = 0.04; $P = 0.1$) when cows were supplemented yeast. No differences in milk fatty acid composition were seen, with the exception of a tendency for a greater concentration of 18:2, *cis*-9, *cis*-12 fatty acid (2.71 vs. 2.48% of total FA; SE = 0.13; $P = 0.08$) when cows were yeast supplemented. Yeast supplemented cows had lower mean ruminal temperature (38.4 vs. 38.5°C; SE = 0.01; $P = 0.02$), spent less time with rumen temperature above 39.0°C (353.1 vs. 366.9 min/d; SE = 5.5; $P = 0.001$), and tended to spend less time with rumen temperature above 38.0°C (693.9 vs. 780.0 min/d; SE = 29.1; $P = 0.06$). The results suggest that live yeast supplementation had a beneficial impact on rumen fermentation as evidenced by improvements in meal patterns and rumination, milk fat production, and rumen temperature.

Key Words: live yeast, rumination, meal pattern

1609 (M323) The effect of supplementing dairy cows with a hydrolyzed yeast product (ProgutRumen) on milk production and somatic cell scores.

D. J. Gaffney*[1], M. R. Sheehy[2,3], J. A. Vuorenmaa[1], and A. G. Fahey[4], *[1]Hankkija Oy/Suomen Rehu, Hyvinkää, Finland, [2]Devenish Nutrition, Belfast, Northern Ireland, [3]School of Veterinary Medicine, University College Dublin, Ireland, [4]School of Agriculture and Food Science, University College Dublin, Ireland.*

The object of this study was to determine if supplementing Holstein-Friesian cows with hydrolyzed yeast product (ProgutRumen) had an effect on milk production and somatic cell score (SCS). Holstein-Friesian dairy cows ($n = 248$) were balanced for DIM, pre-experimental milk yield, and milk composition and assigned to either a control ($n = 127$) or hydrolyzed yeast (Progut, $n = 121$) treatment. Cows were put into two large pens and after each milking the cows were rotated into a new pen to account for environmental effects in the shed. Cows were individually fed the Control and Progut Rumen (10 g/cow/day) treatments in the milking parlor during the morning milking. Therefore, the cow was considered the experimental unit. The trial was performed over two seasons (for a 10-wk period and a 8-wk period) and on weekly intervals milk yield was recorded and milk composition (fat yield and %, protein yield and %, lactose yield and %) and somatic cell score was determined. The dataset was divided in three ways for the analysis; the entire dataset, all cows with an average daily milk yield > 24kg, and finally all cows with an average daily milk yield > 30kg. All data were analyzed in SAS with a repeated measures mixed model with the appropriate covariance structure determined by Bayesian Information Criterion. The fixed effects included treatment, season, parity (1 to ≥ 5), and week and the interactions between treatment and parity, and treatment and week with a random effect included for cow. There were no significant differences between the Control and Progut Rumen treatments for the milk composition traits. There was a significant increase in milk yield for the Progut Rumen treatment in the entire dataset ($P < 0.01$), > 24kg dataset ($P < 0.01$) and the > 30 kg dataset ($P < 0.05$). There was a significant decrease in SCS for Progut Rumen compared to the Control treatment in the entire dataset ($P < 0.01$), > 24kg dataset ($P < 0.05$) and the > 30 kg dataset ($P < 0.05$). In conclusion supplementing dairy cow diets with Progut Rumen did not alter milk composition, however it increased milk yield and decreased SCS indicating possible beneficial effects on the dairy cows' immune system.

Key Words: hydrolysed yeast, milk yield, somatic cell score

1610 (M324) Effect of live yeast vs. sodium sesquicarbonate supplementation on milk yield and milk components in dairy cows.

M. B. de Ondarza[1], E. Chevaux*[2] and A. Hall[2], *[1]Paradox Nutrition, LLC, West Chazy, NY, [2]Lallemand Animal Nutrition, Milwaukee, WI.*

The trial objective was to determine the effect of supplemental live yeast (LY) ($10x10^9$ cfu/cow/d; *Saccharomyces cerevisiae* CNCM I-1077) vs. sodium sesquicarbonate (SS) (227 g/cow/d) on milk yield, milk components, and DMI. Four pens of Holstein cows (200–230 cows/pen) in a freestall barn were paired as follows: Parity 1 and Parity 2+. Each pair was balanced pre-trial for parity, DIM, milk yield, and milk components. One pen per pair received LY and one pen per pair received SS. The study was 16 wk in length with 12 wk of diet adaptation and 4 wk of data collection. Parity 1 and Parity 2+ diets were similar except Parity 2+ contained 25% BMR corn silage and forage NDF was higher (24.26 vs. 23.45%).

Daily milk yield of individual cows was recorded. Individual milk components were assessed twice with a 2-wk interval between tests. Data was analyzed using JMP statistical software. Only cows remaining in study pens for the entire 16 wk were included (LY = 295 cows; SS = 279 cows). The statistical model for milk yield and components included treatment, DIM category, and pair as fixed effects with cow within pen as random. Pre-trial milk yield and componentswere included as covariates. Pair-wise comparisons were recalculated using JMP's contrast analysis which utilizes Student's *t* test. The statistical model for DMI used treatment and pair within treatment as fixed effects. Daily milk yield (kg/d) was unaffected by treatment. Weekly average daily milk yields around component test days tended ($P = 0.10$) to be higher for LY, especially in Parity 2+ cows (42.08 vs. 40.26 kg/d for LY and SS, respectively (SE = 0.56)) ($P = 0.01$). Percent milk fat and milk true protein were not affected ($P > 0.10$) by treatment. For all cows, yield of 3.5% FCM tended to be 1.29 kg higher with LY ($P = 0.08$) but for mature cows only, yield of 3.5% FCM was significantly higher with LY (45.66 vs. 43.56 kg/cow for LY and SS, respectively (SE = 0.63)) ($P = 0.01$). Live yeast improved ($P = 0.02$) overall milk true protein yield by 0.04 kg/d. Mature cows responded to LY with higher DMI (28.24 vs. 26.88 kg/d for LY and SS, respectively) ($P < 0.01$). Yield of milk and milk components was similar or higher with LY. Mature cows consuming a diet with more digestible forage NDF had a greater positive 3.5% FCM yield response to LY than first-lactation cows.

Key Words: live yeast, sodium sesquicarbonate, milk yield, milk components

1611 (M325) Milk production of dairy cows fed sugarcane silage based diets.
L. L. Cardoso, M. I. Marcondes*, K. G. Ribeiro, O. G. Pereira, G. F. Bayao, and M. M. D. Castro, *Universidade Federal de Viçosa, Minas Gerais, Brazil.*

This study aimed to evaluate the use sugarcane silage for Holstein high and medium producing cows. The treatments consisted of corn silage (CS) in forage: concentrate ratio 60:40, and four diets based on sugarcane in forage: concentrate ratio 40:60:fresh sugarcane (FSC), sugarcane silage control (SCC), sugar ane silage with *Lactobacillus buchneri* (SCLB), and sugarcane silage with *Lactobacillus plantarum* plus *Pediococcus pentosaceus* (SCLP). Fifteen cows were blocked for milk production (25, 30, and 35 kg/day), and were evaluated in five periods of 15 d. Animals were distributed in a randomized block design in a scheme of repeated measures. Data was analyzed according to the follow contrasts: CS vs. sugarcane diets; FSC vs. sugarcane silage diets; SSC vs. sugarcane silage with additives; SCLB vs. SCLP. DM, OM, NDF, NFC intakes did not differ between treatments ($P > 0.05$). The digestible OM intake was also not affected ($P = 0.05$). CP intake was greater ($P = 0.02$) for diets containing sugarcane silage. CS had higher DM ($P = 0.04$) and OM ($P = 0.03$) digestibility compared to diets containing sugarcane silage. It was also observed that digestibility of NDF in CS was greater ($P = 0.02$) than other diets, and SCLB promoted the lowest vules of NDF digestibility. We observed no differences ($P = 0.580$) for production of milk (25,8 kg/day), corrected milk 4% fat (23.19 kg/day), milk fat (3.34%), milk lactose (4.00%) and total solids (11.43%), whereas there was a higher crude protein content in milk ($P = 0.04$) for FSC (3.09%) and lowest level for SCLP (2.62%). Sugarcane diets contained higher levels of plasma urea nitrogen (*P*UN; 0.010), and FSC presented lower values compared to others sugarcane diets. Urea nitrogen in urine (UNU) and microbial efficiency (EFMIC) did not differ between diets ($P > 0.05$). The average daily gain (ADG) also did not differ ($P = 0.42$) between treatments (0.31 kg/day). It was concluded that diets with 60% concentrate added to sugarcane silage can allow support mean yields 25.8 kg/day of milk, similarly to other bulky sources.

Key Words: digestibility, milk, consumption

1612 (M326) Fecal sample starch content deteriorates over time after sampling.
K. Haerr*[1,2], J. P. Goeser[2,3], and C. R. Heuer[2,3], *[1]University of Illinois, Urbana, [2]Rock River Laboratory, Inc, Watertown, WI, [3]Dep. of Dairy Science, University of Wisconsin–Madison, Madison.*

Dairy and beef cattle fecal samples are typically taken from commercial dairies and feedlots to assess starch utilization. Greater fecal starch content is related to lesser ruminal and total tract starch degradation and animal performance. Fecal sample starch concentration may change during time in transit to analysis laboratory, which in some cases can be 5 d or more. Dairy cattle fecal samples (at least 10 250-g subsamples) were collected from manure piles at each of two commercial dairies in Wisconsin in July 2013. Subsamples were thoroughly mixed, immediately split on farm into air-tight plastic containers (250 g), and stored for 0 (control), 1, 2, or 5d. Samples stored for 1, 2, or 5d were also held at approximately 2°C (cold), 22°C (room), or ambient (variable, daily high 27°C) temperatures. The 0-h sample was processed on the same day samples were gathered. These combinations were organized in a factorial arrangement and chosen to simulate sample environment during shipping to analysis lab. Samples were oven dried (50°C for 48 h) and ground to 1 mm following treatment. Starch content (% of DM) was measured in each sample and total tract starch digestibility (% of starch, TTSD) was calculated using the Ferraretto and Shaver 2012 equation: 100 X (0.9997- 0.0125 × fecal starch). Data were analyzed with multiple linear regression using SAS JMPv10 and model effects chosen using forward selection. Temperature and time were entered as fixed effects and farm was random. Temperature ($P < 0.05$) and time ($P < 0.01$) were significantly related to fecal starch content and predicted TTSD. Fecal starch content

averaged 4.3, 5.4, 4.3, and 4.1% for control, cold, room, and ambient temperature exposures, respectively. The numerically greater starch content at cold-storage temp relative to control was unexplained, and warrants further evaluation. Fecal starch content raw data averaged 5.4 and 3.7% at 0 and 5d, respectively. Predicted TTSD data averaged 93.3 and 95.4% at 0 and 5 d, respectively. Model parameter slope estimates were -0.017 and 0.02 per h for fecal starch and TTSD, respectively. Results warrant further evaluation, but suggest fecal starch content and animal digestion estimates will change during extended time in transit. The amount of time between sampling and starch analysis should be considered and minimized.

Key Words: fecal, starch, digestion

1613 (M327) Effects of pH and incubation duration on the stability of the endoglucanase activity of seventeen exogenous fibrolytic enzyme preparations. A. F. Campos[1], B. Y. Coy[2], K. G. Arriola[*2], and A. T. Adesogan[2], *[1]São Paulo State University, Dep. of Animal Science, Brazil, [2]University of Florida, Dep. of Animal Sciences, Gainesville.*

This study examined effects of pH and incubation duration on the stability of the endoglucanase activity of various exogenous fibrolytic enzymes (EFE). Seventeen commercial EFE sourced from *Trichoderma reesei* or and *Aspergillus spp.* were assayed in triplicate for endoglucanase (EN) activity at pH 4.0, 5.0 and 6.0 after incubation for 0, 24, 48, and 168 h at 40°C. Endoglucanase activity was assayed in a 15-mL tube containing 1.0 mL of 1.0% (wt/vol) carboxymethyl cellulose as substrate and 0.9 mL of citrate-phosphate buffer (pH 4.0, 5.0 or 6.0). For the 0-h incubation, after a 10-min preincubation period, 0.1 mL of diluted EFE was added to cellulose to initiate the reaction and the suspension was incubated for 5 min. The reaction was terminated with 3 mL of dinitrosalicylic acid. For the other incubation periods, tubes were kept in a water bath at 40°C degrees for the respective durations. The unit of EN activity was the amount of EFE required to release 1 µmol of reducing glucose equivalents min^{-1} mg^{-1}. Treatments were arranged in a 17 (enzymes) × 3 (*P*H) × 4 (incubation duration) factorial layout and data were analyzed with a model including these terms and the interactions using the GLM procedure of SAS. Endoglucanase activity was greatest ($P < 0.0001$) for all EFE at pH 4.0 after 0 h of incubation except for one EFE, which exhibited the greatest activity at pH 6.0 after 0 h of incubation. For 13 of the 17 EFE, increasing the incubation duration or the pH quadratically ($P < 0.0001$) decreased EN activity. However, simultaneously increasing the pH and incubation duration linearly ($P < 0.0001$) decreased EN activity. Within 24 h of incubation, between 97.9 and 99.6% of the EN activity was lost from each EFE. Therefore, EN activity decreased substantially as the incubation duration increased. This study shows that the EN activities of the EFE decreased with increasing pH and or incubation time. Endoglucanase activities were much lower at the usual ruminal pH of lacting dairy cows than at those (pH 4 to 5) typically used to assay EFE activities in the laboratory.

Key Words: endoglucanase, exogenous enzyme, incubation duration, pH

1614 (M328) Evaluation of a source of α-amylase and a protease in the diet of lambs on nutrient intake and digestibility and blood parameters. *B*. Quintana[*1], L. C. Solorzano[2], and A. A. Rodriguez[1], *[1]University of Puerto Rico, Mayaguez, [2]DSM Nutritional Products, Parsippany, NJ.*

The effects of a commercial source of α-amylase and an experimental protease or their combination on nutrient intake and digestibility and blood parameters were determined in lambs fed 21% dietary starch. Twelve crossbred lambs (14.2 kg) were assigned to one of four diets; no additive (control) or diets containing α-amylase (RONOZYME RumiStar), an experimental protease, or their combination. Diets were offered daily at 4% of animal BW/DMB in four 28-d experimental periods consisting of 21 d of adaptation to the diet followed by 7 d of complete fecal collection. In each period, feed offered, orts, and feces were collected, quantified, and analyzed for DM, starch, CP, and NDF contents to determine intake and digestibility. Disease incidence was observed and recorded during the experiment. Blood samples were collected from each lamb at the end of each experimental period to determine glucose, BHB, NEFA, and insulin concentrations. Data were analyzed according to a 4 × 4 Latin Square experimental design. Treatments contrasts were performed using least squares means adjustment for multiple comparisons (Tukey-Kramer) between diets as follows: containing enzymes versus no enzymes, amylases versus no amylases, proteases versus no proteases, and amylases versus proteases. Adding proteases to the diet decreased ($P < 0.05$) starch consumption as compared to that of lambs fed without the experimental enzyme (248.5 vs. 255 g/d). Starch digestibility also tended ($P < 0.10$) to be higher in lambs fed with the protease than with α-amylase (98.9 vs. 98.5%). Adding enzymes to the diet tended ($P < 0.10$) to decrease BHB concentration (4.26 vs. 4.68 mg/dL). NEFA concentration tended to decrease ($P < 0.10$) for lambs fed α-amylase as compared to lambs fed diets without α-amylase (0.128 vs. 0.156 mEq/L). Insulin levels were lowered ($P < 0.05$) by addition of α-amylase in lambs diets as compared to those of animals fed with protease (73.3 vs. 80.3 pmol/L). Insulin level also tended ($P < .10$) to increase in lambs fed the experimental protease as compared to lambs fed the enzyme (80.3 vs. 78.7 pmol/L). In summary, adding the experimental proteases to lambs diets containing 21% dietary starch decrease starch consumption and tended to increase starch digestibility. Both exogenous enzymes influenced blood metabolites; however, a greater effect was observed in lambs fed with the experimental protease.

Key Words: enzymes, α-amylase, protease

1615 (M329) Evaluation of a source of α-amylase and a protease in the diet of lambs on nutrient intake and digestibility and blood parameters. B. Quintana*[1], L. C. Solorzano[2], and A. A. Rodriguez[1], *[1]University of Puerto Rico, Mayaguez, [2]DSM Nutritional Products, Parsippany, NJ.*

The effects of a commercial source of α-amylase, an experimental protease or their combination on nutrient intake and digestibility and blood parameters were determined in lambs fed a basal diet of 34% ground corn, 40% tropical grass hay, and 26% soybean meal providing 21% dietary starch. Twelve crossbred lambs (14.2 kg) were assigned to one of four diets: no additive or diets containing α-amylase (RONOZYMERumiStar), an experimental protease, or their combination. Diets (DM basis) were offered daily at 4% of animal BW in four 28-d experimental periods consisting of 21 d of adaptation to the diet followed by 7 d of complete fecal collection. In each period, feed offered, orts, and feces were collected, quantified, and analyzed for DM, starch, CP, and NDF contents to determine intake and digestibility. Disease incidence was observed and recorded during the experiment. Blood samples were collected from each lamb at the end of each experimental period to determine glucose, BHB, NEFA, and insulin concentrations. Data were analyzed according to a 4 × 4 Latin Square experimental design. Treatments contrasts were performed using least squares means adjustment for multiple comparisons (Tukey-Kramer) between diets as follows: enzymes versus no enzymes, amylase versus no amylase, protease versus no protease, and amylase versus protease. DM intake was similar across treatments (1106.1, 1087.5, 1104.8 and 1088.5 g/d for control, and diets containing α-amylase, experimental protease or their combination, respectively). Adding protease to the diet decreased ($P < 0.05$) starch consumption as compared to that of lambs fed without the experimental enzyme (248.5 vs. 255 g/d). Starch digestibility tended ($P < 0.10$) to be higher in lambs fed the protease than α-amylase (98.9% vs. 98.5%). Adding enzymes to the diet tended ($P < 0.10$) to decrease BHB concentration (4.26 vs. 4.68 mg/dL). NEFA concentration tended to decrease ($P < 0.10$) for lambs fed α-amylase compared to lambs fed diets without α-amylase (0.128 vs. 0.156 mEq/L). Insulin levels were lowered ($P < 0.05$) by addition of α-amylase in lambs diets as compared to those of animals fed with protease (73.3 vs. 80.3 pmol/L). Insulin level also tended ($P < .10$) to increase in lambs fed the experimental protease as compared to lambs fed the enzyme (80.3 vs. 78.7 pmol/L). In summary, adding the experimental protease to lambs diets containing 21% dietary starch decreased starch consumption and tended to increase starch digestibility. Both exogenous enzymes influenced blood metabolites, however a greater effect was observed in lambs fed the experimental protease.

Key Words: enzymes, amylase, protease

1616 (M330) Utilization of industrial enzymes in the evaluation of neutral detergent insoluble fiber content in high-starch samples. C. Batista Sampaio*[1], D. I. Gomes[2], E. Detmann[3], S. de Campos Valadares Filho[1], H. Valentim Nunes Machado[4], and M. de Oliveira Franco[1], *[1]Universidade Federal de Viçosa, Dep. of Animal Science, Minas Gerais, Brazil, [2]Universidade Federal do Pará, Parauapebas, Pará, Brazil, [3]Universidade Federal de Viçosa, Minas Gerais, Brazil, [4]Universidade Federal de São João Del Rei, Minas Gerais, Brazil.*

The method of analysis of fibrous components called "detergent system" was initially developed to evaluate forage and subsequently extended to other types of feeds. However, its application to analizing non-fibrous feeds is associated with some analytical problems, noticiably with high starch feeds. The use of a α-amylase is recomemended by AOAC International as a standard procedure to promote solubilization of the starch in feeds samples to obtain insoluble fiber with accuracy. Diferent amylases are available for industrial activities, which have, in general, certificated quality and activity. However, the type and amount of industrial enzymes that could potentially be used in evaluating the insoluble fiber have not established. It were performed two experiments to evaluate the utilization of industrial enzymes in the evaluation of neutral detergent fiber (NDF) contents in high-starch materials. In the first experiment, it was verified the accuracy of estimates of NDF obtained with the utilization of three industrial enzymes (Termamyl 2X, Liquozyme Supra 2.2.X, and Amylase AG 300L-Novozymes) at different volumes (50, 100, 250 or 500 μL/sample). Samples were simulated to contain starch at 0, 100, 300, 500, and 1000 g/kg using purified cellulose and starch ($n = 240$). Estimates of the bias of NDF contents were evaluated by analysis of variance, acording in a completely randomized design in a 3 × 4 × 5 (three types and four volumes of enzymes and five concentrations of starch). In the second experiment, samples of corn grain and sorghum grain were evaluated considering the same enzyme types and volumes used in the first experimente, also incluiding aliquots without using enzyme addition ($n = 104$). There was no significant bias of NDF recovery for simulated samples containing starch up to 300 g/kg ($P > 0.01$). Considering those samples, none difference among enzymes was observed ($P > 0.01$). The results obtained from the evaluation of corn and sorghum suggest the use of 250 μL volume and enzyme necessary for the extraction of starch. Therefore, it can be recommended the utilization of 250 μL the α-amylases evaluated.

Key Words: α-amilase; feed analysis; fiber

1617 (M331) In situ degradation and fermentation of a diet with an exogenous phytase for lambs.

L. H. Vallejo-Hernandez*[1], G. Buendia-Rodriguez[2], J. E. Ramirez-Bribiesca[3], L. A. Miranda-Romero[4], M. M. Crosby-Galvan[3], and S. S. Gonzalez[5], *[1]Universidad Autonoma del Estado de México, Toluca, [2]CENIDFyMA INIFAP, Queretaro, México, [3]Colegio de Postgraduados, Montecillo, México, [4]Universidad Autonoma de Chapingo, México, [5]Colegio de Postgraduados, Montecillo Estado de México.*

Close to 70% of phosphorus (*P*) from cereal grains and oleaginous seeds is linked to phytic acid as phytate, which is little utilized or not at all by non-ruminants. Diets containing more than 50% of the P as phytate will decrease hydrolysis of the phytate by rumen microorganisms. Therefore, the objective of this in situ trial was to evaluate the effect of an exogenous phytase added to a diet for lambs. Treatments were: 0, 540, and 720 g of phytase Ronozyme-HiPhos (DMS Nutritional Products, 5000 FTU/g) added to a 70% sorghum grain diet and fed to six Criollo lambs (40 ± 2 kg live BW) with ruminal and duodenal cannulas, and housed on individual metabolic cages during 45 d (plus 15 d for adaptation). The experimental design was a 3 × 3 Latin square repeated on time, data were analyzed using GLM procedure (SAS v. 9.2) and treatment means were compared with the Tukey test ($P \leq 0.05$). Variables were dry matter intake (DMI), pH and VFA concentration in ruminal fluid, NH_3–N and P concentration in ruminal and duodenal fluid, fecal and urine P, and plasma P; samplings were performed at 3, 6, 9, 12, 24, 48, and 72 h. Phytate of the diet was 67.74% of the total P. For 0, 540, and 720 g phytase, differences ($P \leq 0.05$) were found only for DMI (1053.32ab, 988.70b, 1141.32a g/day) and fecal P (2.32a, 2.01ab, 1.85b % P/g DM). Thus, it may be concluded that this exogenous phytase did not change pH, VFA, P in ruminal fluid, P in urine or plasma. But since fecal P excretion was reduced, soil contamination could be decreased.

Key Words: phytase, P excretion, lamb.

1618 (M332) Sources of sulfur in protein supplements and fiber degradability.

F. P. Leonel*[1], C. J. Silva[2], L. M. Moreira[1], J. C. Pereira[3], J. M. Carvalho[1], J. C. Carvalho[3], R. A. Vieira[4], and M. M. Assis[1], *[1]Federal University of São João del Rei (UFSJBrazil, [2]National University of Brasília, Brazil, [3]Federal University of Viçosa, Brazil, [4]Norte Fluminense State University, Campos dos Goytacazes, Brazil.*

The present work is focused on the evaluation of different sulfur sources in protein supplements for cattle. Crossbred steers were fed with *Brachiaria dictyoneura* hay, with different sulfur sources in the protein supplement: 70S elementary sulfur (ES70S); 98S elementary sulfur (ES98S); hydrated calcium sulfate (HCS); anhydrous calcium sulfate (ACS) and ammonium sulfate (AS). The nutritional effects observed to the steers in relation to the different sulfur sources were evaluated by means of different aspects, such as nutrient intake, apparent digestibility, fiber degradability and particle flow-rate. An 11:1 nitrogen:sulfur ratio was employed, being that five steers fistulated in the rumen and abomasum were utilized through distribution in a 5 × 5 Latin square. The different sulfur sources in the supplement did not affect ($P > 0.05$) the intakes of dry matter of hay; crude protein (CP); neutral detergent fiber corrected for ash and protein (NDFap); organic matter (OM); nonfiber carbohydrate (NFC); ether extract (EE); and total digestible nutrients (TDN). The respective sulfur sources do not generated significant alterations ($P > 0.05$) regarding the digestibility coefficients of NDFap and CP.

In this study, NDF degradation profiles were encountered in agreement with the solid transit kinetics parameters model and estimations. The data were adjusted to different double-compartment models (G1G1, G2G1, G3G1, G4G1, G5G1 and G6G1). The models G2G1, G3G1, G5G1, G4G1 and G3G1 were more efficient in accordance with the estimations of the following treatments: G2G1 to 70S elementary sulfur; G3G1 to 98S elementary sulfur; G5G1 to calcium sulfate (hydrated gypsum); G4G1 to calcium sulfate (anhydrous gypsum) and G3G1 to ammonium sulfate. It was possible to infer that the sulfur sources employed in the present work influenced slightly the ruminal fiber degradation.

Key Words: degradability, fiber, intake, nitrogen sulfur ration

Table 1618. Medium values and coefficients of variation (CV) for daily intake of dry matter (DM), crude protein (CP), neutral detergent fiber corrected for ash and protein (NDFap), organic matter (OM), total digestible nutrients (TDN), as function of sulfur sources in the protein supplements

1619 (M333) Effect of weight gain rates in the post-weaning phase and forage allowance in the finishing phase with high supplementation on performance of Nellore cattle. *V*. A. C. Mota[1], G. F. Berti[2], J. A. Alves Neto[3], R. M. Fernandes[4], P. H. Gonçalves[2], B. C. Carvalho[2], M. A. P. Alves[2], I. M. de Oliveira*[5], F. D. D. Resende[5], and G. R. Siqueira[5], *[1]UNESP/FCAV, Jaboticabal, Brazil, [2]Centro Universitário da Fundação Educacional de Barretos–Unifeb, Barretos, Brazil, [3]Universidade Estadual Paulista, Jaboticabal, Brazil, [4]UNESP-FCAV, Jaboticabal, Brazil, [5]APTA–Agência Paulista de Tecnologia dos Agronegócios, Colina, Brazil.*

The study analyzed the effect of forage allowance in the finishing phase of beef cattle fed high levels of supplementation and its interaction with the rate of weight gain in the post-weaning phase. Sixty four non-castrated Nellore cattle with an average body weight (BW) of 386.0 kg, were distributed into 16 paddocks (experimental units) of *Brachiaria brizantha* cv. Marandu and fed 2% of their BW in supplement containing 34% of corn, 51% of citrus pulp pellets and 15% of mineral mix. Treatments consisted of animals managed during the post-weaning phase on 15- or 35-cm-tall pastures receiving mineral mix 50 g/100 Kg BW and sub-divided into lots with low and high forage allowance in the finishing phase. In the post-weaning phase, the pasture height provided different ADG (0.761 kg d^{-1} for the 15 cm and 1.076 kg d^{-1} 35 cm pasture), and different forage allowances were obtained in the finishing phase, with the same stocking rate in the paddocks, with different initial masses (3.370 and 8.470 kg DM ha^{-1}) provided by the management of 15- and 35-cm-tall pastures during the post-weaning phase, respectively. The experimental period was 120 d, in a completely randomized blocks design in a 2 × 2 factorial arrangement, in which data were analyzed by using a mixed model through the PROC MIXED of SAS (SAS 9.2), significance at $P < 0.10$ by the *t* test. The animals that had the lowest weight gain and were in the treatment with the highest forage allowance in finishing had the greatest ADG (1.123 kg d^{-1}; $P = 0.02$), and the other nutritional strategies did not differ from each other ($P > 0.10$), averaging 0.929; 0.901 (biggest gain in post-weaning and low and high bid on finishing respectively) and 0.920 kg d^{-1} (lower gain in post-weaning and finishing in low supply). The supplement intake was affected by the post-weaning treatment ($P = 0.01$) and no effect of forage allowance in the finishing was observed ($P = 0.74$). Animals kept on 35-cm pastures in the post-weaning started the finishing heavier consumed more supplement (7.8 kg d^{-1}) than those reared on 15-cm pastures (7.3 kg d^{-1}). In relation the quantity of concentrate to gain 1 kg of BW, the animals on the lowest forage allowance level in the finishing showed an upward trend ($P = 0.15$; 7.7 vs. 8.9 kg supplement kg BW). *Supported by CAPES/UNESP/CONNAN.*

Key Words: gain, consumed, Marandu

1620 (M334) Nutritional evaluation of forage Kochia (*Kochia prostrata*) as an alternative forage for beef cattle using a dual-flow continuous culture system. E. Marostegan de Paula*, L. Galoro da Silva, T. Shenkoru, Y. L. Yeh, J. Bunkers, and A. Faciola, *University of Nevada.*

Forage Kochia (FK; *Kochia prostrata*) has the potential to be used as forage for beef cattle due to its high nutritional value and ability to grow well on soils with low moisture content. The objective of this experiment was to determine the nutritional value and rumen fermentation characteristics of FK as compared to alfalfa hay (AH) and orchardgrass hay (OH). Diets were randomly assigned to six dual-flow continuous culture fermenters (1200 to 1250 mL) in a replicated 3 × 3 Latin square arrangement with three 10-d experimental periods consisted of 7 d for diet adaptation and 3 d for sample collection. Fermenters were fed a total of 72 g of DM/d equally divided in 12 portions of one of three diets: 1) 100% AH, 2) 100% OH, and 3) 100% FK. Liquid and solid dilution rates were adjusted daily to 10%/h and 5%/h, respectively. A sample of 500mL from each fermenter was taken on d 8, 9, and 10. Two subsamples of 10ml were filtered through two layers of cheesecloth, and were preserved with 0.2 mL of 50% sulfuric acid and were centrifuged for subsequent ruminal NH_3–N and VFA analysis. Statistical analyses were performed using the GLM procedure in SAS. There were no differences ($P > 0.05$) among treatments for total VFA, molar proportion of acetate, propionate, butyrate, and branched-chain VFA (Table 1620). However, there were differences ($P < 0.05$) for NH_3–N. Ruminal NH_3–N observed was greater for FK compared with AH and OH, indicating a greater N availability for microbial growth; nevertheless, there were no significant differences between AH and OH. Results from this experiment indicated that FK may be a viable alternative for beef cattle producers. This is especially important for areas in which conventional forages may not grow well such as the U.S. Great Basin area.

1621 (M335) Effect of using either barley straw or alfalfa hay on intake and digestibility in growing Simmental heifers fed high-concentrate diets.

A. Madruga*[1], E. Mainau[1], J. L. Ruiz[1], X. Manteca[1], M. Rodríguez[1], L. A. González[2], and A. Ferret[1], *[1]Animal Nutrition and Welfare Service, Dep. of Animal and Food Sciences, Universitat Autònoma de Barcelona, Bellaterra, Spain, [2]Centre for Carbon, Water and Food, Dep. of Plant and Food Sciences, Faculty of Agriculture and Environment, University of Sydney, Camden, Australia.*

The objective of this experiment was to compare the effects of using two different forage sources on intake and digestibility in growing heifers fed high-concentrate diets. Eight Simmental heifers (141 ± 15.5 d old and with an average initial BW of 147.4 ± 10.8 kg) were used in a crossover design experiment. Treatments tested were: a) total mixed ration with barley straw as forage source (BS), and b) total mixed ration with alfalfa hay as forage source (AH). Forages were coarsely chopped before their incorporation to total mixed ration. Diets were offered on an ad libitum basis, with a forage to concentrate ratio of 8:92, and formulated to be isocaloric (2.91 Mcal ME/kg DM) and isonitrogenous (15% CP on DM basis). The experiment was performed in two 28-d periods, and sampling was performed in the last week of each period. Heifers were weighed before feeding on two consecutive d at the beginning and at the end of the experiment, and the first and last d of the sampling week. Feed offered and refusal samples of each heifer were collected daily for 7 d in the sampling week for DM determination and chemical analysis. Dry matter digestibility was estimated using acid-insoluble ash as an internal marker. Fecal samples were collected from the rectum at d 6 and 7 of each sampling period. Differences were analyzed by using the PROC MIXED of SAS. The model contained the fixed effects of treatment, period and their interaction, and the random effect of heifer nested within sequence. Intake of DM, CP and NDF was unaffected by treatment, being on average 6.4, 0.8 and 1.6 kg/d, respectively. Average daily gain of heifers fed BS tended to be greater than that of heifers fed AH (1.7 and 1.5, respectively; $P = 0.10$). Gain to feed ratio tended ($P = 0.07$) to be greater in heifers fed BS than AH (0.29 and 0.27, respectively). Dry matter digestibility and intake of digestible DM was unaffected by treatment, being on average 63.5% and 4.1 kg/d, respectively. In conclusion, at 8% of incorporation, barley straw tended to result in a better performance than alfalfa hay when these forage sources were offered as total mixed ration to growing beef heifers.

Key Words: beef cattle, forage source, high concentrate diet

1622 (M336) Metabolism of nitrogenous compounds in beef cattle fed tropical forage supplemented with protein in the rumen, abomasum or both.

E. D. Batista*[1], E. Detmann[1], D. I. Gomes[2], L. M. A. Rufino[1], A. R. Lopes[1], S. C. Valadares Filho[1], M. F. Paulino[1], and E. C. Titgemeyer[3], *[1]Universidade Federal Viçosa, Minas Gerais, Brazil, [2]Universidade Federal Rural da Amazônia, Parauapebas, Pará, Brazil, [3]Kansas State University, Manhattan.*

Four Nellore steers, averaging 280 ± 10 kg BW, fitted with ruminal and abomasal cannulas were used in a 4 × 4 balanced Latin square design to evaluate the effect of protein supplementation in the rumen and/or abomasum on N metabolism in cattle fed tropical forage. The treatments were: 1) control (without supplementation); 2) ruminal supplementation (250 g/d casein); 3) ruminal plus abomasal supplementation (125 g/d casein in the rumen and 125 g/d in the abomasum); and 4) abomasal supplementation (250 g/d casein). Supplements and hay were provided twice per day at 0600 h and 1800 h. The animals were fed with Tifton-85 hay (9.9% CP; 71.5% NDFap) for ad libitum intake. Each period lasted 20 d, comprising 15 d of adaptation and 6 d for sampling. On d 16 through 19 of each period, eight spot samples of abomasal digesta and feces were collected, oven-dried, composited and subsequently analyzed. On d 20 total urine collection was performed. On d 21 blood samples and ruminal fluid were taken every 6 h (beginning at 0600 h) and composited on a daily basis. Supplementation increased ($P < 0.10$) N intake, N total digestibility, N balance, ruminal ammonia-N (RAN), serum urea-N (SUN), renal urea clearance (RUC), RUC proportion excreted, and urinary N and urea excretion. However, there were no differences ($P > 0.10$) between sites of supplementation, except for RAN, SUN, RUC, and urinary N and urea excretion which presented a negative linear effect ($P < 0.10$) by the displacement of supplementation rumen to the abomasum. Ruminal N digestibility, microbial N flow, as well as N retained/N intake were not affected by supplementation ($P > 0.10$). Intestinal N digestibility was increased ($P < 0.10$) by supplementation. Moreover, there was a positive linear effect ($P < 0.10$) on N intestinal digestibility when supplement was changed from the rumen to the abomasum. Fecal N excretion was not affected ($P > 0.10$) by treatments. These results indicate that protein supplementation either in the rumen or in the abomasum, exerts similar effects on efficiency of N utilization, but with different metabolic events.

Key Words: beef cattle, metabolism, nitrogen

1623 (M337) Effect of Amaferm on digestion of diets containing forages with high or low neutral detergent fiber digestibility. A. B. Chestnut*, J. M. Aldrich, W. Hu, W. B. Fokkink, and H. G. Bateman, *Provimi North America, Brookville, OH.*

Amaferm (AF), an extract obtained from fermenting *Aspergillus oryzae*, has been reported to stimulate fiber degrading ruminal fungi and bacteria. The objective of this study was to measure effects of AF on fermentation of typical lactation dairy cow rations containing forages with high NDF digestibility (NDFd) or low NDFd. Corn silage (CS) and alfalfa haylage (AH) with 30 h NDFd of 66.4 and 41.4% of NDF, respectively, were used as the only forages to formulate a high NDFd ration (HFd). A CS and AH with 30-h NDFd of 51.2 and 34.3% of NDF, respectively, were used as the only forages to formulate a low NDFd ration (LFd). Diets were formulated to contain (DM basis) 16.0% NDF from CS and 8.0% NDF from AH. Corn, soybean meal, urea, blood meal, Megalac and molasses were adjusted to equalize CP, soluble CP, starch, nonfiber carbohydrates and fat between diets. A completely randomized experimental design was used with a 2 × 2 factorial arrangement of diet forage NDFd (high or low) and level of AF (0.0 or 0.06% of DM). Diets were fermented in triplicate in continuous culture fermentors at the Rumen Fermentation Profiling Laboratory, West Virginia University, Morgantown, WV. Data on pH were reduced to daily means for each fermentor. Fermentation data were analyzed using the PROC MIXED of SAS with a repeated-measures model. Fermentor was treated as a random variable. First-order autoregressive structure type was selected as the appropriate covariance structure based on the goodness-of-fit criteria. Digestibility (%) of DM, NDF, and nonstructural carbohydrates (NSC) were, respectively, 67.8, 41.4, and 79.3 for HFd, 66.2, 34.8, and 77.5 for HFd + AF, 62.9, 34.9, and 79.3 for LFd and 65.8, 39.6, and 79.5 for LFd + AF. DM digestibility tended to be more for high NDFd vs. low NDFd treatments ($P = 0.08$). Digestibility of NSC was similar among treatments. Adding AF improved NDF digestion of LFd but reduced NDF digestion of HFd (forage NDFd x AF interaction; $P < 0.01$). Average fermentor pH for HFd, HFd + AF, LFd and LFd + AF were 6.03, 6.08, 6.31 and 6.24, respectively, with a main effect due to forage NDFd observed ($P < 0.01$). Adding AF improved NDF digestion of the LFd diet but not the HFd diet. The difference in response of HFd and LFd diets to AF may be related to differences in fermentor pH.

Key Words: Amaferm, NDF digestion

1624 (M338) Differences in forage utilization between *Bos taurus* and *Bos indicus* steers fed low-quality forage and supplemented soybean meal. M. de Oliveira Franco*[1,2], J. E. Sawyer[3], J. R. Baber[4], N. L. Bell[4], E. Detmann[5], and T. A. Wickersham[4], *[1]Universidade Federal de Viçosa, Dep. of Animal Science, Minas Gerais, Brazil, [2]sponsored by CAPES, Brasília, Brazil, [3]Texas AgriLife Research, College Station, [4]Texas A&M University, College Station, [5]Universidade Federal de Viçosa, Minas Gerais, Brazil.*

Five *Bos taurus* (Angus) and five *Bos indicus* steers (Brahman) fitted with ruminal and duodenal cannulae were used in concurrent 5 × 5 Latin squares to determine effects of protein supplementation with varying levels of low quality forage access. Treatments consisted of a control (CON; no supplement and ad libitum access to hay; 2.8% CP, 83.0% NDF) and four treatments arranged as a 2 × 2 factorial: two levels of hay intake (ad libitum and restricted, 1% of initial BW) and two levels of protein (50 and 100 mg N/kg BW, provided as soybean meal 48.5% CP). Periods were 14 d long, with 7 d adaptation and 7 d of sample collection. Data were analyzed using the PROC MIXED of SAS. Terms in the model included treatment, breed, period and treatment × breed, with steer as a random effect. The repeated statement was used for fermentation responses. There were no significant breed differences or treatment × breed interactions for hay intake, digestion, or ruminal fermentation ($P > 0.05$). Supplementation linearly increased ($P < 0.01$) hay intake, total OM intake, and total digestible OM intake in steers given ad libitum access to hay. Feeding 50 or 100 mg N/kg increased total digestible OM intake 34 and 54%, respectively versus CON. Ruminal N balance decreased linearly ($P < 0.01$) in ad libitum fed steers from 36.6 g/d for CON to -30.1 g/d for 100 mg N/kg, suggesting a net influx of urea into the rumen for CON and net absorption of ammonia from the rumen for 100 mg N/kg. When supplement was provided at 50 mg N/kg steers with ad libitum access to hay had greater ($P < 0.01$) ruminal N balance (11.2 g/d) than restricted steers (-3.6 g/d); however, there was only a tendency ($P = 0.09$) for a difference between ad libitum and restricted steers supplemented 100 mg N/kg. Ruminal ammonia N increased linearly ($P < 0.01$) with increasing protein supplementation and was greater ($P < 0.01$) when hay intake was restricted for both levels of N supplement. Similarly, total VFA concentrations were linearly increased ($P < 0.01$) with increasing supplementation; however, VFA concentrations were lower ($P = 0.03$) for both levels of supplementation when hay intake was restricted rather than ad libitum. These data suggest that the forage utilization response to supplemental protein was similar among the subspecies of cattle.

Key Words: low quality forage, protein, supplementation

1625 (M339) Impact of supplementation during the dry season on performance of young Nellore bulls in the post-weaning phase on pasture in the wet season. I. M. de Oliveira*[1], M. H. Moretti[2], A. D. Moreira[3], J. A. Alves Neto[3], R. M. Fernandes[2], P. H. Gonçalves[4], M. A. P. Alves[4], G. F. Berti[4], G. R. Siqueira[1], and F. D. D. Resende[1], *[1]APTA–Agência Paulista de Tecnologia dos Agronegócios, Colina, Brazil, [2]UNESP-FCAV, Jaboticabal, Brazil, [3]Universidade Estadual Paulista, Jaboticabal, Brazil, [4]Centro Universitário da Fundação Educacional de Barretos, Brazil.*

This study evaluated the impact of nutritional strategies on the performance of young Nellore bulls during the post-weaning phase. The experimental period was divided into dry (July to November 2012) and wet (November 2012 to May 2013) seasons. The design was completely randomized, using 60 young Nellore bulls which were distributed into 12 paddocks (experimental units) formed by *Brachiaria brizantha* pastures (5 animals/lot; 6 lots/treatment). In the summer, the paddocks were subdivided (three from each dry season treatment in each new wet season treatment). In the dry season, the animals were assigned to two treatments: a) protein supplement (1 g/kg of body weight; BW) and b) protein and energy supplement (5 g/kg of BW); in the summer were assigned to two treatments: a) mineral supplement ad libitum and b) protein and energy supplement (5 g/kg of BW). To determine the average daily gain (ADG), the animals were weighed at time zero (onset of the experiment) and subsequently every 28 d after being deprived of feed and liquids for 16 h. The data were analyzed as repeated measures over time using the PROC PROC MIXED of SAS. In the dry season, the protein and energy supplementation provided greater ADG (0.434 kg) as compared with the protein supplement (0.293 kg), resulting in heavier animals at the end of this season (225.38 and 208.87 kg, respectively; $P = 0.093$). In the summer, animals fed the protein and energy supplement gained more weight (0.972 kg/day; $P < 0.0001$) in relation to those fed mineral salt (0.623 kg/day). Although no interaction was found in ADG ($P = 0.4798$) between the nutritional plants of dry and wet seasons, the animals which received protein and energy supplementation in the dry season gained less weight (0.766 kg/day; $P < 0.001$) in comparison with those supplemented with protein (0.830 kg/day); this made it possible, at the end of the summer, to eliminate the difference in BW obtained during the dry season. At the end of the post-weaning phase, the young bulls fed protein and energy supplement in the summer completed the period heavier as compared with those fed mineral salt (286.75 and 261.76 kg, respectively; $P = 0.0045$). Protein and energy supplementation during the dry season had negative impact on the ADG in the summer, and increased the BW of the animals at the end of the dry and wet season by 7 and 9%, respectively.

Key Words: energy, performance, protein

1626 (M340) Use of modulators additives the ruminal fermentation in supplements high intake for finished bovines in pasture. J. A. Alves Neto[1], J. M. B. Benatti[1], M. H. Moretti[1], A. D. Moreira[1], R. C. Silva[1], I. M. de Oliveira*[2], P. H. Gonçalves[3], M. A. P. Alves[3], F. D. D. Resende[2], and G. R. Siqueira[2], *[1]Universidade Estadual Paulista, Jaboticabal, Brazil, [2]Agência Paulista de Tecnologia dos Agronegócios, Colina, Brazil, [3]Centro Universitário da Fundação Educacional de Barretos, Brazil.*

Performance of young grazing cattle has been improved by energy supplementation. Additionally, several antibiotics (monensin, lasalocid) have resulted in a consistent grown response. On the other hand, data concerning the effect of virginiamycin in grazing cattle are scarce. Therefore, 96 Nellore bull (480 ± 28 kg BW) were divided in five treatments with different level of supplement and additives blend (T1 = 0.5% BW, T2 = 2% BW, T3 = 2% BW + virginiamycin (25 ppm), T4 = 2% BW + virginiamycin (25 ppm) + monensin (20 ppm), T5 = 2% BW + virginiamycin (25 ppm) + salinomycin (10 ppm). Continue grazing was practiced in *Panicum maximum* cv. Tanzania pasture during dry-season. We used a randomized block design. Twenty paddock (four/treatment) were used divided two blocks (four bull/paddock). Average daily gain (ADG) was calculated using the initial and final individual live weight divided by the number of experimental days. Animals were slaughter in commercial slaughter room and hot carcass weights were obtained to calculate carcass dressing (CD). Statistic analyzer were determined according Proc Mixed SAS 9.0. Paddocks were used as experimental units. Treatments were considered fixed effect and, block aleatory effect. Treatments effects were tested using the following contrasts: 0.5 vs. 2% BW. Animals supplemented with 2% BW shown higher ADG ($P < 0.01$) and had highest CD when compared treatment 2% BW (1.313 vs. 0.534 and 58.4 vs. 53.9, respectively). The effect of virginiamycin and other treatments with 2% BW were tested using contrasts. There were difference ($P < 0.01$) for liveweight gain between treatments 2% BW + virginiamycin (25 ppm) (1.225 kg/d) and 2% BW + virginiamycin (25 ppm) + monensin (20 ppm) (1.505 kg/d), However, 2% BW and 2% BW + virginiamycin (25 ppm) + salinomycin (10 ppm) were not statistically different, the ADG for this treatments were 1.229 kg/d and 1.296 kg/d, respectively. Animals supplemented with virginiamycin ($P < 0.01$) had the highest carcass dressing (59.2) when compared with treatment 2% BW (57.8). Contrast with other treatments not shown statistic difference, achieved 58.7 and 58.0 for treatments 2% BW + virginiamycin (25 ppm) + monensin (20 ppm) and 2% BW + virginiamycin (25 ppm) + salinomycin (10 ppm), respectively. Therefore, increasing supplementation and use of additives may increase animal performance. *Acknowledgment: Phibro Animal Health Corporation.*

Key Words: monensin, pasture, virginiamycin.

1627 (M341) Effects of heights of Marandu pastures and sources of energy supplements on the intake, digestibility of nutrients by young Nellore bulls during the rainy season. A. A. Oliveira[1], M. V. Azenha[*2], S. S. Santana[2], A. L. S. Valente[2], J. P. R. Costa[2], T. T. Berchielli[2], A. C. Ruggieri[2], and R. A. Reis[2], *[1]UNESP, Jaboticabal, Brazil, [2]University of Sao Paulo State, Jaboticabal, Brazil.*

The study was conducted to evaluate the sward heights, and energy supplementation with different sources effects on the forage nutritive value, total DM intake, and digestibility of nutrients by young Nellore bull yearling in pastures of *Urochloa brizantha* cv. Marandu in continuous stocking grazing system during the rainy season. Effects of three sward heights (15, 25, and 35 cm) and three supplements (mineral mixture and two protein-energy supplements, based on corn and other on citrus pulp), were studied. Both energy/protein supplements contained 19.0% of crude protein were supplied at 0.3% of body weight/day. Forage mass, and animal body weight were determined monthly to calculate the forage allowance and the amount of supplement. Experiment was conducted from January to April, at this time forage was sampling by hand plucking methodology to evaluate the nutritive value. Fecal production was estimated using an external marker LIPE; (*Eucalyptus grandis* lignin isolated, purified and enriched). Individual supplement intake was estimated using titanium dioxide (TiO_2) as external marker. Experiment was conducted according to a randomized completely design whit a combination of three pasture heights and three supplements. The average value of NFC was 20.0, 20.0, and 18.9% in pastures of 15, 25, and 35 cm height. There was a linear increase in the levels of NDFap (52.9, 53.6, and 55.9%), and a reduction on the CP levels (16.3, 15.3, and 14.7%) in response to the pasture heights (15, 25, and 35 cm, respectively). Pasture maintained at 15 cm presented highest NPN of total nitrogen, and with 35 cm, showed highest values of N associated to NDF fraction. Intake of DM, OM, and NDF increased linearly in response to sward heights, however diet digestibility decreased. Citrus pulp supplementation as an energy source provided a greatest intake of DM, OM, CP, TDN and also increased the digestibility of DM, OM and CP compared to the others treatments. There was a reduction of NDF digestibility in response to corn supplementation. Swards grazed in lowest height, resulted in lower dry matter intake, but the CP and no fiber carbohydrate intake did not differ among heights, due to the greater proportion of these nutrients in the lowest pastures. It was concluded that swards grazed at lowest height provided forage with better nutritive value. Citrus pulp utilization as a source of energy of supplement increased the intake and digestibility of nutrients.

Key Words: beef cattle, citrus pulp, digestibility, tropical grass

1628 (M342) Within laboratory repeatability of the in situ nylon bag method. H. V. Laar* and J. Doorenbos*, Nutreco R&D, Boxmeer, Netherlands.*

The in situ nylon bag method is the basis of rumen degradation parameters for most feed evaluation models. In our laboratory, over a period of 10 yr all in situ rumen incubations contained a standard sample to study within laboratory repeatability. For raw materials (RM) the standard was a mix of corn, soybean meal and grass meal (1:1:1) to represent starch, crude protein (CP) and fiber fermentation, analyzed in 21 runs. For forage standards were two sequential grass (GS) and corn silages (CS) analyzed in 12 and 11 runs. Approximately 5 g of DM was weighed into 9x18-cm (inner size) nylon bags (40 µm pore size, 30% open surface, Radiometer, The Netherlands). Two or three bags were incubated in the rumen of three lactating fistulated dairy cows at eight time points (up to 336 h). After incubation bags were washed in a washing machine, along with four non-incubated bags per sample (0 h). Samples were pooled over cows by incubation time and analyzed for dry matter (DM), CP, starch and NDF. For each component, washable (W) and undegradable (U) fraction were equated to 0-h loss and 336-h residue. Degradation rate (k_d) was estimated by NLIN procedure of SAS. Effective degradability (ED) was calculated as $ED = W + (100\text{-}W\text{-}U)*(k_d/(k_d+k_p))$ with a k_p (*P*assage rate) of 0.06 for raw material and 0.045 forage standards. Coefficient of variation (CV) was used as measure of repeatability. For the forages CV was based on pooled variation and mean of both standards. Table 1628 shows the CV for ED of various components in RM, GS and CS. CV for NDF is numerically highest for all feeds. For RM, CV of DM is lowest, whereas for GS and CS, CV of CP and starch is lowest. For most components within feedstuff, CV of W, U and k_d(results not shown) was higher than that of ED. These results show that the lowest values for within laboratory repeatability of the in situ nylon bag method are in the range considered poor for analytical laboratory measurements, whereas repeatability values found for NDF are extremely high.

Key Words: In situ, repeatability, fermentation

Table 1628. Coefficients of variation (%) for effective degradation of chemical components of feedstuffs

CV% of ED	Raw Material	Grass Silage	Corn Silage
DM	3.9	5.0	12.2
CP	8.9	3.7	5.6
Starch	10.5	x	5.2
NDF	13.6	9.6	16.4

1629 (M343) Comparison of fermentation kinetics of four feedstuffs using an in vitro gas production system and the ANKOM gas production system.

J. G. L. Regadas Filho*[1], L. O. Tedeschi[2], M. A. Fonseca[2], and L. F. L. Cavalcanti[3], *[1]Universidade Federal de Viçosa, Brazil, [2]Texas A&M University, College Station, [3]Universidade Federal de Minas Gerais, Belo Horizonte, Brazil.*

The objective of this study was to perform a comparison between two computerized systems that are used to determine the fermentation kinetics of in vitro gas anaerobic incubation of feedstuffs. The evaluated systems were the ANKOM^{RF} Gas Production Systems (aIVGP) and the in vitro anaerobic fermentation system (tIVGP) as used at Texas A&M University. The aIVGP uses a wireless system, while the tIVGP a wired system to collect the measures. Four different samples of ground corn, alfalfa hay, dried distillers grain, and dried forage were used (n = 16). All components of the fermentation were maintained constant between the IVGP systems (sample: 0.20 g to tIVGP and 0.39 g to aIVGP; rumen fluid: 4.0 mL to tIVGP and 7.8 mL to aIVGP; media: 14.0 mL to tIVGP and 27.3 to aIVGP; and bottle volume: 158 mL to tIVGP and 307 mL to aIVGP). After 48-h, the concentrations of methane in the bottle's headspace was collected and analyzed using a gas chromatographer. The solution pH was measured and the profiles of the feedstuffs were interpreted using nonlinear model. The total gas production (ml/100 mg of DM), fractional production rate of gas (h^{-1}), pH of the solution and methane concentrations (µmole/ml of gas) were used to compare the systems. The levels of agreement between the IVGP systems were determined using the coefficient of determination (r^2) between both predictions (X axis = aIVGP and Y axis = tIVGP), bias correction (Cb); concordance correlation coefficient (CCC) and mean bias (MB). The IVGP systems had similar values for total gas production (mean X = 17.70; mean Y = 21.23; r^2 = 0.81; Cb = 0.85; CCC = 0.77; MB = 3.58; P = 0.2165), methane concentration (mean X = 2.15; mean Y = 2.66; r^2 = 0.89; Cb = 0.83; CCC = 0.79; MB = 0.51; P = 0.0787) and solution pH (mean X = 6.35; mean Y = 6.31; r^2 = 0.90; Cb = 0.98; CCC = 0.93; MB = -0.04; P = 0.6480). However, the estimated values of fractional production rate of gas were different (mean X = 0.1255; mean Y = 0.1031; r^2 = 0.44; Cb = 0.79; CCC = 0.52; MB = -0.022; P = 0.0032). The results suggest that both IVGP systems had similar fermentations patterns. The difference in the fractional production rate of gas between these IVGP systems may be due to difference in the headspace gas composition.

Key Words: gas production, headspace, in vitro systems

1630 (M344) The influence of source and quality of water and a water treatment system on the ruminal fermentation and nutrient digestibility of a total mixed ration using an in vitro gas production measurement system.

D. Casper* and I. P. Acharya, *South Dakota State University, Brookings.*

There is a wide range in water quality available in South Dakota and this variation could have an impact on the performance of lactating dairy cows. In addition, little is known regarding water treatment systems influence on ruminal fermentation. This study was to evaluate the water source and a water treatment system on the rate and/or extent of ruminal fermentation and nutrient digestibility. A standard TMR consisting of alfalfa haylage, corn silage, and a grain mix was dried at 55°C and ground through a ultracentrifuge mill having a 1.0-mm screen. One g of ground TMR was placed in a 50-µm dacron bag, heat sealed, and then placed in a 500-mL Ankom Gas Fermentation Bottle (GFB) to measure rate and extent of digestion. Treatments were: Control (C): laboratory distilled water; KCU: water taken from a local SD dairy operation before the water treatment system; KCT: water taken after treatment with H_2O_2 product; and DRTF: Municipal water used at the SDSU Dairy Research & Training Farm. Treatments were replicated four times as individual GFB and study was conducted in four blocks. Rumen fluid was collected from a ruminally cannulated lactating dairy cow fed the same TMR and strained through four layers of cheesecloth. Twenty mL of rumen fluid with 200 mL of buffer prepared from each of the water treatments were added to the GFB. Bottles were incubated in a circulating water bath at 39°C and gas measurements were collected every 5 min for 30 h. At the completion of 30 h fermentations, Dacron bags were removed, rinsed, and dried to calculate dry matter disappearance (DMD) and NDF concentrations to calculate NDF digestibility. The rate of gas production was greater (P < 0.01) for C (distilled lab water) compared to other treatments. (16.4, 9.50, 9.66 and 9.71%/h for C, KCU, KCT, DRTF, respectively). The DMD (82.0, 81.6, 80.8 and 81.6% for C, KCW, KCT, and DRTF, respectively) tended to be lower (P < 0.09) for KCT water compared to C water, with all other treatments being intermediate and similar (P > 0.10). The digestibility of NDF (60.0, 59.0, 58.3, and 59.6% of NDF) was similar (P > 0.10) for all treatments. The quality of water can influence rate of ruminal fermentation and the use of a water treatment system had minimal influence on ruminal fermentation and digestibility.

Key Words: gas production, nutrient digestibility, water quality

1631 (M345) Relationships between dry matter degradation, in vitro gas production and chemical composition of 15 feedstuffs. Y. J. Xu, M. Zhao, and D. P. Bu*, *State Key Laboratory of Animal Nutrition, Institute of Animal Science, Chinese Academy of Agricultural Sciences, Beijing, China.*

This study was designed to investigate the relationships of in vitro true digestibility of dry matter (IVTD) and in vitro gas production of feedstuffs. Fifteen ruminant feedstuffs were selected in Xinjiang province in China (corn, corn bran, bran, cottonseed meal, soybean meal, DDGS, urea gelatinized corn protein, corn gluten meal, monosodium glutamate residue, grape seed meal, cottonseed hulls, alfalfa meal, alfalfa hay, corn silage and tomato sauce residue). Gas production, volatile fatty acid (VFA) and IVTD at 24-h incubation were measured. Statistical analysis was performed using the PROC CORR procedure of SAS 9.1. The results revealed that strong negative correlation was observed between neutral detergent fiber (NDF) and IVTD ($r^2 = 0.81$, $P < 0.001$). Positive correlation was observed between non-fibern carbohydrate (NFC) and IVTD ($r^2 = 0.74$, $P < 0.001$). In vitro gas production at 24 h was negatively related with NDF content ($r^2 = 0.54$, $P < 0.05$) and positively related with NFC content ($r^2 = 0.92$, $P < 0.001$). In vitro gas production at 24h was positively related with total VFA production ($r^2 = 0.93$, $P < 0.001$). There was strong positive correlation between NFC content and total VFA production ($r^2 = 0.81$, $P < 0.001$). Therefore, chemical composition of feedstuffs were highly related with in vitro gas production, in vitro true digestibility of dry matter.

Key Words: chemical composition, in vitro gas production, in vitro true digestibility of dry matter

1632 (M346) In vitro gas production and dry matter degradability of a high concentrate diet: influence of exogenous enzymes level. D. López[1,2], J. F. Vázquez-Armijo[1], A. F. Z. M. Salem[3], J. Hernández[2], R. Rojo[*1], and J. Cedillo[1], *[1]Centro Universitario UAEM Temascaltepec, México, [2]Universidad Autónoma de Tamaulipas, Ciudad Victoria, México, [3]Universidad Autónoma del Estado de México, El Cerrillo Piedras Blancas, México.*

This study was conducted to evaluate the influence of an exogenous enzyme mixture on in vitro gas production (GP), in vitro dry matter degradability (DMD), metabolizable energy (ME) and short chain fatty acid (SCFA) production in growing lambs fed a high concentrate diet (219 g/kg CP), made with ground sorghum (550 g/kg), alfalfa hay (150 g/kg), soybean meal (220 g/kg), fishmeal (35 g/kg), salt (20 g/kg) and a mineral/vitamins premix (25 g/kg). ZADO (ENZ) is a powdered, commercially available multi-enzyme feed additive produced from *Ruminococcus flavefaciens*. Four levels of ENZ (i.e., 0, 5, 10, and 20 mg/g DM; or E0, E5, E10 and E20, respectively) were applied directly to the substrate inside the incubation bottles before addition of buffer medium and rumen fluid, and the treatments were assayed by triplicate in three runs for different weeks. Bottles were incubated at 39°C for 96 h. The volume of gas produced was recorded at 2, 4, 6, 8, 10, 12, 24, 48, 72, and 96 h after inoculation. A mathematical model was used for estimate lag time, asymptotic gas production and rate of gas production. DMD was determined at end of incubation by filtration of the residue. ME and SCFA were calculated. Data were analyzed as a randomized design and linear and quadratic effects were calculated at $P < 0.05$. Addition of ENZ linearly increased ($P < 0.05$) GP at 6 (74.5, 81.1, 83.7 and 87.5 mL/g DM) and 96 h (334.1, 336.1, 338.5 and 346.8 mL/g DM) of incubation and tended ($P = 0.08$) to linearly increase GP at 12, 48, and 72 h of incubation. Asymptotic GP (334.7, 336.6, 339.1 and 347.3 mL/g DM) was increased linearly ($P = 0.05$) as the level of ENZ increased and the lag time decreased linearly (2.34, 2.12, 1.78 and 1.73 h) ($P = 0.003$). Concurrently, DMD (709, 809, 820, 843 g/kg, repectively) increased linearly ($P < 0.001$) as the level of ENZ increased, but level of ENZ had no effect on SCFA and ME. Finally, level of ENZ had no influence on rate of gas production. Results suggest that this enzyme preparation has potential to improve efficiency of utilization of high concentrate diets fed to growing lambs.

Key Words: enzymes, degradability, gas production.

1633 (M347) In vitro ruminal fermentation with three sources of inoculum in diets containing *Acrocomia aculeate*. S. L. S. Cabral Filho[*1], L. S. Murata[1], R. A. Mandarino[2], C. Eufrásio de Souza[3], D. Leornadi Migotto[3], F. Lopes da Silva[3], J. Artemio Marin Beltrame[4], and J. H. Bernardes Pereira[3], *[1]University of Brasilia, Brazil, [2]Universidade Federal de Minas Gerais, Brasilia, Brazil, [3]Universidade de Brasília, Brazil, [4]Universidade Federal de Mato Grosso do Sul, Campo Grande, Brazil.*

The aim of this study was to determine the potential of different inoculum sources using in vitro gas production technique. Three different sources of inoculum were used for fermentation of gas production analysis: ruminal liquor from fistulated bovine grazing *Brachiaria brizantha* (LR); extracted from slaughtered pig cecum (CS); and cattle feces (FC) collected from the rectum and diluted with distilled water in 10% base. The substrate consisted in three diets content 100% of *Acrocomia aculeate* pulp (AA), 20% AA pulp + 80% of basal diet (20AA) and 10% AA pulp + 90% of basal diet. The basal diet was composed by soy bean meal and corn grains to attempt pig growth requirements. The cumulative volume of gas produced was measured at 0, 3, 6, 9, 12, 16, 24, 48, 72, and 96 h after incubation. The mathematical model used was described by France et al. (1993). The experimental design was one completely randomized blocks in factorial arrange-

ment with eight repetitions (8x3x3). All inoculums showed fermentative capacity and the time of colonization in each trial was lower ($P < 0.05$) for CS followed by LR and FC, was 2.5, 3.2 and 3.7 h, respectively. The substrate with higher potential of gas production was 20AA and presented lower value for FC (205.93 mL) and the difference between LR and CS ($P < 0.05$) (265.05 mL and 299.23 mL). The rates for gas production were: AAxCS, AAxFR, AAxLR (00014 mL.-1h, 0015 mL.-1h and 0028 mL.-1h), 10AAxLR, 10AAxCS, 10AAxFR (00276 mL.-1h, 00410 mL.-1h and 00437 mL.-1h) and 20AAxFR, 20AAxLR, 20AAxCS (00351 mL.-1h, 00365 mL.-1h and 00432 mL.-1h) showed no statistical difference $P > 0.05$). As a conclusion the CS inoculums can be used for the evaluation of gas production.

Key Words: gas production, alternative feed, biogas

1634 (M348) Relationship of protein structural conformation to protein functional property, buffer and water solubility, rumen digestive behaviors, and intestinal availability of common feeds in ruminants. Q. Peng[1,2], N. A. Khan[1], Z. Wang[2], X. Huang[*1], and P. Yu[1], *[1]University of Saskatchewan, Saskatoon, Canada, [2]Sichuan Agriculture University, Sichuan, China*.

The objectives of this study were to determine the relationship between the intrinsic molecular structures of protein feeds and their protein solubility, and rumen and intestinal digestibility in dairy cattle. The feeds investigated were barley, corn, oat, wheat, lentil, peas, canola meal, expeller meal (extruded canola meal), soybean meal, mill feeds (pelleted byproducts from cereal grains), lantic sugar beet pulp, blood meal and meat meal. The protein molecular structure makeup of the feeds was revealed using attenuated total reflectance-Fourier transform infrared molecular spectroscopy (ATR-FTIR). The spectral data on unique bands such as amid I, amide II, and protein secondary structures such as α-helix and β sheet and their ratios were analyzed for differences in intrinsic molecular structures. Moreover, multivariate analysis, agglomerative hierarchical cluster analysis and principal component analysis were computed on the molecular spectral data to distinguish the overall differences in intrinsic molecular structures among the feeds. The protein functional property, solubility, rumen and intestinal digestibility were determined directly using dairy cattle. The PROC MIXED of SAS was used to analyze the univariate spectra data, water-and buffer-based protein solubility, rumen and intestinal protein digestibility. Pearson correlation coefficients between the protein spectral data and protein digestibility were computed using the PROC CORR procedure. A stepwise multiple regression procedure of SAS was performed to determine which of the protein molecular structural features could be used to estimate protein solubility, degradability and digestibility of the prairie feeds. The stepwise option was used with variable selection criteria: SLENTRY = 0.05, SLSTAY = 0.05. The variance inflation factor (VIF) option was used to detect and avoid collinearity among the independent variables. The results showed a large variation in water-and buffer-based protein solubility; ruminal, intestinal and total protein digestibility; and in the inherent structure makeup of protein among the feeds. The protein structural conformation in terms of amide I-and II and protein secondary structures (α-helix and β sheet) were strongly correlated with protein solubility, and ruminal and intestinal digestibility in dairy cattle. The protein structure spectral parameters of amid II area and β sheet height could be used to predict protein intestinal and total digestible content of prairie feeds in dairy cattle. In conclusion, this study report a novel data on protein molecular structure and showed that protein structural makeup was associated with protein nutritional value and digestive behavior in dairy cattle.

Key Words: protein molecular structure, molecular spectroscopy, nutrient availability, metabolic characteristics of protein, ruminants

1635 (M349) Carbohydrate-protein matrix structure impacts protein and other primary nutrient digestion in common prairie feeds with different soluble and insoluble fractions. Q. Peng[1,2], X. Huang[*1], Z. Wang[2], and P. Yu[1], *[1]University of Saskatchewan, Saskatoon, Canada, [2]Sichuan Agriculture University, China.*

An experiment was conducted to investigate the relationship of carbohydrates molecular spectral characteristics to rumen degradability of primary nutrients in Prairie feeds in dairy cattle. In total, 12 different types of feeds were selected, each type of feed was from three different source with total 37 samples. Six types of them were energy-sourced feeds and the others were protein-sourced feeds. These feeds included various barley, corn, oat, wheat, lentil, peas, canola meal, expeller meal (extruded canola meal), soybean meal, mill feeds (*P*elleted byproducts from cereal grains), lantic sugar beet pulp, blood meal, meat meal etc. The carbohydrates molecular spectral intensity of various functional groups were collected using Fourier transform infrared attenuated total reflectance (ATR-FT/IR) spectroscopy. In the in situ study, the results showed that the rumen digestibility and digestible fractions of primary nutrients (DM, OM, NCP, and CP) were significantly different ($P < 0.05$) among the feeds. The spectral bands features were significantly different ($P < 0.05$) among the feeds. Spectral intensities of A_Cell, H_1415 and H_1370 were weakly positively correlated with in situ rumen digestibility and digestible fractions of DM, OM and NCP. Spectral intensities of H_1150, H_1015, A_1, and A_3 were weakly negatively associated with in situ rumen degradation of CP. Spectral intensities of A_1240 and H_1240, mainly associated with cellulosic compounds, were correlated with rumen CP degradation. The multiple regression analysis demonstrated that the spectral intensities of A_3 and H_1415

played the most important role and could be used as a potential tool to predict rumen protein degradation of feeds in dairy cattle. In conclusion, this study showed that the carbohydrates as a whole have an effect on protein rumen degradation, rather than cellulose alone, indicating carbohydrate-protein matrix structure impact protein utilization in dairy cattle. The non-invasive molecular spectral technique (ATR-FT/IR) could be used as a rapid potential tool to predict rumen protein degradation of feedstuffs by using molecular spectral bands intensities in carbohydrate fingerprint region.

Key Words: carbohydrate-protein matrix structure, rumen degradability, molecular spectral bands

1636 (M350) Performance and dry matter digestibility of finishing lambs fed diets with ground canola grains. N. I. Ortega-Alvarez[1], G. Buendia-Rodriguez[2], J. A. Cuaron-Ibarguengoytia[2], G. D. Mendoza-Martinez[3], and S. S. Gonzalez-Muñoz[*4], *[1]Universidad Nacional Autonoma de México, México D.F., [2]CENIDFyMA INIFAP, Queretaro, México, [3]Universidad Autonoma Metropolitana, Unidad Xochimilco, México D.F., [4]Colegio de Postgraduados, Montecillo, Estado de México.*

Canola seeds have 42–43% EE, 20% CP, and they can be used as a source of protein and energy for ruminants. The objective of this experiment was to evaluate the effect of ground canola grain (GCG) or canola meal (CM) and canola oilseed (CO) added to a concentrate diet (14.59% CP and 2.8 Mcal ME/kg DM) on finishing 21 Pelibuey x Texel lambs (32.09 ± 5.48 kg initial BW) housed in metabolic cages during 42 d. The experimental design was completely randomized with three treatments: T0: 4.6% CM, 67% sorghum grain, 19.5% alfalfa hay; T1: 7.5% GCG, 63.5% sorghum grain, 19.5% alfalfa hay; T2: 4.5% CM, 3% CO, 64% sorghum grain, 19.5% alfalfa hay (all diets contained 5% cornstalk, 2% cane molasses, 1% urea, 1% premix); and seven replications (lambs) per treatment. Variables were average daily gain (ADG, g), daily DM intake (DDMI, g), feed conversion (FC), carcass yield (CY, %) and DM digestibility (DMD, %). Data were analyzed using PROC MIXED (SAS v 9.0) and treatment means were compared with Tukey test ($P \leq 0.05$). Addition of ground canola grain to the diet did not change ADG (321, 382, 391 g; $P = 0.14$), DDMI (1796, 1671, 1790 g; $P = 0.54$), FC (5.75, 4.47, 4.64; $P = 0.09$), CY (54.13, 52.15, 52.16%; $P = 0.45$) and DMD (74.14, 78.80, 73.87%; $P = 0.13$). Since there were no differences among treatments, it may be concluded that ground canola grain can be used in diets for finishing lambs.

Key Words: canola grain, performance and digestibility, lambs

1637 (M351) Ruminal pH and epithelial function as affected by increasing compound feed supply in growing Holstein heifers. A. Navarro-Villa[1], M. A. Steele[*2], J. A. Metcalf[2], and J. Martin Tereso[1], *[1]Nutreco Research, and Development, Boxmeer, Netherlands, [2]Nutreco Canada Agresearch, Guelph, ON.*

Adaptation to high-concentrate diets involve changes in ruminal milieu and epithelium that remain largely undescribed. Changes in ruminal pH and epithelial function were studied by gradually introducing compound feed (CF)(from 0 to 8kg/d as-fed; Δ+0.5kg/d) in the diet of four fistulated Holstein heifers (8 ± 0.*32* mo of age) with ad libitum access to chopped barley straw. Loggers placed in the ventral rumen continuously monitored pH over 16 d. Cumulative time (min/d) spent below pH cut-off points was calculated for each animal and fitted to a logistic curve (AlZahal et al., 2007), where the slope (β_0; indication of daily pH range) and inflection point (β_1; median pH value) were calculated. Linear correlation between these parameters and CF supply was calculated. Rumen papillae samples were biopsied for RNA extraction and subsequent gene expression analyses when cattle consumed 0, 4, and 8kg of CF/d. Total DM intake was 5.8 ± 0.76, 6.9 ± 1.08 and 8.9 ± 0.71kg/d and straw intake 4.0 ± 0.76, 3.3 ± 1.08 and 1.7 ± 0.71kg/d for CF levels of 0, 4, and 8kg/d, respectively. The daily minimum pH was 6.4 ± 0.19, 6.0 ± 0.12 and 5.8 ± 0.17 at 0, 4, and 8kg/d CF, respectively. In contrast, no changes in daily maximum pH (from 7.3 ± 0.17 to 7.3 ± 0.31) and subtle decreases in daily mean pH (from 6.9 ± 0.1 to 6.7 ± 0.24) were observed with increasing CF intake. The slope of the logistic curve decreased ($P < 0.05$) as the intake of CF increased resulting in 8.7 ± 0.69, 6.6 ± 0.69 and 2.1 ± 0.69 for 0, 4, and 8kg CF/d, respectively. The inflection point decreased ($P < 0.05$) with CF supply but was not affected by CF dose (6.8 ± 0.13, 6.6 ± 0.11 and 6.3 ± 0.21 for 0, 4, and 8 kg CF/d, respectively). Slope correlated better to CF intake [$\beta_0 = 9.5(\pm 0.48)$-$0.6(\pm 0.10)\times$CF(kg); $R^2 = 39$] than inflection point [$\beta_1 = 6.8(\pm 0.06)$-$0.008(\pm 0.010)\times$CF(kg); $R^2 = 0.01$]. The relative mRNA expression of tight junction genes claudin1 (CLDN1) and claudin4 (CLDN4) were downregulated ($P < 0.05$) by 0.77 ± 0.03 and 0.85 ± 0.06-fold between 0 and 4 kg CF inclusion, respectively. Moreover, the relative mRNA expression from 0 to 4 and 0 to 8 kg CF supply was up-regulated ($P < 0.05$) for putative anion transporter 1 (PAT1) (1.25 ± 0.07; 1.39 ± 0.15) and carbonic anhydrase 1 (CA1) (1.20 ± 0.09; 1.30 ± 0.20). Based on the results of this study, adaptation to high-concentrate diets was associated more extreme fluctuations in rumen pH rather than obvious declines in average ruminal daily pH. In addition, adaption to high-concentrate diets involved changes in gene expression of key transport (PAT1), metabolic (CA1) and tight junction genes (CLDN1 and CLDN4) in the epithelium.

Key Words: rumen pH, adaptation, gene expression

1638 (M352) Metabolic characteristics of grazing Nellore bulls receiving concentrated supplementation with additives. J. A. C. Lima[*1,2], H. J. Fernandes[2], E. P. Rosa[2], L. S. Caramalac[2], K. A. Silveira[2], G. C. Silva[2], B. D. D'auria[2], and A. Aguiar[3], *[1]Federal University of Viçosa, Brazil, [2]State University of Mato Grosso do Sul, Aquidauana, Brazil, [3]University of Florida, Gainesville.*

The objective of this study was to evaluate the effect of a commercial concentrate supplement with additives in the metabolic characteristics of grazing bulls, during the dry/rainy transition season in Aquidauana–MS, Brazil. Twelve Nellore bulls (initial body weight of 370 ± 15 kg) were randomly assigned to twelve *Brachiaria decumbens* Stapf pastures (1.0-ha/pasture; one bull/pasture) on a completely randomized design. Treatments were: 1) concentrate supplement Lipomax with homeopathic additives (Convert H, Sodo 100, Figotonus) and Virginiamicina (Lipomax treatment), and 2) concentrate supplement with a similar protein content (18% CP), and without additives (Control treatment). Animals were feed daily at rate of 0.5% of the animal's body weight. After 53 d, when the animals achieved body weight of 426 ± 27.3 kg, urine "spot" and blood samples of the animals were collected, 4 h after the concentrate supplement was offered. Urine samples were analyzed for creatinine (for daily urine total production estimative), N-urea and total-N, and blood samples for serum urea. A significance level of 5% was adopted. Serum urea, and urine N-urea and total-N excretion of the grazing animals showed no difference ($P > 0.05$) when the additives were used in the concentrate supplementation (Table 1638). The low levels of these metabolic parameters for grazing animals indicated an efficient use of the diet metabolizable protein, and the use of additives could not increase this efficiency.

Key Words: grazing bulls, protein metabolism, tropical environment

Table 1638. Parameters of protein metabolism of Nellore bulls grazing brachiaria grass and receiving concentrated supplement with or without additives

	Treatments			
Item	Control	Lipomax	CV (%)	P-value
URbl[1] (md/dl)	15.1	14.7	10.3	0.690
Nururine[2] (g/d)	35.9	33.0	28.6	0.622
Ntotur[3] (g/d)	45.9	55.1	24.8	0.231

[1] URbl is the blood urea, mg/dl.

[2] Nururine is the N-urea in urine, g/d.

[3] Ntotur is the N total in urine, g/d.

1639 (M353) Productive parameters, metabolic and economic viability of dairy cows supplemented with different levels of urea in diets based on sugarcane. R. C. D. Souza[*1], R. B. Reis[2], F. C. F. Lopes[3], J. M. Leão[2], and M. H. F. Mourthé[4], *[1]PUC Minas, Betim, Brazil, [2]UFMG, Belo Horizonte, Brazil, [3]Embrapa Gado de Leite, Juiz de Fora, Brazil, [4]Universidade Federal dos Vales do Jequitinhonha e Mucuri, Diamantina, Brazil.*

Sugarcane has been recommended for dairy farms that utilize low-yielding cows, used in to feeding regimes that do not seek to obtain high lactating performance per animal. The utilization of sugarcane and other feedstuffs, should be based on dietary formulations that incorporate nutritional-model recommendations of practical use (NRC, 2001). Sugarcane was also considered adequate for dairy cattle producing 20 kg of milk per day. The sugarcane yield support potential, in balanced diets, must be defined more precisely to allow recommendations to be specifically targeted. No scientific data exist to support the use of sugarcane in diets formulated for high-performance lactating animals. Sugarcane has been used for animals of higher production due to its qualities, among them, the low cost of dry matter. However, the appropriate level of urea in to add to cane sugar diets feed to high production animal is still questionable. The objective of this study was to evaluate feed intake, nutrient digestibility, feed efficiency, production and milk composition, metabolic parameters and the economic viability of lactating cows fed diets based on sugarcane supplemented with increasing levels of urea: sulfate on dry matter basis (0, 0.5 and 1.0%). Twelve multiparous cows and six primiparous Holstein and Holstein x Gir, with 83 + 7 d of lactation, average milk yield of 21.3 ± 0.8 kg/d, average body weight of 580 + 18.3 kg, fed with total mixed ration 50:50, assigned to reversion assay type switch-back, 3 × 3. Cows fed the diet with 1.0% urea had lower ($P < 0.05$) dry matter intake (DMI) and organic matter intake (OMI), but feed efficiency higher on this diet. DMI, OMI and feed efficiency was 19.64, 19.66 and 18.33 kg/d, 18.24, 18.31 and 17.03 kg/d and 1.14, 1.17 and 1.71 kg/kg, respectively for diets containing 0.0, 0.5, and 1.0% of urea. There was no effect of diet

on nutrient digestibility, milk yield, milk composition and on plasma concentration of urea, glucose and insulin ($P > 0.05$). All diets had a positive balance if considered only cost with food, however the 1% urea diet showed the best outcome per cow. For dairy cows, with an average milk yield of 22 kg/d, sugarcane supplemented with 1% urea in green matter basis despite decreasing the dry matter intake, may be used, without causing any adverse effect on production and metabolic and improve parameters of cost.

Key Words: sugarcane, urea, productive parameters.

1640 (M354) Chia seed supplementation increases ruminal propionate concentration in alfalfa hay based diets evaluated in a dual-flow continuous culture system. J. Bunkers*, E. Marostegan de Paula, L. Galoro da Silva, T. Shenkoru, Y. L. Yeh, B. Amorati, D. Holcombe, and A. Faciola, *University of Nevada, Reno.*

Chia seed (CS) and flaxseed (FS) are rich in omega-3 fatty acids which may provide health benefits when added to animals' diets. However, data on the effects of CS supplementation on ruminal metabolism is scarce. The objective of this experiment was to determine nutrient digestibility, rumen fermentation characteristics, microbial protein synthesis, and long-chain fatty acids flow of supplemented alfalfa hay (AH) diet with either CS or FS. Diets were randomly assigned to six dual-flow continuous culture fermenters (1200 to 1250 mL) in a replicated 3 × 3 Latin square arrangement with three 10-d experimental periods consisted of 7 d for diet adaptation and 3 d for sample collection. Fermenters were fed a total of 72 g of DM/d equally divided in four portions. Diets consisted of (DM basis) 95% AH supplemented with: 5% Megalac (Diet A), 5% FS (Diet B), and 5% CS (Diet C). Liquid and solid dilution rates were adjusted daily to 10%/h and 5%/h, respectively. A sample of 500mL from each fermenter was taken on d 8, 9, and 10. Two subsamples of 10 mL were filtered through two layers of cheesecloth, were preserved with 0.2mL of 50% sulfuric acid and centrifuged for ruminal NH_3 and VFA analysis. Statistical analyses were performed using the GLM procedure in SAS. Ruminal metabolism data are presented in the table. Supplementing CS increased the molar proportion of propionate and decreased Acetate:Propionate ratio. There were no differences among treatments for ruminal NH_3 concentration, total VFA concentration, and molar proportions of acetate, butyrate, and branched-chain VFA. Results from this experiment indicate that CS supplementation may change ruminal metabolism by increasing ruminal propionate concentration which may be energetically beneficial for glucose synthesis in ruminants.

Key Words: dual-flow continuous culture, chia seed, flaxseed

1641 (M355) Analysis of rumen motility patterns using a wireless telemetry system to characterize bovine reticuloruminal contractions. A. M. Egert*[1], K. R. McLeod[1], J. L. Klotz[2], and D. L. Harmon[1], *[1]University of Kentucky, Lexington, [2]USDA-ARS, FAPRU, Lexington, KY.*

The objective of this study was to characterize rumen motility patterns of cattle fed once daily. Eight ruminally-cannulated Holstein steers (BW = 321 ± 11 kg) were fed alfalfa cubes once daily at 1.5 × NE_m top-dressed with a TM-salt pre-mix. Three 24-h collection periods were conducted and each commenced immediately following feeding. A wireless telemetry system (emkaPACK*4G* telemetry system, emka TECHNOLOGIES USA, Falls Church, VA) was used to monitor real-time pressure changes in the rumen. Pressure transducers and transmitters were housed in a plastic container with screw-on lid that served as the cannula cap. A weighted (300 g), water-filled (1 L), balloon-tipped catheter was connected to the transducer through an adaptor and placed below the mat in the ventral sac of the rumen. Data were recorded and stored using iox2 software (iox 2.9.4.27, emka TECHNOLOGIES USA) which utilized a rhythmic analyzer to analyze the raw rumen pressure data, identify ruminal contractions, and calculate the following parameters for each contraction: baseline pressure, peak pressure, amplitude, frequency, time to peak, relaxation time, duration, and area under the curve. Mean results were calculated for each parameter (Table 1641). All parameters were affected ($P < 0.0001$) by animal and hour. Baseline and peak pressure of contractions increased through 14 h post-feeding, which may have been due to animals laying down more often. Amplitude of ruminal contractions was greatest the first 5 h post-feeding and then decreased quickly. Frequency, duration, and area decreased throughout the collection period, but increased shortly before the next feeding. Mean water intakes for the first and second 12 h post-feeding were 35.5 ± 2.19 L and 0.92 ± 0.26 L, respectively. These data demonstrate that wireless telemetry can be used to non-invasively monitor rumen motility patterns in freely moving steers. Feeding management impacts the values obtained and must be considered when designing experiments.

Key Words: forestomach, motility, rumen pressure

1642 (M356) Use of grouped samples of orts does not compromise feed intake data in studies of confined cattle. D. Zanetti[1], S. C. Valadares Filho*[1], M. V. C. Pacheco[1], L. F. Prados[1], E. Detmann[1], L. A. Godoi[1], F. C. Rodrigues[1], R. C. D. O. Ribeiro[2], J. M. D. Silva Júnior[1], and S. A. Santos[5], *[1]Universidade Federal de Viçosa, Minas Gerais, Brazil, [2]Universidade Federal de Minas Gerais, Belo Horizonte, Brazil, [3]Universidade Federal da Bahia, Salvador, Brazil.*

The orts in the feed bunk are commonly analyzed as composited samples, which are collected within periods of 7 or 28 d for each animal. In this context, the use of only one grouped sample of orts per animal for the entire experimental period may reduce the labor and costs of laboratorial analysis. Therefore, this study aimed to compare samples of orts collected weekly with a grouped sample collected within 12 wk of feedlot. A total of 24 castrated cattle with average body weight of 397.3 kg were fed diets with 70:30 or 40:60 roughage:concentrate ratio using sugarcane as the only roughage source. Diets were provided, sampled and adjusted daily so the orts remained around 5% of the total offered. Orts were sampled daily and proportionally grouped weekly. Sample of orts were analyzed individually or as grouped samples, formed by grouping 12-wk samples of the experiment according to the proportion of orts in the feed bunk. Comparisons of nutrient intake were evaluated using the linear regression model of the values observed for the two sampling methods and the simultaneous hypothesis were tested as it follows: H_o: $\beta 0 = 0$ e $\beta 1 = 1$. Sampling methods were considered similar when the null hypothesis was not rejected. All the statistical analysis was performed by using SAS and differences were considered at $\alpha = 0.05$. The use of these diets allowed a great variation in the composition of orts where the levels of DM ranged from 25.06 to 82.21%, CP ranged from 4.01 to 14.11%, and NDF ranged from 32.52 to 77.06%. Comparisons of the estimates of nutrient intake are presented in Table 1642. In all cases, $H_0$was not rejected ($P > 0.05$) which indicates that dry matter and nutrient intake does not vary comparing orts collected weekly of a composite sample of 12 wk. We conclude that the use of a single sample of orts in the period of 12 wk for each animal is viable and reduces the time and cost of chemical analyzes.

Key Words: feedlot, nutrient intake, orts

1643 (M357) Three dimensional imaging of rumen tissue for morphometric analysis using micro-computed tomography. M. A. Steele*[1], F. Garcia[2], M. Lowerison[3], K. Gordon[2], J. A. Metcalf[1], and M. Hurtig[2], *[1]Nutreco Canada AgResearch, Guelph, ON, [2]University of Guelph, ON, Canada, [3]University of Calgary, AB, Canada.*

Rumen development in calves has been evaluated microscopically by measuring papillae height, width and density. Although common in the literature, there are disadvantages such as large variations in rumen papillae size and shape, small numbers of total papillae being measured and the time required. The objective of this study was to develop a more effective technique for assessing rumen papillae using micro-computed tomography (micro-CT) and to compare this technique with microscopy. Rumen tissue was collected from the ventral sac of 20 bull calves at 55 d of age, immediately fixed in 10% Neutral Buffered Formalin for 48 h and stored in 70% ethanol at 4°C before the contrast enhancement. After evaluation of contrast enhancement protocols which included phosphotungstic acid, osmium tetroxide, and mercury chloride it was determined that mercury provided the most pronounced contrast for accurate micro-computed tomography imaging based on relatively density of the papillae. A 1 cm^2 tissue section from the ventral sac of all bull calves was tensioned on rapid prototype curved plastic holders and imaged at 45-µm resolution for 56 min using a GE Locus Explore micro-CT. MicroView V2.2 software created a three dimensional model of the entire sample. The height and width of 20 papillae per micro-CT section were measured three dimensionally and compared with measurements of 20 papillae under the light microscope taken from the same region using a mixed model equation with a random effect for calf. The length and width measurements using micro-CT (2.47 ± 0.12mm and 0.55 ± 0.01mm) compared to light microscope (2.96 ± 0.03mm and 0.86 ± 0.01mm) were significantly smaller ($P < 0.0001$). The difference may reflect a more accurate determination in the base of the rumen tissue with micro-CT or the specificity of mercury to bind only intact rumen tissue. The mean number of papillae per cm^2 viewed using micro-CT was 128.5 ± 33.9 with a total surface area of 681.8 ± 112.4 mm^2 and volume of 156.2 ± 33.2 mm^3 per sample. Micro-CT data showed that surface area and volume are positively associated ($P = 0.04$) and that papillae length was negatively associated ($P < 0.001$) with papillae per cm^2 and positively associated ($P = 0.02$) with total volume of tissue section as determined by Pearson Correlations. This study represents the first time that micro-CT has been being used to assess morphology of gastrointestinal tissue. Micro-CT has the potential to improve the accuracy and efficiency of rumen tissue measurements however more standardization of each factor involved in tissue preparation and imaging is required.

Key Words: rumen, morphology, development

1644 (M358) Kinetics of gas production of soybean meal, cotton seed meal and fish meal is affected using different zeolites. F. Kafilzadeh, M. Karimi Zandi, and G. Taasoli*, *Razi University, Kermanshah, Iran.*

An in vitro experiment was performed to study the effect of four types of zeolites (Clinoptilolite 1, Clinoptilolite 2, Clinoptilolite A and Heulandites) on kinetics of gas production of three different protein sources (soybean meal, cotton seed meal and fish meal). The cumulative gas production was measured at 2, 6, 10, 14, 18, 22, 24, and 48 h of incubation using a pressure transducer. Each sample was incubated in three replicates. The incubation inoculum was prepared by diluting the rumen liquor with a buffer solution (Tilley and Terry, 1963). Fifteen mL of buffered rumen fluid (20% rumen fluid + 80% buffer solution) prepared and were anaerobically dispensed in each tube at 39°C. All the tubes were crimped, placed in an incubatorat 39°C, and shaken at regular times. A factorial experiment within completely randomized design (CRD) was performed for data on gas production parameters from different protein sources and difference zeolites. All analyses were done on MSTATC program. The result of in vitro gas production showed that there were significant differences between total gas production and lag time of different protein sources ($P < 0.05$). Total gas production was affected by different zeolites ($P < 0.05$). A significant effect of feed × zeolite was observed for the rate at which gas was produced (c) ($P < 0.05$). The mean value for total gas production, lag time and the rate of gas production were 15.68 (ml/125 mg DM), 0.06 (%/h) and 0.31 (h), respectively. Fish meal, among the different protein sources and Clinoptilolite 2 among the different zeolites resulted in the highest gas production rate (0.08). Heulandites produced the highest cumulative gas production (17.41ml/125mg DM) as compared to the other zeolites.

Key Words: gas production, zeolites, protein sources

1645 (M359) Effects of zilpaterol hydrochloride on feedlot performance and carcass characteristics of hair-breed ram lambs. A. Mendoza-García[1], R. Rojo-Rubio[*2], U. Macias-Cruz[3], L. Avendaño-Reyes[4], A. F. Z. M. Salem[5], M. A. Jaime[1], and J. F. Vázquez-Armijo[1], *[1]Universidad Autónoma del Estado de México, Temascaltepec, [2]Universidad Autonoma del Estado de México, Temascaltepec, [3]Universidad Autonoma de Baja California, Mexicali, México, [4]Universidad Autonoma de Baja California, Calexico, [5]Universidad Autónoma del Estado de México, El Cerrillo Piedras Blancas.*

Twenty-one Dorper × Pelibuey croosbred ram lambs (39.01 ± 1.09 kg; 4 mo of age) were individually housed in pens equipped with shade, feed troughs and automatic waterer. Ram lambs were adapted to pens and basal diet, during a 20-d period. One wk before initiation of the experimental phase, lambs were individually weighed, stratified by BW and randomly assigned to treatments under a completely randomized design to evaluate effects of zilpaterol hydrochloride (ZH) levels (ZH; 0, 10, and 20 mg/Lamb daily; to ensure a total intake of ZH, 133.33 g was mixed with 19.1 kg of wheat meal, and 30 g/Lamb daily of mixture was offered to lambs before the morning feeding) on feedlot performance, carcass characteristics, and wholesale cut yield of ram lambs. After a 30-d feeding period, all lambs were harvested. Entire feeding period, ZH increased ($P \leq 0.05$) ADG and tended to increase ($P = 0.076$) feed intake. G:F was not affected ($P = 0.38$). In addition, ZH improved hot carcass weight, cold carcass weight, conformation (ranked 1: bad and 10: excellent), and dressing percent ($P \leq 0.05$). ZH don´t affected ($P \geq 0.05$) KPH fat, but tended ($P = 0.08$) to improved LM area (cm^2). ZH at 10 mg/Lamb dose increased ($P = 0.005$) carcass length (cm), but ZH at 20 mg/Lamb dose showed the highest leg perimeter ($P \leq 0.01$). ZH affected ($P \leq 0.05$) LM pH at 24 h postmortem ($P \leq 0.05$). All non-carcass components were not affected ($P \geq 0.05$) by ZH doses. Leg yield ($P = 0.01$) and plain loin ($P = 0.04$) decreased with ZH and yields of other wholesale cuts were not affected ($P \geq 0.1$). Inclusion of ZH improve some variables of feedlot performance and carcass characteristics of economic importance such as ADG, feed intake and LM area, carcass leg and leg perimeter.

Key Words: β-adrenergic agonist, feedlot sheep, growth rate, carcass characteristics

1646 (M360) Effect of particle size on dry matter intake and ruminal pH in goats fed with alfalfa hay and sorghum silage. D. Esparza[*1], R. Rodriguez[1], G. Veliz[1], C. Meza-Herrera[2], and P. Robles-Trillo[1], *[1]Universidad Autonoma Agraria Antonio Narro, Torreon, México, [2]Universidad Autonoma Chapingo, Unidad Regional Universitaria de Zonas Aridas, Bermejillo, México.*

The aim of this work was to evaluate the effect of particle size on dry matter intake and ruminal pH in Alpine goats. The experiment was designed as a 4 × 4 latin square with eight goats at the end of lactation. Treatments considered a 2 × 2 factorial arrangement; two forage particle lengths of alfalfa hay [short (1 ± 0.03 cm) and long (4 ± 0.05 cm)], combined with two different alfalfa hay and sorghum silage ratio (75:25 or 50:50). The forage:concentrate ratio was 60:40 for all rations. The particle size distribution of the diets was determined with the Penn State Particle Separator using the screen 2 and 3. Each period consisted of 11-d of adaptation stage and 3-d of experimental measurements. Subsequently, diets were exchanged during three periods. Offered food and orts were measured and recorded daily during the last 3 d of each period to calculate food intake. Ruminal fluid was collected on d 14 at 0700, 1100, 1500, 1900, 2300, and 0300 h and ruminal pH was immediately measured. According to our results, alfalfa hay particle

size did not affect voluntary intake (Table 1646), while silage can replace hay without affecting food intake or ruminal pH.

Key Words: goat, particle size, dry matter intake, ruminal pH

1647 (M361) Milk composition of Murrah buffalo grazing on pasture in the Municipality of Taipu, Rio Grande do Norte, Brazil.

J. M. D. Silva Júnior*[1], T. D. S. Martins[1], R. M. D. Paula[1], L. C. Alves[1], D. Zanetti[2], J. A. D. C. Lima[1], L. F. Prados[1], L. N. Rennó[1], G. J. Melo[3], and W. G. D. Nascimento[3], *[1]Federal University Viçosa, Brazil, [2]Universidade Federal de Viçosa, Minas Gerais, Brazil, [3]Rural Federal University of Pernambuco, Garanhuns, Brazil.*

Brazil produces 27.75 billion liters of milk annually, with 92.3 million L coming from buffalo. There are 2500 establishments registered with the Brazilian Association of Breeders of Buffalo. It is estimated that the country has 2 million buffalo, with 82,000 contributing to milk production. Previous research indicates that buffalo-derived milk has numerically greater fat and total solids when compared to milk from dairy cattle, making it valuable for the dairy industry, especially in the production of mozzarella. The objective of this experiment was to evaluate the milk composition from buffalo within a herd at Tapuio Farm (Taipu, Rio Grande do Norte, Brazil) during the dry season (January to March). Total milk production was measured from 300 multiparous females each d over 1 wk. Samples of milk were collected from each female three times over the same wk. Immediately after collection, samples were sent to the Dep. of Animal Science at the Federal Rural University of Pernambuco for analysis. An overall average was obtained for milk production and composition from the entire herd. The milk composition results are shown in Table 1647 which compares the national average of buffalo, dairy cattle, and the results from this study. The farm's average milk production was 2500 kg/d, with an average individual animal production of 8.3 kg/d. This is above the national average of 7 kg/d for buffalo. However, numerically reduced values were observed for fat and total solids when compared to national averages for buffalo. This may have been due to poor pasture quality, caused by regional drought at the time of sample collection. These results reaffirm the superiority of the milk composition of buffalo compared to dairy cattle. With the improved milk composition of buffalo, it is possible to achieve a 40% yield improvement in the industrialization process when compared to the yield from cattle. This improvement in yield results in increased economic returns to the producer.

Key Words: buffalo, milk composition, yield

Table 1647. A comparison of milk composition between buffalo[1], cattle[1], and buffalo at Farm Tapuio

Nutrient (%)	Buffalo	Cattle	Farm Tapuio
Fat	7.15	3.5	6.42
Protein	4.15	3.6	4.56
Lactose	4.95	4.5	4.55
Total solids	16.86	11.9	16.52

1648 (M362) Performance and morphometry of the gastrointestinal tract of goats kept on pasture during the dry period of the semiarid Pernambuco.

J. M. D. Silva Júnior*[1], K. P. Pereira[2], A. S. C. Veras[3], D. K. D. A. Silva[2], J. S. Lima[3], G. J. Melo[2], D. Zanetti[1], T. D. S. Martins[1], R. M. D. Paula[1], L. C. Alves[1], and L. N. Rennó[1], *[1]Federal University of Viçosa, Minas Gerais, Brazil, [2]Rural Federal University of Pernambuco, Garanhuns, Brazil, [3]Rural Federal University of Pernambuco, Recife, Brazil*.

The carcass length, your characteristics and of non-carcass components are directly related to the nutritional composition of the diet. The production of good quality protein also depends on the genotype and the environment in which the animal is held, which points to the importance of the use of supplementation, at the time of low rainfall, which creates food shortages, especially in native pasture, which is characterized by high variation in the chemical composition throughout the year, especially when it comes to semiarid region, Caatinga vegetation, which has its own characteristics, such as loss of leaves and disappearance of native species in the dry season. The experiment aimed to evaluate the endogenous losses in goats kept in grazing unrestricted with and without supplementation, and restricted grazing. Eighteen animals were used without pattern purebred (WPPB), neutered, with average live weight of 16 kg ± 0.22 BW with 90 d of age, undergoing an adjustment period for 15 d. The animals were divided into three treatments: grazing at will without supplementation to slaughter (GWS), grazing at will over supplementation with forage palm + soybean meal (GS) and restricted grazing (RG), with access to pasture during about four h/d, or according to the maintenance of BW. For statistical analysis was used the test F with 5% of probability. A significant difference was observed for slaughter weight ($P = 0.00023$) with higher means for the treatment GS (22.74 BW) when compared with others treatments, however there was no difference between the GWS (18.12 BW) and RG (16 BW) treatments. The same behavior was also observed for weight empty body (18.4 BW, 14.34 BW and 12.60 BW, respectively) ($P = 0.00026$). A significant

difference (P = 0.00965) was observed for rumen/reticulum, omasum, small intestine, and total gastrointestinal tract to the GS did not differing between GWS and RG. WPPB goats supplemented during the dry period had higher values of morphometric gastrointestinal tract in relation to goats kept on pasture only or restricted grazing.

Key Words: goats, growth, pasture

1649 (M363) Effects of replacing alfalfa hay and corn silage with corn straw in diets on milk production and composition of dairy cows. Y. Zhang[1,2,3], N. Zheng[1,2,3], D. P. Bu[3], M. Zhao[3], X. Q. Zhou[3], and J. Wang[*1,2,3], *[1]Ministry of Agriculture–Laboratory of Quality and Safety Risk Assessment for Dairy Products, Beijing, China, [2]Ministry of Agriculture–Milk and Dairy Product Inspection Center, Beijing, China, [3]State Key Laboratory of Animal Nutrition, Institute of Animal Science, Chinese Academy of Agricultural Sciences, Beijing, China.*

A study was conducted to determine the effects of replacing alfalfa hay and corn silage as the only forage source with corn straw on milk production and composition. Thirty-two primiparous Holstein cows (55 ± 15 d, days in milk) were divided into two groups fed ad libitum a TMR containing either 17.30% alfalfa hay and 18.77% corn silage (control group) or 36.07% corn straw (CS group). The experiment period was 105 d with 14-d adaptation. Cows were fed individually with auto feeding system and food intake was recorded continuously using a computerized monitoring system (RIC system, Insentec B.V., Marknesse, Netherlands). Data were analyzed using the PROC MIXED of SAS (SAS 8.2; SAS Institute Inc., Cary, NC). Dry matter intake (21.35 vs. 17.43 kg/d, $P < 0.01$), crude protein intake (3.84 vs. 2.90 kg/d, $P < 0.01$) and consumption rate (103.25 vs. 68.65 g DM/min) were higher in the control cows, indicating more attractiveness to the cows. Higher milk yield (30.45 vs. 23.12 kg/d, $P < 0.01$), milk protein content (3.66 vs. 3.32%, $P < 0.01$) and yield (1.11 vs. 0.77 kg/d, $P < 0.01$), milk fat yield (1.34 vs. 1.02 kg/d, $P < 0.01$), milk lactose yield (1.47 vs. 1.13 kg/d, $P < 0.01$) were observed in the control cows, whereas milk fat content (4.46 vs. 4.38%, $P = 0.65$), and milk lactose content (4.86 vs. 4.80%, $P = 0.09$) were similar in the two groups. Feed efficiency (1.45 vs. 1.32%, $P < 0.01$), and milk N efficiency (29.68 vs. 26.67%, $P < 0.01$) were higher for control group compared with CS group. In conclusion, replacing alfalfa hay and corn silage with corn straw decreased milk production, and affected milk composition.

Key Words: milk composition, forage, dairy cow

1650 (M364) The use of favored or unfavored ingredients in starter feeds for preweaned calves. M. Terré[*1], and A. Bach[2], *[1]IRTA, Caldes de Montbui, Spain, [2]Dep. of Ruminant Production, IRTA, Caldes de Montbui, Spain.*

When calves are allowed to choose among different ingredients, soybean meal and wheat are the most consumed ingredients commonly used in starter concentrates, whereas canola and oats are among the least consumed. The objective of this study was to evaluate three different starter feeds containing ingredients of different acceptance by calves. Sixty-three (n = 21) Holstein male calves (41 ± 1.3 kg BW, 9 ± 0.9 d of age) were grouped in three treatments: a starter feed (18.6% CP, 21.4% NDF) based on soybean meal (17.5%), wheat (22%) and corn (24%), a starter feed (18.1% CP, 21.5% NDF) based on canola (15%), wheat (22%) and corn (18%), and a starter feed (20.3% CP, 18.5% NDF) based on soybean meal (18.5%), oats (24%) and corn (26.5%). All starter feeds were in a pellet form, and straw was also offered ad libitum. The milk replacer feeding program was the same for all three treatments: 4 L/d at 12.5% DM concentration from 1 to 7 d of study, 6 L/d at 12.5% DM from 8 to 35 d of study, and 3 L/d at 12.5% DM from 36 to 42 d (weaning). Animals were weighed weekly until the end of the study at 49 d, and milk replacer and starter feed intake measured daily. At 30 and 50 d of study, liquid rumen samples were obtained to determine rumen pH. Data were analyzed by PROC MIXED of SAS with repeated measures, being concentrate ingredients composition and week of the study, and their interaction the main effects, and initial BW as a covariate. Animals in all three treatments had similar performance and intake parameters (0.64 ± 0.045 kg DM/d of starter intake, 0.62 ± 0.027 kg/d of ADG). There were no differences in rumen pH (5.65 ± 0.084 pH) among the three treatments. In conclusion, the inclusion of a non-favored ingredient such as canola or oats in a pelleted starter feed did not affect performance parameters of preweaned calves.

RUMINANT NUTRITION II

1651 (T264) In vitro assessment of *Saccharomyces cerevisiae* cell fractions (YCF) using bovine epithelial cells and macrophages. Z. Li[*1], Q. You[1], F. Ossa[2], P. Mead[1], and N. A. Karrow[3], *[1]University of Guelph, Guelph, ON, Canada, [2]Lallemand Inc., Montreal, QC, Canada, [3]Dep. of Animal and Poultry Science, University of Guelph, ON, Canada.*

Since yeast *Saccharomyces cerevisiae* and its cell fractions (yeast cell fractions) are being used for the prevention and treatment of enteric diseases in different species, they may also be useful for preventing Johne's disease, a chronic inflammatory bowel disease of ruminants caused by *Mycobacterium avium* ssp. *paratuberculosis* (MAP). In this study, the adhesion of mCherry-labeled MAP to bovine mammary epithelial cells (Mac-T) co-cultured with CFs from two specific yeast strains (A and B)from the Lallemand culture collection was investigated. Additionally, bovine macrophages (BoMacs) were used to assess potential immunomodulatory properties of these yeast CFs by measuring BoMac viability, reactive oxygen species (ROS) production, and phagocytosis of mCherry-MAP. The Mac-T cells were treated for 6 h with the two CFs at different concentrations (0.25, 0.5, 1, 2, 4, 8, and 16 mg/ml). The highest concentration of CFs that did not affect the Mac-T cell viability was 4 mg/ml for the strain A, and 2 mg/ml for strain B. Non-cytotoxic concentrations of yeast CFs from both strains reduced MAP adhesion to Mac-T cells in a concentration-dependent manner. BoMac cell viability was also assessed after a 6-hour treatment with both yeast CFs, and concentrations $\leq$ 4 mg/ml were deemed non-cytotoxic. BoMac ROS production was measured at non-cytotoxic yeast CF concentrations, and a dose-dependent increase in ROS production was found for both yeast CFs, with strain A being more potent than strain B. Finally, BoMac phagocytosis of m-Cherry-MAP, assessed after 6 h, was prevented by co-culture with non-cytotoxic concentrations of yeast CFs. In summary, yeast CFs may be useful for preventing MAP adhesion to the gastrointestinal epithelium and for stimulating macrophage antimicrobial ROS production.

Key Words: prebiotic, immunomodulation, bovine mammary epithelial cells (Mac-T)

Table 1652. Digestibility of the diet of grazing Nellore bulls receiving concentrated supplementation with or without additives

	Treatments			
Item, %	Control	Lipomax	CV (%)	*P*-value
CDEE1	79.0a	67.9b	7.19	0.004
CDCP2	77.8	75.2	7.46	0.359
CDNDF3	68.2	67.8	7.88	0.817

ME5 (Mcal/Kg)	2.488	2.395	4.68	0.187

[1] CDEE is the coefficient of digestibility of ether extract
[2] CDCP is the coefficient of digestibility of CP.
[3] CDNDF is the coefficient of digestibility of NDF.
[4] CDNFC is the coefficient of digestibility of non-fiber carbohydrates.
[5] ME is the metabolizable energy of the diet.

1652 (T265) Digestibility of the diet of grazing Nellore bulls receiving concentrated supplementation with additives. J. A. C. Lima[*1,2], H. J. Fernandes[2], M. F. Paulino[1], E. P. Rosa[2], L. S. Caramalac[2], K. A. Silveira[2], B. D. D'auria[2], and A. Aguiar[3], *[1]Federal University of Viçosa, Brazil, [2]State University of Mato Grosso do Sul, Aquidauana, Brazil, [3]University of Florida, Gainesville.*

The objective of this study was to evaluate the effect of a commercial concentrate supplement with additives in the digestibility of the nutrients on grazing bulls, during the dry/rainy transition season in Aquidauana–MS, Brazil. Twelve Nellore bulls (initial body weight of 370 ± 15 kg) were randomly assigned to 12 *Brachiaria decumbens* Stapf pastures (1.0 ha/pasture; one bull/pasture) on a completely randomized design. Treatments were: 1) concentrate supplement Lipomax with homeopathic additives (Convert H, Sodo 100, Figotonus) and Virginiamicina (Lipomax treatment), and 2) concentrate supplement with a similar protein content (18% CP), and without additives (Control treatment). Animals were feed daily at rate of 0.5% of the animal's body weight. After 45 d, when the animals achieved body weight closed to 420 kg, the digestibility trial started. Digestibility was estimated using the enriched and purified lignin (LIPE) as marker for fecal excretion estimation, and the indigestible neutral detergent fiber as internal marker. Forage nutritive value was estimated by hand-plucked sampling, and supplement intake was measured directly for each animal. A significance level of 5% was adopted. The coefficients of digestibility (CD) of the nutrients were obtained by the intake and composition of the forage and the supplement, and by analysis of feces, which was collected for five consecutive days. A significance level of 5% was adopted. The digestibility of the ether extract differed ($P < 0.05$), was greater in the Control treatment (Table 1652) and no other differences were significant. The similarity in composition between concentrated supplements, and the fact that the concentrate represented just around 10% of the diet of the animals influenced these results. The additives appears to work just in the animal's metabolism, without affecting the diet digestibility.

Key Words: additives, digestibility, grazing bulls

1653 (T266) Pre- and post-weaning performance and health of calves fed 24% crude protein and 20% fat milk replacer at different feeding rates.

B. M. Strayer*[1], D. Ziegler[2], D. Schimek[3], B. Ziegler[3], M. Raeth-Knight[4], H. Chester-Jones[2], and D. Casper[1], *[1]South Dakota State University, Brookings, [2]University of Minnesota Southern Research and Outreach Center, Waseca, [3]Hubbard Feeds Inc., Mankato, MN, [4]University of Minnesota, St. Paul.*

In our previous work, calves fed greater amounts of milk replacer (MR) and CP demonstrated improved growth. The current study was to evaluate the pre- (d 1 to 42) and post- (d 43 to 56) weaning performance and health of calves fed a 24% CP and 20% fat MR at different feeding rates (FR). One hundred four (1- to 5-d-old) individually fed Holstein heifer calves (40 ± 0.69 kg) were randomly assigned to one of four treatments in a randomized complete block design. The same all milk MR was fed at 14.7% solids with treatments being 1) Control (MR57): MR fed at 0.284 kg in water twice daily for 35 d; 2) MR71: MR fed at 0.34 kg twice daily from d 1 to 7 and at 0.34 kg twice daily from d 8 to 35; 3) MR85: MR fed at 0.34 kg twice daily from d 1 to 7 and at 0.43 kg twice daily from d 8 to 35; and 4) MR99: MR fed at 0.34 kg twice daily from d 1 to 7 and at 0.497 kg twice daily from d 8 to 35. All treatments were fed once daily MR from d 36 to weaning at d 42 with water and an 18% CP texturized calf starter (CS) offered free choice. Pre-weaning and overall ADG (0.78, 0.82, 0.83 and 0.85 kg/d for MR57, MR71, MR85, and MR99, respectively) were higher ($P < 0.05$) for MR99 calves vs. MR57 calves with other calves being intermediate. Overall d 1 to 56 CS intakes were higher for MR57 calves vs. other calf groups. There were no differences ($P > 0.05$) in total DMI. Pre-weaning gain/feed was lowest ($P < 0.05$) for MR57 calves. Gain/feed d 1 to 56 (0.49, 0.52, 0.52 and 0.54 kg/kg DM) was higher for MR99 vs. MR57 calves with other calves being intermediate. This study demonstrated that feeding higher FR of a 24:20 MR resulted in higher ADG's and feed conversions (gain/feed).

Key Words: milk replacers, feeding rate, calf performance

1654 (T267) Pre- and post-weaning performance and health of calves fed milk replacers with two protein concentrations and two feeding rates.

B. M. Strayer*[1], D. Ziegler[2], D. Schimek[3], B. Ziegler[3], M. Raeth-Knight[4], H. Chester-Jones[2], and D. Casper[1], *[1]South Dakota State University, Brookings, [2]University of Minnesota Southern Research and Outreach Center, Waseca, [3]Hubbard Feeds Inc., Mankato, MN, [4]University of Minnesota, St. Paul.*

One hundred eight (1- to 5-d-old) Holstein heifer calves (39.3 ± 0.66 kg) were randomly assigned to one of four milk replacers (MR) to evaluate pre- (d 1 to 42) and post- (d 43 to 56) weaning performance in a 2 × 2 factorial design of crude protein (CP) concentrations (20% (CP) and 24% (HP)) with feeding rates (FR; 0.57 (1) and 0.68 (2) kg/d). Treatments were MR fed at 15% solids of: 1) Control (CP1): a 20% CP:20% fat MR fed at 0.284 kg 2x/d for 35 d; 2) CP2: the 20:20 MR fed at 0.34 kg 2x/d for 35 d; 3) HP1: a 24:20 MR fed at CP1 rate; and 4) HP2: the 24:20 MR fed at CP2 rate. All MR's were fed at 1x/d from d 36 to weaning at d 42 with water and 18% CP texturized calf starter (CS) offered free choice through d 56. No significant ($P > 0.10$) interactions of CP by FR were detected for growth parameters. During d 1 to 14, calves fed CP2 and HP2 had the greatest ADG (0.36, 0.44, 0.36, and 0.45 kg/d for CP1, CP2, HP1 and HP2, respectively) compared to calves fed CP1 and HP1, but the interaction was nonsignificant ($P > 0.10$). Pre-weaning ADG's (d 1 to 42) were similar ($P > 0.10$). Calves fed HP2 had numerically greatest overall ADG d 1 to 56 compared to calves fed CP1 and HP1 with CP2 being intermediate. Intake of CS from d 1 to 56 was similar ($P > 0.10$) for calves fed MR with different CP concentrations (0.77 and 0.78 kg/d), while CS intake (0.81 and 0.74 kg/d) was reduced ($P < 0.05$) for calves fed higher MR FR. Feed conversions from d 1 to 56 were similar for calves fed different CP concentrations (0.54 and 0.55 kg/kg), but were improved when fed higher MR FR (0.53 and 0.56 kg/kg). However, a trend ($P < 0.11$) of CP by FR interaction from d 43 to 56 demonstrated calves fed CP2 having greater feed conversions (0.46, 0.53, 0.46 and 0.49 kg/kg for C-, C+, HP-, and HP+, respectively) compared CP1, HP1 and HP2 calves. Thus, indicating a carryover effect on post-weaning performance for CP2 calves. The results demonstrate calves fed a conventional MR at different FR with different CP concentrations performed similarly. Calves fed higher CP MR at higher FR had numerically the greatest ADG.

Key Words: milk replacers, protein concentration, feeding rate

1655 (T268) The effect of dietary supplementation of artificial sweetener on performance of milk-fed calves.

A. Siurana*[1], E. H. Wall[2], M. Rodríguez[1], L. Castillejos[1], A. Ferret[1], and S. Calsamiglia[1], *[1]Animal Nutrition and Welfare Service, Dep. of Animal and Food Sciences, Universitat Autònoma de Barcelona, Bellaterra, Spain, [2]Pancosma, Geneva, Switzerland.*

The small intestine contains nutrient receptors that react to changes in the composition of ingested feed. The feed additive Sucram (Pancosma, Switzerland) is an artificial sweetener that has been shown to increase absorption of glucose from the small intestine by activating sweet taste receptors in swine, this response results in improved animal performance. Recently, it was reported that a similar increase in glucose absorption was observed in calves supplemented with Sucram; however, it was unclear if there is a corresponding improvement in calf performance. Therefore, the current experiment was per-

formed to determine the effect of Sucram on performance of milk-fed calves. Sixteen male Holstein calves were assigned to two treatments (n = 8 per treatment): control (no additive), or Sucram (daily supplementation of 400 mg g Sucram per kg dry matter of milk replacer). All calves received 2 feeding/d of 2 L of milk replacer plus ad libitum commercial concentrate until weaning (50 d of age). Calves were weighed at the beginning and at the end of the experiment. Individual calf concentrate intake was measured weekly. Blood samples were collected the last day of the trial before feeding to analyze levels of insulin and glucose. Feed efficiency was calculated for each animal (total weight gain/average weekly concentrate intake from wk 2 to 5). Data were subjected to analysis of variance using the PROC MIXED of SAS. For body weight and concentrate intake, data for wk 1 were used as a covariate in the analysis. There were no effect of Sucram on final body weight (67.0 *vs.* 67.3 kg; P = 0.93), but there was a decrease in feed intake of Sucram calves (6.5 vs. 5.7 kg/wk; P = 0.10). Therefore, efficiency of feed was higher in animals supplemented with Sucram (gain/feed = 4.8 vs. 5.71; P = 0.10). There was no effect of Sucram on the concentration of serum insulin (0.23 vs. 0.21 µg/L; P = 0.74) or glucose (78.8 vs. 82.6 mg/dL; P = 0.45). We conclude that supplementation of milk-fed calves with artificial sweetener improves feed efficiency. However, additional experiments are needed to determine the mechanism underlying this response. The use of Sucram in milk replacer represents a potential management tool for dairy producers to increase feed efficiency of milk-fed calves and decrease the cost of animal rearing on commercial farms.

Key Words: sweetener, performance, milk-fed calves

1656 (T269) The effect of supplementation with a blend of capsicum, carvacrol, and cinnamaldehyde on performance of milk-fed calves. A. Siurana*[1], E. H. Wall[2], M. Rodríguez[1], L. Castillejos[1], A. Ferret[1], and S. Calsamiglia[1], *[1]Animal Nutrition and Welfare Service, Dep. of Animal and Food Sciences, Universitat Autònoma de Barcelona, Bellaterra, Spain, [2]Pancosma, Geneva, Switzerland.*

Plant extracts have antimicrobial properties that may reduce the risk of disease and improve the health and performance of young animals. The objective of this experiment was to study the effect of an essential oil feed additive (EO; XT-6930; Pancosma, Switzerland) on the performance of milk-fed calves. Eight male Holstein calves were randomly assigned to one of two treatments (n = 4 per treatment): control (no additive) or EO (115 mg/calf/d of XT-6930 added to milk replacer). Calves were housed in individual hutches and received 2 feeding/d of 2 L of milk replacer (22.4% CP, 20.6% fat) plus ad libitum access to commercial concentrate (16.9% CP; 5.3% crude fiber) until weaning (50 d of age). Calves were weighed at the start and the end of the experiment and concentrate intake was measured individually once a week. Feed efficiency was calculated for each calf as the ratio of body weight gain to average concentrate intake during the experimental period (wk 2 to 5). Blood samples were collected from the jugular vein on the last day of the experiment before feeding to analyze insulin and glucose concentrations. Average daily weight gain was higher (P = 0.02) in EO calves (0.83 kg/d) compared with control (0.63 kg/d) and feed intake was also higher (P = 0.01) in EO compared to control calves (7.23 vs. 5.71 kg/wk, respectively). The efficiency of feed conversion was not affected by treatment (gain/feed = 4.11 vs. 4.09 for EO and control calves, respectively; P = 0.95). There was no effect of treatment on serum concentrations of insulin (0.80 vs. 1.69 µg/L for control and EO, respectively; P = 0.31) or glucose (91.6 vs. 106.2 mg/dL for control and EO, respectively; P = 0.29). We conclude that supplementation of milk replacer with EO increased concentrate intake of milk-fed calves. Although there was no effect on feed efficiency, the increase in average daily weight gain has implications for decreasing costs associated with animal rearing. In addition, the increase in the intake of starter grain may enhance development of the rumen and subsequent animal performance.

Key Words: plant extracts, performance, calves

1657 (T270) Effect of milk replacer solids content on intake, growth and fecal characteristics of Holstein calves. J. D. Quigley*, T. M. Hill, H. G. Bateman, II, J. M. Aldrich, and R. L. Schlotterbeck, *Provimi North America, Brookville, OH.*

Increased energy intake during cold weather is required to maintain adequate calf growth. Many producers have limited ability to increase volume of liquid offered to calves; therefore, increasing solids content (SC) of the MR solution can increase energy content of milk replacer (MR). Common SC are 12 to 13%, but calves may be fed MR with SC up to 18% in some situations. It is unclear whether changing SC may affect performance, intake or health of young calves fed MR. Our objective was to compare different SC in calves fed MR to 56 d. Holstein bull calves (n = 48; initial BW = 45.4 ± 4.0 kg; 2 to 3 d of age) were assigned randomly to receive a commercial MR (Nurture Plus EZ, Provimi North America, Brookville OH) at 0.625 kg of MR powder from 0 to 39 d, then 0.313 kg/d until weaning at d 42. The MR (23% protein and 21% fat, DM basis) was diluted to 10.0, 12.5, 15.0, or 17.5% SC and offered twice daily in open pails. Amount of reconstituted MR offered was 6.25, 5.00, 4.17 and 3.57 kg/d for 10.0, 12.5, 15.0 and 17.5% SC, respectively. Texturized calf starter (CS; 20% CP, DM basis) and water were available for ad libitum consumption throughout the study. Data were analyzed as a completely randomized design using a repeated measures ANOVA. Orthogonal polynomials were used to determine linear and quadratic effects of SC. Pen was the experimental unit. There was no effect (P > 0.10) of SC on average daily gain (0.57 ± 0.027 kg/d), CS intake (0.74 ± 0.06 kg/d), MR intake (0.603 kg/d to weaning),

gain to feed ratio (0.48 ± 0.017 kg ADG/kg DM intake), or hip width change (0.1 ± 0.01 cm/d) from d 0 to 56. Number of abnormal fecal days and medical days preweaning declined linearly ($P < 0.05$) with increasing SC. Number of preweaning abnormal fecal days were 0.22, 0.13, 0.13 and 0.07 ± 0.039 and preweaning medical days were 0.32, 0.25, 0.19 and 0.08 ± 0.056, respectively, for calves fed 10.0, 12.5, 15.0, and 17.5% SC. Increasing milk replacer SC reduced abnormal fecal days and number of treatments.

Key Words: calves, milk replacer, growth

1658 (T271) Pre- and post-weaning performance and health of dairy calves fed all-milk protein milk replacers or partially replacing milk protein in milk replacers with plasma, wheat proteins and soy protein concentrate. D. Ziegler[*1], H. Chester-Jones[1], B. Ziegler[2], D. Schimek[2], M. Raeth-Knight[3], and D. L. Cook[4], *[1]University of Minnesota Southern Research and Outreach Center, Waseca,, [2]Hubbard Feeds Inc., Mankato, MN, [3]University of Minnesota, St. Paul, [4]Milk Products, Chilton, WI.*

One hundred five (2- to 5-d-old) individually fed Holstein heifer calves (39.8 ± 0.73kg) were randomly assigned to one of four treatments to evaluate pre- (d 1 to 42) and post weaning (d 43 to 56) calf performance and health when fed milk replacers (MR) with alternative protein sources. Calves were assigned to non-medicated MR with 1) All milk protein (AM), 2) 50% of total protein from wheat and plasma (WPL), 3) 50% of total protein from soybean protein concentrate (SPC) and plasma (SPL), and 4) 50% combination of wheat, SPC and plasma (SWP). All calves were fed a non- medicated 20% fat:20% CP MR at 0.284 kg in 1.99 L water (12.5% solids) 2x/d for the first 35 d and 1x/d d 36 to weaning at 42 d. Day 1 to 14, 1:1 neomycin:oxytetracycline was added to the MR solution to provide 22 mg/kg BW/d. Calf starter (CS; 18% CP) and water were fed free choice from d 1. Osmolality of the MR were 469, 421, 395, and 412 mOsm/L for AM, WPL, SPL, and SWP, respectively. There were no pre- ($P = 0.11$) or post ($P = 0.30$) weaning ADG differences. Calves averaged 0.74 kg/d gain for the 56-d study. There were no differences in CS ($P = 0.22$) or total DMI ($P = 0.33$) intake, which averaged 55.3 and 77.08 kg for the 56-d study, respectively. Pre-weaning gain/feed was higher ($P < 0.05$) in calves fed WPL vs. those fed SPL and SWP but similar to AM calves. There were no overall 56-d differences in gain/feed ($P = 0.19$). Across treatments, calves doubled their initial BW and gained > 10.2 cm in frame growth. Fecal scores d 1 to 14 and overall were higher ($P < 0.05$) for AM fed calves compared to WPL, SPL, and SWP treatments. The number of scouring d pre-weaning were also higher ($P < 0.05$) for AM calves vs. those fed SPL and SWP with WPL calves being intermediate. There were no differences in health treatment costs. Under the conditions of this study, replacing 50% of the total milk protein in MR with alternative sources resulted in calf performance and health similar to all milk protein.

Key Words: calf performance, milk replacers, alternative proteins.

1659 (T272) Effect of Radix Bupleuri herbal supplementation on diversity of the bacterial community and cellulolytic bacteria in the rumen of lactating dairy cows analyzed by DGGE and RT-PCR. L. Pan, D. P. Bu*, J. Q. Wang, J. B. Cheng, X. Z. Sun, and W. Liu, *State Key Laboratory of Animal Nutrition, Institute of Animal Science, Chinese Academy of Agricultural Sciences, Beijing, China*.

Numerous studies have been completed on use of herbal medicine in substitute for chemical feed additives to modify rumen fermentation. This experiment was conducted to investigate effects of *Radix Bupleuri* herbal supplementation (RBH) on diversity of the bacterial community and cellulolytic bacteria including *Fibrobacter Succinogenes, Ruminococcus albus* and *Ruminococcus flavefaciens* in the rumen of lactating dairy cows analyzed by DGGE and RT-PCR. Forty Holstein cows were assigned to one of 4 groups ($n = 10$) according to milk yield (37.5 ± 1.8 kg/d), day in milk (75 ± 15) and parity (1.7 ± 0.4) in a completely randomized block design. Four treatment diets consisted of supplemental RBH at 0, 0.25, 0.5 or 1.0 g/kg based on dry matter, which were randomly assigned to one of 4 groups. Cows were individually fed the treatment diets, and the experiment lasted for 10 wk in Shanghai. Rumen fluid samples were collected at 2 h post-feeding using stomach-tube on wk 6 of the trial. Rumen samples were strained through four layers of cheesecloth and frozen at -20°C until being analyzed. Rumen microbial DNA was extracted with CTAB plus bead beating and analyzed by DGGE with subsequent cluster and optimal density of the bands analysis. The copy number of rumen cellulolytic bacteria was detected by quantitative RT-PCR with species-specific PCR primers amplifying partial 16S rDNA regions. Diversity index values and data of copy numbers of 16s rDNA were analyzed using GLM procedure of SAS 9.2. DGGE profiles showed that the quantity of bands was similar, while the optimal density was different between control and treatment. The dendrogram of the DGGE fingerprint showed that they were assigned to different clusters by different supplemental levels with DGGE fingerprint similarity less than 0.54 overall. Shannon-Weiner index decreased ($P < 0.05$) especially with 1.0 g/kg RBH, while the dominance index increased ($P < 0.05$) especially at 0.25 and 0.5 g/kg levels compared with the control. RT-PCR revealed no difference in cellulolytic bacteria among groups. In total, RBH supplementation proved little effects on diversity of the bacterial community and cellulolytic bacteria in the rumen of lactating dairy cows potentially owing to gradual adaptation of rumen bacteria to the RBH supplementation.

Key Words: bacterial community, cellulolytic bacteria, Radix Bupleuri

1660 (T273) The effect of soluble propolis in milk on the performance of Holstein suckling calves.

P. Peravian*[1], K. Rezayazdi[2], and G. Nehzati[3], *[1]University of Tehran, Iran, [2]Dep. of Animal Science, Faculty of Agriculture, University of Tehran, Karaj, Iran, [3]University of Tehran, Karaj, Iran.*

This study was conducted to evaluate the effect of added soluble propolis in milk on the dry matter intake, body weight, digestibility and feed efficiency of Holstein suckling calves. Propolis in this experiment was come from Taleghan vicinity (near Tehran). Forty female Holstein calves with average 41 ± 1 kg birth weight were used from 14 to 65 d old. Calves were fed according to completely randomized design with four treatments (rations) and 10 replicates (calves) in each treatment. Treatments included: 1) Control (without Monensin in starter and without propolis in milk), 2) Starter without Monensin and 500ppm soluble propolis powder in milk, 3) Starter without Monensin and 1000ppm soluble propolis powder in milk, and 4) Monensin in starter and without propolis in milk. To reduce the stress of weaning, calves stayed in their boxes after weaning for 9 d. Individual dry matter intake was measured daily, and weight gain was measured each 14 d. Digestibility was measured with fecal sampling after weaning and the marker was acid insoluble ash (AIA). The results showed that dry matter intake had no significant differences among treatments in suckling period. But differences among dry matter intake of calves after suckling period were significant ($P = 0.01$). Means feed intake in whole period for treatments 1 to 4 were 1115.51, 1034.24, 1054.76, 920.81 g/d, respectively, and their differences were significant ($P = 0.04$). Means body weight for treatments 1 to 4 were 64.67, 60.84, 64.89, 62.25 kg, respectively, and there was a significant differences among treatments ($P = 0.01$). The feed efficiency for treatments 1 to 4 were 0.402, 0.393, 0.410, 0.404, and there were no significant differences among treatments ($P = 0.9$). Apparent digestibility of OM (76.76, 76.89, 78.03, and 78.11%), DM (78.97, 76.12, 77.32, and 77.42%) and NDF (57.99, 52.49, 52.89, and 52.60%) for treatments 1 to 4 respectively had no significant differences. The results showed the positive effect of propolis (biological additive) on the both dry matter intake and body weight in compare of Monensin (synthetic additive) which had the lowest dry matter intake and low body weight. Therefore, this study suggested that propolis could improve performance of calves.

Key Words: propolis, performance of calves, Monensin

1661 (T274) Supplementation of lysine and methionine for dairy calves on a step down milk-replacer feeding program.

J. T. Silva*, G. Santos, N. B. Rocha, E. Miqueo, T. Manzoni, and C. M. M. Bittar, *University of Sao Paulo, Piracicaba, Brazil.*

The aim of this study was to evaluate the performance of calves receiving starter concentrate or milk replacer supplemented with lysine and methionine to reach daily intakes of 17 g/d and 5.3 g/d, respectively. Forty-five newborn Holstein male calves were used in a randomized blocks experimental design and distributed into three treatments: 1) Control: no amino acid (AA) supplementation; 2) Starter concentrate: supplementation of lysine and methionine in the concentrate starter; 3) Milk replacer: supplementation of lysine and methionine in the milk replacer. Calves were housed in individual shelters, with free access to water, starter concentrate, and received milk replacer (20CP:16EE; 12.5% solids) according to the program: 4 L/d, until wk 2 of life; 8L/d from the 2 to 6 wk of life; and 4L/d from the 6 to 8 wk, when they were weaned. Calves were followed until the 10 wk of life. Starter concentrate and milk replacer intakes, as well as fecal scores were monitored daily. Body weight, withers height, heart girth and hip width were weekly measured. Supplementation of amino acids in the milk replacer resulted in lower total dry matter after weaning, which resulted on lower daily gain in the same period.

Key Words: amino acids, growth, weaning

Table 1661. Performance of dairy calves receiving starter concentrate or milk replacer supplemented with lysine and methionine

	Control	Starter concentrate	Milk replacer	SEM	$P <$
Body weight, kg					
Initial	36.3	36.3	37.4	2.06	0.267
At weaning	47.57	47.74	48.80	2.06	0.267
Final	54.55	54.73	56.1	2.07	0.267
Daily gain, g					
Before weaning	193.9	232.0	151.7	34.44	0.275
After weaning	553.5 ab	676.1 a	344.0 b	141.41	0.028
Starter intake, g/d					
At weaning	306.1	348.4	180.2	68.21	0.423
Final	1502.7	1615.61	1235.1	94.4	0.372
Total dry matter intake, g/d					
Before weaning	793.7	850.2	787.6	20.98	0.078
After weaning	1293.5 a	1341.3 a	950.6 b	90.69	0.009
Feed efficiency, daily gain/total intake	0.23	0.24	0.14	0.04	0.120
Fecal score	2.35	1.83	2.02	0.35	0.640
Height withers gain, cm/week	0.64	0.76	0.65	0.41	0.976
Heart girth gain, cm/week	1.09	1.44	0.96	0.18	0.184
Hip width gain, cm/week	0.33	0.30	0.31	0.03	0.889

[ab] means with different letters differ at $P < 0.5$

1662 (T275) Response of newborn calves to injectable vitamins A, D and E. D. B. Snider[*1], J. Gaska[2], D. E. Gockowski[3], and R. L. Stuart[4], *[1]Iowa State University, Ames, [2]Gaska Dairy Health Services, Columbus, WI, [3]North Ridge Veterinary Service, Sturgeon Lake, MN, [4]Stuart Products Inc, Bedford, TX*.

Due to poor placental transfer, newborn calves depend mainly on colostrum and milk to supply fat-soluble vitamin needs. If the dam has not received sufficient fat-soluble vitamins during gestation, colostrum may be deficient in these critically important vitamins resulting in deficiencies in the newborn. Weak-calf syndrome has been shown to be partly due to vitamins E and A deficiencies in calves. Injecting fat-soluble vitamins at birth is a method to enhance fat-soluble vitamin status during the first few weeks after birth. Two experiments were conducted to measure efficacy of a commercial product (VITAL E-Newborn, Stuart Products, Inc.) in newborn beef and dairy calves. The product contained 500 I.U. vitamin E, 50,000 I.U. vitamin A and 50,000 I.U. vitamin D per mL. In experiment 1, newborn beef calves (n = 4) were not injected and calves (n = 4) injected S.Q. with 5 mL VITAL E-Newborn. Serum samples were taken initially and Days 1, 2, and 7 post-injection and analyzed for α-tocopherol, total vitamin A (retinol plus retinyl-palmitate), and 25-OH-D3. In experiment 2, newborn dairy calves (n = 4) were not injected and calves (n = 7) were injected S.Q. with 5 mL VITAL E-Newborn. Serum samples were taken 62 h post-injection and analyzed for α-tocopherol, retinol and 25-OH-D3. For experiment 1, serum α-tocopherol concentrations in non-injected calves were 0.26, 0.46, 0.63, and 1.14 μg/mL; total vitamin A concentrations were 0.077, 0.126, 0.152, and 0.123 μg/mL; and 25-OH-D3 concentrations were 10.0, 9.0, 9.3, and 10.6 hg/mL, for d 0, 1, 2, and 7, respectively. Vitamin-injected calves had serum α-tocopherol concentrations of 0.40, 16.4, 12.6, 5.9 μg/mL; total vitamin A concentrations of 0.053, 0.262, 0.270, and 0.151 μg/mL; and 25-OH-D3 concentrations of 6.0, 23.0, 42.1 and 54.7 hg/mL for d 0, 1, 2, and 7, respectively. All post-injection serum vitamin concentrations between treatments were different (P < 0.001). Experiment 2 had similar results as experiment 1. At 62 h post-injection, average serum α-tocopherol concentrations were 1.30 and 10.20 (P < 0.001); average serum retinol concentrations were 0.128 and 0.154 μg/mL (P < 0.10); and average serum 25-OH-D3 concentrations were 24.2 and 78.6 hg/mL (P < 0.001) for control and injected calves, respectively. Injecting newborn calves with a bioavailable source of fat-soluble vitamins is an excellent method to assure that newborn beef and dairy calves have adequate levels of these critically important vitamins after birth.

Key Words: vitamin A, vitamin E, vitamin D, newborn, injectable

1663 (T276) Fecal scores, hemogasometry and blood metabolites of diarrheic calves fed concentrate containing sugarcane molasses or glucose syrup as a replacement for corn. M. C. Soares[1], G. G. O. Nápoles[1], C. E. Oltramari[2], J. T. Silva[1], M. R. De Paula[1], and C. M. M. Bittar[*1], *[1]University of Sao Paulo, Piracicaba, Brazil, [2]University of Santa Catarina State, Chapecó, Brazil.*

During the milk-feeding period, 32 calves were distributed into four treatments: 1) Control: starter feed containing corn as the main energy source (65% corn; 24% soybean meal; 10% soybean hulls, 1% minerals and vitamins, on dry matter basis); 2) 5SCM: 5% (DM) of sugarcane molasses replacing corn; 3) 10SCM: 10% (DM) of sugarcane molasses replacing corn; 4) 5GS: 5% glucose syrup (DM) replacing corn. Animals were individually housed, with free access to water and concentrate, and received 4 L/d of milk replacer (20:16; 12.5% solids). After the diagnosis of diarrhea, evaluations of fecal score and measurement of respiratory and heart beat rates as well as rectal temperature were performed 3x/d, during three consecutive d. Blood samples were collected for blood cells count, electrolytes, blood gases and biochemical parameters analysis. Concentrate composition had no negative effect (P > 0.05) on fecal score, which were higher than 2.5 during the first 4 wk and decreased thereafter for all treatments. There was a tendency (P < 0.09) for higher rectal temperature (39.1; 39.4; 39.5; 39.1 for Control, 5SCM, 10SCM and 5GS, respectively) and respiratory rate (36.2; 41.9; 46.3; 34.0 breaths/min for Control, 5SCM, 10SCM and 5GS, respectively) for calves fed both levels of molasses. Respiratory rate, heart beat rate and rectal temperature increased during the day, as temperature-humidity index also increased. Replacement of corn by co-products had no effect (P > 0.05) on total erythrocytes (6.87×10^6/μL), mean corpuscular volume (37.9 fL) and hemoglobin (8.99 g/DL), however hematocrit was increased (P < 0.05) as co-products were fed (23.0a; 26.4b; 28.9c; 25.1b for Control, 5SCM, 10SCM and 5GS, respectively). There were no concentrate composition effects on blood pH (7.33), HCO_3 (28.18 mmol/L), PCO_2 (52.6 mmHg), K and Na (4.9 and 135.7 mEq/L, respectively), anion gap (13.38 mmol/L) and base excess (2.33 mmol/L) concentration. Plasma metabolites were also not affected by replacement of corn by co-products in the concentrate, with values of BHBA (0.06 mml/L), glucose (82.5 mg/dL), total protein (6.8 g/dL), PUN (7.1 mg/dL) and total lactate (16.45 mg/dL) within the normal physiological range for dairy calves during the milk-feeding period. Replacement of corn with molasses or glucose syrup in the supplement did not affect animals' metabolism in response to the occurrence of diarrhea and can be used as an alternative for feeding dairy calves.

Key Words: byproducts, metabolic disorders, milk-feeding, starter feed

1664 (T277) Fecal scores, hemogasometry and blood parameters of diarrheic calves fed concentrate containing citrus pulp as a replacement for corn. M. C. Soares[1], C. E. Oltramari[2], J. T. Silva[1], M. R. De Paula[1], M. P. Gallo[1], and C. M. M. Bittar[*1], [1]*University of Sao Paulo, Piracicaba, Brazil,* [2]*University of Santa Catarina State, Chapecó, Brazil.*

During the milk-feeding period, 24 calves were distributed into three treatments: 1) Control: starter feed containing corn as the main energy source (64% corn; 26% soybean meal; 6% wheat meal; 3% limestone; 1% minerals and vitamins, on dry matter basis); 2) 50CP: 50% (DM) of citrus pulp replacing corn, 3) 100CP: 100% (DM) of citrus pulp replacing corn. Animals were individually housed, with free access to water and concentrate, and received 4 L/d of milk replacer (20:16; 12.5% solids). After the diagnosis of diarrhea, evaluations of fecal score and measurement of respiratory and heart beat rate and rectal temperature were performed 3x/d, during three consecutive days. Blood samples were collected for blood cells count, electrolytes, blood gases and biochemical parameters analysis. Concentrate composition had no negative effect ($P > 0.05$) on fecal score, which were higher than 2.5 during the first 4 wk and decreased thereafter. Respiratory and heart beat rates were not affected ($P > 0.05$), as well as rectal temperature, however values were always lower at 7 h as compared to 12 h and 19 h evaluations, suggesting high impact of environmental conditions for sick calves. Inclusion of citrus pulp in concentrate had no effect ($P > 0.05$) on hematocrit (23.9%) and total erythrocytes (6.93×10^6/μL), but affected the mean corpuscular volume, with the highest value for animals fed 50CP (40.3fL). Increase of total leukocytes and neutrophils suggests the occurrence of an infectious instead of an alimentary diarrhea. Blood gases, electrolytes and biochemical data did differ ($P > 0.05$) nor resulted in dehydration, acidosis, or any other metabolic disturbance in animals. There were no concentrate composition effects on blood pH (7.36), HCO_3 (27.16 mmol/L), PCO_2 (52.3 mmHg), K and Na (4.6 and 134.1 mEq/L, respectively), anion gap (12.2 mmol/L) and base excess (4.7 mmol/L). Plasma metabolites such as BHBA (0.057mml/L), glucose (85.6 mg/dL) and PUN (7.96 mg/dL) were not affected; however, total lactate and D-lactate were lower ($P < 0.05$) for calves fed 50CP (16.0; 9.17 mg/dL respectively), as compared to control (20.8; 14.7 mg/dL) and 100CP (23.8; 14.4 mg/dL); while L-lactate lowest for 100CP (9.42; 6.8; 6.1 mg/dL for 100CP, 50CP and control, respectively). Replacement of corn by citrus pulp in the concentrate did not affect animals' metabolism in response to the occurrence of diarrhea, being an alternative for feeding dairy calves.

Key Words: byproducts; metabolic disorders; milk-feeding; starter feed

1665 (T278) Effect of diet particle size on sorting, eating rate, rumen ph and digestibility in dairy heifers. F. H. Pino*, A. J. Heinrichs, and C. Castro, *Pennsylvania State University, University Park.*

Eight cannulated dairy heifers (19.3 ± 0.8 mo of age and 524.51 ± 10.01 kg of BW) were fed either long (62.7mm; LCS) or short (6.1mm; SCS) cut corn silage at 1.65% BW in individual stalls to determine eating behavior and digestion parameters. Diets consisted of 70% corn silage, 11% ground corn, 8% citrus pulp, 6% canola meal, 2% soy bean hulls, 1.2% Optigen and 2% mineral/vitamin mix fed once daily. Heifers were subject to a cross over design study with 18-d periods; 14 d adaptation 4 d sampling. Particle size of theTMR was measured at 0 and 2 h after feeding. Feces were collected (d 14 to 18) to determine DM digestibility. Rumen contents were sampled (d 17 to 18) to measure pH at 0, 1, 2, 4, 8, 12, 16, 20, and 22 h after feeding. Data were analyzed with PROC MIXED of SAS 9.4. The LCS ration had an increase of 91% of long (> 19 mm) feed particles 2 h after feeding with no change in feed particles on the SCS diet. Feed particles retained on the eight 4-mm and pan sieves decreased 7, 30, and 35%, respectively. The overall rate of eating was not different between treatments (2.75 vs. 2.37 kg/h SCS and LCS, respectively; $P = 0.47$). Rumen pH changed throughout the day from 7.1 to 4.7 from feeding to 8 h post feeding but was not different between treatments ($P = 0.55$). It is likely that these variables were not different because the heifers were fed a restricted diet (8.73 ± 0.19 kg of DMI) that was consumed by 4 h after feeding. The DM digestibility of diets (75.24 ± 2.2%) was not different ($P = 0.37$). In conclusion, there are no differences in rumen pH, eating rate and DM digestiblity with different particle size diets. Differences in the TMR particle size 2 h after feeding suggest that heifers sort the diets indicating selective consumption of the small particles and selective refusal for the long feed particles. This sorting could promote competition and selective consumption of feed particles by the more dominant heifers, which could lead to inappropriate and variable nutrition for heifers with group fed animals.

Key Words: heifers, sorting, DM digestibility

1666 (T279) Fatty acid profiles of *Longissimus dorsi* from Nellore cattle on pasture supplemented with crude glycerin and whole cottonseed. J. T. Zervoudakis[*1], A. J. Possamai[2], L. K. Hatamoto-Zervoudakis[1], A. S. Oliveira[3], L. B. D. Freiria[1], R. P. D. Silva[1], A. C. Barboza[2], and J. W. Koscheck[4], [1]*Federal University of Mato Grosso, Cuiaba, Brazil,* [2]*UFMT, Cuiabá, Brazil,* [3]*UFMT, Sinop, Brazil,* [4]*UNESP, Jaboticabal, Brazil.*

There is interest in the composition of fatty acids (FA) in beef for reduction of short-chain FA, with increment of medium-chain and omega-3 FA, by their anticarcinogenic and

immune-stimulatory effects. Nutritional strategies to improve meat quality should be studied to possibility better meat FA profile in this products. The aim of this experiment was to evaluate whole cottonseed and crude glycerin association in multiple supplements for 50 Nellore cattle in the fattening phase at *Brachiaria brizantha* pastures on longisssimus dorse FA profile. Animals were supplemented with 4 kg/d (21% of crude protein). The experiment was performed in a 2 × 2 factorial design (two levels of crude glycerin (0 and 15%) and two levels of whole cottonseed (0 and 25%). Orthogonal contrasts were used to evaluated the effect of crude glycerine, whole cottonseed and the interaction, adopting 0.05 to the critical level of probability. Inclusion of whole cottonseed reduced the quantity of hypercholesterolemic FA: C14:C19 ($P = 0.049$), C16:0 ($P = 0.038$), C16:C19 ($P = 0.006$) and C17:0 ($P = 0.028$). However, inclusion of crude glycerin increased C17:0 ($P = 0.002$) and C17:1 ($P = 0.003$). The cottonseed promoted an increase in the concentration of C18:0 ($P < 0.001$) possibly due to extensive biohydrogenation of isomers C18:1, C18:2 and C18:3 ($P < 0.001$). The glycerin promoted an increase in C18:2c9*t*11 conjugated linoleic acid ($P = 0.046$) due to reduction in lipolysis of FA in the rumen, with limited biohydrogenation. The C20:1 ($P = 0.02$) was reduced by feeding of cottonseed, due to the low concentration of this fatty acid in the ingredient. There was no influence of the inclusion of glycerin and/or cottonseed on the total of saturated FA, monounsaturated or polyunsaturated FA, as well as their relations ($P > 0.05$). The supply of glycerin and whole cottonseed modify the FA profile, because of ruminal biohydrogenation modulation by glycerine, for healthy meat production.

Key Words: meat quality, supplementation, stearic acid

1667 (T280) Performance and carcass attributes of Nellore heifers fed with zilpaterol hydrochloride.

N. R. B. Cônsolo[*1], R. S. Goulart[2], F. Rodriguez[1], M. O. Frasseto[1], J. M. Souza[1], L. F. P. Silva[1], and V. B. Ferrari[1], *[1]University of Sao Paulo, Pirassununga, Brazil, [2]MSD Saúde Animal, Sao Paulo, Brazil.*

Greater efficiency of production is mandatory in modern beef cattle industry, and use of feed additives, such as β-adrenergic agonists, have demonstrated positive results with *Bos taurus* cattle. However, there are no consistent data on the effects of these substances in Nellore (*Bos indicus*), which accounts for more than 70% of the Brazilian beef cattle. Therefore it was the objective of this study to evaluate the effects of zilpaterol hydrochloride (Zilmax) on the performance and carcass attributes of Nellore heifers. Seventy-two animals with 267 kg of BW and 18 mo of age were fed in a feedlot system for 135 d. Heifers were separated into two treatment groups: Control (C) and Zilpaterol (Z), which received the same diet containing 14% of crude protein, and formulated with corn silage, ground corn, soybean meal and mineral premix. The Z group received Zilmax at 8.3 mg/kg dry matter. Heifers were allotted to 18 pens ($n = 9$) and assigned in a completely randomized design. Animals were weighed at 21-d intervals after 16-h fasting to evaluate growth performance. Zilmax was administrated during the last 30 d of feeding, allowing 3 d of withdraw before slaughter. All animals were slaughtered in a commercial plant, according to proper welfare guidelines. Hot carcass weight, carcass yield, kidney, pelvic and abdominal fat weight were measured. Twenty-4 h later, longissimus muscle area and backfat thickness were measured at the interface of the 12th and 13th ribs. Zilpaterol administration increased ($P < 0.01$) final body weight (404 vs. 387 kg), average dairy gain (1.46 vs. 1.14 kg/d), hot carcass weight (224 vs. 208kg), and dressing percentage (56 vs. 54%) compared with control. However, no effects ($P > 0.10$) were noted in the longissimus muscle area (73.1 vs. 83.5 cm^2) and subcutaneous fat depth (5.2 vs. 4.8 mm) between C and Z group, respectively. In addition, there was a reduction in kidney and pelvic fat by zilpaterol administration compared with C (4.6 vs. 5.7% of hot carcass weight). In conclusion, zilpaterol treatment improved the performance and carcass characteristics of Nellore heifers in feedlot system.

Key Words: heifers, Nellore, zilpaterol

1668 (T281) Carcass characteristics of Nellore steers fed whole corn diets containing feed antibiotics.

B. J. M. Lemos[1], F. G. F. Castro[2], B. P. C. Mendonça[2], C. E. Dambros[1], D. B. Fernandes[2], A. L. Braga Netto[2], V. R. M. Couto[1], and J. J. R. Fernandes[*1], *[1]Universidade Federal de Goiás, Goiânia, Brazil, [2]AgroCria, Goiânia, Brazil.*

The objective was to investigate the effects of feed antibiotics on carcass characteristics of feedlot steers fed whole corn diets. Ninety-seven Nellore steers (302 ± 47 kg of BW and 24 mo of age) were assigned to a randomized complete block design experiment with four blocks (based on initial BW) and five treatments (Mon30: monensin 30 ppm; Virg25: virginiamycin 25 ppm; Mon20+Virg25: monensin 20 ppm + virginiamycin 25 ppm; Fla40: flavomycin 40 ppm; Mon20+Fla20: monensin 20 ppm + flavomycin 20 ppm). Pen was the experimental unit. The steers were slaughtered after a 100-d period of feeding. Steers were fed TMR (88.2% DM, 12.5% CP, 71.5% TDN) with 85% whole grain corn and 15% pelleted protein concentrate on a DM basis. Feed was supplied ad libitum. Steers were weighed after a 16-h fast on d 100 of the experimental period to determine final body weight. Hot carcass weight was determined after skinning and evisceration. Hot carcass yield was obtained at the time of slaughter. Subcutaneous fat thickness (FT) was measurement in *Longissumus dorsi*muscle at 12th rib. No carcass characteristic measures of feedlot Nellore steers fed whole corn diets were affected by the different feed antibiotics (Table 1668). Carcass characteristic values were higher than data reported previously for Nellore steers fed high-concentrate diets based on corn (267.0 kg HCW, 54.6% HCY), except by FT (3.9 mm) (Silva, 2009).

A relatively short number of animals ($n = 97$) was used in this experiment. It is not known if a higher number would have affected the variables studied.

Key Words: beef cattle, feedlot, finishing

1669 (T282) Fatty acids ratio of loin from lambs fed with increasing levels of crude glycerin in feedlot.

C. M. Cunha[1], A. R. M. Fernandes[1], H. A. Ricardo[*1], L. V. C. Girão[2], R. O. Roça[3], L. O. Seno[1], M. A. P. Orrico Junior[1], J. C. S. Osório[1], and F. M. Vargas Junior[1], *[1]Grande Dourados Federal University (UFGD), Dourados, Brazil, [2]Uberlândia Federal University (UFU), Uberlândia, Brazil, [3]São Paulo State University (FCA/UNESP), Botucatu, Brazil.*

The crude glycerin (CG) has been successfully used in ruminant nutrition as energy concentrate substitute. The objective of the study was to evaluate the effect of increasing levels of CG on loin fatty acids (FA) ratio. Lambs (24) with a mean body weight of 20.0 kg were used. Animals used in the study belong to a group of native sheep of the State of Mato Grosso do Sul, Brazil, called Pantaneiros. The experiment was conducted in a completely randomized design with four treatments: 0, 2.5, 5.0, and 7.5% of CG inclusion as a % of diet dry matter (DM). Diets were formulated to be isonitrogenous and isocaloric only varying the inclusion of CG to replace coarse ground corn, to provide an average gain of 250 g/day. Oat hay was used as roughage and concentrate was composed of corn and/or CG, soybean meal, ground soybean and mineral mix, with a roughage:concentrate ratio of 25:75. Body condition (BC) was used as slaughter criterion. As soon animals had a BC between 3.0 and 3.5 slaughter was performed. After 24 h of chilling at 4°C, loin cuts obtained from deboned *Longissimus* between first and least lumbar vertebra of left side of the carcasses were used to determine FA profile (% of total FA) and ratio. There was no effect ($P = 0.1052$) of CG level on polyunsaturated (PUFA), monounsaturated (MUFA), saturated fatty acids (SFA), and ω6 percentages and on PUFA:SFA, and MUFA:SFA ratio. As CG increased, there was a linear decrease in unsaturated fatty acids (UFA) percentage ($P = 0.0304$; $R^2 = 0.16$; RSD = 2.49), and a linear decrease in ω3% ($P = 0.0084$; $R^2 = 0.26$; RSD = 0.13). UFA:SFA decreased linearly with the CG inclusion ($P = 0.0321$; $R^2 = 0.10$; RSD = 0.09) while ω6:ω3 had a linear increase ($P = 0.0289$; $R^2 = 0.18$; RSD = 1.58).

Key Words: crude glycerin, fatty acids ratio, lamb loin

1670 (T283) Performance and carcass yield of finishing lambs fed diets with safflower meal.

P. A. Meneses-Tapia[1], G. Buendia-Rodriguez[2], F. E. Martinez-Castañeda[1], C. G. Peñuelas-Rivas[1], and S. S. Gonzalez-Muñoz[*3], *[1]Universidad Autonoma del Estado de México, Toluca, [2]CENIDFyMA INIFAP, Queretaro, México, [3]Colegio de Postgraduados, Montecillo Estado de México.*

Studies about oilseed meals are important due to its relationship with fatty acids content and nutritive value of meat. So far, information is scarce about levels of fatty acids in tissues of lambs fed safflower meals. Therefore, the objective of this experiment was to evaluate the effect of a concentrated diet (30% sorghum, 30% corn grain, 15% alfalfa hay; 14.5% CP and 2.98 Mcal EM) plus three levels (treatments) of safflower meal: 0% (control), 10% and 15%, fed to 24 Dorper lambs (22.18 ± 2.6 live BW) housed in metabolic cages during 60 d. The experimental design was completely randomized with three treatments and eight replications. Data were analyzed using GLM procedure (SAS v9.2) and treatments means were compared with Tukey test ($P \leq 0.05$). Variables evaluated were daily dry matter intake (DDMI, g), average daily gain (ADG, g), feed conversion (FC), dry matter digestibility (DMD, %) and carcass yield (CY, %). Safflower meal (0, 10, and 15%) changed ($P \leq 0.05$) ADG (328^b, 367^a, 365^a g), DDMI (1534^b, 1621^a, 1573^b g) and CY (47.8^b, 51.0^a, $51.2\%^a$); however, it did not affect ($P > 0.05$) FC (4.68, 4.42, 4.30 g) neither DMD (65.87, 66.74, 64.89%). These results allow concluding that safflower meal increased average daily gain and carcass yield in finishing lambs.

Key Words: lambs, safflower meal, performance and carcass yield

1671 (T284) Quality traits of *Longissimus* muscle of two genetic groups fed with crude glycerin.

I. M. de Oliveira[*1], J. P. I. S. Monnerat[2], N. V. L. Serão[3], M. S. Duarte[4], V. R. M. Couto[5], S. C. Valadares Filho[4], M. L. Chizzotti[4], and P. V. R. Paulino[6], *[1]APTA– Agência Paulista de Tecnologia dos Agronegócios, Colina, Brazil, [2]Universidade Federal de Viçosa, Brazil, [3]Iowa State University, Ames, [4]Universidade Federal de Viçosa, Minas Gerais, Brazil, [5]Universidade Federal de Goiás, Goiânia, Brazil, [6]Nutron Alimentos Ltda., Campinas, Brazil.*

Quality traits of *Longissimus* muscle of two genetic groups: Nellore (NE) and F1 Red Angus x Nellore (NA), with 18 mo

of age, fed diets containing 5 and 15% of crude glycerin for 84 d, were evaluated. Higher concentration of blood glucose was observed in NE (P = 0.0097) than in F1 cross, and it was not affected by diet (P = 0.9573). No effects of genetic group (P = 0.0908) and crude glycerin (P = 0.0733) were observed on serum insulin, carcass pH and final temperature, frequency of muscle fiber type and size of type IIB fiber, beef color, shear-force, myofibrillar fragmentation index, purge loss, ether extract, ashes, and moisture content. The size of type I muscle fiber did not differ (P = 0.0521) among genetic groups and was larger in muscle from animals fed 15% of crude glycerin (P = 0.0244). The size of type IIA muscle fibers was greater in *Longissimus* muscle of F1 cross (P = 0.0002) than NE cattle, and in *Longissimus* muscle from animals fed 15% crude glycerin (P = 0.0068) compared to those fed diets with other levels evaluated. Collagen solubility was greater in meat of F1 cross (P < 0.0001) compared to NE cattle and was not affected by diet (P = 0.1146). There was interaction among genetic group and diet on total collagen amount (P = 0.0002) in beef. Greater crude protein level was observed on beef from animals fed 15% of crude glycerin (P = 0.0468). However, crude protein was not affected (P = 0.2197) by genetic group. The inclusion of crude glycerin in diets does not affect beef quality traits. These data show that it is possible to produce beef with desirable quality traits by using F1 Red Angus x Nellore and Nellore cattle.

Key Words: collagen, fiber, insulin

1672 (T285) Effects of corn processing method and dietary starch level on finishing performance of Nellore bulls.

M. Caetano[1,2], R. S. Goulart[3], S. Luz e Silva[4], J. S. Drouillard[5], P. R. Leme[4], and D. P. D. Lanna[*1], *[1]University of Sao Paulo/ESALQ, Piracicaba, Brazil, [2]University of Adelaide, Roseworthy, Australia, [3]MSD Saúde Animal, Sao Paulo, Brazil, [4]University of Sao Paulo/FZEA, Pirassununga, Brazil, [5]Kansas State University, Manhattan.*

The objective of this study was to evaluate flint corn processing method (CPM) and level of starch for finishing Nellore bulls with high-concentrate, corn-based diets. Nellore bulls (n = 112; 378.25 ± 21.28 kg) were used in a randomized complete block design in a 4 × 2 factorial arrangement. Four starch levels (30, 35, 40, and 45% of diet DM) were evaluated for two CPM: high moisture corn (HMC) and finely ground dry corn (FGC). Animals were offered ad libitum access to diets delivered twice daily in individual pens. Flint corn had 77.2% vitreousness, and corn geometric particle sizes were 1.30 and 5.84 mm for FGC and HMC, respectively. Bulls were adapted to the finishing diet over a 18 d period and fed a total of 75 d. To determine fecal starch (FS) concentration, each animal was sampled by rectal palpation on d 47 of the feeding period. The first derivative was solved of a second order polynomial to determine optimal dietary starch level (DSL). Interaction between CPM and DSL was observed for G:F (P = 0.04). Animals fed HMC 35% up to 45% DSL were more efficient than those fed HMC 30% DSL. However, G:F for bulls fed FGC 30% up to 45% DSL had no difference. DMI was 13.6% greater for FGC than those fed HMC (P < 0.01), but the final BW and ADG was not affected by CPM. Increases in the DSL resulted quadratic decreases in the DMI (P = 0.02) and linear decreases in the ME intake (P < 0.01). Interactions between CPM and DSL were found (P = 0.02), bulls fed HMC showed a linear increase in NEm (P = 0.02), NEg (P = 0.02) and ME (P = 0.02) when the DSL increased. However, NEm, NEg and ME for bulls fed FGC were not different with inclusions of DSL. Bulls fed HMC showed 2.75 times lower FS than those bulls fed FGC (P < 0.01), consequently the fecal pH was greater for HMC than FGC (P < 0.01). Fecal DM were 31.4% greater for FGC than HMC (P < 0.01), consequently the density was greater for FGC feces than HMC (1.120 vs. 1.098 g/mL; P = 0.02). In conclusion, HMC improved growth efficiency of Nellore cattle and the proportion of DSL required to optimize performance was dependent on CPM.

Key Words: feedlot, starch, Zebu

1673 (T286) Effect of wheat dried distillers grains with soubles inclusion and fibrolytic enzyme supplementation on ruminal fermentation and digestibility in beef heifers fed backgrounding diet.

Z. He[*1,2], N. D. Walker[3], T. A. McAllister[4], and W. Yang[1], *[1]Lethbridge Research Centre, Agriculture and Agri-Food Canada, Lethbridge, AB, [2]Key Laboratory for Agro-Ecological Processes in Subtropical Region, Institute of Subtropical Agriculture, Chinese Academy of Sciences, Changsha, China, [3]AB Vista Feed Ingredients, Marlborough, UK, [4]Agriculture and Agri-Food Canada, Lethbridge, AB.*

A metabolic study was conducted to evaluate the effects of wheat dried distillers grain with solubles (DDGS) inclusion and fibrolytic enzyme (FE) application on digestibility, ruminal pH and fermentation in beef heifers. Six ruminally cannulated Angus heifers (averaged BW 794 kg) were used in a 6 × 6 Latin square design with 2 × 3 factorial arrangement. Treatments were control (CON; 50% barley silage, 10% grass hay, and 40% barley grain-based concentrate) and WDG (CON diet substituting 15% DDGS for barley grain) diets combined with 3 FE dosages (0, 1, and 2 mL FE/kg diet DM). Ruminal digestibility of wheat DDGS, barley silage and grass hay was measured using in situ technique and total digestibility was determined using Yb as external digesta marker. Heifers were fed at restriction of 90% ad libitum. Statistical analyses were conducted using the PROC MIXED of SAS with model including fixed effects of diet, FE and their interaction. In situ ruminal DM disappearance (DMD) of DDGS and grass hay

did not differ between WDG and CON after 12, 24, or 48 h of incubation, whereas in situ ruminal DMD (34.0 vs. 36.9%; $P = 0.01$) of barley silage was greater in heifers fed WDG than CON after 24 h of incubation. Increasing FE application quadratically ($P = 0.04$) changed in situ DMD (61.1, 63.1 to 59.3%) of DDGS after 24 h of incubation and linearly ($P = 0.03$) increased in situ NDFD of barley silage (14.9 to 18.9%) after 24 h of incubation. There was no interaction between diet and FE dosages on total digestibility and ruminal pH and VFA concentration. Inclusion of DDGS increased the digestibility (CON vs. WDG) of CP (58.9 vs. 67.6%; $P < 0.01$), NDF (32.7 vs. 37.4%; $P = 0.04$) and ADF (25.0 vs. 31.0%; $P = 0.03$). Increasing FE linearly ($P = 0.03$) increased CP digestibility from 61.8, 63.5 to 64.5% without affecting the digestibility of other nutrients. There were no effects of DDGS inclusion and FE dosages on ruminal pH and VFA concentration except the concentration of propionate was greater ($P = 0.04$) with WDG (19.5 m*M*) than CON (18.5 m*M*). These results indicate that inclusion of wheat DDGS or supplementation of FE in barley silage-based background diet improved ruminal and total digestibility of NDF and CP, and had potential to improve feed efficiency in beef cattle.

Key Words: backgrounding beef heifers, fibrolytic enzyme, wheat distillers grain

---

1674 (T287) Increasing condensed corn distillers solubles affects gene expression in rumen epithelial tissue. J. C. McCann[*1], S. Alqarni[1], J. R. Segers[2], D. W. Shike[1], and J. J. Loor[1], [1]*University of Illinois, Urbana,* [2]*University of Georgia, Tifton, GA.*

Five ruminally-fistulated steers were used in a 5 × 5 Latin square design to determine the effects of increasing dietary fat from corn distillers solubles (CDS) on the gene expression within rumen epithelial tissue. Treatments included a corn-based control (CON), and four levels of CDS (0, 10, 19, and 27%) in a coproduct-based (corn gluten feed and soybean hulls) diet. Fat concentrations were formulated to 3, 5, 7, and 9%, respectively, for diets containing CDS, and all steers were fed to ad libitum intake once daily. After 18 d of adaptation to the diet, ruminal epithelium tissue was collected and frozen in liquid N. Real-time quantitative PCR was used to determine dietary effects on expression of genes related to fatty acid oxidation, ketogenesis, transcriptional regulation, and monocarboxylic transporters. Data were analyzed using the PROC MIXED of SAS with treatment and period as fixed effects and steer as the random effect. Pairwise comparisons were implemented to separate means. Genes associated with long chain fatty oxidation (CPTIA, ACADS, and ACADS) were affected by treatment ($P \leq 0.01$). Steers fed 10% CDS diet had the least epithelial mRNA expression of CPTIA and ACADSB compared with all other treatments ($P < 0.01$). ACADS epithelial mRNA expression was decreased in epithelial tissues of steers fed 0 and 10% CDS diets. Among genes related to ketogenesis, HMGCS2 was affected by treatment ($P = 0.02$); epithelial mRNA expression remained similar for CON, 0%, 19%, and 27% CDS, but HMGCS2 was downregulated for steers fed 10% CDS diet. Although ACAT1 was affected by treatment ($P = 0.04$), CON and 10% CDS had less expression compared to 19% CDS treatment ($P \leq 0.01$). Expression of transcriptional regulation-associated genes (PPARA and RXRA) in rumen epithelium was not consistent. PPARA mRNA expression was the greatest for 27% CDS treatment and alternatively the least for 10% CDS. However, RXRA was affected by treatment ($P = 0.04$); epithelial mRNA expression was decreased at 10, 19, and 27% inclusion of CDS compared with the greatest expression for steers fed CON diet. SLC16A1, a monocarboxylic transporter-related gene, expression was increased for steers fed 0% CDS compared with 10 and 27% CDS treatments. Results indicate different concentrations of CDS alter the rumen epithelium transcriptome.

Key Words: rumen, epithelium, gene expression

1675 (T288) Crude glycerin as an energy source in finishing beef diets. P. Del Bianco Benedeti[*1,2], P. V. R. Paulino[3], M. I. Marcondes[1], A. Faciola[2], I. França Smith Maciel[1], and M. Custódio da Silva[1], [1]*Federal University of Viçosa, Viçosa, Brazil,* [2]*University of Nevada, Reno,* [3]*Nutron Alimentos Ltda., Campinas, Brazil.*

The objective of this study was to evaluate the effects of replacing dry ground corn with crude glycerin (CG) on DMI, digestibility, performance, and carcass characteristics of finishing beef bulls. An experiment in a completely randomized design with 25 d for adaptation and 95 d for sample collection was conducted, in which 3640 Nellore bulls (367 ± 37 kg) were blocked by BW and assigned to 20 pens. Animals were randomly assigned to one of four treatments: 0, 5, 10, and 15% (DM basis) CG in diet. All diets contained 85% concentrate and were formulated to meet NRC (2000) recommendations. Diets were isocaloric, isonitrogenous, and allowed 1.4 kg/d BW gain. Initially, 20 animals were slaughtered to serve as reference to estimate initial empty BW, which allowed carcass gain calculation. Bulls were weighted at the beginning and end of the experiment for performance calculation. Measurements of ribeye area (RA), back fat (BF) and rump fat (RF) were obtained by ultrasound. Data were analyzed using the PROC MIXEDs in SAS, and results are reported in the Table 1675. Intake of DM decreased linearly ($P < 0.01$) with CG inclusion. A quadratic effect was observed ($P < 0.01$) for DM and TDN digestibility. However, CG inclusion did not change ($P > 0.10$) ADG, final BW, carcass gain, carcass dressing, feed:gain ratio, RA, BF, and RF. These results suggest that CG may be included in finishing beef cattle diets without affecting performance and carcass characteristics.

Key Words: glycerin, feedlot, performance

1676 (T289) Ruminal fermentation of steers fed crude glycerin replacing starch- vs. fiber-based energy ingredients at low or high concentrate diets.

J. F. Lage*[1], A. F. Ribeiro[1], E. San Vito[1], C. S. Ribeiro Júnior[1], L. M. Delevatti[1], E. E. Dalanttonia[1], F. Baldi[2], R. A. Reis[3], and T. T. Berchielli[1], *[1]Universidade Estadual "Paulista Júlio de Mesquita Filho", Jaboticabal, Brazil, [2]Universidade Estadual Paulista "Júlio de Mesquita Filho", Faculdade de Ciências Agrárias e Veterinárias, Jaboticabal, Brazil, [3]University of Sao Paulo State, Jaboticabal, Brazil.*

Twelve ruminally cannulated Nellore steers (401.0 ± 41.5 kg) and 24 mo were used in a replicated truncated Latin Square arrangement of treatments with six animals in six treatments and four periods to evaluate the effect of crude glycerin (CG; 80.34% of glycerol) replacing starch- or fiber-based energy ingredients in the concentrate on ruminal pH, ammonia-N concentration and VFA's production of the steers fed in feedlot. Experimental periods were 15 d (14 d for adaptation and 1 d to sampling). Diets were: CO, without CG and corn as ingredient of concentrate; CGC, inclusion of CG (10% of DM) replacing corn in the concentrate; and CGSH, inclusion of CG (10% of DM) replacing soybean hulls (SH) in the concentrate. All three diets were offered at a low (LC) or high concentrate (HC; 40 or 60%). Ruminal contents were obtained at 0, 2, 4, 6, 8, 10, and 12 h after 0700 h feeding. Data were analyzed as a truncated Latin square using the PROC MIXED of SAS. The pH, ammonia-N and VFA, were analyzed as a repeated measurements. The least-squares means were generated and compared ($P \leq 0.05$) using Tukey's test. The pH was lower to animals fed HC diets than pH from animals fed LC diets ($P < 0.01$). No differences were detected in pH when animals were fed with CGC or CGSH. Animals fed diets CGSH had lower ammonia-N concentration than animals fed diets without CG or CGC ($P < 0.01$). The propionate concentrations ($P < 0.01$) and A:P ratio ($P < 0.01$) were affected by inclusion of CG in diets replacing corn or SH in the concentrate. Animals fed diets CGC or CGSH had higher propionate concentrations and lower A:P ratio in ruminal fluid ($P < 0.05$). There was an interaction between concentrate level and the diets for acetate ($P = 0.03$) and butyrate concentrations ($P = 0.05$). The decrease in acetate concentrations were observed in animals fed CGC or CGSH in LC than animals fed LC diets without CG. Butyrate concentrations were greater in diets CGC or CGSH, mainly in LC diets ($P = 0.05$). The inclusion of CG in diets did not alter the ruminal pH, but increase butyrate and reduces the A:P ratio as a result of increases of propionate concentrations.

Key Words: glycerol, propionate, ruminal pH

1677 (T290) Supplements containing different crude glycerin concentration does not affect the intake and digestibility of Nellore grass-fed beef.

E. San Vito*, L. Maneck Delevatti, E. E. Dalanttonia, J. F. Lage, M. B. Abra, C. S. Ribeiro Júnior, L. R. Simonetti, M. Machado, and T. T. Berchielli, *Universidade Estadual Paulista "Júlio de Mesquita Filho", Jaboticabal, Brazil.*

The aim of this work was to evaluate the effect of crude glycerin (CG)- 80% of glycerol- inclusion as a substitute to corn grain in the intake and digestibility (DM, OM, CP, NDF and TDN) of Nellore steers on pasture, supplemented in the dry season. Ten rumen-cannulated Nellore steers, with average body weight of 427 ± 15.76 kg were randomly assigned in double Latin square 5 × 5. The animals were distributed in five paddocks, of 0.4 ha each (two animals per paddocks). Treatments were constituted by five concentrations of CG in the supplement: 0, 70, 140, 210, and 280 g/kg dry matter of CG. Animals were supplemented individually, daily in a proportion of 300 g/100 kg of BW. The supplement was constituted of corn grain, soybean meal, urea, gluten meal and commercial premix, containing 300 g/kg DM of crude protein. Each experimental period lasted 14 d, so the first 10 d were for animal's adaptation and the remaining days to collect

samples. Intake and nutrient digestibility were estimated using two markers: isolated, purified and enriched lignin (LIPE) and indigestible neutral detergent fiber (iNDF), used for estimation of fecal excretion and forage intake, respectively. Fecal samples were collected directly from the rectum, 2x/d for 3 d, totaling six samples, with an interval of 2 h between collections. Data were analyzed in two simultaneous 5 × 5 latin squares by PROC MIXED of SAS (version 9.1), the effects of treatments were considered significant at $P < 0.05$. There was no statistical significance among the treatments, for intake of DM ($P = 0.239$), OM ($P = 0.183$), CP ($P = 0.076$), NDF ($P = 0.179$) and TDN ($P = 0.218$) with mean values of 7.59, 7.05, 1.24, 3.9 and 3.88, respectively. The inclusion of glycerin had no effect in the digestibility for DM ($P = 0.286$), OM (0.315), CP ($P = 0.339$) and NDF (0.270), with mean values of 44.26, 51.50, 57.20 and 43.04, respectively. The inclusion of crude glycerin until the level of 280 g/kg DM in the supplement did not affect the intake and digestibility of Nellore steers fed on tropical pasture in the dry season.

Key Words: pasture, co-product, biodiesel, glycerol

1678 (T291) Whole cottonseed and crude glycerin for Nellore cattle on pasture: Intake and digestibility of nutrients.

A. J. Possamai[1], J. T. Zervoudakis[*2], L. K. Hatamoto-Zervoudakis[2], A. S. Oliveira[3], E. R. Donida[2], P. I. J. L. R. Silva[1], A. C. Barboza[1], R. G. D. P. Junior[2], and J. W. Koscheck[4], *[1]UFMT, Cuiabá, Brazil, [2]Federal University of Mato Grosso, Cuiaba, Brazil, [3]UFMT, Sinop, Brazil, [4]UNESP, Jaboticabal, Brazil.*

Use of by-products in the beef cattle diets have important function to reduce production costs and needs to be evaluate in different production systems. The aim of this experiment was to evaluate intake and digestibility of nutrients in beef cattle diet with associations of whole cottonseed and crude glycerin in multiple supplements for Nellore cattle in the fattening phase at *Brachiaria brizantha* pastures in the rainy season. Animals were supplemented with 4 kg/d (21% of crude protein). The experiment was performed in a 5 × 5 (five supplements and five periods) Latin square design and structured in a factorial design 2 × 2 + 1 [two levels of crude glycerin (0 and 15%), two levels of cottonseed (0 and 25%) and supply of mineral mix (control)]. Orthogonal contrasts were used to evaluate effect of crude glycerine, whole cottonseed and interaction, adopting 0.05 to the critical level of probability. The supplementation increased dry matter intake at 2.25 kg/day ($P = 0.037$), due largest apparent digestibility of dry matter in function of fed supplements (65.83%) in relation to the control treatment (55.69%) ($P < 0.05$). Multiple supplements increased intake of ether extract (0.370 vs. 0.170 kg/d) ($P < 0.05$), crude protein (1.380 vs. 0.720 kg/d) ($P < 0.001$), and no fiber carbohydrates (3.715 vs. 2.07 kg/d) ($P < 0.001$), due to higher content of these nutrients in supplements when compared with only forage/mineral mix. Ether extract intake was still affected by the inclusion of whole cottonseed in supplement ($P < 0.05$) due high concentration of oil in this ingredient. Apparent digestibility of ether extract in the diets evaluated was affected by supplementation ($P < 0.05$) and whole cottonseed inclusion ($P < 0.05$) and assigning it lower contribution of endogenous excretion of ether extract when their content is high in diet. Intake and digestibility of neutral detergent fiber were not affected ($P > 0.05$), evidencing that extra supply of nutrients did not affect the cellulolytic microbiota, with appropriate digestibility of most abundant energy unit in grazing production system. By-products that reduce diets costs and improve voluntary dry matter intake are important in nutritional formulations because are responsible for most of the variations in productive performance.

Key Words: by-products, Nellore, pastures

1679 (T292) Crude glycerin in multiple supplements for beef cattle in grazing: pH and ammoniacal nitrogen.

R. G. D. P. Junior[*1], A. J. Possamai[2], J. T. Zervoudakis[1], L. D. S. Cabral[1], L. K. Hatamoto-Zervoudakis[1], A. C. Barboza[2], L. B. D. Freiria[1], J. B. Azevedo[3], and A. S. Oliveira[4], *[1]Federal University of Mato Grosso, Cuiaba, Brazil, [2]UFMT, Cuiabá, Brazil, [3]Federal University of Mato Grosso, Cuiabá, Brazil, [4]UFMT, Sinop, Brazil.*

Objective was evaluate the pH and concentration of ruminal ammoniacal nitrogen (NH_3–N) in beef cattle receiving multiple supplementation in grazing, with increasing levels of crude glycerin, in the rainy season. It has been utilized five Nellore beef cattle, male, non-castrated. The pastures were divided into five picket of 0.25 ha each, covered with *Brachiaria brizantha* cv. Marandu. The experiment was divided into 5 × 5 Latin square design, composed by five experimental periods of 19 d each and five animals. The strategy adopted was to provide 4 kg/animal/day of multiple supplements with four levels of crude glycerin (0; 8; 16 and 24%) and the mineral mixture (MM) was offered ad libitum(control). Ruminal liquid samples were collected for measuring the pH and quantification of NH_3–N by gavage, in two times (0 and 4 h after supplementation). The pH values for the time 0 and 4 h did not differ between the supplements ($P > 0.05$) (Table 1679), with average value of 6.83 and 6.59, respectively. It was verified decrease in measuring 4 h after the supplementation in comparison to time 0 ($P < 0.01$), demonstrating that there is a normal diurnal variation in the pH value without it being influenced by the multiple supplementation, important fact in the maintenance of ruminal fermentation. The content of NH_3–N has not been influenced by the supplementation before the concentration being supplied ($P > 0.05$) with average between the treatments of 4.98 mg/dL. It was observed at time four the raise in the content of NH_3–N for multiple supplementation regardless the formulation utilized ($P < 0.01$), while the control has not promoted such effect

($P > 0.05$). The average values of NH_3–N from animals receiving multiple supplementation was of 11.08 mg/dL, adequate for microbial development and ruminal fermentation.

1680 (T293) Grain processing methods and concentration of corn silage NDF in the finishing diet of Nellore bulls.

C. Sitta*[1], D. A. Fleury[1], J. D. Souza[1], F. Batistel[2], W. F. Angolini[1], M. A. P. Meschiatti[1], N. C. G. Barbosa[1], G. G. Rosa[1], B. A. V. Arthur[1], P. D. Andrade[1], A. Paro[1], A. C. Aoki[1], M. R. R. Soares[1], and F. A. P. Santos[2], *[1]University of Sao Paulo, Piracicaba, Brazil, [2]University of São Paulo, Piracicaba, Brazil.*

Grain processing methods disrupt the protein matrix of starch granules and increase surface area allowing more starch to be digested and higher animal performance of cattle fed high concentrate diets. There are some interaction of grain processing and NDF concentration. Inadequate fiber concentration could result in metabolic disturbs decreasing animal performance. This study evaluated two grain processing methods (coarsely ground and steam flaked corn) and these methods interaction with four corn silage NDF concentrations (4, 7, 10, and 13%) on animal performance. Two hundred thirty-seven Nellore bulls (336 kg BW ± 1.53) were fed diets containing corn silage; corn; soybean meal; urea and a mineral and vitamin premix. The animals were blocked by initial BW and randomly allocated to 24 pens in groups of six animals and to eight pens in groups of 12 animals. The parameters evaluated were DMI, ADG and FE. The experiment lasted 117 d and the data was analyzed using PROC MIXED of the SAS package. Block was considered the random effect. Grain processing method, NDF concentration and grain processing method X NDF concentration were considered fixed effects. Linear and quadratic effects of NDF concentration were tested for each grain processing method. Animals fed flaked corn had higher FE than animals fed ground corn. From all concentrations of corn silage NDF, 7 and 4%, had higher FE for treatments containing ground corn and flaked corn, respectively. It was concluded that corn flaking is an efficient way to improve performance of Nellore cattle in feedlot in comparison to ground corn and that 4 to 7% of NDF from corn silage are efficient concentrations to obtain good results on animal performance.

Key Words: grain processing, NDF concentration, Nellore

1681 (T294) Effect of corn processing methods and dietary concentrations of sugarcane bagasse fiber on finishing Nellore bulls performance.

A. H. F. Melo*, D. F. A. Costa, C. A. B. Delveaux, J. D. Souza, F. Batistel, D. C. Basto, P. R. Gabarra, A. C. Aoki, and F. A. P. Santos, *University of Sao Paulo, Piracicaba, Brazil.*

The objective of this experiment was to evaluate processing methods of flint corn grain (ground corn, particle size: 3.18 mm and steam-flaked corn with bulk density of 360 g/L) combined with dietary contents of 4, 7, 10 or 13% roughage NDF (DM basis) using sugarcane bagasse as source of fiber on performance of Nellore bulls finished in feedlot. Two hundred forty Nellore bulls (initial BW = 350 ± 2.4 kg) were fed diets containing 76 to 86% corn and were randomly allocated to 32 pens in a factorial arrangement of 2 × 4. Animals were blocked based on initial BW. The parameters evaluated were dry matter intake (DMI), average daily gain (ADG), feed efficiency (ADG/DMI) and final BW after 120 d on feed. The data were analyzed using PROC MIXED of SAS and means were compared by F test considering the block as random effect and corn grain processing method, roughage NDF and corn grain processing method * roughage NDF effects. There

Table 1680. Performance of cattle receiving diets with two grain processing methods and different concentrations of corn silage NDF

Grain processing method	Ground corn						Flaked corn					
	Corn silage NDF concentrations				Contrast		Corn silage NDF concentrations				Contrast	
	4	7	10	13	L	Q	4	7	10	13	L	Q
IBW, kg	344.0	344.1	343.9	343.9	NS	NS	343.8	343.9	344.1	343.9	NS	NS
FBW, kg	512.1	518.2	527.2	517.6	0.05	0.001	520.3	517.5	521.1	535.7	0.01	0.001
DMI, kg	8.55	8.85	9.45	9.5	0.01	0.12	8.48	8.75	8.8	9.68	0.01	0.001
ADG, kg	1.44	1.49	1.57	1.48	0.05	0.002	1.51	1.48	1.51	1.64	0.01	0.001
ADG/DMI	0.168	0.169	0.166	0.157	0.01	0.15	0.181	0.172	0.172	0.169	0.04	0.38

was no interaction between the concentrations of sugarcane bagasse NDF and processing methods. Cattle fed steam-flaked corn diets presented less ($P < 0.05$) DMI (8.57 vs. 9.31 kg.d^{-1}), 26.3% greater ($P < 0.05$) final BW (509 vs. 493.3 kg), 12.3% greater ($P < 0.05$) ADG (1.37 kg.d^{-1} vs. 1.22 kg.d^{-1}) and 21.97% greater ($P < 0.05$) feed efficiency (0.161 vs. 0.132) than cattle fed coarsely ground corn. Increasing roughage NDF content of the diets caused a quadratic response ($P = 0.01$) for DMI (8.37, 9.13, 9.02 and 9.25 respectively), had no effect ($P > 0.05$) on cattle final weight (496.8, 506.3, 498.4 and 503.9 kg, respectively) and cattle ADG (1.26, 1.34, 1.28 and 1.31 kg.d^{-1}respectively) and it caused a linear decrease ($P = 0.04$) in feed efficiency (0.150, 0.148, 0.142 and 0.144 respectively). In conclusion, steam flaking of flint corn improved performance of finishing Nellore bulls in comparison to ground corn with particle size of 3.18 mm. Nellore bulls were mor efficient when diets containing 4% sugarcane bagasse NDF were fed compared to diets with greater roughage NDF contents.

Key Words: ground corn, steam-flaked corn, feedlot

1682 (T295) Predicting ruminal and total tract starch digestion as influence by changes in density of steam-flaked corn: Flake thickness, enzymatic reactivity, fecal starch. M. A. Franco[*1], J. F. Calderon-Cortes[2], L. Corona[1], A. Plascencia[2], and R. A. Zinn[3], *[1]UNAM, México City, [2]UABC, Mexicali, México, [3]University of California–Davis, El Centro.*

Six Holstein steers (153 kg ± 11) with cannulas in the rumen and proximal duodenum were used in a 6 × 6 Latin square design experiment to compare flake density (FD, kg/L), flake thickness (FT, mm), amyloglucosidase reactivity (AGR, %), and fecal starch (FS, %) as predictors of ruminal (RSD, %) and total tract (TSD, %) starch digestion. Based on FD, RSD = 92.5– 36.6FD ($r^2 = 0.76$) and TSD = 96.5 + 30.2FD– 68.6FD^2 ($r^2 = 0.99$). Based on FT, RSD = 88.9– 4.45FT ($r^2 = 0.83$) and TSD = 97.1 + 3.77FT– 1.43FT^2 ($r^2 = 0.99$). Based on AGR, RSD = 72.0 + 0.43AGR ($r^2 = 0.94$) and TSD = 90.9 + 0.695AGR– 0.0138AGR^2 ($r^2 = 0.91$). Based on FS, RSD = 85.9– 2.88FS + 0.204FS^2 ($r^2 = 0.97$) and TSD = 100.0– 0.40FS ($r^2 = 1.00$). Measures of fecal starch were the best single predictor of ruminal and total tract starch digestion in catte fed steam-flaked corn-based diets. Fecal starch has the additional advantage of being equally effective when data for dry rolled corn are included in the dataset. Whereas AGR was a good predictor of ruminal starch digestion, it was the least effective of the measures for estimation of total tract starch digestion. Due to the ease of its determination, flake thickness may be the more convenient and reliable measure for assessment of day-to-day process adequacy.

Key Words: starch, maize, digestion

1683 (T296) Intake and performance of crossbred dairy calves fed spineless cactus in transition. R. Gomes[1], M. F. S. Queiroz[*2], S. Gonzaga Neto[3], R. G. Costa[4], J. S. Oliveira[3], G. O. Mendes[4], R. L. Galati[2], and G. R. Beltrão da Cruz[4], *[1]University of Paraiba, CCA/UFPB, Areia, Brazil, [2]University of Mato Grosso–DZER/UFMT, Cuiabá, Brazil, [3]University of Paraiba–CCA/UFPB, Areia, Brazil, [4]University of Paraiba–CCHSA/UFPB, Bananeiras, Brazil.*

A study was conducted to evaluate the intake and performance of crossbred calves (Holstein x Zebu) in the transition from a liquid diet to a solid diet fed spineless cactus replacing Tifton 85 hay. Sixteen crossbred calves with initial body weight of 50.04 ± 6.3 kg were used. Calves were housed in individual hutches, and suckled artificially with 4 L of milk x d^{-1}until 30 d of life. After completing 31 d the experimental period was initiated in which the calves began to receive the liquid diet in the same amount (4 L) also solid foods according treatment. Treatments consisted of the replacement of Tifton 85 hay diet by spineless cactus (*Opuntia ficus indica*, MILL) as follows: T1 (DPA): 70% concentrate + 30% Tifton hay, T2 (SPV): 70% concentrate + 15% Tifton hay + 15% spineless cactus, T3 (STV): 70% concentrate + 30% spineless cactus, T4 (SCV): 50% concentrate + 17% Tifton hay + 33% spineless cactus. The experiment was analyzed as a completely randomized design with ANOVA being conducted with the GLS procedure of SAS and the averages compared by Tukey's test at 5% probability. The DMI, BW, body measurements, body score and fecal score were performed weekly until 67 d of life. The DMI (0.48 kg x d^{-1}), final BW (55.9 kg), body measurements (wither height: 84.2 cm; hip height: 88.0 cm and heart girth: 88.4 cm) and body score (2.4) of the animals were not affected by treatments ($P > 0.05$). The average daily weight gain was influenced ($P < 0.01$) by the treatments, the greatest gains were observed in the treatment SPV (421 g x d^{-1}), the DPA and SCV (388 g x d^{-1}) treatments were no longer different from other while the smaller ADG were obtained in treatment STV (289 g x d^{-1}). The fecal average scores observed during the entire experimental period shows that there was no incidence of diarrhea in animals. In conclusion the use of spineless cactus replacing the Tifton hay as roughage in the diet of crossbred calves in the transition phase from a liquid diet to a solid diet is indicated assisting in early weaning without affecting the growth and development of these animals.

Key Words: average daily gain, body score, body weight

1684 (T297) Carcass characteristics of crossbred dairy calves fed spineless cactus in transition. R. Gomes[1], M. F. S. Queiroz[*2], R. G. Costa[3], S. Gonzaga Neto[4], J. S. Oliveira[4], G. O. Mendes[3], G. R. Beltrão da Cruz[3], and J. Jordão Filho[3], *[1]University of Paraiba, CCA/UFPB, Areia, Brazil, [2]University of Mato Grosso–DZER/UFMT, Cuiabá, Brazil, [3]University of Paraiba–CCHSA/UFPB, Bananeiras, Brazil, [4]University of Paraiba–CCA/UFPB, Areia, Brazil.*

A study was conducted to evaluate the carcass characteristics of crossbred calves (Holstein x Zebu) in the transition from a liquid diet to a solid diet fed spineless cactus replacing Tifton 85 hay. Sixteen crossbred calves with initial body weight of 50.04 ± 6.3 kg were used. Calves were housed in individual hutches, and suckled artificially with 4 L of milk.d^{-1} until 30 d of life. After completing 31 d the experimental period was initiated in which the calves began to receive the liquid diet in the same amount (4 L) also solid foods according treatment. Treatments consisted of the replacement of Tifton 85 hay diet by spineless cactus (*Opuntia ficus indica*, MILL) as follows: T1 (DPA): 70% concentrate + 30% Tifton hay, T2 (SPV): 70% concentrate + 15% Tifton hay + 15% palm, T3 (STV): 70% concentrate + 30% palm, T4 (SCV): 50% concentrate + 17% Tifton hay + 33% palm. The experiment was analyzed as a completely randomized design with ANOVA being conducted with the GLS procedure of SAS and the averages compared by Tukey's test at 5% probability. The DMI, BW, body measurements, BS and fecal score were performed weekly until 67 d of life, when these animals were slaughtered to evaluate carcass yield. There was no significant difference ($P > 0.05$) in final BW (55.9 kg), hot carcass weight (30.4 kg) and chilled carcass weight (30.0 kg) with the replacement of Tifton by spineless cactus. As the treatments did not affect ($P > 0.05$) hot carcass yield (55.8%) and chilled carcass yield (54.1%). Measures of carcass, carcass length (72.4 cm), leg length (50.8 cm) and perimeter of cushion (44.4 cm) were not affected ($P > 0.05$) by treatments. Average of 20.9 cm for the areas of rib eye area, and 0.96 cm in the fat thickness were observed, both without influence of treatments ($P > 0.05$). In conclusion the use of spineless cactus replacing the Tifton hay in the diet of crossbred calves is indicated without affecting the carcass characteristics of these animals.

Key Words: forage cactus; rib eye area; veal

1685 (T298) Effect of chitosan and soybean oil combination on ruminal fermentation and milk yield and composition of dairy cows. *T*. A. Del Valle[*1], F. C. R. D. Santos[1], P. G. D. Paiva[2], E. F. Jesus[2], F. Zanferari[1], M. K. Kametani[1], A. G. B. V. B. Costa[1], and F. P. Rennó[1], *[1]School of Veterinary Medicine and Animal Science, University of São Paulo, Pirassununga, Brazil, [2]School of Agricultural and Veterinary Sciences of UNESP, Jaboticabal, Brazil.*

The aim of this study was to evaluate the effects of chitosan addition in mid-lactating dairy diet without or with soybean oil on ruminal fermentation and milk composition. Twenty-four Holstein cows (four ruminally cannulated), averaging 174.7 ± 53.1 DIM, were randomly assigned in six Latin square design with a 2 × 2 factorial arrangement of treatments. The diets contained Chitosan (150mg/kg of body weight) and soybean oil (3.3% of the diet DM). Each experiment period had a 14-d adaptation period and a 7-d for collection data. Sampling of milk was done on Days 16, 17, and 18 of each period to evaluate the composition. On d 21 of each period, rumen fluid samples were collected from cannulated cows in seven times to evaluate the effect of the diets on ruminal fermentation. The results of milk composition were subjected to analysis of variance, while fermentation data were analyzed as repeated measures, both by PROC MIXED of SAS. There was no interaction effect ($P > 0.05$) of factors and the time on ruminal fermentation. The addition of soybean oil in the diet increased the concentration of propionate and decreased acetate and the total concentration of short chain fatty acids (SCFA) in mmol.L^{-1}, however the ratio acetate:propionate was decreased. Those diets decreased ($P < 0.05$) the levels of milk fat in 5 g/kg on average. The addition of chitosan in the diet reduced the total concentration of SCFA, although ruminal fermentation and milk composition was not altered significantly. The protein contents in milk were on average 3.06% and were not affected by diets. There was interaction ($P < 0.05$) of the factors for milk yield. Milk yield was same in control and chitosan diets and was higher in diet with soybean oil than diet with chitosan and soybean oil, with averages of 33.87, 32.85, 32.86 and 31.26, respectively. In conclusion, the use of chitosan as a feed additive for dairy cattle was positive in increasing the milk production, when in diet of low lipids level, not altering, however, ruminal fermentation and milk composition.

Key Words: additive, milk fat, rumen

1686 (T299) Growth performance and total tract nutrient digestion for Holstein heifers precision-fed diets high in distillers grains with different forage particle size. R. D. Lawrence*, J. L. Anderson, T. J. Vanderwerf, A. K. Manthey, K. F. Kalscheur, and D. P. Casper, *South Dakota State University, Brookings.*

This study evaluated dairy heifer growth performance and total tract nutrient digestion when fed diets high in dried distillers grains with solubles (DDGS) with different forage particle size, achieved by utilizing alfalfa hay that was processed differently. An 8-wk randomized complete block design study was conducted using twenty-two Holstein heifers (123 ± 32 d of age; initial body weight (BW) of 140 ± 23.5 kg). Treatments were either 15% chopped (CHOP) or 15% pelleted (*P*ELL) alfalfa hay on a dry matter (DM) basis. Both diets also contained 30% DDGS, 53.75% corn silage, and 1.25% mineral mix. Rations were precision-fed for a dry matter intake (DMI) of 2.3% of BW. Frame sizes, BW, and body condition scores (BCS) were taken on two consecutive days during wk 0, 2, 4, 6, and 8. During wk 8, titanium dioxide was fed and fecal grab samples were collected to measure total tract nutrient digestion. Heifer DMI increased ($P < 0.01$) when fed CHOP versus PELL (4.42 and 4.19 kg/d for CHOP and PELL, respectively). Body weights (167.4 and 164.0 kg) and average daily gain (0.83 and 0.96 kg/d) were similar ($P > 0.05$) between treatments. Gain to feed was less ($P < 0.01$) in CHOP versus PELL (0.21 and 0.25). Hip height (110.7 and 110.9 cm), wither height (106.7 and 106.6 cm), and body length (95.1 and 94.9 cm) were similar between treatments. Paunch girth (153.6 and 150.4 cm), heart girth (122.4 and 120.4 cm), and hip width (30.2 and 29.6 cm) were greater ($P < 0.05$) for CHOP versus PELL. Body condition score was less ($P < 0.01$) for CHOP compared to PELL (3.03 and 3.09). For growth measurements there were no significant treatment by week interactions or differences in average daily changes. Total tract digestibility of DM (67.5 and 67.3%), neutral detergent fiber (51.2 and 50.1% of DM), and crude protein (68.3 and 67.9% of DM) were similar between treatments. Heifers fed diets containing 30% DDGS with 15% chopped or pelleted alfalfa hay had similar total tract nutrient digestion and growth performance, with some very minor differences in frame growth and feed to gain. Overall, this study demonstrated that feeding dairy heifers diets with different forage particle sizes, achieved by inclusion of chopped or pelleted alfalfa hay, does not affect utilization of DDGS.

Key Words: dairy heifer, distillers grains, particle size

1687 (T300) Comparison of efficiency of energy use in Holstein and Jersey dairy cows offered diets containing reduce fat distillers grains RFDDGS. G. Garcia Gomez*[1], A. Foth[1], P. J. Kononoff[1], T. Brown-Brandl[2], and H. C. Freetly[2], [1]*University of Nebraska, Lincoln,* [2]*ARS–USDA, Clay Center, NE.*

Fifty six energy balances were completed with eight Holstein (H) and eight Jersey (J) multiparous lactating cows to examine the effect of breed on the efficiency of milk production and energy use. Two dietary treatments were fed in a repeated switch back design to compare breeds. Dietary treatments consisted of 24.5% corn silage, 18.4% alfalfa hay, 6.9% grass hay, with either 22.9% rolled corn and 14.8% soybean meal or 4.51% rolled corn, 0% SBM, and 14.5% RFDDGS (dry matter basis). Diets were offered ad libitum for a 28-d adaptation period and 95% ad libitum for a 4-d collection period. During the collection days, ration digestibility and energy use was measured, indirect calorimeter respiration head boxes were used to determine heat production. Across the two treatments, Holstein cows had a significantly higher intake of gross energy (GE) (30 ± 3.96 Mcal/d; $P = < 0.01$), and higher energy output in feces, urine, methane, heat production (HP), and milk energy (6.5 ± 1.24, 0.11 ± 0.11, 1.2 ± 0.15, 8.95 ± 0.74, and 8.54 ± 1.27 Mcal/d, respectively; $P = < 0.01$) than did Jersey cows. Jersey cows produced milk with higher fat content (4.96% vs. 3.69% ± 0.19 for Jersey and Holstein, respectively; $P = < 0.01$), protein (3.75% and 3.20% ± 0.1 for Jersey and Holstein, respectively; $P < 0.01$), and energy concentrations, compared with those of the Holstein cows. Metabolizable energy (ME) and digestible energy (DE) intake as a proportion of GE intake were significantly higher for Holstein cows (0.03 ± 0.01 and 0.03 ± 0.007, respectively; $P = < 0.01$ and 0.02). However, breed had no significant effects on ME/DE (0.88 ± 0.01), HP/ME (0.56 ± 0.02), DE/DMI (2.78 ± 0.06), ME/DMI (0.45 ± 0.06), methane energy/DE (0.08 ± 0.004), and urine energy/DE (0.04 ± 0.002). No significant interaction was found between breed and treatment for any of the ratios of energy use examined. In addition, no significant differences in energy partitioning between milk (milk energy/ME intake) (0.40 ± 0.18), and body tissue (retention energy/ME intake) (0.04 ± 0.0034) were found between Holstein and Jersey dairy cows. In conclusion, breed had no effect on the overall production efficiency of dairy cows in terms of efficiency of ME use for lactation, and energy partitioning between milk and body tissue.

Key Words: energy efficiency, Holstein, Jersey.

1688 (T301) Effects of feeding canola meal (CM) and wheat dried distillers grains with solubles (W-DDGS) as the major protein source in low or high crude protein diets on ruminal nitrogen utilization, omasal nutrient flow, and milk production in dairy cows. T. Mutsvangwa[*1], and K. Doranalli[2], *[1]University of Saskatchewan, Saskatoon, Canada, [2]Evonik (SEA) Pte. Ltd., Singapore.*

The objective was to determine the effects of feeding CM or W-DDGS as the major source of protein in diets varying in CP content on ruminal N utilization, omasal flows, and milk production. Eight Holstein cows (109 ± 36 DIM) were used in a replicated 4 × 4 Latin square design with 28-d periods. Four cows in one Latin square were ruminally-cannulated to facilitate ruminal and omasal sampling. Treatments were: 1) source of protein (CM vs. W-DDGS); and 2) dietary CP content (15 vs. 17%). Interactions between source of protein x CP content were nonsignificant. Dry matter intake and milk yield were unaffected by diet ($P > 0.05$). Feeding CM increased milk lactose content compared to feeding W-DDGS ($P = 0.003$). Milk urea-nitrogen ($P < 0.001$) and ruminal NH_3–N ($P = 0.05$) concentrations were greater in cows fed the high CP compared to those fed the low CP diet. Dry matter apparently digested in the rumen was greater in cows fed the high CP compared to those fed the low CP diet, with the difference in DM apparently digested in the rumen being greater in cows fed W-DDGS as compared to those fed CM (interaction, $P = 0.02$). The RDP supply was greater in cows fed the high CP when compared to those fed the low CP diet when diets contained CM, whereas RDP supply was lower in cows fed the high CP when compared to those fed the low CP diet when diets contained W-DDGS (tendency for interaction, $P = 0.08$). The omasal flow of NH_3–N was greater in cows fed CM when compared to those fed W-DDGS ($P = 0.03$). The RUP supply was greater in cows fed the low CP when compared to those fed the high CP diet when diets contained CM, whereas RUP supply was lower in cows fed the low CP when compared to those fed the high CP diet when diets contained W-DDGS (tendency for interaction, $P = 0.06$). Omasal flows of threonine and tryptophan were greater ($P \leq 0.03$), whereas that of histidine and lysine tended ($P \leq 0.08$) to be greater, in cows fed CM when compared to those fed W-DDGS. In conclusion, when diets are formulated to contain 15 or 17% CP, CM or W-DDGS can support similar levels of milk production when used as the major protein source.

Key Words: canola meal, milk production, wheat dried distillers grains with solubles

1689 (T302) Performance, digestibility, and blood acid-base balance of dairy cows in response to the replacement of corn by crude glycerin. O. F. Zacaroni[1], F. F. Cardoso[1], R. A. N. Pereira[2,3], and M. N. Pereira[*1,3], *[1]Universidade Federal de Lavras, Brazil, [2]Empresa de Pesquisa Agropecuaria de Minas Gerais, Lavras, Brazil, [3]Better Nature Research Center, Ijaci, Brazil.*

This experiment evaluated the response of late lactation dairy cows to the partial replacement of corn by methanol rich, crude glycerin. The tallow derived glycerin contained 70.2% DM and 7.3% methanol on an as-fed basis. Twelve Holsteins (219 ± 57 DIM), three primiparous, were assigned to 35-d periods, 3 × 3 Latin squares. The isonitrogenous diets (15.8% CP) contained (DM basis): 11.8% finely ground mature corn and 17.2% soybean meal (T0); 4.9% glycerin, 5.9% corn, and 18.3% soybean meal (T5); or 9.7% glycerin and 19.4% soybean meal (T10). Other ingredients were: 31.9% corn silage, 28.2% sugarcane silage, and 6.2% high moisture corn. Statistical analysis was performed with PROC MIXED of SAS, with a model containing the random effect of cow and the fixed effects of period and treatment. Two contrasts were evaluated: Linear = T0 vs. T10, and Quadratic = T5 vs. (T0+T10). The replacement of corn by glycerin induced linear decreases in milk (22.2, 21.1, 20.0 kg/d, $P < 0.01$) and lactose secretions ($P < 0.01$), without affecting DMI (17.8 kg/d, $P = 0.53$), reducing feed efficiency ($P < 0.01$). Milk contents of fat (4.11, 4.33, 4.37%, $P = 0.01$) and protein (3.47, 3.64, 3.73%, $P < 0.01$) were linearly increased by glycerin, but daily secretions were similar ($P > 0.86$). Milk urea nitrogen was similar (13.8 mg/dL, $P = 0.51$), as well as chewing activity ($P > 0.32$), except the daily ingestion time, reduced by glycerin ($P = 0.05$). Total tract apparent digestibility of the non-NDF organic matter was linearly increased by glycerin (90.3, 91.4, 93.2% of intake, $P = 0.05$), but the intake of digestible organic matter was similar (10.6 kg/d, $P = 0.66$). The ratio of the daily milk energy secretion to the intake of digestible organic matter was linearly reduced by glycerin (1.58, 1.55, 1.42 Mcal/kg, $P = 0.05$). Rumen pH 12-h post feeding was similar (5.67, $P = 0.72$). The intake of crude glycerin was 1.24 kg/d in T5 and 2.5 kg/d in T10, methanol intake was 134 mg/kg of BW in T5 and 269 mg/kg of BW in T10. Health disorders were not observed. However, glycerin reduced the partial pressure of CO_2 ($P = 0.02$) and increased the saturation of hemoglobin with O_2 ($P = 0.05$) in jugular blood samples obtained 6-h post feeding, suggesting an induction of hyperventilation. Venous blood pH, bicarbonate level, base excess, and the partial pressure of O_2 were not affected by treatment ($P > 0.64$). The replacement of corn by crude glycerin reduced milk yield, feed efficiency, and the response was associated to low milk lactose secretion.

Key Words: digestibility, glycerin, methanol

1690 (T303) Effects of crude glycerin supplementation on fatty acids composition of milk fat from primiparous lactating cows on irrigated tropical pasture. M. C. A. Santana*[1], H. A. Santana Junior[2], M. P. Figueiredo[3], E. O. C. Santana[4], G. A. Filho[4], C. B. Figueiredo[2], M. S. Maciel[2], and J. I. Simionato[5], *[1]Emater, Goiânia, Brazil, [2]Universidade Estadual do Piauí, Corrente, Brazil, [3]Universidade Estadual do Sudoeste da Bahia, Vitória da Conquista, Brazil, [4]Universidade Estadual do Sudoeste da Bahia, Itapetinga, Brazil, [5]Universidade Estadual de Londrina, Brazil.*

The objective of this study was to evaluate the effect of different levels of crude glycerin suplementation on fatty acids composition of milk fat from primiparous lactating cows grazing on irrigated tropical pasture. The experiment was conducted at Rancho Santana farm, located in Jequié city, Bahia, Brazil, in the period from Dec. 21, 2010, to March 16, 2011. Ten 3/4 Holstein × 1/4 Dairy Gyr lactating primiparous cows, with 109 ± 24 d of lactation and a mean age of 30 ± 6 mo and mean body weight of 426.2 ± 68.29 kg were distributed into five treatments, using two simultaneous 5 × 5 Latin squares. Treatments consisted of inclusion levels (0, 94, 191, 289, 389 g/kg dry matter basis) of crude glycerin (CG) in the supplement. Fatty acid methyl esters were analyzed by Thermo Finnigan Trace-GC-Ultra gas chromatography. Results were statistically analyzed by variance and regression analyses at 0.05 probablity. Results showed effects on milk fat saturated fatty acids— caproic (6:0), caprylic (8:0), capric (10:0), lauric (12:0), pentadecanoic (15:0) and stearic (18:0)— when the crude protein concentrations in supplement increased. The increase of CG level in the supplement did not differ the polyunsaturated fatty acids ($P < 0.05$). To determine the ratio between pro- and anti-atherogenic acids, the atherogenic index (IA) and thrombogenic index (IT) were calculated, and difference was verified only for IA ($P < 0.05$). Treatments affected a few of the saturated and monounsaturated fatty acids. Overall, this data indicated that the addition of glycerin did not cause effects on the variables that express the milk quality, so the recommended crude glycerin level could be increased to 389 g (171 g glycerol) per kg of supplement.

Key Words: glycerol, biohydrogenation, biodiesel

1691 (T304) Effect of grain processing and fat supplementation on ruminal pH dynamics of cows grazing a tropical pasture. J. D. Souza*, F. Batistel, E. Miqueo, P. D. Andrade, M. M. V. Silva, C. Sitta, and F. A. P. Santos, *University of Sao Paulo, Piracicaba, Brazil.*

The objective of this experiment was to investigate the effects of grain processing and fat supplementation to dairy cows grazing a tropical pasture on ruminal pH dynamics and incidence of acidosis. Four rumen cannulated lactating cows (165 ± 32 DIM) were used in a Latin square design and subjected to the following treatments: a) fine ground corn without fat (FGC); b) fine ground corn + 400 g calcium salts of palm oil cow^{-1} d^{-1} (FGCCS); c) steam-flaked corn without fat (SFC); d) steam-flaked corn + 400 g of calcium salts of palm oil cow^{-1} d^{-1} (SFCCS). The fine ground corn had a particle size of 1.3 mm and steam-flaked corn a density of 360 g/L. Treatment periods were 24 d in length and cows grazed paddocks of *Pennisetum purpureum* and received 6.0 kg cow^{-1} d^{-1} (DM) of concentrate twice daily. Ruminal pH was continuously measured using a LRC pH measurement system. The in-dwelling electrode measured and recorded the ruminal pH every 10 min over the measurement period. Each electrode was standardized using pH 4.0 and 7.0 standards at the beginning and end of each period. The pH data were first summarized by day and then averaged across each measurement period as mean, maximum, and minimum pH and time in which pH was below 6.2, 6.0, and 5.8 as an index of severity of ruminal acidosis. Data were analyzed as repeated measures using a PROC MIXED model with period and animal as random effect and grain processing, fat supplementation and grain processing × fat supplementation as fixed effects. The means were compared by Tukey test at 5%. The mean pH, minimum pH and maximum pH were not affected by treatments. The mean pH was 6.63, 6.73, 6.68 and 6.64 for FGC, FGCCS, SFC and SFCCS, respectively. The minimum pH was 6.02, 6.10, 6.02 and 6.15 and the maximum pH was 7.04, 7.12, 7.02 and 7.06 for FGC, FGCCS, SFC and SFCCS, respectively. No pH measurements below 5.8 were observed. The time that the pH was below 6.0 was greater in steam-flaked compared with fine ground corn (5.2 vs. 2.6 h/d), and the time that pH was below 6.2 was also greater in steam-flaked diets (14.0 vs. 11.4 h/d). In conclusion, steam-flaked corn diets decreased the ruminal pH, but not below 5.8, which suggest no acidosis occurrence in dairy cows grazing a tropical pasture.

Key Words: steam-flaked corn, fat, tropical pasture

1692 (T305) Grain processing and fat supplementation on milk yield and milk composition of dairy cows grazing a tropical pasture. F. Batistel*, J. D. Souza, M. R. R. Soares, C. S. M. Motta, E. Miqueo, and F. A. P. Santos, *University of São Paulo, Piracicaba, Brazil.*

The objective of this experiment was to investigate the effects of grain processing and fat supplementation to early lactation dairy cows grazing a tropical pasture on milk production and composition. Forty early lactation cows (15 ± 4 DIM) were used in a randomized block design and subjected to the following treatments: a) fine ground corn without fat; b) fine ground corn + 400 g calcium salts of palm oil cow^{-1} d^{-1}; c) steam-flaked corn without fat; d) steam-flaked corn + 400 g of calcium salts of palm oil cow^{-1} d^{-1}. Treatment periods were 90 d in length and cows grazed paddocks of *Pennisetum purpureum* and received

9 kg cow^{-1} d^{-1} (DM) of concentrate twice daily. Milk yield was measured every 2 d and milk composition was analyzed every 6 d. Data were analyzed as repeated measures using a mixed model with block as random effect and grain processing, fat supplementation and grain processing × fat supplementation as fixed effects. The means were compared by Tukey test. Steam-flaked corn increased (P = 0.001) milk yield compared with fine ground corn (23.9 vs. 22.2 kg/d) and supplementation with fat also increased (P = 0.0001) milk production (24.7 vs. 21.3 kg/d). Milk fat content was reduced (P = 0.01) in steam-flaked corn in comparison with fine ground corn diets (3.22 vs. 3.30%). There was a pronounced increased (P = 0.0001) in milk protein content in steam-flaked corn compared with fine ground corn diets (3.41 vs. 3.15%). In addition, milk casein content was increased (P = 0.0001; 2.47 vs. 2.33%) and milk urea nitrogen was decreased (P = 0.002; 12.1 vs. 16.3 mg/dL) in steam-flaked diets indicating greater efficiency of N utilization in these treatments. Total solids content was reduced (P = 0.05) by fat supplementation (12.19 vs. 12.05%), which is associated with the tendency of reduction in milk protein content (P = 0.10; 3.29 vs. 3.22%). Milk fat yield was unaffected by grain processing (P = 0.18; 0.75 vs. 0.77 kg/d for fine ground corn and steam-flaked corn, respectively), but fat supplementation increased (P = 0.001) milk fat yield (0.80 vs. 0.71 kg/d). Steam-flaked corn increased (P = 0.001) milk protein yield compared with fine ground corn (0.81 vs. 0.71 kg/d). In grazing dairy cows, steam-flaked corn increased milk yield and milk protein, and fat supplementation increased milk yield and milk fat yield, and when combined (steam-flaked corn + fat) allowed the greatest milk yield, milk fat yield and milk protein yield.

Key Words: palm oil, flaked corn, tropical pasture

1693 (T306) Effect of grain type (corn versus milo), particle size (600 versus 1000 microns) and steam-flaked corn on productive and metabolite responses of early lactating Holstein cows. E. Mahjoubi[1], J. R. Johnson[*2], B. J. Bradford[2], and M. J. Brouk[2], [1]*Dep. of Animal Science, University of Zanjan, Iran,* [2]*Dep. of Animal Sciences and Industry, Kansas State University, Manhattan.*

Ten early lactation Holstein dairy cows (five multiparous and five primiparous) were used in a duplicated Latin square design to evaluate diets that differed in grain type (corn vs. milo) and grain particle size (fine vs. coarse roller-milled); a steam-flaked corn (SF-C) diet was also included for comparison. Periods were 21 d with 17 d for adaptation and 4 d for data collection, and data were subjected to PROC MIXED model analysis with contrasts used to evaluate effects of grain type, particle size, and processing method. Mean particle size of fine and coarse rolled corn, fine and coarse rolled milo and SF-C was 724, 1087, 636, 980, and 3356 microns, respectively. Daily dry matter intake was not influenced (P > 0.05) by treatment (26.6, 26.6, 27.8, 26.6 and 26.4 ± 1.7 kg, respectively), nor was milk yield (41.5, 41.5, 40.5, 40.9 and 41.6 ± 3.2 kg, respectively). Treatment did not affect (P > 0.05) milk component concentrations or yields except that when fed corn, cows yielded greater (P = 0.03) amounts of milk protein due to numerically greater milk yield and milk protein concentration. Efficiencies of milk production, energy correct production and fat corrected production were not impacted by treatment. However, feeding corn resulted in a trend for greater (P = 0.06) milk production efficiency when compared to milo. Milk urea nitrogen (MUN) was decreased (P = 0.05) when feeding corn compared to milo. Similar blood glucose levels were observed pre and post feeding for all treatments. Circulating NEFA was higher (P < 0.05) for rolled corn diets versus SF-C and milo diets. Period changes in body weight and body condition score were unaffected by treatment (P > 0.05). Data demonstrates that rolling corn or milo to 600 or 1000 microns resulted in similar milk production and milk production efficiency as compared to SF-C. Processing corn or milo to a particle size smaller than 1000 microns did not result in increased milk production or efficiency of production suggesting that it is not necessary to reduce particle size of corn or milo below 1000 microns when included in a total mixed ration (TMR) resulting in reduced processing expense. Similar milk production and production efficiency for milo versus corn suggests that relative pricing should be utilized to determine if corn or milo should be included in lactating dairy cow diets when corn or milo is processed to a similar particle size and fed in a TMR.

Key Words: grain processing, particle size, sorghum

1694 (T307) Effect of concentrate source (cottonseed vs. barley) on milk performance and fatty acids profile of spring calving Holstein-Friesian cows feeding an indoors silage regime. A. I. Roca-Fernández* and A. González-Rodríguez, *Agrarian Research Centre of Mabegondo, La Coruña, Spain.*

Milk performance and fatty acids (FA) profile of spring-calving Holstein-Friesian cows (n = 36) at end of lactation (200 d in milk) were examined. Cows were fed indoors with a total mixed ration (TMR) containing: 70% silage (grass: maize, 36:64) and 30% concentrate. Two sources of concentrate were investigated: cottonseed (C) at two levels, low (5 kg DM/cow/d) or high (7 kg DM/cow/d), and barley (B) at high level (7 kg DM/cow/d). Animals were randomly assigned to one of three indoor (n = 12) feeding regimes (C5, C7 and B7), during 10 wk in autumn. The B and C concentrates were composed of corn flour (B, 43.1 vs. C, 31.0%), soybean hulls (B, 28.5 vs. C, 34.0%), soybean meal (B, 23.5 vs. C, 20.0%), barley flour (B, 1.4 vs. C, 0%), cottonseed (B, 0 vs. C, 12.0%) amender (B, 1.0 *vs.* C, 1.0%), calcium carbonate (B, 1.5 vs. C, 1.0%) and dicalcium phosphate (B, 1.0 vs. C, 1.0%). Average chemical composition of B and C concentrates was: crude protein (166 vs. 168 g/kg DM), neutral detergent fiber (249 vs. 418 g/kg DM) and crude fat (31 vs. 49 g/kg DM), respectively. Daily

milk yield was higher ($P < 0.001$) at the high level of supplementation (B7, 18.1 and C7, 17.9 kg/cow/d) compared to the low level (C5, 15.7 kg/cow/d), and dairy cows at the high level of concentrate showed higher ($P < 0.05$) body weight values (B7, 605 and C7, 598 kg) compared to those at the low level (567 kg). Milk protein was lower ($P < 0.05$) at the high level of concentrate in the cottonseed (C7, 30.7 g/kg DM) than in the barley treatment (B7, 32.7 g/kg DM). There were no differences among treatments in milk fat and milk urea content. No differences were also found among treatments in short, medium and long chain FA. Despite this, higher ($P < 0.05$) content of polyunsaturated FA and linoleic acid were observed in the C7 compared to the C5 treatment (2.48 and 2.22 vs. 2.16 and 1.92 g/100 g of FA). These results might be explained by alterations in rumen biohydrogenation pathways of milk FA from dairy cows supplemented with cottonseed concentrate at high level. Linolenic acid was, however, higher ($P < 0.01$) in the B7 (0.27 g/100 g of FA) than in the C5 treatment (0.24 g/100 g of FA).

Key Words: dairy cow, lipid feed supplements, milk fatty acids composition

---

1695 (T308) Ruminal starch degradation of maize silage affected by ensiling time and dry matter content.

J. Doorenbos* and H. V. Laar, *Nutreco R&D, Boxmeer, Netherlands.*

Quantitative evaluation of rumen degradation of maize silage is relevant for accurate determination of its nutritional value. Our objective was to quantify combined effects of ensiling time and dry matter (DM) at harvesting on effective rumen degradation (ED) of starch, crude protein (CP) and NDF in maize silage. Maize silage (hybrid Nutreka) was harvested at 30, 35 or 40% DM with 2-wk intervals, allowing different maturity to develop in the same crop. Fresh samples were stored at -18°C. 25 L plastic vessels were filled with thin layers of material and compressed manually to remove air. Full vessels were sealed then stored for 4, 8 or 12 mo at ambient temperature. After opening, samples were stored at -18°C. Three fistulated mid-lactation Holstein cows fed a basal ration consisting of maize silage, grass silage, hay and compound feed, were used to incubate nylon bags. Bags (pore size 37 µm) were inserted at 0800 h and removed after 3, 8, 16, 32, 56, 96, and 336 h. All bags were machine washed, freeze-dried and weighed. Outliers were removed using Dixon Q-test. Residues were analyzed by NIRS for DM, starch, CP and NDF using calibration lines specifically developed for maize silage residues. Washable and undegradable fractions were based on residues after 0 and 336-h incubation, respectively. Rate of degradation (k_d) was calculated in SAS using PROC NLIN. ED was calculated as Washable + Degradable x (k_d/(k_d+ passage rate)) and analyzed in SAS using PROC MIXED for significant differences between treatments using ensiling time and DM as fixed factors and cow as random factor. Starch and CP ED increased with increasing time ensiled ($P < 0.0001$) from 63.3 to 85.4% and from 42.2 to 71.4%, respectively. Starch and CP ED decreased with increasing DM ($P < 0.0001$) from 82.3 to 71.7% and from 63.9 to 58.5%, respectively. Higher DM at ensiling led to a more pronounced effect of ensiling time on starch and CP ED ($P < 0.0001$ for interaction time x DM). NDF ED was not significantly affected by ensiling time or DM ($P > 0.10$). It can be concluded that ED of starch and CP in maize silage is affected by combined effects of ensiling time and DM at harvesting. These results can be applied in ration formulation systems for dairy cows to further optimize nutrient utilization and rumen conditions.

Key Words: maize silage, ensiling time, rumen starch degradability

1696 (T309) Relationship of in vitro starch digestion to corn kernel measurements from farms in Michigan.

D. Bolinger[1], L. Nuzback[2], and F. N. Owens*[2], *[1]DuPont Pioneer, Perrinton, MI, [2]DuPont Pioneer, Johnston, IA.*

With mature grain, increased kernel vitreousness and prolamin content reduce in vitro starch digestion. Does this apply for grain harvested at corn silage maturity? To answer this question, samples of whole plant corn silage and shelled grain from five Pioneer hybrids at silage harvest were gathered from 15 environmentally diverse locations in Michigan in 2013. Starch availability (7 h in vitro starch disappearance) and nutrient composition were evaluated at a commercial laboratory; vitreousness was appraised as kernel specific gravity by gas displacement. Impacts of hybrid and location on nutrient composition, starch availability, and vitreousness were evaluated by GLM procedures of SAS. Differences ($P < 0.01$) among hybrids were noted for DM, CP, fat, starch, and pycnometer density, and for starch availability ($P < 0.02$). Farm of origin also had an impact ($P < 0.02$) on every component except NDF content of grain. Across all samples, prolamin content was not closely related to in vitro starch availability ($r = -0.06$; $P = 0.63$) but increased as CP content of grain increased ($r = 0.74$; $P < 0.01$). Among all measurements, in vitro starch availability was predicted best but still poorly (R2 = 0.17) by the equation: Starch availability = 38.33– 0.124 × grain DM + 0.585 × grain starch percentage. As harvest DM increased, specific gravity and prolamin content tended ($P < 0.10$) to increase. Starch availability decreased as kernel specific gravity increased ($P < 0.05$). Perhaps because of its high dependence on kernel protein content, prolamin content was not closely related to starch availability of grain samples harvested when corn silage was harvested. Had all grain samples had been obtained from fields equal in N fertility, the relationship of prolamin to starch availability likely would have been closer. The range in starch digestibility among these silage hybrids was less than half the range among farms (2.9 vs. 6.3% points); this questions the accuracy of predicting starch availability from hybrid genetics alone. Low in

vitro starch digestion of dry vitreous hybrids may reflect high prevalence of larger particles from dry coarsely ground grain although other factors (e.g., fine grinding, fermentation) also will impact on in vivo starch availability.

Key Words: prolamin, starch digestion, vitreousness

1697 (T310) Effect of particle size and time of rumen fluid collection on in vitro starch digestibility of corn and sorghum. E. Raffrenato[*1,2], L. J. Erasmus[1], W. A. van Niekerk[1], and C. Engelbrecht[1], *[1]University of Pretoria, South Africa, [2]Stellenbosch University, South Africa.*

Starch digestibility affects rumen health and milk production in dairy cows. Corn and sorghum are among the most common starch sources, but the least digestible when unprocessed. Grinding is the preferred way to increase starch digestibility. However, time of rumen fluid collection is often not considered as source of variation when analyzing in vitro starch digestibility. In addition, interaction between particle size and time of feeding may further bias the digestibility results. Objectives of the study were to assess the effects of: 1) different particle sizes in corn and sorghum, 2) time of rumen fluid collection relative to feeding (ad libitum feeding, i.e., 8 h after first morning feeding, AL vs. collection after 8 h of fasting, FA), and 3) their interaction on in vitro starch digestibility (IVSD). Several cultivars of corn and sorghum were analyzed for starch and CP content and ground at 1, 2, 4, and 6 mm, using an ultra-centrifugal mill. Rumen fluid was collected from two cows fed a lactation diet containing 25% starch. Residual starch of the fermented samples were obtained at 0, 1, 2, 4, 6, 8, 12, and 24 h. Density of grains were also measured for all particle sizes and correlated with IVSD. Rates of starch digestion were computed assuming a first order decay and the parameters were estimated using PROC NLIN in SAS. Rates of digestion were on average higher for the FA rumen fluid ($P < 0.05$) compared to the AL rumen fluid with 0.21 vs. 0.16 and 0.14 vs. 0.10 h^{-1} for corn and sorghum, respectively. Furthermore, interaction between particle size and rumen fluid was highly significant ($P < 0.001$). Finer corn and sorghum had in fact consistently higher rates of starch digestion, increasing with decreasing particle size ($P < 0.001$), only within the AL rumen fluid. When using the FA rumen fluid, particle size did not have any influence on starch digestibility ($P = 0.67$). Both density and CP were also negatively correlated (-0.65 and -0.78, $P < 0.05$) with IVSD. This proves the importance of time of collection of rumen fluid but it could also imply important consequences for rumen health when feeding starch separately, after hours of fasting.

Key Words: in vitro starch digestibility, rumen fluid, rumen health

1698 (T311) Effect of reducing dietary starch on intake, lactation performance, and ruminal parameters of dairy cows: A meta-analysis. S. M. Fredin*, L. F. Ferraretto, and R. D. Shaver, *University of Wisconsin, Madison.*

A meta-analysis was conducted to determine the effect of feeding reduced-starch diets on intake, lactation performance, and ruminal parameters of dairy cows from a data set comprising 131 treatments means from 56 peer-reviewed trials from 1993 to 2014. Reduction in dietary starch was achieved by partially replacing cereal grains with non-forage fiber sources, forages, or sugars. Dependent variables were calculated as the difference between observations on the higher starch (% of DM) diet and observations on the reduced-starch diet(s) within trial. The higher starch concentration was used as a covariate within trial when $P \leq 0.15$. Data were analyzed using PROC MIXED of SAS with treatment as a Fixed effect and trial as a Random effect. Dietary CP and NDF contents (% of DM) were (mean ± SD) 17.8 ± 2.3 and 31.8 ± 5.5%, respectively, across all trials. The higher starch diet and reduced-starch diets contained (mean ± SD) 28.9 ± 5.0% and 21.5 ± 4.8% starch, respectively, across all trials. Dry matter intake was 24.3 ± 2.6 kg/d across all trials, and decreased 0.1 kg/d per %-unit (DM basis) decrease in dietary starch content ($P < 0.001$). Milk yield (kg/d) decreased 0.2 kg/d per %-unit decrease in dietary starch content ($P < 0.001$). Fat- and energy-corrected milk followed a similar pattern ($P < 0.001$). Feeding reduced-starch diets decreased milk fat (7 g/d), protein (9 g/d), and lactose (12 g/d) yields per %-unit decrease in dietary starch ($P < 0.001$). Milk fat concentration was unaffected by reduced dietary starch ($P = 0.60$), whereas milk protein (0.005%) and lactose (0.004%) concentrations were decreased per %-unit decrease in dietary starch ($P \leq 0.01$). There was a trend for lower feed conversion (kg milk/dkg DMI) on reduced-starch diets ($P = 0.06$). Total ruminal VFA concentrations were decreased 0.4 m*M* per %-unit decrease in dietary starch ($P = 0.03$), however, ruminal acetate and butyrate (mol/100 mol) concentrations ($P \geq 0.41$) were unaffected. There was a trend for a decrease of 0.09 mol/100 mol for ruminal propionate concentration on reduced-starch diets ($P = 0.09$), and rumen acetate: propionate ratio was increased ($P = 0.03$) on reduced-starch diets. Rumen ammonia (mg/dL) and pH ($P \geq 0.32$) were unaffected by reducing dietary starch content. Dry matter intake, milk, and component yields were decreased for dairy cows when fed reduced-starch diets.

Key Words: dairy cow, lactation, starch

1699 (T312) Effect of rehydration and silage storage period of corn with medium vitreous endosperm on chemical composition and dry matter in situ degradability. M. A. Arcari, C. Martins, J. Gonçalves, D. Sousa*, T. Tomazi, L. F. P. Silva, and M. Veiga dos Santos, *University of São Paulo, Pirassununga, Brazil.*

The aim of this study was to evaluate the effects of rehydration process and storage period of milled, rehydrated and ensiled corn (MREC) with medium vitreousness (67 ± 3%) on chemical composition and in situ DM degradability. Corn grains were harvested with 83% DM concentration and dried to obtain 87% DM concentration. After dried, corn grains were milled (2 mm), rehydrated to 67% DM, and ensiled (silo density of 880 kg/m^3) in mini-silos. Furthermore, the MREC samples were evaluated in different storage periods (3 to 330 d). The MREC were analyzed for nutrient contents, fermentation products and in situ DM degradability. The data were modeled according to Mehrez and Ørskov (1977), and the effects of MREC storage time on degradability were evaluated by the PROC MIXED of SAS ($\alpha = 0.05$), in a completely randomized design with two replications. No effect of ensiling period was observed for MREC DM and CP content. The ensiling period reduced the MREC starch content ($P < 0.001$). The MREC starch content was 2.4% points lower in the silos with 330 d of storage compared to the silos with 3 d of storage. The MREC with 330 d of storage had greater ($P < 0.001$) concentrations of NH_3–N, ethanol, lactate, acetate, propionate, and butyrate were increased by 8.5, 2.4, 3.45, 4.1, 1.7, and 2.8-folds, respectively. Likewise, the storage time of MREC increased ($P < 0.001$) in situ DM degradability. The percentage of rapidly degradable DM fraction (fraction A), the degradation rate of the slowly degradable DM fraction (fraction C) and the potentially degradable DM (PD) were increased by 3.04, 2.42 and 1.009 folds after 330 d of storage. The C fraction (slowly degradable DM fraction) from the MREC stored for 330 d decreased by 1.91-fold in comparison to the MREC stored for 3 d. The effective DM degradability, which was adjusted for rumen passage rates of 0.02, 0.05 and 0.08%/h, increased ($P < 0.001$) from 81 to 93.3%, from 66.6 to 88.6%, and from 57.6 to 84.9%, respectively. In conclusion, the storage period affected the chemical composition and increased the in situ DM degradability of MREC with medium vitreous endosperm.

Key Words: ensiling, in situ degradability, vitreousness

1700 (T313) Factors affecting 7-hour starch digestibility on conventional corn silage, BMR corn silage, and high moisture corn grain. A. J. Miner*[1], M. Tetreault[2], C. J. Sniffen[3], and R. Ward[4], *[1]Poulin Grain Inc., Newport, VT, [2]Poulin Graing Inc., Newport, VT, [3]Fencrest, LLC, Holderness, NH, [4]Cumberland Valley Analytical Services Inc., Hagerstown, MD.*

Previous research has shown that there appears to be a relationship between time after ensiling and starch digestibility in lactating dairy cows. The objective of this study was to measure how time after ensiling and other factors affect 7-hour starch digestibility in conventional corn silage, BMR corn silage, and high moisture corn grain. Samples were taken monthly on 16 farms in New York and Vermont from November 2010 to October 2011. All samples were sent to Cumberland Valley Analytical Services to have 7-hour starch digestibility and dry matter analysis determined on all samples. Linear analysis was performed on samples grouped by physical characteristics (Conventional vs. BMR vs. High Moisture Corn) comparing impact of time after ensiling and other factors on the 7 h starch digestibility of the starch in the feedstuffs. The analysis of the conventional corn silage demonstrated that time after ensiling has the largest impact on 7 h starch digestibility ($P = 0.0007$) however dry matter and farm that sample was taken from also has an impact. When time after ensiling, dry matter, and farm name was accounted for analysis showed a linear realtionship ($R^2 = 0.17$; $P = 0.11$). For the bmr corn silage there appeared to be a strong relationship for time after ensiling on 7-hour starch digestibility ($P > 0.99$); however, when dry matter and farm were applied to the data, there was a linear relationship ($R^2 = 0.54$; $P = 0.01$). It appears that the farm the sample came from had the biggest impact on the 7-hour starch digestibility of the BMR corn silage ($P = 0.04$). On the high moisture corn grain again there was a time after ensiling effect with a good relationship with 7-hour starch digestibility ($P < 0.01$). Dry matter and farm also have a linear relationship ($R^2 = 0.47$; $P = 0.01$). In conclusion time after ensiling has a significant impact on 7-hour starch digestibility of both the conventional corn silage and high moisture corn grain; it does not have a significant impact on BMR corn silage. The variation that was accounted for by the farm that the samples came from indicates that other factors such as soil type, corn hybrid, amount of processing, and other farm factors can have an impact on 7-hour starch digestibility.

Key Words: starch digestibility, time after ensiling, corn silage

1701 (T314) Glycerol exacerbates effects of sorghum-based tannins extract on in vitro fermentative activity of mixed ruminal microorganisms.

E. San Vito*[1], T. J. Herald[2], P. Gadgil[2], and J. S. Drouillard[3], [1]*Universidade Estadual Paulista Júlio de Mesquita Filho–UNESP, Jaboticabal, Brazil,* [2]*USDA–ARS, Grain Quality and Structure Research Unit, Manhattan,* [3]*Kansas State University, Manhattan.*

Tannins have been observed to impact ruminal metabolism, affecting protein degradation, predisposition to bloat, and production of methane and conjugated linoleic acid; however, these effects on rumen modulation and animal performance have not been consistent. Glycerin is a by-product from biodiesel production and is a major component of distiller's grains, and thus is frequently present in diets of finishing cattle. The aim of this work was to evaluate interactive effects of sorghum-derived tannins and glycerol on fermentative activity (in vitro dry matter digestibility, IVDMD; ammonia, NH3; and volatile fat acid, VFA profiles) of in vitro cultures of mixed ruminal microorganisms. Tannins were prepared from sorghum bran by extraction with acetone and lyophilized. For in vitro fermentations, 40 mL of modified McDougall's buffer (no urea) were placed into 100 mL plastic bottles along with 20 mL of strained ruminal fluid and 2 g of substrate. Ruminal fluid was obtained from fistulated cattle fed a diet consisting of approximately 50:50 forage:concentrate (alfalfa hay, corn silage, corn flake, dry distilled grain, mineral mix). Substrate for in vitro fermentations consisted of finely ground (< 1 mm) corn and soybean meal in a 90:10 ratio (C) or partial replacement of corn with glycerol (G; 10% of substrate), tannin (T; 1%) or a mix (TG). After incubating 24 h at 39C, IVDMD and concentrations of NH3 and VFA were measured. Data were analyzed as a randomized complete block design by using the PROC MIXED of SAS, and results are summarized below. Shifts in concentrations of ammonia and VFA in cultures fed glycerol generally were exacerbated by the presence of tannins. The observed interaction between glycerol and tannin may explain the varying results found in studies that use glycerol as a substitute for cereals grains in diets of ruminants.

Key Words: glycerin, tannin, sorghum

Table 1701. Effect of glycerol and sorghum-based tannins extract on in vitrofermentative activity of mixed ruminal microorganisms

	Treatment					
Item	C	G	T	TG	SEM	*P*-value*
IVDMD, %	55.2	53.7	53.1	52.5	0.91	0.104

1702 (T315) Use of byproducts from corn industry and citric acid on dairy heifer diet. I. D. C. Hermisdorff, R. M. Dos Santos*, M. F. Gonçalves, A. M. França, M. Visoná-Oliveira, H. Nogueira, A. Santos and I. C. Ferreira, *Universidade Federal de Uberlândia, Uberlândia, Brazil*

The use of byproducts in animal nutrition is an interesting alternative. Besides minimizing cost of livestock production, is a way to absorb part of the growing residue of industrial production, thus improving environmental conditions. By-products of sugar production, such as mycelium, precoat, and rafinate have become available for use. The mycelium is composed of cellular material from the fermentation of sugar by the fungus *Aspergillus niger*. The rafinate results from the purification process of the citric acid, the principal product formed from the fermentation of sugar. The precoat filter is derived from the step of glucose syrup production. The aim of this study was to evaluate performance of crossbred dairy heifers fed diets with wet byproducts. Forty heifers weighing on average 240 kg were randomly assigned to four treatments receiving control diet ($n = 10$) and diets containing: precoat ($n = 10$), mycelium ($n = 10$) and rafinate ($n = 10$). The control diet was formulated with sugar cane bagasse, and wet corn gluten feed (WCGF), corn gluten feed (CGF) and cracked corn. The other diets were formulated with the same ingredients, but with the inclusion of byproducts cited in their respective treatments. The average dry matter intake (DMI) was estimated by the difference between dry matter offered and orts, divided by the number of animals in treatment. Samples of offered and orts were collected daily and sent for chemical analysis. The design was randomized and analyzed variables were subjected to statistical analysis, considering significance at 5% probability. There were significant differences in dry matter intake (DMI) ($P < 0.01$), where mycelium showed the highest and control the lowest intake. There were no significant differences in consumption of neutral detergent fiber by the animals, initial and final body weight, total and average daily gains and feed efficiency (FE) of the heifers ($P > 0.05$). Control and rafinate groups showed better FE ($P < 0.01$) compared to the mycelium, whereas precoat performed equally to all treatments. The inclusion of wet byproducts mycelium, precoat and rafinate in the diet of crossbred dairy heifers at 5.5, 3.4 and 4.8% of fresh matter, respectively, provides satisfactory performance of the animals. However, more studies are needed to determine the economic viability of using these byproducts in ruminant diet.

Key Words: mycelium, precoat, rafinate, dry matter intake

1703 (T316) Monensin increases endotoxin concentration in an in vitro rumen fermentation model. N. Reisinger[1], S. Schaumberger[*2], I. Dohnal[1], C. Emsenhuber[1], C. Stoiber[1] and G. Schatzmayr[1], *[1]Biomin Research Center, Tulln, Austria, [2]Biomin Holding GmbH, Herzogenburg, Austria.*

Administration of antibiotics (e. g. Beta-lactam), which effect gram-negative bacteria, can lead to an increased concentration of endotoxins in the rumen. This increase can lead to endotoxin associated effects like inflammation, immune response and diseases risks, e.g. mastitis, endometritis and laminitis. Monensin has a wide range of application indications in ruminants: coccidiosis, ketosis, pulmonal edema, pneumonia, and is even used as growth promoter. This ionophore inhibits the growth of gram-positive bacteria, but there is no literature available on the effects on endotoxin release by increase of gram-negative bacteria. The objective of this study was, therefore, to test the effect of monensin on the ruminal endotoxin concentration in an in vitro rumen fermentation model. Rumen fluid was incubated under anaerobic conditions at 39°C and a continuous flow of synthetic saliva for 336 hours. Fresh feed (50% chopped hay; 50% cereal nutrient) was supplied in nylon bags every 24 hours. Six reactors were treated with monensin (10 mg/L), the other six reactors served as untreated control. Samples of the rumen fluid were taken after 24 and 336 hours. Samples were centrifuged; heat inactivated and filtrated before dilution with endotoxin free water. Endotoxin concentration was measured with the chromogenic *Limulus-Amebocyte* Lysate assay, according to manufacturer's instructions. Total bacterial count was performed with the flow cytometer. There was no significant difference in the endotoxin concentration of the control reactors (895 EU/ml) compared to the monensin treated reactors (1.715 EU/ml) after 24 hours ($P > 0.05$). In contrast, after 336 hours incubation, the endotoxin concentration in monensin-treated reactors (12.485 EU/ml) significantly ($P < 0.05$) increased compared to the control reactors (1.471 EU/ml). The total bacterial count was also significantly increased after 336 hours in the monensin-treated reactors compared to the control reactors ($P < 0.05$). Results of this in vitro experiment showed that monensin led to an increase of endotoxins in rumen fluid. This might be a result of the expected bacterial shift from gram-positive to gram-negative bacteria. Further investigations are necessary to verify these results and to clarify the mechanism of monensin in the in vitro rumen fermentation model. In addition, it will be useful to test other antibiotics, to avoid negative effects on bacterial populations and increase of endotoxins.

Key Words: endotoxins, monensin, rumen

1704 (T317) Effect of a calcareous algae and monensin on feed intake and rumen parameters of cattle fed abruptly high concentrate diets. R. Ferreira Carvalho[1], A. P. S. Silva[1], M. Rezende Mazon[2], C. A. Zotti[1], L. Silva Oliviera[1], S. Luz e Silva[*1] and P. R. Leme[1], *[1]University of Sao Paulo/FZEA, Pirassununga, Brazil, [2]University of Sao Paulo, Pirassununga, Brazil*

Additives are used in high concentrate diets to prevent metabolic disorders. The use of calcareous algae (*Lithothamnium calcareum*), a natural and renewable product, may be an alternative. The effect of a calcareous algae product (Top Buffer Sanphar, Campinas, Brazil) and monensin (Bovensin Phibro, Guarulhos, Brazil) on feed intake, rumen pH, short chain fatty acids, lactate and ammonia nitrogen concentration in the rumen of Nellore steers transitioned abruptly to a high concentrate diet was evaluated.. On d 1, the diet of all animals was abruptly changed from hay to a high concentrate diet (82.41% corn, 7.75% sugar cane bagasse, 6.78%, soybean meal, 1.29% urea and 1.77% mineral mixture). The diet was provided once a day during four periods of 21 days, and treatments consisted of different additives: limestone 7.1 g/kg DM, calcareous algae product 7.4 g/kg DM, limestone and monensin 30mg/kg DM and calcareous algae product and monensin 30mg/kg. Rumen pH was measured continuously from d -3 to d 21 through an indwelling pH probe (Dascor, Escondido, Canada) inserted in the rumen. Rumen samples were taken six hours after feeding on days -1, 4, 7 and 14. Feed intake was adjusted daily, allowing ten percent orts. There was no interaction ($P > 0.050$) between calcium source and monensin for feed intake, ruminal pH and total concentration of short chain fatty acids. There was no influence ($P > 0.050$) of calcium sources on feed intake, total concentration of short chain fatty acids, acetate:propionate ratio, lactate and ammonia nitrogen concentration. Diet with the calcareous algae product resulted in higher ($P = 0.040$) average rumen pH than limestone (6.09 vs. 6.01, respectively) and lower ($P < 0.001$) time bellow pH 5.2 (1hr29min vs. 2hrs43min). Treatments with the presence of monensin resulted in higher ($P = 0.008$) concentration of ammonia nitrogen (4.69 vs. 3.94 mg/dL without monesin) and lower ($P = 0.023$) time bellow pH 5.2 (1hr45min vs. 2hrs27min without monensin). Calcareous algae product was more efficient in controlling rumen pH than limestone without influencing feed intake and the concentration of short-chain fatty acids. Monensin was also beneficial in preventing rumen disorders.

Key Words: Nellore, additives, acidosis

1705 (T318) Effect of post-extraction algal residue supplementation on the rumen microbiome of steers consuming low-quality forage.

J. C. McCann*[1], M. L. Drewery[2], W. E. Pinchak[3], J. E. Sawyer[4] and T. A. Wickersham[2], [1]*University of Illinois, Urbana,* [2]*Texas A&M University, College Station,* [3]*Texas A&M Agrilife Research, Vernon,* [4]*Texas AgriLife Research, College Station*

Cattle consuming low-quality forages require protein supplementation to increase forage utilization and ruminal fermentation. Production of algal biomass for biofuel would result in large quantities of post-extraction algal residue (PEAR, 17.9% CP) which has the potential to elicit similar low-quality forage utilization responses to cottonseed meal (CSM, 42.9% CP); however, its effect on ruminal bacterial communities is unknown. Five ruminally and duodenally cannulated Angus steers in a 5 × 5 Latin square had ad libitum access to oat straw (4.5% CP, 80% NDF). Treatments were infused ruminally and consisted of an unsupplemented control (CON), PEAR at 50, 100, and 150 mg N/kg BW, and CSM at 100 mg N/kg BW. Rumen samples were collected 4 h after supplementation on d 14 of each period and separated into liquid and solid fractions. After DNA extraction, amplification of the V4-V6 region of the 16S rRNA gene and 454 pyrosequencing was performed on liquid and solid rumen samples. After denoising, chimera checking, and quality trimming, 8364 ± 2745 sequences were generated per sample. Weighted UniFrac analysis and Morisita-Horn index demonstrated different community composition between liquid and solid fractions. Greater homogeneity was observed within solid samples. At the phyla level, *Bacteroidetes* characterized more than 75% of sequences in the solid fraction, while relative abundance of *Firmicutes* in the liquid fraction increased linearly with PEAR supplementation ($P = 0.02$). *Prevotella* represented over 25% of sequences in all treatments and decreased in the solid fraction with increasing PEAR provision (linear, $P = 0.01$). *Lachnospiraceae*, *Ruminococcaceae*, and *Clostridiaceae* increased in the liquid fraction with greater PEAR supplementation (linear, $P \leq 0.03$). *Fibrobacter* and *Treponema* decreased in the liquid fraction with increasing PEAR (linear, $P < 0.10$). Bacterial community composition was similar between CON and 100 mg N/kg BW CSM treatments. Results suggest increased forage utilization from PEAR supplementation may be linked to changes within the liquid fraction of the rumen microbiome.

Key Words: microbiome, post-extraction algal residue, supplementation

1706 (T319) Effect of concentrate diets contrasting in fatty acid profiles on lamb performance, carcass characteristics, fatty acid composition and wool production.

S. J. Meale[1,2], A. V. Chaves[1], M. He[2] and T. A. McAllister*[2], [1]*The University of Sydney, Sydney NSW, Australia,* [2]*Agriculture and Agri-Food Canada, Lethbridge, AB, Canada*

Knowledge of the health benefits associated with the consumption of *n*-3 PUFA has led to the selective inclusion of dietary lipids in ruminant diets in attempts to increase tissue incorporation. Increasing the *n*-3 fatty acid content of ruminant tissues requires the inclusion of dietary lipids that contain unsaturated fatty acids capable of withstanding ruminal biohydrogenation. Tasco a commercial algal product manufactured from the brown alga *Ascophyllum nodosum* (TA; 2% DM) was compared to canola (CO), flax (FO) and safflower oils (SO) for effects on performance, fatty acid profiles of skirt muscle, subcutaneous and perirenal adipose tissues and wool yield and quality characteristics of Canadian Arcott lambs. Fifty-six lambs were randomly assigned to four diets. Diets consisted of a pelleted, barley-based finishing diet with lipid sources included at 2% DM. Feed deliveries and orts were recorded daily with lambs weighed weekly and slaughtered once they reached ≥ 45 kg LW. Carcass characteristics and rumen pH were determined at slaughter. Dye-bands were used to determine wool growth, micron and staple length. Data were analyzed using mixed procedure in SAS. No effects were observed on intake, growth, feed efficiency or carcass characteristics. An increase ($P < 0.05$) in staple strength of CO lambs was the only effect observed in wool. Supplementing Tasco at 2% DM in the diet of Canadian Arcott lambs increased ($P \leq 0.002$) the SFA/PUFA ratio in skirt muscle and subcutaneous and visceral adipose tissues in comparison to the supplementation of oils. Additionally, Tasco supplementation did not improve concentrations of long chain *n*-3 PUFA or total *n*-3 concentrations in skirt muscle or adipose tissue when compared to lambs fed canola, flax or safflower oils. In contrast, supplementing FO increased total *n*-3 accumulation and reduced the *n*-6/*n*-3 ratio in all tissues ($P < 0.001$), suggesting that the supplementation of Tasco did not beneficially alter the FA profile of lamb tissues in comparison to other dietary lipids.

Key Words: fatty acids, lambs, micro-algae

1707 (T320) Feed value for ruminants of newly developed black and yellow type of canola seeds.
K. Theodoridou[*1], P. Yu[2,3], H. Xin[1] and X. Huang[1], *[1]University of Saskatchewan, Department Animal and Poultry Science, Saskatoon, SK, Canada, [2]Department of Animal Science, Tianjin Agricultural University, Tianjin, SK, China, [3]University of Saskatchewan, Saskatoon, SK, Canada*

Canola is one of the most valuable agricultural crops in world trade and a major oilseed crop in western Canada. The objective was to evaluate the nutritive value of canola seed, for ruminants, in terms of: 1) nutritional profiles, 2) degradation kinetics, 4) in vitro intestinal protein digestibility, and 4) energy values. Yellow (CS_Y) and black (CS_B) canola seeds (n = 4) were collected from two harvest years (2010, 2011). Three dry Holstein cows with rumen cannula were used in an *in situ* trial; then a three-step in vitro procedure was conducted to determine protein intestinal digestibility. According to this procedure the dried ground rumen residues, (contain 15 mg of N) after 12h of ruminal incubation, were exposed to HCl solution containing pepsin. The pH was neutralized with NaOH and phosphate buffer (pH 7.8) containing pancreatin, which were added to the solution and incubated. After 24h incubation, trichloroacetic acid (TCA) was added to precipitate undigested proteins. The samples were centrifuged and the supernatant was analyzed for N. Protein digestibility was calculated as TCA-soluble N divided by the amount of N in the 12h residue sample. The non-protein N (NPN) was analyzed by precipitating of true protein with tungstic acid and calculated as the difference between total N and the N of the residue after filtration. Soluble CP (SCP) was determined by incubating the sample with bicarbonate-phosphate buffer and filtering. The study revealed that the CS_Y was lower in NDF (122.1 vs. 154.5 g kg^{-1} DM, $P < 0.05$), ADF (60.7 vs. 98.6 g kg^{-1} DM, $P < 0.05$), NPN (g kg^{-1} SCP), ADICP (g kg^{-1} DM), soluble protein fraction (28.59 vs. 34.11, $P < 0.05$) and higher (67.28 vs. 59.02, $P < 0.05$) in degradable protein fraction and in vitro intestinal digestibility (56.6 vs. 44.6 g kg^{-1} CP in ruminally incubated residues, $P < 0.05$) than the CS_B. CS_Y contain lower amount of total phenolics compared to CS_B (626.0 vs. 718.0 mg/100g). No significant differences were obtained between the two canola varieties, for the total fatty acids (902.0 vs. 910.7 mg FA/g, SEM 5.17, $P > 0.05$), the CP (g kg^{-1} DM) and the SCP (7.0 vs. 8.5, $P > 0.05$). Total digestible nutrients, metabolizable and digestible energy was higher ($P < 0.05$) for the CS_Y than for the CS_B. Overall, the results demonstrated that the yellow-seeded canola has the potential to be a greater source for energy and protein supply for ruminants compared to the black canola seed.

Key Words: canola, protein supply, ruminal and intestinal digestion

1708 (T321) Could lactic acid treatment decrease in-vitro gas production of barley grain.
M. Dehghan banadaky[*1], A. Zali[2], M. Ganjkhanlou[2], K. Rezayazdi[3], M. Nematpoor[2] and A. Laki[2], *[1]Department of Animal Science, Faculty of Agriculture, University of Tehran, Karaj, Iran, [2]University of Tehran, Karaj, Iran, [3]Department of Animal Science, University of Tehran, Karaj, Tehran, Iran*

The aim of present study was evaluation the effects of treatment barley grain with lactic acid on gas production characteristics. Rolled barley steeped in an equal quantity (wt/vol) of tap water containing 2.5, 5 and 7.5 mL lactic acid (LA) per liter for 24 h. Treated barley were dried and was ground through a 1-mm screen. Then 300 mg of ground barley pre-loaded into 125-ml serum vials. Ruminal fluid was collected from three fistulated Holstein cows. Cow's ruminal fluid mixed in equal quantity and mixed Menke and sreingass, 1988 buffer solution. Inoculums was dispensed anaerobically (40 ml/vial) under a steam of 0_2–free with co_2, followed immediately by sealing and affixing to incubator at 39 ^{0}c. Triplicate vials containing no substrate were also prepared as blank controls. Gas produced was measured at 2, 4, 6, 8, 10, 12, 24 and 48 h of incubation. Cumulative gas production data were fitted to a model of $Y = b (1\text{-}e^{-ct})$; Y = potential of gas production at time t; b = the asymptotic gas volume (ml); c = gas production constant rate (ml/h); t = incubation time (h). Data analyzed by GLM procedure of SAS (2003). According to the result of this study steeping barley in water containing 7.5 gr LA for 24 h decreased gas volume in the early time of incubation and gas production constant rate in comparison to dry rolled barely. On the other hands, it showed that treated barley grain with 7.5 gr LA decreased barely grain digestibility until 6 h of incubation and may be decrease acidosis in ruminant.

Key Words: rolled barley, lactic acid and steeping

1709 (T322) Microwave irradiation induced changes in protein inherent structure, protein chemical profile, protein subfractions and digestive behavior of different types of new hulless barley in the rumen and intestine of dairy cows.
X. Yan[1,2], N. Khan[1], X. Huang[*1] and P. Yu[1], *[1]University of Saskatchewan, Saskatoon, SK, Canada, [2]Jilin Academy of Agricultural Sciences, Jilin, China*

The objectives of this study were to evaluate microwave irradiation (MIR) induced changes in nutritive value of three types of hulless barley (*Hordeum vulgare*) in ruminant nutrition, and to quantify the MIR induced changes in protein molecular structures in relation to protein chemical profiles and digestive behavior in the rumen and intestine of the dairy cow. In this study, three barley varieties with in two consecutive years from 2009 to 2010 were chosen. All samples were cultivated and harvested from the university testing farm. The

grains were either kept as raw or irradiated in a microwave, operated at a power of 900 W with irradiation frequency of 2450 MHz, for 3 min (MIR3) or 5 min (MIR5). Mixed procedure of SAS was performed to analyze data with a RCBD model. PROC CRRR was adopted to determine the correlation. Tukey was used to compare treatment means. Significance was declared at $P < 0.05$. Compared to non-irradiated grains, MIR5 markedly decreased (50.8 to 17.6%) soluble protein and increased NDIP (13.3 to 26.2%) and ADIP (1.0 to 5.3%) in total CP ($P < 0.05$). As consequence, the CNCPS CP rapidly degradable fraction substantially decreased (45.2 to 6.4% CP) with a simultaneous increase in the intermediately degradable (35.8 to 56.2% CP), slowly degradable (12.4 to 20.9% CP) and non-degradable (1.0 to 5.3% CP) fractions ($P < 0.05$). The MIR for 5min decreased soluble CP fraction (6.5 to 0.0%) and degradation rate (8.2 to 3.5%/h) of potentially degradable fraction ($P < 0.05$). As a consequence the RDP markedly decreased (55.7 to 34.1% CP) with a concomitant increase (43.3 to 65.9% CP) in RUP supply to the post-ruminal tract ($P < 0.05$). Except the CNCPS rapidly degradable and in situ soluble fraction, the MIR3 did not alter protein chemical profiles, CNCPS subfraction, rumen degradability and intestinal digestibility of RUP. However, the MIR5 decreased (79.4 to 67.9% RUP) intestinal digestibility of RUP. The molecular structure study revealed that MIR for 3 and 5 min consistently decreased the spectral intensities of amide I and II, α-helix and β-sheet, and increased their ratios. The changes in protein spectral intensities were strongly correlated with the changes in protein chemical profiles, CNCPS subfractions and in situ degradation characteristics. Our results showed that MIR for a short period with a lower energy input can improve the nutritive value and utilization of protein in barely grains.

Key Words: different hulless barley, microwave irradiation, nutrient availability, protein molecular structure

1710 (T323) Protein and energy availability of sorghum wet distiller grains without solubles in comparison to the parental grain. M. D. L. A. Bruni[1] and A. I. Trujillo[*2], *[1]Facultad de Agronomia Universidad de la Republica, Paysandu, Uruguay, [2]Facultad de Agronomia, Universidad de la Republica, Montevideo, Uruguay*

Sorghum can be an alternative for ethanol industry in Uruguay and its by-product (SWDG) can be used as animal feed. An accurate characterization of protein fractions and energy is required for ruminant diets formulation. The chemical profile (in % ± standard deviation) of SWDG presented high values of moisture (66.7 ± 2.6), crude protein (CP, 31.4 ± 0.7), fat (11.0 ± 0.7) and neutral detergent fiber (70.2 ± 2.2).The objective of this study was to characterize the protein fractions and estimate energy digestible (ED) content of three batches of SWDG and its parental grain (SG). In addition, intestinal digestible protein (IDP) of SWDG was measured. Protein fractions were assessed according to the Cornell Net Carbohydrate and Protein System (rapidly protein degradable: A+B1; intermediate degradability: B2; slowly degradable: B3 and undegradable fraction: C, as percentage of CP). The rumen undegradable protein (RUP) was evaluated by in situ assay. Pepsin-pancreatin digestion of rumen pre-incubated (12 h) samples was used to estimate IDP. Digestible energy content was estimated using summative equation computed from digestibility's nutrients by chemical (NRC, 2001) or in situ (using 48 h of nutrient disappearance) approach. Data was analyzed with PROC GLM in a completely randomized design and compared with Tukey test. No differences were found between batches, neither in SWDG nor in SG. The SWDG presented lower ($P < 0.005$) values of A+B1 and B2 fractions than SG (2.3 vs. 4.2% and 36.3 vs. 60.5%) respectively; however B3 and C fractions were greater ($P < 0.018$) than SG (27.7 vs. 13.2% and 33.7 vs. 22.1%). The SWDG presented greater ($P < 0.05$) RUP (estimated using passage rate = 2%/h) compared with SG (75.5 vs. 42.2% CP). The IDP of the SWDG was 51.1 ± 4.5%RUP providing an average value of total digestible protein of 63.6%. Digestible energy estimations of SDWG were lower ($P < 0.003$) than SG (3.16 vs. 3.7 and 2.5 vs.3.7 Mcal/kg DM for chemical or in situ approach, respectively). The greatest difference between the two approaches was observed in SWDG which could be probably explained by estimation of truly digestible CP and NDF fractions. The potential supply of protein fractions of the SWDG was modified by the industrial process increasing slowly degradable and undegradable fractions. The potential of absorbable protein of SWDG was around half of a soybean meal while its ED content represent 70-80% of energetic value of SG.

Key Words: distillers grain, nutritive value, intestinal digestibility

1711 (T324) Effect of crude glycerin on dry matter and nutrient digestibility of feed ingredients in dairy cows. F. D. O. Scarpino van Cleef[*1,2], J. M. Bertocco Ezequiel[1], J. Borsari Dourado Sancanari[3] and E. H. C. B. Van Cleef[1,4], *[1]UNESP, Jaboticabal, Brazil, [2]CNPq, Brasilia, Brazil, [3]UCB, Jaboticabal, Brazil, [4]FAPESP, Sao Paulo, Brazil*

Rumen-cannulated Holstein cows ($n = 6$; 587 ± 39 kg BW; 114 ± 29 DIM; 20 ± 1.5 kg milk/d), were used to evaluate the effects of crude glycerin on in vitro digestibility of dry matter, and nutrients (CP and NDF) of feed ingredients. Cows were assigned to a replicated 3 × 3 Latin square. The three isoenergetic and isonitrogenous diets composed of corn silage, cracked corn grain, sunflower meal, corn gluten, urea, mineral premix, and 0 (G0), 15 (G15), or 30% (G30) crude glycerin. The experiment lasted 69 d, with three periods of 23 d each. For in vitro determinations, the Daisy II fermenter was used. The ingredients were ground (1 mm), and placed in F57 bags

(0.5 g/bag; 25 bags/treatment). At d 20 of each experimental period, rumen content was manually collected and strained with cheesecloth. Then, 400 ml of strained rumen content were placed in each fermentation jar, with 1330 ml buffer A and 266 ml buffer B. The jars were purged with CO_2, and incubated at 39°C for 72 h. When the incubation was completed 48 h, 8 g pepsin and 40 ml HCl 6N were added to each jar. The pH and ammonia-N (NH_3–N) were determined at 0, 48, and 72 h of incubation. Data were analyzed as mixed model with fixed effects of diet and period, and random effects of cow (diet) and residuals. Crude glycerin inclusion did not affect pH and NH_3–N concentration (pH = 6.5, 6.4, 3.4; NH_3–*N* = 20.5, 8.3, and 8.5 mg/dl, respectively for 0, 48, and 72 h incubation). The addition of 15% crude glycerin decreased ($P < 0.05$) IVDMD and IVCPD of sunflower meal, and corn grain. When 30% crude glycerin were added, a decrease in IVDMD was observed for corn gluten ($P < 0.05$), and in vitro NDF digestibility for corn silage ($P < 0.01$). No differences were observed on IVDMD and IVCPD of corn silage. The addition of up to 30% crude glycerin in lactating cows diets affected digestibility of feed ingredients. Caution should be taken when combining glycerin with roughages, due to the negative effect on NDF digestibility.

Key Words: dairy cow, digestion, glycerol.

1712 (T325) Positive effect of fat supplementation in the early postpartum period can continue throughout lactation after fat supplementation ceases.

M. Garcia*[1], L. F. Greco[2], W. W. Thatcher[2], J. E. P. Santos[2] and C. R. Staples[2], *[1]Department of Animal and Avian Sciences, University of Maryland, College Park, [2]Department of Animal Sciences, University of Florida, Gainesville.*

Objective was to determine whether increased milk yield detected during the period of fat supplementation in early lactation would continue throughout lactation after supplemental fat was removed from the diet. Three studies were conducted at the University of Florida dairy farm in which Holstein cows produced more milk in response to fat supplementation in the early postpartum period. Experiments 1 and 2 had the same dietary treatments. Cows consumed a control diet without fatty acid (FA) supplementation, a diet supplemented with mostly saturated free FA (SFA; 1.9% of dietary DM), or a diet supplemented with Ca salts enriched with essential FA (EFA; 2.4% of dietary DM). In the first experiment, cows (n = 74) were assigned randomly to treatments 56 d before calving and treatments were maintained until 90 DIM. In the second experiment, cows (n = 30) were fed the same 3 dietary treatments from 15 to 106 DIM. In experiment 3, Holstein cows (n = 39) were assigned to diets supplemented with a mixture of Ca salts of fish, safflower, and palm oils (1.4% of dietary DM) to create 3 supplemental ratios of 4, 5, or 6 parts of n-6 to 1 part of n-3 FA (R4, R5, and R6). Diets were fed from 15 to 105 DIM. Cows in experiment 2 and 3 had a covariate based on milk produced during the first 6 to 10 DIM. Milk production was recorded through 43 wk of lactation using AFI-MILK system. Orthogonal contrasts were used to test for effects of fat supplements during the fat-feeding period and for the complete lactation. In general, when fat supplementation improved or tended to improve milk production during the fat-feeding period, milk yield also was improved or tended to be improved for the whole lactation. Milk composition was minimally changed. Strategic feeding of FA during early lactation can benefit milk yield after fat is removed from the diet.

Key Words: dairy cow, fatty acids, milk yield

1713 T326) Sources and levels of rumen protected fat on energy balance of dairy cows grazing a tropical pasture.

F. Batistel*[1], J. D. Souza[2] and F. A. P. Santos[1], *[1]University of São Paulo, Piracicaba, Brazil, [2]University of Sao Paulo, Piracicaba, Brazil*

The objective of this experiment was to investigate the effects of supplementation lactating cows grazing a tropical pasture receiving two levels of calcium salts of palm oil (CSPO) or calcium salts of soybean oil (CSSO) on energy balance. Five rumen-cannulated cows (115 ± 8.1 DIM) were used in a Latin square 5x5 and subjected to the following treatments: a) control (no fat); b) 400 g CSSO cow^{-1} d^{-1}; c) 700 g CSSO cow^{-1} d^{-1}; d) 400 g CSPO cow^{-1} d^{-1}; and e) 700 g CSPO cow^{-1} d^{-1}. Treatment periods were 24 d in length and cows grazed paddocks of *Pennisetum purpureum* and received 8 kg cow^{-1} d^{-1} (DM) of concentrate. Concentrate of treatment control was composed by ground corn (82.8%), soybean mean (12%), urea (0.2%), sodium bicarbonate (1%) and mineral/vitamin premix (4%) and fat supplementation replaced ground corn. To estimate fecal excretion, cows were orally dosed with titanium dioxide twice daily for 15 d. Forage intake was calculated from total

fecal excretion and feed digestibility. Indigestible NDF (estimated as NDF residue after 240 h of in situ incubation) was used as an internal marker to estimate digestibility. NE_L intake, milk NE_L and NE_L in empty BW gain was calculated according to NRC (2001). Data were analyzed using a mixed model with animal and period as random effects. The means were compared using a Tukey test. Both levels of CSPO increased NE_L intake (27.7 Mcal/d). There was no difference in NE_L intake between control and 400 g CSSO (26.1 vs. 26.0 Mcal/d), but both were greater than 700 g CSSO (25.4 Mcal/d). The milk NE_L (Mcal/d) was greater for 400 g CSPO (13.1) and 700 g CSPO (12.9) in comparison to control (12.1) and 400 g CSSO (11.6). The lowest milk NE_L was observed in 700 g CSSO (10.3), due to the lowest milk yield and milk NE_L per kg of milk observed in this treatment. The NE_L in empty BW gain (Mcal/d) was greater in 700 g CSSO (3.03) compared with 400 g CSSO (2.65), and both levels of CSPO (2.05 and 2.28 for 400 and 700 g, respectively). The control showed the lowest NE_L in empty BW gain (1.63) among the treatments. Dairy cows grazing tropical pasture supplemented with sources of fat increased energy intake with CSPO and the energy consumed was used differently according to the source of fat supplemented.

Key Words: palm oil, soybean oil

1714 (T327) Saturated fat supplementation interacts with dietary forage NDF concentration during the postpartum period in Holstein cows: Energy balance, nutrient digestibility, and metabolism.

P. Piantoni*, A. L. Lock and M. S. Allen, *Michigan State University, East Lansing*

Forty-eight multiparous cows were used in a randomized complete block design experiment with a 2x2 factorial arrangement of treatments. Treatment diets were offered from 1 to 29 d postpartum and contained 20% or 26% forage NDF (fNDF) and 0% or 2% saturated free fatty acid supplement (Energy Booster 100; FAT). The 2% FAT treatment increased total tract digestibility of OM and NDF in the low fNDF diet (67.6% vs. 65.9% and 44.0% vs. 40.1%, respectively), but not in the high fNDF diet (interactions $P \leq 0.08$). Overall, low fNDF vs. high fNDF and 2% FAT vs. 0% FAT increased digestible energy intake (DEI) (67.5 vs. 62.2 Mcal/d and 68.1 vs. 61.6 Mcal/d, respectively; both $P < 0.01$). An interaction between fNDF and FAT with time was detected for net energy balance (NEB): the low fNDF diet with FAT had higher NEB than the other treatments early but treatment differences diminished over time (interaction $P = 0.10$). Overall, low fNDF vs. high fNDF diets and 2% FAT vs. 0% FAT improved NEB (-13.0 vs. -16.3 Mcal/d and -12.0 vs. -17.3, respectively; both $P < 0.05$) but decreased efficiency of utilization of DEI for milk (Milk NE_L/DEI; 0.575 vs. 0.634 and 0.565 vs. 0.643, respectively; both $P < 0.05$). Low fNDF diets increased plasma insulin (0.308 vs. 0.137 µg/L) and glucose concentrations (50.5 vs. 45.7 mg/dL), and decreased concentrations of NEFA (606 vs. 917 µEq/L) and BHBA (9.29 vs. 16.5 mg/dL; all $P \leq 0.001$). The 2% FAT treatment tended to decrease plasma NEFA concentration (695 vs. 827 µEq/L; $P = 0.06$) compared with 0% FAT, but treatment differences diminished over time (interaction $P < 0.05$). The 2% FAT treatment increased maximum plasma insulin concentration during a glucose tolerance test in the low fNDF diet (84.5 vs. 44.6 µIU/mL) compared with the high fNDF diets (40.4 vs. 38.0 µIU/mL; interaction $P = 0.07$). FAT tended to interact with dietary fNDF concentration for insulin area under the curve: 2% FAT increased insulin area under the curve by 64% when included in the low fNDF diet (2586 vs. 1575 min*µIU/mL), but only by 5.1% when included in the high fNDF diet (1307 vs. 1243 min*µIU/mL; interaction $P = 0.12$). Supplementation of FAT and low fNDF diets increased DEI and improved NEB, but decreased apparent efficiency of utilization of DEI for milk production in the postpartum period.

Key Words: energy balance, postpartum, prilled fat

1715 (T328) Production performance parameters of early lactation Iranian Holstein cows fed diets containing high levels of palmitic acid or Ca-salt of unsaturated fatty acids.

H. Khalilvandi-Behroozyar[1], M. Dehghan Banadaky*[2], K. Rezayazdi[2] and M. Ghaffarzadeh[3], *[1]Department of Animal Science, Urmia University, Urmia, Iran, [2]Department of Animal Science, University of Tehran, Karaj, Tehran, Iran, [3]Chemistry and Chemical Engineering Research Center of Iran, Tehran, Iran*

Fat supplements can improve energy balance, feed efficiency, and the yields of milk and milk fat. However, the effects of different FA profiles have not yet been adequately studied. The aim of this study was to evaluate the milk fatty acid profile in early lactating dairy cows supplemented with protected unsaturated fatty acids sources and prilled source of palm fatty acids. Twenty four multiparous Iranian Holstein cows were assigned to diets with different fatty acid profiles and supplemented through 30 days prior to expect calving date to 50 days in milk. Dietary treatments consisted of (1) Prilled Pam fatty acids (PO) [Energizer RP10 , 2 and 2.25% DM in pre- and postpartum, respectively]; (2) Ca-salts of sunflower oil (SO) [Persia Fat- SO]; (3) Ca-salts of fish oil (FO) [Persia Fat- FO] and (4) equal amounts of Persia Fat- FO and Persia Fat- SO. Calcium salts were supplemented as 2.2 and 2.5% of dietary DM in pre- and postpartum period, respectively Milk yield and the dry matter intake were measured daily throughout the experimental period. The milk samples were obtained weekly (2 consecutive days, 3 daily milking, Individual milk samples were analyzed for fat, true protein, and lactose concentration by mid-infrared spectroscopy by the Iranian Dairy Herd Improvement Association. Yields of 3.5% FCM, ECM, and milk components were calculated using milk yield and component concentrations for each milking. Data were analyzed using PROC MIXED of SAS 9.1 according with re-

peated measures in time function. Milk and milk component yields were greater with Persia Fat than with palmitic fatty acid prill. However feed efficiency was not statistically different (1.84 kg FCM/kg DMI vs. 1.89, 1.88 and.86, for treatments 1 to 4, respectively). Cows fed Persia Fat had greater DMI than those fed Palm oil fatty acids (20.17 kg DM vs. 23.56, 22.25 and 22.53, for treatments 1 to 4, respectively). Milk protein concentration was higher for PO compared with Persia Fat (3.27% vs. 3.14, 3.12 and 3.08, for treatments 1 to 4, respectively), but Persia Fat fed cows produced more milk protein per day. Based on results we conclude that different fatty acids have different digestibilities, absorption and/or differing biological effects post absorption.

Key Words: PUFA, palmitic acid, FCM

1716 (T329) Characterization of the role of long-chain fatty acids in the regulation of lipogenic gene expression via LXRα in goat mammary epithelial cells. W. Zhao*[1,2], J. Luo[1], P. Dovc[3] and J. J. Loor[2], *[1]Northwest A&F University, Yangling, China, [2]University of Illinois, Urbana, [3]University of Ljubljana, Domzale, Slovenia*

In dairy cows and goats, liver X receptor α (*LXRα*) is a nuclear receptor considered as a potentially important regulator of de novo long-chain fatty acid (LCFA) synthesis. Previous data in bovine MacT cells indicated that activation of *LXRα* with the agonist T0901317 (T09) up-regulates the expression of some lipogenic target genes, hence, could play a role in de novo FA synthesis regulation. In vitro, long-chain fatty acids (LCFA) could have an agonistic capacity on *LXRα*, thus, serving as an alternate mechanism for regulating milk fat synthesis. In order to characterize the roles of *LXRα* and LCFA in the regulation of lipid synthesis in goat mammary epithelial cells (GMEC), primary mammary cells isolated from mammary gland of Saanen dairy goats cultivated in lactogenic medium were cultured in triplicate and for 12 h with 50 μM of the specific *LXRα* agonist T0901317 (T09) or the specific *LXRα* antagonist GGPP (GP), 100 μM of several LCFA (16:0, 18:0, t10,c12- conjugated linoleic acid (CLA), docosahexaenoic acid (DHA), and eicosapentaenoic acid (EPA)), and a combination of GP with 100 μM of several LCFA (16:0, 18:0, t10,c12-CLA, DHA, and EPA) (for a total of 7 treatments excluding controls). Expression of 17 genes involved in LCFA plus 3 internal control genes was detected using qPCR. Data were statistically analyzed using the GLM of SAS. The multiple comparisons were corrected using Tukey's test and accepted as significant at $P < 0.05$. Although T09 did not alter *LXRα*, data from the cells treated with GP alone revealed that a minimum activation of *LXRα* is essential for the up-regulation ($P < 0.05$) of *INSIG1, LPIN1, FASN, SREBF1*, *AGPAT6,* and *SCD*. The marked up-regulation ($P < 0.05$) of *SREBF1*, *FASN*, *ACACA*, and *SCD* with T09 vs. control suggests their expression is partly controlled by *LXRα* as reported in MacT cells. Expression of *PPARG* did not respond to T09 or GP but when the LCFA were combined with GP, its expression was up-regulated ($P = 0.0001$) by 13-18 fold over the control. Both 16:0 and 18:0 when combined with GP up-regulated ($P < 0.05$) *SREBF1*, *INSIG1*, *SCD*, *ACSS2*, *AGPAT6*, and *LPIN1* but had no effect on *ACACA* or *FASN*. Data obtained with the combination of GP and LCFA revealed a complex scenario. However, data indicate that the LCFA effect could have been driven partly via *PPARG* as demonstrated previously in MacT cells. Overall, data suggest that LCFA could partly act as competitive agonists of *LXRα* in GMEC.

Key Words: nutrigenomics, milk fat synthesis, nuclear receptor

---

1717 (T330) Effects of feeding protected unsaturated fatty acids (Persia Fat)on milk fatty acid profile of Iranian Holstein dairy cows. H. Khalilvandi-Behroozyar[1], M. Dehghan Banadaky*[2] and M. Ghaffarzadeh[3], *[1]Department of Animal Science, Urmia University, Urmia, Iran, [2]Department of Animal Science, University of Tehran, Karaj, Tehran, Iran, [3]Chemistry and Chemical Engineering Research Center of Iran, Tehran, Iran*

In recent years, consumer concerns about contribution of milk and dairy products to total intake of saturated fatty acids has driven extensive research about effectiveness of protected fatty acid sources in modification of milk fatty acids. The aim of this study was to evaluate the milk fatty acid profile in early lactating dairy cows supplemented with protected unsaturated fatty acids sources and prilled source of palm fatty acids. Twenty four multiparous Iranian Holstein cows were assigned to diets with different fatty acid profiles and supplemented through 30 days prior to expected calving date to 50 days in milk. Dietary treatments consisted of (1) Prilled Pam fatty acids (PO) [Energizer RP10 , 2 and 2.25% DM in pre- and postpartum, respectively]; (2) Ca-salts of sunflower oil (SO) [Persia Fat-SO]; (3) Ca-salts of fish oil (FO) [Persia Fat- FO] and (4) equal amounts of Persia Fat- FO and Persia Fat- SO. Calcium salts were supplemented as 2.2 and 2.5% of dietary DM in pre- and postpartum period, respectively Milk yield and the dry matter intake were measured daily throughout the experimental period. The milk samples used for evaluating fatty acids profile were obtained weekly (2 consecutive days, each sample coming from the 3 daily milking, and were quantified by gas chromatography (Varian CP-3800, FID detector, 100 m CP-Sil88 column, GLC 463). Data were analyzed using PROC MIXED of SAS 9.1 with repeated measures in time function. Cows fed PO produced milk with higher saturated (69.90 vs. 58.14, 56.45 and 56.74, for treatments 1 to 4, respectively) and lower monounsaturated (23.37 vs. 32.22, 32.54 and 32.36, for treatments 1 to 4, respectively) polyunsaturated (2.80 vs. 7.13, 7.58 and 6.98, for treatments 1 to 4, respectively) fatty acid concentrations than cows fed diets with unsaturated fatty

acid sources. All of the differences between PO and Persia Fat sources were statistically significant, but not between unsaturated fatty acid sources. Feeding Persia Fat increased the milk concentration of C18:0, whereas that of C16:0 was increased by PO supplementation (39.13 vs. 25.92, 23.60 and 23.72, for treatments 1 to 4, respectively). Supplementation with PO significantly increased C16 and < C16 fatty acids, whereas decreased > C16 fatty acids in milk fat. Highest (statistically significant) n-3 and n-6 fatty acids contents were belong to Persia Fat- FO and Persia Fat- SO, respectively.

Key Words: PUFA, palmitic acid, omega-3,omega-6

1718 (T331) Milk yield and milk fat responses to increasing levels of stearic acid supplementation of dairy cows. J. P. Boerman* and A. L. Lock, *Michigan State University, East Lansing*

Dose-dependent effects of a stearic acid-enriched fat supplement on feed intake, production responses, and the maximum amount of stearic acid that can be incorporated into milk fat were evaluated. Multiparous Holstein cows (n = 32; 145 ± 66 DIM) with a wide range in milk yield (25– 70 kg/d) were blocked by milk yield and assigned to replicated 4 x 4 Latin squares. Treatments were diets supplemented with a stearic acid-enriched fat (SA; 87% C18:0) at 0, 0.8, 1.6, or 2.4% of diet DM. Periods were 21 d with the final 5 d used for data and sample collection. The corn silage and alfalfa silage-based diets were formulated to contain 25.8% forage NDF and 17.0% CP. The statistical model included the random effect of cow and the fixed effects of treatment, period, and their interaction. Linear, quadratic, and cubic contrasts were used to determine the effects of increasing doses of SA. Intake of DM increased as SA supplementation increased (28.4, 29.0, 29.5, and 29.9 kg/d; linear, P = 0.02). Milk fat concentration was 3.78, 3.73, 3.74, and 3.82% for increasing doses of SA (quadratic, P = 0.10). Treatment had no effect on milk yield (38.2 kg/d, P = 0.54), milk fat yield (1.41 kg/d, P = 0.75), milk protein yield (1.32 kg/d, P = 0.51), or milk protein concentration (3.49%, P = 0.88). Feed efficiency (ECM/DMI) was 1.43, 1.39, 1.36, and 1.36 for increasing doses of SA (linear, P = 0.0003). Supplementation of SA had no effect on BW or BCS (P > 0.23). The yield of C18:0 plus *cis*-9 C18:1 in milk fat was increased by SA supplementation (linear, P = 0.005); however, the increase from 0 to 2.4% SA was only 17 g/d resulting in no effect of SA supplementation on yield of total preformed milk FA (> 16-carbons, P = 0.69). The yield of de novo (< 16-carbons) and 16-carbon FA in milk fat were also unaffected by SA supplementation (P = 0.72 and P = 0.33, respectively). In conclusion, although increasing SA supplementation increased DMI it had no effect on the yield of milk or milk components. While SA supplementation increased the yield of C18:0 plus *cis*-9 C18:1 in milk fat, it had no overall effect on the yield of de novo or preformed FA in milk.

Key Words: fat supplementation, milk fat, stearic acid

1719 (T332) Effect of different dietary fatty acid profiles on individual milk fatty acid yields by dairy cattle fed diets with less than 3% total fatty acids. C. M. Stoffel and L. E. Armentano*, *University of Wisconsin-Madison, Madison.*

Dietary fatty acid (FA) composition can affect milk fat yield but also relative yields of different FA. This study examined the effects on yield of individual milk FA resulting from different dietary FA profiles at FA levels below 3% of diet dry matter (DM). Trial design and production performance data were discussed in a 2013 ADSA abstract. Briefly, 60 cows were paired (within parity) to form 30 experimental units. Pairs were fed six diets in five 6x6 balanced Latin squares with 21-d periods. There were two control diets: a corn control diet (CC) containing 1.8% FA and a low oil control (LOC) containing 1.2% FA. A portion of the food grade corn starch in LOC was replaced with 1.7% diet DM of a 50/50 blend of corn and high linoleic safflower oils (CO), high oleic sunflower oil (OO), palm oil (PO), or 1.8% diet DM calcium salts of palm FA (ML, Megalac) to create four treatment diets that were enriched in either linoleic (CO), oleic (OO), or palmitic acid (PO and ML). Milk FA composition was measured on d 20, and milk yield and fat concentration were measured for the last 5 d of each period; these data were combined to determine yield of individual milk FA. There were significant treatment effects on the yield of 31 out 53 milk FA measured including 10 out of 14 C18:1 isomers (P < 0.05). Palmitic acid (C16) yield was lower for CO compared to other treatments (P < 0.01) and C18:1 and total C18 yield were higher for OO when compared to PO and ML (P < 0.01, P < 0.01). Trans-10 C18:1 yield was higher for CO when compared to the other treatments (P < 0.01) and for OO compared to PO and ML (P = 0.01). Trans-10, cis-12 yield was also higher for CO when compared to all other treatments (P < 0.01). Linear regression analysis was also conducted to examine the effect on milk FA yield of the increased dietary linoleic, oleic, and palmitic acid concentrations of the treatment diets over LOC. Dietary linoleic decreased short chain (< C16) and C16 FA yield (P = 0.02, P < 0.01), dietary oleic increased total C18 yield (P < 0.01), and dietary palmitic increased C16 yield (P < 0.01). These differences in milk FA profile are consistent with the idea that linoleic acid depresses short chain and C16 FA, resulting in milk fat depression even at dietary FA levels below 3%.

Key Words: biohydrogenation, milk fat depression, milk fatty acid

1720 (T333) Effect of specific essential oil blend on performance of Nellore young bulls in feedlot.

A. L. D. S. Valente*, J. M. Serra, E. Romanzini, R. A. Reis, R. Barbero, T. Araujo, S. Santos, L. Delevatti and F. Souza, *Unesp, Jaboticabal, Brazil*

The European Union has prohibited the use of growth-promoting antibiotics in animal feeds. These restrictions, based around concerns that the use of antibiotics for livestock can give rise to transmissible resistance factors that may compromise the therapeutic use of antibiotic in humans (Casewell et al., 2003). In this sense, natural plant products such as essential oils (EO) become an alternative to manipulate rumen fermentation (Iason, 2005). Chao et al., 2000 suggested that gram-negative bacteria's shows a trend to have higher resistance to essential oils than gram-positive bacteria. Decreasing gram + bacteria may improve animal performance. Therefore, seventy two Nellore bulls (375 ± 14 kg BW) were fed 15% of sugar-cane bagasse and 85% of concentrate for 81d in individual pens. The treatments compound different combinations of essential oil blend or monensin (M) or both (1*: 100mg EO; 2*: 20 mg of M + 100 mg of EO; 3*: 20 mg of M + 200 mg of EO; 4*: 200 mg of EO; 5*: 20 mg of M and 6*: 10 mg of M + 100 mg of EO). Treatment mixes were incorporated into the concentrate ration, which was composed by corn, soybean meal and citrus pulp. Diets were isoenergetic and isonitrogenous. Throughout the entire experimental period, the provided feed amounts were adjusted to allow approximately 100g/kg residue comparing with the total consumed on previous day. Average daily gain was calculated using the initial and final individual live weight divided by the number of experimental days. Data was subjected to analysis of variance compared by orthogonal contrast. Animals fed 20mg of M had the greatest liveweight gain (1.242 kg/d), treatments 20mg of M + 100mg of EO and 100mg of EO achieved 0.909 and 0.910kg/d, respectively. Animals supplemented with 10mg of M + 100 mg of EO and 20mg of M + 100mg of EO had lower average daily gain than 5* but higher than 2*. However, 6* and 3* were not statistically different, the ADG for this treatment were 1.174 kg/d and 1.008 kg/d, respectively. The data of feed conversion (kg DM/ADG) shown for treatment 1* feed intake of 9.278 kg DM/d to gain 1kg liveweight, and the treatments 2*, 3*, 4*, 6*; 9.196, 8.398, 8.244, 8.385, respectively. Animals the treatment 5* had the lower intake (7.137). Therefore, strategic use of essential oil did not improve the animal performance.

Key Words: essential oil, feedlot, monensin

1721 (T334) Effect of coconut oil and lauric acid on omasal nutrient flow and microbial protein synthesis in dairy cows.

A. Faciola[*1] and G. A. Broderick[2], [1]*University of Nevada, Reno,* [2]*Broderick Nutrition* and *Research, LLC, Madison, WI*

Ruminal protozoa (RP) contribute to ruminal bacterial turnover. Previously, feeding lauric acid (LA; C12:0), sharply decreased RP. However, despite reducing RP, LA reduced DMI and milk yield. In this trial, we tested coconut oil (CO), which contains about 50% LA, as a practical defaunating agent and assessed its effects on nutrient and microbial omasal flow. Six cows fitted with ruminal cannulae were blocked by DIM into 2 blocks of 3 cows and randomly assigned within blocks to 3 dietary treatments in a 3X3 replicated Latin square with 21 days of adaptation and 7 days of sampling. The basal diet contained (DM basis) 50% alfalfa silage, 10% corn silage, and 40% concentrate (corn, molasses, and soybean), 16% CP and 29% NDF. Diets A and C provided the same amount of fat: A) 3% Megalac and C) 3% CO. Diets B and C provided the same amount of LA (287g/d). Data were analyzed using the mixed procedure in SAS. Results are reported in Table 1721. DMI was similar among treatments; however, diet B increased NDF flow at the omasal canal and decreased ruminal NDF apparently digestibility. There were trends for reduced DM flow at the omasal canal, ruminal N digestibility and RDP supply, and increased RUP omasal flow, when diet B was fed.

Key Words: coconut oil, omasal flow, protozoa

Table 1721. Ruminal metabolism and omasal flows

Item	Control	LA	CO	SEM	*P*-value

1722 (T335) Supplementation of lemongrass oil and a mixture of garlic and ginger oil improved in vitro feed digestion. A. Nanon[1], W. Suksombat[1] and W. Yang*[2], [1]*Suranaree University of Technology, Muang, Thailand,* [2]*Lethbridge Research Centre, Agriculture and Agri-Food Canada, Lethbridge, AB, Canada*

Lemongrass has shown antibacterial, antioxidant, and anti-hyper-NH_3–producing ruminal bacterial activities. However, the lemongrass, especially its essential oil (EO) has little been evaluated on its effect on ruminal fermentation. The objective of this study was to investigate the effect of lemongrass oil (LMO) and a mixture (1:1) of garlic and ginger oil (CEO) on gas production (GP) and feed digestion in batch culture. Four feeds: wheat distillers dried grains with solubles (DDGS), barley grain, grass hay, and a total mixed ration (TMR) were used as substrate with varying EO dosages from 0, 100, 200 to 300 mg/kg substrate DM. The TMR consisted of 35% grass hay, 15% alfalfa hay, 20% barley grain, 10% corn DDGS, 10% wheat DDGS, 5% canola meal, and 5% vitamin and mineral supplement. GP was measured at 3, 6, 12, 24, 36, and 48 h post incubation, and disappearance of DM (DMD) and neutral detergent fiber (NDFD) were determined at 24 and 48 h of incubation, respectively. There was no interaction on in vitro DMD and NDFD between the EO source and EO dose. DMD (% of input) were greater ($P < 0.05$) with CEO compared to LMO for wheat DDGS (48.6 vs. 47.9) and barley grain (61.5 vs. 60.3), but less ($P < 0.03$) for TMR (40.9 vs. 41.8) after 24 h of incubation. Increasing dosage of either CEO or LMO linearly ($P < 0.01$) increased DMD and NDFD of grass hay and TMR at 24 and 48 h of incubation, whereas increasing CEO or LMO dosages linearly ($P < 0.01$) increased only DMD of wheat DDGS and barley grain at 24 h of incubation. Cumulative GP was affected ($P < 0.03$) by both LMO and CEO in a quadratic manner after 24, 36 or 48 h of incubation with greatest GP at 200 mg/kg grass hay or TMR. These results suggested that the LMO and CEO appeared to be more effective to improve the DMD of fibrous feeds and modulated the digestive microorganisms in a dose-dependent manner. The EO used in the present study could be potentially developed as rumen modifier to improve feed digestion in ruminant.

Key Words: dry matter disappearance, in vitro, lemongrass oil

1723 (T336) Use of lemongrass oil for manipulation of ruminal fermentation using Rusitec technique. A. Nanon[1], W. Suksombat[1] and W. Yang*[2], [1]*Suranaree University of Technology, Muang, Thailand,* [2]*Lethbridge Research Centre, Agriculture and Agri-Food Canada, Lethbridge, AB, Canada*

Supplementation of lemongrass powder or meal has revealed a positive impact on ruminal fermentation in beef cattle. However, lemongrass essential oil (LMO) has little been evaluated on its effect on ruminal fermentation. A study using Rusitec technique was conducted to investigate the effect of increasing dose of LMO supplementation on fermentation characteristics of a dairy cow diet. Experiment was a completely randomized design with 4 replications in each treatment and consisted of 10 d of adaptation and 6 d of data collection. The substrate consisted of 35% grass hay, 15% alfalfa hay, 25% barley grain, 20% wheat dried distillers grains with solubles, and 5% vitamin and mineral supplement. Four treatments were: 1) control (no additives), 2) low LMO (100 mg LMO/kg DM), 3) high LMO (200 mg LMO/kg DM), and 4) monensin (30 mg/kg diet DM). Increasing LMO supplementation affected neither volatile fatty acid (VFA) concentration (averaged 26.0 m*M*) nor molar proportion (mol/100 mol) of acetate (49.0), propionate (23.3) or butyrate (16.2). However, increasing LMO linearly ($P < 0.01$) increased large peptide N from 2.6, 3.1 to 3.3 mg/mL and small peptide N from 3.3, 4.1 to 4.5 mg/mL, and linearly ($P < 0.01$) reduced ammonia N concentration from 8.8, 8.3 to 7.9 mg/mL in fermentation media. Increasing LMO addition also linearly ($P < 0.02$) increased bacterial protein production from 66.3, 66.2 to 70.1 mg/d N, and tended ($P = 0.10$) to improve bacterial efficiency from 12.7, 12.9 to 13.3 g N/kg digested OM. However, digestibility (% of input) of DM (52.8), NDF (41.9), starch (76.5), and CP (59.0) was not affected by increasing LMO addition. Supplementation of monensin did not affect fermentation characteristics, feed digestion, and bacterial protein production. These results suggest that supplementation of a dairy cow diet with LMO inhibited deamination process by possibly altering microbial populations such as proteolytic bacteria.

Key Words: fermentation, lemongrass oil, Rusitec

1724 (T337) Effect of tea oil and sunflower oil on rumen fermentation, milk composition and rumen microbial population in water buffaloes fed elephant grass-based diets. C. Yang*, X. Liang, S. Wei, X. Liang, S. Li, C. Zou, B. Yang and L. Li, *Buffalo Research Institute, Chinese Academy of Agricultural Sciences, Nanning, China.*

The objective of this study was to investigate the effect of tea oil and sunflower oil on rumen fermentation, milk composition and rumen microbial population in water buffaloes fed elephant grass-based diets. Thirty two lactating water buffaloes were allocated at random to 1 of 4 treatments composed of elephant grass and concentrates containing no additional oil (Control group), or supplemented with 200g of sunflower oil(SF group), 200 g tea oil(TO group), 200 g sunflower oil and tea oil (SF:TO = 1:1, ST group). On d 7, 14, 21, 28, samples of milk were collected for milk composition analysis using GC and a MilkoScan FT120. On day 28, rumen fluids was collected by stomach tube and used for pH, VFA, NH_3–N determination and DNA extraction. Total bacteria, Methanogens, fungi, protozoa, *R. flavefaciens*, *F. succinogenes*, and

Butyrivibrio group were quantified by relative real-time PCR. Compared with the control, dietary supplements of 200 g tea oil or sunflower oil alone or in combination with each other decreased the concentration of NH_3–N and milk production significantly ($P < 0.05$). Concentrations of milk fat and total solids were greater than control group after oil supplementation ($P < 0.05$). Oils supplementations have no effect on concentrations of milk protein and lactose. Acetate: propionate ratios were significantly increased after oils supplementation ($P < 0.05$). Concentrations of acetate, propionate, butyrate and total VFAs were not affected by oils supplementation. C18:2 and c9t11-CLA were increased by sunflower oil or the combination of sunflower and tea oil ($P < 0.05$). Only Cis9 C18:1 was increased after tea oil supplement alone ($P < 0.05$). Inclusion tea oil resulted in greater concentration of milk fat, Cis9 C18:1 and total solids and less concentration of NH_3–N and milk production. Methanogens, fungi, protozoa, *R. flavefaciens*, *F. succinogenes*, and *Butyrivibrio* group populations were not influenced by oil supplementation. In conclusion, tea oil or sunflower oil manipulated ruminal fermentation and milk composition without effect on abundance of fibrolytic bacteria and *Butyrivibrio* group when water buffaloes were fed elephant-grass based diets.

Key Words: water buffalo, rumen, milk composition

1725 (T338) Effects of echium and flaxseed oil on ruminal fatty acid metabolism in vitro.

L. Jin[*1,2], C. Li[2], M. He[2], Y. Wang[2], T. W. Alexander[2] and T. A. McAllister[2], *[1]Department of Animal Science and Technology, Northeast Agricultural University, Harbin, China, [2]Lethbridge Research Centre, Agriculture and Agri-Food Canada, Lethbridge, AB, Canada.*

Echium oil (EO) contains high level of γ-linolenic acid (*c*6, *c*9, *c*12) and stearidonic acid (*c*6, *c*9, *c*12, *c*15) and is considered to be a more desirable source of n-3 fatty acids (FA) than flaxseed oil (FO). However, there is little information on the metabolism of EO in the rumen. An in vitro study was designed as 2 × 2 (oil type × dose) + 1 (control) to assess the effect of EO and FO on ruminal FA profiles. A mixture of barley silage, barley grain and minerals and vitamin supplement (75:22:3, DM basis) was incubated with 0 (control), 3 or 6% of EO or FO in serum vials with rumen fluid. Each treatment was triplicated and incubated for 0, 3, 6, 24, and 48 h. The experiment was repeated (run) three times. The statistical model included run and treatments for the fixed effects and vial as unit. The whole content was freeze-dried and extracted for total FA which was used to determine the individual FA profile by GC. Percentage of C18:0 (g/100g total FA) was lower ($P < 0.001$) for 6% EO treatment than in other treatments at both 24 and 48 h of incubation. Both oil treatments had higher ($P < 0.001$) *cis* 15-C18:1 percentage than control. Inclusion of 3% and 6% FO resulted in higher ($P < 0.001$) *cis* 15-C18:1 than EO at 6, 24 and 48 h. However, incubation with 6% EO yielded FA with the highest ($P < 0.001$) *trans* 9-C18:1 and *trans* 11-C18:1 percentage at 24 and 48 h. *Cis*-9, *trans*-11-C18:2 was increased ($P < 0.001$) by both oil treatments. The total unsaturated FA and *trans* FA were higher ($P < 0.01$) with the addition of oil groups and 6% EO was the greatest ($P < 0.001$). The increased *trans* 11-C18:1 with EO but not FO suggests that EO is more desirable in that it produced more *trans* 11-C18:1, the precursor of *cis*-9, *trans*-11-C18:2 which has been reported to benefit human health.

Key Words: echium oil, fatty acids, in vitro

1726 (T339) Effects of linseed oil and propolis additives on protozoa population in dairy cows.

E. H. Yoshimura[1], L. M. Zeoula[*1], R. Franzolin[2], N. W. Santos[1], E. Machado[1], B. C. Agustinho[1], L. D. M. Pereira[1] and F. Alves[1], *[1]Universidade Estadual de Maringá, Maringá, Brazil, [2]Universidade de São Paulo- Faculdade de Zootecnia e Engenharia de Alimentos, Pirassununga-SP, Brazil*

Although the role of protozoa in the rumen fermentation is unquestionable, the truth is that its elimination may represent, in some cases, an additional benefit to the ruminant as increased microbial N outflow. The objective of this experiment was to examine the effect of linseed oil and additives on the population of ciliate protozoa in the rumen of dairy cow. Four lactating Holstein cows were used in a 4X4 Latin square design. Diets were composed of 600:400 forage:concentrate (dry matter basis-DM). The treatments were: basal diet (C); basal diet + linseed oil (25 $g.kg^{-1}$ DM) (LO); basal diet + linseed oil + propolis (10 mg $flavonoids.kg^{-1}$ DM) (LOP); basal diet + linseed oil + propolis + vitamin E (375 $UI.kg^{-1}$ DM) (LOPE). Samples of rumen contents were obtained (2 days in each period) manually through the fistula approximately 30 min before feeding and were fixed by diluting with an equal volume of formalin solution (18.5% formaldehyde final concentration). Total counts and generic distribution of protozoa were made in 100 microscopic fields at a magnification of 100x according to Dehority (1993). Statistical analyses were performed by analysis of variance ($P < 0.05$) and orthogonal contrasts to compare effects of 1) Linseed oil (C vs. LO, LOP and LOPE), 2) Propolis (LO vs. LOP and LOPE); 3) Vitamin E interaction (LOP vs. LOPE). There were no effects of linseed oil on the species of *Entodinium* ($P = 0.097$), *Isotricha* ($P = 0.143$) and total protozoa population ($P = 0.092$). In general, the *Endodinium* species was represented by the largest proportion (99.69%) and a lower *Isotricha* species (0.30%). However, the Diplodiniinae subfamily was not identified. It can be conclued that linseed oil and propolis additives do not change protozoa population.

Key Words: microbiology, omega-3, additives

1727 (T340) Effect of linoleic and linolenic acid sources supplementation on in vitro rumen fermentation characteristics and microbial diversity.

S. M. Amanullah[1], S. C. Kim[*1], D. Kim[1], H. Lee[1], Y. Joo[1] and I. H. Choi[2], *[1]Division of Applied Life Science (BK21Plus, Insti. of Agri.* and *Life Sci.), Gyeongsang National University, Jinju, South Korea, [2]Department of Companion Animal and Animal Resources Science, Joongbu University, Geumsan-gun, South Korea*

An in vitro experiment was conducted to estimate the effects of oil sources on rumen fermentation characteristics and microbial diversity. Oil sources were corn oil (CO), linseed oil (LSO) and Ca-salts of linoleic acid (CaSalt). Rumen fluid was collected from 2 canulated Hanwoo steers fed rice straw and concentrate mixture in 2:8 ratio. Incubation was performed in 50 ml glass serum bottles containing 150 mg of synthetic diet (411 g cellulose, 411 g starch, and 178 g casein/kg DM), 7 mg (µl) of either oil sources, and 15 ml of incubation medium (rumen fluid + Van Soest medium = 1:2) at 37 °C for 0, 3, 6, 12 and 24 h with 5 replications and 5 blanks for each time period. After 24 h of incubation, total gas volume and the concentrations of ammonia-N and total VFA were unaffected ($P > 0.05$). The pH was higher ($P = 0.024$) in CaSalt with a concomitant lower in lactate concentration ($P = 0.001$). Acetate concentration was significantly higher in CaSalt ($P = 0.013$), but propionate concentration was higher in CO than that in others ($P = 0.007$). Concomitantly, acetate to propionate ratio was higher in CaSalt than in CO ($P = 0.016$). The real time PCR analysis was conducted for relative quantification of microbial DNA. At 12 and 24 h of incubation, *F. succinogens*, *R. flavefaciens*, and *R. albus* were significantly higher ($P < 0.05$) in CaSalt than those in CO and LSO. However, *S. bovis*was observed higher in LSO at both of those time periods ($P < 0.05$). On the other hand, after 24 h, Methanogenic archaea and ciliate protozoa was highest in LSO and CO, respectively ($P < 0.005$). It is concluded that CaSalt showed lowered rumen methanogenic archaea and ciliate protozoa, while less toxic effects on fibrolytic bacteria compared to other oil sources, as also evidenced from higher acetate production in this treatment.

Key Words: corn oil, linseed oil, Ca-salts of linoleic acid, rumen fermentation, rumen microbes

1728 (T341) Intake and daily gain of grazing Nellore bulls receiving concentrated supplementation with additives.

J. A. C. Lima[*1,2], H. J. Fernandes[2], M. F. Paulino[1], E. P. Rosa[2], L. S. Caramalac[2], K. A. Silveira[2], G. C. Silva[2] and A. Aguiar[3], *[1]Federal University of Viçosa, Viçosa, Brazil, [2]State University of Mato Grosso do Sul, Aquidauana, Brazil, [3]University of Florida, Gainesville, FL*

The objective of this study was to evaluate the effect of a commercial concentrate supplement with additives in the intake and daily gain of grazing bulls, during the dry/rainy transition season in Aquidauana-MS, Brazil. Twelve Nellore bulls (initial body weight of 370 ± 15 kg) were randomly assigned to twelve *Brachiaria decumbens* Stapf pastures (1.0 ha/pasture; one bull/pasture) on a completely randomized design. Treatments were: 1) concentrate supplement Lipomax with homeopathic additives (Convert H, Sodo 100, Figotonus) and Virginiamicina (Lipomax treatment), and 2) concentrate supplement with a similar protein content (18% CP), and without additives (Control treatment). Animals were feed daily at rate of 0.5% of the animal's body weight. The animals were weighed (shrunk body weight) at beginning of the experiment and 104 d after, to evaluate the weight gain. After 45 days, a trial for estimated intake was made using the enriched and purified lignin (LIPE) as marker for fecal excretion estimation, and the indigestible neutral detergent fiber as internal marker. Forage nutritive value was estimated by hand-plucked sampling, and supplement intake was measured directly for each animal. A significance level of 5% was adopted. The forage (DMfor), supplement (DMsuppl), total dry matter, crude protein and TDN intakes showed no difference ($P > 0.05$) between treatments (Table 1728). However, DMsuppl intake was 50% higher when using additives (Lipomax treatment) with similar quantity reduction on DMfor. The lack of significance, in this case, could be explained by the high coefficient of variation of DMsuppl. The average daily gain was higher ($P < 0.05$) when using concentrate supplement with additives. In conclusion, additives in concentrate supplement increased the efficiency of nutrient use for grazing animals.

Key Words: grazing bulls, intake, performance

Table 1728. Intake and daily gain of Nellore bulls grazing brachiaria grass receiving concentrated supplementation with or without additives

Item	Treatment		CV (%)	*P*-value
	Control	Lipomax		
	kg/d

[1]DMfor is dry matter intake of pasture.
[2]DMsuppl is dry matter intake of supplement.
[3]DMtot is the total dry matter intake.
[4]CPint is crude protein intake. [5]TDN is total digestible nutrients intake.

1729 (T342) Effects of concentrate level and combined use of virginiamycin and salinomycin on nutrient intake and digestibility of Nellore steers.
A. J. C. Nuñez[1], V. V. Almeida[2], I. E. Borges[1], F. Pinese[1], F. T. Mercado[1], S. L. Silva[*1], P. R. Leme[1] and J. C. M. Nogueira Filho[1], *[1]Department of Animal Science- FZEA/USP, Pirassununga/SP, Brazil, [2]Department of Animal Science- FCAV/UNESP, Jaboticabal/SP, Brazil*

Eight ruminally cannulated Nellore steers (434 ± 35 kg initial BW) were allotted to a 4x4 replicated Latin square design (21-d periods) to evaluate the effects of concentrate and virginiamycin levels in diets containing salinomycin on nutrient intake and digestibility. Treatments were arranged as a 2x2 factorial, with 2 concentrate levels (70C and 90C diets had 70 and 90% concentrate, respectively) and 2 virginiamycin levels (0 and 15 ppm) in the diet DM. Steers were fed once daily at 0800 and salinomycin was included in all diets (13 ppm). The 70C diet contained 33% starch, 16% CP, and 31% NDF, whereas the 90C diet contained 47% starch, 16% CP, and 19% NDF on DM basis. Dry matter, CP, NDF, and starch intakes were calculated as the difference between the amount of nutrient offered and refused. Apparent digestibilities of nutrients were determined by total fecal collection for 3 d on each experimental period. Statistical analyses were performed using the MIXED procedure of SAS. No interactions between concentrate and virginiamycin levels were observed for any analyzed variable. Steers receiving the 90C diet showed greater ($P \leq 0.01$) DM (7.73 and 8.23 ± 0.19 kg/d for 70C and 90C, respectively), CP (1.24 and 1.32 ± 0.03 kg/d for 70C and 90C, respectively), and starch intakes (2.58 and 3.78 ± 0.13 kg/d for 70C and 90C, respectively), whereas NDF intake was greater ($P \leq 0.01$) for steers fed the 70C diet (2.28 and 1.57 ± 0.07 kg/d for 70C and 90C, respectively). Intake variables were not affected by virginiamycin inclusion. Animals receiving the 90C diet showed greater ($P < 0.01$) apparent digestibilities of DM (66.21 and 73.70 ± 0.94% for 70C and 90C, respectively) and CP (71.23 and 77.35 ± 0.83% for 70C and 90C, respectively), whereas NDF and starch digestibilities did not differ between concentrate levels. Steers fed only salinomycin showed greater ($P = 0.05$) starch digestibility in comparison with those receiving both additives (90.90 and 88.98 ± 0.78% for 0 and 15 ppm virginiamycin, respectively). There were no effects of virginiamycin inclusion on DM, CP, and NDF digestibilities. In conclusion, nutrient intake and apparent digestibility of Nellore steers are affected by dietary concentrate levels, whereas the effects of the combined use of virginiamycin and salinomycin on these variables are less pronounced.

Key Words: antibiotic, ionophore, Zebu cattle

1730 (T343) A meta-analysis of effects of feeding nitrate on toxicity, production, and enteric methane emissions in ruminants.
C. Lee* and K. A. Beauchemin, *Lethbridge Research Centre, Agriculture and Agri-Food Canada, Lethbridge, AB, Canada*

Nitrate is usually considered an undesirable compound in ruminant feeds due to its potential toxicity (methemoglobinaemia). Despite this concern, nitrate has recently received attention as an electron acceptor in the rumen that could possibly reduce enteric methane emissions. It was also proposed that nitrate might be a useful non-protein nitrogen source as a substitute for urea. Therefore, a meta-analysis was conducted to investigate the effects of feeding nitrate on its toxicity and effects on animal production and enteric methane emissions. Data were collected from published literature (PubMed, ScienceDirect and CAB direct) and analyzed using the MIXED procedure of SAS with study as a random effect. When nitrate was fed without a gradual acclimation (stepwise increases in nitrate in diets) or infused into the rumen, blood methemoglobin levels (MetHg, % of total hemoglobin) linearly responded to nitrate levels [9 studies with 25 treatments; MetHg (%) = 41.3 × nitrate (g/kg BW/d) + 1.2; $R^2 = 0.76$, $P < 0.001$]. However, when nitrate was fed using a gradual acclimation, the potential toxicity of nitrate was considerably lowered [3 studies with 11 treatments; MetHg (%) = 4.2 × nitrate (g/kg BW/d) + 0.4, $R^2 = 0.76$, $P = 0.002$]. Animals fed nitrate reduced enteric methane emissions in a dose–response manner [8 studies and 25 treatments; CH_4 (g/kg DMI) = −8.3 × nitrate (g/kg BW/d) + 15.2, $R^2 = 0.80$, $P < 0.001$]. Three studies examined the persistent efficacy of nitrate on reducing enteric methane emissions (54, 90, and 92 d, respectively). Animals fed nitrate (2.1 to 2.7% of dietary DM) reduced methane emissions persistently by 16.5 to 35.4% (treatments × time, $P > 0.31$). However, dry matter intake (DMI) and live weight gain (LWG) of cattle were not affected by nitrate (DMI, 20 studies and 46 treatments; $R^2 = 0.007$, $P = 0.65$; LWG, 12 studies and 35 treatments; $R^2 = 0.03$, $P = 0.31$). In conclusion, the potential toxicity of nitrate can be reduced by acclimatizing the animals to nitrate gradually. Nitrate is a potential feed additive to re-

duce enteric methane emissions and its efficacy is persistent. However, lowering methane production using nitrate may not re-direct additional metabolizable energy towards animal production. This meta-analysis, however, needs to be interpreted with caution because of the small number of studies used.

Key Words: meta-analysis, nitrate, ruminants

1731 (T344) Methane production of Nellore young bulls on pasture in the rainy season supplemented with crude glycerin associated energy sources.

A. José Neto*[1], L. G. Rossi[2], A. F. Ribeiro[1], B. R. Vieira[3], I. Pena Carvalho de Carvalho[2], E. E. Dalanttonia[4], A. S. Gómez I[3] and T. T. Berchielli[4], *[1]Universidade Estadual Paulista "Julio de Mesquita Filho", Jaboticabal, Brazil, [2]Universidade Estadual Paulista, Jaboticabal, Brazil, [3]Universidade Estadual Paulista Júlio de Mesquita Filho, Jaboticabal, São Paulo, Brazil, [4]Universidade Estadual Paulista Júlio de Mesquita Filho- UNESP, Jaboticabal, Brazil*

The objective of this study was to evaluate the effect of adding 28% crude glycerin (CG) in the supplement (DM basis), replacing corn or soybean hulls, with or without a source of oil, on enteric methane emission, average daily gain (ADG) and daily carcass gain (GC) of young bulls in the pasture. A total of 36 young Nellore bulls with an average initial BW of 333.20 ± 41.60 kg were distributed in a completely randomized design (three animals per paddock and three paddocks per treatment) with nine replicates. Treatments were arranged as a 2x2 factorial (high or low starch, with or without a source of oil). Paddock was the experimental unit, and the model effects included treatment. These animals were grazed on *Brachiaria brizantha* cv. Xaraés in the rainy season (January 2013 to May 2013), with the same treatments and supplemented at the rate of 500 g/100 kg BW. The supplements were: T1- CG with high starch (corn), T2- CG with low starch (soybean hulls), T3- CG with high starch associated to a source of oil (corn and soybeans) and T4- CG with low starch associated to a source of oil (soybean hulls in soybean grain). The sulfur hexafluoride (SF_6) tracer method for measuring eructated CH_4 was used in this study (Johnson et al., 1994). To determine daily carcass gain, eight animals were slaughtered as a reference at the beginning of the experiment and after 133 days of the experiment, eight more animals were slaughtered. Data were analyzed using the SAS PROC GLM, considering the significance of $P < 0.05$. Daily carcass gain (GC, kg.day^{-1}) and average daily gain (ADG, kg.day^{-1}) of the animals was evaluated. The methane emission were expressed in kilogram of methane emitted per year (kg CH_4.yr^{-1}), gram per day (g CH_4.day^{-1}), kilogram per kilogram of carcass produced (kg CH_4.kg CAR^{-1}) and kilogram per kilogram of average daily gain (kg CH_4.kg ADG^{-1}). Differences were not detected ($P > 0.05$) between treatments, with average values of 0.54 kg.day^{-1}, 0.88 kg.day^{-1}, 44.03 kg.yr^{-1}, 120.64 g.day^{-1}, 0.22 kg.kg CAR^{-1} and 0.16 kg CH_4.kg ADG^{-1}, respectively. Crude glycerin associated with high or low levels of starch, with or without a source of oil, did not alter the methane production of Nellore bulls on pasture supplemented during the rainy season.

Key Words: energy, environment, ruminant

1732 (T345) Effects of encapsulated nitrate on toxicity, feed intake and feed consumption rates in beef cattle.

C. Lee*[1], R. C. Araujo[2,3], K. M. Koenig[1] and K. A. Beauchemin[1], *[1]Lethbridge Research Centre, Agriculture and Agri-Food Canada, Lethbridge, AB, Canada, [2]GRASP Ind.* and *Com. LTDA, Curitiba, Brazil, [3]EW|Nutrition GMBH, Visbek, Germany.*

Slow-release encapsulated nitrate [EN; 66.9% nitrate in DM; GRASP Ind. and Com. LTDA, Paraná, Brazil] was investigated for its effects on toxicity threshold, feed intake, and feed consumption rates in 2 experiments. In Exp. 1, 5 beef heifers were fed once daily a diet (55:45 forage:concentrate) at 75% of ad libitum intake. The proportion of EN in the diet was increased by 1% every 4 days to 1.0, 2.0, 2.9, 3.9, 4.8, and 5.8% of dietary DM (10.3 to 15.6% CP at 0 to 5.8% EN). In Exp. 2, 8 beef heifers were used in a replicated 4 × 4 Latin square design and fed ad libitum once daily diets (iso-nitrogenous, 12.7% CP; 55:45 forage:concentrate) containing 0, 1, 2, and 3% EN (DM basis) using a 21-d stepwise adaptation. In Exp. 1 with restrictive feeding, a heifer was removed due to rapid feed consumption causing nitrate-poisoning at 3% EN and another due to refusal to eat the 2% EN diet. Comparing 0% with 5.8% EN, feed consumption from 0 to 3 h after feeding was decreased (70.3 to 48.6% of total; $P = 0.03$), that from 12 to 24 h was increased (0.6 to 22.6%; $P = 0.01$), and feed consumed over 24 h was decreased (100 to 92.3%; $P = 0.01$). Animals showed negligible blood methemoglobin levels (< 1%; MetHb, % of hemoglobin) at 1% EN. However, MetHb levels were greater (avg. 8.6 vs. 3.3% and max. 23.6 vs. 13.6% at 3 h) at 2.0 and 2.9% EN than at 3.9% or more EN because of sorting of the concentrates containing higher levels of EN. The MetHb level peaked 3 h after feeding for all EN levels and the magnitude of the peak was dependent on the amount of feed consumed from 0 to 3 h. In Exp. 2 with ad libitum feeding, feed consumption rates were not different (41.8% of total from 0 to 3 h) among EN levels. Although MetHb levels increased ($P < 0.01$) with increasing EN level, the magnitude was lower for Exp. 2 compared with Exp. 1 (avg. 2.8 vs. 8.4%; max. 7.2 vs. 23.6% at 3% EN). Sorting of the EN diets was not observed in Exp. 2. In conclusion, MetHb responses to EN levels were dependent on feed consumption rates after feeding. Offering a diet containing EN for ad libitum intake minimized risks of nitrate toxicity.

Key Words: encapsulated nitrate, methemoglobin, beef cattle

1733 (T346) Effects of the combined use of virginiamycin and salinomycin on rumen fluid kinetics of Nellore steers. A. J. C. Nuñez[1], V. V. Almeida[2], F. Pinese[1], I. E. Borges[1], F. T. Mercado[1], S. L. Silva[*1], P. R. Leme[1] and J. C. M. Nogueira Filho[1], *[1]Department of Animal Science- FZEA/USP, Pirassununga/SP, Brazil, [2]Department of Animal Science- FCAV/UNESP, Jaboticabal/SP, Brazil*

Two experiments were conducted to evaluate the combination of dietary virginiamycin and salinomycin on rumen fluid kinetics of Nellore steers fed high concentrate diets. In experiment one, 8 Nellore steers (322 ± 26 kg initial BW) were allotted to a replicated 4x4 Latin square design (21-d periods), in a 2x2 factorial arrangement of treatments, with 2 salinomycin concentrations (0 and 13 ppm) and 2 virginiamycin concentrations (0 and 15 ppm) in the diet DM, which contained 80% concentrate. In experiment two, 8 Nellore steers (434 ± 35 kg initial BW) were allotted to the same experimental design, with 2 concentrate inclusions (70C and 90C diets had 70 and 90% concentrate, respectively) and 2 virginiamycin concentrations (0 and 15 ppm) in the diet DM. Salinomycin was included in all diets (13 ppm). In both experiments, on d 20 of each period, 300 g of polyethylene glycol 4000 (PEG) were diluted in 600 mL of deionized water and infused into the rumen of each steer at 0800. Rumen fluid samples were collected before infusion and at 1.5, 3, 6, 12, and 24h after infusion, and PEG concentrations were determined by colorimetry. Ruminal fluid rate of passage (RP; %/h) and volume (FV; L) were calculated from linear regression of the natural logarithm of PEG concentration on time. Fluid retention time (RT; h) was determined as the inverse of RP, whereas flow rate (FR; L/h) was calculated as RP multiplied by FV. Statistical analyses were performed using the MIXED procedure of SAS, and the model included the random effects of animal, period, and Latin square, and the fixed effects of salinomycin or concentrate, virginiamycin, and the two-way interaction. No interactions were observed for any variable. In experiment one, rumen fluid kinetics variables were not affected by treatments. In experiment two, steers receiving the 70C diet showed greater ($P \leq 0.02$) RP (9.90 and 7.92 ± 0.48%/h for 70C and 90C, respectively), FV (39.07 and 31.47 ± 1.89 L for 70C and 90C, respectively), and FR (3.69 and 2.55 ± 0.23 L/h for 70C and 90C, respectively), whereas RT was greater ($P < 0.01$) for steers fed the 90C diet (9.77 and 13.24 ± 1.15 h for 70C and 90C, respectively). No effects of virginiamycin were observed for any variable. In conclusion, rumen fluid kinetics of Nellore steers is affected by dietary concentrate inclusion, but not by the combined use of virginiamycin and salinomycin.

Key Words: antibiotic, ionophore, Zebu

1734 (T347) Monensin, virginiamycin and functional oils on rumen health of Nellore cattle fed high concentrate diets without adaptation. A. P. dos Santos Silva[1], R. Ferreira Carvalho[2], C. A. Zotti[2], M. Rezende Mazon[1], L. Silva Oliviera[2], S. Luz e Silva[*2] and P. R. Leme[1], *[1]University of Sao Paulo, Pirassununga, Brazil, [2]University of Sao Paulo/FZEA, Pirassununga, Brazil*

Feed additives and adaptation strategies are used to prevent metabolic disorders in feedlot cattle. The extent on how additives can contribute to rumen health of Zebu cattle that are not adapted to high grain diets is still unknown. To evaluate the different feed additives on rumen health, 48 Nellore bulls (322 ± 23 kg of BW, 20 months old) were submitted to a diet change, without adaptation, from grass pasture to a high concentrate diet (92% grains) fed ad libitum during 120 days. The treatments were different feed additives added to the basal diet: monensin at 30 mg/kg DM (M30), monensin at 40 mg/kg DM (M40) fed during the first 14 days, decreasing to 30 mg/kg after this period, monensin at 30 mg/kg DM + virginiamycin at 25 mg/kg DM (MV) and functional oils (a blend of castor oil and cashew oil) at 400 mg/kg DM (FO). After 120 days animals were slaughtered and the livers were examined for abscesses. Rumen pH was measured and the incidence of ruminites (IR) was classified according to a 0 to 10 scale. Fragments of 3 cm^2 were taken from the cranial sac of the rumen and kept in buffer solution for the measurements of papillae number (PN), papillary area (PA) and absorption surface (AS). PN was counted by 3 evaluators and PA and AS were measured on the UTHSCA Image Tool free software. Animals fed FO diet had higher ($P = 0.01$) daily DMI than M30 and MV. However, there was no difference ($P = 0.22$) between OF and M40.There was no difference among treatments for ADG ($P = 0.13$), final BW ($P = 0.16$) and G:F ($P = 0.10$). No difference ($P = 0.86$) was verified for rumen pH (6.37 ± 0.51). There was no incidence of liver abscesses and low IR ($P = 0.61$; 1,09 ± 1,42). No differences ($P = 0,90$) were found on PN (53.18 ± 14.25), on PA ($P = 0.60$; 0.7 ± 0.26) and also on AS ($P = 0.82$; 38.07 ± 17.89). No metabolic disorders occurred and there was no decrease in animal performance indicating a relative protection of the additives and the possibility of feeding high concentrate diets to Nellore cattle without adaptation. Also, FO, a natural product, may substitute ionophores and antibiotics as additives for rumen protection when high concentrate diets are fed.

Key Words: feed additives, Zebu, feedlot

1735 (T348) Effects of grain source and monensin level on site and extent of digestion in feedlot heifers.

W. Yang*[1], L. Xu[2], Y. Zhao[1,3] and T. A. McAllister[1], *[1]Lethbridge Research Centre, Agriculture and Agri-Food Canada, Lethbridge, AB, Canada, [2]Bao Tou Light Industry Vocational Technical College, Bao Tou, China, [3]College of Animal Science, Inner Mongolia Agricultural University, Hohhot, China.*

Many feedlot producers include wheat grain into the rations due to increasing supplies of feed wheat in North America, whereas few studies have documented the effects of wheat source on animal response. A study was conducted to examine feed intake and site and extent of digestion by substituting wheat grain (soft or hard) for barley and to determine whether increasing monensin level would improve feed digestion in feedlot heifers. Five ruminally and duodenally cannulated beef heifers were used in a 5 × 5 Latin square design with 2 × 2 + 1 factorial. Treatments were barley (10% barley silage, 90% barley-based concentrate, and 28 mg/kg monensin), and diets substituting soft or hard wheat for barley combining with 28 (low) or 44 (high) mg/kg monensin. The barley diet is a standard feedlot diet used in western Canadian feedlots. Contrasts were generated to compare barley vs. wheat diets in low monensin; soft vs. hard wheat; and low vs. high menensin in wheat diets. Intake of DM was affected neither by grain source (8.3 kg/d) nor by wheat source (7.7 kg/d), whereas increased monensin level reduced ($P < 0.02$) DMI from 8.1 to 7.3 kg/d. Inclusion of wheat in place of barley grain did not affect the flows of OM to the duodenum (3.8 kg/d) and digestibility (% of intake) of OM in the rumen (64.2%) and in the total tract (80.5%). However, digestibility of NDF (barley vs. wheat; 60.6 vs. 48.3%; $P < 0.01$) and that of starch (barley vs. wheat; 95.5 vs. 97.6%; $P < 0.03$) in the total digestive tract were different. Feeding soft vs. hard wheat delivered lower ($P < 0.03$) OM (soft vs. hard; 3.4 vs. 3.6 kg/d) and non-ammonia N (soft vs. hard; 164 vs. 178 g/d) to the duodenum with no differences in ruminal and intestinal digestibility of OM. Increased monensin supplementation decreased ($P < 0.05$) duodenal flows of OM from 3.7 to 3.3 kg/d, total N from 182 to 168 g/d, and microbial N from 99 to 87 g/d without affecting the site and extent of feed digestibility. These results indicated that wheat exhibited similar feed value to barley; high level monensin may potentially alleviate ruminal acidosis by reducing DMI of finishing cattle.

Key Words: feedlot heifers, grain source, digestibility

1736 (T349) Effects of different doses of sodium monensin on rumen tissue histology of feedlot cattle.

A. L. Rigueiro*[1], A. C. J. Pinto[1], M. C. Pereira[1], D. H. Watanabe[1], C. A. Oliveira[1], T. V. Carrara[2], D. D. Estevam[2], D. P. Silva[1], F. T. Pereira[1] and D. D. Millen[1,3], *[1]São Paulo State University (UNESP), Dracena campus, Dracena, Brazil, [2]São Paulo State University (UNESP), Botucatu campus, Botucatu, Brazil, [3]São Paulo State Foundation (FAPESP), São Paulo, Brazil*

This study, conducted at the São Paulo State University feedlot, Dracena Campus, Brazil, was designed to determine the effects of different doses of sodium monensin on rumen tissue histological variables of feedlot cattle. The experiment was designed as a completely randomized block, with 12 replications per treatment, in which 60 20-mo-old yearling Nellore bulls (402.52 ± 33.0 kg) were fed in individual pens for 84 days according to the different doses of monensin (DM basis): 1) 0 ppm (D0); 2) 9 ppm (D9); 3) 18 ppm (D18); 4) 27 ppm (D27), and 5) 36 ppm (D36). The adaptation program consisted of ad libitum feeding of two adaptation diets over period of 14-d with concentrate level increasing from 68% to 84% of diet DM. The finishing diet contained: 71.5% cracked corn grain, 16.0% sugarcane bagasse, 7.7% soybean meal, 3.0% supplement, 1.2% urea, and 0.6% limestone (DM basis). At harvest, a 1-cm^2 fragment of each rumen ($n = 60$) was collected from ventral sac for histological assessment. Histological sections were stained with hematoxylin and eosin, embedded in paraffin wax, and sectioned. Morphometric measurements, such as papillae surface area, papillae height, papillae width, keratinized layer thickness, and mitotic index, were determined in four papillae per animal using computer-aided light microscope image analysis. Orthogonal contrasts were used to evaluate linear, quadratic, cubic and quartic relationship between doses of monensin and the dependent variable. The use of different doses of sodium monensin did not affect ($P > 0.10$) keratinized layer thickness. However, as doses of sodium monensin increased, papillae width in mm (D0 = 0.46; D9 = 0.42; D18 = 0.44; D27 = 0.45; D36 = 0.38), papillae surface area in cm^2 (D0 = 2.43; D9 = 2.12; D18 = 2,25; D27 = 2.68; D36 = 1.72) and mitotic index, as % of basal cells (D0 = 2.57; D9 = 3.15; D18 = 2.92; D27 = 2.71; D36 = 3.11) were affected ($P < 0.05$) cubically. The papillae height in mm (D0 = 4.98; D9 = 5.42; D18 = 5.04; D27 = 6.21; D36 = 4.71) was affected ($P = 0.05$) quadratically as dose of sodium monensin increased. Thus, increasing doses of sodium monensin affected histological variables of rumen tissue. The feeding of either 9 ppm or 27 ppm of sodium monensin seemed to be the best options in this study.

Key Words: Nellore, mitosis, papillae

1737 (T350) Effects of different doses of sodium monensin on DMI variation and selective consumption by feedlot cattle. D. H. Watanabe*[1], M. C. Pereira[1], J. Silva[1], T. V. Carrara[2], A. L. Rigueiro[1], L. A. Tomaz[1], D. P. Silva[1], D. V. Vicari[1], A. C. J. Pinto[1], D. D. Estevam[2], M. D. Arrigoni[2] and D. D. Millen[1,3], *[1]São Paulo State University (UNESP), Dracena campus, Dracena, Brazil, [2]São Paulo State University (UNESP), Botucatu campus, Botucatu, Brazil, [3]São Paulo State Foundation (FAPESP), São Paulo, Brazil*

This study, conducted at the São Paulo State University feedlot, Dracena Campus, Brazil, was designed to determine the effects of different doses of sodium monensin on DMI variation and selective consumption (sorting) of diets by Nellore cattle. The experiment was designed as a completely randomized block, replicated 12 times, in which 60 20-mo-old yearling Nellore bulls (402.52 ± 33.0 kg) were fed in individual pens for 84 days according to the following treatments (DM basis): 1) 0 ppm (D0); 2) 9 ppm (D9); 3) 18 ppm (D18); 4) 27 ppm (D27), and 5) 36 ppm (D36). The adaptation program consisted of ad libitum feeding of two adaptation diets over period of 14-d with concentrate level increasing from 68% to 84% of diet DM. The finishing diet contained: 71.5% cracked corn grain, 16.0% sugarcane bagasse, 7.7% soybean meal, 3.0% supplement, 1.2% urea, and 0.6% limestone (DM basis). The DMI variation was calculated for each individual pen as the difference in intake, expressed as % of variation, between consecutive days throughout the study. Samples of orts and diets were collected on days 10 and 40 of the study for particle size distribution determination, which was performed by sieving using the Penn State Particle Size Separator and reported on as-fed basis. Values equal to 1.0 indicate no sorting, < 1.0 show selective refusals, and > 1.0 indicate preferential consumption. Orthogonal contrasts were used to assess linear, quadratic, cubic and quartic relationship between doses of monensin and the dependent variable. During the period of adaptation, DMI variation was affected (P = 0.02) quadratically as dose of sodium monensin increased (D0: 15.3%; D9: 14.6%; D18: 13.6%; D27: 13.5%; D36: 18.5%); however, the use of different doses of sodium monensin did not affect (P > 0.10) DMI variation during the finishing period. Increasing doses of sodium monensin only affected particle sorting during the adaptation period, in which as dose of sodium monensin increased, sorting for screens one (diagonal opening = 19.0 mm; D0 = 0.986; D9 = 0.962; D18 = 0.947; D27 = 0.928; D36 = 1.021), two (diagonal opening = 8.0 mm; D0 = 0.992; D9 = 1.013; D18 = 1.014; D27 = 0.936; D36 = 0.932), and three (diagonal opening = 1.18 mm; D0 = 1.001; D9 = 1.015; D18 = 1.065; D27 = 1.043; D36 = 0.993), and bottom pan (D0 = 0.938; D9 = 1.022; D18 = 1.020; D27 = 1.074; D36 = 1.016) were affected (P < 0.05) quadratically. Thus, the feeding of sodium monensin up to 27 ppm reduced DMI variation, but increased diet sorting during the adaptation period.

Key Words: fluctuation, Nellore, sorting

1738 (T351) Feeding monensin or essential oils in high corn or byproduct finishing diets for Nellore bulls. L. J. Chagas*[1], M. G. DOS Santos[1], A. H. De Melo[1], J. R. R. Dórea[2], D. F. A. Costa[2] and F. A. P. Santos[2], *[1]University of São Paulo- ESALQ, Piracicaba, Brazil, [2]University of São Paulo, Piracicaba, Brazil*

The objective of this study was to evaluate the effects of sodium monensin replacement for essential oils on behavior, DMI, ruminal pH and ammonium concentration in feedlot cattle. Sixteen Nellore bulls (339 ± 30 Kg initial BW) were allocated in individual pens to four 4 × 4 Latin square (LS) design, consisting of 21 d (including 14 d of adaptation). One of two basal diets used had 5% sugar cane bagasse, 50% wet corn gluten feed, 43.5% soybean hulls and 1.5% mineral and vitamin mix and the other had 80.6% ground corn, 12% sugar cane bagasse, 4% soybean meal, 0.9% urea, and 2.5% mineral and vitamin mix (DM basis). Each basal diet was used in two 4 × 4 LS. Feed additives were mixed within the mineral and vitamin mix according to treatments: 1) Control (CON), no additives;2) Monensin (MON), 25 mg/kg of DM (Rumensin); 3) Essential oil (EO), 0.5 g/kg of DM (commercial additive extracted from castor and cashew oils, Essential); and 4) Essential oil plus monensin (E+M), 0.3 g/kg of DM and 25 mg/kg of DM, respectively. There were no differences between the basal diets for DMI (8.2 kg/d), feeding and idle time (193 and 1104 min in 24 h), feeding frequency (9.5 feed/d) and meal size (22 min/feed). Supplementing essential oils at 0.5 g/kg of DM (EO) decreased (P < 0.05) rumination in 37% compared to control, 130 vs. 208, respectively. Essential oils only, or E+M increased (P < 0.01) ruminal pH and ammonia nitrogen, 6.06 and 6.01 vs. 5.79 and 5.89 mg/dL, respectively for EO, E+M, CON and MON. Feeding frequency was the only parameter affected (P < 0.05) when byproducts were used, with 12.9 and 8.1 meal/d, for CON and MON, EO and M+E, respectively. In conclusion, castor and cashew essential oils have some beneficial effects on cattle physiology in the short time, such as the 21 days adaptation period to high grain diets.

Key Words: feedlot, feed additives, ionophores

1739 (T352) The effect of a citrus extract rich in flavonoids (Bioflavex) and its main components on rumen fermentation and microbial population under in vitro system using steers fed high concentrate diet as rumen liquor donors.

A. R. Seradj[1], J. Crespo[*2], M. Fondevila[3] and J. Balcells[1], *[1]University of Lleida, Lleida, Spain, [2]Interquim S. A. (Ferrer Health Tech), Barcelona, Spain, [3]University of Zaragoza, Zaragoza, Spain*

To evaluate the effect of flavonoids on rumen fermentation and microbial population an in vitro assay was designed. Four sets of incubation series (batches) were separately conducted using a complete randomized block design. Four steers fed high concentrate ration (90:10 comemercial concentrate:barley straw) were used as donors. Serum glass bottles (120 ml) were filled with 80 ml of an incubation solution under a CO_2 stream. A mixture of the same concentrate and barley straw (600:60 mg/bottle) was used as substrate. Bioflavex (BF) was tested against its main flavonoid components (Hesperidine [HS]; Isonaringine [IN]; Naringine [NG]; Neoeriocitrine [NE]; Neohesperidine [NH] and Poncirine [PC]) at 200µg/g DM, and the substrate without flavonoids was considered as a control (CTR). Bottles were incubated at 39 ± 1°C and two bottles per treatment opened after 12 h, and sampled for pH, NH_3–N, volatile fatty acids (VFAs) and microbiota analyses. The DNA was extracted using QIAamp DNA Stool Mini Kit. qPCR was used to quantify the protozoa and hydrogenotrophic methanogenic archaea (HMA) concentration, moreover specific primers were used to determine the relative abundance of *Streptococcus bovis*, *Selenomonas ruminantium* and *Megasphaera elsdenii* in relation to the total bacteria while HMA and the acetoclastic *Methanosarcina* spp. were refered to total archaea. The treatments did not alter pH and no differences were recorded in NH_3 nor in total VFA concentration. However, in relation to the CTR, the addition of flavonoids (except for HS), altered the VFA profile, reducing acetate and increasing propionate proportion. Ciliate protozoa concentration was reduced by BF, NG, NH and PC ($P < 0.05$). Flavonoids, did not alter the relative abundance of *S. bovis* as lactate producing bacteria, (except for NE) although they enhanced ($P < 0.05$) *M. elsdenii* propotion in relation to the CTR (except for HS, IN and NE). A clear inhibition of flavonoids on the relative abundance of HMA was observed although only PC, NH, NG and BF reduced the relative abundance of *Methanosarcina* spp. ($P < 0.05$). Flavonoids exert significant changes in the fermentation end products and also altered the concentration and composition of lactate-utilizing bacteria, methanogenic population and ciliate protozoa. However, the different tested flavonoids substances did not interact homogeneously against rumen population.

Key Words: absolute and relative microbiota quantifications, in vitro incubation and pure flavonoids

1740 (T353) Use of a citrus flavonoids extract (Bioflavex) to improve rumen fermentation efficiency and performance in steers consuming high concentrate diets.

A. R. Seradj[1], B. A. Refat[1], A. Jimeno[2], J. Crespo[*3] and J. Balcells[1], *[1]University of Lleida, Lleida, Spain, [2]University of Zaragoza, Zaragoza, Spain, [3]Interquim S. A. (Ferrer Health Tech), Barcelona, Spain*

To study the effects of a citrus ñavonoids extract (Bioñavex; BF) on fermentation and performance in steers fed high concentrate diets (90:10 Concentrate:Barley straw), two experiments were performed. In the first one, eight Friesian bulls (398 ± 12.2 kg BW) fitted with rumen cannula and were housed in individual pens and assigned to one of two treatments, they received the basal concentrate (CTR) or the basal concentrate supplemented with Bioflavex (450 mg/kg DM) in 2×4 cross over design. The trial lasted for 24 days and was divided in 2 experimental periods of 12 days, 10 days for dietary changeover followed by two sampling days. In the second experiment, 32 Friesian steers (395 ± 10.1 kg BW) were weighed and blocked in 2 homogeneous groups (BW basis) receiving the same treatments as Exp. 1 (CTR and BF) and were weighed at day 7 and 24 of the experiment. Concentrate and barley straw were offered ad libitum, once a day (0800 h) for 24 days. At the sampling days of 1st trial, rumen was sampled (at 0, 4 and 8 h post feeding) for pH, NH_3–N, volatile fatty acids (VFAs) and microbiota analyses. BF in the concentrate improved pH values (6.1 vs. 5.8 for BF and CTR; SEM 0.05; $P < 0.01$) and molar proportion of propionate (24. 2 vs. 22.5 SEM 0.60; $P = 0.05$). Flavonoids did not alter absolute abundances of total bacteria nor relative abundance of *Streptococcus bovis* while relative abundances of *Selenomonas ruminantium* ($P < 0.01$) and *Megaesphera elsdenii* ($P = 0.05$) were enhanced by the presence of BF in the concentrate. In the second trial no differences were observed neither in the final BW (425 vs. 420 kg SEM 10.9) nor in average daily gain (1.1 vs. 1.2 Kg/d SEM 0.14, for CTR and BF respectively) but feed conversion ratio was lower in BF than CTR steers (6.1 vs.6.8 SEM 0.8; $P = 0.05$). Flavonoid supplementation might be effective in improving rumen fermentation and animal's performance which may be explained changes induced by BF in the microbial flora.

Key Words: animal's performance, flavonoids and ruminal fermentation

1741 (T354) Effect of blend *Enterococcus faecium* plus *Saccharomyces cerevisiae* in different doses on intake and digestibility of steers in feedlot.

A. A. Oliveira, J. Koscheck*, A. L. D. S. Valente, F. Basso, C. Rabelo, U. Carneiro and R. A. Reis, *Unesp, Jaboticabal, Brazil*

The goal of this study was to evaluate the effect of different probiotic doses on the intake and partial digestibility of dry matter.

Were evaluated six Nellore steers fitted with ruminal cannulas and allocated to a double 3 x 3 Latin square design with three treatments and tree periods on two simultaneous repetitions. The blend of *Enterococcus faecium* (5 x 10^9 ufc/g of product) and *Saccharomyces cerevisiae* (5 x 10^9 ufc/g of product) in different doses (0, 1 or 2 g/day) were provided on the rumen. Steers were fed a diet containing 200 g/kg of corn silage and 800 g/kg concentrate. Within each experimental period, 18 days were to adaptation, DMI and digestibility were recorded from d 19 to 21. The statistical analyzes were conducted using PROC MIXED from SAS and means were compared using Tukey test ($P < 0.05$). Different doses of probiotic did not affect ($P > 0.05$) DMI, whereas the digestibility of OM (746.4, 697.9, 689.2 g/kg), and carbohydrates (757.4, 715.8, 706.6 g/kg) showed a quadratic response to 0, 1 and 2 g/day, respectively.

Key Words: concentrate, digestibility, probiotic

1742 (T355) Effect of doses at *Enterococcus faecium* and *Saccharomyces cerevisiae* on ruminal parameters responses of feeder cattle.

A. A. Oliveira, J. Koscheck*, A. L. D. S. Valente, F. Basso, C. Rabelo, U. Carneiro and R. A. Reis, *Unesp, Jaboticabal, Brazil*

This study aimed to evaluate the effect of doses of *Enterococcus faecium* and *Saccharomyces cerevisiae* on the pH, ruminal ammonia nitrogen (RAN) and short-chain fatty acids (SCFA) in beef cattle in feedlot. Six Nellore steers fitted with ruminal cannulas, with initial average body weight of 460 kg were used in a double Latin square 3 x 3. Within each experimental period, 18 days were to adaptation and three days for sampling. Steers were fed a diet containing 200 g/kg of maize silage and 800 g/kg of concentrate. The following treatments: 0, 1 or 2 g/day of a blend with *Enterococcus faecium* (5 x 10^9 cfu/g of product) and *Saccharomyces cerevisiae* (5 x 10^9 cfu/g of product) provided in the rumen were evaluated. The statistical analyzes were conducted using PROC MIXED from SAS and means were compared using Tukey test ($P < 0.05$). Different doses of probiotic did not showed statistic difference ($P > 0.05$) for the variables evaluated, however, statistical difference were achieved to the time of sampling ($P > 0.05$). The pH was highest up to 6 hours after feeding the animals. Highest level of ammonia nitrogen (36.28 mg/dL) was observed 3 hours after feed supply. Concentrations of acetic acid was highest (72.59 mmol/L) 9 hours after feed supply ($P < 0.05$), however the highest level of propionic (22.94 mmol/L) occur after 12 hours ($P < 0.05$), and butiric acid had highest level 15 hours after feed supply ($P < 0.001$). The use of different doses of the blend with *Enterococcus faecium* and *Saccharomyces cerevisiae* did not affect the ruminal parameters.

Key Words: feedlot, probiotic, ruminal parameter

1743 (T356) Influence of soybean meal supplementation with tannins extracted from pistachio hulls on performance and feed efficiency of Holstein bulls.

A. Jolazadeh[1], M. Dehghan banadaky[*2] and K. Rezayazdi[2], *[1]University of Tehran, Karaj, Iran, [2]Department of Animal Science, Faculty of Agriculture, University of Tehran, Karaj, Iran.*

The objective of this study was to examine the effects of soybean meal (SBM) supplementation with pistachio concentrated extract (PEC) on performance and feed efficiency of Holstein bulls. The sun dried pistachio hulls was grounded through a 0.5 mm screen and soaked with ratio of 1:10 in (pistachio: water). Filtered extract was concentrated by heating at 95 ℃. The SBM was treated with PCE containing 11.14% total phenol and 7.13% total tannin/DM of extract. The experiment duration was 14 weeks and involved 28 growing young bulls (256 ± 56 kg BW) in a completely randomized design. The study lasted 94 d (10 d adaption). Treatments included: (1); control (SBM without PEC) (2); SBM with 5% PEC (3); SBM with 10% PEC and (4); SBM treated with 15% (kg PEC/100kg DM SBM). Diets were formulated to meet nutrient requirements according to NRC (1996) and to be isocaloric and isonitrogenous, with forage concentration ratio of 30:70. The TMRs were supplied ad-libitum to bulls in two equal meals (08.00 and 17.00) and bulls had free access to fresh water. Body weight (BW) of each calf was recorded every 28 days before the morning feeding. Results indicate that, tannin supplementation did not affect ($P < 0.05$) final BW and dry matter intake but there were significant differences among treatment 15% and control in average daily gain (1.25 Vs. 1.06 consequently, $P < 0.01$) and feed efficiency (gain: feed) (6.62 Vs. 7.82 consequently, $P < 0.05$). So it seems that the high level of PCE can improve performance and feed efficiency of Holstein bulls.

Key Words: Holstein bulls, pistachios hulls, soybean meal, tannin

1744 (T357) Depression of rumen ammonia and protozoal population of Holstein bulls fed soybean meal treated with tannins extracted from pistachio hulls.

A. Jolazadeh[1], M. Dehghan banadaky[*2] and K. Rezayazdi[2], *[1]University of Tehran, Karaj, Iran, [2]Department of Animal Science, Faculty of Agriculture, University of Tehran, Karaj, Iran.*

An experiment was conducted to determine the effects of soybean meal (SBM) supplementation with tannins extracted from pistachio hulls (TEP) on some ruminal parameter such as: pH, rumen ammonia and protozoal population of Holstein growing bulls. Twenty-eight Holstein young bulls (average initial weigh 256 ± 63kg) were used in a completely randomized design with four treatments and seven replicates for 94 days. Tannin were extracted from pistachio hulls (TEP) and

contained 11.14% total phenol and 7.13% total tannin/DM of extract. Treatments included: (1); control (SBM without TEP) (2); SBM with 5% TEP (3); SBM with 10% TEP and (4); SBM treated with 15% (kg TEP/100kg DM SBM. Rumen fluid was collected via stomach tube 4h after morning feeding. The pH was determined in ruminal samples immediately after sampling and then Protozoa were counted using Burker counting chamber on days 83 and 85. Rumen fluid was transported to the laboratory and frozen for ammonia analysis. According to results, there was a significant decrease ($P < 0.05$) in the rumen ciliate protozoa population caused by feeding 15% levels of TEP. On the other hand, there was a significant decrease ($P < 0.05$) of tannin supplementation on ammonia concentrations and pH among treatment 15% TEP and control. This result indicates that tannin are able to reduce protein degradation in the rumen and increase bacterial flow to the duodenum by effecting defaunation in male bulls.

Key Words: Holstein young bulls, pistachios hulls, protozoal, rumen ammonia,tannin

---

1745 (T358) Could soybean meal supplementation with crude extract of pistachio hulls change the blood metabolites of Holstein male bulls? M. Dehghan banadaky*[1], A. Jolazadeh[2], K. Rezayazdi[1] and N. Vahdani[2], [1]*Department of Animal Science, Faculty of Agriculture, University of Tehran, Karaj, Iran,* [2]*University of Tehran, Karaj, Iran.*

An experiment was carried out to determine the effect of soybean meal (SBM) supplementation with crude extract of pistachio hulls (CEP) on blood metabolites of Holstein bulls. CEP were extracted from hulls of pistachio containing 7.13% total tannin/DM of extract. Twenty-eight bulls 256 ± 63kg (mean ± SEM) were assigned randomly to one of the four treatment groups with seven replicates in a completely randomized design for 94 days. The bulls were housed in individual tie stalls and had free access to water. They were fed twice daily at 08:00 and 17:00 h. Four iso-energetic and iso-nitrogenous diets were offered to the experimental animals. Treatments included: (1); control (SBM without CEP) (2); SBM with 5% CEP (3); SBM with 10% CEP and (4); SBM treated with 15% (kg CEP/100kg DM SBM). Blood samples were taken from each bull at end of each month prior to morning feeding via coccygeal venipuncture and immediately chilled. According to results, Plasma total protein and albumin concentration was greater ($P = 0.001$) for bulls fed SBM with 15% CEP compared with other levels and Control. Plasma Glucose, BUN and Triglycerides concentrations were not affected by treatments ($P > 0.05$). Probably, in this experiment tannin able to reduce protein degradation in the rumen by formation tannin-protein complex and bypass them to the small intestine and increase digestive utilization of dietary protein is the reason for increase Plasma albumin and total protein concentration ($P < 0.001$) in bulls. It was therefore concluded that CEP could be used as chemical additives for improving the digestive utilization of protein-rich feeds in Holstein bulls.

Key Words: blood metabolites, pistachios hulls, tannin

1746 (T359) Effect of Saikosaponin on rumen gas production, volatile fatty acid concentrations and microbial populations in vitro. L. Pan*, D. P. Bu, J. Q. Wang, J. B. Cheng and X. Z. Sun, *State Key Laboratory of Animal Nutrition, Institute of Animal Science, Chinese Academy of Agricultural Sciences, Beijing, China*

There has been increasing interest to exploit bioactive saponins for improving rumen metabolism. This experiment was conducted to investigate effects of Saikosaponin (SSA) on rumen gas production, volatile fatty acid concentrations and microbial populations using batch cultures in vitro. It was anaerobically incubated in triplicates together with 0.5 g TMR, 50 mL basal media and 25 mL rumen fluid obtained from rumen-cannulated lactating Holstein dairy cows. Four treatments consisted of supplemental SSA at 0 (control), 0.25, 0.5 and 1.0 mg/g of dry matter,which were assigned randomly to 5 of 20 incubation bottles. Cumulative gas production (GP) was continuously measured in an automated trace gas recording system (AGRS-III, Beijing) at 39 °C during 48 h of incubation, after which the pH values were measured immediately and 10.0 mL of culture fluid sample were kept for analysis of volatile fatty acids (VFAs) by a gas chromatographic and the copy number of rumen bacteria populations by quantitative RT-PCR with species-specific PCR primers amplifying partial 16S rDNA regions. Data were analyzed using GLM procedure of SAS 9.2. Results revealed that SSA did not affect GP kinetics and fermentation gas pattern, while the increase of SSA addition improved the total gas production (131.78^{a}, 112.56^{ab} and 123.50^{ab} vs. 107.50^{b} ml/g DM, $P < 0.05$) and dry matter degradability (53.49^{a}, 50.36^{ab} and 51.83^{ab} vs. 48.67^{b} %, $P = 0.07$) compared with the control. The concentrations of acetate (54.88^{a}, 53.82^{a} and 54.00^{a} vs. 52.13^{b} mmol/L, $P < 0.05$), propionate (20.83^{a}, 20.32^{ab} and 20.25^{ab} vs. 19.74^{b} mmol/L, $P < 0.05$) and total VFA (91.58^{a}, 89.19^{a} and 89.34^{a} vs. 86.53^{b} mmol/L, $P < 0.05$) were increased, whereas molar proportions of acetate to propionate ratio were not influenced by supplementing SSA. There was no treatment effect on Ruminococcus flavefaciens and Butyrivibrio fibrisolvens, while the relative copy number of the following bacterial species: Ruminococcus albus, Prevotella ruminicola, Anaerovibrio lipolytica, Streptococcus bovis and Fibrobacter succinogene were increased ($P < 0.05$) compared to the control. Overall, SSA supplementation improved gas production, VFA concentrations and major microbial species in the culture fluid in vitro, therefore Saikosaponin may be beneficial to manipulate rumen microbial fermentation in vitro.

Key Words: microbial populations; Saikosaponin; volatile fatty acid

1747 (T360) Methane production from dairy cows fed red clover- or corn silage-based diets supplemented with linseed oil. C. Benchaar*[1], F. Hassanat[1], R. Gervais[2] and R. Martineau[1], [1]*Agriculture and Agri-Food Canada, Dairy and Swine Research and Development Centre, Sherbrooke, QC, Canada,* [2]*Université Laval, Québec, QC, Canada*

The objective of this study was to examine the effect of linseed oil (LO) supplementation on enteric CH_4 emissions from dairy cow fed red clover-(RC) or corn silage (CS)-based diets. Twelve lactating, multiparous Holstein cows (DIM = 91 ± 25; milk yield = 45.2 ± 4.7 kg) were used in a replicated 4 × 4 Latin square (35-d period; 14-d adaptation) with a 2 × 2 factorial arrangement of treatments. Cows were fed (ad libitum; 5% orts on an as-fed basis) a TMR (60:40, forage:concentrate ratio) not supplemented or supplemented with 4% LO (DM basis) and with the forage portion of the TMR consisting of either RC or CS. Production of CH_4 was determined (3 consecutive days) using respiration chambers, while milk performance was determined over 6 consecutive days. Main effects of forage source, LO supplementation and interactions (LO × forage source) were determined using the MIXED Procedure of SAS and significance was declared at $P \leq 0.05$. Significant interactions between LO and forage source were observed for DM intake, and yield of fat-corrected milk, which were not changed by adding LO to RC-based diets but decreased when LO was added in CS-based diets. Similarly, CH_4 production (g/d or as a proportion of gross energy intake) was unaffected by supplementing LO to RC-based diets, but declined by 25% when LO was included in CS-based diets (LO × forage source interaction; $P < 0.01$). When expressed on FCM yield basis, CH_4 production decreased with LO addition regardless the source of forage used (12.7 vs. 14.4 g CH_4/kg FCM). Results of this study show that 4% LO had no effect on CH_4 production when supplemented to RC-based diets, but decreased daily CH_4 emissions and CH_4 energy losses if supplemented to CS-based diets.

Key Words: dairy cow, methane, corn silage, red clover silage, linseed oil

1748 (T361) Replacing alfalfa with panicled-tick clover or sericea lespedeza in a dairy diet decreases ruminal methane but not total gas production. H. D. Naumann*[1], S. A. Armstrong[2,3], M. A. Fonseca[4], B. D. Lambert[5,6] and L. O. Tedeschi[4], [1]*University of Missouri, Columbia,* [2]*Prince Agri Products, Inc, Quincy, IL,* [3]*Oregon State University, Corvallis,* [4]*Texas A&M University, College Station,* [5]*Texas A&M AgriLife Research, Stephenville,* [6]*Tarleton State University, Stephenville, TX*

Enteric methane (CH_4) emissions by ruminants represent a decrease in gross-energy intake by the animal. Biologically active forage plant polyphenols, condensed tannins (CT), are known to suppress enteric CH_4 production in ruminants that consume them. However, consumption of these forages alone, or in too great of quantities could result in antinutritional effects, negatively impacting ruminant efficiency and growth. The objective of this study was to determine the effects of replacing the forage component of a traditional dairy diet (50% corn grain, 50% alfalfa; CRN:ALF) with that of forages containing CT on enteric methane and total gas production. *Desmodium paniculatum* (panicled-tick clover; PTC) and *Lespedeza cuneata* (sericea lespedeza; SL) were evaluated as an alfalfa replacement at levels of 15%, 30% and 45%. Methane production was determined using an in vitro gas production technique. In a randomized complete block design, replications consisted of two fermentation events, 06/25/2012 and 09/16/2012, where each diet was fermented in each of two fermentation chambers. Fermentation chamber was considered a random variable, whereas fermentation flasks within each fermentation chamber were considered random factors. Two ruminally-cannulated steers not adapted to forage containing CT were used for rumen fluid collection. Forages were individually fermented anaerobically in rumen fluid for 48h. Methane concentrations were determined by gas chromatography following fermentation. LS-means were determined and a value of $P < 0.05$ was considered significant. There was no difference in CH_4 production among PTC 15%, SL 15% and CRN:ALF (130.5, 132.2 and110.8 g/kg fermentable-organic matter; FOM, respectively). Fermentation of PTC 30% and SL 30% produced 85.5 and 89.7 g CH_4/kg FOM, respectively, which did not differ from CRN:ALF. However, fermentation of PTC 45% resulted in the least amount of CH_4 produced (38.1 g/kg FOM), which was 54% less than that of SL 45% (84.0 g/kg FOM; $P = 0.0022$) and 65% less than that of CRN:ALF ($P < 0.0001$). Total gas production did not differ among treatments compared to the CRN:ALF control. Results from this study suggest that 45% replacement of alfalfa with PTC or SL will suppress ruminal CH_4 with no compromise in total gas production (i.e. FOM).

Key Words: condensed tannin, legume, ruminal fermentation

1749 (T362) Effects of forage source and NDF concentration on methane emissions and milk production of dairy cows. K. J. Hammond*, A. K. Jones, D. J. Humphries, L. A. Crompton and C. K. Reynolds, *University of Reading, Reading, United Kingdom*

Strategies to mitigate greenhouse gas emissions from dairy cows are unlikely to be adopted if production or profitability is reduced. Dietary manipulation to reduce methane emissions can be readily used and may benefit productivity. The objectives of this study were to examine the effects of silage type and diet NDF concentration on methane emissions and milk production of dairy cows. A 12-week randomized block con-

tinuous design was used with 40 mid-lactation Holstein cows (74 DIM ± SEM 2.57) assigned to one of 4 treatments (10 cows each) according to calving date, parity and milk yield. Milk production and DMI were measured daily and milk composition measured weekly (weeks 3 to 12), and methane emissions estimated using a GreenFeed automated head chamber (weeks 10 to 12). Four isonitrogenous diets were fed as total mixed rations (TMR) containing 50% silage (DM basis) offered ad libitum. Silage was comprised of either 25:75 (MS) or 75:25 (GS) grass silage:maize silage on a DM basis, without or with additional NDF from chopped straw and soy hulls (+ 47 g NDF/kg TMR DM). A commercial calf pellet was included in the TMR (weeks 1 to 8) or provided via the GreenFeed (weeks 9 to 12). Data (weeks 10 to 12) were analyzed using mixed models for effects of silage, NDF, and their interaction. Cows fed MS had a greater milk yield ($P < 0.01$; 34.5 vs. 29.0 kg/d), milk protein yield ($P < 0.001$; 1076 vs. 926 g/d), DMI ($P < 0.001$; 24.6 vs. 19.3 kg/d), lower milk fat concentration ($P < 0.001$; 3.59 vs. 4.19%) and lactose yield ($P < 0.01$; 1540 vs. 1286 g/d), and lower methane yield ($P < 0.001$; 17.7 vs. 24.1 g/kg DMI), compared to GS. Added NDF increased methane production (410 vs. 461 g/d) and yield (16.5 vs. 18.9 g/kg DMI) when MS was fed, but not GS (460 g/d and 24.0 g/kg DMI, respectively), as indicated through a silage by NDF interaction ($P < 0.10$). Effects of silage type and NDF on methane emissions may be attributable to changes in rumen digesta dynamics, including rumen outflow and retention time, and warrants further investigation.

Key Words: methane, dairy cows, forage NDF

1750 (T363) Changes of rumen methanogen diversity associated with different types of forage and protein in diets. X. W. Wang, J. Q. Wang*, D. P. Bu and S. G. Zhao, *State Key Laboratory of Animal Nutrition, Institute of Animal Science, Chinese Academy of Agricultural Sciences, Beijing, China*

The objective of this study was to compare the methanogenic community and number in the rumen of dairy cows fed with different types of forage and protein in diet. Forty-eight healthy Chinese Holstein dairy cows were randomly assigned into three groups according to milk yield and day in milking. The diets in three treatments were as follows: MF (alfalfa and corn silage, soybean meal), CSA (corn stover, soybean meal), CSB (corn stover, cottonseed and rapeseed meal). The cows were fed with different diets (MF, CSA, CSB) for 91 days. Rumen fluid samples were collected before and after feeding using stomach-tube on d 91. Mothur software was used to assign clones to operational taxonomic units (OTUs) based on a 94% sequence identity cutoff. The results showed that the copy number of total methanogen of CSA was greater than that of CSB ($P = 0.049$). However, there was no difference between CSA and MF ($P = 0.67$). A total of 739 clones isolated from six methanogen mcrA gene clone libraries (samples from MF, CSA and CSB groups before or after feeding) were assigned to 25 species-level OTUs. The average OTU coverage of clone libraries was 96% (from 95% to 97.6%). Libshuff analysis showed methanogenic community of CSA and CSB, MF and CSA were different ($P = 0.03$ and $P = 0.04$, respectively). MF (2.08) and CSB (2.24) had lower diversity of methanogen based on Shannon index, compared with CSA (2.31). Additionally, Rumen cluster C (RCC, 73.2%) and *Methanobacteriales* (26.3%) were the predominant methanogenic archaea in the rumen. However, OTU10 were only found in CSA and CSB, and OTU20 only in MF. Meanwhile, OTU11 was only found in CSA and MF, while OTU21 only in CSB. Taxonomy analysis showed that OTU10, OTU20, OTU11 and OTU21 were closely related to *Candidatus methanomethylophilus alvus Mx1201* (83%), *Thermoplasmatales archaeon BRNA* (100%), *Methanobrevibacter ruminantium M1* (94%) and *Methanomassiliicoccus luminyensis B10* (78%), respectively. In conclusion, soybean diet could promote the number of total methanogen and increase the diversity of methanogen compared with rapeseed diet in rumen, and the diet with corn straw had higher diversity than the alfalfa and corn silage diet.

Key Words: methanogen, forage, protein

1751 (T364) Effect of cashew nut shell liquid on lactation performance and rumen methane production in dairy cows. A. F. Branco[1], F. Giallongo*[2], T. Frederick[2], H. Weeks[2], J. Oh[2] and A. N. Hristov[2], *[1]Universidade Estadual de Maringá, Paraná, Brazil, [2]Department of Animal Science, The Pennsylvania State University, University Park*

Technical cashew nut shell liquid (CNSL) is a by-product of the cashew nut industry in tropical countries, and is known to exhibit a wide range of biological activities, including inhibitory effect against gram-positive bacteria. This study was conducted to investigate the effects of CNSL (73.3% cardanol, 16.4% cardol, and 3.0% metilcardol) on DMI, milk yield and composition, rumen fermentation and CH_4 and CO_2 production, and nutrient digestibility in dairy cows. Eight multiparous Holstein cows (DIM, 140 ± 14 d; BW, 669 ± 47.8 kg) were used in a crossover design trial with two, 21-d periods. The TMR was based on corn silage and alfalfa haylage, and was formulated to meet or exceed the NE_L and metabolizable protein requirements of the cows (NRC, 2001). The diet contained (DM basis): 15.5% CP, 32.0% NDF, and 1.53 Mcal/kg NE_L. Treatments were: control (no CNSL supplementation), or 30 g/cow/d CNSL. The daily dose of CNSL was mixed with about 2 kg of TMR and top-dressed. Dry matter intake (average 26.6 ± 1.0 kg/d), 3.5% FCM (38.8 ± 1.6 kg/d), and milk composition (fat 3.32 ± 0.28% and true protein 3.09 ± 0.05%) were not affected by CNSL. Milk yield was numerically increased ($P = 0.13$) by CNSL (40.9 kg/d) compared with the control (39.0 kg/d). Rumen CO_2 production, measured using GreenFeed (C-Lock Inc., Rapid City, SD), was

not affected by CNSL. Compared with the control, CNSL numerically decreased (P = 0.12) rumen CH_4 production (534 vs. 505 ± 39.6 g/cow/d, respectively) and CH_4 emission intensity (P = 0.16; 13.3 vs. 12.3 ± 1.05 g/kg milk) and tended to decrease (P = 0.08) CH_4 production per kg of DMI (20.3 vs. 19.1 ± 0.83 g/kg). CNSL did not affect total tract apparent digestibility of nutrients, except NDF digestibility tended to be increased compared with the control (P = 0.09; 36.8 vs. 34.2 ± 1.47%, respectively). Total urinary N, urea N, and urinary purine derivatives excretions were not affected by treatment. MUN concentration was numerically increased (P < 0.13) in cows receiving CNSL (8.57 vs. 7.50 ± 0.62 mg/dL, respectively). Plasma urea and glucose concentrations were not affected by CNSL. In this study, CNSL tended to decrease rumen CH_4production per kg DMI and numerically increased milk yield without affecting DMI in dairy cows.

Key Words: cashew nut shell liquid, methane, dairy cow

1752 (T365) Metabolism of dairy cows as affected by dietary starch level and supplementation with monensin during early lactation. M. M. McCarthy*[1], T. Yasui[1], C. M. Ryan[1], S. H. Pelton[1], G. D. Mechor[2] and T. R. Overton[1], *[1]Cornell University, Department of Animal Science, Ithaca, NY, [2]Elanco Animal Health, Greenfield, IN*

The objective of this study was to evaluate the impact of dietary starch level and monensin (M) on metabolism of dairy cows during early lactation. Primiparous (n = 21) and multiparous (n = 49) Holstein cows were fed high starch (HS; 26.2% starch, 34.3% NDF, 22.7% ADF, 15.5% CP) or low starch (LS; 21.5% starch, 36.9% NDF, 25.2% ADF, 15.4% CP) TMR beginning at parturition until 21 DIM with a topdress pellet containing 0 or 450 mg/d M in a completely randomized design with a 2 × 2 factorial arrangement of treatments. Prior to parturition all cows were fed a common controlled energy diet with daily topdress of either 0 or 400 mg/d M consistent with postpartum treatment. Postpartum blood samples were collected 3× per wk and liver biopsies were taken on d 7 ± 4. Cows fed HS had higher plasma glucose (57.5 vs. 53.9 mg/dL; P = 0.003) and insulin (0.26 vs. 0.19 ng/mL; P = 0.008), and lower NEFA (533.1 vs. 696.6 μEq/L; P = 0.002) than cows fed LS. Cows fed LS had elevated BHBA during 11 to 21 DIM compared to cows fed HS (starch × d; P = 0.04). There was no effect of M on postpartum plasma NEFA. Cows fed M had higher plasma glucose compared to controls (58.1 vs. 53.3 mg/dL; P < 0.001) which was driven by a M × parity interaction in which heifers fed M had greater plasma glucose concentrations than controls (62.0 vs. 54.2 mg/dL; P = 0.008). Cows fed M had lower plasma BHBA compared to controls (10.08 vs. 12.66 mg/dL) which was contributed to by a M × parity interaction in which heifers fed M had lower BHBA concentrations than controls (10.11 vs. 13.99 mg/dL; P = 0.03). There was no effect of starch treatment on overall liver triglyceride content. Heifers fed M had increased liver triglyceride content compared to control heifers and cows fed M had decreased liver triglyceride content compared to control cows (M × parity; P = 0.05). Cows fed LS with M had higher liver glycogen content than cows fed the LS without M, with no effect of M treatment for cows fed HS (starch × M; P = 0.008). Overall, animals fed HS postpartum and M throughout the transition period exhibited improvements in energy metabolism during early lactation.

Key Words: starch, monensin, metabolism

1753 (T366) Effect of dietary monensin supplementation and amino acid balancing on lactation performance by dairy cows. A. L. Hagen*[1,2], L. F. Ferraretto[1], R. D. Shaver[1] and R. Martin[2], *[1]University of Wisconsin, Madison, [2]Vita Plus Corporation, Madison, WI*

A continuous-lactation experiment was conducted to evaluate the effect of dietary monensin supplementation and amino acid balancing (Lysine and Methionine) on milk yield, composition, component yields, and feed conversions (kg actual or component-corrected milk/kg DMI). Multiparous (n = 96) and primiparous (n = 32) Holstein (n = 112) and Holstein × Jersey cross-bred (n = 16) cows were stratified by breed, parity, and DIM (104 ± 39 at trial initiation) and randomly assigned to 16 pens of 8 cows each. Pens were randomly assigned to 1 of 4 treatments in a 2 × 2 factorial arrangement of treatments: control (CN; no monensin or amino acid balancing), amino acid balanced (AA), CN plus monensin (CNMN), or AA plus monensin (AAMN) for a 2-wk covariate period with cows fed a common non-experimental diet followed by a 10-wk treatment period with cows fed their assigned treatment diet. The TMR contained on average (DM basis) corn silage (37.5%), alfalfa silage (23%), and concentrate mixture (39.5%). The AA and AAMN treatments were supplemented with blood meal and a ruminally-protected Methionine source (Ultramet, Vita Plus Corp.; contains MetaSmart, Adisseo) to achieve a 3:1 Lysine:Methionine ratio in the metabolizable protein. The MN and AAMN treatments were formulated using Rumensin 90 (Elanco Animal Health) to provide a monensin intake of 540 mg/cow/d. Data were analyzed using Proc Mixed in SAS with covariate, monensin, amino acids, monensin x amino acids, week, and treatment x week interactions as Fixed effects and pen within treatment as a Random effect. DMI was reduced by monensin (26.6 vs 28.1 kg/d; P < 0.01). Milk yield was unaffected (P > 0.10) by treatment. Actual milk feed conversion was greater for cows fed monensin (1.82 vs. 1.73 kg milk/kg DMI; P = 0.03). Milk protein percentage and yield were increased by amino acids (3.16% vs. 3.09% [P < 0.01] and 1.53 vs. 1.50 kg/d [P = 0.03]), respectively. Component-corrected feed conversions were greater (P < 0.05) for cows fed diets containing monensin. Monensin × amino

acid interactions were not ($P > 0.10$) detected for any of the parameters measured. Dietary monensin supplementation increased feed conversions, while milk protein percentage and yield were greater for cows fed the amino acid balanced diets.

Key Words: monensin, amino acids, dairy cows

1754 (T367) Effects of beta-extract of *Humulus lupulus* (hops) on fermentation by rumen microbes in continuous culture. S. W. Fessenden*, I. J. Salfer and M. D. Stern, *University of Minnesota, Saint Paul*

Beta-acids in hops (*Humulus lupulus*) have been shown to exhibit selective bacteriostatic properties toward Gram-positive and hyper-ammonia producing bacteria in pure and co-culture. Previous work with whole or ground hops in batch culture fermentations with rumen microbes demonstrated promising results toward altering microbial output, however confounding factors such as additional fermentable substrate and presence of condensed tannins in hops can be difficult to control. Use of hop beta-acid extract can eliminate major confounding factors and improve consistency of administration. The objective of this experiment was to evaluate effects of beta-acid extract from hops on microbial fermentation in continuous culture. Eight dual-flow continuous culture fermenters were used in two consecutive 10-d periods consisting of 7 d of adaptation followed by 3 d of sampling. A basal diet containing 44% corn silage, 14% alfalfa hay, 13% ground corn, 11% protein mix, 10% corn gluten feed, 5% cottonseed, and 3% liquid vitamin and mineral supplement on a DM basis was provided to the fermenters at a rate of 75 g of DM/L of fermenter volume/d. Hop beta-extract (BE) was added daily to the artificial saliva to supply 0, 600, 1200, or 1800 mg of β-acids/kg of diet DM/day. Effluents from sampling days were composited by fermenter within period, resulting in 4 reps/treatment. Beta extract inclusion had no effects on DM, OM or fiber digestion ($P > 0.05$). Volatile fatty acid production and N metabolism were not affected by BE inclusion ($P > 0.05$). Mean and maximum fermentation pH tended ($P = 0.09$) to increase linearly with increasing levels of BE inclusion. Time spent above pH 6.2 tended to increase linearly with greater BE inclusion ($P = 0.08$), while time spent between pH 5.8 and 6.2 tended to decrease linearly ($P = 0.07$). Changes in pH were less than biologically relevant levels. Increasing concentration of BE had very limited effects on fermentation measurements by rumen microbes using continuous culture fermenters.

Key Words: continuous culture, hops, beta-acids, rumen

1755 (T368) Evaluation of Celmanax SCP on lactational performance and ruminal fermentation of Holstein dairy cows fed corn silage based diets with a moderate starch content. H. M. Dann*[1], P. Ji[1], K. W. Cotanch[1], C. S. Ballard[1], R. J. Grant[1] and C. C. Elrod[2], *[1]William H. Miner Agricultural Research Institute, Chazy, NY, [2]Vi-COR, Inc., Mason City, IA*

Primiparous ($n = 21$) and multiparous ($n = 39$) Holstein cows averaging 123 ± 28 (SD) days in milk were used in a randomized complete block design (RCBD) study to evaluate the effect of supplemental yeast culture plus enzymatically hydrolyzed yeast cell wall (Celmanax SCP; Vi-COR, Mason, City, IA) on lactational performance and ruminal fermentation. Following a 2-wk covariate period with a yeast-free diet, cows (20/treatment) were fed a diet supplemented with 0, 3, or 5 g of Celmanax SCP per day for a 4-wk treatment period. The diet contained 30.8% bmr corn silage, 16.2% corn silage, 9.7% haycrop silage, and 43.3% concentrates with a nutrient content of 16.5% crude protein, 36.3% neutral detergent fiber, and 24.3% starch. Cows were fed individually, housed in freestalls, and milked 3× daily. Dry matter intake (DMI) and milk yield were measured daily and milk composition was measured weekly. Fifteen ruminally cannulated cows (5/treatment) were sampled during the last week of the covariate and treatment periods for ruminal pH (72-h period) and volatile fatty acids (VFA; 24-h period). Data from wk 3 and 4 of the treatment period were analyzed as a RCBD by ANOVA using the MIXED procedure of SAS. Least squares means were adjusted using data from the covariate period. On average, cows ate 27.3 kg DMI/d and produced 45.5 kg milk/d containing 3.88% fat and 3.21% true protein. There was a quadratic effect of supplementing Celmanax SCP on feed efficiency with feed efficiency highest at 3 g/d. Ruminal pH averaged 6.05 over a 24-h period with 308 min/d below 5.8. Celmanax SCP supplementation linearly increased the concentration of total VFA and acetate with no effect on propionate. Supplementation of Celmanax SCP improved feed efficiency potentially through changes in ruminal fermentation.

1756 (T369) Effects of *Bacillus subtilis* and yeast cell wall on diarrhea incidence and immune function of dairy calves. J. Freitas*, *University of Parana, Palotina, Brazil*

The effects of *Bacillus subtilis* spores and spray-dried yeast cell wall (YCW) on health of dairy calves in the first 60 d of age were evaluated using 30 animals in three treatments. In control treatment, dairy calves received 8 liter of milk/day, after the 2nd day of live and a 20% pellet ration fed "ad libtum", in treatment 2 the calves received the same ration of treatment 1 plus $3x10^9$ viable spores/calf/d of *Bacillus subtilis* (Calpis Co. Ltda, Tokyo, Japan), in treatment 3 it was offered treatment 2 + 4 g/calves/d of YCW (Alltech of Brazil, Brazil). The *Bacillus subtilis* spores and YCW were mixed with milk and fed directly to the calves. The animals were housed in individual pens, with free access to water, starter feed and milk (give three times a day) until weaning that occurs on 9th week of life. Fecal consistency (FC) was scored as 1 when firm, 2 when soft or of moderate consistency, 3 when runny or mild diarrhea, and 4 when watery and profuse diarrhea. The FC 1 and 2 were considered no diarrhea. The supplementation with *Bacillus subtilis* tended ($P = 0.08$) to increased number of calves without diarrhea (Table 1756). Dairy calves feeding with probiotic and YCW showed higher rectal temperature. However, there is no difference ($P > 0.05$) in the levels of serum *immunoglobulin* G (IgG). The use of *Bacillus subtilis* reduced diarrhea incidence of pre-weaning calves without effects on serum immunoglobulin levels.

1758 (T371) Effects of different doses of *Bacillus subtilis* Natto on in vitro rumen fermentation parameters.

J. Li[1,2,3], D. P. Bu[2], J. Q. Wang[*1,2], P. Sun[2] and F. D. Li[3], *[1]Heilongjiang Bayi Agricultural University, Daqing, China, [2]State Key Laboratory of Animal Nutrition, Institute of Animal Science, Chinese Academy of Agricultural Sciences, Beijing, China, [3]College of Animal Science and Technology, Gansu Agricultural University, Lanzhou, China*

This experiment was conducted to investigate the effects of different doses (0 (contrl), 0.2×10^{11}cfu/ml (BSL),1×10^{11}cfu/ml (BSM), 5×10^{11}cfu/ml (BSH)) of *Bacillus subtilis Natto* culture (BSN) on rumen fermentation in vitro. Ruminal fluid was collected from three lactating Holstein dairy cows (BW = 558 ± 10 kg, DIM = 153 ± 16 d) fed diets contained (DM basis) Chinese wildrye (3.7%), Alfalfa hay (28.4%), Corn silage (26.7%), Corn (22.6%), Soybean meal (11.8%), Cottonseed fuzzy (5.1%), $CaHPO_4$ (0.6%), NaCl (0.5%), Premix (0.6%). Diets were mixed with phosphate buffer (1:2), incubated (90ml) anaerobically at 39°C for 0h, 12h, 24h, 36h and shaken at 50rpm. Each substrate (500mg DM basis) which had same concentrate mixture with donors was added to. Four sets of bottles were sealed anaerobically under CO_2 atmosphere with butyl rubber stoppers and capped with aluminum. One set (0h) were sampling immediately after mixed, other sets were incubated 12h, 24h, 36h respectively. Each set contained four levels of supplements, and for each level, three bottles were incubated. Statistical analysis was carried out by ANOVA (GLM) using SAS (SAS9.2). Medium pH was unaffected (P = 0.61) by BSN in all treatments, ammonia-N tended to increase linearly with increasing BSN dose ($P < 0.01$). Compared with the control, the molar proportion of acetate(46.66 vs 57.32, 60.96 and 68.17, $P < 0.01$), propionate (19.23 vs 22.88, 24.48 and 29.98 linear, $P < 0.01$), iso-butyrate (0.83 vs 2.18, 2.50 and 3.70, $P < 0.01$), iso-valerate (1.55 vs 4.50, 5.02 and 7.70, $P < 0.01$), valerate (1.52 vs 4.38, 5.04 and 6.89, $P < 0.01$) and total VFA (79.93 vs 102.77, 110.12 and 131.03, $P < 0.01$) was enhanced significantly with increasing concentrations of BSN. The molar proportion of butyrate of BSL treatment was increased ($P < 0.05$) and BSM and BSH treatment were increased significantly ($P < 0.01$). The molar proportion of acetate:propionate was increased ($P < 0.05$) in BSL and BSM treatment compared with control, however, decreased significantly in BSH treatment ($P < 0.01$). The results indicated that the *Bacillus subtilis Natto* culture can stimulated in vitro fermentation by increase the molar proportion of VFA and change the rumen fermentation type by change the molar proportion of acetate:propionate, and the diets should consist of a minimum of 10^{10}cfu/g (DM) of BSN to make sure it's effect.

Key Words: *Bacillus subtilis Natto*, in vitro, rumen fermentation

1759 (T372) An on-farm application of feed probiotics to increase total tract starch digestibility (TTSD) in high producing, lactating dairy cows.

W. L. Braman*, K. A. Bryan and J. E. Kurtz, *Chr. Hansen Animal Health and Nutrition, Milwaukee, WI*

With the increased cost of grains and forages in the USA, dairy producers have turned their attention to the feed efficiency of milk production. Two reviews of starch digestibility in lactating dairy cows have suggested that over 50% of TTSD takes place in the lower digestive tract. Low on-farm starch digestibility contributes to reduced feed efficiency. Several researchers have demonstrated that measuring fecal starch is highly correlated to TTSD in lactating dairy cows. Our previous studies using a dairy feed probiotic (Probios Complete, Chr. Hansen, Inc., Milwaukee, Wisconsin USA) demonstrated increases in TTSD, production performance, and feed efficiency in lactating dairy cows fed high starch + sugar diets (32% and 35%, respectively). To further validate this probiotic research, field trials were conducted to test a similar probiotic, Probios Precise containing 3 strains of *Enterococcus faecium* and live yeast, on fecal starch on farm. Total mixed ration and fecal samples were collected from the same pen at 30-d day intervals for 90 d on 10 commercial dairy farms averaging 2041 cows located in Wisconsin, Texas, New Mexico and Minnesota. Fresh floor fecal samples were collected from at least 20 cows per pen from cows less than 120 d-in-milk. Total mixed rations and fecal samples were analysed by Rock River Laboratories (Watertown, WI). Fecal components including starch (FS), protein, NDF, 120 h-indigestible NDF, fat, and ash (DM basis) were measured. Samples on d 0 were taken prior to adding Probios Precise to each herd's diet which averaged 23.7% starch (DM basis). Subsequent samples taken at 30, 60, and 90 d were analysed to measure the response from the probiotic treatment. The REG procedure of SAS was used to analyse the relationship between days fed Probios Precise and FS. As days fed the probiotic increased, there was a reduction in FS ($R^2 = 0.31$; $P < 0.001$; 5.41, 3.95, 3.09, and 3.04%, respectively for d 0, 30, 60, and 90 sampling times). These results suggest that feeding the probiotic decreased FS confirming earlier trials that indicated certain feed probiotics decreased FS and increased TTSD in early lactation dairy cows. Thus,

supplementing the dairy feed probiotics, Probios Complete and Probios Precise, can be a management tool to decrease FS, increase TTSD, with potential increase in feed efficiency.

Key Words: dairy, probiotics, starch

1760 (T373) Effect of feeding yeast culture (YC) on lactation performance of dairy cows fed diets differing in rumen fermentability. A. L. Dias*, R. A. Azevedo, J. A. Freitas, B. Micai, T. V. Silva, G. C. Gomes, E. S. Ribeiro, L. F. Greco, P. M. Leopoldo Junior and J. E. P. Santos, *Department of Animal Sciences, University of Florida, Gainesville*

Objectives were to evaluate the effect of feeding YC (*Saccharomyces cerevisiae*, Rumen Yeast, ICC, Brazil) on lactation performance of dairy cows fed diets with two concentrations of starch. Fifty-six Holstein cows at 42 d postpartum were blocked by parity and milk production and randomly assigned to 1 of 4 treatments, low starch no YC (22% starch and control; LSC), low starch and YC (22% starch and 15 g/d of YC; LSYC), high starch no YC (28% starch and control; HSC), and high starch with YC (28% starch and 15 g/d of YC; HSYC). The study lasted 13 weeks and milk yield, body weight, and dry matter intake were measured daily. Milk samples were collected weekly to determine concentrations of milk components and somatic cells. Data was analyzed by ANOVA for repeated measures using the MIXED procedure of SAS. Results are presented in Table 1760. Feeding high starch improved yields of milk and milk protein, whereas inclusion of YC improved yields of milk and all milk components regardless of starch in the diet.

Key Words: dairy cow, lactation, yeast culture.

1761 (T374) Milk fatty acid profile in cows fed red clover or alfalfa based diets differing in rumen-degradable protein supply. M. Leduc*[1], P. Y. Chouinard[1], R. Gervais[1], E. Baumann[1], Y. Lebeuf[1] and G. Tremblay[2], *[1]Université Laval, Québec, QC, Canada, [2]Agriculture and Agri-Food Canada, Soils and Crops Research and Development Centre, Quebec, QC, Canada*

Polyphenol oxidase in red clover silage (RCS) has been shown to reduce lipolysis and consequently protect its constituent fatty acid (FA) against biohydrogenation by ruminal microorganisms. Fatty acid biohydrogenation could be further inhibited by reducing the supply of nitrogen to ruminal bacteria. To compare the effects of RCS and alfalfa silage (AS) fed in diets differing in rumen-degraded protein (RDP) supply on milk FA profile, 8 multiparous Holstein dairy cows (72 ± 17 DIM) were used in a replicated 4×4 Latin square design (21-d periods, 14-d adaptation). Four treatments were compared in a 2×2 factorial arrangement with AS or RCS fed in diets formulated to provide 85% (RDP85) or 100% (RDP100) of calculated RDP requirements. Untreated and heat-treated (AminoPlus) soybean meals were used to adjust dietary RDP. No significant interaction of silage by RDP was observed on milk FA profile ($P > 0.05$). As compared with AS, feeding RCS increased ($P < 0.01$) c9c12c15-18:3 (6.89 vs. 4.26 mg/g fat) and c9c12-18:2 (18.64 vs. 16.50mg/g), but decreased ($P < 0.01$) t11-18:1 (5.87 vs. 6.75 mg/g; $P < 0.01$) and t11c15-18:2 (0.63 vs. 0.82 mg/g) concentrations in milk fat. As compared with AS, feeding RCS increased ($P < 0.03$) milk fat content of iso 13:0 (0.23 vs. 0.21 mg/g), iso 14:0 (1.23 vs. 0.89 mg/g), iso 15:0 (1.46 vs. 1.22 mg/g), iso 16:0 (2.25 vs. 1.84 mg/g), iso 17:0 (1.90 vs. 1.77 mg/g), anteiso 15:0 (4.01 vs. 3.57 mg/g), and anteiso 17:0 (3.58 vs. 3.10 mg/g), but decreased ($P < 0.01$) milk fat content of 11:0 (0.60 vs. 1.32 mg/g), 13:0 (0.98 vs. 1.83 mg/g), 15:0 (10.64 vs. 15.77 mg/g), 17:0 (4.99 vs. 5.87 mg/g), and c9-17:1 (1.65 vs. 2.05 mg/g). The supply of RDP had only minor effects on milk FA with higher concentrations ($P < 0.01$) of iso 13:0, iso 15:0, and iso 17:0 observed with RDP100 (0.23, 1.41, 1.91 mg/g, respectively) as compared with RDP85 (0.21, 1.28, 1.76 mg/g, respectively). In conclusion, cows fed RCS as compared with those fed AS produced milk with greater concentrations of major forage FA (i.e. c9c12c15-18:3 and c9c12-18:2) and lower proportions of intermediates (i.e. t11-18:1 and t11c15-18:2) that are produced during the ruminal biohydrogenation of these FA. Variations in milk fat concentrations of odd and branched chain FA, which are known to be synthesized in the rumen by various microbial populations, may reflect the effect of forage legume species on ruminal fermentation.

Key Words: biohydrogenation, odd and branched chain fatty acids, polyphenol oxidase

1762 (T375) Use of virginiamycin and monensin sodium in diets of confined beef steers. F. R. Camilo[1], A. M. Mobiglia[1], R. K. Grizotto[2], J. A. Alves Neto[3], M. Q. Manella[4], F. D. D. Resende[2], G. R. Siqueira[2] and J. J. R. Fernandes[*5], *[1]Escola de Veterinária e Zootecnia da UFG, Goiânia, Brazil, [2]APTA-Agência Paulista de Tecnologia dos Agronegócios, Colina, Brazil, [3]Universidade Estadual Paulista, Jaboticabal, Brazil, [4]Phibro Animal Health Corporation, Guarulhos, Brazil, [5]Universidade Federal de Goiás, Goiânia, Brazil*

Feed additives are used as tool of nutrition management to enable the supply of high concentrate diets. The association of antibiotics may improve the response of ruminal fermentation manipulation and increase performance. The objective of this study was to evaluate the isolated and combined effects of the virginiamycin (VM) and monensin sodium (MON) in diets of crossbreed steers in feedlot. The animals were kept in feedlot in group pens for 105-d with a 28-d adaptation period. Three hundred and thirty nine 1/2Nellore x 1/2 Guzera beef steers (402.7 ± 1.3 kg of initial BW) were used in a randomized complete block design with 5 treatments and 7 replicates. The blocks were defined by initial BW. Treatments were defined by levels of VM and MON (mg/kg of dry matter) as follows: 30MON; 15VM+30MON; 25VM+30MON; 34VM+ 30MON e 34VM. Animals were fed < *i* > ad libitum < /*i* > twice daily with isonitrogenous and isoenergetic diets, with a 88:12 concentrate:forage (sugarcane bagasse) ratio. Steers were weighed at the beginning, after the adaptation period and at the end of the trial. Data are shown in Table 1762. Dry matter intake (DMI), final BW and average daily gain (ADG) were not affected ($P > 0.05$) by treatments. However, effects ($P < 0.05$) were observed on DMI for percentage of body weight (BW) between 34VM and 25VM + 30 MON, with lower DMI/BW (%) for the intermediate association. The treatment 30 MON showed higher feed efficiency (FE) than 34VM. In conclusion, the MON showed higher FE in relation to VM, however, no effects were observed on treatments with different association levels of feed additives. Supported by Phibro/Minerva/FAPEG.

Key Words: feed additives, feedlot, performance

1763 (T376) GLOBAL NETWORK for the development of nutrition-related strategies for mitigation of methane and nitrous oxide emissions from ruminant livestock. A. N. Hristov[*1], E. Kebreab[2], Z. T. Yu[3], C. Martin[4], M. Eugène[4], D. R. Yáñez–Ruiz[5], K. J. Shingfield[6], S. Ahvenjärvi[6], P. O'Kiely[7], C. K. Reynolds[8], K. J. Hammond[8], J. Dijkstra[9], A. Bannink[10], A. Schwarm[11] and M. Kreuzer[12], *[1]Department of Animal Science, The Pennsylvania State University, University Park, [2]University of California, Davis, Davis, [3]The Ohio State University, Columbus, [4]INRA, Clermont-Ferrand, France, [5]Estacion Experimental del Zaidin, CSIC, Granada, Spain, [6]MTT Agrifood Research, Animal Production Research, Jokioinen, Finland, [7]7Animal and Grassland Research and Innovation Centre, Teagasc, Dunsany, Ireland, [8]University of Reading, Reading, United Kingdom, [9]Animal Nutrition Group, Wageningen University, Wageningen, Netherlands, [10]Animal Nutrition, Wageningen UR Livestock Research, Lelystad, Netherlands, [11]ETH Zurich, Institute of Agricultural Sciences, Zurich, Switzerland, [12]ETH Zurich, Zurich, Switzerland*

Ruminant husbandry is a major source of anthropogenic greenhouse gases (GHG). There is a large body of existing nutrition-related GHG and ammonia (NH_3) mitigation data that are not well organized. The main objective of the GLOBAL NETWORK consortium, a 4-yr project funded through The Joint Programming Initiative on Agriculture, Food Security and Climate Change (FACCE-JPI), is to accumulate and analyze ruminant GHG mitigation data. The specific goals of this collaborative project are to: (1) Create, update, and expand animal and feed databases for the mitigation of enteric methane (CH_4); (2) Gain understanding of the contribution of genetic and microbial factors to the variation in enteric CH_4 production, digestion, and nutrient utilization; (3) Validate markers of enteric methanogenesis for the development and monitoring of CH_4 mitigation strategies in ruminants; (4) Create, update, and expand a database of mitigation strategies aimed at improving dietary N utilization and lowering N excretion and decreasing NH_3 and nitrous oxide (N_2O) emissions from manure; (5) Develop Standard Operating Procedures (SOP) and guidelines for conducting and assessing data from in vitro and in vivo studies designed to evaluate nutritional strategies for mitigation of CH_4, NH_3, and N_2O emissions; (6) Develop new and evaluate existing models for predicting CH_4 emission and N excretions under various nutritional, animal, and farm management scenarios; and (7) Identify and recommend CH_4, NH_3, and N_2O mitigation technologies that are both practical and feasible for implementation in various ruminant livestock production systems. These activities will be integrated with those of the "Network and Database on Feed and Nutrition in Relation to GHG Emissions" (FNN; http://animalscience.

psu.edu/fnn), which is an activity of the Livestock Research Group (LRG) of the Global Research Alliance (GRA) on Agricultural GHG. The newly created GLOBAL NETWORK consortium intends to fill important knowledge gaps and provide the much needed expert recommendations for future research priorities, methodologies, and science-based GHG mitigation solutions to governments and non-governmental organizations, advisory/extension networks, and the ruminant livestock sector. Animal scientists with an interest in GHG mitigation research are encouraged to contact members of the consortium to identify areas and opportunities for future collaboration and contribution of data.

Key Words: livestock, greenhouse gas, mitigation, database

1764 (T377) Effect of oat grain variety on methane emissions from mature sheep.

J. M. Moorby*, H. R. Fleming and S. A. Cowan, *Aberystwyth University, Aberystwyth, United Kingdom*

Methane emissions from ruminants are driven by DM intake and feeds characteristics such as oil concentration and OM fermentability; an oat breeding program at Aberystwyth aims to breed new varieties for livestock feeding that help reduce pollutant emissions by manipulating nutritional characteristics. To study the effect of feeding different varieties of oat grains on enteric methane emissions from sheep, eight mature barren ewes, four each of two breeds (Welsh Mountain and Welsh Mule; mean LW 41.5 ± 1.93 and 64.9 ± 1.46 kg respectively) were fed diets comprising ryegrass silage and oats in a 1:1 ratio (on a DM basis) in a Latin square changeover design experiment. Feed was offered at rates (i.e. restricted) designed to supply ME requirements for maintenance (according to AFRC 1992 guidelines). The same grass silage was used throughout, fed with 1 of 4 oat grain treatments: A) a husked oat, cv Balado, B) a naked oat, cv Racoon, C) a new breeding line husked oat, NewLine, and D) a 1:1 (fresh) mix of B and C, Mix. Each of the 4 periods of the experiment consisted of 14 days for diet adaptation and 6 days for measurements of feed intake, whole tract apparent diet DM digestibility, and methane emission. Methane emissions were measured for each animal for 3 days in open-circuit respirations chambers. There were no significant sheep breed effects on measurements except for LW and therefore DMI (grand mean 637 g/d). There were significant effects of oat variety on methane emissions, both in g/d and when expressed in relation to intake and metabolic LW. Differences in methane emissions from the sheep are likely to be related to differences in fiber and oil concentrations of the oat grains. In conclusion, the Mix treatment composition is a good breeding target for new varieties of oats.

Key Words: sheep, oats, methane

1765 (T378) Effect of acetate, propionate and pH on aqueous concentration and gaseous methane and hydrogen production in continuous culture.

S. Ghimire*[1], B. A. Wenner[2], R. A. Kohn[3], J. L. Firkins[2] and M. D. Hanigan[1], *[1]Virginia Polytechnic Institute and State University, Blacksburg, [2]The Ohio State University, Columbus, [3]The University of Maryland, College Park*

Four continuous culture fermenters were used to determine the effect of varying volatile fatty acid concentrations and pH on hydrogen and methane production. The experiment constituted 4 treatments applied in 4 periods. Treatments were: control, 20 mmol/d acetate infusion (INFAC), 7 mmol/d propionate infusion (INFPR), and low pH (LOWPH). In LOWPH buffer flow was adjusted to lower pH by 0.5 units compared to control. The fermenters were fed 40 g of a pelleted 50:50 alfalfa: concentrate diet once daily. One week of adjustment occurred each period before sampling. Filtered liquid effluent (20 ml) from the fermenters was sampled at 0, 2, 4, 6, 8, 12, 16, and 22 h after feeding for measurement of aqueous hydrogen and methane concentrations. Daily cumulative gas production and hourly production rate were analyzed for headspace methane and hydrogen. The effects of treatments are shown in Table 1765. Headspace methane production was lower ($P < 0.05$) in LOWPH compared to other treatments. Methane production rate in LOWPH was lower ($P < 0.05$) than other treatments from 2 to 9 h, and was lower ($P < 0.05$) compared to INFAC and INFPR at 10 h. Aqueous methane concentrations were higher ($P < 0.05$) in LOWPH compared to control and INFAC, whereas in INFPR it was higher than control ($P < 0.05$). The differences were significant ($P < 0.05$) at 16 h. Headspace hydrogen production was higher in INFAC, followed by INFPR and control, and LOWPH ($P < 0.05$). Production rate of headspace hydrogen from INFAC was higher ($P < 0.05$) than others from 2 to 7 h. The effect of treatment on aqueous hydrogen concentration was not significant ($P > 0.05$). These results reveal that headspace methane and hydrogen was lowered by low pH, and acetate infusion increased the headspace hydrogen in a continuous culture. Aqueous hydrogen was unaffected

by the treatments, whereas aqueous methane was increased by low pH and propionate infusion.

Key Words: fermenter, hydrogen, methane

1766 (T379) Ruminal parameters of confined steers fed with diets containing virginiamycin and monensin sodium. F. R. Camilo[1], A. M. Mobiglia[1], G. F. Berti[2], N. M. Jerônimo[2], R. K. Grizotto[3], M. Q. Manella[4], F. D. D. Resende[3], G. R. Siqueira[3] and J. J. R. Fernandes[*5], *[1]Escola de Veterinária e Zootecnia da UFG, Goiânia, Brazil, [2]Centro Universitário da Fundação Educacional de Barretos-Unifeb, Barretos, Brazil, [3]APTA- Agência Paulista de Tecnologia dos Agronegócios, Colina, Brazil, [4]Phibro Animal Health Corporation, Guarulhos, Brazil, [5]Universidade Federal de Goiás, Goiânia, Brazil*

Ionophore and non-ionophore antibiotics are known for their abilility to manipulate rumen fermentation and increase efficiency of high concentrate diets. The aim of this trial was to evaluate the effects on ruminal parameters of confined Nellore steers fed with diets using isolated and combined levels of virginiamycin (VM) and monensin sodium (MON). Fifteen Nellore steers (536 kg of BW) with ruminal cannula were used in a randomized complete block design with five treatments and three replicates. The blocks were defined by initial BW. The animals were kept in feedlot in individual pens for 28-d. Ruminal ammoniacal nitrogen (NH_3–N), short-chain fatty acids (SCFA) and ruminal fluid pH were measured before feeding (T0) and 6 and 12 hours after feeding (T6 and T12, respectively). Treatments were defined by levels of VM and MON (mg/kg of dry matter) as follows: 30MON; 15VM+30MON; 25VM+30MON; 34VM+ 30MON and 34VM. Animals were fed ad libitum twice daily with isonitrogenous and isoenergetic diets, with a 88:12 concentrate:forage (sugarcane bagasse) ratio. Data are shown in Table 1767. There were not effects ($P > 0.05$) on NH_3–N concentration between treatments. However, pH and SCFA presented differences in T0 for the treatments, with lower SCFA concentration in 34VM+30MON than in 34VM. Acetate:propionate ratio (A:P) did not show differences ($P > 0.05$) between treatments. In conclusion, the different levels of isolated and combined associations of VM and MON did not affect pH, NH_3–N, SCFA and A:P ratio, except for pH and SCFA measured at T0, when we observed differences between treatments. *Supported by Phibro/Minerva/FAPEG.*

Key Words: feed additives, feedlot, ruminal fermentation

1767 (T380) Ruminal parameters of young Nellore bulls in a feedlot fed Yea-Sacc8417 live yeast, monensin and their combination. J. M. B. Benatti[1], N. M. Geronimo[2], J. A. Alves Neto[1], I. M. de Oliveira[*3], A. D. Moreira[1], C. L. Francisco[4], G. R. Siqueira[3] and F. D. D. Resende[3], *[1]Universidade Estadual Paulista, Jaboticabal, Brazil, [2]UNIFEB, Barretos, Brazil, [3]APTA- Agência Paulista de Tecnologia dos Agronegócios, Colina, Brazil, [4]Universidade Estadual Paulista- FMVZ, Botucatu, Brazil*

The objective of this study was to analyze the ruminal parameters of young Nellore bulls in a feedlot for 109 days. The treatments consisted of a control diet with monensin sodium (27.0 mg kg DM^{-1}), a diet with Yea-Sacc^{8417} live yeast (2.0 g $animal^{-1}$) and a diet with the two additives combined. Diets (10.00% sugarcane bagasse, 73.60% ground corn, 6.40% cottonseed, 6.40% soybean meal, 0.26% corn gluten, 0.79% urea and 2.55% mineral mix) varied only in the inclusion of additives. We used 16 non-castrated Nellore bulls (422.00 ± 80.26 kg) cannulated in the rumen. The experiment was arranged in a completely randomized blocks design (four replicates) as a function of the initial body weight. Data were analyzed by the MIXED procedure of SAS software and means were compared by Fisher's test at 10% significance. The animals were kept in individual pens and were considered the experimental unit. Dry matter intake (DMI) did not differ among the studied diets (9.6 kg DM day^{-1}), and neither did ($P > 0.10$) the digestibility of DM (65.8%). The rate of intake was also not affected ($P > 0.10$) by inclusion of additives, and 90.4% was consumed in the first 12 hours after the 1st feed. Monensin sodium increased ($P = 0.0150$) the selectivity for concentrate (0.8% more concentrate) as compared with the other diets (0.3% more concentrate). Live yeast, alone or combined with monensin, elevated ($P = 0.0420$) the acetate content in the rumen (58.15%) in relation to control diet and the treatment of monensin alone (56.97%). Monensin not combined with yeast reduced ($P = 0.0373$) the acetate-to-propionate ratio in the rumen (1.79) over the other diets (2.05). When supplied separately, the additives monensin sodium and live yeast showed lower values ($P = 0.0345$) for the rumen pH (5.74 and 5.93 for monensin and yeast, respectively) compared with the other

diet (6.07). The combination of the additives live yeast and monensin sodium controlled ($P = 0.0376$) the decrease in the rumen pH 12 hours after the feed (6.08) as compared with the diet with these additives supplied alone. Sodium monensin not combined with live yeast increased ($P = 0.0367$) the daily fluctuations of rumen pH (0.19) in relation to the other treatments (0.10). The monensin reduces the acetate-to-propionate ration and yeast increase the acetate proportion. The use additives live yeast and monensin sodium combined has an additive effect on the rumen pH. *Supported by FAPESP and Alltech.*

1768 (T381) Optimal ration of combined origanum essential oils to reduce methane emissions under in vitro ruminal fermentation.

A. Castañeda-Correa*[1], A. Corral-Luna[1], F. A. Rodriguez-Almeida[1], L. De la Torre-Saenz[2], R. Silva-Vázquez[3], L. Carlos-Valdez[1], H. Gutiérrez-Bañuelos[4] and O. Ruiz-Barrera[1], *[1]Universidad Autonoma de Chihuahua, Chihuahua, Mexico, [2]CIMAV, Chihuahua, Mexico, [3]CIRENA, Salaices, Mexico, [4]Universidad Autonoma de Zacatecas, Zacatecas, Mexico*

Origanum (*Origanum vulgare*) essential oils (EO; thymol T and carvacol C) have been reported as potential anti-methanogenic additives for dairy cattle rations. An in vitro fermentation trial was conducted to determine the optimal T:C ratio (100:0, 80:20, 60:40, 40:60, 80:20 and 0:100) in an EO combined dose of 100 mg/L added to a total mixed ration (TMR; 65:35 concentrate:forage). The incubation was carried out in 60 mL flasks in triplicate for each T:C ratio and the control. The in vitro buffered solution was prepared anaerobically. Inside of anaerobic chamber 20 mL of buffered medium and 10 mL of rumen fluid were dispensed in each flask containing 200 mg of the ground substrate. The flasks were sealed with butyl rubbers and aluminum seals and incubated at 39 °C for 24 h with a constant shaking at 150 rpm. After 24h of incubation, gas production was recorded and sampled to determine its composition and 5mL of liquid content were taken from each flask and preserve with metaphosphoric acid to determine VFA. Gas composition and VFA concentration were determined by chromatography. Dry matter digestibility (IVDMD) was determined by the DAISY procedure. Data were analyzed by PROC GLM of SAS (SAS, 1992) by a complete randomized design considering the EO ratio as sole effect. Adding EO to the ration did reduce total gas production ($P < 0.0001$) in all C:T ratios (Table 1768). Also, methane production was decreased ($P < 0.05$) by the EO in all treatments. However, the 80:20 T:C ratio showed the greatest reduction ($P < 0.0001$). Total VFA concentration and IVDMA was not affected ($P > 0.70$ and 0.93, respectively) by EO addition. The molar proportion of acetate was decreased by the 60:40 T:C ratio. These results suggest that 80:20 T:C ratio has the best potential to decrease methane emissions of dairy cattle without DM digestibility decreases.

Key Words: thymol, carvacrol, methane

Table 1768.

1769 (T382) Effect of phytogenic feed additives on performance parameters and health of bull calves under commercial conditions.

C. Schieder*[1], T. Steiner[1] and M. Friedrichkeit[2], *[1]BIOMIN Holding GmbH, Herzogenburg, Austria, [2]Commercial farm, Reisenberg, Austria*

The increased emphasis on achieving a good health status for adequate growth rates in calves and the ban on sub-therapeutic antibiotics in the European Union in 2006 have resulted in growing interest in alternative feeding strategies. Phytogenic feed additives (PFA) exert strong anti-inflammatory, anti-oxidative and anti-microbial activities, and all of which offer potential benefits for improving performance and preventing intestinal disorders. The aim of the study was to evaluate the efficacy of PFA on growth performance, feed-to-gain ratio and number of medical treatments in commercial calves. During the trial period of 56 days, 53 calves with an average initial body weight of 93.2 kg were assigned to either the control ($n = 26$) or treatment group ($n = 27$) based on their initial body weight and breed (Simmental and Belgian Blue). Calves were housed in groups (1 pen/group) and were fed

twice a day receiving calf milk replacer (CMR), calf starter (CS), corn silage, hay and a concentrate mixture consisting of corn, cereals, soybean and rapeseed meal. Control calves received a standard non-medicated CMR and CS. Experimental calves received CMR and CS supplemented with two different mixtures of PFA including herbs, spices and plant extracts [Digestarom Milk in CMR (500 g/t) and Digestarom Calf in CS (300 g/t), BIOMIN Phytogenics GmbH, Stadtoldendorf, Germany]. Feeding CMR was restricted during the first 3 wk, whereas CS was offered ad libitum. Calves were weighed individually on d 1, 21, 42 and 56. Feed intake was determined per group on a weekly basis. Medical treatments were recorded throughout the trial. Data for body weight and weight gain was statistically analyzed with the independent *t* test using SPSS. Calves offered CMR and CS containing PFA were superior in average daily gain (1.33 vs. 1.23 kg; $P = 0.06$) and exhibited a higher average final body weight (168.1 vs. 161.2 kg; $P = 0.02$). Adding PFA resulted in a slightly increased average dry matter intake (2.46 vs. 2.41 kg) and improved feed efficiency (feed-to-gain ratio 1.86 vs. 1.97). Moreover, PFA supplementation positively influenced the health status of calves, as indicated by a reduced number of animals treated for health problems (fever and diarrhea). This led to reduced medication costs and higher farm profits. In conclusion, PFA supplementation in the CMR and CS is a suitable tool to improve growth rates and reduce medication costs in commercial beef calves.

Key Words: phytogenic feed additive, calves, performance

1770 (T383) Efficacy of *Propionibacterium* strains in mitigating methane emissions from beef heifers fed a high forage diet.

D. Vyas*[1], A. Alazzeh[1], S. M. McGinn[1], O. M. Harstad[2], H. Holo[2], T. A. McAllister[1] and K. A. Beauchemin[1], *[1]Lethbridge Research Centre, Agriculture and Agri-Food Canada, Lethbridge, AB, Canada, [2]Department of Animal and Aquacultureal Sciences, Norwegian University of Life Sciences, Ås, Norway.*

The objective of this study was to test the efficacy of *Propionibacterium* strains to mitigate methane (CH_4) emissions in beef heifers fed a high forage diet. Sixteen ruminally cannulated beef heifers were used in a randomized complete block design with 21-d periods. Treatments included: 1) Control, 2) *Propionibacterium freudenreichii* T114, 3) *P. thoenii* T159, and 4) *P. freudenreichii* T54. Strains (10×10^{11} CFU) were administered daily directly into the rumen prior to feeding. All heifers were fed a basal diet consisting of 60:40 barley silage:barley grain. Environmental chambers were used for CH_4 measurements. No treatment effects were observed for overall DMI ($P = 0.76$) or DMI in chambers ($P = 0.67$). Mean ruminal pH averaged 6.17 and was not affected by treatments ($P = 0.62$). Likewise, both minimum and maximum ruminal pH were similar for all treatments ($P > 0.10$). No treatment differences were observed for total VFA ($P = 0.44$) or ammonia-N concentration ($P = 0.79$). However, proportions of individual VFA changed with acetate being reduced with *Propionibacterium* T159 (61.1 vs 63.8; $P = 0.02$), whereas ruminal isobutyrate (1.18 vs 1.00; $P < 0.01$) and acetate:propionate ratio (3.95 vs 3.40; $P = 0.04$) were greater with *Propionibacterium* T114, relative to the Control. Total daily enteric CH_4 production averaged 188 g/d and was not affected by *Propionibacterium* strains ($P = 0.57$). Enteric CH_4 emission intensity averaged 22 g/kg of DMI and was numerically greater with *Propionibacterium* T114; however, treatment effects were not significant ($P = 0.19$). In conclusion, *Propionibacterium* strains, T159 and T54, did not affect total enteric CH_4 production possibly due to their inability to increase ruminal propionate concentrations. On the contrary, *Propionibacterium* T114 numerically increased CH_4 emission intensity and the effects could be attributed to greater acetate:propionate ratio observed with the inoculated strain.

Key Words: beef, methane, *Propionibacterium*

1771 (T384) Effect of a commercially probiotic on in vitro gas production of alfalfa hay and barley grain.

S. Payandeh[1], F. Kafilzadeh[1], E. Maleki[1], G. Taasoli*[1] and A. Kamyab[2], *[1]Razi University, Kermanshah, Iran, [2]University of Columbia, Columbia*

Effect of addition of a commercial multi-strain probiotic (PrimaLac, Star Labs, St. Joseph, MO) was studied on Kinetics of fermentation of alfalfa hay and barley grain using in vitro gas production technique. Thirty six ml of buffered rumen fluid (30% rumen fluid + 70% buffer solution) was added to 300 mg of either ground alfalfa hay or barley grain with or without 20 mg PrimaLac. Each sample was incubated in three replicates. The pressure of gas produced in each tube was recorded using a pressure transducer (Manometer Digital testo 512) in barley grain and alfalfa hay at 2, 4, 6, 8, 12, 18, 24 and 48h after the start of the incubation and at 2, 4, 6, 8, 12, 18, 24, 48, 72 and 96h after the start of the incubation, respectively. The data were subjected to analysis of variance using General Linear Model procedure of SAS (2003). Mean separation was performed by the T-tests. Potential gas production (ml/300 mg DM) significantly ($P < 0.05$) increased in alfalfa hay and barley grain (75.85 vs 73.66 and 131.30 vs 113.55 respectively) due to the addition of the probiotic. Rate of gas production in half life (ml/h), lag time (h) and half-life (h, at which half of the total gas production is produced) was affected by PrimaLac both in alfalfa and barley grain ($P < 0.05$) Also, total rate of gas production (b) was increased significantly ($P < 0.05$) in Alfalfa hay (0.0162 vs 0.0082), but was not significant in barley grain. From the result of this experiment it appears that addition of PrimaLac at the level used has a pronounce effect on the fermentation of hay and grains.

Key Words: probiotic, Primalac, alfalfa hay, barley, in vitro gas production

1772 (T385) *Lactobacillus brevis* YM 3-30, a γ-aminobutyric acid producing bacteria, decreases blood endotoxin level of Hanwoo cattle.

S. S. Lee[*1], B. S. Ku[1], L. L. Mamuad[1], S. H. Kim[1], C. D. Jeong[1], Y. J. Choi[1], A. P. Soriano[1], K. Lee[2] and K. K. Park[3], *[1]Sunchon National University, Suncheon, South Korea, [2]The Ohio State University, Columbus, [3]Konkuk University, Seoul, South Korea*

This study was conducted to determine the effects and significance of *Lactobacillus brevis* YM 3-30, a γ-amino butyric acid (GABA) producing bacteria (GPB) on growth performance, meat quality and blood endotoxin level of Hanwoo cattle. Twenty seven Hanwoo steers (602.06 ± 10.13 kg) were subjected to a 129-day feeding trial and were fed daily with commercially available total mixed ration (TMR) supplemented with different inclusion rates of GABA produced by GPB: 3 g/kg (T1), 5 g/kg (T2) or non addition (Con) of GABA. The data gathered were gain in weight, feed conversion ratio (FCR), average daily gain (ADG), marbling score, and blood endotoxin. Hanwoo steers fed with GPB-produced GABA had superior weight performance than the control animals. Additionally, mean weight gains in T1 and T2 were 6.50 kg and 18.34 kg higher than those of the control, respectively, which resulted in higher ADG values in T1 (0.76 kg) and T2 (0.85 kg) than the control (0.71 kg). However, these differences were not statistically significant. The marbling score of meat from animals upon slaughter also did not differ significantly among treatments. However, animals in T1 and T2 had lower ($P < 0.05$) blood endotoxin levels of 17.23 and 16.42 EU/ml, respectively, than the control group at 29.23 EU/ml. Hanwoo cattle fed with GPB-produced GABA diet decreased the plasma endotoxin level and comparable ADG, FCR, and beef marbling scores upon slaughter.

Key Words: blood endotoxin, γ-amino butyric acid, Hanwoo cattle

1773 (T386) Probiotic levels, chemical composition and fermentative characteristics in the solid state fermentation of paper sludge for ruminant feeding.

O. Ruiz-Barrera[*1], Y. Castillo-Castillo[2], C. Rodriguez-Muela[1], L. M. Carrillo-Chan[3], C. Arzola-Alvarez[1], J. Lopez-Morones[3] and A. Corral-Luna[1], *[1]Universidad Autónoma de Chihuahua, Chihuahua, Mexico, [2]University of Ciudad Juarez, Cd. Juarez, Mexico, [3]University of Chihuahua, Chihuahua, Mexico*

Sludge from the paper industry could be used for animal feeding when treated with probiotics upon solid state fermentation process. This study assessed the effects of four probiotic levels (PT) on chemical and fermentative characteristics in SSF of the paper sludge (PS) at controlled temperature (30°C) in laboratory scale. The probiotic used in this experiment is a mexican commercial trademark (Prozoot15) rich in yeasts and lactobacilli, organic acids and vitamins. The tested treatments (T) were: T1 (0% PS), T2 (50 g/kg PS), T3 (100 g/kg PS) and T4 (150 g/kg PS), which were fermented at 0, 24, 48 and 72 h, according to a completely randomized design, in a 4 × 4 factorial arrangement with six repetitions per sampling. All treatments included (g/kg DM) 300 molasses, 15 urea, 20 ammonium sulfate, 9 calcium carbonate and 5 of vitamin and mineral premix, plus the PS which was substituted by the PT at 0, 50, 100 and 150 g/kg DM. The results showed a decrease in pH in all treatments at 24 h; however the lowest pH was at 72 h of fermentation. At 72 h of fermentation, the PT addition in T4 increased crude protein, true protein and yeast counts ($P < 0.05$), and decreased pH ($P < 0.05$). In all fermentation time, the PT addition increased ether extract, lactic acid and ammonia nitrogen ($P < 0.05$) and decreased dry matter, ash, NDF and ADF ($P < 0.05$). It was concluded that the addition of 150 g/kg of PT in SSF of paper sludge improves crude and true protein, ether extract, lactic acid, and ammonia. This treated byproduct may have a potential use in animal feeding.

Key Words: fermentation; paper sludge; yeast

1774 (T387) *Lactobacillus brevis* YM 3-30, a γ-aminobutyric acid producing bacteria, increases antioxidant concentration and reduces biogenic amines.

S. S. Lee[*1], B. S. Ku[1], L. L. Mamuad[1], S. H. Kim[1], C. D. Jeong[1], Y. J. Choi[1], A. P. Soriano[1], K. Lee[2] and K. K. Park[3], *[1]Sunchon National University, Suncheon, South Korea, [2]The Ohio State University, Columbus, [3]Konkuk University, Seoul, South Korea*

This study was conducted to determine the effects of *Lactobacillus brevis* YM 3-30, a γ-amino butyric acid (GABA) producing bacteria (GPB), on in vitro rumen fermentation. Also, evaluation of biogenic amines and antioxidant concentration were analyzed. Ruminal samples were collected from ruminally cannulated Hanwoo cattle and soybean meal was used as substrate at 1g dry matter (DM) per 100ml buffered rumen fluid. Different inclusion rates of GABA produced by GPB, *L. brevis* YM 3-30, were investigated using in vitro rumen fermentation. The following treatments were: 2 g/kg and 5 g/kg fresh GABA, 2 g/kg and 5 g/kg autoclaved GABA, and non addition of GABA and, hereafter referred to as treatments 2, 3, 4, 5, and 1, respectively. Fresh culture of GPB was added in treatments 2 and 3 while autoclaved GPB for treatments 4 and 5. The GPB was autoclaved at 121°C for 15 min prior to inclusion into the fermentation bottles. Addition of GABA produced by GPB had no significant effect on pH and total gas production, but did increase ($P < 0.05$) the ammonia nitrogen (NH_3–N) and reduce ($P < 0.05$) the total biogenic amines (TBA). Treatment groups containing GPB-produced GABA

(T2 and T3) having the lowest ($P < 0.05$) volumes of TBA with 10.62 mM to 11.21 mM. Additionally, histamine was produced in the highest levels in T1 at 15.99 mM. Acetate, propionate, and butyrate concentrations and acetate:propionate (A:P) ratio did not differ significantly among treatments. The volume of production of SOD and GSH-Px were significantly highest in treatments added with 5 g/kg GABA (T3) after 24 h of incubation with 76.60 U/ml and 38.51 U/ml, respectively. The addition of GABA produced by GPB improves in vitro fermentation by reducing biogenic amines production while increasing antioxidant activity and NH_3–N production.

Key Words: antioxidant, biogenic amines, γ-amino butyric acid

---

1775 (T388) Effects of lactobacilli and fibrolytic enzymes on chemical composition, ferementation traits, conservation characteristics and in situ digestibility of mixed cereal silage. L. Jin[*1], L. Duniere[1], Y. Wang[2] and T. A. McAllister[2], *[1]Lethbridge Research Centre, Agriculture and Agri-Food Canada, Lethbridge, AB, Canada, [2]Agriculture and Agri-Food Canada, Lethbridge, AB, Canada*

Growing mixed cereal crops for silage offers benefits in terms of increased yields and enhanced disease resistance. Little information is available regarding the effects of silage additives on the conservation characteristics and nutritional value of mixed cereal crops. This study was to determine the effect of lactic acid-producing bacteria (LAB) and fibrolytic enzymes on chemical composition, conservation characteristics and in situ digestibility of a mixed cereal crop consisting of barley, oats and spring triticale seeded 1:1:1. Forage was harvested at the mid-dough stage, wilted to 33% DM, chopped to 1 cm and either not treated (Control) or inoculated with a mixture of esterase-producing *Lactobacillus buchneri*, *L plantarum* and *L casei* (T1), a mixture of non-esterase-producing *L. buchneri*, *L. plantarum* and *E. faecium* (T2) or T2 plus exogenous enzymes (Rovabio Excel LC, T3). The MIXED procedure of SAS was used for this study with completely randomized design. The fixed factors were bacteria treatment, run and cow for in ensiling, in vitro and in situ trials respectively. After treatment, forage was packed and stored in mini-silos for 90 d, prior to measurement of ensiling characteristics and in vitro and in situ digestibility. Both T1 and T2 silage had higher NDF ($P < 0.001$) than Control or T3. All inoculants increased populations of LAB ($P < 0.01$) but, reduced concentrations of water soluble carbohydrate ($P < 0.01$), ammonia ($P < 0.001$) and pH ($P < 0.001$) in mixed crop silage. Compared with Control, T1 silage had lower ($P < 0.001$) whereas T2 and T3 silage had higher ($P < 0.001$) concentrations of acetic acid and total VFA. Concentration of lactic acid was similar among all silages. All silages had similar DM disappearance and VFA production during 48-h of in vitro ruminal incubation. However, in situ NDF disappearance of T1 silage was higher ($P < 0.001$) than that of Control and T3 silage. Applying esterase-producing *Lactobacillus* at ensiling to a mixture of barley, oats and spring triticale has potential to improve fermentation traits and enhance the fibre digestibility of silage.

Key Words: *Lactobacillus,* mixed cereal silage, rumen digestion

1776 (T389) Use of Yea-Sacc8417 live yeast, monensin and their combination in diets for young Nellore bulls in a feedlot. J. M. B. Benatti[1], N. M. Geronimo[2], J. A. Alves Neto[1], R. C. Silva[1], I. M. de Oliveira[*3], C. L. Francisco[4], G. R. Siqueira[3] and F. D. D. Resende[3], *[1]Universidade Estadual Paulista, Jaboticabal, Brazil, [2]UNIFEB, Barretos, Brazil, [3]APTA- Agência Paulista de Tecnologia dos Agronegócios, Colina, Brazil, [4]Universidade Estadual Paulista- FMVZ, Botucatu, Brazil*

The objective of this study was to analyze the effects of different food additives administered solely or combined in diets for young Nellore bulls in a feedlot for 109 days. The treatments consisted of a control diet with monensin sodium (27.0 mg kg DM^{-1}), a diet with Yea-$Sacc^{8417}$ live yeast (2.0 g $animal^{-1}$) and a diet with the two additives combined. Diets (10.00% sugarcane bagasse, 73.60% ground corn, 6.40% cottonseed, 6.40% soybean meal, 0.26% corn gluten, 0.79% urea and 2.55% mineral mix) varied only in the inclusion of additives. We used 66 non-castrated Nellore bulls (387.24 ± 21.17 kg), 22 of which were slaughtered in the course of the experiment (6 at the beginning and 16 right after the adaptation period [25 days]) to measure the empty body weight (EBW) and served as reference animals. The experiment was arranged in a completely randomized blocks design (11 replicates) as a function of the initial body weight. Data were analyzed by the MIXED procedure of SAS software and means were compared by Fisher's test at 10% significance. The animals were kept in individual pens and were considered the experimental unit. The dry matter intake (DMI) was lower ($P = 0.0798$) (8.47 kg DM day^{-1}) in the treatments containing monensin in relation to control diet (10.20 kg DM day^{-1}). The yeast supplied alone did not interfere ($P > 0.10$) on DMI. The supply of net energy (NE) by the diet was greater ($P = 0.0055$) in the two treatments containing monensin (1.98 and 1.33 Mcal kg DM^{-1} for maintenance and gain, respectively) as compared with the control diet and with yeast alone (1.90 and 1.17 Mcal kg DM^{-1} for maintenance and gain, respectively). The average daily gain evaluated as body weight (BW) (1.47 kg day^{-1}) and as EBW (1.58 kg day^{-1}) did not differ ($P > 0.10$) among diets, but when evaluated as carcass, the diets with monensin reduced ($P < 0.10$) the values (0.89 kg day^{-1}) as compared with the others (1.04 kg day^{-1}). There was no difference ($P > 0.10$) among treatments regarding the final BW (521.01 ± 37.59 kg); however, the diets with monensin reduced ($P < 0.10$) the final carcass weight (293.37 kg) in relation to control

diet and the diet with yeast alone (304.96 kg). Live yeast does not change the DMI or performance of young Nellore bulls in a feedlot. Monensin reduces DMI and reduces the carcass weight. Supported by FAPESP and Alltech.

Key Words: carcass, empty body weight, performance

1777 (T390) Effects of lactobacilli and fibrolytic enzymes on ensiling as well as in vitro and in situ digestibility of of barley silage.

L. Jin*[1], L. Duniere[1], Y. Wang[2] and T. A. McAllister[2], [1]*Lethbridge Research Centre, Agriculture and Agri-Food Canada, Lethbridge, AB, Canada,* [2]*Agriculture and Agri-Food Canada, Lethbridge, AB, Canada*

Lactobacilli-based inoculants have been shown to improve the ensiling and aerobic stability of barley silage and there is evidence that those with esterase activity may improve fibre digestion. This study aimed to compare the effects of esterase-producing lactobacilli-inoculant to non-esterase or exogenous fibrolytic enzymes inoculants on ensiling characteristic and in situ digestibility. Whole barley crop was cut at the mid-dough stage, wilted to 33% DM and chopped to 1 cm. Chopped barley was subject to the following treatments: 1) control (C; sprayed with water) 2), T1 (inoculated with a mixture of esterase-producing *L. buchneri*, *L. plantarum* and *L. casei*), 3) T2 (inoculated with a mixture of non-esterase-producing *L. buchneri*, *L. plantarum*, and *E. faecium*) and T3 (inoculated with T2 plus exogenous enzymes (Rovabio Excel LC)). Forage was ensiled in PVC laboratory silos for 90 d at which point fermentation characteristics as well as in vitro and in situ digestibility were measured. Silages in T1 and T2 treatment had higher NDF concentration ($P < 0.01$), but lower water soluble carbohydrate content ($P < 0.01$) than C or T3 silage. Control silage had lower pH and concentrations of acetic acid, total VFA, total bacteria and lactic acid producing bacteria ($P < 0.01$), but higher levels of lactic acid and lactic acid: acetic acid ($P < 0.01$) than other silages. Gas production was lower in T3 silage than other treatments ($P < 0.01$) whereas C silage had a greater ($P < 0.01$) in vitro total gas production and rate of gas production. In situ NDF digestibility of T1 silage was greater ($P < 0.01$) than C silage whereas T3 silage had the lowest ($P < 0.01$) NDF digestibility. Esterase-producing *Lactobacillus buchneri* improved the ruminal NDF digestibility of barley silage, a response that was not observed if the inoculant lacked esterase activity or if fibrolytic enzymes were applied exogenously to the forage at the time of ensiling.

Key Words: *Lactobacillus,* barley silage, rumen digestion

1778 (T391) Effect of direct-fed microbials and monensin on in vitro fermentation of a high-froage substrate.

S. Wingard*, E. S. Vanzant, D. L. Harmon and K. R. McLeod, *University of Kentucky, Lexington, KY*

An in vitro experiment was conducted to determine effects of direct-fed microbials (DFM) on rumen fermentation of a forage-based diet in the presence and absence of monensin (MON). In vitro treatments were arranged in a 2 x 2 factorial and included 2 levels of DFM (0 and 50,000 cfu; consisting of primarily *Lactobacillus acidophilus* and *Enterococcus faecium*) and 2 levels of monensin (0 and 5 ppm). In vitro runs were conducted on 3 separate days, with each run consisting of 4 vessels/treatment ($n = 12$/treatment). Inoculum for in vitro experiments consisted of buffer plus a composite of strained rumen fluid obtained from 4 steers fed an 80:20 forage:concentrate (alfalfa/corn/SBM/urea) diet. Fermentation vessels were supplied with common substrate (400 mg of donor steer diet) and incubated in a water bath (39 C) for 30 h. Gas pressure was measured at 5-min intervals and samples were collected at termination for determination of methane production, pH, and concentrations of VFA and ammonia. Data were analyzed as a randomized complete block design with run as the blocking factor. An exponential model without lag was determined to be the best fit model for gas production data and was used to calculate rate and total production of gas. Interactions between DFM and MON were absent ($P > 0.10$) for gas production and fermentative end products, with the exception of a DFM x MON tendency ($P = 0.07$) for total VFA concentration. In the case of the latter, DFM increased total VFA concentration in the absence but not in the presence of MON. Addition of DFM did not affect ($P > 0.10$) gas production or fermentative end products except for a tendency ($P = 0.08$) for a slight increase in proportion of isovalerate. In contrast, MON decreased ($P < 0.001$) CH_4 production and rate and production of total gases. Similarly, MON decreased ($P < 0.001$) total VFA and NH_3 concentrations and molar proportions of acetate and butyrate and increased ($P < 0.001$) proportions of propionate, valerate, and isobutyrate and isovalerate. Independently, DFM and MON increased ($P < 0.001$) end point pH, resulting in an additive effect when the two treatments were combined. Addition of MON altered fermentation and was not influenced by DFM. In contrast, fermentation characteristics were largely unaffected by DFM with two exceptions: a slight increase in total VFA in the absence of MON and a small increase in pH that appeared to occur through a different mechanism than that for MON.

Key Words: direct-fed microbials, monensin, fermentation

RUMINANT NUTRITION III

1779 (W238) Prevalence of subclinical ketosis detected by near infra-red analysis of BHB in DHI milk samples. D. E. Santschi*, R. K. Moore and D. M. Lefebvre, *Valacta, Ste-Anne-de-Bellevue, QC, Canada*

Subclinical ketosis is a common early lactation disorder. Herd prevalence is often unknown because there are no specific clinical symptoms and because individual testing of dairy cows can be costly and time consuming. Since October 2011, Valacta (Dairy Centre of Expertise, Quebec and Atlantic Canada) offers routine infra-red testing of β-hydroxybutyrate (BHB) in DHI milk samples. Over 293,000 milk samples from fresh cows (DIM 5-35) from 4179 dairy herds have been analyzed for BHB concentration (199,003 multiparous and 94,036 primiparous cows). Based on a previously published trial comparing blood and milk BHB concentrations, thresholds were established as follows: cows with milk BHB concentrations $\geq$ 0.20 mM were declared ketotic (POS); cows with milk BHB concentrations below 0.15 mM were declared non-ketotic (NEG); and cows with intermediate BHB concentrations were classified as potentially ketotic (SUSPECT). Overall incidence of subclinical ketosis (POS and SUSPECT) was 24.7% over the first 5 weeks of lactation. Incidence for DIM 5 to 35 was 21.5% and 26.6% for primiparous and multiparous cows, respectively. Distribution of incidence in relation to DIM was different between primiparous and multiparous cows. Highest incidence for primiparous cows (33.7%) was in the first week postpartum but in the third week for multiparous cows (33.5%). By DIM 35, incidence declined to 13.1% and 17.9% for primiparous and multiparous cows, respectively. Among herds with at least 10 cows analyzed for BHB (n = 3560), within herd prevalence of ketosis for the 10th, 25th, 50th, 75th and 90th percentile were 11, 17, 24, 33 and 43% respectively. Ketosis prevalence was affected by month of calving ($P < 0.001$). Highest incidence was observed for cows calving in May-June and October-November whereas lowest incidence was observed for cows calving in August and September. Ketosis prevalence was also affected by breed ($P < 0.001$). Prevalence for Ayrshire (n = 12,443), Brown Swiss (n = 1814), Holstein (n = 271,367) and Jersey (n = 6554) cows was 24.4, 22.7, 24.7 and 34.6%, respectively. Milk BHB concentration was negatively correlated with milk Fat:Protein ratio (R = -0.39; $P < 0.001$) and the correlation was affected by breed. Correlations between milk BHB and Fat:Protein ratio were -0.34, -0.35, -0.39 and -0.32 for Ayrshire, Brown Swiss, Holstein and Jersey cows, respectively ($P < 0.001$). Results indicate subclinical ketosis incidence varies greatly among dairy herds and is influenced by breed and season. Monitoring of subclinical ketosis prevalence is important as a first step towards greater transition success.

Key Words: ketosis, dairy cow, DHI

1780 (W239) Role of treatment soybean meal with pistachio extract on total tract nutrients digestibility of Holstein bulls. A. Jolazadeh[1], M. Dehghan banadaky*[2], K. Rezayazdi[3] and N. Vahdani[4], *[1]University of Tehran, Karaj, Iran, [2]Department of Animal Science, Faculty of Agriculture, University of Tehran, karaj, Iran, [3]Department of Animal Science, Faculty of Agriculture, University of Tehran, Karaj, Iran, [4]university of Tehran, karaj, Iran*

This experiment was conducted to study the effects of treatment soybean meal (SBM) with pistachio extract on total tract nutrients digestibility of Holstein bulls. The sun dried pistachio hulls were grounded through a 0.5 mm screen and soaked in water (1 pistachio: 10 water). Filtered extract was concentrated by heating at 95 ℃. SBM was treated with pistachio concentrated extract (PCE) containing 11.14% total phenol and 7.13% total tannin/DM of extract. Twenty-eight Holstein bulls (average initial weight 256 ± 63kg) were assigned randomly to one of four treatments with seven replicates in a completely randomized design for 94 days. Bulls were fed 70% concentrate diets and had free access to balanced total mixed ration (TMR) and fresh water. All bulls were individually fed and 10 d before the start of the experiment were adapted to the experimental diets. Treatments included: 1; control (SBM without PCE) 2; SBM with 5% PEC 3; SBM with 10% PEC and 4; SBM treated with 15% (kg PEC/100kg DM SBM). Total-tract apparent digestibility of DM, organic matter (OM), CP, NDF and EE were determined using acid-insoluble ash as a marker. There was no effect ($P <$ 0.05) of tannin supplementation on total tract nutrient digestibility such as: DM, OM, CP, EE and NDF. These results suggested that high levels of PCE can be used in diet without any adverse effects on total tract nutrient digestibility in bulls.

Key Words: nutrients digestibility, pistachios hulls, tannin

1781 (W240) Effect of polyherbal supplementation as feed additive on milk production and composition in lactating goats. K. Rezayazdi*[1], F. Mirzaei[2] and M. Hosseinabadi[3], *[1]Department of Animal Science, Faculty of Agriculture, University of Tehran, Karaj, Iran, [2]Animal Science Research Institute, Karaj, Iran, [3]University of Tehran, Karaj, Iran*

The objective of this study was to evaluate the effect of adding a dried mixture of 7 herbal plants including thyme, mint, oregano, cumin, camel thorn, garlic and eucalyptus as a natural additive to the ration on milk production and composition in lactating goats. Because previously other researchers had studied about effects of these herbal plants on animals indivisually.Twenty goats (21 DIM, 2–3 years old, average BW 34.45 kg) were used in a completely randomized design with 2 treatments for a 40 day trial. Treatments were (1) control

ration (basal diet), (2) control ration + 250 mg kg^{-1} BW per d of a mixture of herbal plants. Animals were pen fed and all of data were analyzed with PROC MIXED procedure of SAS. Average milk production at the start of the experiment was similar in both groups (900 g/d). Milk production data and milk samples were collected every 10 day and milk composition was determined. The results showed that milk production (1073 and 1031 g/day for treatment 1 and 2, respectively) was not affected by addition of herbal plant mixture. Milk fat (2.76 and 2.79% for treatments 1 and 2, respectively), milk protein (2.76 and 2.79%) and milk lactose (5.44 and 5.40%) were not significantly different. It is concluded that herbal plant mixture were used in this study had no significant effect on milk production and composition in dairy goats.

Key Words: herbal plants, milk production and composition, dairy goats

---

1782 (W241) Changes of protozoal diversity in response to forage and protein of diets in the rumen of dairy cows. J. Zhang, D. Bu*, S. Zhao and J. Wang, *State Key Laboratory of Animal Science, Institute of Animal Science, Chinese Academy of Agricultural Science, Beijing, China*

The present study was conducted to investigate the changes of quantity and diversity of rumen protozoa in dairy cows fed with different forage and protein diets. Forty-eight healthy Chinese Holstein dairy cows were utilized in randomized block design, and the sixteen cows in every group had similar body conditions. The treatments were as follows: MF (forage sources: alfalfa hay and corn silage; protein sources: soybean meal and miscellaneous meals), CSA (forage sources: corn stover; protein sources: soybean meal and miscellaneous meals), CSB (forage sources: corn stover; protein sources: miscellaneous meals). Rumen fluid was collected via a stomach tube before and after morning feeding on 31, 61, and 91 d of experiment. Microbial DNA in rumen fluid sampled on 91 d was extracted by a CTAB plus bead beating method. The 18S rRNA gene sequences were trimmed and imported to MOTHUR for OTU analysis at 98% identity level. Results showed that the number of protozoa was not different among three groups based on microscopic counting and qPCR. Totally, 726 clones were obtained from three groups. There were 61 OTUs in three groups, 20 OTUs in CSA, 20 OTUs in CSB and 22 OTUs in MF. The three groups shared 10 OTUs, while CSA, CSB and MF had 6, 5 and 7 unique OTUs respectively. Compared with CSA (54.0), MF (46.2) and CSB (30.1) had lower species richness of protozoa based on ACE index. Compared with CSA (0.25), MF (0.11) and CSB (0.23) had higher diversity of protozoa based on Simpson index. Taxonomy analysis showed that *Dasytricha* (54.8%), *Entodinium* (16.4%), *Eudiplodinium* (14.2%), *Diplodinium* (7.7%) and *Isotricha* (3.3%) were the predominant genera in the rumen fluid. In different forage groups, *Diplodinium dentatum, Epidinium caudatum*, *Eudiplodinium maggii* were only found in CSA, while *Isotricha intestinalis, Ophryoscolex purkynjei* were only found in MF. But in different protein groups, there was no apparently changed protozoal species. In conclusion, different sources of forage and protein in diets had no significant effect on the number of rum. However, feeding corn stover can result in higher protozoal abundance, and feeding soybean meal can lead to lower protozoal diversity.

Key Words: protozoa; diversity; forages.

1783 (W242) Pyrosequencing-based profiling of bacterial 16S rRNA genes identifies the unique Proteobacteria attached to the rumen epithelium of bovines. S. Zhao, J. Wang* and D. Bu, *State Key Laboratory of Animal Science, Institute of Animal Science, Chinese Academy of Agricultural Science, Beijing, China*

The objective of this research is to characterize the unique bacterial community attached to the rumen epithelium in both dairy cows and beef cattle. The rumen content and rumen epithelium samples were collected from four Chinese Holstein dairy cows and five Australian beef cattle when the animals were slaughtered. The microbial DNA was extracted from rumen content and epithelium using CTAB plus bead beating method. Community compositions of bacterial 16S rRNA genes from content and wall were examined using a tag-encoded amplicon pyrosequencing assay with bacterial-targeting universal primers 8F and 533R. The sequencing was performed with Roche 454 GS FLX instrument. The platform QIIME was used for reads trimming and OTU analysis. The reads sharing more than 97% identity were clustered into OTUs. The results showed that 158 729 trimmed sequences with the length of 300-560 bp were kept. After OTU picking, 2735 OTUs were formed, and the average reads counts per sample was 7280. The bacterial species richness from epithelium was significantly lower ($P < 0.01$) than that from content according to Chao1 index, and bacterial α diversity from epithelium was also significantly lower ($P < 0.01$) than that from content according to Shannon index. The PCoA analysis revealed that epimural bacterial community was distinctly different from that in content, which implied some unique bacterial community attached to the epithelium of bovine. To further find out what the unique community was, taxonomy and significance test were carried out. While the *Fimicutes* (~42%) and *Bacteroidetes* (~20%) were the predominant abundant bacteria on epithelium, significant higher ($P < 0.01$) abundance of *Proteobacteria* (~26%) were present on epithelium than that in content (~3%). *Hylemonella*, *Desulfobulbus*, *Campylobacter* and unclassified *Neisseriaceae* were the predominant bacteria attached to epithelium compared to the content in both dairy cows and beef. These unique bacteria were microaerophilic (except for *Desulfobulbus*), and all of them were able to hydrolyze urea, which could further certify

the function of oxygen scavenging and urea hydrolysis for bacteria community attached to epithelium.

Key Words: rumen epithelium, bacterial community, pyrosequencing

1784 (W243) Genetic diversity of dipeptidyl peptidase IV from anaerobic bacterial cultivation in vitro **in dairy cow.**

J. W. Zhao[*1], J. Q. Wang[2], S. G. Zhao[2] and D. P. Bu[2], *[1]College of Animal Science and Technology of Inner Mongolia University for the Nationalities, Tongliao, China, [2]State Key Laboratory of Animal Nutrition, Institute of Animal Science, Chinese Academy of Agricultural Sciences, Beijing, China*

The objective of this experiment was to reveal the genetic diversity of dipeptidyl peptidase IV (DPP-IV) gene from anaerobic bacterial cultivation in vitro and the influence of monensin to bacteria containing DPP-IV gene. There were two groups: one group substrate was casein (P), the other group substrate was casein with monensin added (M). Each group had three duplicated samples. Anaerobic culture was done after inoculating with rumen fluid. And then anaerobic bacterium was collected after 12 h culture and its DNA was extracted. DPP-IV gene library was established through PCR. Samples were detected by quantitative real-time PCR. Sixty-six sequence of DPP-IV gene were obtained from picking clones. The results of BLASTP analysis showed these sequences matched with *Prevotella ruminicola*, *Prevotella marshii* and *Paraprevotella xylaniphila*. Twenty-three operational taxonomic units (OTU) were found by Mothur software analysis, and OTU9 might be a DPP-IV gene of protein degradation bacteria sensitising to monensin. Quantitative analysis showed that the copy number of DPP-IV gene in P group was significantly higher than that of M group ($P < 0.01$). These results suggested that monensin affected the amount of bacteria containing DPP-IV gene.

Key Words: anaerobic bacterial cultivation in vitro, dipeptidyl peptidases IV, genetic diversity

1785 (W244) Effects of test weight, precision processing and processing index on in situ ruminal digestibility of barley grain in beef heifers.

Y. Zhao[1,2], S. Yan[2], Z. He[1,3], U. Anele[1], M. L. Swift[4], T. A. McAllister[5] and W. Yang[*1], *[1]Lethbridge Research Centre, Agriculture and Agri-Food Canada, Lethbridge, AB, Canada, [2]College of Animal Science, Inner Mongolia Agricultural University, Hohhot, China, [3]Key Laboratory for Agro-Ecological Processes in Subtropical Region, Institute of Subtropical Agriculture, The Chinese Academy of Sciences, Changsha, China, [4]Alberta Agriculture and Rural Development, Lethbridge, AB, Canada, [5]Agriculture and Agri-Food Canada, Lethbridge, AB, Canada*

The objective of this study was to evaluate the effects of test weight (TW; g/L), precision processing (PP) and processing index (PI) of barley grain on kinetics of in situ ruminal digestion. The study was designed as a 2×2×2 factorial arrangement with treatments: TW (low vs. high), PP (control vs. PP) and PI (75 vs. 85%). Ten barley samples with 5 low (574 g/L) and 5 high (632 g/L) TW were either dry-rolled with single roller setting (control) or sieved into small and large kernels, then dry-rolled based on kernel size of each fraction (i.e., PP). Each sample was dry-rolled moderately or coarsely with PI of 75 or 85%, which was calculated as TW after rolling/TW before rolling × 100%. Three beef heifers (650 ± 25 kg BW) fitted with rumen cannulas and fed diet consisting of 70% barley silage and 30% barley grain concentrate were used for in situ incubation. Kinetics of DM digestibility in situ after 0, 3, 6, 12, 24, and 48 h of incubation was estimated using the model: $y = a+b\ (1-e^{-ct})$. Effective ruminal degradability (ED) of DM was estimated using equation $ED = a + bc/(c + k)$ with k = 6%/h. There was no interaction between TW and PI on kinetic parameters, however, there was interaction between TW and PP on ED of DM ($P < 0.01$), and between PP and PI on potential degradable fraction, b ($P < 0.01$) and rate of degradation, c ($P < 0.04$). Overall, the TW of barley grain did not affect the kinetic parameters except that the ED was greater ($P < 0.01$) with high (43.4%) than low (41.8%) TW in control, but not in PP (low vs. high TW; 44.5 vs. 44.1%). Compared to control, PP reduced ($P < 0.01$) soluble fraction a (PP vs. control; 3.0 vs. 4.6%) and the b (73.6 vs. 75.4%), but increased ($P < 0.01$) the c (7.8 vs. 6.4%/h) and ED (44.3 vs. 42.6%). Decreasing PI from 85 to 75% considerably increased ($P < 0.01$) kinetics parameters, a (3.0 vs. 4.5%), b (71.7 vs. 77.3%), c (5.7 vs. 8.6%/h), and ED (37.2 vs. 49.7%). These results indicated that manipulating processing method such as PP and PI could effectively alter ruminal digestion kinetics of barley grain, whereas the effect of varying TW is limited.

Key Words: barley grain processing, in situ DM digestibility, beef heifers

1786 (W245) Longitudinal shifts in the rumen bacterial communities of dairy cows during the transition period. D. W. Pitta[1], S. Kumar[*1], B. Veiccharelli[1], B. Bhukya[1], K. Bittinger[2], D. Shirley[2] and J. Ferguson[2], *[1]University of Pennsylvania, Kennett Square, PA, [2]University of Pennsylvania, Philadelphia, PA*

The transition period in dairy cows refers to the period three weeks prior to calving to three weeks post-calving and is critical for sustained milk production and animal health. We evaluated the rumen microbial dynamics in primiparous and multiparous cows during their transition period. In the current study, ten animals from primiparous (n = 5) and multiparous groups (n = 5) were randomly selected based on the freshening date (expected date for parturition). Each animal was sampled for rumen contents by stomach tube, two hours after feeding, at four time points i.e., three weeks prior to the anticipated freshening date (S1), soon after the animal freshened (S2), four weeks (S3) and eight weeks (S4) into lactation. Both groups received the same dry cow ration (CP-14.65%; NDF-43.66%; Starch-21.9%) prior to calving and the same lactating cow ration (CP-17.21%; NDF-33.14%; Starch-27.19%) post calving. The genomic DNA form rumen samples was extracted and amplified using the primers BSF8 (27F) and BSR357 annealing to the V1-V2 region of the 16S rDNA bacterial gene. The amplicon libraries were sequenced on a 454 Jr Roche platform and analyzed for bacterial diversity using QIIME. A total of forty bacterial communities were analyzed that involved annotations of 100,000 reads, which were assigned to 15,861 operational taxonomic units (OTU). Bacterial community comparisons were based on the Uni-Frac distance metric which revealed that both study group and study day had an independent effect on the community compositions ($P < 0.05$; Permanova test). The most abundant phyla observed were *Bacteroidetes* and *Firmicutes* across all communities. As the cows transitioned into lactation, the ratio of *Bacteroidetes* to *Firmicutes* increased from 6:1 to 12:1 ($P < 0.05$; Mann-Whitney U test) and this ratio was higher in primiparous than in multiparous animals ($P < 0.05$). This study elucidated distinct shifts in the rumen microbiome confounded by dietary and physiological changes in both primiparous and multiparous dairy cows in their transition period. However, validating these results using more animals per lactation group is warranted.

Key Words: dairy cows, transition period, rumen bacteria, pyrosequencing, 16S pyrotags

1787 (W246) Effects of assumptions on estimating energetic efficiencies in lactating dairy cows. K. M. Kennedy* and C. C. Calvert, *University of California- Davis, Davis*

Theoretical estimates of efficiencies of metabolic and physiological processes have proven useful in teaching undergraduate and graduate courses in animal metabolism and bioenergetics. To maintain accurate numbers, new understandings have been applied to various biochemical pathways in ruminants. Further understanding of the mammalian ATP synthase, costs of membrane transport, electron transport, and oxidative phosphorylation have improved the accuracy of estimated theoretical efficiencies of energy metabolism. Advances include identifying the costs of: 1) the malate-aspartate shuttle for transporting protons and electrons into the mitochondria, 2) pyruvate transport into the mitochondria, and 3) counter transport of ATP and GTP out of the mitochondria with the concomitant cost of transporting ADP, GDP, and inorganic phosphorous into the mitochondria. As currently accepted, electron transport results in 10 and 6 protons pumped from the matrix to the intermitochondrial space when the electrons are derived from NADH + H^+ and $FADH_2$, respectively. The discovery that bovine heart ATP synthase requires the flow of 8 protons from the intermitochondrial membrane space into the mitochondrial matrix through the ATP synthase to produce 3 ATP is critical to estimating energetic efficiency in mammalians. Consequently, 2.7 ATP are produced from each NADH + H^+ formed in the mitochondria, 2.5 ATP from each NADH + H^+ formed in the cytosol, and 1.6 ATP from each mitochondrial $FADH_2$ when each is coupled to oxidative phosphorylation. Mitochondrial GTP formed in the TCA cycle is equivalent to 0.7 ATP when GTP is transported out of the mitochondria. Energy available from ATP hydrolysis varies from 32 to 52 kJ/mole of ATP with an average of 42 kJ/mol. Using these data, theoretical efficiencies and net ATP production/cost were calculated and compared to those of Baldwin [*Journal of dairy science* **51**(1): 104-111. (1968)] (Table 1787). These values demonstrate the importance of applying current research and ideas to create accurate values of theoretically estimated metabolic and physiological pathways.

Key Words: energy, metabolism, ATP

Table 1787. Theoretically estimated efficiencies and net ATP production/cost for various biochemical pathways

	Current		Baldwin, 1968	
Pathway	ATP Produced	Efficiency	ATP Produced	Efficiency
Propionate to glucose	-4.7	-	-4	-
Glucose to CO_2 and H_2O	32.9	49%	38	56%
2 Propionate to CO_2 and H_2O	28.2	38%	34	46%
Fat turnover	45.7	36%	-17	-
Milk lactose synthesis	-	76%	-	78%
Milk protein synthesis (100 g)	-	77%	-	82%
Milk fat synthesis	-	71%	-	72%
Total milk synthesis	-	75%	-	76%

1788 (W247) Nutrient supply estimations errors when using free ruminal bacteria as reference sample.

F. Díaz-Royón*, J. M. Arroyo and J. Gonzalez, *Departamento de Producción Animal, Escuela Técnica Superior de Ingenieros Agrónomos, Universidad Politécnica de Madrid, Madrid, Spain*

The chemical composition of bacteria associated with solid (SAB) and liquid (LAB) rumen-digesta phases was studied to confirm errors when LAB is used as reference sample to estimate nutrient supply from SAB (González et al., 2012). Three rumen and duodenum cannulated wethers were fed three isoproteic diets for three successive periods. Diets included protein concentrates (sunflower meal and spring pea) untreated or treated with malic or ortophosphoric acid and heat supplied in this order. Diets were formulated with 45% oat (avena sativa) hay and 55% concentrate (fresh matter basis; 30% corn grain, 30% barley grain, 15% sunflower meal, 22% spring pea, 3% minerals and vitamins) and offered daily at 45 g/kg BW0.75 in six identical meals. Bacterial samples (SAB and LAB) were isolated after 12 d of continuous intraruminal infusion of (15NH4)2SO4 (25 mg 15N/d). Results were compared by variance analysis considering wethers (as blocks) and diets in the model. Compared with SAB, LAB showed consistently lower contents (g/kg DM) of OM (780 vs. 693; $P < 0.001$), starch- glucose (33.4 vs. 19.9; $P = 0.013$), and total lipids (221 vs. 113; $P < 0.001$), but greater CP content (402 vs. 429; $P = 0.007$) and 15N enrichment (atoms %: 0.0585 vs. 0.0817; $P = 0.005$). Present data fitted well with the relationship predicting SAB 15N enrichment from the same LAB value reported in the previously cited study (variation coefficient of the mean prediction error = 13.0%). The mean ratio 15N-SAB/15N-LAB allows establishing CP supply from synthesized SAB is under evaluated by 25.6% when LAB is used as reference. This under evaluation was even greater for starch-glucose (44.2%) and lipids (61.9%) supply. These under evaluations were close to those previously reported by González et al., 2012. Taking into consideration that SAB is the main microbial source of nutrient supply, these errors should be factored in when attempting to improve ruminant nutrition. Predictions using 15N as marker are useful for correcting errors associated with the traditional use of LAB as reference sample, and therefore to obtain a more accurate estimate of microbial nutrient supply to the ruminant.

Key Words: rumen bacteria, chemical composition, 15N enrichment

1789 (W248) Evaluation of the Nordic dairy cow model Karoline in predicting methane emissions.

M. Ramin[*1] and P. Huhtanen[2], [1]*Swedish University of Agricultural Sciences (SLU), Umeå, Sweden,* [2]*Swedish University of Agricultural Sciences (SLU), Umea, Sweden*

Models are widely used to predict methane (CH_4) emissions, and are used to develop mitigation options and policies. In the current study, the performance of the Nordic dairy cow model Karoline was evaluated in predicting CH_4 emissions. Karoline is a dynamic, deterministic and mechanistic simulation model describing the digestion and metabolism of nutrients, and production in a dairy cow. The model was evaluated against observed data from studies reporting CH_4 emissions from respiration chamber studies. The dataset included a total of 184 treatment means from 31 published papers. The dietary and animal characteristics used for the model evaluation represent the typical range of diets fed to dairy cattle. When analyzed with a fixed regression analysis, there was a good relationship between predicted and observed CH_4 emissions measured from respiration chamber studies ($R^2 = 0.93$) with a small root mean square error of prediction (RMSPE = 10.1% of the observed mean). The mean bias was small but statistically significant, and there was no slope bias. Most of the error was due to random bias (96.4%), whereas the contributions of mean and slope bias were small (3.4 and 0.2%, respectively). By considering study as the random effect in the model (mixed model regression analysis), the fit improved to $R^2 = 0.98$ and RMSPE decreased to 6.1% of the observed mean. The influence of some input variables such as total DM intake, dietary concentrations of CP, NDF and ether extract, and OM digestibility (OMD) on the residuals (observed– predicted) of CH_4 emissions were not significant. The residuals of both CH_4 emissions and OMD were significantly related to each other, indicating the Karoline model requires accurate estimates of digestion kinetic parameters as input variables. It is concluded that the Nordic dairy cow model Karoline is a useful tool in predicting CH_4 emissions and understanding the system behavior. The model can also be used in developing mitigation strategies for the national inventories of CH_4emissions.

Key Words: Karoline model; methane emissions; mechanistic model

1790 (W249) Effects of different feeding frequencies on rumen tissue histology and cell proliferation of feedlot cattle. T. V. Carrara[*1], J. Silva[2], M. C. Pereira[2], I. C. Batista Júnior[2], C. A. Oliveira[2], A. C. J. Pinto[2], D. D. Estevam[1], M. D. Arrigoni[1], F. T. Pereira[2] and D. D. Millen[2,3], *[1]São Paulo State University (UNESP), Botucatu campus, Botucatu, Brazil, [2]São Paulo State University (UNESP), Dracena campus, Dracena, Brazil, [3]Supported by São Paulo State Foundation (FAPESP), São Paulo, Brazil*

This study, conducted at the São Paulo State University feedlot, Dracena Campus, Brazil, was designed to determine the effects of different feeding frequencies on rumen tissue histology and cell proliferation of rumen papillae of feedlot cattle. The experiment was designed as a completely randomized block, replicated 12 times, in which 48 18-mo-old yearling Nellore bulls (358.2 ± 19.4 kg) were fed in individual pens for 94-d according to the following treatments: 1) feeding one time daily (1x; 0800), 2) feeding two times daily (2x; 0800 and 1400), 3) feeding three times daily (3x; 0800, 1100 and 1400), and 4) feeding four times daily (4x; 0800, 1100, 1400 and 1700). The adaptation program consisted of ad libitum feeding of two adaptation diets over period of 14-d with concentrate level increasing from 60% to 86% of diet DM. The finishing diet contained: 67.0% cracked corn grain, 14.0% sugarcane bagasse, 9.0% soybean hulls, 5.5% soybean meal, 4.0% supplement containing 30% of urea, and 0.5% limestone (DM basis). At harvest, a 1-cm^2 fragment of each rumen was collected from ventral sac for histological assessment. Histological sections were stained with hematoxylin and eosin, embedded in paraffin wax, and sectioned. Morphometric measurements, such as papillae surface area, papillae height, papillae width, keratinized layer thickness, and mitotic index, were determined in four papillae per animal using computer-aided light microscope image analysis. In addition, cell proliferation was determined by immunohistochemistry technique using the monoclonal mouse anti-proliferating cell nuclear antigen. Orthogonal contrasts were used to assess linear, quadratic, and cubic relationship between feeding frequency and the dependent variable. Feeding frequency did not affect ($P > 0.10$) papillae width, keratinized layer thickness, and cell proliferation. However, as feeding frequency increased, papillae surface area in cm^2 (1x = 1.11; 2x = 1.11; 3x = 1.29; 4x = 1.22), papillae height in mm (1x = 2.85; 2x = 2.79; 3x = 3.29; 4x = 3.14), and mitotic index, as % of basal cells (1x = 9:12; 2x = 10.60; 3x = 12.85; 4x = 12.63) linearly increased ($P < 0.05$). Papillae surface area and papillae height were also affected ($P = 0.01$) cubically as feeding frequency increased. Thus, increasing feeding frequencies affected rumen tissue histology variables. In a practical way, feeding yearling Nellore bulls three times daily seems to be the most feasible option.

Key Words: mitosis, Nellore, papillae

1791 (W250) Survey of nutritional recommendations used by dairy cattle nutritionists in Brazil in 2013. D. P. Silva[*1], A. M. Pedroso[2], T. V. Carrara[3] and D. D. Millen[1,4], *[1]São Paulo State University (UNESP), Dracena campus, Dracena, Brazil, [2]EMBRAPA, São Carlos, Brazil, [3]São Paulo State University (UNESP), Botucatu campus, Botucatu, Brazil, [4]Supported by São Paulo State Foundation (FAPESP), São Paulo, Brazil*

This survey was designed to describe the nutritional recommendations and management practices adopted by Brazilian dairy cattle nutritionists in 2013. Forty-three nutritionists responsible for about 960 dairy farms, completed the survey within 1-mo, which was available online (www.surveymonkey.com) and consisted of 77 questions. The level of grains included in lactation diets recommended by 22 (55.0%) participants ranged from 31% to 50%, but 8 (20.0%) nutritionists recommended diets with 51% to 60%, and 10 (25.0%) used less than 31% grains. Likewise, the level of concentrate included in lactation diets recommended by 18 (43.9%) participants ranged from 41% to 50%, but 11 (26.8%) nutritionists recommended diets with 51% to 60%, and 12 (29.3%) used less than 31% concentrate. Corn was the primary source of grain used in lactation diets ($n = 37$; 97.4%). With respect to the energy unit used to formulate lactation diets, 40.5% ($n = 15$) nutritionists used TDN, followed by the NFC (29.7%; $n = 11$). The main source of information for feed energy values was the NRC (73.2%, $n = 30$), followed by CPM-Dairy (17.1%, $n = 7$). The typical range of roughage inclusion in finishing diets was 50.5%, and corn silage was the primary roughage source, being used by 30 nutritionists (79.0%). Moreover, the average recommended concentrations of NDF were 35.4%. Also, NDF was the fiber analysis method of choice by 29 of the nutritionists (76.3%), whereas physically effective NDF was cited by 7 (18.4%) of the respondents. Regarding coproduct use in lactation diets, citrus pulp pellets was the primary coproduct included in lactation diets, being used by 20 (51.3%) of the nutritionists. Use of whole cottonseed was reported by 8 (20.5%) nutritionists, whereas soybean hulls was reported by 7 (17.9%) of the respondents. When asked about feeding frequency, most of the clients served by the nutritionists surveyed typically feed twice daily (70.7%; $n = 29$), whereas 10 participants (24.4%) reported that their clients feed cows three times daily. This study presents a part of an overview of the practices and management recommendations currently applied by dairy cattle nutritionists from all regions in Brazil. Also, this survey may help to identify and solve problems in Brazilian dairy cattle operations, and moreover, these data may facilitate the design of industry-oriented research.

Key Words: Brazil, dairy, survey

1792 (W251) Effects of type of base forage on the Beta-carotene content of milk and blood plasma in lactating Holstein cows. H. C. Leicester[*1,2] and L. J. Erasmus[2], *[1]UC Davis, Davis, [2]University of Pretoria, Pretoria, South Africa*

It is well established that β-carotene has a positive effect on fertility of dairy cattle (Arechiga et al., 1998; J. Dairy Sci. 81, 390-402). The aim of this project was to determine the β-carotene content and variability of the main forage fed, blood plasma and milk of lactating Holstein cows managed in three typical South African production systems which differ in the base forage. These were pasture based systems (S1), predominantly corn silage based total mixed ration (TMR) systems (S2), and predominantly hay and alfalfa based TMR systems (S3). Within each system, 10 farms were selected based on their management and diet similarity within system and, from each farm, 20 cows where selected which had > 60 days in milk and were in lactation 2 or higher. The 20 cows/farm were chosen randomly from cows meeting these criteria. From each farm, a representative sample of the main forage, plasma samples from the 20 cows and a 2 liter bulk tank milk sample were collected. All samples were analyzed for β-carotene. The β-Carotene analyses of the predominant forages in each system revealed values of; S1; 20.9 ± 6.78 mg/Kg, S2; 3.1 ± 2.59 mg/Kg and S3; 22.4± 15.05 mg/Kg. Mean plasma β-Carotene of S1 cows was 5.5 ± 2.39 mg/L and this differed ($P < 0.05$) from S3 with values of 3.0 ± 0.66 mg/L, which tended ($P < 0.10$) to differ from S2 at 1.7 ± 0.06 mg/L. Bulk milk tank samples had β-Carotene levels of S1 (15.4 ± 7.40 mg/L), S2 (2.3 ± 0.43 mg/L) and S3 (4.1 ± 2.30 mg/L). While no guidelines exist for adequacy of β-Carotene levels in milk, plasma β-Carotene levels of < 1.5 mg/L is defined as 'deficient', 1.5 to 3.5 is 'marginal' and levels > 3.5 are 'optimal' (Schweigert and Immig, 2007; Int. Dairy Topics, 6,4). On this basis, S1 cows had 'optimal' plasma β-Carotene levels whereas S2 and S3 cows had 'marginal' β-Carotene levels, which suggests that dietary β-Carotene supplementation is required. However the wide variation in the β-Carotene levels of the base forages, both among and within systems, suggests that dietary β-Carotene supplementation should not be based solely on system, but should include β-Carotene analysis of the base forage.

Key Words: fertility production ICheck

1793 (W252) Effect of acute exposure to ergot alkaloids on short-chain fatty acid absorption and barrier function of isolated bovine ruminal epithelium. A. P. Foote[*1], G. B. Penner[2], M. E. Walpole[2], J. L. Klotz[3], L. P. Bush[4] and D. L. Harmon[4], *[1]USDA, ARS, US Meat Animal Research Center, Clay Center, NE, [2]University of Saskatchewan, Saskatoon, SK, Canada, [3]USDA-ARS, FAPRU, Lexington, KY, [4]University of Kentucky, Lexington*

Ergot alkaloids present in endophyte-infected tall fescue are the causative agents for fescue toxicosis in cattle. Ergot alkaloids have been shown to cause a reduction in blood flow to the rumen epithelium as well as a decrease in short-chain fatty acid (SCFA) absorption from the washed rumen of steers. It is possible that ergot alkaloids could negatively impact SCFA transport pathways and the barrier function of the rumen epithelium. An experiment was conducted to determine if acute exposure to an endophyte-infected tall fescue seed extract (EXT) would affect total, passive, or facilitated acetate and butyrate flux across the isolated bovine rumen epithelium as well as the barrier function measured by inulin flux and tissue conductance (G_t). Flux of ergovaline across the ruminal epithelium was also evaluated. Ruminal tissue from the caudal dorsal sac of Holstein steers ($n = 6$), fed a common diet, was collected and isolated shortly after slaughter and mounted between two halves of Ussing chambers under voltage clamp conditions. In vitro treatments included vehicle control (0.4% methanol), Low EXT (50 ng ergovaline/mL), and High EXT (250 ng ergovaline/mL). Results indicate that there was no effect of an acute exposure to ergot alkaloids on total, passive, or facilitated flux of acetate or butyrate across the isolate bovine rumen epithelium ($P > 0.51$). Inulin flux ($P = 0.16$) and G_t ($P > 0.17$) also were not affected by EXT treatment, indicating no alteration in barrier function due to acute ergot alkaloid exposure. Based on ergovaline concentrations measured in the serosal buffer of the High EXT treatment, the flux rate is approximately 0.25– 0.44 ng/(cm^2 · h). These data indicate that specific pathways for SCFA absorption and barrier function of the ruminal epithelium are not affected by acute exposure to an extract of tall fescue seed at the concentrations tested. Ergovaline has the potential to cross the rumen epithelium of cattle which could contribute to the reduced foregut blood flow seen in previous experiments and lead to reduced growth rates of cattle.

Key Words: ergot alkaloids, ergovaline absorption, fescue toxicosis

1794 (W253) Evaluation of the CNCPS v6.5 for predicting metabolizable energy and protein allowable milk in sugarcane based diets.

E. A. Collao-Saenz*[1], A. Foskolos[2], R. J. Higgs[2], M. N. Pereira[3] and M. E. Van Amburgh[2], *[1]Universidade Federal de Goiás, Jatai-GO, Brazil, [2]Cornell University, Ithaca, NY, [3]Universidade Federal de Lavras, Lavras, Brazil*

Sugarcane is a high energy yielding crop, and is an alternative feed for dairy cows in tropical regions. This experiment evaluated the sensitivity of CNCPSv6.5 for predicting milk yield in sugarcane based diets. Data for evaluation were obtained from 13 published experiments, representing 50 treatments. Metabolizable energy (ME) and protein (MP) allowable milk were predicted based on reported DMI and diet composition. An algorithm was used to adjust the nutrient composition of individual ingredients from commercial laboratory databases when feed chemistry data were incomplete. The correlation coefficients between observed and predicted milk yield were based on BLUP (R^2_{BLUP}) and model predictions using the mean study effect (R^2_{MP}). When milk yield was predicted based on the first limiting nutrient, either ME or MP, the correlation coefficient generated with R^2_{BLUP} was 0.985 and with R^2_{MP} was 0.81. With ME predicted milk yield, the R^2_{BLUP} correlation coefficient was 0.989 and for R^2_{MP}it was 0.81, and when the predictor was MP they were 0.92 and 0.67, respectively. The Bayesian Information Criterion was 219 for MP or ME, 110 for ME, and 127 for MP. The Mean Square Prediction Error (MSPE) using MP to predict milk yield was 5.4, and it was 10.8 when ME or MP or ME were predictors. When the MSPE was partitioned, 0.22%, 0.01% and 3.6% of the error was due to mean bias for the MP or ME, ME, or MP predicted milk yield, respectively, 35.41%, 32.94% and 30.72% was due to systematic bias, and 64.37%, 67.05% and 65.68% was due to random variation. Concordance Correlation Coefficients were computed to account for the accuracy and precision of the predictions, values were: 0.79 for MP or ME, 0.83 for ME, and 0.75 for MP. Using CNCPSv.6.5 to predict milk yield responses in sugarcane based diets was reliable. In the available data sets, the prediction of ME allowable milk yield was better than MP and this most likely reflects differences in actual rates of digestion and library values along with ingredient bias.

Key Words: dairy cattle, model evaluation, tropical feed

1795 (W254) Effects of different feeding frequencies on DMI variation and selective consumption by feedlot cattle.

J. Silva*[1], T. V. Carrara[2], M. C. Pereira[1], D. V. Vicari[1], I. C. Batista Júnior[1], L. A. Tomaz[1], D. H. Watanabe[1], A. L. Rigueiro[1], M. D. Arrigoni[2] and D. D. Millen[1,3], *[1]São Paulo State University (UNESP), Dracena campus, Dracena, Brazil, [2]São Paulo State University (UNESP), Botucatu campus, Botucatu, Brazil, [3]São Paulo State Foundation (FAPESP), São Paulo, Brazil*

This study, conducted at the São Paulo State University feedlot, Dracena Campus, Brazil, was designed to determine the effects of different feeding frequencies on DMI variation and selective consumption (sorting) of diets by Nellore cattle. The experiment was designed as a completely randomized block, replicated 12 times, in which 48 18-mo-old yearling Nellore bulls (358.2 ± 19.4 kg) were fed in individual pens for 94-d according to the following treatments: 1) feeding one time daily (1x; 0800), 2) feeding two times daily (2x; 0800 and 1400), 3) feeding three times daily (3x; 0800, 1100 and 1400), and 4) feeding four times daily (4x; 0800, 1100, 1400 and 1700). The adaptation program consisted of ad libitum feeding of two adaptation diets over period of 14-d with concentrate level increasing from 60% to 86% of diet DM. The finishing diet contained: 67.0% cracked corn grain, 14.0% sugarcane bagasse, 9.0% soybean hulls, 5.5% soybean meal, 4.0% supplement containing 30% of urea, and 0.5% limestone (DM basis). The DMI variation was calculated for each individual yearling bull as the difference in intake, expressed as % of variation, between consecutive days throughout the study. Samples of orts and diets were collected on days 12 and 51 of the study for particle size distribution determination, which was performed by sieving using the Penn State Particle Size Separator and reported on as-fed basis. Values equal to 1.0 indicate no sorting, < 1.0 show selective refusals, and > 1.0 indicate preferential consumption. Orthogonal contrasts were used to assess linear, quadratic, and cubic relationship between feeding frequency and the dependent variable. During the period of adaptation, DMI variation was affected ($P < 0.01$) cubically as feeding frequency increased (1x = 16.1%; 2x = 23.2%; 3x = 14.4%; 4x = 15.9%), however, feeding frequency did not affect ($P > 0.10$) DMI variation during the finishing period. Feeding frequency only affected particle sorting during the adaptation period, in which as feeding frequency increased, sorting for screen 3 (diagonal opening = 1.18 mm) was affected ($P < 0.01$) quadratically (1x = 0.993; 2x = 0.995; 3x = 0.999; 4x = 0.985). Thus, based on the results of this study, feeding frequency affects DMI variation and diet sorting only during the adaptation period. Cattle fed three times daily presented lower DMI variation and lesser extent of sorting.

Key Words: fluctuation, Nellore, sorting

1796 (W255) Evaluation of mineral excretion of lactating Holstein dairy cows supplemented with copper, manganese and zinc in organic and inorganic forms. G. Acetoze*[1], A. M. Gehman[2], K. A. Dawson[3] and H. A. Rossow[4], [1]*University of California- Davis, Tulare,* [2]*Alltech, Inc., Nicholasville, KY,* [3]*Center for Animal Nutrigenomics and Applied Animal Nutrition, Alltech, Nicholasville, KY,* [4]*VMTRC, University of California, Tulare, CA*

Forms of minerals, organic and inorganic, impact the amount of mineral available for intestinal absorption. However, in the ruminant, when inorganic minerals dissociate they can associate with feed components decreasing their availability for intestinal absorption. The objective of this study was to evaluate the impact of level of feeding organic and inorganic forms of Cu, Mn and Zn (Bioplex Cu, Mn, and Zn; Alltech, Inc.) on mineral fecal excretion of lactating dairy cows on a commercial dairy. Fifty lactating Holstein dairy cows (70 DIM) were randomly assigned to five treatments: Control, Organic75, Organic100, Organic125, and Inorganics ($CuSO_4 \cdot 5H_2O$, $MnSO_4 \cdot H_2O$ and ZnSO4 $\cdot$ H_2O) (Table 1796). Therefore control cows received only the levels of minerals present in the TMR based on NRC. Minerals were given by daily dosing individual cows with an oral solution of the mineral treatment for 28 d (24 d for adaptation, and 4 d of sample collection). Fecal samples were collected rectally twice a day (am and pm), combined for a 24h sample and sent for analysis of mineral content and composition. For 11 d, Cr was supplemented (10g/d) with minerals to estimate total fecal output. Statistical analysis was performed in R (version 2.15.1) using ANOVA. No differences were observed for fecal output (kg/d) ($P = 0.35$) and manganese excretion (g/d) ($P = 0.23$) among treatments. Copper and zinc excretion levels did differ among treatments ($P < 0.001$). Averages (g/d) for copper excretion were 0.48, 0.66, 0.68, 0.76 and 0.58 for Control, Organic75, Organic100, Organic125 and Inorganic, respectively; and averages for zinc excretion were 2.70, 3.21, 3.04, 3.42, 2.78 for Control, Organic75, Organic100, Organic125 and Inorganic, respectively. Greatest concentrations of mineral excretion were observed in cows supplemented with 25% above NRC requirement levels of Bioplex Cu and Zn while lowest levels of mineral excretion were observed in cows dosed with control and Inorganics. In conclusion, this study shows that mineral form only affects copper and zinc excretion. However, treatment comparisons are not corrected for contributions of minerals from other dietary components (DMI), so conclusions on levels of mineral fecal excretion may change when considering apparent absorption.

Key Words: minerals, fecal excretion, dairy cattle

Table 1796. Levels of minerals supplemented on top of TMR (control diet) for each treatment

	Control	Organic75	Organic100	Organic125	Inorganics
	(mg/d)				
Mn	354.00	125.07	166.76	208.45	166.76
Cu	472.00	215.07	286.76	358.45	286.76
Zn	1409.00	375.88	501.18	626.48	501.18

1797 (W256) Evaluation of milk yield and composition of F1 Holstein x Gir lactating cows supplemented with rumen-protected choline during the transition period. R. C. D. Souza*[1], R. C. Souza[1], A. B. D. Pereira[2], R. F. Cota[1], T. A. Torres[1], I. B. Fortes[1] and G. V. Fonseca[3], [1]*PUC Minas, Betim, Brazil,* [2]*University of New Hampshire, Durham,* [3]*PUC, Betim, Brazil*

The use of rumen-protected choline (RPC) is a strategy to improve fat metabolism in the liver and reduce the prejudicial effects of negative energy balance in dairy cows during the peripartum. The objective of this study was to evaluate milk yield and composition of cows supplemented with RPC during the transition period (from 21 d pre-partum until 21 d post-partum). Thirty two lactating F1 Holstein x Gir cows (16 multiparous and 16 primiparous) were blocked by parity and randomly assigned to one of two dietary treatments: no addition of RPC (NC) and addition of 60 g of RPC (AC; Toplac Transition, Nutrifarma, Taió, PR, Brazil). Diets contained 60% forage as corn silage and were isonitrogenous and isocaloric according to the NRC (2001) model. Supplementation of RPC was done from 21 d before expected parturition until 21 d post-partum. The experiment was analyzed as a randomized complete block design using the MIXED procedure for SAS and least square means were reported according to the tukey post-hoc test. Milk production was lower for multiparous cows in the NC diet (32.2 kg/d) compared to the AC diet (34.4 kg/d, $P < 0.05$), but no effect was observed for primiparous animals. A difference between treatments was observed for milk fat yield for multiparous cows (0.88 kg/d and 1.17 kg/d for NC and AC, respectively, $P < 0.05$) and primiparous cows (1.02 kg/d and 1.17 kg/d for NC and AC, respectively, $P < 0.05$) and somatic cells count for multiparous cows (401 x 10^3 cells and 258 x 10^3 cells for NC and AC, respectively, $P < 0.05$) but not for primiparous cows (143 cells/mL and 93.8 cells/mL for NC and AC, respectively, $P > 0.05$). Also, no difference was found between treatments and parity level for milk fat percentage, milk protein or milk solids non-fat. Rumen protected choline supplementation to F1 Holstein x Gir multiparous cows improved milk production and milk fat yield. Effect on primiparous cows was observed only on milk fat yield.

Key Words: rumen protected choline, milk yield, milk composition.

1798 (W257) Effects of supplemental bupleurum extract on blood material metabolism in heat-stressed dairy cows. X. Sun*, *Ministry of Agriculture-Laboratory of Quality* and *Safety Risk Assessment for Dairy Products (Beijing), Beijing, China*

This study investigated the effect of bupleurum extract (BE) on blood material metabolism of lactating dairy cows under heat stress. Forty lactating Chinese Holstein cows (75 ± 15 DIM, 37.5 ± 1.8 kg of milk/d, and 1.7 ± 0.4 parity) were randomly assigned to four groups and were individually fed a basal diet with 0, 0.25, 0.5, or 1.0 g BE/kg DM. The experiment lasted 10 weeks. Average temperature–humidity index (THI) was more than 72 throughout the experimental period. Blood samples were collected from all of animals via tail vein before the morning feeding on days 0, 21, 42, and 63. Data were analyzed by MIXED model procedure of SAS 9.2. Supplementation of BE decreased urea nitrogen (BUN) contents (5.65, 5.58, 5.81 vs 5.95 mmol/L, $P < 0.05$), but increased blood total protein (80.97, 81.08, 81.00 vs 77.22 g/L, $P < 0.05$) level. Cows fed 0.25 or 0.5 g/kg BE increased albumin content (38.61, 37.53 vs 36.18 g/L, $P < 0.05$) compared with control cows, but BE supplementation had no effects ($P > 0.05$) on blood glucose (GLU), nonesterified fatty (NEFA), total triglyceride (TG), low density liporotein cholesterin (LDL-C) and high density liporotein cholesterin (HDL-C). Sodium (Na) (136.63, 134.72, 136.05 vs 137.90 mmol/L; $P < 0.01$) and phosphorus (P) (1.94, 1.96, 1.81 vs 2.13 mmol/L; $P = 0.05$) concentrations in serum were decreased by BE supplementation, while potassium (K) (3.80, 3.83, 3.90 vs 3.48 mmol/L; $P < 0.01$) and calcium (Ca) (2.56, 2.59, 2.66 mmol/L; $P < 0.01$) concentrations were decerased than in controls, but BE supplementation had no effect ($P > 0.05$) on serum magnesium (Mg) concentration. Serum chlorine (Cl) concentration was increased in cows fed 0.5 g/kg BE (148.01 vs 140.79 mmol/L; $P < 0.05$) compared with control cows, and tended to be higher (144.08 vs 140.79 mmol/L; $P < 0.1$) in cows fed 0.25 g/kg BE, but was not affected in cows fed 1.0 g/kg BE. These findings suggest that BE supplementation could improved the protein metabolism and maintain the balance of electrolyte concentration.

Key Words: bupleurum extract; heat stress; blood material metabolism

1799 (W258) Evaluation of the updated version of CNCPS (v6.5). A. Foskolos*[1], E. A. Collao-Saenz[2], D. A. Ross[1], R. J. Higgs[1] and M. E. Van Amburgh[1], *[1]Cornell University, Ithaca, NY, [2]Universidade Federal de Goiás, Jatai-GO, Brazil*

The first version of The Cornell Net Carbohydrate and Protein System (CNCPS) was released in 1991, and since then it has been continuously under evolution. Our objectives are to describe the latest updates of the model resulting in version 6.5 and to evaluate model predictions against both literature and on-farm data. Degradation rates of protein and carbohydrate fractions were modified to meet new fractionation schemes, updated amino acid (AA) profiles on a whole feed basis were made and a combined efficiency of essential AA use was adopted representing an improved understanding of AA metabolism. Three different datasets were developed to evaluate lysine (Lys) and methionine (Met) requirements (AA dataset), rumen N balance (rumen dataset) and metabolizable energy (ME) and protein (MP) allowable (lactation dataset). In total 96 peer-reviewed studies with 367 treatments and 15 regional farms with 50 different diets were included. The AA dataset was used to estimate the concentration of Lys and Met that maximizes milk protein yield and content according to the broken line model with plateau: results suggested concentrations of 7.00 and 2.60%MP for Lys and Met, respectively for maximal protein yield and 6.77 and 2.85%MP for Lys and Met, respectively for maximal protein content. Proposed concentrations are slightly higher for Lys and 11-18% higher for Met compared with CNCPSv6.0 which can be attributed to changes in the AA profile of feeds. The ability of the model to predict post-ruminal flows of N and milk yield was assessed using the correlation coefficient based on the BLUP (R^2_{BLUP}) or model predictions using a mean study effect (R^2_{MP}) and the concordance correlation coefficients (CCC) to simultaneously account for accuracy and precision. The model predicted accurate and precise post-ruminal flows of rumen degraded and undegraded N (RDN and RUN, respectively; $R^2_{BLUP=}$ 0.98 and 0.92 and CCC = 0.88 and 0.80 for RDN and RUN, respectively), bacterial N ($R^2_{BLUP=}$ 0.97; CCC = 0.84) and provided a uniform offset of non-ammonia N that is robust with little bias ($R^2_{BLUP=}$ 0.98; CCC = 0.92). For the lactation dataset, the model predicted accurate and precise milk yield according to the first limiting nutrient (MP or ME) with a $R^2_{BLUP=}$ 0.95, $R^2_{MP=}$ 0.78 and CCC = 0.83. Results suggest a significant improvement of the model due to current updates.

Key Words: CNCPS, evaluation, dairy cattle

1800 (W259) Effects of bupleurum extract on performance and health status in heat-stressed late lactation dairy cows. B. Shi[1,2], N. Zheng[1], J. Cheng[1,2], L. Min[1], C. Yin[1] and J. Wang*[1,3], *[1]Ministry of Agriculture- Laboratory of Quality* and *Safety Risk Assessment for Dairy Products (Beijing), Beijing, China, [2]College of Animal Science and Technology, Anhui Agricultural University, Hefei, China, [3]State Key Laboratory of Animal Nutrition, Institute of Animal Science, Chinese Academy of Agricultural Sciences, Beijing, China*

This study was conducted to investigate the effects of bupleurum extract (BE) on performance and health status in heat-stressed Chinese Holstein dairy cows. Forty lactating cows (days in milk = 207.98 ± 12.2; average milk yield = 30.96 ±

3.96 kg/d; parity = 1.96 ± 1.07) were randomly assigned to 1 of 4 treatments according to a completely randomized block design. Cows were individually housed in pens and fed ad libitum three times daily. Treatments consisted of 0, 0.5, 2.5 or 5% BE of dry matter (CG, LG, MG or HG).The experiment lasted for 11 weeks in hot summer. Ambient temperature and relative humidity were recorded daily (0600, 1400, and 2200). Milk yields, dry matter intake (DMI), respiration rates (RR) and rectal temperatures (RT) were recorded twice a week and milk samples were collected twice a week. Blood was collected in evacuated tubes via caudal venipuncture at 0, 3, 6, 9, 11 week. Data were analyzed by repeated measures using Proc Mixed procedure of SAS 9.2. During the experiment, average temperature-humidity index were 76.8 ± 6.3, 82 ± 6.54 and 78.3 ± 6.1 respectively at 0600h, 1400h and 2200h. There was no treatment effect on RR, RT, DMI and milk yield, while the values of DMI (19.41, 19.04, 18.61 vs. 19.19 kg/d) tended to decrease with increasing dose. Milk urea nitrogen in MG was lower (12.06 vs. 12.92 mg/dL, $P < 0.05$) than that in CG, while contents of milk fat, milk protein, lactose, total solids and somatic cell counts were not significantly affected ($P > 0.05$). The mean corpuscular hemoglobin in HG was lower than that in CG (16.56 vs. 16.98 pg, $P < 0.05$). The Mean corpuscular hemoglobin concentration (346.35, 347.81, 344.87 vs. 351.28 g/L, $P < 0.05$) was decreased due to BE supplementation. No significant difference in the number of leukocytes, red blood cell count, hematocrit, lymphocytes, mean corpuscular volume, mean platelet volume and red blood cell distribution width were detected among groups. There was no treatment effect on glutamic-pyruvic transaminase, glutamic oxalacetic transaminase, globulin, albumin, total protein and alkaline phosphatase. These results indicate that BE supplemented with high dose of 5% had no negative effect on the performance and health status in heat stressed late lactation dairy cows, and 5% is safety dose.

Key Words: bupleurum extract, performance, health status

1801 (W260) Estimation of NDF pool in the rumen of cattle using fecal excretion and diet characteristics.

H. C. Bonfa*[1], E. Detmann[2], S. Krizsan[3], S. C. Valadares Filho[2] and P. Huhtanen[3], *[1]UFV, Universidade Federal de Viçosa, Department of Animal Science, Viçosa, Minas Gerais, Brazil, [2]Universidade Federal de Viçosa, Viçosa, Minas Gerais, Brazil, [3]Swedish University of Agricultural Sciences (SLU), Umea, Sweden*

The objective of this work was to estimate ruminal pool of NDF in cattle from the fecal excretion of fiber and diet characteristics using a meta-analytical approach. The dataset was compiled from 60 experiments with lactating cows and growing cattle carried out in Europe and Brazil, totaling 227 treatment means. The dataset was analyzed using linear mixed models according to meta-analysis techniques. The variation among experiments was considered as a random effect in the models. An unstructured (co)variance matrix was used. The evaluation of the effect of animal category was accomplished on intercept and slopes through a "dummy" variable D (i.e. binary variable),where D = 0 for lactating dairy cows and D = 1 for growing cattle. All analyses were performed using the MIXED procedure of SAS 9.2.Different models were adjusted considering two different units for NDF pool (pNDF): kg and g/kg BW. The independent variables were selected based on biological relevance and also on estimates of partial Pearson's correlation with the dependent variable. In this way, the independent variables were: fecal excretion of NDF (fNDF), representing the undigested fiber pool; dietary NDF content (dNDF), representing the dietary input of fiber; and the ratio between dietary iNDF (indigestible NDF) and dNDF (iNDF/dNDF), representing the quality of dietary fiber.The adjusted models were: pNDF (kg) = 2.95 -2.75 × D + 1.217 ×fNDF(kg)– 0.08034 × $fNDF^2$ (kg) + 0.003×dNDF(g/kg DM)– 1.606 × (iNDF/dNDF), $R^2 = 0.95$, $s_{XY} = 0.54$, where D = 0 for lactating cows and D = 1 for growing cattle; and pNDF (g/kg BW) = 5.20– 3.62 × D + 1.067 × fNDF (g/kg BW)– 0.03324 × $fNDF^2$ (g/kg BW) + 0.005 × dNDF (g/kg DM)– 2.809 × (iNDF/dNDF), $R^2 = 0.93$, $s_{XY} = 0.94$. All terms were found significant ($P < 0.05$) and there was no lack of fit for both models ($P > 0.63$). The meta-analysis results brought into evidence that NDF rumen pool can be estimated from fecal and diet characteristics avoiding the utilization of invasive techniques.

Key Words: meta-analysis, mixed models, ruminal evacuation

1802 (W261) Performance and carcass traits of immunocastrated Nellore cattle fed to β-agonists.

D. Silva Antonelo[1], M. Rezende Mazon[1], K. Eduardo Zanoni Nubiato[1], D. Juliana Brigida[1], J. Fernando Morales Gomes[2], B. Luis Nery Garcia[1], M. Zanata[1], P. R. Leme[1] and S. Luz e Silva*[3], *[1]University of Sao Paulo, Pirassununga, Brazil, [2]University of Cundinamarca, Fusagasugá, Colombia, [3]University of Sao Paulo/FZEA, Pirassununga, Brazil*

Beta-adrenergic agonists (βAA) have been used to improve performance and carcass traits of feedlot cattle. The use of non-castrated males for meat production is a common practice because they grow fast, use energy more efficiently and produce leaner and high-yielding carcasses. This work was developed to evaluate the effect of βAA and immunocastration on the performance of feedlot finished Nellore cattle. Ninety-six males (409 ± 50 kg LW; 20 mo old) were divided in two groups and half of them received two doses of immunocastration vaccine (Bopriva) within 30 days interval. Animals were fed for 70 days a common diet containing 76% concentrate and 24% roughage (corn silage). Following they were split in 3 groups ($n = 32$) and fed 30 more days one of the follow-

ing treatments: control diet without βAA (CON); control diet plus 80mg/d zilpaterol hydrochloride (Zilmax) (ZIL); control diet plus 300mg/d of ractopamine hydrochloride (Optaflexx) (RAC). Individual DMI, ADG and F:G were recorded. Data was analyzed as complete block randomized design in a 2x3 factorial arrangement. No interaction was observed between sex condition and treatments. There was no difference in DMI (9.1 kg/d) but non-castrated males were heavier (551 vs 520 kg; $P = 0.0004$), tended to have a greater ADG (1.21 vs 1.06 kg/d; $P = 0.1084$) and F:G ratio (132 vs 115 g of DMI/kg ADG; $P = 0.1102$) than immunocastrated, respectively. Immunocastrated animals had smaller hot carcass weight (HCW; 304 vs 323 kg; $P = 0.0006$) without difference in dressing percentage (DP; 58.5%). Animals fed ZIL showed highest ADG and F:G ratio (1.39 kg/d and 156 g of DMI/kg ADG, respectively; $P < 0.05$). CON treatment showed the smallest ADG and F:G ratio (0.89 kg/d and 94 g of DMI/kg ADG, respectively; $P < 0.05$). Treatment RAC showed intermediate results (ADG 1.1 kg/d and F:G 122 g of DMI/kg ADG, respectively; $P < 0.0001$) compared to ZIL and CON. There was no effect of treatment on final BW, DMI and HCW. Animals fed βAA showed heavier carcasses (313 kg RAC; 320 kg ZIL) than CON (308 kg) resulting in a higher DP for ZIL (59.1%) when compared to RAC (58.3%; $P = 0.0351$) and CON (58%; $P = 0.0048$), respectively. Non-castrated animals have better feedlot performance and βAA improves animal efficiency in feedlot.

Key Words: feedlot, growth, ruminant nutrition

1803 (W262) Effects of nicotinamide on hormone levels, antioxidant status and immune function of cows in heat stressed dairy cows. J. Cheng[1,2,3], N. Zheng[1,3,4], X. Sun[1,2,3], D. P. Bu[3], L. Pan[3] and J. Wang[*1,3,4], *[1]Ministry of Agriculture- Laboratory of Quality* and *Safety Risk Assessment for Dairy Products (Beijing), Beijing, China, [2]College of Animal Science and Technology, Anhui Agricultural University, Hefei, China, [3]State Key Laboratory of Animal Nutrition, Institute of Animal Science, Chinese Academy of Agricultural Sciences, Beijing, China, [4]Ministry of Agriculture- Milk and Dairy Product Inspection Center (Beijing), Beijing, China*

The experiment was conducted to investigate the effects of nicotinamide on the blood hormone levels, antioxidant status and immune function of heat-stressed dairy cows. Twenty healthy early lactation Holstein cows (78.8 ± 11.0 DIM, 37.7 ± 1.8 kg of milk/d, 1.7 ± 0.4 parity) were randomly arranged to control and nicotinamide supplementation group. Cows were fed basic diet in control group and basic diet plus 8 g/d nicotinamide in nicotinamide group for 10 weeks. Average temperature–humidity index (THI) was more than 72 throughout the experimental period. Blood samples were collected from all of animals via tail vein before the morning feeding on days 0, 21, 42, and 56. Data were analyzed by MIXED model procedure of SAS 9.2. Compared with control cows, cows fed nicotinamide had higher contents of insulin (0.37 vs 0.34 ng/mL; $P = 0.03$), triiodotyronine (1.43 vs 1.27 ng/mL; $P = 0.03$) and leptin (2.74 vs 2.25 ng/mL; $P = 0.02$). Nicotinamide supplementation had the tendency to increase the thyroxine (29.02 vs 27.57 ng/mL; $P = 0.08$) and heat shock protein 70 (3.06 vs 2.29 ng/mL; $P = 0.10$), but had no effect ($P > 0.05$) on the contents of glucagon, insulin-like growth factor-1, growth hormone, prolactin and neuropeptide in blood. Cows fed nicotinamide had the tendency to elevate the activity of superoxide dismutase (10.29 vs 9.63 U/mL; $P = 0.07$), but had no effects ($P > 0.05$) on the activity of glutathione peroxidase, the levels of total antioxidant capacity and malondialdehyde. The contents of immunoglobulin (Ig) A (238.83 vs 160.38 μg/mL; $P = 0.01$), IgG (34.90 vs 21.54 μg/mL; $P = 0.03$), interleukin-4 (IL-4) (91.23 vs 77.19 pg/mL; $P = 0.04$) and IL-6 (138.81 vs 97.79 μg/mL; $P = 0.01$) were increased, and the ratio of $CD4^+/CD8^+$ were higher tendency (1.47 vs 1.16; $P = 0.10$) in cows fed 8g/d nicotinamide than in controls, while the levels of IgM, tumor necrosis factor-α, lymphocytes and the proportion of $CD4^+$ and $CD8^+$ T lymphocytes had no difference ($P > 0.05$) compared with the control. These results indicate that nicotinamide supplementation helps to alleviate the hormone metabolism disorder, improve antioxidant activity, and enhance the immune function in heat-stressed dairy cows.

Key Words: nicotinamide, dairy cows, blood metabolism

1804 (W263) Effects of supplemental bupleurum extract on blood material metabolism in heat-stressed dairy cows. X. Sun[1,2,3], N. Zheng[1,3,4], J. Cheng[1,2,3], D. P. Bu[3], L. Pan[3] and J. Wang[*1,3,4], *[1]Ministry of Agriculture- Laboratory of Quality* and *Safety Risk Assessment for Dairy Products (Beijing), Beijing, China, [2]College of Animal Science and Technology, Anhui Agricultural University, Hefei, China, [3]State Key Laboratory of Animal Nutrition, Institute of Animal Science, Chinese Academy of Agricultural Sciences, Beijing, China, [4]Ministry of Agriculture- Milk and Dairy Product Inspection Center (Beijing), Beijing, China*

This study investigated the effect of bupleurum chinense DC. extract (BE) on blood metabolism of lactating dairy cows under heat stress. Forty lactating Chinese Holstein cows (75 ± 15 DIM, 37.5 ± 1.8 kg of milk/d, and 1.7 ± 0.4 parity) were randomly assigned to four groups and were individually fed a basic diet(CP = 17.2%, NDF = 53.4%) with 0, 0.25, 0.5, or 1.0 g BE/kg DM, respectively. The experiment lasted 10 weeks. Average temperature–humidity index (THI) was more than 72 throughout the experimental period. Dry matter intake was recorded twice a week. Blood samples were collected from all of animals via tail vein before the morning feeding on days 0, 21, 42, and 63. Data were analyzed by MIXED model

procedure of SAS 9.2. Supplementation of BE increased dry matter intake (20.80, 21.61, 22.13 vs 20.91 kg/d, $P = 0.02$) and blood total protein (80.97, 81.08, 81.00 vs 77.22 g/L, $P = 0.03$) level, but decreased urea nitrogen (BUN) contents (5.65, 5.58, 5.81 vs 5.95 mmol/L, $P = 0.04$). Cows fed 0.25 or 0.5 g/kg BE increased albumin content (38.61, 37.53 vs 36.18 g/L, $P = 0.01$) compared with control cows, but BE supplementation had no effects ($P > 0.05$) on blood glucose (GLU), nonesterified fatty (NEFA), total triglyceride (TG), low density liporotein cholesterin (LDL-C) and high density liporotein cholesterin (HDL-C). Sodium (Na) (136.63, 134.72, 136.05 vs 137.90 mmol/L, $P < 0.01$) and phosphorus (P) (1.94, 1.96, 1.81 vs 2.13 mmol/L, $P = 0.05$) concentrations in serum were decreased by BE supplementation, while potassium (K) (3.80, 3.83, 3.90 vs 3.48 mmol/L, $P < 0.01$) and calcium (Ca) (2.56, 2.59, 2.66 vs 2.46 mmol/L, $P < 0.01$) concentrations were decerased than in controls, but BE supplementation had no effect ($P > 0.05$) on serum magnesium (Mg) concentration. Serum chlorine (Cl) concentration was increased in cows fed 0.5 g/kg BE (148.01 vs 140.79 mmol/L, $P = 0.04$) compared with control cows, and tended to be higher (144.08 vs 140.79 mmol/L, $P = 0.08$) in cows fed 0.25 g/kg BE, but was not affected in cows fed 1.0 g/kg BE. These findings suggest that BE supplementation could improved the protein metabolism and maintain the balance of electrolyte concentration.

Key Words: bupleurum extract; dairy cows; blood metabolism

1805 (W264) Effects of nicotinamide on blood material metabolism of dairy cows under heat stress. X. Sun[1,2,3], N. Zheng[2,3,4], D. P. Bu[3], L. Pan[3] and J. Cheng[*1,2,3], *[1]College of Animal Science and Technology, Anhui Agricultural University, Hefei, China, [2]Ministry of Agriculture- Laboratory of Quality and Safety Risk Assessment for Dairy Products (Beijing), Beijing, China, [3]State Key Laboratory of Animal Nutrition, Institute of Animal Science, Chinese Academy of Agricultural Sciences, Beijing, China, [4]Ministry of Agriculture- Milk and Dairy Product Inspection Center (Beijing), Beijing, China*

The experiment was conducted to determine the effects of nicotinamide on the metabolism of carbohydrate, lipid, protein and the mineral of serum in heat-stressed cows under hot environment. Twenty healthy early lactation holstein cows (78.8 ± 11 DIM, 37.7 ± 1.8 kg of milk/d, 1.7 ± 0.4 parity) were randomly assigned to control and nicotinamide supplementation group. Cows were individually fed basic diet (*CP* = 17.2%,NDF = 53.4%) in control group and fed basic diet plus 8 g/d nicotinamide in nicotinamide group. The trial lasted 10 weeks. Average temperature–humidity index (THI) was more than 72 throughout the experimental period. Feed intake was recorded twice a week. Blood samples were collected from all of animals via tail vein before the morning feeding on days 0, 21, 42, and 63. Data were analyzed by MIXED model procedure of SAS 9.2. There was no significant difference in dry matter intake between treatments (20.60 vs 20.71 kg/d; $P > 0.05$). The concentrations of nonestesterifiedfattyacid (221.25 vs 250.08 uEq/L; $P = 0.03$), total triglyceride (0.13 vs 0.15 mmol/L; $P = 0.03$), total cholesterol (5.79 vs 6.57 mmol/L; $P = 0.04$), and low density lipoprotein cholesterol (1.43 vs 1.76 mmol/L; $P = 0.04$) were decreased significantly by nicotinamide supplementation. Nicotinamide supplementation had the tendency to decrease β-hydroxybutyricacid level (0.66 vs 0.76 mmol/L; $P = 0.10$), but had no effect ($P > 0.05$) on the levels of serum glucose, total protein, albumin and urea nitrogen. Compared with control group, the levels of sodion (139.59 vs 137.90 mmol/L; $P = 0.03$) and chloridion ion (148.72 vs 139.75 mmol/L; $P = 0.05$) in serum were increased significantly by nicotinamide supplementation, but there was no difference ($P > 0.05$) in the levels of serum kalium, magnesium, phosphonium between the two groups. These findings suggest that nicotinamide supplementation can improved the lipid metabolism and maintain electrolyte balance of cows under heat stress.

Key Words: nicotinamide; dairy cow; blood metabolism

1806 (W265) Supplementation of selenium plus vitamin E vs. canola oil in the diet of feedlot cattle: which one can improve nutritional quality of meat modifying gene expression? G. F. Greghi[*1], A. Saran Neto[2], H. Fukumasu[1], J. C. D. C. Balieiro[3], A. O. Latorre[4], L. B. Correa[1] and M. A. Zanetti[1], *[1]University of São Paulo- USP/FZEA, Pirassununga, Brazil, [2]University of São Paulo, Pirassununga, Brazil, [3]University of São Paulo- USP/FMVZ, Pirassununga, Brazil, [4]Adolfo Lutz Institute, São Paulo, Brazil*

The metabolic conversion of dietary components is a control mechanism for gene expression, so the present study aimed to evaluate the effects of selenium (Se), vitamin E and canola oil on the expression of antioxidant and lipogenic genes. Forty-eight Nellore bulls at calan gate allocated in the Department of Animal Science USP-FZEA-Brazil were divided into four groups: Control(C): basal diet (30% forage- corn silage- and 70% concentrate, dry matter according to the nutrient requirements recommended by NRC,1996); Se+Vit E: addition of 2.5mg Se+500 IU vitamin E; Canola: addition of 3% canola oil; Se+Vit E+Canola: addition of 3% canola oil+2.5mg Se+500 IU of vitamin E(/kg DM, always). After 12 weeks, the animals were slaughtered at the Abattoir-School Campus and liver samples collected. Total RNA was extracted using RNeasy Tissue Kit (Qiagen), measured at 260 and 280nm, analyzed by agarose gel. RNA was converted into cDNA using DNase I and High Capacity RNA-to-cDNA kit and it was used for determination of gene expression by RT-qPCR using Taqman probes, 18S as endogenous control (Applied Biosys-

Table 1806. Gene expression

GENE	C	Se+Vit E	Canola	Se+Vit E +Canola	Pr > F	C1	C2	C3
NRF2	1.1661	1.8295	0.8032	1.121	0.0525	0.7904	0.5756	0.0079
GPX-1	1.1209	1.6099	0.8125	1.1594	0.08	0.783	0.8467	0.0109
GPX-4	1.3153	2.6565	1.1741	1.0114	0.0265	0.553	0.1032	0.0118
SCD	1.4732	2.3247	1.0792	2.674	0.0568	0.289	0.0751	0.0572

tems) and calculated by Pfaffl's equation. The data were analyzed by Mixed SAS 2009 and contrasts used were: control vs. other (C1); Se+Vit E and Canola vs. Se+Vit E+Canola (C2); Se+Vit E vs. Canola (C3). The results are in Table 1806. The supplementation with Se+Vit E and Canola didn't show effects when compared to the control (C1), but differences were observed between Se+Vit E and Canola (C3), which had opposite effects. Se+Vit E induced expression of cytoprotectives genes (NRF2, GPXs, GSS) and increased the expression of responsible gene for the synthesis of CLAs (SCD) encouraging studies to improve nutritional quality of meat, but caution is needed because it can induce the synthesis of cholesterol through the expression of the gene HMG-CoA-R. Although Canola didn't increase the expression SCD gene, canola oil reduced the expression of HMG-CoA-R gene.

Key Words: antioxidants, bovine, cholesterol.

1807 (W266) Effects of feeding a corn straw or mixed forage diet on immune function in dairy cows.

P. Sun[1], C. Qin[1,2], D. P. Bu[1], J. Q. Wang[*1] and P. Zhang[2], *[1]State Key Laboratory of Animal Nutrition, Institute of Animal Science, Chinese Academy of Agricultural Sciences, Beijing, China, [2]Hunan Provincial Key Laboratory for Genetic Improvement of Domestic Animal, College of Animal Science and Technology, Hunan Agricultural University, Changsha, China*

It has been demonstrated in previous researches that dietary nutrients affect immune function through their regulations on producing and activating immune factors. This study was conducted to evaluate the effects of feeding a corn straw or mixed forage diet on immunity of lactating cows by analysing compositions of serum immunoglobulins (Igs), cytokines, inflammation factors and plasma lymphocyte subsets. Twenty primiparous, lactating and ruminally fistulated Holstein cows were used in this study. Cows were randomly assigned to high forage diet (HF, forage: concentrate = 60: 40) with Chinese wildrye, alfalfa hay and corn silage as the forage source or low forage diet (LF, forage: concentrate = 40: 60) with corn straw as the forage source. This experiment lasted for 2 months, and blood samples were obtained via jugular vein before morning feeding at the last day of the trial period. Plasma lymphocyte subsets were determined by flow cytometry and other indexes were measured with ELISA kits. Data were analyzed using the PROC MIXED procedure of SAS 9.1. The results showed that levels of serum IgA (37.81 and 39.77 ng/mL), secretory IgA (sIgA) (1.55 and 1.59 ng/mL), interleukin-2 (IL-2) (132.55 and 137.96 ng/L), IL-4 (33.53 and 35.22 ng/L), IL-6 (8.27 and 8.53 ng/L), IL-10 (37.65 and 39.47 ng/L), IL-12 (31.57 and 33.66 ng/L), interferon-α (IFN-α) (16.71 and 16.94 ng/L), IFN-γ (865.44 and 851.58 ng/L), tumor necrosis factor-α (TNF-α) (199.49 and 206.46 ng/L), prostaglandin E_2 (PGE_2) (152.86 and 160.95 ng/L) and plasma $CD4^+$ lymphocyte subset (27.88 and 30.54%), $CD8^+$ lymphocyte subset (21.02 and 22.25%) and $CD4^+/CD8^+$ ratio (1.57 and 1.57) were not affected by experimental treatments ($P > 0.05$), and cows in LF group tended to have higher serum IgE (498.55 and 469.64 ng/mL, $P = 0.09$), IgM (195.01 and 182.75 ng/mL, $P = 0.09$) and insulin-like growth factors-1 (IGF-1) (15.14 and 13.78 μg/L, $P = 0.06$) concentrations than those in HF group, while serum IgG (16.57 and 17.46 μg/mL, $P = 0.09$) level tended to be higher in HF group ($P < 0.10$). The results of this study indicated that different dietary systems had no effect on immunity in lactating cows.

Key Words: diet system, dairy cow, immunity

1808 (W267) Fatty acid composition of milk from cows supplemented with canola oil.

K. C. Welter, C. M. de Magalhães Rodrigues Martins, M. M. Martins, B. Roqueto dos Reis, J. G. Rebelato Forti, A. Soligo Vizeu de Palma, B. L. Unglaube Schmidt and A. Saran Netto*, *University of São Paulo, Pirassununga, Brazil*

The objective of this study was to evaluate the inclusion of canola oil in the diet of dairy cows on the fatty acid (FA) composition of milk. Eighteen lactating Holstein cows were distributed in 6 contemporary 3 x 3 Latin Square, 3 periods and 3 treatments: T1 = control diet (without oil), T2 = inclusion of 3% canola oil and T3 = 6% inclusion of canola oil in the diet (dry matter). The cows were individually fed. The experiment was conducted during three periods of 21 days, with 14 days for adaptation and seven days to collections. The milk samples were collected to determine the fatty acid composition on the last day of each experimental period. Identification and quantification of fatty acid were done by gas chromatograph (column of 100 meters using hydrogen carrier gas). The results were analyzed using the MIXED procedure of SAS (2001). The effects of treatments were analyzed using two orthogonal polynomial contrasts: linear (L) and quadratic (Q), the significance

Table 1808. Fatty acid composition (g/100g total FA) of milk from cows fed canola oil

Fatty acid composition	Inclusion of canola oil (%)				*P*	
	0	3	6	*SEM*	*L*	*Q*
Saturated	64.91	55.29	51.42	1.25	< 0.0001	= 0.033
Y = 63.97(1.11)– 2.1958(0.1677)X						
Unsaturated	34.48	43.53	47.52	0.98	< 0.0001	= 0.0049
Y = 35.4756(1.1284) + 2.1664(0.1748)X						
Omega-3	0.20	0.39	0.43	0.02	< 0.0001	= 0.0008
Y = 0.2286(0.0268) + 0.03369(0.005927)X						
Omega-6	1.98	2.08	2.11	0.05	0.273ns*	0.728ns
Omega-6/Omega-3	11.51	5.52	5.33	0.06	< 0.0001	= 0.0002
Y = 10.49(0.6779)– 1.055(0.1728)X						
Thrombogenicity	2.92	1.99	1.74	0.09	< 0.0001	= 0.001
Y = 2.78(0.10)– 0.1948(0.02030)X						
Atherogenicity	2.43	1.52	1.25	0.09	< 0.0001	= 0.0002
Y = 2.32(0.096)– 0.1952(0.01845)X						

ns = not significant.

declared at $P \leq 0.05$. The inclusion of 6% of canola oil in the diet increased 53.49% of milk omega-3 concentration and reduced 53.69% of omega-6/omega-3 ratio, in compare with the control treatment. The thrombogenicity (capacity to promote heart attacks and strokes) and atherogenicity (capacity to promote atherosclerosis) decreased linearly ($P < 0.0001$) with the inclusion of canola oil in the diet (Table 1808). In conclusion, canola oil alters the fatty acid composition of milk, resulting in healthier milk with nutraceutical properties.

Key Words: omega-3, dairy, nutraceutical, health

1809 (W268) Effects of a corn straw or mixed forage diet on bovine milk fatty acid biosynthesis. M. Zhao[1], D. P. Bu[1], J. Q. Wang[*1], X. Q. Zhou[1,2], Y. Zhang[1] and P. Sun[1], *[1]State Key Laboratory of Animal Nutrition, Institute of Animal Science, Chinese Academy of Agricultural Sciences, Beijing, China, [2]Northeast Agricultural University, Harbin, China*

The study was designed to investigate the effects of different forage types on milk fatty acid (FA) profile. Thirty two dairy cows were divided into group MF (alfalfa and corn silage as forage source) and group CS (corn stover as forage source). The whole experiment lasted for 15 wk (2-wk adaptation and 13-wk experimental period) following 2-wk covariate period (a total of 17-wk). Milk fat content and fatty acid profile were measured. Statistical analysis was performed using the PROC MIXED procedure of SAS 9.0. The results showed that milk fat content in group MF was higher than group CS, but no difference was observed (4.46 vs 4.38%, $P > 0.05$). The proportion of milk saturated fatty acid (SFA) was significantly higher in group MF (74.77 vs 69.93%). However, unsaturated fatty acid (UFA) in group CS was higher than group MF (25.23 vs 30.07%). Unlike polysaturated fatty acid (PUFA), proportion of monounsaturated fatty acid (MUFA) in group CS exhibited significantly higher level mainly due to the large proportion of *cis*-9 C18:1 (MUFA, 21.62 vs 26.51%). Feeding the MF diet significantly increased short- and medium-chain fatty acid (SMCFA) proportion but decreased long-chain fatty acid proportion in group MF (SMCFA, 47.38 vs 41.02%; LCFA, 52.62 vs 58.98%). Therefore, corn stover as forage source in the diet could increase the proportion of UFA but decrease the proportion of SMCFA in milk.

Key Words: alfalfa, corn silage, corn stover

1810 (W269) Influence of forage level and corn processing method on feeding behavior of Nellore bulls. M. Caetano[1,2], A. R. Cabral[3], G. B. Feltrin[1], R. S. Goulart[4], S. Luz e Silva[3], P. R. Leme[3] and D. P. D. Lanna[*1], *[1]University of Sao Paulo/ESALQ, Piracicaba, Brazil, [2]University of Adelaide, Roseworthy, Australia, [3]University of Sao Paulo/FZEA, Pirassununga, Brazil, [4]MSD Saúde Animal, Sao Paulo, Brazil*

The objective of this study was to investigate the influence of neutral detergent fiber from forage (NDFf) levels and corn processing methods (CPM) on feeding behavior of finishing *Bos indicus* cattle fed high-concentrate corn-based diets. Forty Nellore bulls (388.1 ± 25.8 kg) were used in a randomized complete block design in a 4 x 2 factorial arrangement. Four levels of NDFf (3, 8, 13, and 18% sugarcane silage DM basis) were evaluated for two CPM: high moisture corn (HMC) and finely ground dry corn (FGC). Animals were fed ad libitum for 81 d, with diets delivered twice daily in individual pens. Sugarcane silage contained 64.0% NDF and 10.8 mm of mean particle size, all diets had 8% of whole linted cottonseed and the geometric particle sizes were 1.30 and 5.84 mm for FGC and HMC, respectively. Feeding behavior was evaluated twice (24 h each period) with fixed intervals of five min. Activities evaluated were eating, drinking, ruminating (R), chewing (C) and idling (min/d). Intake (IN), rumination (RU) and total chewing rate (TCR) were calculated (min/kg of DM). Number of meals (NM), interval between meals (IR) and meal duration

(MD) were estimated (min). The first derivative was solved of a 2nd order polynomial to determine optimal NDFf level. Animals fed HMC had 12.6% lower DMI ($P < 0.01$) and 6.1% lower ME intake (MEI; $P = 0.04$) compared to those fed FGC, but the IN was 21.6% greater for HMC than FGC ($P < 0.01$). There was a quadratic effect of NDFf on DMI ($P < 0.01$), MEI ($P < 0.01$) and IN ($P < 0.01$), with 10.8, 11.4 and 10.0% NDFf yielding the highest intakes, respectively. These NDFf levels to achieve maximum DMI and MEI are greater than recommendations in literature. Interactions between CPM and NDFf were observed for R ($P < 0.01$) and C ($P < 0.01$), however, when the RU and TCR were calculated, linear effects of NDFf were found for both. Increasing NDFf level increases the RU ($P < 0.01$) and TCR ($P < 0.01$). The HMC increases NM ($P < 0.01$) and decreases IR ($P < 0.01$) and MD ($P < 0.01$) when compared to FGC. Increasing NDFf level increased linearly the MD ($P < 0.01$). In conclusion, zebu cattle required around 11% NDFf to maximize DMI and MEI. The HMC increased the NM (min) and the IN (min/kg of DM).

Key Words: behavior, feedlot, zebu

1811 (W270) Evaluation of a hand-held meter to detect subclinical ketosis in dairy cows. Z. J. Cao*, S. S. Xu and S. L. Li, *State Key Laboratory of Animal Nutrition, College of Animal Science and Technology, China Agricultural University, Beijing, China*

TNN is a new hand-held meter for detecting subclinical ketosis of dairy cows by determining blood β-hydroxybutyrate (BHBA). The objective of this study was to evaluate the performance of this new cowside test by comparing BHBA results obtained using the hand-held meter with those results made with a laboratory method and comparing the accuracy between diagnostic performance using blood and using milk and urine. 275 blood samples and 97 urine samples and 85 milk samples from clinically healthy Holstein cows between 1 and 58 days post-calving were analysed. The correlation coefficients for BHBA with TNN versus laboratory methods were 0.92. Based on Bland-Altman plot, agreement between two methods was good for BHBA. In this study, the TNN test had sensitivities of 75 and 88% at 1.2 and 1.4 mmol of BHBA/L of whole blood, respectively. Specificities were 97 and 99%, respectively. Compared with TNN the sensitivities and specificities of urine test and milk test were lower. The sensitivities and specificities were 57 and 80% for milk tests, respectively, and 71 and 94% for urine tests, respectively, when 1.2mmol/L of blood was defined as the threshold. Raising the threshold of laboratory method to 1.4mmol/L, The sensitivities and specificities were 75 and 79% for milk tests, respectively, and 75 and 93% for urine tests, respectively. We conclude that TNN is a useful tool to diagnose subclinical ketosis and blood tests are better methods than urine tests and milk tests due to higher sensitivity and specificity.

Key Words: subclinical ketosis, β- hydroxybutyrate, diagnostic

1812 (W271) Effects of rumen protected choline supplementation on milk yield and plasma metabolites in dairy cows fed hay based diets. L. Pinotti*, M. Ottoboni, V. Caprarulo, A. Pilotto, A. Agazzi, G. Invernizzi, A. Baldi and G. Savoini, *Università degli Studi di Milano, Dep. VESPA, Milan, Italy*

Most of studies on the effect of rumen protected choline (RPC) supplementation in dairy cows have been done using silage based diets. Accordingly, the aim of the study was to evaluate the effect of RPC supplementation in early lactating dairy cow receiving hay-based diet. For this purpose 12 Italian Holstein multiparous cows, in the first month of lactation (28 DIM), were divided into two experimental groups: control group (CTR) receiving no choline, and RPC group receiving 20 g/day of choline in rumen protected form (Balchem Inc., New Hampton, NY). Diets contained 50% hay (alfalfa and Meadow Hay), and 50% concentrates. Cows were housed at the Animal Production and Research of the Università degli Studi di Milano, fed in a Roughage Intake Control feeding system, and milked twice a day. The experiment lasted 9 weeks. Dry matter intake and milk yield were measured daily. Plasma was collected on week 1, 2, 3, 5, and 9 of the experimental period and analyzed for glucose, cholesterol, triglycerides, nonesterified fatty acids, betaidrossibutirrate and urea N. Before statistical analysis, daily measurements for DMI and milk yield were condensed to weekly means. Data were analysed as a completely randomized design by Proc MIXED procedure of SAS using treatment and time as fixed factors and cow within treatment as a random factor. The REPEATED statement was used for variables measured over time. Through the 9 weeks, treatment did not affect DMI (22.7 vs. 23.5 kg/d in CTR and RPC respectively) and milk yield (28.2 vs. 29.4 kg/d). Dietary treatment did not affect the metabolic profile of experimental cows, except for plasma glucose concentrations that tended ($P = .010$) to be higher in RPC cows than those of CRT (61.08 vs. 56.75 mg/dL). In this study RPC supplementation did not reveal any alterations in milk yield and serum metabolites in dairy cow receiving a hay-based diet, even though an exhaustive comparison with silage-based diet, merit further investigations.

Key Words: choline, hay based diet, milk yield

1813 (W272) Liver metabolism of Holstein cows is altered by nutrient supply but not by lipopolysaccharide in vitro. M. Garcia*, B. J. Bequette and K. M. Moyes, *Department of Animal and Avian Sciences, University of Maryland, College Park*

Recent work suggests liver function is reduced during inflammation. To our knowledge, no studies have examined whether increased amino acid or propionate supply improves hepatic function during inflammation and how this is altered by stage of lactation. The objective of the current study was to characterize the effect of nutrient supply and lipopolysaccharide (LPS) challenge on hepatic intermediate metabolism for cows in early and mid-lactation by employing gas chromatography–mass spectrometry (GC-MS) and stable isotope tracer ([$^{13}C_3$] pyruvate). Liver samples were collected via biopsy from healthy early (n = 6, < 21 DIM) and mid-lactation (n = 6, < 110 DIM) Holstein cows. Liver slices were incubated for 2 h at 37°C in 3 mL of Krebs-Ringer bicarbonate buffer containing 2 mM of a 50:50 mix of labeled and unlabeled [$^{13}C_3$]pyruvate with addition of either phosphate buffered saline (control), 2 mM propionate, or 2 mM amino acids, with or without addition of LPS (200 ng/mL). Krebs cycle intermediates were determined by GC-MS by monitoring alanine, aspartate, and glutamate, which are in metabolic equilibrium with Krebs cycle intermediates. Data were analyzed as a randomized block design in a 3×2×2 factorial arrangement. Significance was declared at $P < 0.05$. Overall, LPS challenge had minimal effects on intermediary metabolism. Regardless of nutrient supply, the ^{13}C kinetics demonstrated that the liver of early lactation cows exhibits higher relative activity of phosphoenolpyruvate carboxykinase (PEPCK), a tendency for greater flux of pyruvate to oxaloacetate ($P = 0.07$, 82 vs. 74%), and a lower relative activity of pyruvate dehydrogenase (PDH) compared to pyruvate carboxylase (PC) when compared to cows in mid-lactation. Regardless of stage of lactation, propionate and amino acids increased the proportion of acetyl-CoA derived from pyruvate (13 and 10%, respectively) compared to control (7%), with no difference in the flux of oxaloacetate that derived from pyruvate. Moreover, propionate increased the relative activity of PDH compared to PC. In conclusion, results suggest that the LPS endotoxin exposure in vitro does not impair liver metabolic function and that cows in early lactation had a greater gluconeogenic capacity than cows in mid-lactation.

Key Words: cows, liver, nutrient flux

1814 (W273) Effect of postruminal infusion of fructose on hepatic steatosis. K. E. Boesche*, J. E. Sibray, S. L. Koser and S. S. Donkin, *Purdue University, West Lafayette, IN*

Periparturient dairy cattle are prone to metabolic disease and frequently experience hepatic steatosis. A more complete understanding of the development and impact of hepatic steatosis has been hampered by the lack of a predictable and convenient steatosis induction model. Intensive fructose consumption in both rats and humans rapidly results in hepatic steatosis and insulin resistance, but the impacts of fructose on hepatic steatosis in dairy cattle are unknown. The objective of this study was to examine the effects of postruminal fructose supply on accumulation of liver triglycerides (TG) and other parameters of fatty liver disease in lactating dairy cattle. Eighteen multiparous late-lactation (241.7 ± 28.5 d in milk) Holstein cattle were assigned to either control (CON), postruminal fructose infusion (INF), or a pair-fed (PAIR) group. INF cows were previously fitted with rumen cannulae and received 1000 g/d D-fructose for 7 d as a 16.67% w/v fructose solution delivered postruminally. Fructose dose averaged 1.47 g ± 0.11/kg body weight (BW) and was delivered over a 23 h period. Amount of feed offered to PAIR group was matched to the previous 24 h intake of INF cows to account for any potential impact of fructose infusion on voluntary feed intake. CON group was fed ad libitum. There were no differences ($P > 0.1$) between groups in BW or body condition score before or after the infusion period. Milk production decreased (26.2, 23.1, 23.3 ± 0.79 kg for CON, INF, PAIR, respectively; $P < 0.05$) in both INF and PAIR groups during infusion period and was accompanied by decreased feed intake (23.5, 20.1, 19.4 ± 1.21 kg/d dry matter intake; $P < 0.05$). Plasma TG levels were not significantly different ($P > 0.1$) before, during, or after fructose infusion, but were numerically lower in INF, compared to PAIR, after infusion. Liver TG levels did not differ ($P > 0.1$) by group before or after infusion. Plasma fructose levels tended to remain high (602.9, 485.8 ± 44.60 μM for INF, PAIR, respectively; $P < 0.1$) in INF group after infusion period. Plasma glucose levels did not differ ($P > 0.1$) by group, nor did serum nonesterified fatty acid levels ($P > 0.1$). Data do not support the use of 7 d postruminal infusion of D-fructose at 1000 g/d as a model to study hepatic steatosis in lactating dairy cattle.

Key Words: fructose, hepatic steatosis, postruminal infusion

1815 (W274) Effects of rare earth-chitosan chelate on liver and kidney parameters in lactating dairy cows. J. Li[1,2], J. Q. Wang[1], P. Sun[1], F. D. Li[2] and D. P. Bu*[1], *[1]State Key Laboratory of Animal Nutrition, Institute of Animal Science, Chinese Academy of Agricultural Sciences, Beijing, China, [2]College of Animal Science and Technology, Gansu Agricultural University, Lanzhou, China*

Rare earth-chitosan chelate (RECC) formed by β-NH_2 and rare earth ions with glucosamine molecule (1,4)-OH on the glycosidic bond, have been used as a new chelating ligand feed additives to promote efficient feed utilization in ruminants and improve animal productivity while reducing the need for

antibiotics and chemical additives. Numerous reports have indicated that suitable amount of RECC mixtures in the diet increase not only the liveweight gain of livestock and poultry but also milk and egg production. The objective of this study was to determine the effect of different proportion of rare earth-chitosan chelate (RECC) on hepatic and renal function of lactating dairy cows. Forty-eight lactating Holstein dairy cows (DIM = 130 ± 5, average milk yield = 33.2 ± 5.1 kg/d) were randomly assigned to 4 treatments (n = 12) with addition of RECC (0 (control), 0.15%, 0.75%, and 1.5%, respectively) in diets. The experiment lasted for 9wk with the first week for adaptation. Blood was collected in evacuated tubes via caudal venipuncture at 0, 2, 4, 6, 8 week and the tubes with blood samples were centrifuged at 3500 × g for 15 min to obtain serum, which was separated into several aliquots and stored at −80°C in an ultra-low-temperature freezer until further analysis. Data were analyzed by mixed or GLM procedure of SAS software. No significant differences (P > 0.05) were found for the activity of glutamic-pyruvic transaminase (ALT) and glutamic oxalacetic transaminase (AST), total protein (TP), albumin (ALB), globulin (GLB), Uric Acid (UA) and urea nitrogen(UREA) in all the dietary treatments. Compared with control, there were no difference (P > 0.05) in total bile acid (TBA) and creatinine (CRE) between 0.15% RECC and 0.75% RECC treatments, while increased (P < 0.05) when the RECC adding dose up to 1.5%. Feeding 0.15% or 1.5% RECC resulted in higher total bilirubin(TBIL)(5.77, 6.05 umol/L vs. 4.89, 4.89 umol/L) and indirect bilirubin (DBIL) (2.30, 2.54 umol/L vs. 2.00, 1.93 umol/L) vs. control and 0.75% RECC group (P < 0.01). These results suggested that the adding doses of RECC in dietary did not affect the activity of ALT and AST, while TBA, CRE, TBIL and DBIL were significantly increased in 0.15% RECC. So it was concluded that adding 1.5% RECC in dietary has a negative effect on the function of liver and kidney in dairy cows.

Key Words: dairy cows, liver and kidney parameters, rare earth-chitosan chelate

1816 (W275) Supplementation of *Aspergillus oryzae* α-amylase on ruminal volatile fatty acid distribution and digestive tract gene expression in beef steers fed a steam-flaked corn based finishing diet.

B. N. Gordon[1], S. W. Hahm[*1], J. J. Wagner[1], J. S. Jennings[2], H. Han[1] and T. E. Engle[1], [1]*Colorado State University, Fort Collins,* [2]*Texas A&M AgriLife Research, Amarillo*

The objective of this study was to investigate the impact of *Aspergillus oryzae* α-amylase (AAM) supplementation on rumen VFA profile and relative abundance of mRNA associated with nutrient absorption in ruminal and duodenal tissue from beef steers. Nine crossbred steers (average BW 622 ± 50 kg), with rumen and duodenal fistulas were housed in individual stations and fed a high concentrate finishing diet twice daily for 8 d. Treatments included CON (corn meal; n = 5) and AAM (750 fungal α-amylase units/g; n = 4). Dietary treatment supplements were applied as a top dress (3 g of α-amylase or corn meal into 150 g of dried distiller's grains (DDG) for the AM feeding and 2 g of α-amylase or corn meal into 100 g of DDG for PM feeding). On d 5, rumen fluid samples were obtained every 4 h for 24 h and analyzed for VFA concentration. On d 9, rumen papillae and duodenal mucosal tissue samples were collected. Total tissue RNA was extracted for real-time PCR analysis. Sodium/potassium ATPase pump α1, glucose transporter 2 and 5, putative anion transporter, isoform1, sodium/hydrogen antiporter isoforms1, 2 and 3, 3-hydroxy 3-methylglutaryl coenzyme A synthase isoform2, down regulated in adenoma, monocarboxylate co-transporter isoform1, and glyceraldehyde-3-phosphate dehydrogenase mRNA were tested. Relative expression (fold change) of mRNA in ruminal and duodenal tissues were analyzed using PROC GLM and VFA distribution was analyzed as a randomized block design with repeated measures using the MIXED procedure of SAS. Concentrations of VFA and the acetate to propionate ratio were similar across treatments. However, acetate:propionate ratio and butyrate molar percentage were numerically greater (P = 0.17) in AAM steers compared to controls. Genes tested were not significantly changed by AAM supplementation in the rumen or duodenum. However, genes involved in nutrient absorption were numerically decreased in the rumen and increased in the duodenum in the AAM supplemented steers compared to the controls.

Key Words: duodenum, fungal α-amylase, gene, rumen, steer, volatile fatty acids

1817 (W276) Effects of rumen-protected choline during the transition period on nonesterified fatty acids and β-hydroxybutyrate concentrations in periparturient dairy cattle.

I. M. Lima[1], R. A. Silva[1], C. H. Ramires[1], S. L. Viechnieski[2] and R. D. Almeida[*1], [1]*Universidade Federal do Paraná, Curitiba- Paraná, Brazil,* [2]*StarMilk Farm, Céu Azul- Paraná, Brazil*

The effects of rumen-protected choline (RPC) on nonesterified fatty acids (NEFA) and β-hydroxybutyrate (BHBA) concentrations, body condition score (BCS), and milk fat to protein ratio (FPR) were evaluated in periparturient dairy cows. Pregnant Holstein cows (n = 106) and heifers (n = 52) in a commercial farm in Southern Brazil were blocked by parity and expected day of calving and randomly assigned to 2 treatments. Cows in the first treatment were supplemented with rumen-protected choline (RPC; Reashure, Balchem Corp.), whereas cows in the second treatment were not supplemented (CON). All animals were housed together in transition pens, and RPC cows were individually top-dressed 60 g/d RPC to provide 17.3 g of choline while restrained in feedline headlocks from 21 d before to 28 d after calving. The CON diets

were top-dressed with 60 g/d of corn meal. Four blood samples were collected from each animal (7 d before calving, at calving, 7 and 14 d after calving). Data was analyzed using MIXED procedure of SAS with a model containing the effects of block, treatment, time, and treatment*time interaction as fixed effects, prepartum BCS as a covariable, and cow within treatment as a random effect. Body condition score did not differ ($P > 0.05$) between RPC and CON cows in all three observations (21 d before calving, at calving, and 28 d after calving). Multiparous cows showed greater ($P < 0.01$) NEFA and BHBA concentrations than primiparous ones; 0.361 ± 0.017 mmo/L vs. 0.294 ± 0.023 mmol/L; and 0.646 ± 0.019 mmo/L vs. 0.562 ± 0.024 mmol/L, respectively. Concentrations of NEFA peaked ($P < 0.01$) at calving; 0.473 ± 0.021 mmo/L, whereas BHBA concentrations peaked ($P < 0.01$) at 14 d after calving; 0.724 ± 0.044 mmol/L. Nonesterified fatty acids concentrations did not differ ($P > 0.05$) between RPC and CON cows; 0.355 ± 0.017 mmol/L vs. 0.324 ± 0.017 mmol/L. Similarly, BHBA concentrations did not differ ($P > 0.05$) between treatments; 0.633 ± 0.020 mmol/L vs. 0.606 ± 0.020 mmol/L, respectively for RPC and CON cows. Finally no milk FPR differences ($P > 0.05$) were observed between RPC and CON cows in the first test-day after calving; 1.30 vs. 1.34. In the particular conditions of this on-farm trial with very modest lipid mobilization (3.35 BCS at 21 d before calving and 3.10 BCS at 28 d after calving) no benefits on RPC supplementation were detected.

Key Words: choline, dairy cows, ketosis

1818 (W277) Effects of replacing alfalfa hay and corn silage with corn straw in diets on main hormones in blood of dairy cows.

X. Q. Zhou[1,2], D. P. Bu[2], Y. D. Zhang[2], M. Zhao[2], P. Sun[2] and J. Q. Wang[*1,2], *[1]Heilongjiang Bayi Agricultural University, Daqing, China, [2]State Key Laboratory of Animal Nutrition, Institute of Animal Science, Chinese Academy of Agricultural Sciences, Beijing, China*

To study the effects of replacing alfalfa hay and corn silage with corn straw in diets on main hormones related to metabolism in blood of Holstein cows, Twenty-four firstborn and healthy Holstein lactating dairy cows with similar DIM (55 ± 27 d) and body weight (520 ± 25 kg) were randomly divided into 2 groups. Diets contained similar concentrate mixtures with the same forage-to-concentrate ratio of 36:64 (dry matter basis). Different forage sources were then added: 17.30% alfalfa hay and 18.77% corn silage (MF); 36.07% corn straw (CS). The preliminary experiment lasted for 2 wks followed by a 60-day former experiment. The blood samples on d 61 were collected and evaluated the concentrations of insulin (INS), growth hormone (GH), leptin (LEP),cortisol (COR), insulin-like growth factor-1(IGF-1) and prolactin (PRL) in serum. Compared with the MF group, the concentrations of IGF-1 (384.31 vs 311.73%, $P < 0.01$) and LEP (3.67 vs 3.12%, $P < 0.05$) in CS group were significanly increased, but the concentrations of PRL (175.51 vs 230.37%, $P < 0.05$) was decreased. No difference was observed in other hormones ($P > 0.05$). Results showed that under the condition of the same concentrate, different forages can greatly affect concentrations of some hormones in the blood which closely relate to the changes of body's immune and production performance.

Key Words: corn straw, dairy cows, hormones

1819 (W278) Body condition score at calving alters the hepatic transcriptome in grazing dairy cattle.

H. Akbar[1], Z. Zhou[*1], K. Macdonald[2], K. E. Schütz[3], G. Verkerk[2], J. R. Webster[3], S. L. Rodriguez Zas[1], J. R. Roche[2] and J. J. Loor[1], *[1]University of Illinois, Urbana, [2]DairyNZ, Hamilton, New Zealand, [3]AgResearch, Hamilton, New Zealand*

The objective of this study was to use transcriptomics and bioinformatics to evaluate changes in hepatic gene expression profiles in cows managed to achieve a high (H, 5.5 BCS), medium (M, 4.5 BCS), or low (L, 3.5 BCS) BCS (10-point scale). Target BCS at calving were achieved by managing feed allowance before dry off. Post-calving cows were allocated pasture and pasture silage. Liver from 10 cows per BCS group was biopsied on wk 1, 3, and 5 relative to parturition. A whole-transcriptome bovine microarray (Agilent) was used. An ANOVA with repeated measures using PROC MIXED resulted in 5888 DEG due to the main effect of BCS and 327 differentially expressed genes (DEG; False Discovery Rate < 0.05) due to BCS × wk. Bioinformatics analysis was performed with the Dynamic Impact Approach (DIA), focusing on pathways from the KEGG database. The BCS × wk DEG, analysis of most-impacted pathways revealed marked differences on wk 1 for H vs. L and M vs. L; 'fatty acid biosynthesis', 'biosynthesis of unsaturated fatty acids', 'ascorbate and aldarate metabolism', and 'steroid biosynthesis' were among the top 5 highly-impacted pathways when comparing H vs. L and L vs. M. All were highly-inhibited in H vs. L, but highly-activated in L vs. M. The degree of impact on pathways was quite low when comparing H vs. M on wk 1 and there were few differences in pathway flux (i.e. little change in activation/inhibition). Remarkably, on wk 3, pathways in L vs. M remained activated but signaling pathways such as NOD-like receptor, p53 signaling, and RIG-I-like receptor were among the most-impacted. The most-impacted pathways in H vs. L on wk 3 were, for the most part, the same as those observed on wk 1. 'Fatty acid biosynthesis' on wk 3 was the most-impacted pathway and markedly inhibited in H vs. M. Data from wk 5 indicate a lesser effect of BCS at calving on the transcriptome because impact values, regardless of BCS, were substantially lower than those in wk 1 and 3. However, it is noteworthy that the 'sulfur relay system' pathway, key for post-transcriptional RNA modifications in mammals, was the most impacted and inhibited pathway in H vs. M. Preliminary bioinformatics anal-

yses underscored the role of BCS at calving on liver function through alterations of the molecular phenotype and indicate a likely optimum BCS between 4.5 and 5.5.

Key Words: bioinformatics, nutrition, lactation

1820 (W279) Short term feed restriction increases afternoon but not morning milk fat concentration in lactating dairy cows. A. M. Abdelatty[*1,2], M. E. Iwaniuk[2], A. E. Weidman[2], B. B. Teter[2], M. A. Tony[1], F. F. Mohammad[1] and R. A. Erdman[2], *[1]Cairo University, Cairo, Egypt, [2]University of Maryland, College Park*

The elevated milk fat concentration exhibited by cows during the early periparturient period is related to the degree of body tissue mobilization. We hypothesized that feed restriction could be used as tool to study temporal changes in milk composition. Our objective was to test the effect of short-term feed restriction on milk fat concentration. Ten multiparous Holstein cows (100 + 17 DIM) were used in the 21 d study. During d 1 to 14, all cows were allowed ad libitum access to a total mixed ration that was formulated to meet 2001 NRC nutrient requirements for 40 kg/d milk production and this period was used as covariate in the ANOVA. Treatments (Trt) consisted of either ad libitum (AL) or restricted (RES) feeding during d 15 to 18 where RES cows were fed 60% of their d 1 to 14 ad libitum intakes. All cows returned to ad libitum feeding on d 19 to 21. Cows were milked twice daily at 0630 and 1630 h and fed once daily at 0900 h. Milk production and composition were measured at each milking on d 13 to 21. As expected, milking time influenced milk production and composition ($P < 0.001$) for fat and protein. While feed restriction decreased ($P < 0.001$) milk production, but not milk protein and fat percent. There were treatment by milking time interactions for milk fat ($P < 0.001$) and protein ($P = 0.008$) percent which were increased at the 1630 h but not the 0630 h milking. A day by treatment by milking time interaction ($P < 0.02$) was observed for milk fat which showed the greatest elevation at the 1630 h milking on d 16. These results demonstrate that feed restriction can be used to study temporal changes in milk composition.

Key Words: feed restriction, milk composition, dairy cows

1821 (W280) The mRNA expression of the classical genes of enzymes involved in milk fatty acid synthesis does not explain milk fat depression in dairy cows. A. Siurana*, D. Gallardo and S. Calsamiglia, *Animal Nutrition and Welfare Service, Department of Animal and Food Sciences, Universitat Autònoma de Barcelona, Bellaterra, Spain*

Feeding polyunsaturated fatty acids (PUFA) to dairy cows results in milk fat depression (MFD) in some, but not all cows. The objective of this research was to compare the mRNA expression of enzymes involved in fatty acid (FA) synthesis in the mammary gland of cows resistant or sensitive to MFD resulting from feeding PUFA. Four cows were selected from a dairy farm after a switch from a control diet to a linseed-rich diet: two were resistant to MFD and had high milk fat content before and after the change (R-MFD); and two were sensitive to MFD and milk fat content decreased after the change into the linseed diet (S-MFD). Fresh milk samples were collected from each cow the week before and two weeks after the diet change, and analyzed for milk fat content, milk FA profile and transcriptional profiling of mRNA by Illumina RNA-sequencing technology. The study focused on the enzymes reported to be involved in MFD: acetyl-CoA carboxylase (ACACA), fatty acid synthase (FASN), glycerol-3-phosphate acyltransferase (GPAT), acylglycerol-3-phosphate acyltransferase (AGPAT), stearoyl-CoA desaturase (SCD1), fatty acid binding protein (FABP), lipoprotein lipase (LPL), sterol regulatory element binding protein (SREBP1) and spot 14 (S14). When S-MFD cows were fed linseed, milk fat decreased from 3.56 to 2.54%, the unsaturated:saturated FA ratio increased from 41/59 to 45/55 and short- and medium-chain FA proportion (C4 to C14 and 50% C16; SMFA) decreased from 33.9 to 32.8%, as expected, but there were no significant changes in the mRNA expression of the genes tested. When R-MFD cows were fed linseed, milk fat unexpectedly increased from 4.06 to 4.36%, the unsaturated:saturated FA ratio increased from 35/65 to 39/61,

Table 1820.

Milking:	0630 h		1600 h			*P* =		
Treatment	AL	RES	AL	RES	SEM	Time	Trt	Trt*Time
Milk, kg	21.6	19.2	18.8	15.2	0.72	0.007	0.001	0.014
Milk protein, %	2.88	2.87	2.73	2.87	0.058	0.001	0.392	0.001
Milk other solids, %	5.66	5.54	5.54	5.54	0.028	0.073	0.065	0.008
Milk Fat %								
Day 15	2.98	2.69	4.32	4.10	0.24	0.001	0.274	0.001
Day 16	2.96	2.89	4.30	5.86				
Day 17	2.96	2.87	4.20	4.94				
Day 18	3.00	2.89	4.16	5.10				
Days 19 to 21	3.03	2.86	4.12	3.89	0.13	0.001	0.232	0.742

SMFA proportion did not change (average of 31.4%) and only the expression of ACACA decreased and that of AGPAT6 and FABP3 increased. The unexpected over expression of AGPAT6 and FABP3 transcripts in R-MFD cows may be potential candidate genes involved in the MFD-resistance. Other genes that may also be involved need to be identified.

Key Words: milk fat depression, mRNA expression, extruded linseed.

1822 (W281) Effects of niacin supplementation and forage type on milk, digestibility, blood parameters and body temperature in lactating dairy cows.

R. B. Standish*, P. S. Erickson, N. L. Whitehouse, B. J. Isenberg, E. M. Barron, J. Y. Buckley and A. M. Pike, *University of New Hampshire, Durham*

This experiment evaluated the effect of niacin combined with either corn silage (CS) or grass silage (GS) based diets on apparent total tract nutrient digestibility, milk yield and composition, body temperature, and blood parameters. Four ruminally-cannulated Holstein cows were used in a 4 x 4 Latin square design with a 2 x 2 factorial arrangement of treatments with 28-d periods. Treatments were CS or GS based diets without or with 12 g niacin/d. One primiparous and three multiparous late lactation cows (225 ± 12 d in milk) were used. One cow was removed during the third period due to unrelated causes. Each period, dry matter intake (DMI) and milk production were recorded (d 19-28), and samples of blood (1300h, d 28), milk (0630 and 1730 h for 2 d), feeds (0545 and 1745 h on d 19-28), feces, and body temperature (both at 2-h intervals on d 26-28) were taken. Serum was analyzed for glucose and non-esterified fatty acids. Feed and feces were analyzed for acid insoluble ash, and digestibility was determined for dry matter (DM), organic matter (OM), crude protein (CP), neutral detergent fiber (NDF), acid detergent fiber (ADF), starch, fat, and hemicellulose (NDF-ADF). Data were analyzed using the mixed procedure of SAS. Orthogonal comparisons were used to evaluate main effects and interactions. Repeated measures were used to analyze body temperature and means were separated using Tukey's test. Intake of DM was greater (P = 0.01) for cows fed CS than for cows fed GS (29.01 and 24.09 kg/d, respectively). Digestibility of NDF was greater (P = 0.002) for cows fed GS than for cows fed CS (63.7 and 45.8%, respectively). Digestibilities of DM, OM, ADF, CP, and starch were similar among treatments. Hemicellulose digestibility was greater (P = 0.002) for cows fed GS versus cows fed CS (82.2 and 53.1%, respectively) because cows fed GS had lower DMI. Fat digestibility was greater (P = 0.02) for cows fed CS versus cows fed GS (93.0 and 82.4%, respectively). Milk yield was less for cows fed GS versus CS (20.0 and 29.9 kg/d, respectively). Fat (0.77 and 1.07 kg) and protein yields (0.61 and 0.96 kg) were less for cows fed GS versus CS (P = 0.02 and 0.04, respectively). Body temperature tended (P = 0.08) to be lower for cows fed GS and niacin (37.7°C) versus cows fed only CS (38°C). Niacin did not improve any parameter except for lowered body temperature.

Key Words: niacin corn silage grass silage

1823 (W282) Differences in hepatic transcriptional regulatory networks due to body condition score at calving in grazing dairy cattle.

H. Akbar[1], Z. Zhou*[1], K. Macdonald[2], K. E. Schütz[3], G. Verkerk[2], J. R. Webster[3], S. L. Rodriguez Zas[1], J. R. Roche[2] and J. J. Loor[1], *[1]University of Illinois, Urbana, [2]DairyNZ, Hamilton, New Zealand, [3]AgResearch, Hamilton, New Zealand*

Despite recent progress in nutrigenomics of peripartal dairy cattle, many components of transcriptional regulation in hepatic networks remain unknown. The objective of this study was to use gene network analysis on hepatic microarray data to identify transcription regulators (TR) and their target genes. Holstein-Friesian cows managed to achieve a high (H, 5.5 BCS), medium (M, 4.5 BCS), or low (L, 3.5 BCS) BCS (10-point scale) were used. Target BCS at calving were achieved by managing feed allowance before dry off. Post-calving, cows were allocated pasture and pasture silage (predominantly perennial ryegrass). Liver from 10 cows per BCS group was biopsied on wk 1, 3, and 5 postpartum. A whole-transcriptome bovine microarray (Agilent) was used. An ANOVA with repeated measures using PROC MIXED resulted in 5888 differentially-expressed genes (DEG) due to main effect of BCS (False Discovery Rate < 0.05) and 327 differentially expressed genes due to BCS × wk. TF network analysis was performed with Ingenuity Pathway Analysis (IPA). The network analysis uncovered TP53 as a central hub regulating a large spectrum of genes altered by BCS. Expression of TP53 was overall greater in H vs. M and L vs. M, but lower in H vs L. Other important TR altered by BCS were CTNNB1, SREBF1, RXRA, STAT1, NFKBIA and YWHAH. Among DEG with a BCS × wk effect due to H vs. M or L vs. M on wk 1, HNF4A was among 10 TR uncovered to have the greatest number of targets. Unlike wk 1, out of 9 TR identified in wk 3, the expression of MYC was downregulated in H vs. L but this TR had the greatest number of targets. Similarly, MYC had the greatest number of targets in L vs. M on wk 3 but was upregulated. Contrary to wk 1, on wk 5 the expression of MYC was upregulated in H vs. L and FOXP3 was identified as an important TR. Expression of FOXP3 on wk 5 was downregulated in H vs. M but among 16 TR identified it had the greatest number of targets. It is noteworthy that TP53, MYC, and FOXP3 are key controllers of cell proliferation/apoptosis in non-ruminant tissues/cells. Although HNF4A also is related with liver development, it has broader functions in terms of controlling expression of metabolic genes. Preliminary interpretation suggests an important role of a few TR in the control of liver function.

Key Words: gene networks, bioinformatics, systems biology

1824 (W283) Effects of a corn straw or mixed forage diet on mammary gland function and its endocrine regulation in early lactation dairy cows. T. Qin[1], H. Y. Wang[1], D. P. Bu[*2] and H. B. Zhu[1], *[1]Embryo Biotechnology and Reproduction Laboratory, Institute of Animal Science, Chinese Academy of Agricultural Sciences, Beijing, China, [2]State Key Laboratory of Animal Nutrition, Institute of Animal Science, Chinese Academy of Agricultural Sciences, Beijing, China*

The forage system is critical to lactation performance in dairy cows. The objective of this study was to evaluate the effects of two different forage patterns on the mammary gland and the endocrine regulation of its functions. Twelve multiparous, early-lactation Holstein cows were randomly assigned to high forage diet (MF, forage: concentrate = 60: 40) with Chinese wildrye, alfalfa hay and corn silage as the forage source or low forage diet (CS, forage: concentrate = 40: 60) with corn straw as the forage source. Body weight (BW), body condition score (BCS) and dry matter intake (DMI) of each cow were recorded. Milk yield were recorded daily,and milk compositions and somatic cell count (SCC) were detected. Blood samples were collected weekly, and mammary biopsies were taken on 16 days postpartum. Data were analyzed using the PROC MIXED procedure of SAS 9.1. From the 6-wk of lactation, cows fed MF diet produced more milk (23.05 and 18.24 kg/d; $P < 0.05$), and tended to produce more milk fat (1.08 and 0.81kg/d; $P = 0.07$) and protein (0.69 and 0.59kg/d; $P = 0.10$) compared with cows fed CS diet. In CS group, the milk SCC were greater than those in MF group (Somatic cell score: −5.25 and −6.88; $P = 0.02$). There were no differences in BW, BCS and DMI ($P > 0.05$). Compared to MF cows, insulin like growth factor-I (IGF-1) in blood (70.21 and 50.49 ng/mL; $P < 0.05$) and *IGF-1R* expression in mammary (1.86 ± 0.15 and 1.45 ± 0.11; $P = 0.02$) were lesser in CS group. Mean concentrations of serum BHBA (1.64 vs 0.51 mmol/L; $P < 0.0001$) and NEFA (832.3 vs 309.0 μEq/L; $P < 0.01$) in MF cows peaked in week 2 after calving, and greater than CS group. The secretory activity of mammary epithelial cells (MEC) and the rate of mammary cell proliferation in both groups had no significant difference ($P > 0.05$),but the rate of cell apoptosis in CS group were greater relative to the MF group (1429 ± 103 and 679 ± 128 counts/mm^2; $P = 0.003$). The results indicated that lactation performance of dairy cows were affected by forage patterns, which was closely related to their endocrine regulation in dairy cows.

Key Words: forage sources,mammary gland function,endocrine regulation

1825 (W284) Milk fatty acid profile of dairy cows grazing a tropical pasture supplemented with sources of rumen protected fat. J. D. Souza[*1], F. Batistel[2], C. Sitta[1] and F. A. P. Santos[2], *[1]University of Sao Paulo, Piracicaba, Brazil, [2]University of São Paulo, Piracicaba, Brazil*

The objective of this experiment was to investigate the effects of supplementation of early lactation dairy cows grazing a tropical pasture with diets containing calcium salts of palm oil (CSPO) or calcium salts of soybean oil (CSSO) on milk fatty acid profile. Twenty-seven cows (15 ± 3 DIM) were used in a randomized block design and subjected to the following treatments: a) control (no fat); b) 400 g CSSO cow^{-1} d^{-1}; c) 400 g CSPO cow^{-1} d^{-1}. Cows grazed paddocks of *Pennisetum purpureum* and received 8 kg cow^{-1} d^{-1} (DM) of concentrate twice daily. Treatment periods were 90 d in length and milk samples were taken at 30, 60 and 90 d of experimental period for milk fatty acid analysis by gas chromatography. Data were analyzed as repeated measures using a mixed model with block as random effect and means were compared by Tukey test. The CSSO increased C18:2 cis-9 trans-12, CLA cis-9 trans-11 and CLA trans-10 cis-12 in the milk fat compared with control and CSPO. Both fat sources increased C18:3 cis-9 cis-12 cis-15 in the milk fat. The *de novo* synthesis was reduced by both fat sources and the CSPO increased mixed fatty acids (C16 + C16:1), due to greater incorporation of C16 from the diet. The preformed fatty acids were increased by CSSO supplementation. The CSSO decreased total saturated fatty acids, and increased MUFA and PUFA compared to control and CSPO. Overall, both sources of fat changed the milk fatty acid profile, and CSSO increased unsaturated fatty acid whereas CSPO increased saturated fatty acids.

Key Words: palm oil, soybean oil, tropical pasture

Table 1825. Milk fatty acid profile of grazing dairy cows supplemented with fat

g/100g of fat	Control	CSSO	CSPO	SEM	*P*-value
C18:2 cis-9 trans-12	1.66^{c}	2.07^{a}	1.92^{b}	0.09	0.002
C18:3 cis-9 cis-12 cis-15	0.33^{b}	0.43^{a}	0.39^{a}	0.02	0.07
CLA cis-9 trans-11	0.66^{b}	0.86^{a}	0.69^{b}	0.05	0.005
CLA trans-10 cis-12	0.02^{b}	0.09^{a}	0.019^{b}	0.003	0.0001
De novo	25.6^{a}	20.8^{b}	21.4^{b}	0.99	0.005
Mixed	30.7^{b}	30.2^{b}	33.9^{a}	1.4	0.04
Preformed	43.7^{b}	49.0^{a}	44.7^{b}	2.2	0.04
Total of saturated	66.9^{a}	61.5^{b}	64.1^{a}	1.76	0.01
Total of MUFA	28.9^{b}	33.6^{a}	31.6^{ab}	1.3	0.04
Total of PUFA	4.2^{b}	4.9^{a}	4.3^{b}	0.24	0.02

1826 (W285) Evaluating daily variation in body weight, milk production, and rumination activity on a commercial dairy with robotic milking.
R. W. Bender*, D. E. Cook, T. L. Chandler, H. M. White and D. K. Combs, *Department of Dairy Science University of Wisconsin, Madison*

Emerging technologies allow commercial dairy producers to collect a wide array of individual cow data on a daily basis, with the potential to profoundly influence managerial and nutritional decision-making on a pen basis. The objective of this study was to utilize daily body weights, rumination activity, and milk production data from lactating dairy cows to evaluate random variation that exists on a commercial dairy. Data were obtained from a commercial robotic dairy farm in Melrose, WI via the Lely T4C herd management system for either a whole year (daily body weights and daily milk production) or one week (rumination). Data from approximately 500 cows in seven pens (1 pen per robot, approximately 70 cows per pen) was utilized. Cows were assigned to a pen post-calving and remained there until dry off. All data is presented as mean ± standard deviation. On this dairy, milk production averaged 37.4 kg, with a standard deviation of 1.0 kg among days within a pen, 14.4 kg among individual cows within a pen, and 21.2 kg among days within individual cows. Body weight averaged 689.2 kg, with a standard deviation of 4.5 kg among days within a pen, 75.6 kg among individual cows within a pen, and 34.6 kg among days within individual cows. Rumination (min per day) averaged 461.1 min, with a standard deviation of 6.1 min among days within a pen, 128.0 min among individual cows within a pen, and 43.6 min among days within individual cows. A statistical power calculation would suggest that with 7 pens and 95% confidence, a difference of 1.5 kg mean milk production, 6.5 kg mean body weight, or 8.0 min mean rumination time could be deemed statistically significant from day to day within this herd. Understanding the magnitude of the variability among these parameters could be a powerful tool to monitor pen level changes over a short period of time and implement immediate managerial modifications.

Key Words: body weight, milk production, rumination

1827 (W286) Peroxisome proliferator activated receptor-γ controls lipogenic gene networks in goat mammary epithelial cells.
W. Zhao[*1,2], J. Luo[1] and J. J. Loor[2], [1]*Northwest A&F University, Yangling, China,* [2]*University of Illinois, Urbana*

In non-ruminants, peroxisome proliferator-activated receptor-γ (*PPARG*) plays a crucial role in fatty acid (FA) metabolism through the regulation of lipogenic gene expression. However, whether or how *PPARG* regulates the activity of mammary lipogenic genes in ruminant mammary cells remains largely unknown. This study explored the potential role of *PPARG* in regulating mRNA expression of lipogenic genes in lactating goat primary mammary epithelial cells (GMEC). Adenoviral transfection of the *PPARG* response element into GMEC was used in this study. The *PPARG* agonist rosiglitazone (ROSI) was used to study gene expression changes in response to PPARG activation. Expression of 39 genes involved in milk fat synthesis plus 3 internal control genes was measured using qPCR. Data from triplicate cultures were log-transformed and statistically analyzed using the GLM of SAS. The multiple comparisons were corrected using Tukey's test and significance set at $P < 0.05$. Over-expression of *PPARG* without (Ad-PPARG+DMSO) or with (Ad-PPARG+ROSI) ROSI markedly upregulated ($P = 0.0001$) the expression of *PPARG* compared with the control (Ad-GFP (Green fluorescent protein)+DMSO) and ROSI (Ad-GFP+ROSI) treatments. Over-expression of *PPARG* without ROSI up-regulated ($P < 0.05$) the expression of some lipogenic enzymes (*ACSS2, ACSL1, SCD, DGAT1, FADS1, GPAM, LPIN1*), transcription regulators (*LXRα, MLXIPL, PPARG, PPARGC1B),* and components of the circadian CLOCK network (*CRY1, CRY2*). After ROSI treatment of PPARG-overexpressing GMEC there was a further and marked increase ($P < 0.05$) in the mRNA expression of lipogenic enzymes (*FASN, ACSS2, GPAM, LPIN1, ACSL1, SCD*), transcription regulators (*LXRα, PPARG, SREBF1, PPARGC1B*), and components of the circadian CLOCK network (*CLOCK, CRY1, CRY2*). It was noteworthy that expression of *RXRα*, a partner of *PPARG*, was down-regulated in PPARG-overexpressing GMEC with or without ROSI treatment. These results provide direct evidence that *PPARG* plays a crucial role in regulating fatty acid metabolism in goat mammary cells and underscore the importance of *PPARG* in the mammary gland during lactation.

Key Words: PPAR, nutrigenomics, milk fa synthesis

1828 (W287) Effects of ergot alkaloid exposure on serotonin receptor mRNA in the smooth muscle of the bovine gastrointestinal tract.
J. L. Klotz[*1], D. Kim[2], A. P. Foote[2] and D. L. Harmon[2], [1]*USDA-ARS, FAPRU, Lexington, KY,* [2]*University of Kentucky, Lexington*

Various serotonin (5HT) receptor subtypes have been located in the gastrointestinal tract and some are associated with gut motility. Cattle exposed to ergot alkaloids through consumption of contaminated feedstuffs have demonstrated signs (e.g.- increased rumen DM content and total content) that suggest a reduction in gut motility. Ergot alkaloids have been shown to interact with biogenic amine receptors and specifically serotonin receptors. Therefore, the objective of this study was to evaluate the effect of dietary exposure to ergot alkaloids has on the expression of 5HT receptor subtypes 5HTR2A (NM_001001157.1) and 5HTR4 (NM_001010485.1) in the smooth muscle of the reticulum, rumen, omasum, abomasum, duodenum, jejunum, ileum, cecum and colon of cattle. Ruminally cannulated Angus steers ($n = 12$; BW = 547 ± 31 kg)

were paired by weight and randomly assigned to 6 blocks. Steers were fed alfalfa cubes at 1.5 × NE_m and were ruminally dosed daily with 1 kg of either endophyte-infected (E+; 4.45 ppm ergovaline) or endophyte-free (E-) tall fescue seed for 21 d prior to slaughter. On d 22 steers were slaughtered and samples of smooth muscle from the different sites of the gastrointestinal tract were sampled, rinsed, homogenized in Tri-reagent, and total RNA was isolated. Semi-quantitative real-time PCR was conducted using SYBR green and glyceraldehyde 3-phosphate dehydrogenase (NM_001034034.2) as a reference gene. Resultant data were analyzed using mixed models of SAS. There was no interaction of sampling location by seed treatment for either gene evaluated. For 5HTR4 only the main effect of sampling location was significant ($P < 0.001$) with ileum and jejunum having the greatest amount of transcript ($P < 0.05$) followed by the colon and duodenum ($P < 0.05$). The remaining tissue sites did not differ. Expression of 5HTR2A in E- steers was greater ($P = 0.04$) than E+ steers with lower relative quantities of 5HTR2A in E+ steers for all tissue sampling locations except the abomasum ($P = 0.054$). The enteric 5HTR2A receptor is associated with smooth muscle contraction and the observed decrease in expression in E+ treated steers suggests that ergot alkaloids may play a role in negatively affecting gut motility. Future work will explore the effects alkaloids might have on genes that encode for the G proteins and other downstream signal transduction proteins associated with these 5HT receptors.

Key Words: bovine, ergot alkaloids, serotonin receptor

1829 (W288) Effect of mineral supplementation on lactational performance in early-lactating dairy cows fed a high-concentrate diet.

A. R. Alfonso-Avila[*1], E. Charbonneau[1], P. Y. Chouinard[1], G. Tremblay[2] and R. Gervais[1], *[1]Université Laval, Québec, QC, Canada, [2]Agriculture and Agri-Food Canada, Soils and Crops Research and Development Centre, Quebec, QC, Canada*

Previous studies reported an increase in milk fat synthesis when lactating dairy cows were fed diets with higher dietary cation-anion difference (DCAD) or K, supplied as K_2CO_3. This study investigated the effects of DCAD, cation source, and buffering capacity of the mineral supplement on lactational performance of early-lactating dairy cows fed a high concentrate diet. Ten primiparous and 25 multiparous Holstein cows averaging 38 ± 13 DIM were distributed according to a randomized block design (7 blocks) for 5 wk, including a 1-wk pretreatment collection period, used as a covariate. Treatments consisted of C) a basal diet formulated to contain 40% forage (60% corn silage) and 60% concentrate (16% CP, 47% non-fibrous carbohydrates, 29% NDF, DCAD +65 mEq/kg) as control; K1) C + 1.8% K_2CO_3 (DCAD: +326); K2) C + 2.6% $KHCO_3$ (DCAD: +324); K3) C + 1.9% KCl (DCAD +64); and Na) C + 1.4% Na_2CO_3 (+322). Orthogonal contrasts were used to assess the effects of K_2CO_3 (C vs. K1), buffering capacity (K1 vs. K2), DCAD (K1 vs. K3), and cation type (K1 vs. Na). Treatment period was 28 d with the last 5 d used for data and sample collection. The selected comparisons detected no effect of treatments on DMI (24.1 ± 1.2 kg/d; $P > 0.14$) and milk yield (36.8 ± 1.8 kg/d; $P > 0.12$). Blood K^+ concentration was higher in cows fed K1 (3.99 mmol/L) as compared with C (3.75; $P < 0.01$), K2 (3.79; $P = 0.02$), and Na (3.68; $P < 0.01$), whereas no difference was observed with cows fed K3 (3.89; $P = 0.20$). Blood Cl^- concentration was lower in cows fed K1 (106.1 mmol/L) as compared with Na (108.3; $P = 0.01$). However, no difference was observed in blood Na^+ concentration of cows fed K1 and Na (139.9 ± 0.4 mmol/L; $P = 0.18$). As compared with Na, cows fed K1 had a higher milk protein content (3.12 vs 2.93%; $P = 0.04$) but a similar milk protein yield (1087 ± 67 g/d; $P = 0.56$). Milk fat percentage was higher in cows fed K1 compared with C (4.03 vs 3.26%; $P = 0.02$), whereas milk fat yield (1305 ± 134 g/d; $P = 0.21$) or 4% fat corrected milk (34.0 ± 2.6 kg/d; $P = 0.61$) were not affected. As opposed to previously published results, under conditions of the current experiment, increasing DCAD or K^+ concentration in a high concentrate diet did not improve milk fat yield in early lactating cows.

Key Words: DCAD, potassium carbonate, milk fat synthesis

1830 (W289) Mineral profile, inmunoglobulins and antioxidant activity in culls cows fed DDGS.

A. Flores-Mariñelarena[*1], E. Acosta Sánchez[1], G. Corral-Flores[1], C. Rodríguez-Muela[1], J. A. Ramírez-Godínez[1], J. Dominguez-Viveros[1], A. Anchondo-Garay[1] and H. Ramírez-Garduño[2], *[1]Universidad Autónoma de Chihuahua, Chihuahua, Mexico, [2]INIFAP, Chihuahua, Mexico*

The objective was to evaluate the effect of four levels of Distillery Dry Grains (DDGS) in the diet of cull beef cows on body weight (BW) and average daily gain (ADG) every 15 d and the mineral profile (Zn, Mn and Cu) and immunoglobulins in blood serum, and the antioxidant activity (AA) in blood plasma (d 0 and d60). Thirty five mature cows of different genotypes with an average live weight of 350 ± 40 kg were randomly divided into four treatments with different levels of DDGS: T1 (Control, 0%, $n = 9$), T2 (5.7%, $n = 9$), T3 (11,23%, $n = 8$) and T4 (16.45%, $n = 9$). A completely randomized design with treatment and time of sampling as fixed effects was used. Data was analyzed with the GLM of SAS. For the multiple comparisons of means a Tukey's test was used. The BW and ADG were similar ($P > 0.05$) between treatments. Serum levels of Zn, Cu, and Mn between treatments did not differ ($P > 0.05$). During the feeding period the serum levels of Zn and Cu were similar ($P > 0.05$). However, levels of Mn were higher ($P < 0.05$) at d 0 than at d 60 (1.69 ± 0.11 μmol/L vs 1.36 ± 0.11 μmol/L, respectively). The AA

and immunoglobulins were similar ($P > 0.05$) between treatments at d 60, but were different ($P < 0.05$) at d 0 (5.74 ± 0.32 g *100 mL ^{1}) vs d 60 (8.12 ± 0.33 g *100 mL ^{1}) of the feeding period. It was concluded that the inclusion of DDG's in the diet of cull beef cows did not affect the ADG, the mineral profile and the AA. However, Mn concentration was reduced and immunoglobulin increased during the 60 d feeding period.

Key Words: cull cows, antioxidant activity, mineral profile, immunoglobulin

1831 (W290) Metabolic characteristics and truly metabolizable protein supply to dairy cattle from new cool-season forage corn varieties in western Canada. S. Abeysekara, D. A. Christensen, N. A. Khan, X. Huang* and P. Yu, *University of Saskatchewan, Saskatoon, SK, Canada*

The objectives of the present study were to quantitatively evaluate the metabolic characteristics of protein in the rumen and intestine of dairy cattle and to estimate the content of truly metabolizable protein (MP) in newly developed cool-season forage corn varieties. Six new corn cultivars, including 3 Pioneer (PNR) and 3 Hyland (HL), coded as PNR-7443R, PNR-P7213R, PNR-7535R, HL-SR06, HL-SR22, HL-BAX-XOS-RR, were evaluated in the present study. The metabolic characteristics, MP supply to dairy cattle, and energy synchronization properties were modeled by the DVE/OEB system and the NRC-2001 model. The parameters evaluated were (1) potential microbial protein (MCP) synthesis in the rumen from available degraded protein and energy (2) truly absorbable rumen synthesized microbial protein (AMCP) (3) truly absorbable rumen undegraded feed protein (ARUP) (4) truly absorbed rumen endogenous protein and (5) total truly MP (6) the degraded protein balance (DPB). Both models estimated significant ($P < 0.05$) differences in contents of MCP synthesized from rumen degraded protein (RDP) and ARUP among the cultivars. The NRC-2001 model estimated significant ($P < 0.05$) differences in total truly MP and DPB among the cultivars. According to NRC-2001 model, the contents AMCP, ARUP and total truly MP contents were higher ($P < 0.05$) for cultivar HL-SR06, resulting in the lowest ($P < 0.05$) DPB. Cultivar, HL-SR06 also had the highest rumen available N/kg of organic matter (OM) and high hourly effective degradability ratios among the corn cultivars. However, none of the cultivars reached the optimal target hourly effective degradability ratio (25 g N g/kg OM), demonstrating N deficiency in the rumen. Hyland-SR06 had the highest contents of MCP synthesized from RDP, ARUP and total truly MP. However, regardless of the differences among cultivars, forage corn based rations of dairy cows needs to be balanced with a high protein containing concentrate to improve the rumen degradable protein deficit.

Key Words: corn, protein metabolic characteristics, protein evaluation system

1832 (W291) Hepatic expression of genes associated with glutathione and fatty acid metabolism during the peripartal period reveal beneficial effects of MetaSmart and Smartamine M supplementation on health status in dairy cows. J. S. Osorio[1], P. Ji[2], J. K. Drackley[3], D. N. Luchini[4] and J. J. Loor*[3], *[1]University of Illinois, Champaign, [2]William H. Miner Agricultural Research Institute, Chazy, NY, [3]University of Illinois, Urbana, [4]Adisseo S.A.S., Alpharetta, GA.*

Fifty-seven multiparous Holstein cows were fed a control diet (CON, $n = 24$; 1.49 Mcal/kg DM prepartum and 1.75 Mcal/kg DM postpartum), CON plus MetaSmart (MS, $n = 15$; Adisseo France S.A.S.), or CON plus Smartamine M (SM, $n = 18$; Adisseo France S.A.S.). Treatments began on -21 days in milk (DIM) and continued through 30 DIM. MetaSmart (0.19% of DM) and SM (0.07% of DM) were top-dressed on the CON diet. Liver samples (n = 8-9/treatment) collected at -10, 7, and 21 DIM were used for real-time qPCR of genes associated with metabolism of Met, glutathione, fatty acid, and gluconeogenesis as well as inflammation, oxidative stress, hepatokines, growth hormone signaling, and DNA methylation. Data were analyzed using the MIXED procedure of SAS with the preplanned contrast CON vs. MS+SM. Expression of Met adenosyltransferase 1A (*MAT1A*) increased ($P = 0.001$) over time (-10 vs 21 d) in Met-supplemented cows while it decreased ($P = 0.002$) in CON cows. Glutathione metabolism-related genes such as glutathione reductase (*GSR*; $P = 0.02$) and glutathione synthase (*GSS*; $P = 0.004$) had lower expression at 21 DIM in Met-supplemented cows, while glutamate-cysteine ligase catalytic tended (*GCLC*; $P = 0.07$) to have a similar pattern as *GSR* and *GSS*. Expression of 3-hydroxy-3-methylglutaryl-Coenzyme A synthase 2 (*HMGCS2*) was lower ($P = 0.02$) in Met-supplemented cows at 21 DIM. *HMGCS2* is highly corelated with ketogenesis. Expression of peroxisome proliferator-activated receptor α (*PPARA*; $P = 0.04$) and phosphoenolpyruvate carboxykinase 1 (*PCK1*; $P = 0.03$) was greater in Met-supplemented cows, while a trend ($P = 0.06$) was observed for the hepatokine fibroblast growth factor 21 (*FGF21*). Increased expression of *MAT1A* over time in Met-supplemented cows coupled with greater *PPARA* expression is suggestive that Met, a methyl donor, might have promoted the activation of *PPARA* via S-adenosylmethionine by reducing DNA methylation of the PPARA promoter region. The role of the *PPARA-FGF21* axis as an activator of gluconeogenesis was underscored by the concomitant upregulation of *PCK1* in Met-supplemented cows. Postpartal down-regulation of *HMGCS2* in Met-supplemented cows could be related with a lower production of ketones bodies, which agrees with the trend ($P = 0.15$) observed in the overall group ($n = 57$) suggesting a lower predisposition to developing ketosis. The parallel down-regulation of *GSR*, *GSS*, and *GCLC*at 21 d might indicate a lower requirement for the antioxidant activity of glutathione in Met-supplemented cows.

Key Words: transition cows, gene expression, methionine

1833 (W292) Feed intake and feeding behavior of lactating dairy cows were affected by dietary fatty acid profile. H. Khalilvandi-Behroozyar[1], M. Dehghan Banadaky[*2], M. Ghaffarzadeh[3] and K. Rezayazdi[2], *[1]Department of Animal Science, Urmia University, Urmia, Iran, [2]Department of Animal Science, University of Tehran, Karaj, Tehran, Iran, [3]Chemistry and Chemical Engineering Research Center of Iran, Tehran, Iran*

There are quite rare data regarding effects of dietary fatty acid profile on feeding and chewing behavior. The aim of this study was to evaluate the milk fatty acid profile in early lactating dairy cows supplemented with protected unsaturated fatty acids sources and prilled source of palm fatty acids. Twenty four multiparous Iranian Holstein cows individually were assigned to diets with different fatty acid profiles and supplemented through 30 days before expect calving date to 50 days in milk. Dietary treatments consisted of (1) Prilled Pam fatty acids (PO) [Energizer RP10 , 2 & 2.25% DM in pre- and postpartum, respectively]; (2) Ca-salts of sunflower oil (SO) [Persia Fat- SO]; (3) Ca-salts of fish oil (FO) [Persia Fat- FO] and (4) equal amounts of Persia Fat- FO & Persia Fat- SO. Calcium salts were supplemented as 2.2 and 2.5% of dietary DM in pre- and postpartum period, respectively. All rations contained identical forage and concentrate components. Feeding behavior was continuously monitored for 5 consecutive days in 15, 30 and 45 days in milk using video recordings. Data were analyzed using PROC MIXED of SAS 9.1 with repeated measures in time function. Dry matter intake for PO was less than Persia Fat with different FA profiles (20.17 vs. 23.56, 22.25 and 2.53, for treatments 1 to 4, respectively, $P < 0.05$). Supplementation of palm fatty acids decreased meal number, meal length and time to consume 1 kg of DM or NDF, but amount of feed intake in each meal was not affected. Time interval between meals was numerically increased ($P > 0.05$) by supplementation of PO (2.74 vs. 2.28, 2.51 and 2.53, for treatments 1 to 4, respectively).The PO treatment increased time spent ruminating in each bout, but increased rumination bout intervals. Total number of rumination bouts was not affected by fat supplement type. Total rumination time (660.48 min vs. 587.86, 584.8 and 73.75, for treatments 1 to 4, respectively) and rumination per kg of DM (32.74 min vs. 24.95, 26.28 and 25.47, for treatments 1 to 4, respectively) and NDF (102.39 min vs. 78.02, 82.21 and 79.62, for treatments 1 to 4, respectively) were increased for PO than PUFA supplemented cows. We conclude that saturated fat supplement suppress DMI via increase time spend to consume or rumination feed.

Key Words: palm oil, PUFA, rumination

1834 (W293) Whole cottonseed and vitamin E in diets for Nellore cattle finished in feedlot: Performance traits and Feed conversion. A. M. Ferrinho[*1], F. Baldi[2], B. M. Toda[1], F. B. Mendonça[1], B. L. Utembergue[1], R. R. Germano[1], A. S. C. Pereira[1], P. R. Leme[1] and S. L. Silva[1], *[1]Universidade de São Paulo, Pirassununga, Brazil, [2]Universidade Estadual Paulista "Júlio de Mesquita Filho"- UNESP, Faculdade de Ciências Agrárias e Veterinárias, Jaboticabal, Brazil*

This study aimed to evaluate the daily live weight gain, live weight evolution, feed efficiency (ratio live weight gain/dry matter intake), hot and cold carcass weight and carcass yield of bulls finished in feedlot feeding. A total of 54 bulls were confined, with approximately 350 kg initial weight, average age of 24 months, in a randomized blocks design with factorial arrangement of treatments (3 x 3), totaling 9 treatments with 6 animals in each treatment. The animals were fed three diets: 1) control without cottonseed (CTL), 2) containing cottonseed at 30% of DM (CAR) and 3) diet containing cottonseed at 30% of DM and 500 IU vitamin E/kg of DM (VITE). The diets used were composed of different concentrates, including dry corn grain, citrus pulp, sugarcane bagasse raw and soybean meal with forage concentrate ratio of 86:14 and an average of 55% CP in the three diets The animals were kept in pens, three to three, and fed once a day, for 83, 104 and 111 days and slaughtered. For feed conversion and carcass weight, the the fixed effects of treatment, slaughter period and the interaction between them, and the block random effect were included in the model. For repeated measured traits, the fixed effects of treatment, weighing period and the interaction between them, and the block random effect were included in the model. The data were submitted to an analysis of variance using the proc mixed command (SAS statistical program) applying a significance level of 5%. The interaction between treatment x slaughter period was significant ($P < 0.05$) for feed conversion where animals fed the VITE and CAR diets and slaughtered at 111 days showed better feed conversion efficiency with averages of 4.68 kg DM and 4.94 kg DM respectively. The interaction treatment x slaughter period was also significant ($P < 0.05$) for live weight evolution ($P < 0.01$). The mean daily live weight gains were 4.10 kg, 3.74 kg and 0.6 kg for CAR, VITE and CTL respectively. There was a significant effect of diets containing whole cottonseed (CAR and VITE) on hot and cold carcass weight compared to the diet without whole cottonseed ($P < 0.01$), while for carcass yield, animals slaughtered at 111 days showed higher (56,33%) than animals slaughtered before ($P < 0.05$). The animals fed diets with cottonseed have better performance for live weight gain, feed conversion and carcass weight.

Key Words: cottonseed, feed efficiency, daily live gain

1835 (W294) Effect of chitosan and lipid source combination on energy intake and milk yield and composition of dairy cows. T. A. Del Valle*[1], V. C. Galvão[1], F. C. R. D. Santos[1], E. F. Jesus[2], A. G. B. V. B. Costa[1], C. E. C. Consentini[1], G. F. D. Almeida[1], G. F. Cabral[3], F. Zanferari[1] and F. P. Rennó[1], *[1]School of Veterinary Medicine and Animal Science, University of São Paulo, Pirassununga, Brazil, [2]School of Agricultural and Veterinary Sciences of UNESP, Jaboticabal, Brazil, [3]School of Animal Science and Food Engineering of University of São Paulo, Pirassunga, Brazil*

The aim of this study was to evaluate the effects of chitosan and soybean oil in the dairy cow's diets, on energy intake and milk yield. Twenty-four Holstein averaging 174.7 ± 53.1 DIM, were randomly assigned in six Latin Square design with a two by two factorial arrangement of treatments. The diets contained chitosan (150 mg.kg^{-1} of body weight) and/or soybean oil (3.3% of the diet DM). Each experiment period had a 14 d adaptation period and an seven for collection data. Sampling of milk was done on days 16, 17 and 18 of each period to evaluate the composition. The net energy intake (NEI), energy requirement for maintenance (NE_m) and lactation (NE_L) were obtained from the equations of NRC (2001). NEI was decrease with the use of chitosan in the diets without supplementation of soybean oil, but has no difference between diets containing soybean oil as well as the dry matter intake. The NE_L was decrease by addition of soybean oil in the diet, regardless of the addition of chitosan. This occurred due to the reduction of on average 5.0 g.kg^{-1} the synthesis of fat in milk of animals fed soybean oil. Although the animals receiving chitosan and soybean oil had less milk yield (31.26 kg) compared with animals receiving only the soybean oil (32.86 kg) and in this diet decrease fat concentration was only 3.7g. kg^{-1}, making fat corrected milk unchanged. Milk yield did not differ between cows fed chitosan diet (33.87 kg) and control diet (32.85 kg).The net energy balance was decrease on chitosan diet (2.97 Mcal) compared with control diet (5.33 Mcal) and was not influenced by the addition of chitosan on diets containing soybean oil (5.0 Mcal). The efficiency of use of energy, measured by the ration between the NE_L and digestibility energy intake, was decrease by the addition of chitosan in diets with soybean oil and increased in diets without oil. Chitosan increases energy efficiency in dairy cows, provided that the diet has a low level of ether extract.

Key Words: fat, feed additive, milk energy

1836 (W295) Plasma urea concentration of beef heifers fed with different lipid sources and frequency supplementation. M. C. A. Santana*[1], V. C. Modesto[2], G. T. Pereira[2], R. A. Reis[2], G. M. P. Melo[2], H. J. U. Costa[2], T. T. Berchielli[2] and L. P. L. Moreira[2], *[1]Emater, Goiânia, Brazil, [2]UNESP, Jaboticabal, Brazil*

This research aims to evaluate urea plasma responses under different lipid sources and supplementation frequencies. The experiment was conducted throughout a 4-mo period during the dry season. The experiment was completely random, using a 3 × 2 factorial arrangement (3 supplements and 2 supplementation frequencies). The supplements were derived from 3 different sources, soybean grains, soybean oil and protected fat (Megalac-E), the 2 supplement frequencies were (D) daily or 3 days of week (Monday, Wednesday and Friday) called "alternate" (A). In the 4-mo experimental period, August–November, blood samples were taken from the jugular vein four hour after the morning feeding. Subsequently, these samples were centrifuged and stored until the urea blood level was evaluated. In all treatments, no urea levels differences were observed in August and September ($P > 0.05$). The Megalac–E that was supplied daily presented a higher urea plasma level in comparison to the alternate supplement of soybean oil in October ($P < 0.05$).The animals that were given soybean oil supplements daily showed lower urea plasma concentration values ($P < 0.05$) in November by treatments and periods. Overall, this data indicated that the urea blood level can be influenced according to the feeding strategy during the dry season.

Key Words: soybean grains, soybean oil, protect fat

Table 1836. Plasma urea concentration of heifers supplemented with different lipid sources at two different frequencies (mg/dL)

	D-SG	A-SG	D-SO	A-SO	D-ML	A-ML
August	27.5^{Aa}	26.8^{Aa}	27.6^{Aa}	26.7^{Aa}	27.8^{Aa}	26.2^{Aa}

1837 (W296) Effects of selenium supply, maternal plane of nutrition, and physiological stage on nitrogen flow, microbial efficiency, and metabolizable protein in primiparous ewes. K. J. McLean[*1], A. M. Meyer[2], L. R. Coupe[1], G. P. Lardy[1], K. A. Vonnahme[1] and J. S. Caton[1], *[1]North Dakota State University, Fargo, [2]Division of Animal Sciences, University of Missouri, Columbia*

Primiparous Rambouillet ewes (n = 84, age = 240 ± 17 d, BW = 52.1 ± 6.2 kg) were allocated to 2 × 3 × 2 factorial arrangement to evaluate dietary Se (adequate Se [11.5 µg/kg BW] or high Se [77.0 µg/kg BW]), nutritional plane (60% [restricted], 100% [control], or 140% [high]), and physiological stage at necropsy (parturition or d 20 of lactation) effects on nitrogen digestion and microbial CP production. At parturition, lambs were removed from all ewes and 42 ewes (n = 7 per treatment) were necropsied. Remaining ewes were transitioned to a common lactation diet to meet NRC requirements and machine milked for 20 d. Differences between treatments were determined by the GLM procedure in SAS. No three way interactions were present (P > 0.10), but many 2-way interactions were found (P < 0.05). Selenium did not influence N intake (P = 0.23). Nitrogen intake increased with plane of nutrition during gestation and lactation (P < 0.001; 13.3 vs. 20.2 vs. 31.4 ± 0.6 g during pregnancy and 40.4 vs. 41.6 vs. 42.2 ± 0.5 g during lactation for restricted, control, and high ewes, respectively). Microbial efficiency of ewes on restricted diets (7.0 ± 1.04 g microbial nitrogen/kg truly fermented) was decreased compared with control and high ewes (13.4 and 14.9 ± 1.04 g microbial nitrogen/kg truly fermented) but these differences were gone after 20 d of lactation (P > 0.15). Supranutritional Se supply and restricted and adequate nutrient planes increased microbial efficiency regardless of physiological stage (P = 0.04). Selenium supplementation increased (P = 0.04) total tract N digestion during gestation (69.3 and 71.4 ± 1.0%, respectively) but decreased N digestion during lactation (74.7 and 72.9 ± 0.9%, respectively). Ruminal N digestion was greater (P = 0.01) during gestation in restricted ewes compared with control or high ewes (59.1 vs. 44.9 and 39.9 ± 2.8%, respectively); however, post-ruminal N digestion was less (P = 0.02) in restricted ewes compared with control and high nutritional planes (13.1 vs. 26.1 and 28.1 ± 2.8%, respectively). Metabolizable protein increased (P < 0.001) during gestation with increasing nutritional intake but did not differ during lactation. Nutritional plane and Se supplementation had different effects on nitrogen digestion and microbial efficiency but those effects were dependent on physiologic stage.

Key Words: ewes, microbial efficiency, selenium

1838 (W297) Effect of prototype sequestering agents on performance and milk aflatoxin M1 concentrations of dairy cows fed aflatoxin B1-contaminated diets. I. M. Ogunade[*1], K. G. Arriola[1], R. M. Martins[1], B. Y. Coy[1], C. L. Curry[2], D. K. Terkoski[1], A. Rubright[1], M. G. Zenobi[2], Z. Ma[2], C. R. Staples[2] and A. T. Adesogan[2], *[1]University of Florida, Department of Animal Sciences, Gainesville, [2]Dep. of Animal Sciences, University of Florida, Gainesville*

This study examined if 3 in-feed mycotoxin-sequestering agents could reduce milk aflatoxin M_1 (AFM_1) concentration and improve the performance and immunological responses of dairy cattle fed diets contaminated with aflatoxin B_1 (AFB_1). Fifteen lactating cows were used in a 5 × 5 Latin square design with four 28-d periods and 3 replicate squares. Treatments included a Control diet (C), a toxin (T) diet containing 75 ug of AFB_1/kg of TMR DM and 3 diets containing T and one of three prototype sequestering agents (S1, S2, and S3). The AFB_1 was mixed with corn and molasses and dosed in gelatin capsules orally to cows before the TMR was fed on d 21 to 25. Milk was sampled twice daily on d 20 to 28 and plasma was sampled on d 20 and 25. The statistical model contained effects of diet, period, square, appropriate interactions and cow nested within square. Feeding T increased the milk AFM_1 concentration beyond the FDA safety threshold (0.5 ug/kg) and values were greater (P < 0.001) than those in cows fed C. Sequestering agents (S1, S2 and S3) did not reduce the transfer of AFB_1 to AFM_1. Feeding T reduced (P = 0.03) milk fat (0.93 vs. 1.05 kg/d) and protein (0.78 vs. 0.89 kg/d) yield and tended (P = 0.09) to reduce milk fat (3.74 vs. 3.84%) and protein (3.12 vs. 3.24%) concentrations compared to C. Feeding sequestering agents prevented these reductions in yields and concentrations of milk components except that S3 reduced milk fat yield. Cows fed S3 had lower (P = 0.01) DMI and greater (P = 0.01) feed efficiency (FCM/DMI; 1.34 vs. 1.12) than those fed C. Feeding T instead of C reduced (P < 0.05) red blood cell counts and hemoglobin concentration. Plasma acid-soluble protein concentration and monocyte counts were lower (P < 0.05) in cows fed S1, S2 and S3 compared to those fed T reflecting attenuation of the immunological challenge posed by feeding AFB_1. Sequestering agents had no effect on milk AFM_1 concentration but prevented adverse effects of AFB_1 on milk component yields and concentrations and immunological response indices

Key Words: milk, mycotoxin, sequestering agents

1839 (W298) Blood glucose concentrations and deposition of muscular and subcutaneous fat tissues of Nellore young bulls finished in pasture supplemented with crude glycerin. E. San Vito*, J. F. Lage, L. Maneck Delevatti, E. E. Dalanttonia, L. R. Simonetti, M. B. Abra and T. T. Berchielli, *Universidade Estadual Paulista Júlio de Mesquita Filho- UNESP, Jaboticabal, Brazil*

This trial aimed to evaluate the effects of feeding crude glycerin (CG)- 80% of glycerol- included as a substitute to corn grain in supplements of young bulls finished in pasture on rainy season on deposition of muscular and subcutaneous fat tissues and blood glucose concentration. The longissimus muscle area (LMA), rib fat thickness between the 12 and 13 ribs (RFT) and subcutaneous fat thickness in the region P8 (P8) were evaluated. Fifty Nellore young bulls with initial shrunk body weight of 427 ± 15.76 kg were randomly assigned to five treatments consisted of increasing crude glycerin concentration in the supplement: 0, 7, 14, 21, and 28% of dry matter. The CG used was derived from soybean biodiesel production. Animals were distributed in 10 paddocks of *Brachiaria brizantha* cv. Xaraés, with 1.8 ha each (2 paddocks per treatment). The animals were supplemented daily in a proportion of 300 g/100kg of BW. The supplement control was constituted of corn grain, soybean meal, urea, gluten meal and mineralized salt, containing 370 g/kg DM of CG. The measurements were done in the beginning of the experiment and in each 28 d, by ultrasound (Model Aloka 500, linear carcass probe with 17.2 cm and frequency of 3.5 MHz), to evaluate the deposition of muscular and subcutaneous fat tissues. Blood was collected in vacutainer tubes from the tail vein after 16 h withdrawal period from feed and water. Data was analyzed using the GLM procedure of SAS program and the effects of treatments (linear and quadratic) were considered significant at P>0.05. There was no statistical significance (P>0.05) among the treatments, and the final average values observed were: 71.5 cm < su*P* > 2 < /su*P* > to LMA, 4.4 mm to P8 and 3.7 mm to RFT. The gain observed in the variables (initial value– final value) LMA, P8 and RFT were 13.3 cm < su*P* > 2 < /su*P* > 1.7 mm and 1.3 mm, respectively. CG inclusion did not affect the blood glucose concentrations (P>0.05), however the values showed a quadratic effect (*P* = 0.020), with the highest concentration (81.8 mg/dL) in the level of 14% inclusion of crude glycerin. Addition of crude glycerin in supplement (28% of DM) does not affect the deposition of muscular and subcutaneous fat tissues or blood glucose concentrations of Nellore young bulls finished in pasture on rainy season.

Key Words: beef cattle, glycerol, pasture

1840 (W299) Effect of propolis on plasma metabolites and hematocrit of Holstein calves. P. Peravian*[1], K. Rezayazdi[2] and G. Nehzati[3], [1]*University of Tehran, Tehran, Iran,* [2]*Department of Animal Science, Faculty of Agriculture, University of Tehran, Karaj, Iran,* [3]*University of Tehran, Karaj, Iran*

The object of this study was to investigate the effect of propolis powder on the plasma metabolites and hematocrit of suckling calves. Propolis in this experiment was come from Taleghan vicinity (near Tehran). 40 Holstein female calves with 41 ± 1 kg of body weight from 14 to 65 d of old were used in a completely randomized design with 4 treatments and 10 replicates in each treatment. Treatments were 1) Control (without Monensin in starter and without propolis in milk), 2) Starter without Monensin and 500ppm soluble propolis powder in milk, 3) Starter without Monensin and 1000ppm soluble propolis powder in milk and 4) Monensin in starter and without propolis in milk. Starter was formulated according to NRC 2001 (21.6% CP and 2.89 ME (mcal/kg)). Calves received 6 L/d of milk replacer (milk protein based, 22% CP, 19% EE) for the 6 wk. Blood sample were collected every 14 d (3hours after feeding), then transferred to laboratory and hematocrit (platelets, hemoglobin, red blood cell, white blood cell, lymphocyte) were measured. Blood samples centrifuged and plasma separated from blood to measure metabolites (total protein, albumin, Immunoglobulin G). Results showed that mean concentration of Platelets (3.06, 4.95, 3.18, 5.63 *10^5/ml) and Lymphocytes (69.50, 72.25, 75.25, 71.75%) were not affected by treatments. Hemoglobin (11.12, 8.8, 10.15, 9.6 g/dl) red blood cell (11.28, 8.07, 10.19, 10.28 *$10^{6/}$ml) for treatments 1–4 respectively were not affected by treatments. For white blood cell (50.75, 60.75, 71.50, 52.25 *10^3/ml for treatment 1–4 respectively) there was a tendency to be affected by treatments (P = 0.06). Mean concentration of Total Protein (10.94, 11.31, 11.68, 11.54 g/dl) had a trend to significance (P = 0.09). Albumin (6.13, 5.63, 6.13, 5.66 g/dl) and Immunoglobulin G (1.91, 1.73, 2.00, 1.47(g/dl) for treatment 1–4 respectively) significantly affected by treatments (P < 0.05). It is concluded that 1000 ppm propolis in compare of Monensin has potential to improve immune responses through its effect on the WBC, Albumin and IgG of Holstein female calves.

Key Words: propolis, Holstein female calves, immune responses

1841 (W300) Effects of maternal plane of nutrition, selenium supply, and physiological stage on digestibility and ruminal fermentation in ewes.

K. J. McLean*[1], A. M. Meyer[2], L. R. Coupe[1], G. P. Lardy[1], K. A. Vonnahme[1] and J. S. Caton[1], *[1]North Dakota State University, Fargo, [2]Division of Animal Sciences, University of Missouri, Columbia*

Objectives were to investigate effects of nutritional plane and Se supply during gestation on digestibility and ruminal fermentation at parturition and early lactation. Primiparous Rambouillet ewes (n = 84, age = 240 ± 17 d, BW = 52.1 ± 6.2 kg) were allocated to 2 × 3 × 2 factorial arrangement of treatments. Factors included dietary Se (adequate Se [11.5 µg/kg BW] or high Se [77.0 µg/kg BW]), nutritional plane (60% [restricted], 100% [control], or 140% [high]), and physiological stage at necropsy (parturition or d 20 of lactation). At parturition, lambs were removed from all ewes and 42 ewes (n = 7 per treatment) were necropsied. Remaining ewes were transitioned to a common diet, which met lactation requirements, and mechanically milked for 20 d. Three way interactions were not present ($P > 0.10$). As expected, DMI was altered by both nutritional plane and physiological stage. In pregnancy and lactation, DMI increased with plane of nutrition ($P < 0.001$; 500 vs. 755 vs. 1183 and 1173 vs. 1237 vs. 1295 ± 19 g for restricted, control, and high ewes during pregnancy and lactation, respectively). Neither DMI nor total OM digestion were altered by Se supply. Total OM digestion was greater ($P = 0.03$) in restricted compared with high ewes during both gestation (75.8 and 67.0 ± 1.2%, respectively) and lactation (68.4 and 64.8 ± 1.2%, respectively). Both apparent ($P < 0.01$) and true ($P = 0.04$) ruminal OM digestion was greater in restricted (60.7 ± 1.42%) vs. control and high ewes (56.4 and 54.4 ± 1.42%, respectively). Ewes fed high Se during gestation had greater ($P = 0.03$) apparent and true ruminal OM digestion during gestation but were not different at d 20 of lactation. Ruminal acetate proportions were lower ($P = 0.03$) and the ratio of acetate + butyrate over propionate tended ($P = 0.09$) to be greater in high Se vs. adequate Se fed ewes. Ewes fed restricted diets had greater acetate ($P < 0.001$), lower propionate proportions ($P < 0.001$), and lower total VFA concentrations ($P < 0.01$). Ewes at parturition had greater total VFA ($P < 0.001$) than ewes during lactation. These data indicate that maternal plane of nutrition, Se supply, and physiological stage all impact digestion and ruminal fermentation which will influence circulating nutrients available for fetal growth and milk production.

Key Words: digestibility, ewes, selenium

1842 (W301) Effect of reduced energy density of close-up diet on dry matter intake, milk yield and energy balance in multiparous Holstein cows.

W. M. Huang*, A. Simayi, A. Yasheng, Z. H. Wu, S. L. Li and Z. J. Cao, *State Key Laboratory of Animal Nutrition, College of Animal Science and Technology, China Agricultural University, Beijing, China*

The objective of this study was to determine the effect of reduced energy density of close-up diet on DMI, milk yield and energy balance (EB) in multiparous Holstein cows which were fed for ad libitum intake. Thirty-nine dry cows were blocked and assigned randomly into 1 of 3 energy concentrations (6.8, 6.2, 5.4 MJ of NE_L/kg; 14.0% CP) diets to meet 100% (100NRC; n = 13), 90% (90NRC; n = 13), 80% (80NRC; n = 13) of the NRC (2001) dietary NE_L recommendation, respectively, from 21 d before expected day of calving. After parturition, all cows were fed the same lactation diet to 70 d in milk (DIM). Data were analyzed by SPSS with repeated measures procedure or One-Way ANOVA procedure. The DMI (14.3, 13.6, 12.6 kg/d; $P = 0.009$) and NE_L intake (NEI, 97.1, 83.3, 68.6 MJ/d; $P < 0.001$) prepartum were significantly different for 100NRC, 90NRC and 80NRC groups. In the last 24 h before calving, the 80NRC group consumed 1.3 kg and 0.7 kg more diet (DM) than the 100NRC and 90NRC groups ($P > 0.05$), respectively, but the NEI was very similar among the 3 treatments. During the first 4 wk postpartum, the DMI and NEI for the 80NRC group were numerically greater than those for the 100NRC ($P > 0.05$). The milk yields of 90NRC and 80NRC groups were numerically greater than 100NRC from 1 to 10 wk (36.6, 38.6, 38.7 kg/d; $P > 0.05$), but the 4% fat-corrected milk yields (45.4, 45.7, 45.4 kg/d; $P > 0.05$) were very similar due to the significantly higher milk fat content for 100NRC. The energy consumption for 100NRC, 90NRC and 80NRC were 149.8%, 126.2% and 101.1% of their calculated energy requirements prepartum, and 72.7%, 73.1% and 75.2% during the first 4 wk postpartum, respectively. In conclusion, the low energy density prepartum diet was effective in controlling NEI prepartum, and was beneficial in increasing DMI, whilst alleviating negative EB postpartum.

Key Words: dietary energy density, dry matter intake, milk yield

1843 (W302) Effects of lysolecithin on milk fat synthesis and milk fatty acid profile of cows fed diets differing in fiber and unsaturated fatty acid concentration.

D. E. Rico*, J. Y. Ying and K. J. Harvatine, *Penn State University, University Park*

Thirteen multiparous Holstein cows (> 70 DIM) were used in a crossover design that tested the effect of lysolecithin under diets differing in fermentability and polyunsaturated fatty acid (FA) concentration. Experimental periods were 20 d and

included two 10 d phases. During phase 1, a standard fiber and low fat diet was fed (32% NDF, no added oil) and during phase 2 a lower NDF higher oil diet was fed (30.5% NDF and 2% oil from whole soybeans and soybean oil). A 14 d washout period between experimental periods allowed milk fat recovery. Treatments were control and lysolecithin (10 g/d/cow of LYSOFORTE$_{brand}$, Kemin Industries, Des Moines, IA) extended in a ground corn carrier. Milk was sampled on d 0, 5, and 10 of each phase for determination of fat and protein concentration and FA profile. There was no effect of treatment or treatment by time interaction for DMI or milk yield, however on d 5 of phase 2 lysolecithin tended to decrease DMI ($P < 0.10$). There was a treatment by time interaction for milk fat concentration and yield ($P < 0.05$). Milk fat concentration was higher in lysolecithin on d 5 of phase 1, but decreased progressively in both treatments during phase 2. Milk fat yield was not different among treatments during phase 1, but was lower in lysolecithin on d 5 and tended to be lower on d 10 of phase 2 ($P < 0.10$). There was no effect of treatment or treatment by time interactions for milk protein concentration or yield. No treatment by time interactions were detected for the concentrations of milk de novo (< 16 C) or preformed (> 16 C) FA. Concentrations of de novo FA decreased, but preformed FA increased during phase 2 ($P < 0.001$) and no treatment differences were detected at any time point. There was an effect of time, but no treatment by time interactions for milk *trans* FA isomers ($P < 0.05$). Briefly, *trans* 11 C18:1 and *cis*-9, *trans*-11 conjugated linoleic acid (CLA) decreased progressively during phase 2 as *trans* 10 C18:1 and *trans*-10, *cis*-12 CLA increased progressively. Lysolecithin increased milk fat concentration when feeding a higher fiber and lower fat diet, but decreased milk fat yield when feeding a lower fiber and higher fat diet, although biohydrogenation pathways were not modified.

Key Words: dairy cows, lysolecithin, milk fat depression

1844 (W303) Effects of fescue toxicosis induced by endophyte-infected tall fescue seed on forestomach epithelial gene expression in Angus steers.

D. Kim[*1,2], J. L. Klotz[3] and D. L. Harmon[1], *[1]University of Kentucky, Lexington, [2]National Institute of Animal Science, Rural Development Administration, Suwon, South Korea, [3]USDA-ARS, FAPRU, Lexington, KY*

A previous report demonstrated that steers exposed to an endophyte-infected tall fescue seed extract had altered rumen epithelial blood flow and decreased ruminal flux of VFA. Thus, this study was conducted to determine whether there are differences in gene expression related to VFA absorption between steers dosed with endophyte-infected (E+; 4.45 mg ergovaline/kg) or endophyte-free (E-) tall fescue seed. Twelve ruminally cannulated Angus steers (BW = 547 ± 9 kg) were stratified based on BW and randomly allocated to 6 blocks. The steers were fed alfalfa cubes at 1.5 x NE$_m$ and dosed (1 kg/d) with ground tall fescue seed via rumen cannula once daily for 21 d. On d 22, the steers were slaughtered and tissue samples were immediately collected from rumen, reticulum, omasum, and abomasum. Samples were rinsed extensively with ice-cold physiological saline to remove residual feed and contents before separating epithelia from the underlying tissue. Thereafter, samples of epithelial tissue (1 g) were immediately homogenized with TRI-reagent. The expression levels of monocarboxylate transporter 1, 2, and 4 (MCT1, MCT2, and MCT4, respectively), sodium hydrogen exchanger 1, 2, and 3 (NHE1, NHE2, and NHE3, respectively), putative anion transporter 1 (PAT1), downregulated in adenoma (DRA), anion exchanger 2 (AE2), sodium bicarbonate cotransporter 1 (NBC1), 3-hydroxy 3-methylglutaryl coenzyme A synthase 2 (HMGCS2), and sodium potassium ATPase pump 1 (ATP1) were measured using SYBR-Green and abundances were quantified by qPCR using glyceraldehyde-3-phosphate dehydrogenase as the control gene. The levels of MCT1 and MCT4 expression were lower ($P < 0.05$) in the rumen tissue of steers dosed with E+ seed, whereas MCT2 was not different. The expression of NHE2 was lower ($P < 0.05$) for E+ steers, whereas NHE1 and NHE3 were not affected by seed in the rumen epithelium. The levels of DRA and AE2 expression were lower ($P < 0.05$) for E+ steers in the rumen epithelium, whereas PAT1, NBC1, HMGCS2 and ATP1 were not affected by seed treatment. Expression of these genes in reticulum, omasum, and abomasum epithelia, were not affected ($P > 0.05$) by seed treatment. These data indicate that endophyte-infected tall fescue seed may contribute to depression of ruminal VFA absorption in a dissociated state (pH > 5.8) by the depression of MCT1 and MCT4 in the rumen associated with NHE2, DRA and AE2. Consequently, this may contribute to decreased gain associated with fescue toxicosis in cattle.

Key Words: VFA transporter, gene expression, tall fescue

1845 (W304) Replacement of soybean meal by high energy cottonseed meal in diets of dairy cows: milk production and ovarian follicular dynamics.

F. M. Wingert, L. K. Hatamoto-Zervoudakis*, P. N. Cosentino, J. T. Zervoudakis and A. L. Cândida de Resende Fraga, *Federal University of Mato Grosso, Cuiaba, Brazil*

Supply of high biological value protein is key to reproductive and productive performance, however the cost is high. The aim of this study was to evaluate replacement of soybean meal by high energy cottonseed meal like protein source in dairy cows diets on productive and reproductive parameters. Five Girolanda cows with average body weight of 530 kg, distributed in 5x5 Latin square were used (5 levels of substitution of soybean meal by high energy cottonseed meal: 0% (FA0), 15% (FA15), 30% (FA30), 45% (FA40) and 60% (FA60) and 5 periods). Each period lasted 18 d. Milk production (MP) and

Table 1845. Milk production (MP, kg/day), body score condition (BSC, 1–5), number of recruited follicles (NRF), dominant follicle diameter (DFD, mm), and corpus luteum diameter (CLD, mm) of Girolanda cows feeding with diets with substitution of soybean meal by high energy cottonseed meal

Treatment	MP	BSC	NFR	FMD	CLD
FA0	14.4 ± 0.2[a]	2.9 ± 0.03	25.69 ± 1.22	15.10 ± 0.39	20.60 ± 0.7
FA15	12.4 ± 04[c]	2.9 ± 0.07	26.08 ± 1.31	17.90 ± 0.64	21.15 ± 0.7
FA30	14.6 ± 03[a]	2.9 ± 0.05	26.83 ± 1.12	16.90 ± 0.33	21.85 ± 0.6
FA40	14.5 ± 0.2[a]	2.9 ± 0.03	25.89 ± 1.28	14.90 ± 0.34	21.10 ± 0.9
FA60	13.7 ± 04[b]	2.9 ± 0.07	26.08 ± 1.01	18.30 ± 0.32	20.40 ± 1.0
P	< 0.0001	0.3002	0.8133	0.1039	0.6781

FA: diet without substitution; FA15 replacement 15% of soybean meal by high energy cottonseed meal; FA30 replacement 30% of soybean meal by high energy cottonseed meal; FA40 replacement 40% of soybean meal by high energy cottonseed meal; FA60: replacement 60% of soybean meal by high energy cottonseed meal; *P*: significance level
A, b, c…different letters in same column indicate differences by Tukey test

body score condition (BSC) were evaluated on the 18th day and ovarian evaluations (number of recruited follicles (NRF), dominant follicle diameter (DFD), and corpus luteum diameter (CLD)) were conducted from 7 to 18th day of supplementation by trans-rectal ultrasonography. Data were analyzed by Tukey test with 5%of significance level. Replacement of protein source (replacement of soybean meal by high energy cottonseed meal) do not influenced ($P > 0.05$) body score condition, number of recruited follicles, dominant follicle diameter, and corpus luteum diameter. However, could reduce milk production in higher and lower replacements levels (Table 1845). The replacement of soybean meal by high energy cottonseed meal as protein source at level of 30 or 40% is feasible because not alters reproductive and productive performance, and promotes reduced diet cost.

Key Words: protein sources, follicles, girolando

1846 (W305) Supplements with chelated mineral for cows Nellore: Growth performance, oocyte quality and oxidative stress. T. D. P. Trindade, L. K. Hatamoto-Zervoudakis*, C. Pasa, J. T. Zervoudakis, P. P. Tsuneda, F. M. Wingert and A. L. Cândida de Resende Fraga, *Federal University of Mato Grosso, Cuiaba, Brazil*

Nutrition has a major influence on reproductive performance (expression of estrus, follicular development, quality of gametes, ovulation rate, uterine environment, embryo development, maintenance of pregnancy, etc.). Chelated minerals may provided potential benefits to reproduction, enhancing mineral absorption and retention in animal tissues, improved functioning of dependent enzyme systems of minerals (antioxidant systems), best performance (higher daily weight gain, feed conversion, lower mortality, greater production of meat, eggs and milk). The objective of this study was to evaluated oocyte quality and production traits in Nelore cows grazing supplemented with copper, zinc and selenium in chelated form. 24 multiparous Nelore cows were used, with 36 mo of average age, 395 kg of body weight and body condition score of 4.8. Animals were divided into 2 groups: control group (CG, animals supplemented with inorganic mineral) and Supplemented Group (SG, animals supplemented with zinc, copper and selenium in chelated form). Each group was raised in a paddock of *Brachiaria brizantha* cv. Marandu, receiving 1 kg of supplement/animal/day. Every 2 wk the animals were weighed and body condition score (BCS) was evaluated. During experimental period (99 d), two aspirations (59 and 99 d of supplementation) were performed. Oocytes were assessed as viable and non-viable and follicular fluid levels of oxidative stress was measured by TBARS concentration. The experiment was a completely randomized design and data analyzed by ANOVA with a significance level of 5%. Chelated minerals supplementation did not affect ($P > 0.05$) total number of oocytes retrieved ($P = 0.5028$), numbers of viable oocytes ($P = 0.1449$), and body weight ($P = 0.3587$). The use of chelated minerals provided greater BCS at the end of experiment ($P = 0.0500$, 5.27 ± 0.14 versus 4.83 ± 0.17) and higher gain in body condition score ($P = 0.0178$, 0.82 ± 0.18 versus. 0.25 ± 0.13). Animals supplemented with chelated minerals showed less oxidative stress in follicular fluid (0.05 ± 0.01 versus 0.09 ± 0.02, $P = 0.047$). Oral supplementation with minerals zinc, copper and selenium in chelated form at used levels, improved body condition score and reduced oxidative stress in follicular fluid of Nelore cows at pasture during dry- water transition.

Key Words: Body score condition, chelate, oxidative stress

1847 (W306) Contribution of a chelated trace mineral supplement as a methionine source for dairy cows. M. O. Caldeira*[1], R. O. Rodrigues[1], M. R. Waldron[1,2] and G. I. Zanton[3], *[1]University of Missouri, Columbia, [2]Nutrition Professionals, Inc., Chilton, WI, [3]Novus International, Inc., St. Charles, MO*

This experiment sought to determine whether the methionine contained in a trace mineral supplement made a meaningful contribution toward meeting the methionine requirement of the dairy cow. Four multiparous ruminally-cannulated lactating Holstein dairy cows were used in 4 × 4 Latin square design with 7-d periods. Treatments were administered at a rate of 0.08 g of 2-hydroxy-4-methylthio-butanoic acid (HMTBa)/kg of BW on d 0 of each experimental period: 1) HMTBa chelated to Zn, 80% HMTBa, dosed ruminally (MIN; Minitrex Zn, Novus International, St. Charles, MO, USA), 2) Ca-salt of HMTBa,

84% HMTBa, dosed ruminally (MHA; MHA feed supplement, Novus International), 3) HMTBa free acid, 88% HMTBa, dosed ruminally (ALR; Alimet, Novus International), and 4) HMTBa free acid, 88% HMTBa, dosed post-ruminally (APR; Alimet Novus International). Approximately 5 kg of rumen mat contents from each animal were removed through the cannula, mixed with the appropriate treatment dose, and replaced in the rumen. For post-ruminal treatment, a 50cc syringe was placed in the omasal canal, and contents were expelled into the abomasum; all other animals received a post-ruminal infusion of water. Blood samples were collected regularly through each experimental period. Feed was restricted for 30 min before treatment administration, following which, animals were fed for ad libitum consumption. Data were analyzed using MIXED procedure of SAS, using averaged pre-infusion measurements as covariates. Plasma concentrations of methionine did not differ between MIN, MHA, and ALR treatments; however, APR resulted in a greater ($P < 0.001$) concentration of plasma methionine compared with other treatments. A treatment x time interaction ($P < 0.001$) was observed for plasma methionine, in which APR increased at 1.5 h after infusion, reaching peak at 3 h ($P < 0.001$), and leveling with other treatments at 12 h ($P > 0.10$). Greater plasma concentrations of HMTBa ($P < 0.001$) were found in APR than in MIN, MHA and ALR; however, these did not differ between each other ($P > 0.10$). There was a treatment x time interaction ($P < 0.001$) for HMTBa; APR peaked at 1.5 h after infusion ($P < 0.001$), declined sharply until 9 h when lower concentrations of HMTBa were observed compared with other treatments ($P \leq 0.05$). After 12 h, HMTBa treatments no longer differed ($P > 0.10$). In conclusion, the availability of methionine in plasma did not differ between treatments administered ruminally; however, significant increases were observed when treatments were administered post-ruminally. These results suggest that MIN may be used to contribute toward the methionine requirement for dairy cows.

Key Words: HMTBa, rumen, supplementation

1848 (W307) Effect of the supplementation of plant extracts, vitamins and their associations on feedlot performance and carcass traits of Nellore cattle.

M. B. Silva*[1], A. M. Jorge[2], F. D. Resende[3], G. R. Siqueira[4], G. F. Berti[5], C. L. Francisco[1] and A. M. Castilhos[1], *[1]Universidade Estadual Paulista- FMVZ, Botucatu, Brazil, [2]Faculdade de Medicina Veterinária e Zootecnia, Universidade Estadual Paulista, Botucatu-SP, Brazil, [3]Agência Paulista de Tecnologia dos Agronegócios- APTA, Colina, Brazil, [4]APTA-Polo Regional Alta Mogiana, Colina, Brazil, [5]Centro Universitário da Fundação Educacional de Barretos- Unifeb, Barretos, Brazil*

Fifty-six Nellore (*Bos indicus*) young bulls of +360 kg initial weight and +20 mo of age were used to evaluate the effect of the supplementation of vegetable extract, A, D and E vitamins and their associations on the feedlot performance (finishing phase) and carcass characteristics. Animals were maintained in individual pens for 105 d (21 and 84 d, for adaptation and trial period, respectively). Animals were individually weighed, and blocked by initial body weight. Pens within a block were randomly assigned to one of four treatments: (C) Control diet including A, D and E vitamin; (V) Control diet plus 50% A, D and E vitamin; (E) Diet including 0.14% (DM basis) of plant extracts; (A) Diet with association of these two additives (50% A, D and E vitamin + 0.14% (DM basis) of plant extract). The treatments provided the same diet for all animals (85 and 15%, for concentrate and forage, respectively), varying only the inclusion of the different additives. Further, all treatments received monensin (30 mg/kg of concentrate). Feed offered was monitored daily as well as feed refusals were collected and weighed to determine daily dry matter intake (DMI) and feed efficiency (F:G). Animals were weighed every 28 d after 16 h feed withdrawal for calculating average daily gain (ADG). No effects of treatments ($P > 0.10$) were observed for DMI (9.69, 10.28, 10.03, 9.98 kg/day for diets C, V, E, A, respectively), ADG (1.60, 1.66, 1.64, 1.64 kg/day for diets C, V, E, A, respectively), and F:G (0.17, 0.16, 0.16, 0.16 for diets C, V, E, A, respectively). Back fat thickness, LM area, hot carcass weight, cold carcass weight, and cooling losses were not affected by treatments ($P > 0.10$). In conclusion, supplementation of plant extracts, vitamins and their association did not produces additional benefits on the feedlot performance or carcass traits of Nellore cattle. Supported by CAPES/NUTRON.

Key Words: plant extract, feedlot performance, carcass, Nellore

1849 (W308) Body condition score assessment in a grazing Jersey herd in Costa Rica.

A. Saborío-Montero* and J. M. Sánchez, *Centro de Investigaciones en Nutrición Animal y Escuela de Zootecnia, Universidad de Costa Rica, San José, Costa Rica*

The aim of this research was to carry out a body condition score (BCS) observational study in a commercial grazing Jersey herd in Costa Rica (9°55′ N, 83°51′ W, 2350 m of altitude). The study comprised 5864 BCS records from 122 cows (29 primiparous and 93 multiparous) over a 16 mo period. Cows were scored weekly by the same person from ninth wk prepartum to 43th wk postpartum. The 1 to 5 points scale was used (1 = emaciated, 5 = obese). Animals feeding practices were based on intensive grazing of 30 d regrowth kikuyu (*Kikuyuocloa clandestina*) (14.8% DM, 23.4% CP, 54.0% NDF, 25.7% ADF, 1.4 Mcal/kg NE_L (3x), 2.2% Lignin) and supplementation of a balanced concentrate according to physiological stage. During the close up period animals were fed 4 kg of concentrate daily (14% CP, 1.7 Mcal/kg NE_L(1x), 35% Starch, 0.2% Ca), and during lactation 1 kg of concentrate (18.6% CP, 1.9 Mcal/kg

NE_L, 48% Starch, 1.0% Ca)/2.5 to 3 kg of milk. Primiparous and multiparous cows BCS at calving was 4 points (95% CI: 3.80–4.22 points) and 3.8 points (95% CI: 3.71–3.94 points), respectively. BCS nadir after calving differed ($P < 0.05$) between primiparous (3.1 points, 95% CI: 2.97–3.23 points) and multiparous cows (2.9 points, 95% CI: 2.76–2.96 points). When stratifying BCS at calving into values $\leq$ 3.25, 3.50 to 4.00 and $\geq$ 4.25 points, differences ($P < 0.01$) were found in nadir extreme values within primiparous or multiparous groups of cows. Values were 2.63, 2.94 and 3.29 points for primiparous and 2.27, 2.78 and 3.20 points for multiparous, respectively. Likewise, the average BCS change differed ($P < 0.01$) between extreme values in the same group, showing -0.25, -0.81 and -1.19 points for primiparous and -0.71, -0.93 and -1.21 points for multiparous cows in the same order. BCS at calving in primiparous cows was correlated with nadir ($r = 0.65$, $P < 0.001$) and BCS change ($r = -0.76$, $P < 0.001$). Similarly, BCS at calving in multiparous cows was correlated with nadir ($r = 0.62$, $P < 0.001$) and BCS change ($r = -0.55$, $P < 0.001$). Cows that calved with higher BCS, lost more BCS postcalving, but remained at a greater BCS at nadir and the whole lactation. Results suggest that BCS at calving could be used as a partial indicator of BCS nadir and BCS change from calving to nadir; which has important implications on production and fertility of cows. However more research should be done to extend these findings to wider populations.

Key Words: BCS, Body condition score, grazing Jersey cows

1850 (W309) Intake and nutrient digestibility of growing Nellore heifers and steers fed two levels of calcium and phosphorus.

L. F. Costa e Silva[*1], T. E. Engle[1], P. P. Rotta[1], S. C. Valadares Filho[2], R. D. Valadares[3], F. A. S. Silva[3] and E. C. Martins[3], *[1]Colorado State University, Fort Collins, [2]Universidade Federal de Viçosa, Department of Animal Science, Viçosa, Minas Gerais, Brazil, [3]Universidade Federal De Vicosa, Vicosa, Brazil.*

An experiment was conducted to evaluate intake and nutrient digestibility of Nellore heifers and steers fed two levels of calcium and phosphorus. Thirty two Nellore heifers and eighteen Nellore steers were used. Four animals from each gender were used as baseline reference animals and slaughtered at the beginning of the experiment. Four animals from each gender were fed at maintenance (MAIN) and 10 steers and 24 heifers were assigned to the ad libitum (ADLIB) group. The ADLIB heifers were further divided into four groups. Treatments were: 1) Ca and P fed at requirements (CaPR) with a 50:50 of roughage:concentrate (R:C) diet; 2) CaPR with at 70:30 R:C diet; 3) 43% of the Ca and 80% of the P requirement (CaPL) with a 50:50 R:C diet; and 4) CaPL with a 70:30 R:C diet. The ADLIB steers in this experiment were fed CaPR. Half of the steers and the heifers were slaughtered at d 50 and the other animals were slaughtered a d 100 of the feeding period while all MAIN animals were slaughtered at d 100. Total feces and urine were collected from all animals 72 h before slaughter. Dry matter digestibility and apparent absorption and retention of Ca and P were similar across Ca and P treatments. Final body weight and, consequently, average daily gain was higher ($P < 0.05$) in heifers receiving the high concentrate diet compared to the low concentrate diet while the levels of Ca and P did not affected ($P > 0.05$) the performance. Under the conditions of this experiment, the level of dietary Ca and P can be reduced in the diet and not impact intake, digestibility or performance of growing Nellore heifers and steers.

Key Words: minerals, sugarcane, performance

1851 (W310) Ration composition in Wisconsin dairy herds: Factors affecting fertility.

A. H. Souza[*1], P. D. Carvalho[2], C. M. Drake[3], R. D. Shaver[2] and M. C. Wiltbank[2], *[1]University of California Cooperative Extension, Tulare, [2]University of Wisconsin, Madison, [3]University of California, Davis*

The aim of this study was to determine whether composition of total mixed ration (TMR) diets influence reproductive efficiency of dairy farms in Wisconsin. Dairy producers and nutrition consultants from all herds agreed to provide a single snapshot of their complete TMR-ration information used in the post-fresh and high-milk production pens. The nutritional information included all ingredients and nutrient composition of all mixes used, as well as a herd backup that contained accurate production, health and reproductive records with archive files with previous 12 mo. The final database included data from 49 free-stall Holstein-dairy herds in WI (DC305 $n = 44$ and PCDart $n = 5$). Size of herds enrolled in the data collection varied from 143 to 2717 lactating cows (average 719.6 ± 77.2), were milked 2 ($n = 6$) or 3 ($n = 43$) times per day, with average production per cow of 39.0 ± 1.3 Kg/day, and average DMI of 25.1 ± 0.5 Kg/day. Records from PCDart herds were absorbed into DC305 and calculations of reproductive parameters such as conception rate at first AI (CR1AI), overall conception rate (CR), and interval from calving to conception (ICC) were performed with the same standardized command in DC305 to summarize performance records from the previous 12 mo. Statistical analyses were performed with the proc MEANS, proc CORR, and proc MIXED of SAS (version 9.3). There was a great variation in diet composition, with CP varying from 16.0 to 18.7%, RDP from 9.1 to 12.3%, NDF from 24.9 to 35.1%, NFC from 31.7 to 46.6%, Starch 20.1 to 30.8%, and Fat from 3.1 to 6.7%. Milk production level was not associated with CR1AI, CR, or ICC ($P > 0.10$). However, greater DMI tended to be associated with lower CR1AI ($r = -0.25$, $P = 0.10$) and lower CR ($r = -0.25$, $P = 0.11$). Diet CP and RDP did not seem to affect CR1AI, CR, or ICC ($P > 0.10$). Similarly, Fat content did not influenced fertility parameters ($P > 0.10$). Interestingly,

percentage of NDF was positively associated with CR1AI (r = 0.36, P = 0.01). In addition, greater energy content in the diet measured as NFC, NFC-intake, or Starch were all detrimental to CR1AI (NFC: r = -0.54, P < 0.01; NFCi: r = -0.42, P < 0.01; Starch: r = -0.37, P = 0.03), and CR (NFC: r = -0.51, P < 0.01; NFCi: r = -0.44, P < 0.01;Starch: r = -0.21, P = 0.20). In conclusion, although diets should be balanced to meet milk production requirements, maximizing digestible fiber and lowering highly fermentable energy contents should improve fertility of high producing cows.

Key Words: dairy cows, diet composition, fertility

1852 (W311) Milk quality from dairy farms divided in five levels of production. L. L. Cardoso, M. I. Marcondes*, G. A. T. Ferreira, V. L. N. Brandao, A. S. Trece and A. S. Trece, *Universidade Federal de Viçosa, Viçosa, Minas Gerais, Brazil*

This study aimed to characterize the physicochemical properties of milk from different production scales. A databank with 21,917 analyses, from January 2005 to December 2012, of 409 producers was used. Milk samples were collected twice a month and placed directly into milk cooling tanks. The properties were divided according to monthly average of daily milk yield in the following levels: 10 to 100 L of milk per day (N = 7858); 100 to 200 L (N = 6494), 200 to 500 L (N = 5085), 500 to 1000 L (N = 1725), 1000 to 5000 L (N = 755). Years and months were analyzed in a completely randomized split-plot design repeated in a time scheme, with years as plots and months as sub-plots. Within the reported period, 11.32% of the samples were from producers who account for 44.25% of production. Moreover, the great majority of the samples (88.68%) are from producers representing 55.75% of the supplied milk. An urgent need of improvement in management of total bacterial count (TBC) was observed throughout the year, and only August and September presented results below 100,000 CFU/mL. Somatic cell count (SCC), decreases in dry period, where June is the month with the lowest rate, and there is an increase in this SCC in the rainy season. This characterization is important so the industry can establish a protocol for mastitis control and mammary gland health throughout the year. No significant difference was found when correlating levels of production and SCC. However, TBC was affected by levels of production (P < 0.05), which mean that greater producers, in general, have a better management of this item. Protein was not affected by production levels (P > 0.05), and it increases in early dry period, with a subsequent decrease until the beginning of the rainy season. For small producers (up to 500 L, including the first three levels) June had the highest fat production. The data obtained in the study shows that dairy farming in the region is predominantly developed in small properties. However, higher volumes are produced by fewer producers. The quality of milk produced deserves attention from the entire production chain of milk, and it still presents problems as high TBC, high SCC and low total solids, requiring more efficient management techniques.

Key Words: fat, milk, protein

1853 (W312) MasterGraze silage for growing Holstein heifers. D. L. Gadeken*[1], K. Koone[2], S. harris[2], M. kirk[3] and D. Casper[1], *[1]South Dakota State University, Brookings, [2]Masters Choice, Anna, IL, [3]masters Choice, Anna, IL*

MasterGraze (MG) is a new corn silage hybrid that is a grazing corn. The MasterGraze hybrid will develop grain, but harvest is recommended before grain development which results in a plant that is high in sugar and crude protein (CP). Thus, the unique nutritional attributes of MG makes it an attractive forage source for dairy heifers. Twelve growing Holstein heifers weighing 220.1 ± 28.8 kg were assigned to 1 of 2 treatments varying in type of corn silage. The Control (C) ration consisted of conventional corn silage (Dekalb) and the MG ration consisted of MG corn silage. Corn silages were fed at 38.6% (DM basis) with 19.6% alfalfa hay and 41.8% grain mix. The experimental grain mixes consisted of ground shelled corn, soybean meal, urea, minerals and vitamins that were formulated for each corn silage's nutritional profile. The rations were formulated to be 16% CP (DM basis) and meet or exceed all nutrient requirements for a growing Holstein heifer. Due to a limited amount of MG silage, the experiment was conducted for 5 wk. Animals were trained and fed using the Calan feeding door system to determine daily DM intake. All heifers were fed the C corn silage during the training period and measurements were taken for 1 wk to be used as a covariate. Covariate adjusted average body weights (251.5 and 242.7 kg for C and MG, respectively) were similar (P < 0.24) for heifers fed both corn silages. Average dairy gains (1.22 and 1.16 kg/d) were similar for heifers fed both corn silages. Dry matter intakes were similar but, numerically lower for heifers fed MG (6.49 and 4.99 kg/d). Feed conversions were similar (0.23 and 0.34 kg gain/kg feed), but numerically greater for heifers fed MG. The limited animal numbers in this study prevented finding significant differences between treatments, however, the feed costs savings are approximately $0.09/heifer/d feeding growing dairy heifers MG corn silage given the same performance based on ration formulation. Given the numerical differences in DM intakes and feed conversions, the cost advantages are greater than $0.09/heifer/d with MG.

Key Words: vorn dilage, fairy heifers, MasterGraze

1854 (W313) Transcriptome profiling of milk in dairy cows fed linseed. A. Siurana*, D. Gallardo and S. Calsamiglia, *Animal Nutrition and Welfare Service, Department of Animal and Food Sciences, Universitat Autònoma de Barcelona, Bellaterra 08193, Spain*

Feeding linseed to dairy cows results in milk fat depression (MFD), but there is a wide range of sensitivity, with some cows not showing any reduction in milk fat, while others having a strong MFD. The objective of this study was to compare the mRNA expression of transcripts expressed in pelleted milk cells in cows resistant or sensitive to MFD. Four cows were selected from a dairy farm after a switch from a control diet to a linseed-rich diet: two were resistant to MFD and had high milk fat content before (4.06%) and after the change (4.36%) (R-MFD); and two were sensitive to MFD and milk fat content decreased after the change into the linseed diet (3.56 to 2.54%, S-MFD). Fresh milk samples were collected from each cow the week before and 2 wk after the diet change, and transcriptional profiling of mRNA was analyzed by Illumina RNA-sequencing technology. A total of 24,880 transcripts were tested. When S-MFD were fed linseed, 54 transcripts increased mRNA expression by 3 to 23 fold, and 9 transcripts decreased mRNA expression by 3 to fivefold compared with the same cows fed the control diet. When R-MFD cows were fed linseed, 306 transcripts increased mRNA expression by 2 to 12 fold and 544 transcripts decreased mRNA expression by 2 to ninefold compared with the same cows fed the control diet. The largest differences were observed between R-MFD and S-MFD cows when fed linseed, where the R-MFD cows increased mRNA expression of 668 transcripts by 2 to 20 fold and decreased mRNA expression of 1161 transcripts by 2 to 81 fold compared with S-MFD cows. When cows were fed the control diet, the R-MFD cows increased mRNA expression of 156 transcripts by 2 to 23 fold and decreased mRNA expression of 740 transcripts by 2 to 42 fold compared with S-MFD cows. When R-MFD cows were compared with S-MFD cows regardless of the diet fed, 91 mRNA transcripts were expressed more, and 460 transcripts were expressed less in R-MFD compared with S-MFD cows. As an example, the gene of the fatty acid binding protein 7 increased mRNA expression by 19 (in the linseed diet) and 20 (in the control) fold in R-MFD compared with S-MFD cows. This preliminary study show the potential of Illumina RNA-sequencing technique to find new candidate genes implicated in MFD.

Key Words: RNA-sequencing, milk fat depression, linseed

1855 (W314) Feeding diets inducing milk fat depression to heat-stressed dairy cows on performance, energy partitioning, and antioxidant status. S. Kargar[1], M. Khorvash[1], G. R. Ghorbani[1] and D. J. Schingoethe[*2], *[1]Isfahan University of Technology, Isfahan, Iran, [2]South Dakota State University, Brookings, SD*

Effects of grain source and dietary oil supplement on production performance, energy balance, metabolic heat production, and markers of liver function of heat-stressed lactating dairy cows were evaluated using eight multiparous Holstein cows (77.0 d in milk) in a duplicated 4 × 4 Latin square design with a 2 × 2 factorial arrangement of treatments. Experimental diets contained either ground barley or ground corn supplemented with either fish oil or soybean oil at 2% of dietary dry matter. Rectal temperature showed no change (averaging 38.9°C) regardless of diet but respiration rate tended ($P = 0.08$) to be decrease in cows fed fish oil as compared to cows fed soybean oil (58.4 vs. 62.5 breath/min). Dry matter intake tended ($P = 0.09$) to be greater for barley- vs. corn-based diets (23.2 vs. 22.3 kg/d), but was reduced for the fish oil compared to soybean oil supplemented diets (21.1 vs. 24.3 kg/d; $P < 0.001$) which was negatively correlated with plasma concentrations of alkaline phosphatase ($r = -0.45$; $P \leq 0.01$) and malondialdehyde ($r = -0.26$; $P < 0.15$). Actual milk yield and energy-corrected milk yield were not affected by grain source whereas feeding fish oil decreased milk yield as compared to soybean oil. Due to lesser dry matter intake, metabolic heat production was decreased in cows fed fish oil relative to cows fed soybean oil. Although feeding fish oil vs. soybean oil reduced net energy for both maintenance and lactation, net energy balance remained unchanged across treatments. However, back fat thickness positively changed (+4.0 mm) in cows fed corn- but not barley-based diets that were supplemented with fish oil vs. soybean oil ($P = 0.10$). There was an interaction between dietary grain source and oil supplement on in vitro indicators of plasma lipoperoxidation including basal and maximum conjugated dienes and calculated area under the curve which were greater in corn-based diets supplemented with fish oil vs. soybean oil. In vivo plasma lipoperoxidation estimated by the plasma level of the major lipoperoxidation product (malondialdehyde) was greater in cows fed fish oil vs. soybean oil which substantiated increased susceptibility of plasma lipoperoxidation in respective cows. Overall, results from current experiment suggest that in cows fed diets supplemented with soybean- vs. fish-oil biosynthesis in the mammary gland was prioritized over anabolism and oxidation in peripheral adipose and muscle tissues regardless of type of grain used.

Key Words: Milk fat depression, Heat stress, Dairy cow

1856 (W315) Altering ewe nutrition in late gestation; the impact on lamb performance. F. McGovern*[1], F. Campion[1], T. Sweeney[2], S. Fair[3], S. Lott[2] and T. M. Boland[1], [1]*School of Agriculture and Food Science, University College Dublin, Dublin, Ireland,* [2]*College of Agriculture, Food Science and Veterinary Medicine, University College Dublin, Belfield, Dublin, Ireland,* [3]*Department of Life Sciences, University of Limerick, Limerick, Ireland*

Exposing the fetus to adverse conditions in-utero may result in developmental adaptations to the postnatal, structural and physiological growth of the animal. Maternal nutritional status is one of the primary extrinsic factors, contributing to the programming of fetal nutrient availability and nutrient partitioning throughout gestation. Altering the level of nutrition received by the ewe has been shown to affect fetal growth, influencing birth weight, postnatal growth and metabolism, and reproductive function. The objective of this study was to examine the effects of offering ewes 80% (*R*), 100% (M), or 120% (E) of recommended metabolisable energy (ME) requirements from d 105 of gestation to parturition on subsequent ewe and lamb performance. In a randomized complete block design study, sixty twin bearing ewes were allocated to one of three dietary treatments (n = 20). Energy requirements were calculated individually for each ewe and amended according to specific treatment allocation. Ewe liveweight and body condition score (BCS) were recorded throughout the study. Within 1 h of birth, the birth weight, lambing difficulty and skeletal measurements were recorded from all lambs. Ewes were hand milked at 1, 10, and 18 h post-partum and lamb colostrum intake recorded. Lamb live weight was recorded intermittently from birth to slaughter and subsequent average daily gain (ADG) calculated. Restricting the metabolisable energy offered (*R*) to the ewe in late gestation resulted in a decline in ewe body weight ($P < 0.05$) and BCS ($P < 0.01$) at 24 h post-partum when compared to ewes offered the excess energy diet (E). Combined litter weight, colostrum yield at 1 h post-partum and total yield up to 18 h post-partum were greater for ewes offered the E diet than either of the other treatment groups ($P < 0.01$). While there was no difference in individual lamb birth weight ($P > 0.05$), lambs born to ewes offered the R diet had a lower ADG ($P < 0.01$) up to 21 d of age and remained lighter ($P < 0.05$) than those born to ewes offered the E diet up to weaning (d 98 post-partum). In conclusion, offering ewes a restricted level of ME for the final 6 wk of gestation negatively impacted ewe performance to parturition and compromised lamb growth to weaning.

Key Words: fetal programming, late pregnancy nutrition, lamb performance

1857 (W316) A sensory additive alters the eating behavior of dry dairy cows. C. Iglesias[1], F. Bargo*[2], A. Mereu[2], I. Ipharraguerre[2] and A. Bach[1,3], [1]*IRTA, Barcelona, Spain,* [2]*Lucta S.A., Barcelona, Spain,* [3]*ICREA, Barcelona, Spain*

Six Holstein dry cows were used to evaluate the effect of a sensory additive (ProEfficient, Lucta S.A.) on eating behavior in a complete randomized design. Cows divided into 2 pens were randomly assigned to 2 treatments: control TMR or the same TMR supplemented with ProEfficient (PE) at a dose of 15 g/cow/d. The TMR (73:27 concentrate: forage; 14.8% CP, 47.0% NDF, 1.32 Mcal NE_L/kg) was formulated to provide the nutrient requirements of dry cows following NRC (2001) recommendations. Cows were fed ad libitum through 4 automatic feeders mounted on scales within each pen. Feed consumption and feeding bouts were recorded automatically. Data were analyzed with a mixed-effects model with repeated measures using the PROC MIXED procedure of SAS (1999) with cow as a random effect and treatment, time, and their 2-way interaction as fixed effects. Although DM intake was not affected ($P > 0.05$) by treatments (11.4 kg/d ± 0.33 SE), cows receiving PE reduced ($P < 0.05$) the time dedicated to eat (119 vs. 149 min/d ± SE 7.60) whereas increased ($P < 0.05$) the eating rate (106.4 vs. 85.3 g/min ± 5.52 SE) compared with the control cows. Neither number of meals (4.3 ± 0.75 SE) nor meal size (2.66 kg/meal ± 0.19 SE) differed ($P > 0.05$) between treatments. Feeding a sensory additive increased eating rate without affecting total dry matter intake of dry cows.

Key Words: sensory additive, eating time, eating rate

1858 (W317) Effects of restricted versus conventional dietary adaptation over periods of 6, 9, and 14 d on blood lipopolysaccharide binding-protein concentration of feedlot cattle. D. V. Vicari*[1], A. Perdigao[2], L. L. Cursino[1], R. S. Barducci[2], M. D. Arrigoni[2] and D. D. Millen[3], [1]*São Paulo State University (UNESP), Dracena campus, Dracena, Brazil,* [2]*São Paulo State University (UNESP), Botucatu campus, Botucatu, Brazil,* [3]*São Paulo State Foundation (FAPESP), São Paulo, Brazil*

Two studies were conducted to determine the effects of restricting intake of the final finishing diet (REST) as a means of dietary adaptation compared with diets increasing in concentrate (STEP) over periods of six, nine and 14 d on blood lipopolysaccharide binding-protein (LBP) concentration of Nellore cattle. The first study was designed as a completely randomized block with a 2x2 factorial arrangement, replicated six times, in which 120 26-months old yearling Nellore bulls (361.3 ± 30.2 kg) were fed in 24 pens for 84 d according to the treatments: STEP for 9-d or 14-d and REST for 9-d or 14-d. The second study had the same design and characteristics just described, in which 120 22-months old yearling Nellore bulls

(352.03 ± 19.61 kg) were fed according to the treatments: STEP for 6-d or 9-d and REST for 6-d or 9-d. In each study, 48 animals (two per pen) were randomly chosen for blood collection, which was performed at end of the adaptation period and on Day 21 of the studies. Blood samples were collected from the jugular vein, and blood LBP concentration, expressed as $ng \cdot mL^{-1}$, was determined by using a commercial ELISA kit. For the first study, a significant ($P = 0.01$) period main effect was observed, in which animals on Day 21 presented greater concentrations of LBP than those at end of the adaptation period (128.1 vs. 56.7). A significant ($P = 0.01$) interaction was observed between protocols and duration of adaptation, where animals in REST protocol of 14-d had greater blood LBP concentration (157.2) than cattle in STEP protocol of 9-d (91.0), which had greater blood LBP concentrations than animals in REST protocol of 9-d (67.3) and STEP protocol of 14-d (54.2). In the second study, no significant ($P > 0.10$) protocols and duration of adaptation main effects were observed. However, a significant ($P = 0.01$) period main effect was observed, in which animals on Day 21 of the study present greater concentrations of blood LBP when compared to those at the end of the adaptation period (615.3 vs. 136.6). As the normal cattle blood LBP range varies from 50 to 500 $ng \cdot mL^{-1}$, adapting feedlot Nellore cattle in 14-d, regardless of the protocol, seems to be the most feasible option.

Key Words: acidosis, endotoxin, Nellore

1859 (W318) The effects of OmniGen-AF on serum metabolites, calcium concentrations and hormones of the adrenal axis during heat stress in lactating Holstein cows.

L. W. Hall*[1], F. A. Villar[1], J. D. Allen[2], J. D. Chapman[3], N. M. Long[4] and R. J. Collier[1], *[1]The University of Arizona, Tucson, [2]Northwest Missouri State, Maryville, [3]Prince Agri Products, Inc., Quincy, IL, [4]Clemson University, Clemson, SC*

The objective was to evaluate physiological, behavioral and hormonal changes in lactating cows supplemented with OmniGen-AF (Prince Agri Products, Inc.) subjected to heat stress. Thirty lactating Holstein cows from an Arizona were assigned to a control diet (CON, $n = 15$h) or control diet plus OmniGen-AF (OG, $n = 15$h). Cows within diet were balanced by DIM, milk production and parity (91 ± 5.9 DIM, 36.2 ± 2.5 kg/d, and 3.1 ± 1.4). The cows were fed OG at 56 g/h/d for 52 d on the dairy, added to the TMR. On d 52, six cows were randomly selected from each of the diet groups, transported to the Agricultural Research Center (ARC), University of Arizona and housed in environmentally controlled modules (EM). Original diet assignments were continued. The OG was top-dressed 2x/d (28 g/feeding) with molasses as the carrier and the CON cows received the molasses carrier 2x/d. Both were mixed into the top one-third of the TMR. In the EM, all cows were subjected to 7 d of thermal neutral (TN), 10 d of heat stress (HS), and 4 d of TN. Feed intake, milk production, and milk composition were measured daily. Rectal temperatures and respiration rates were recorded 3x/d (0600, 1400, and 1800 h). Blood samples were taken on Days 7 (TN), 8 (HS), 10 (HS), 17 (HS) and 18 (TN) during the ARC phase and analyzed for selected blood metabolites, hormones and immune biomarkers. Serum cortisol levels were highest on d 8 for both the CON and OG fed cows however OG cows had significantly lower cortisol ($P < 0.05$) on Day 8 (CO*N* = 0.8372 ug/dL; OG = 0.4838 ug/dL). No differences were detected at the other time points. Serum insulin and plasma glucose levels were not different between CON and OG cows. The OG cows maintained lower SCC compared to CON ($P < 0.01$). Serum calcium were not different, however, serum NEFA ($P = 0.10$) tended to be greater in OG cows throughout the 21 d ARC phase. Although serum cortisol were lower in OG cows, serum ACTH levels at each sampling point were higher ($P < 0.0001$). Results suggest that feeding OG to lactating cows reduced many of the effects associated with HS by reducing cortisol. However, ACTH increased in OG cows suggesting that OG may alter adrenal response to ACTH. Additional research is needed to determine the cause of reduced serum cortisol and elevated serum ACTH in cows fed OG.

Key Words: heat stress, lactating cows, OmniGen-AF

1860 (W319) Assessment of the effect of plant tannins on rumen fermentation and gut microbial diversity in goats using 16S rDNA amplicon pyrosequencing.

B. R. Min*[1], C. Wright[1], P. Ho[2], J. S. Eun[3], N. Gurung[1] and R. Shang[1], *[1]Tuskegee University, Tuskegee, AL, [2]Montgomery Blair High School, Silver Spring, MD, [3]Utah State University, Logan*

Two grazing experiments were performed to 1) investigate the effects of supplementing condensed tannins (CT)-containing pine bark (PB) powder on ADG, ruminal fermentation, and gut microbial diversity dynamics, and 2) to quantify the influence of different sources of tannins supplementations on ruminal fermentation and gut microbial diversity changes of goats grazing winter pea and ryegrass dominant forages. In Exp. 1, 20 Kiko cross male goats (*Capra hircus*; initial BW = 39.7 ± 2.55 kg) were randomly assigned to 2 experimental diets (alfalfa pellet vs. PB powder). Alfalfa pellet (no CT as a control) or PB (11% CT) was supplemented at 0.8% BW for targeted total DMI of 1.2% BW. The remainder DMI of each diet was obtained from grazing for 60 d. In Exp. 2, 12 Kiko cross goats were used to measure ADG, ruminal fermentation, and gut microbial population in the rumen of goats grazing bermudagrass. The animals were randomly assigned to 3 experimental diets: 1) no tannins (control), 2) chestnut extract at 100 g/d (CTE), and 3) quebracho CT extract at 100 g/d (QCTE). In Exp. 1, ADG was greater ($P < 0.05$) in PB (209 g/d) than the control (188 g/d). However, goats grazing winter pea and ryegrass forages with PB supplementation decreased ($P < 0.05$) concentrations of acetate (14.4 vs. 15.1 mM), propionate (3.34 vs. 3.83 mM),

butyrate (1.82 vs. 2.00 mM), and total VFA (22.5 vs. 23.7 mM) compared to those in the control, respectively. Bacterial population in PB-supplemented group was greater for *Bacteroides* (20.5 vs. 33.2%), *Firmicutes* (67.2 vs. 57.3%), and Proteobacteria (1.15 vs. 1.44%) phylum compared with control group, respectively. In Exp. 2, ADG was greatest for CTE (275 g/d) than QCTE (148 g/d) and the control (79.4 g/d). Goats grazing bermudagrass pasture with CTE had greater ($P < 0.05$) concentrations of acetate, propionate, butyrate, and total VFA compared to those in QCTE and control. Bacterial population in CTE-supplemented group was greatest for *Bacteroides* (51.5, 52.9, and 35.3%), *Firmicutes* (40.2, 36.7, and 55.9%), and Proteobacteria (2.28, 2.18, and 1.49%) phylum compared with QCTE and control group, respectively. Rumen archaeal population, however, was greatest in control group (0.70%) compared with CTE (0.23%) and QCTE (0.22%) group. Supplementing tannins in goat diets such as CTE, QCTE, or PB powder has the potential to improve ADG and modify rumen bacterial and archael population.

Key Words: goats, gut microbial diversity, tannins

1861 (W320) Effect of supplemental chelated Cu, Zn, and Mn on antioxidant status and hoof health of lactating cows.

X. J. Zhao[1], J. H. Wang[2], Y. M. Wang[*3] and L. Wang[1], *[1]College of Animal Science and Veterinary Medicine, Shandong Agriculture University, Taian, China, [2]College of Animal Science, Zhejiang University, Hangzhou, China, [3]Novus International Trading (Shanghai) Co., Ltd, Shanghai, China*

The objective of the study was to evaluate effect of supplemental Cu, Zn, and Mn as chelated trace mineral (CTM) on antioxidant status and hoof health of dairy cows. Forty eight Holstein cows in early lactation (DIM = 65) were randomly assigned into 1 of 2 treatments: 1) basal diet contains 17.2 mg Cu, 70.1 mg Zn, and 63.7 mg Mn/kg dry matter (CON); 2) basal diet supplemented with 150 mg Cu, 320 mg Zn and 130 mg Mn/head/d as CTM (Minitrex). Cows were gait scored using a 5-point Numerical Rating System where 1 and 2 are considered healthy, and $\geq$ 3 lame. Cows in each treatment were blocked as lame cows (n = 12) or healthy cows (n = 12) when data was analyzed. Over the 180 d experiment, DMI, milk yield and milk composition was tested every 10 d. Blood samples and hoof samples were taken at Day 0, 90, and 180 to test the blood antioxidant variables and hoof hardness, respectively. There was no difference in DMI, milk yield and milk composition between healthy and lame cows ($P > 0.05$). Cows receiving CTM had less milk fat concentrations ($P < 0.05$) than CON, but no difference was observed on milk fat yield or other milk components ($P > 0.05$). No differences were detected in blood superoxide dismutase (SOD), reduced glutathione (GSH), oxidized glutathione (GSSG), glutathione peroxidase (GSH-Px), catalase (CAT), and malondialdehyde (MDA) between healthy and lame cows ($P > 0.05$). Compared with CON, blood SOD, GSH, and GSH-Px in CTM cows were significantly increased while MDA and GSSG were significantly decreased ($P < 0.05$), and blood CAT was not affected by treatments ($P > 0.05$). Cows receiving CTM did not have hoof hardness that differed from the CON at Day 0 and 90, but had significant greater values than CON at Day 180 ($P < 0.05$). There was no interaction between CTM and cows health status. It was concluded that supplemental chelated Cu, Zn, and Mn could improve antioxidant status and hoof hardness regardless of lameness status.

Key Words: chelated trace mineral; antioxidant status; hoof health

---

1862 (W321) Effects of supplemental bupleurum extract on serum hormone and immune globulin levels in heat-stressed dairy cows.

X. Sun[1,2,3], J. Cheng[1,2,3], D. P. Bu[3], L. Pan[3], N. Zheng[1,3,4] and J. Wang[*1,3,4], *[1]Ministry of Agriculture- Laboratory of Quality & Safety Risk Assessment for Dairy Products (Beijing), Beijing, China, [2]College of Animal Science and Technology, Anhui Agricultural University, Hefei, China, [3]State Key Laboratory of Animal Nutrition, Institute of Animal Science, Chinese Academy of Agricultural Sciences, Beijing, China, [4]Ministry of Agriculture- Milk and Dairy Product Inspection Center (Beijing), Beijing, China*

This experiment was conducted to evaluate the effects of bupleurum extract (BE) on serum hormone and immune globulin levels in dairy cows under heat stress. Forty lactating Holstein cows (75 ± 15 DIM, 37.5 ± 1.8 kg of milk/d, and 1.7 ± 0.4 parity) were randomly assigned to one of four treatments. Treatments consisted of 0 (control), 0.25, 0.5, or 1.0 g BE/kg DM. The experiment lasted 10 wk. Average temperature–humidity index (THI) was more than 72 throughout the experimental period. Blood samples were collected from all of animals via tail vein before the morning feeding on Days 0, 21, 42, and 63. Data were analyzed by MIXED model procedure of SAS 9.2. Compared with controls, cows fed 1.0 g/kg BE had higher thyroxine (T3) (1.43 vs. 1.16 ng/mL; $P < 0.05$) and prolactin (PRL) (230.50 vs. 188.19 uIU/mL; $P < 0.05$) levels, and 0.5 g/kg BE had the tendence to increase the T3 (1.27 vs. 1.16 ng/mL; $P < 0.10$) level, but 0.25 and 0.5 g/kg BE had no effect ($P > 0.05$) on PRL level. Serum growth hormone (GH) level was increased (2.17 vs. 1.21 ng/mL; $P < 0.05$) in cows fed 0.25 g/kg BE compared with control cows, and tended to be higher (1.76, 1.69 vs. 1.21 ng/mL; $P < 0.10$) in cows fed 0.5 and 1.0 g/kg BE. Supplementation of BE had decreased the cortisol (COR) levels (48.35, 49.43, 49.86 vs. 64.49 ng/mL; $P < 0.05$), but had no effect ($P > 0.05$) on the levels of thyroxine, Insulin, glucagon, neuropeptide Y, leptin, insulin-like growth factor, and heat shock protein 70. Cows fed 0.5 g/kg BE increased the immunoglobulin (Ig) A content (279.25 vs. 179.78 ìg/mL;

$P < 0.05$), and IgG level was increased (36.54, 36.14 vs. 27.13 mg/mL; $P < 0.05$) in cows supplemented with 0.25 or 0.5 g/kg BE, while the IgM and tumor necrosis factor-á (TNF-á) levels showed no difference ($P > 0.05$) when compared with the control cows. These findings suggest that BE supplementation could relieve metabolic disorders and enhance immune function in heat-stressed cows.

Key Words: bupleurum extract;serum hormone; immune globulin

1863 (W322) Dry matter intake, milk yield, and composition of Holstein cows fed organic minerals.

T. A. Del Valle*[1], E. F. Jesus[2], A. G. B. V. B. Costa[1], G. F. Cabral[3], V. C. Galvão[1], P. G. D. Paiva[2], T. S. Acedo[4], L. F. M. Tamassia[4] and F. P. Rennó[1], *[1]School of Veterinary Medicine and Animal Science, University of São Paulo, Pirassununga, Brazil, [2]School of Agricultural and Veterinary Sciences of UNESP, Jaboticabal, Brazil, [3]School of Animal Science and Food Engineering of University of São Paulo, Pirassunga, Brazil, [4]DSM Produtos Nutricionais, São Paulo, Brazil*

The aim of this study was to evaluate the effects of organic sources of minerals diet of dairy cows in mid-lactation on dry matter intake, milk yield and composition. Twenty Holstein cows with an average body weight of 625.30 ± 80.37 kg and DIM averaging 146.83 ± 67.34 were allocated to receive one of two diets: INO (inorganic): diet with addition of inorganic mineral sources; ORG (organic) diet with addition of organic mineral sources (zinc, cooper, selenium, chromium, manganese, cobalt, iron and sulfur; DSM Produtos Nutricionais, Brazil). The design was crossover. Each experimental period had 14 d adaptation and 7 d for sampling. Samples of milk were collected on 16th, 17th and 18th days of each period to evaluate the composition. The cows were allocated in individualy barns type free-stall, fed ad libitum and intake were estimated by bromatological analyzes of feeds and orts. Increases in fat-corrected milk ($P < 0.05$), fat yield ($P < 0.05$) and protein ($P < 0.10$) were observed in the animals receiving the diets containing organic mineral sources compared to those fed inorganic sources. This increasing in fat corrected milk shows an increased efficiency of energy use, most likely due to higher preparation of enzyme apparatus for metabolizing energy. Milk yield has not influenced by the treatments, showed a mean of 32.43 $kg.d^{-1}$ and difference of 0.63 $kg.d^{-1}$ of milk, which, together with the average increase of 1.4 $g.kg^{-1}$ fat led to increase in fat yield ($P < 0.05$). The protein content, although not statistically differ, was 0.8 $g.kg^{-1}$ higher in diet with organic sources and result in increase 0.05 kg the protein yield ($P < 0.10$). The dry matter intake average 21.27 $kg.d^{-1}$ and no effect of experimental diets was observed. Organic minerals increases energy efficiency in dairy cows, increasing the secretion of milk solids without change the intake.

Key Words: dairy cows, efficiency, milk fat

1864 (W323) Effects of sampling position on blood hormone concentration in dairy cattle.

M. Zhao, D. P. Bu, J. Q. Wang*, X. Q. Zhou, Y. Zhang, S. G. Zhao and P. Sun, *State Key Laboratory of Animal Nutrition, Institute of Animal Science, Chinese Academy of Agricultural Sciences, Beijing, China*

To evaluate the effects of sampling position on blood hormone concentration in dairy cattle, ten dairy cows (Milk yield = 28.2 ± 2.1 kg/d, DIM = 121 ± 15 d) were selected. Blood samples from mammary vein, external pudic artery, coccygeal artery and vein were collected. Eight kinds of hormones were determined by radioimmunoassay method including insulin, growth hormone (GH), insulin-like growth factor-1 (IGF-1), leptin, adrenocorticotropic hormone (ACTH), estrogen, prolactin and progestin. Statistical analysis was performed using the PROC MIXED procedure of SAS 9.0. The results showed that no differences were observed in these hormones. Concentrations of hormones in mammary vein, external pudic artery, coccygeal artery and vein were averaged as followed: insulin (5.56 vs. 6.39 vs. 5.35 vs. 5.38 μIU/ml, $P > 0.05$), GH (2.29 vs. 2.34 vs. 2.34 vs. 2.40 ng/ml, $P > 0.05$), IGF-1 (290.57 vs. 260.63 vs. 283.64 vs. 266.99 ng/ml, $P > 0.05$), Leptin (3.04 vs. 3.10 vs. 3.17 vs. 2.97 ng/ml, $P > 0.05$), ACTH (11.35 vs. 11.43 vs. 11.50 vs. 12.15 pg/ml, $P > 0.05$), Estrogen(12.67 vs. 12.70 vs. 14.45 vs. 11.47 pg/ml, $P > 0.05$), Prolactin (315.88 vs. 312.47 vs. 290.28 vs. 302.24 μIU/ml, $P > 0.05$), Progestin(0.21 vs. 0.24 vs. 0.23 vs. 0.33 ng/ml, $P > 0.05$). It was implied that either of the four sampling positions could be representative for hormones measurement when estimating mammary gland metabolism.

Key Words: blood, hormone, mammary gland

1865 (W324) Effects of dietary protein composition on blood hormone levels in dairy cattle.

M. Zhao[1], D. P. Bu[1], J. Q. Wang*[1], X. Q. Zhou[1,2], Y. Zhang[1] and P. Sun[1], *[1]State Key Laboratory of Animal Nutrition, Institute of Animal Science, Chinese Academy of Agricultural Sciences, Beijing, China, [2]Northeast Agricultural University, Harbin, China*

The objective of this experiment was to investigate the effects of different protein sources on blood hormones profile. Thirty two dairy cows were pen fed with total mixed ration (TMR), which were divided into group soybean (corn stover 36.1%, soybean meal 11.3%, extruded soybean 2.1%, whole cottonseed 10.4%, rapeseed meal 4.2%, cottonseed meal 2.1%, beet pulp 4.2%, grind corn 25.6% and other supplements 4.1%) and group non-soybean (corn stover 36.1%, whole cottonseed 10.4%, rapeseed meal 9.6%, cottonseed meal 6.7%, beet pulp 7.5%, grind corn 25.6%, wheat bran 4.5% and other supplements 1.7%). Crude protein (CP) and neutral detergent fiber

(NDF) of TMR were 16.1% vs. 15.1% and 54.0% vs. 57.1% in group soybean and group non-soybean, respectively. The duration of this experiment was 15 wk (2-wk adaptation and 13-wk experimental period). Nine hormones were determined by radioimmunoassay method including insulin, growth hormone (GH), insulin-like growth factor-1 (IGF-1), Adrenocorticotropic hormone (ACTH), Leptin, Estrogen, Cortisol, Prolactin and Progestin. Statistical analysis was performed using the PROC MIXED procedure of SAS 9.0. Dry matter intake (DMI) and milk yield were 17.4 vs. 19.1 kg/d ($P < 0.01$) and 23.2 vs. 22.9 kg/d ($P > 0.05$) in group soybean and group non-soybean. Concentrations of hormones were averaged insulin (13.44 vs. 12.55 μIU/ml, $P > 0.05$), IGF-1 (384.31 vs. 286.33 ng/ml, $P < 0.01$), ACTH (9.67 vs. 6.00 pg/ml, $P < 0.05$), Estrogen (10.69 vs. 10.44 pg/ml, $P > 0.05$), GH (2.37 vs. 2.26, $P > 0.05$), Leptin (3.67 vs. 3.32 ng/ml, $P > 0.05$), Progestin (0.38 vs. 0.36 ng/ml, $P > 0.05$), Prolactin (175.51 vs. 174.00 μIU/ml, $P > 0.05$) and Cortisol (10.92 vs. 7.38, $P > 0.05$) in group soybean and group non-soybean, respectively. It demonstrated that protein sources could significantly influence DMI and have no effect on milk yield, which can also influence the function of hypothalamus pituitary adrenal axis and stimulate the cell proliferate.

Key Words: protein source, blood hormone, dairy nutrition

1866 (W325) The small ruminant nutrition system: Considering the ruminal fiber stratification for goats. J. G. L. Regadas Filho*[1], L. O. Tedeschi[2], A. Cannas[3], M. T. Rodrigues[4] and R. A. Vieira[5], *[1]Universidade Federal de Vicosa, Vicosa, Brazil, [2]Texas A&M University, College Station, [3]Universita Di Sassari, Sassari, Italy, [4]Universidade Federal de Viçosa, Vicosa, Brazil, [5]Norte Fluminense State University, Campos dos Goytacazes, Brazil*

The objective of this research was to assess the ability of a mechanistic model named Small Ruminant Nutrition System (SRNS) to predict the metabolizable energy intake (MEI) and milk yield (MY) by using a heterogeneous ruminal fiber pool scenario (GnG1; Regadas Filho et al., 2014) in comparison to a traditional homogeneous scenario (G1), The GnG1 scenario considers that the first ruminal fiber pool (raft) follows an age-dependent fractional rate for particle transference from a raft to an escapable pool (λ_r) and that the second ruminal fiber pool (escapable) follows an age-independent fractional rate of particle escape from the escapable pool (k_e); for G1, a scenario with only a single fractional rate passage (k_p) is adopted. All parameters were estimated individually by using equations published in the literature; however, for the G1 scenario, two rate passage equations were used, with one from sheep data (G1-S; Cannas et al., 2004) and another from goat data (G1-G; Tedeschi et al., 2012). The MEI, MY and DMI estimated by using these scenarios were compared with the results of an independent dataset ($n = 327$) that contained information regarding the DMI, MEI, MY, BW and milk and dietary compositions. The evaluation of the scenarios was performed using a coefficient of determination (r^2) between the observed and predicted values; mean bias (MB); bias correction factor (C_b) and concordance correlation coefficient (CCC). The MEI estimated by the GnG1 scenario yielded a precision and accuracy ($r^2 = 0.82$; MB = 0.21 Mcal.d^{-1}; $C_b = 0.98$) similar to that of the G1-S ($r^2 = 0.85$; MB = 0.10 Mcal.d^{-1}; $C_b = 0.99$) and G1-G ($r^2 = 0.84$; MB = 0.18 Mcal.d^{-1}; $C_b = 0.98$) scenarios. The results were also similar for the MY; however, a significant MB ($P < 0.01$) was found as follows: GnG1 ($r^2 = 0.74$; MB = 0.70 kg.d^{-1}; $C_b = 0.79$), G1-S ($r^2 = 0.71$; MB = 0.58 kg.d^{-1}; $C_b = 0.85$) and G1-G ($r^2 = 0.71$; MB = 0.65 kg.d^{-1}; $C_b = 0.82$). The GnG1 scenario can be assumed to maintain the theoretical basis of mechanistic models.

Key Words: fiber stratification, goat, heterogeneous fiber pool

---

1867 (W326) Effect of "COGU" technology on glucose uptake and mineral utilization and deposition in growing lambs. A. M. Temple*[1], G. A. Ayangbile[1], D. R. Vandermyde[1] and C. R. Vandermyde[2], *[1]Agri-King Inc., Fulton, IL, [2]Morrison Veterinary Clinic, Morrison, IL*

"COGU" is a proprietary combination of GRAS microbial fermentation extracts meant to diminish the negative impact of mineral interactions that may be responsible for inefficient digestibility, absorption and utilization of nutrients in livestock. The objective of this study was to observe the effect of COGU technology additive (COGU) on blood glucose uptake, mineral utilization and deposition in the ruminant. Twenty-four Katahdin wethers (average BW 15.8 ± 1.5 kg) approximately 55 d of age were fed ad libitum either a silage based control diet (CON), or CON plus 3.4 g/head/d of a supplement containing COGU. Lambs were penned in groups of six with two pens per treatment. ADG was calculated for each animal and DMI was measured for each pen throughout d 100 of the experiment. Jugular blood samples were analyzed for each animal during wk 0, 4, 8, 10, and 12. Eight CON and 9 COGU sheep were housed in crates 5 d for total collection of orts, fecal and urinary samples for digestibility and nutrient utilization. All lambs were euthanized at the end of the experiment, and tissues collected for biological analysis. Data were analyzed by ANOVA CRD. No differences ($P > 0.05$) were observed between dietary treatments for DMI, ADG, or digestibility of nutrients. However, COGU-supplemented lambs had numerically greater digestibility of Na, P, S and Cu. Blood glucose in COGU lambs was higher (CO*N* = 61.90 mg/dL, COGU = 72.98 mg/dL; $P = 0.0005$) throughout the trial. Previous unpublished research also showed higher blood glucose in COGU-supplemented lambs. Liver glycogen was numerically higher ($P > 0.05$) in COGU-supplemented lambs.

No differences were observed in blood NH3, BHBA, BUN, cholesterol, or NEFA. Rumen fluid contents showed COGU tended to increase ($P = 0.054$) the molar proportion of acetate, propionate, and butyrate. Duodenum mucosal cell scrapings in COGU treatment had decreased ($P = 0.019$) Mg. Copper, Mn, and Zn were numerically higher ($P > 0.05$) and Fe lower ($P > 0.05$) in duodenum mucosal cell scrapings of COGU-supplemented lambs. In conclusion, supplemental COGU seems to increase blood glucose uptake in the growing lamb. It also may affect mineral passage and utilization through the duodenum mucosal cell membrane.

Key Words: glucose, mineral, lambs

1868 (W327) Effect on plasma metabolites of Nellore bulls fed ractopamine hydrochloride and protein level.

N. R. B. Cônsolo*[1], F. Rodriguez[1], M. O. Frasseto[1], R. A. P. Maciel[2], V. Rizzi[3] and L. F. P. Silva[1], [1]*University of Sao Paulo, Pirassununga, Brazil,* [2]*University of Sao Paulo, São Paulo, Brazil,* [3]*Ouro Fino, Cravinhos, Brazil*

The aim of this study was to evaluate was to evaluate the effects of ractopamine hydrochloride (RH) and dietary crude protein (CP) on blood metabolites of Nellore young bulls. Forty eight Nellore bulls were grouped by BW, and randomly assigned to treatments in a 2x2 factorial arrangement of treatments. The factors were two levels of dietary CP (100 and 120% of MP requirement), and two levels of RH (0 and 300 mg/animal/d). Treated animal received RH for the final 35d before slaughter. Blood was collected at the beginning and at the end of RH supplementation by venipuncture and/or puncture of the coccygeal artery, before the morning feeding. Blood samples were collected into 10-mL BD Vacutainers, without anticoagulant, for the measurement of serum glucose, total protein, albumin, plasma urea nitrogen (PUN), aspartate aminotransferase (AST), γ-glutamyl transferase (GGT) and alkaline phosphatase (ALP). Blood parameters were analyzed using commercial kits (Laborlab, São Paulo, Brazil and CELM, São Paulo, Brazil) by endpoint or kinetic colorimetric methods in an ABS-200 Automatic Biochemistry Analyzer (CELM). The statistical analyses were conducted using SAS, version 9.1.2 for Windows (SAS Institute Inc., Cary, NC, USA). Data were analyzed as a randomized block design with a 2x2 factorial arrangement of treatments using the MIXED procedure of SAS. There was no effect of treatments, or of interaction, on plasma creatinine, AST or GGT ($P > 0.05$). Dietary CP level tended to increase blood urea (31.2 vs. 40.8 mg/dL, $P = 0.07$). RH supplementation altered glucose, ALP and total protein; however, the effect was dependent on the dietary CP level. RH supplementation decreased plasma glucose concentration at CP100 ($P = 0.05$), and had no effect at CP120 ($P = 0.87$). For ALP activity, RH supplementation increased its activity at CP120 ($P = 0.05$) and had no effect at CP100 ($P = 0.42$). RH supplementation increased plasma total protein at CP 120 ($P = 0.03$) and had no effect at CP100 ($P = 0.17$) In conclusion, RH supplementation and CP levels leads to slight changes on plasma metabolites.

Key Words: crude protein, β-agonist, plasma metabolites

1869 (W328) Impact of "COGU" technology on performance in lactating dairy cows.

A. M. Temple*, G. A. Ayangbile, D. F. Jones and D. A. Spangler, *Agri-King Inc., Fulton, IL*

"COGU" is a proprietary combination of GRAS microbial fermentation extracts meant to diminish the negative impact of mineral interactions that may be responsible for inefficient digestibility, absorption and utilization of nutrients in livestock. Two studies were initiated to investigate the effect of COGU on blood profiles and lactation performance of dairy cows. The first study was conducted on a commercial dairy farm in the Pacific Northwest. Water and forages in this region are known to have certain minerals in excess causing depressed milk production, high somatic cell counts and other metabolic issues. In a Washington herd of 1500 cows, three groups of 130 cows each were selected. Each group contained fresh cows, heifers, or high cows. Cows were fed a supplement containing COGU at a rate of 15 g/head/d in a corn silage based TMR diet for 41 d. Twenty cows averaging 75 DIM (± 3 d) from the high group were randomly selected for blood sampling and milk data collection. Blood samples were obtained 2 wk before feeding COGU (BCOGU), followed by wk 1, 2, and 4 fed COGU (COGU), and subsequently by sampling at wk 1, 3, and 5 after removing COGU (ACOGU) from the diet. On-farm milk production data was collected daily 2 wk before feeding COGU through 4 wk after removing COGU. Data were analyzed by ANOVA CRD. Blood glucose, BUN, and hemoglobin were increased ($P < 0.0002$) for cows fed COGU, and BHBA and NEFA were decreased ($P < 0.0001$). The 150 DIM adjusted production was higher ($P < 0.0001$) for cows fed COGU. In a second study, 180 commercial dairy farms across the United States representing 29,346 cows were randomly selected. COGU was blended into a supplement and fed at a rate of 15 g/head/d. Data for milk yield and components was collected for a minimum of 10 d to maximum of 120 d on these farms. Statistical analysis was performed with Kruskal–Wallis One-Way Nonparametric AOV and Dunn's All-Pairwise Comparison test. There were no differences in DMI intake ($P = 0.98$); however, milk yield, milk butterfat, milk protein, ECM, and ECM feed efficiency were all significantly higher ($P < 0.03$) at the end of the experimental period compared to the start of the experiment. COGU increased glucose uptake and nitrogen utilization as well as improved milk yield and components in dairy cows.

Key Words: glucose, milk yield, dairy cows

1870 (W329) A conceptual model of protein-precipitable polyphenols (condensed tannins) on protein binding and protein digestion in ruminants.

H. D. Naumann*[1], N. M. Cherry[2], L. O. Tedeschi[3], J. P. Muir[2,4] and B. D. Lambert[2,4], *[1]University of Missouri, Columbia, [2]Texas A&M AgriLife Research, Stephenville, [3]Texas A&M University, College Station, [4]Tarleton State University, Stephenville, TX*

There is a need to better understand the mechanisms by which biologically active protein-precipitable polyphenols (PPP) from forages bind to dietary protein in the rumen and how this impacts the ruminant animal's requirement for protein. The objective of this study was to model the effect of biologically active PPP on ruminal protein binding and the potential protection of rumen-bypass protein. Green live-leaf material from six species of warm-season perennial legumes was sampled during August of 2011 and 2012. The effect of biologically active PPP on protein-binding ability was evaluated by combining rhizoma peanut with experimental forages to create separate basal diets (by year) containing PPP ranging from 1–9%. Protein-binding ability was determined by an in vitro protein-precipitable phenolics assay and nitrogen analysis of the protein-phenolic precipitates. Data were analyzed in linear-segmented and quadratic-segmented regressions (PROC NLIN of SAS) to model the effects of biologically active PPP on protein-binding ability. The Model Evaluation System (MES; http://nutritionmodels.tamu.edu/mes.html) was used to compare the correctness of the linear- versus the quadratic-segmented regression. For the linear-segmented regression, β_0 is equal to α, β_1 is equal to β, and α, β, X_m and Y_m were equal to -3.2935, 6.3329, 6.4 and 37.24, respectively. For the quadratic-segmented regression, β_0 is equal to α, β_1 is equal to β, β_2 is equal to γ and α, β, γ, X_m and Y_m were equal to -10.7117, 11.4534, -0.6854, 8.32 and 37.14, respectively. The data pattern suggests that the relationship between PPP and protein bound is not linear in nature. Beyond a certain point, in this case a concentration of PPP occurring between 6.4 and 8.3%, the amount of protein bound does not increase as the concentration of PPP in the diet increases. While both segmented regressions were similar in terms of adequacy, the linear-segmented regression was slightly more precise than the quadratic-segmented regression (R^2 0.811 and 0.809, respectively) at accounting for variation that occurred in observed values. Overall, the regression comparison indicated that the linear-segmented regression is 1.2 times more likely to correctly predict observed values of protein binding by PPP than the quadratic-segmented regression. However, either model would be an acceptable tool for use in modeling the effect of forage PPP on rumen-protein binding and potential protection of rumen-bypass protein and in a decision support system.

Key Words: legume, protein, tannin

1871 (W330) Effect of sprouted barley grain supplementation of an herbage or haylage diet on ruminal fermentation and methane output in continuous culture.

A. N. Hafla*[1], K. J. Soder[1], A. F. Brito[2], M. D. Rubano[1] and C. J. Dell[1], *[1]USDA-Agricultural Research Service, University Park, PA, [2]University of New Hampshire, Durham*

A 4-unit dual-flow continuous culture fermentor system was used to assess the effect of supplementing 7-d sprouted barley (SB) or barley grain (BG), with a pasture (orchardgrass) or haylage diet, on nutrient digestibility, VFA production, bacterial protein synthesis, and methane production. Treatments were randomly assigned to fermentors in a 4 × 4 Latin square design with a 2 × 2 factorial arrangement of treatments using 7 d for diet adaptation and 3 d for sample collection. Treatments were: 1) pasture+SB, 2) pasture+BG, 3) haylage+SB, and 4) haylage+BG. Feedings (60 g of DM) occurred 4 times daily (0730, 1030, 1400, 1900 h) throughout four 10-d periods. Gas samples for methane analysis were collected 6 times daily (0725, 0830, 1000, 1355, 1530, 1630 h). Samples for pH, ammonia-N, and VFA analysis were taken on d 8, 9, and 10 and analyzed for DM, OM, CP, NDF, and ADF for determination of nutrient digestibilities, and estimation of bacterial protein synthesis. Data were analyzed using the MIXED procedure of SAS with period and treatment as fixed effects and fermentor as random. Orthogonal contrasts were tested using haylage vs. pasture and BG vs. SB treatments. Apparent and true DM digestibility was not affected by forage type. True DM digestibility was greater ($P = 0.05$) for diets supplemented with SB. Apparent and true digestibilities of OM and apparent CP were not affected by treatment (68, 83, and 89%, respectively). Apparent NDF and ADF digestibilities of pasture diets were greater ($P < 0.05$) compared to haylage diets (79 vs. 72% and 76 vs. 73%, respectively); however, supplement did not affect fiber digestibility. Diets supplemented with SB had greater ($P < 0.05$) mean and minimum pH than BG. Haylage diets produced greater ($P < 0.01$) concentrations of total VFA compared with pasture diets (72 vs. 61 mmol/L). Supplementation with BG produced a greater ($P = 0.03$) concentration of total VFA compared to diets supplemented with SB (68 vs. 64 mmol/L). Haylage diets produced greater ($P < 0.05$) concentrations of daily methane compared with pasture diets (35 vs. 27 mmol) but supplementation did not affect methane production. Bacterial efficiency was greater ($P < 0.05$) for pasture diets compared with haylage diets with no effect of supplementation. Supplementation with SB increased true DM digestibility of pasture and haylage diets, but did not impact fiber and CP digestibility, methane production, or microbial efficiency, compared to BG.

Key Words: sprouted barley, pasture, methane

1872 (W331) Effect of Lalsil bacterial inoculants on the pH of corn silage with low dry matter. M. Saberi*, K. Rezayazdi and M. Dehghan Banadaky, *Department of Animal Science, Faculty of Agriculture, University of Tehran, Karaj, Iran.*

To study the effect of commercial lactic acid bacteria inoculants (Lalsil) on the pH during the ensiling of corn silage with low dry matter,this experiment was conducted according to completely randomized design with 3 treatments and 4 replicates in each treatment. Treatments were: 1- control (no additives) 2- treated with Lalsil Mso1 (*Lactobacillus plantarum* and *Propionibacterium acidipropionici* applied at 1×10^5 cfu/g of the corn silage) 3- treated with Lalsil Fresh (*Lactobacillus buchneri* applied at 1×10^5cfu/g of the corn silage). pH of corn silage were measured at 1, 3, and 6 wk after ensiling. Statistical analysis of data was performed using PROC GLM and SAS statistical software. The results showed that DM (Dry matter), CP(Crude protein), NDF(Neutral Detergent Fiber) and ADF (Acid Detergent Fiber) composition of the corn silage were 18.87, 9.37, 61.75 and 25.50%, respectively. The difference between the first and sixth weeks of treatment was significant ($P < 0.05$). In the first and sixth weeks, treatment 1 had highest pH (3.92 and 3.80) and treatment contain Lalsil Fresh had lowest pH(3.83 and 3.70). There was no significant difference among treatments in the third week. It can be concluded that Lalsil bacterial inoculants could significantly reduced pH of corn silage, While Lalsil- Fresh was reduced pH of corn silage with low dry matter more effectively.

Key Words: corn silage, bacterial inoculants, pH

1873 (W332) The microbiome composition of the rumen is altered during the peripartal period in dairy cattle. H. Derakhshani[1], S. Alqarni[2], H. Khazanehei*[1], F. C. Cardoso[2], J. C. Plaizier[1], E. Khafipour[1,3] and J. J. Loor[2,3], *[1]Department of Animal Science, University of Manitoba, Winnipeg, MB, Canada, [2]University of Illinois, Urbana, [3]Department of Medical Microbiology and Infectious Diseases, Winnipeg, MB, Canada.*

Alterations in ruminal microbiota composition during the peripartal period were studied using eight multiparous fistulated Holstein dairy cows. Cows were fed a typical TMR to meet NRC (2001) requirements during the dry period and early lactation. Ruminal digesta samples were collected on days −14, −7, +10, +20 and +28 relative to calving. DNA was extracted after physical homogenization and utilized for PCR amplification of the V4 region of the 16S rRNA gene using barcoded universal primers to allow for multiplexing. Amplicons were purified, quantified and subjected to Illumina paired-end sequencing. The PANDAseq assembler was used to merge the paired-end sequences for further analyses using QIIME pipelines. After filtration and removing chimeric reads, assembled sequences were assigned to operational taxonomic units and aligned to Greengenes database. The Chao1 estimator of species richness and Unifrac distance matrices were used to calculate α-diversity and β-diversity of microbial communities, respectively. Differences in bacterial composition across time were tested using the PERMANOVA procedure in PRIMER v6 software. Partial least square discriminant analysis (PLS-DA) of SIMCA was performed to identify taxa that were most characteristic of each time point. A total of 1393,235 sequences were generated and an average of 35,990 high-quality sequences per sample were obtained after quality filtering steps, which resulted in identification of 16 phyla and 303 taxa of which 145 were classified at the genus level. The microbial profile of ruminal digesta differed across time points with highest differences observed when comparing day −14 to day +28 ($P = 0.03$), and day −7 to day +28 ($P = 0.05$). At the phylum level, the abundance of Actinobacteria increased while Armatimonadetes, Cloriflexi, Tenericutes, Verrucomicrobia, and WPS-2 decreased in the postpartum compared with prepartum. At the genus level, the abundance of *Atopobium, Clostridium, Coprococcus*, *Lactobacillus*, *Moryella*, *Olsenella, Pediococcus*, *Shuttleworthia Streptococcus,* and *Weissella* increased postpartum compared with prepartum. Variation in the ruminal microbiota among cows was smaller before calving but gradually increased after calving. This may have been associated with the normal decline in voluntary dry matter intake (DMI) before parturition. The greater dissimilarity postpartum in microbial communities among cows may be due to individual differences in physiological responses. Factors such as DMI, the degree of negative energy balance around parturition, and the occurrence of metabolic disorders during this period could affect the ruminal ecosystem and, thus, alter its microbial composition.

Key Words: dairy cows, rumen microbiota, transition period, illumina sequencing

1874 (W333) Evaluating rations offered to a group of cattle as a component of ration formulation software. J. Ferguson*, Z. Wu, D. T. Galligan, L. Baker and N. Thomsen, *University of Pennsylvania, Kennett Square.*

Rations are typically formulated for a target cow representing a group of cows. Lead factors may be used to select the target milk production for the group. Body weight, lactation number and milk composition are chosen based on mean values for the group of cows to be offered the ration. It is often not known how the offered ration impacts the ME and MP across all cows in the group. To provide an assessment of ME and MP balance for a ration fed to a group of cows, the UPenn Ration Analyzer incorporated a group model within its software program. Records from DHIA milk production (more than 1000,000) from 2000 farms and five breeds were used to construct production curves based on rolling herd averages

(RHA) for parities 1, 2, and 3+. The user inputs breed, lactation number, the mean BW for parities 1, 2, 3, 4+, the range in DIM for the group, and the herd RHA. The group model constructs a production profile of cows based on the user inputs and assigns stochastic variation to production and DIM for the group. Intake of DM for each cow in the group is predicted using the NRC. The ME and MP balance for each cow in the group is calculated based on the formulated diet and plotted by DIM. The user can view graphs of the predicted range in milk production, ME and MP balance by DIM and a table with mean DMI, milk volume, and fat, protein content for the group. The user can adjust the scale of the variance in milk production, the mean milk production, DMI, and fat and protein content if the actual values in the herd differ from predicted. A second model allows imported DHIA milk production records for the group to be fed the formulated diet to compare with the model predicted values. A third model allows the user to least cost the diet for the group within constraints on ME and MP balance for the group of cows. The user can reformulate the ration to better meet the ME and MP needs of the group. Preliminary validation from farms suggests that the group evaluator model provides a useful tool for regrouping cows and evaluating rations for improved ME and MP balances, particularly avoiding excesses in MP.

Key Words: ration formulation, production, cattle groups

1875 (W334) Epidemiological study about the effects of chelated minerals on milk, reproductive performance, and locomotion scores of dairy cattle.

A. Bach[*1,2], A. Pinto[3] and M. Blanch[4], *[1]Department of Ruminant Production, IRTA, Caldes de Montbui, Spain, [2]ICREA, Barcelona, Spain, [3]Department of Ruminant Production, IRTA, Barcelona, Spain, [4]Novus Int. Inc., St Charles, MO*

The objective of this experiment was to evaluate the effects of a partial replacement of chelated trace minerals (CTM) (Mintrex, Zn, Cu, and Mn; with methionine hydroxy-analogue as a ligand; Novus International, MO) compared with a ration containing only inorganic trace minerals (ITM) on locomotion score, milk production, and reproductive performance of dairy cows in different herds. Twenty-seven herds that were feeding the same TMR were enrolled in a 6-mo study. Fifteen herds continued to receive the same TMR (containing ITM), and the remaining 12 herds fed the same TMR with a partial replacement of ITM for CTM. The ITM premix provided 57 ppm of inorganic Zn, 9 ppm of inorganic Cu, and 27 ppm of inorganic Mn; whereas the CTM premix contained 32 ppm of inorganic Zn and 25 ppm of chelated Zn, 3 ppm of inorganic Cu and 6 ppm of chelated Cu, and 17 ppm of inorganic Mn and 10 ppm of chelated Mn. The first month of study was used as a basal line, and then herds were exposed to dietary treatments for 5 mo. Feed composition, feed intake, milk production, lameness score, and reproductive performance were monitored for each herd. All data, except conception rates, were analyzed using a mixed-effects model and conception rates were analyzed with a three-level mixed-effects logistic regression model with herd as experimental unit. There were no differences in feed intake (24.1 ± 0.20 kg/d) and milk production (31.4 ± 0.23 kg/d) between treatments. The overall proportion of cows with a lameness score $\geq$ 3 (considered lame cows) was not different between ITM and CTM herds. However, there was an interaction ($P < 0.001$) between treatment and month of experiment due to a greater incidence of lameness in CTM than in ITM herds during the first 2 mo of study (32.70 vs. 29.47%, respectively), and a lesser incidence in the last 3 mo of study (31.30 vs. 34.73%, respectively). Conception rate was not affected by treatment, but when cows that were serviced with less than 30 d of exposure to treatments were removed from the dataset, cows in the CTM herds had 2.9 greater ($P < 0.05$) odds of becoming pregnant than cows in the ITM herds. It is concluded that a partial replacement of inorganic Zn, Cu, and Mn for organic sources decreases lameness scores over time and improves conception rate after a minimum exposure of 30 d.

Key Words: lameness, reproduction, trace minerals

1876 (W335) Apparent synthesis of thiamin and vitamin B_{12} in rumen of lactating dairy cows fed alfalfa or orchardgrass silages at different maturity stages.

D. S. Castagnino[*1,2], K. Kammes[3], M. S. Allen[3], R. Gervais[1], P. Y. Chouinard[1], D. E. Santschi[4] and C. L. Girard[2], *[1]Université Laval, Québec, QC, Canada, [2]Agriculture & Agri-Food Canada, Sherbrooke, QC, Canada, [3]Michigan State University, East Lansing, MI, [4]Valacta, Ste-Anne-de-Bellevue, QC, Canada*

Effects of maturity stage of forages on apparent ruminal synthesis and post-ruminal supply of thiamin and vitamin B_{12} were evaluated in two experiments. Alfalfa and orchardgrass were harvested and ensiled as a) early-cut, less mature (EC) and b) late-cut, more mature (LC). Diets containing alfalfa or orchardgrass silages of each maturity stage as the sole forage were offered to ruminally and duodenally cannulated lactating Holstein cows in crossover design experiments. Experiment 1 compared diets containing EC and LC alfalfa silage (~22% forage NDF and ~27% total NDF) offered to 16 cows in two 17-d treatment periods. Experiment 2 compared diets containing EC and LC orchardgrass silage (~25% forage NDF and ~30% total NDF) offered to 13 cows in two 18-d treatment periods. Intakes of thiamin increased with maturity stage of forages in Experiment 1 ($P < 0.01$; 79.3 vs. 46.5 ± 2.08 mg/d) and in Experiment 2 ($P < 0.01$; 76.0 vs. 60.9 ± 1.84 mg/d for LC and EC, respectively). In contrast, intakes of vitamin B_{12} were lower for LC than EC in Experiment 1 ($P < 0.01$; 191 vs. 329 ± 8.47 μg/d) and in Experiment 2 ($P < 0.01$; 53.1 vs.

Table 1877. Effects of DCAD concentration on production parameters

	DCAD, meq/kg					*P* <	
Item	250	375	500	625	SEM	Linear	Quadratic
DMI, kg/d	22.3	22.9	23.1	23.6	0.52	0.007	0.902
Milk, kg/d	38.9	39.5	39.5	38.8	1.52	0.937	0.228
Fat, %	3.28	3.50	3.50	3.62	0.146	0.001	0.418
Protein, %	2.95	2.99	2.95	2.92	0.056	0.167	0.152
3.5% FCM, kg/d	37.1	39.2	39.2	39.1	0.98	0.008	0.037
FE, 3.5%FCM/DMI	1.67	1.71	1.71	1.66	0.038	0.759	0.085

76.3 ± 1.71 μg/d). In Experiment 1, duodenal flows of thiamin were greater for LC than EC (P = 0.02; 156 vs. 130 ± 7.21 mg/d) but the duodenal flows of vitamin B_{12} were not affected by treatment (P = 0.21, 12182 ± 556.1 μg/d). In Experiment 2, duodenal flows of vitamins were not affected by treatment (thiamin, P = 0.20, 199 ± 8.47 mg/d; vitamin B_{12}, P = 0.28, 8518 ± 426.0 μg/d). The apparent ruminal synthesis of thiamin and vitamin B_{12} were not affected by treatment in either experiment (Experiment 1: thiamin, P = 0.45, 79.8 ± 6.56 mg/d; vitamin B_{12}, P = 0.28, 11924 ± 426.0 μg/d; Experiment 2: thiamin, P = 0.18, 130 ± 8.57 mg/d; vitamin B_{12}, P = 0.29, 8454 ± 426.0 μg/d). Delaying the harvest of alfalfa or grass resulted in a greater dietary supply of thiamin and a lower supply of vitamin B_{12}. Nevertheless, the stage of maturity did not affect apparent ruminal synthesis and had little or no effect on the post-ruminal supply of these vitamins.

Key Words: dairy cow, thiamin, vitamin B_{12}

1877 (W336) Potassium carbonate as a cation supplement to increase dietary cation anion difference and improve dairy feed efficiency in lactating dairy cows.

A. E. Weidman, M. E. Iwaniuk* and R. A. Erdman, *University of Maryland, College Park*

Supplementation with potassium carbonate (K_2CO_3) increases dietary cation anion difference (DCAD) which results in increased dairy feed efficiency. Our previous study with early lactating Holstein cows showed that increasing DCAD from approximately 250 to 400 meq/kg (Na-K-Cl Equation, DM basis) resulted in a linear increase in 3.5% FCM/DMI [feed efficiency (FE)]. However, the optimal DCAD for maximal FE could not be determined as the maximal FE response was achieved at a DCAD of 400 meq/kg. The objective of this study was to determine the optimal DCAD required for maximal DMI, milk production and FE using a broader range in dietary DCAD concentrations. Twenty Holstein cows (8 primiparous and 12 multiparous) averaging 95 (± 25) DIM were individually fed a basal diet containing 64% corn silage, 6% alfalfa hay, and 30% concentrate (DM basis). Dietary treatments consisted of 250 (basal), 375, 500, and 625 meq/kg DCAD where K_2CO_3 was added to the basal diet to obtain the desired DCAD concentrations. The treatments were applied in a 4 × 4 Latin square design with 3-wk experimental periods. Dietary treatments had no effect on milk production or milk protein concentration. Increasing DCAD from 250 to 625 meq/kg linearly increased DMI (P = 0.007) and milk fat percentage (P < 0.001), while 3.5% FCM increased curvilinearly (linear, P = 0.008; quadratic, P = 0.037) with increasing DCAD. There was a quadratic trend (P = 0.085) for dairy FE where maximal FE occurred at DCAD concentrations of 375 and 500 meq/kg. The optimal DCAD for DMI and fat percent could not be determined since maximums occurred at a DCAD of 625 meq/k. FE and 3.5% FCM were optimized at a DCAD concentration of 442 meq/kg. Results of this and other studies in our laboratory show that DCAD can be used to increased feed efficiency to help dairy producers reduce feed costs and improve profitability.

Key Words: DCAD, feed efficiency, dairy cows

1878 (W337) Degradation ruminal kinetics of organic matter, neutral detergent fiber and crude protein of sorghum wet distiller grain without solubles in comparison to the original sorghum grain.

A. I. Trujillo[*1], M. D. L. A. Bruni[2] and P. Chilibroste[3], *[1]Facultad de Agronomia, Universidad de la Republica, Montevideo, Uruguay, [2]Facultad de Agronomia Universidad de la Republica, Paysandu, Uruguay, [3]Facultad de Agronomia, Universidad de la Republica, Paysandu, Uruguay*

A study was conducted to characterize ruminal crude protein (CP) and energy supply of sorghum wet distillers grains (SWDG; 31.4 ± 0.7% CP and 70.2 ± 2.2% neutral detergent fiber–NDF, 11.0 ± 0.7% fat, dry basis) from an ethanol plant in Uruguay in comparison to the original sorghum grain (SG). In situ technique was conducted to determine ruminal organic matter (OM),NDF and CP degradation kinetics, their respective effective degradability (considering passage rate of 2% h^{-1}, ED) and the relationship between rumen available Nitrogen (N) and fermentable OM (N:OM ratio) from 3 batches of SWDG and SG. Duplicate samples (5 g of 2–mm ground) of each feed were incubated in the rumen of 2 lactating dairy cows for 0, 2, 4, 8, 12, 24, 48, and 72 h. Data were fitted to the nonlinear model $D(t) = a+b(1-e^{-kd(t-t0)})$ with PROC NLIN of SAS program to determine degradation parameters, where D is percentage disappearance of OM, NDF or CP at the time t, (a) soluble fraction, (b) slowly degradable fraction, (c) deg-

radation rate, and t0 is lag time. Parameters were analyzed with PROC GLM in a completely randomized design and compared by Tukey test. There were not differences for any degradation parameters between batches, neither in SWDG nor in SG. Comparing degradation parameters of SWDG with SG the results were: fractions (a) and (b) of OM were lower (8.1 vs. 22.7%, 54.5 vs. 73.9%; $P < 0.05$) but (c) was greater (4.8 vs. 3.5% h^{-1}; $P < 0.05$); (t0) was only present in SWDG (3.1 h); (c) of NDF was greater (6.3 vs. 3.5% h^{-1}, $P < 0.05$) but (c) of CP was lower (1.1 vs. 1.9% h^{-1}; $P < 0.05$); fraction (b) of NDF was lower (69.5 vs. 79.3%, $P < 0.05$) and fraction (b) of CP did not differ (71 vs. 71.7%); fraction (a) of NDF and (t0) were only present in SWDG (5.6% and 2.7 h), and fraction (a) of CP was lower (0.0 vs. 18.2%). The ED of OM and CP were lower in SWDG compared to SG (44.3 vs. 69.8; 25.5 vs. 52.8%, respectively; $P < 0.05$) but the ED of NDF was greater (58.3 vs. 50.6%; $P < 0.05$). The N:OM ratio for microbial growth was better in SWDG than in SG (29.4 vs. 8.4 g of N effectively degraded/kg OM effectively degraded). The SWDG seems to be a good supply of ruminal PC and energy in ruminants' diets.

Key Words: sorghum, ethanol by-product, in situ

1879 (W338) Relative bioavailability of phosphorylated ascorbic acid in lactating dairy cows. C. K. Reynolds*[1], D. J. Humphries[1], C. E. S. Barratt[1], P. C. Aikman[1] and W. Steinberg[2], *[1]University of Reading, Reading, United Kingdom, [2]DSM Nutritional Products, Basel, Switzerland*

Rumen degradation limits ascorbic acid (AA) absorption from the small intestine. The objective of the present study was to determine the relative bioavailability of AA and phosphorylated AA (PAA) introduced into the abomasum of dairy cows. Four rumen fistulated lactating (207 DIM; 33.3 ± 1.8 kg/d milk) Holstein cows were fed a TMR once daily for ad libitum DMI (17.3 ± 0.7 kg/d). Cows initially received one of 4 treatments in a balanced 4 × 4 Latin Square design experiment with 1 wk periods. Treatments were control, 10 g AA in 250 mL saline injected rapidly into a jugular vein (JV) catheter, 10 g AA in 2 gelatine capsules placed into the abomasum via the rumen, or 10 g of AA as PAA (Rovimix Stay-C 35) in 2 gelatine capsules placed into the abomasum. After period 2, abomasal AA and PAA dose was increased to 100 g AA in 750 mL water. Controls were JV saline injection and abomasal gelatine capsules or water. Blood (JV) was sampled at intervals from 1 h before to 8 h after dosing. Urine was collected and sampled at intervals before and for 10 h after AA doses. Blood and urine were sampled at 24, 48, and 72 h after dosing. Samples were treated to convert dehydroascorbic acid to AA, stored at −80°C, and analyzed for total AA within 10 d. The area under the curve (AUC) for plasma AA concentration was calculated and the decrease in plasma AA concentration following the JV dose used to calculate AA kinetics. Data were analysed using mixed models for effects of cow, period, and treatment ($n = 6$). Comparison of the AUC for abomasal versus JV doses suggests the relative bioavailability of AA (7%) and PAA (5%) were similar but very low. The half-life of the JV dose averaged 66 ± 23 min, with an estimated pool size of 178 ± 42 L and a clearance rate of 2.07 ± 0.34 L/min. Urinary excretion accounted for only 7% of the JV dose, and plasma AA concentration remained elevated for 48 h. Estimates of the relative bioavailability of AA and PAA in lactating dairy cows suggest absorption from the small intestine is low. This may in part be due to a lack of previous exposure of small intestinal enterocytes to AA or differences in metabolism of intravenously injected versus absorbed AA.

Key Words: ascorbic acid, dairy cows, absorption

1880 (W339) Changes in serum IgG and total protein concentrations in calves fed differing amounts of colostrum replacer. J. D. Quigley, L. L. Deikun*, T. M. Hill, H. G. Bateman, II, J. M. Aldrich and R. L. Schlotterbeck, *Provimi North America, Brookville, OH*

It is unclear whether differences in serum IgG concentration of calves at 24 h (acquired passive immunity) influence the onset of active IgG production or the age at which serum IgG concentrations normalize. Our objective was to monitor changes in serum IgG and total protein (TP) concentrations in calves fed to achieve high (H) or low (L) passive immunity. Newborn Holstein calves (initial BW = 42.2 ± 4.7 kg) were individually fed a colostrum supplement ($n = 23$; 50 g of IgG/feeding) or a colostrum replacer ($n = 22$; 150 g of IgG/feeding) at 0.5 ± 0.22, 6.6 ± 0.46, and 12.9 ± 1.94 h of age. Blood was collected and serum analyzed for IgG using radial immunodiffusion and total protein using optical refractometer every 7 d from wk 0 (2–3 d of age) to wk 8. Calves were vaccinated with Inforce 3 (Zoetis) on arrival, Bovi-shield Gold 5 (Zoetis) at 2 and 6 wk and Presponse HM (Boehringer Ingelheim Vetmedica) at 5 and 8 wk, as prescribed by a veterinarian. Data were analyzed as a completely randomized design using repeated measures ANOVA. Serum IgG (g/L) and total protein (TP; g/dl) concentrations at 24 h of age were 19.4 ± 0.63 and 4.07 ± 0.076, respectively, in calves fed H, and 8.52 ± 0.62 and 3.32 ± 0.074, respectively, in calves fed L. Serum IgG and TP were affected by a week ´ treatment interaction ($P < 0.001$). Serum IgG concentration in calves fed H declined to 13.7 g/L at wk 3, then increased to 20.7 g/L at wk 8. Serum IgG in calves fed L declined to 6.3 g/L at wk 1, then increased to 20.6 g/L at wk 8. By wk 7, serum IgG concentration were similar ($P > 0.05$). Serum IgG was < 10 g/L for 0.3 and 4.9 wk in calves fed H and L, respectively. Total protein concentrations were lower in calves fed L from wk 0 to 6 ($P < 0.01$); thereafter, differences were not significant. Temporal changes in serum TP and IgG concentrations were independent. Active IgG synthesis was dependent on age of calf and acquisition of passive immunity.

Calves with lower serum IgG concentrations at wk 0 began producing IgG at an earlier age and produced more IgG, so that by wk 7, circulating IgG concentrations were similar to those in calves with successful passive immunity.

Key Words: colostrum, immunoglobulins, calves

1881 (W340) Apparent synthesis of thiamin, riboflavin, vitamin B_6 and vitamin B_{12} in rumen of lactating dairy cows fed 2 concentrations of nitrogen and 2 energy sources.

V. Beaudet[*1,2], R. Gervais[1], P. Y. Chouinard[1], P. Noziere[3], B. Graulet[3], M. Doreau[3] and C. L. Girard[2], *[1]Université Laval, Québec, QC, Canada, [2]Agriculture & Agri-Food Canada, Sherbrooke, QC, Canada, [3]INRA-URH, Saint Genès Champanelle, France*

Effects of nitrogen supply and energy sources on apparent ruminal synthesis (ARS) and post-ruminal supply of thiamin, riboflavin, vitamin B_6, and vitamin B_{12} were evaluated using 4 lactating Holstein cows distributed in a 4 × 4 Latin square design with treatments arranged according to a 2 × 2 factorial. The cows were fitted with cannulas in proximal duodenum. The treatments were 2 concentrations of nitrogen: HIGH: 14% CP, i.e., 110% of the protein requirements and an adequate supply in rumen-degradable protein (RDP), vs. LOW: 11% CP, i.e., 80% of the protein requirements with a shortage in RDP; energy sources were STARCH from barley, corn, and wheat vs. FIBER from soybean hulls and dehydrated beet pulp. Diets were corn silage based, had the same forage: concentrate ratio (60:40, dry matter basis) and were isoenergetic. STARCH resulted in greater ($P < 0.01$) intakes of thiamin (51 vs. 34 ± 2.4 mg/d), riboflavin (1172 vs. 1050 ± 25.8 mg/d) and vitamin B_6 (202 vs. 161 ± 3.9 mg/d) as compared with FIBER, whereas nitrogen concentrations had no effect ($P \geq 0.76$). Vitamin B_{12} intake was not affected by treatments ($P \geq 0.43$) and averaged 86 ± 2.0 µg/d. Duodenal flow ($P = 0.34$; 35 ± 7.0 mg/d) or ARS ($P = 0.46$; −6 ± 7.6 mg/d) of thiamin were not significantly affected by treatments. STARCH increased duodenal flow of riboflavin ($P < 0.01$; 1546 vs. 1091 ± 92.4 mg/d) and vitamin B_6 ($P < 0.01$; 68 vs. 45 ± 4.9 mg/d) but decreased vitamin B_{12} flow ($P < 0.01$; 3127 vs. 9319 ± 731.1 µg/d) as compared with FIBER. HIGH nitrogen increased riboflavin and vitamin B_6 duodenal flows ($P = 0.02$; 1481 vs. 1156 ± 85.5 mg/d and $P = 0.01$; 67 vs. 47 ± 4.6 mg/d, respectively) and ARS ($P = 0.04$; 372 vs. 43 ± 95.2 mg/d and $P = 0.04$; -114 vs. -135 ± 6.3 mg/d, respectively). Nitrogen supply had no effect on vitamin B_{12} duodenal flows ($P = 0.64$) or the ARS ($P = 0.63$). Energy sources had no effect on ARS of vitamin B_6 ($P = 0.11$) but STARCH tended to increase the apparent production of riboflavin ($P = 0.06$; 374 vs. 41 ± 102.3 mg/d). Inversely, FIBER enhanced ARS of vitamin B_{12} ($P < 0.01$; 9234 vs. 3040 ± 730.3 µg/d, respectively). There was no interaction between treatments ($P \geq 0.09$). The apparent ruminal balance was affected by the nitrogen concentration for synthesis of riboflavin and degradation of vitamin B_6, and by the energy sources for synthesis of riboflavin and vitamin B_{12}.

Key Words: apparent ruminal synthesis, B vitamins, dairy cow

1882 (W341) Apparent synthesis of thiamin and vitamin B_{12} in rumen of lactating dairy cows fed alfalfa or orchardgrass silages of different particle lengths.

D. S. Castagnino[*1], K. Kammes[2], M. S. Allen[2], R. Gervais[3], P. Y. Chouinard[3], D. E. Santschi[4] and C. L. Girard[1], *[1]Agriculture & Agri-Food Canada, Sherbrooke, QC, Canada, [2]Michigan State University, East Lansing, MI, [3]Université Laval, Québec, QC, Canada, [4]Valacta, Ste-Anne-de-Bellevue, QC, Canada*

Effects of forage particle length on apparent ruminal synthesis and post-ruminal supply of thiamin and vitamin B_{12} were evaluated in two experiments. Alfalfa and orchardgrass were harvested and ensiled at two theoretical lengths of cut: 19-mm (long cut, LC) or 10-mm (short cut, SC). Within a forage type, rations containing silages of each length of cut as the sole forage were offered to ruminally and duodenally cannulated lactating Holstein cows in crossover design experiments. Experiment 1 compared diets containing LC and SC alfalfa silage (~47% forage, ~20% forage NDF and ~25% total NDF) offered to 13 cows in two 19-d treatment periods. Experiment 2 compared diets containing LC and SC orchardgrass silage (~50% forage, ~23% forage NDF and ~28% total NDF) offered to 15 cows in two 18-d treatment periods. In Experiment 1, intakes of thiamin and vitamin B_{12} were greater ($P < 0.01$) for LC than SC (thiamin: 89.4 vs. 77.5 ± 2.13 mg/d; vitamin B_{12}: 118.6 vs. 67.1 ± 2.55 µg/d). Neither duodenal flows of thiamin ($P = 0.94$, 174.2 ± 18.87 mg/d) and vitamin B_{12} ($P = 0.17$, 8223 ± 713.0 µg/d) nor apparent ruminal synthesis of these vitamins (thiamin, $P = 0.15$, 90.9 ± 17.82 mg/d; vitamin B_{12}, $P = 0.16$, 8131 ± 711.0 µg/d) were affected by treatment in Experiment 1. In Experiment 2, there was no effect of treatment on the intake of vitamins (thiamin, $P = 0.79$, 71.9 ± 2.55 mg/d; vitamin B_{12}, $P = 0.85$, 111 ± 3.9 µg/d), duodenal flows (thiamin, $P = 0.80$, 156 ± 9.5 mg/d; vitamin B_{12}, $P = 0.88$, 6887 ± 476.0 µg/d), or their apparent ruminal synthesis (thiamin, $P = 0.82$, 84.1 ± 8.14 mg/d; vitamin B_{12}, $P = 0.88$, 6725 ± 473.0 µg/d). The reduction of legume particle length decreased the dietary supply of thiamin and vitamin B_{12}. However, forage particle length, in the studied range, did not affect apparent synthesis of thiamin and vitamin B_{12} in rumen or the supply of these vitamins to the sites of absorption.

Key Words: dairy cow, thiamin, vitamin B_{12}

1883 (W342) Concentration of vitamin B12 in colostrum and milk from dairy cows fed different energy levels during the dry period. M. Duplessis[*1,2], S. Mann[3], D. V. Nydam[3], C. L. Girard[2], D. Pellerin[1] and T. R. Overton[4], *[1]Université Laval, Département des sciences animales, Québec, QC, Canada, [2]Agriculture & Agri-Food Canada, Sherbrooke, QC, Canada, [3]Cornell University, Department of Population Medicine and Diagnostic Sciences, Ithaca, NY, [4]Cornell University, Department of Animal Science, Ithaca, NY*

Bovine colostrum and milk are an excellent source of vitamin B_{12} for calves and humans, respectively, who rely on exogenous sources to meet their vitamin B_{12} requirements. The aim of the experiment was to evaluate vitamin B_{12} concentration in colostrum and milk from dairy cows fed different levels of energy during the dry period. A total of 84 Holstein cows were assigned to one of the following dietary treatments 60d before the expected calving date: 1) High energy one-group dry cow diet (HE; 1.35 Mcal NE_m/kg DM; 56% corn silage, 12% wheat straw, and 32% concentrate mix on a daily DM basis); 2) Low energy one-group dry cow diet (LE; 1.14 Mcal NE_m/kg DM; 28% corn silage, 36% wheat straw, and 36% concentrate mix on a daily DM basis); or 3) Intermediate step-up diet (IE; low energy diet from dry off until 30d before the expected calving and then switching to a diet representing a 50:50 blend of the low and high energy diets until parturition). After calving, all cows were fed the same diet using a TMR (44% corn silage, 13% grass silage, and 43% concentrate mix on a daily DM basis) until 42 d in milk (DIM). Colostrum samples were taken at the first milking after the parturition and milk samples were taken during the morning milking at 11 and 39 ± 2 DIM. Data were analyzed using treatment, time as well as treatment x time interaction as fixed effects. A significant treatment × sample interaction was observed ($P = 0.02$; Table 1883). Vitamin B_{12} concentration in colostrum differed among treatments ($P = 0.0002$) whereas no diet effect was observed on milk samples ($P > 0.97$). Colostrum from LE cows had a vitamin B_{12} concentration higher than IE cows ($P = 0.001$; Table 1883). In summary, results suggest that energy levels in diets during the dry period could change vitamin B_{12} concentration in colostrum but had no effect later on milk concentration of vitamin B_{12}.

Key Words: dairy cow, vitamin B_{12}, colostrum

Table 1883. Vitamin B_{12}concentration in colostrum and milk according to treatments

Vitamin B_{12} (pg/mL)[1]	HE	LE	IE
Colostrum	27,815[ab] ± 1353	31,677[b] ± 1353	23,502[a] ± 1378
Sample 1	3932[a] ± 1353	3701[a] ± 1378	3774[a] ± 1378
Sample 2	3339[a] ± 1353	3125[a] ± 1378	3000[a] ± 1378

[a,b] Means in the same row with different superscripts differ ($P < 0.05$)

1884 (W343) Ruminal bacterial community structure of dairy cows fed conventional and reduced-fat dried distillers grains with solubles. *H. A. Ramirez Ramirez, C. J. R. Jenkins*, S. C. Fernando, C. L. Anderson, N. D. Aluthge and P. J. Kononoff, University of Nebraska, Lincoln*

Four lactating, ruminally cannulated Holstein cows with (mean ± SD) 98 ± 11 DIM and 603 ± 52 kg BW were used in a Latin square design to test the effects of feeding regular dried distillers grains with solubles (DDGS) or reduced-fat DDGS (RF-DDGS) combined with rumen inert fat (RIF, as Ca-salts of long chain fatty acids) on ruminal bacterial community structure using a DNA pyrosequencing approach. Cows were housed in a tie-stall barn, fed once daily, and milked twice daily. In each 21-d period, cows were randomly assigned to 1 of 4 dietary treatments (values expressed on a DM basis): control diet (CON) was a conventional dairy ration (no corn ethanol by-products); a second diet (DG) contained 30% DDGS; a third diet (RF) contained 30% LF-DDGS and; a fourth diet (COMBO) contained 30% LF-DDGS supplemented with 1.9% RIF. Ruminal digesta was collected at 0, 8, and 23 h post-feeding on d 21 of each period and was immediately frozen (-20°C) for later analysis of the bacterial community. The rumen bacterial community was evaluated from frozen samples using the Roche 454 pyrosequencing platform. The sequences generated were analyzed using established MOTHUR and QIIME (Quantitative Insights Into Microbial Ecology) pipelines. Diet did not affect bacterial community composition at phylum level. The most abundant phyla were Firmicutes (46 ± 4.78%) and Bacteroidetes (51 ± 4.87%). The phylum TM7 accounted for 2.25 ± 0.41%. The Tenericutes, SR1, and Spirochaetes phyla were grouped as "Others" and accounted for 0.58 ± 0.10%. Time post-feeding had an effect ($P = 0.02$) on phyla distribution; the proportion of Firmicutes decreased from 52 to 39 ± 4% by 9 h post-feeding and increased to 46 ± 4% by 23 h; conversely Bacteroidetes increased from 45 to 58 ± 4% at 9 h post-feeding and decreased to 51 ± 4% by 23 h post-feeding. The results from this experiment demonstrate that phyla distribution is relatively stable across diets; nonetheless diurnal patterns in ruminal bacterial phyla relative to time post-feeding were observed. To our knowledge, this is the first study in dairy cattle that utilizes high throughput sequencing to analyze bacterial community structure to evaluate diurnal variation of the rumen bacterial community.

Key Words: microbial community, bacteria, sequencing

1885 (W344) Diet influences microbial community composition, and methane emission in growing and finishing beef cattle. S. C. Fernando*[1], A. L. Knoell[1], C. L. Anderson[1], A. C. Pesta[2], G. E. Erickson[2] and T. J. Klopfenstein[2], [1]*University of Nebraska, Lincoln,* [2]*University of Nebraska-Lincoln, Lincoln*

Methane production in ruminants via enteric fermentation is dependent on the microbial community within the ruminant animal. The microscale processes of this microbial community are greatly influenced by diet. However, the interactions between diet, microbial community composition, and methane emission are poorly understood. To better understand how diet influences microbial community structure and methane emission, methane/CO_2 ratio and microbial community composition were evaluated in animals on a common diet and under different dietary conditions (high and low quality forage, with and without monensin supplementation, and different levels of modified distillers grain plus solubles (MDGS) supplementation) in a 84-d growing trial, followed by a 125-d finishing trial that evaluated four different fat sources (corn oil, tallow, MGDS, corn-no oil) and monensin supplementation. Methane and CO_2 measurements were made during feeding using an individual feeding facility that contained 120 individual bunks equipped with the Calan gate system and an automated gas collection system. Gases were analyzed using a mobile GC unit. CO_2 was used as an internal standard and the methane/CO_2 ratio was used to determine the effects of diet on methane emission. Samples were collected for microbial community analysis via stomach tubing, and the microbial community structure was analyzed by sequencing the 16S rRNA gene. In growing cattle and finishing cattle, microbial community structure (both archaea and bacteria) and methane levels were similar in all animals on the common diet. In growing cattle, diet quality (high vs. low quality forage) significantly influenced ($P < 0.05$) the methane/CO_2ratio and the microbial community composition, where high quality forage produced higher levels of methane. However, the level of methane emitted did not change by level of supplementation, but the microbial community composition did change significantly. In finishing cattle, methane levels were highest in MDGS diets and significantly decreased ($P < 0.05$) in corn control diet and 3% tallow diets. The microbial community did not show significant changes in total microbial community structure during supplementation of different fat sources. These data suggest dietary intervention can be used in growing cattle to change microbial community structure, which in turn can affect methane emission levels. Identifying the members of the rumen microbial community from high and low methane emitting cattle and diets would help identify microbial community members that influence methane production in cattle, which may lead to dietary and other intervention strategies to change these microbial populations in the rumen.

Key Words: microbial community, methane, archaea

1886 (W345) Dietary fatty acid profile affects plasma metabolic profile of peripartum Holstein cows. H. Khalilvandi-Behroozyar[1], M. Dehghan Banadaky*[2], M. Ghaffarzadeh[3] and K. Rezayazdi[2], [1]*Department of Animal Science, Urmia University, Urmia, Iran,* [2]*Department of Animal Science, University of Tehran, Karaj, Tehran, Iran,* [3]*Chemistry and Chemical Engineering Research Center of Iran, Tehran, Iran*

Concentration of plasma NEFA usually increases around calving due to mobilization of adipose tissue as a result of the inability of high-producing cows to consume enough energy to meet requirements for milk production and maintenance. Elevated NEFA concentration in the periparturient period is the major factor influencing postpartum accumulation of lipid in hepatic tissue. Whereas postpartum fat supplementation is a common practice in the dairy industry, prepartum fat supplementation is less common. The objective of this study was to examine the effect of feeding diets containing fat supplements enriched in either saturated FA or PUFA on metabolic responses of periparturient Holstein cows. Twenty four multiparous Iranian Holstein cows were assigned to diets with different fatty acid profiles and supplemented through 30 d before expected calving date to 50 d in milk. Dietary treatments consisted of (1) Prilled Palm fatty acids (PO) [Energizer RP10 , 2 & 2.25% DM in pre- and postpartum, respectively]; (2) Ca-salts of sunflower oil (SO) [Persia Fat- SO]; (3) Ca-salts of fish oil (FO) [Persia Fat- FO] and (4) equal amounts of Persia Fat- FO & Persia Fat- SO. Calcium salts were supplemented as 2.2 and 2.5% of dietary DM in pre- and postpartum period, respectively. All rations contained identical forage and concentrate components. Metabolite analyses were performed on blood samples collected weekly pre and post-partum and daily from -10 to 10 d relative to expected calving from tail vein. Data were analyzed using PROC MIXED of SAS 9.1 according with repeated measures in time function. Prepartum plasma contents of glucose, triacyl glycerol, cholesterol, total protein, urea, NEFA, BHBA and glycerol were not affected by type of lipid supplement, but Insulin, LDL, HDL, albumin and TNF-α concentration significantly increased in PO supplemented group than those supplemented with Persia Fat. In postpartum period, plasma levels of triacyl glycerol, total protein and urea were not affected by dietary fatty acid profile. However, Feeding Persia Fat, greatly reduced plasma concentration of NEFA, BHBA and glycerol along with lowering effects for TNF-α, suggesting that feeding protected PUFA sources can manage mobilization of body reserves. Statistically significant lower glucose and higher Insulin concentration in PO fed cows, in line with higher TNF-α levels can be a hint to lower insulin sensitivity compared with Persia Fat fed animals. Different profiles of protected PUFA sources didn't have any significant difference.

Key Words: PUFA, palm oil, insulin resistance, NEFA

1887 (W346) Prediction of enteric methane emissions in Holstein dairy cows fed various forage sources.

D. E. Rico[*1], P. Y. Chouinard[1], F. Hassanat[2], C. Benchaar[2] and R. Gervais[1], *[1]Université Laval, Québec, QC, Canada, [2]Agriculture and Agri-Food Canada, Dairy and Swine Research and Development Centre, Sherbrooke, QC, Canada*

Milk fatty acid (FA) profile has been previously used as a predictor of enteric CH_4 output in dairy cows fed diets supplemented with plant oils. The objective of this study was to investigate the relationships between milk FA and enteric CH_4 emissions in lactating dairy cows fed different types of forage. A total of 81 observations from 3 separate 3 × 3 Latin square design (with 32-d periods) experiments using a total of 27 lactating cows (96 ± 27 DIM; Mean ± SD) were used. In all experiments, dietary forages were included at 60% of ration DM and were: 1) 100% corn silage 2) 100% alfalfa silage 3) 100% barley silage 4) 100% timothy silage 5) 50:50 mix of corn and alfalfa silages, 6) 50:50 mix of barley and corn silages, and 7) 50:50 mix of timothy and alfalfa silages. Enteric CH_4 was measured in individual air-flow controlled chambers during 3 consecutive days. Milk was sampled during the 6 d of each period and analyzed for components and FA profile. Test variables included DMI (kg/d), dietary NDF (%), dietary EE (%), milk yield (kg/d), milk components (%), and individual milk FA (% of total FA). Associations between test variables and CH_4 were analyzed using the CORR procedure of SAS. The GLMSELECT procedure was used to identify a set of candidate models using the LASSO and LARS methods. Data were then fitted into a random regression using the MIXED procedure including the random effects of cow and period. The VC and UN covariance structures provided best fit for the random and repeated statements, respectively. Denominator degrees of freedom were calculated by the Satterhwaite equation. A positive association was observed between CH_4 and DMI (r = 0.59, P < 0.001), whereas negative associations were observed between CH_4 and *c*9–17:1 (r = -0.58, P < 0.001), and *t*8, *c*13–18:2 (r = -0.51, P < 0.001). The selected model predicted observations with a coefficient of determination of 0.92 and was: CH_4 (g/d) = 357.1 + 15.2 × DMI– 56.9 × 15:0– 81.7 × *c*9–17:1– *t*10–18:1 × 41.0– *c*11–18:1 × 53.3– *t*8, *c*12–18:2 × 243.0– *t*8, *c*13–18:2 × 563.7.0– t11, c15–18:2 × 242.9. Milk FA profile and DMI can be used to predict CH_4 emissions in dairy cows across a range of dietary forage sources.

Key Words: dairy cows, methane emissions, milk fatty acids.

1888 (W347) RNA-Seq detection of differential gene expression in the rumen of beef steers associated with feed efficiency phenotypes.

R. J. Kern[*1], A. K. Lindholm-Perry[2], H. C. Freetly[2], W. M. Snelling[2], J. R. Miles[2], J. W. Kern[3] and P. A. Ludden[1], *[1]University of Wyoming, Laramie, [2]USDA, ARS, US MARC, Clay Center, NE, [3]Kern Statistical Services, Sauk Rapids, MN*

The efficient utilization of feedstuffs is an economically important trait in beef production. The rumen is important to the digestive process of steers interacting with feed, microbial populations, and volatile fatty acids indicating it may play a critical role in feed efficiency. To gain an understanding of the molecules and pathways involved in gain, intake and utilization and identify candidate genes associated with steer feed efficiency, RNA-Seq was performed on rumen papillae from steers with extreme feed efficiency phenotypes (n = 16). The study population was divided into four Cartesian quadrants for intake × gain and steers (n = 4) from each quadrant were sampled. Three statistical analyses were performed to identify differentially expressed genes among feed efficiency phenotype. Two analyses were performed on total gene expression, the Negative Binomial and the Kruskall-Wallis. A separate analysis was performed by Cofactor Genomics on exon cluster expression. The Negative Binomial analysis identified 27 genes differentially expressed among feed efficiency phenotypes based on false discovery rate (FDR < 0.05). The Kruskall-Wallis analysis identified 19 differentially expressed genes based on P-value (P < 0.05). Cofactor Genomics identified 187 differentially expressed genes based on P-value (P < 0.05) and fold change (FC > 2). All genes identified by the Negative Binomial and Kruskall-Wallis analyses were tested for validation using real-time PCR and a subset of genes (n = 23) identified by Cofactor Genomics were tested for validation. Several genes (*ACAT1, CYP1A2, KLK10, KLK12, MIF, PDEE1A,* and *MYL1)* were identified by at least one analysis in this study and are supported by other studies. Five genes were identified by more than one analysis in this study (*KLK7, KLK10, KLK12, ARHGAP27,* and *RGS5)*. Cell death and survival, immunological disease, and metabolic disease were the top gene networks identified in association with gain, intake, and efficiency, respectively. Genes expressed in rumen papillae of beef steers may play a role in the feed efficiency of the animal. USDA is an equal opportunity provider and employer.

Key Words: RNA-Seq, beef cattle, rumen papillae

1889 (W348) Bioassay activity of different tannin sources by gas production technique. N. Vahdani[1], M. Dehghan banadaky[*2], F. Khalighi-Sigaroudi[3] and K. Rezayazdi[4], *[1]University of Tehran, Karaj, Iran, [2]Department of Animal Science, Faculty of Agriculture, University of Tehran, Karaj, Iran, [3]Institute of Medicinal Plants, Academic Center for Education, Culture and Research (ACECR), Karaj, Iran, [4]Department of Animal Science, University of Tehran, Karaj, Tehran, Iran*

Use of agricultural by-products, (such as pistachio hull, Pomegranate hull, Grape pomace, etc.), is often a useful way of overcoming shortage of animal feeds in many countries. These by-products contain tannins, causing reduction of protein utilization in ruminants. Tannin activity is affected by its source so this study was conducted to evaluate the effect of different sources of tannins on tannin biological effect by gas production technique. Each assay was repeated three times (runs). In all assays, 1 g of each sample was incubated in 120 mL serum bottles with or without 1 gr polyethylene glycol, PEG (MW. 4000), in triplicate. Rate and extent of gas production was determined by reading gas volumes at 2, 4, 6, 8, 12, and 24h of incubation time. Results showed that tea green leaves (1.44 in 2h after incubation) and grape pomace (1.45 in 2h after incubation) had more active tannins than others in all of incubation times ($P < 0.05$). In spite of same TP (180.18 and 182.5 gr/kgDM) and TT (115.35 and 108.38 gr/kgDm) content, pistachio hull and oak fruit tannins had different biological effect. Because there is no significant correlation between TP, TT and biological activity of tannins in all of incubation times. These results prove that independent of tannin content, different sources of tannins have different activities.

Key Words: tannin, bioassay, PEG

1890 (W349) Differences in formulation and bioavailability of commercial injectable fat-soluble vitamin products. D. B. Snider[*1], R. A. Zinn[2] and R. L. Stuart[3], *[1]Iowa State University, Ames, [2]University of California-Davis, El Centro, [3]Stuart Products Inc, Bedford, TX*

Injectable fat-soluble vitamins are utilized more quickly and efficiently than oral products. The major concern with injectables is chemical form and bioavailability of vitamins. A commercial product (VITAL EAD (V); Stuart Products, Inc.) contains retinyl palmitate, the storage form of vitamin A, and another commercial product (Natural EAD (N); Neogen Corp.) contains retinyl propionate. Otherwise, vitamin D and vitamin E sources and concentrations were the same. Two experiments were conducted to compare bioavailability of vitamins E and A. Exp 1 compared bioavailability in serum collected at 0, 24, 48, and 72 h. post-injection, and Exp 2 compared bioavailability at 0, 4, 8, 12, and 24 h post-injection. All serum samples were analyzed for α-tocopherol and total vitamin A. Exp 1 utilized ten animals (130 kg), and Exp 2 utilized eight animals (200 kg). In Exp 1, five animals were injected with 5 mL of either product to provide 500,000 I.U. A, 50,000 I.U. D and 1500 I.U.E per animal. In Exp 2, four animals were injected with 6 mL of either product to provide 600,000 I.U. A, 60,000 I.U. D and 1800 I.U. E per animal. In Exp one, serum α-tocopherol concentrations at 0, 24, 48, and 72 h for V-injected animals were 0.48, 20.02, 5.22, and 4.05 μg/mL, respectively. Total vitamin A concentrations were 0.13, 5.85, 3.39, and 4.18 μg/mL, respectively. For N, serum α-tocopherol concentrations were 0.57, 5.72, 3.74 and 4.00 μg/mL; and total serum vitamin A concentrations were 0.13, 0.17, 0.07, and 0.08 μg/mL for the four sampling times. At 24 and 48 h samplings, serum α-tocopherol concentrations were different between the two products ($P < 0.01$). For total vitamin A, all sampling periods were different ($P < 0.001$). In Exp 2, serum α-tocopherol concentrations at 0, 4, 8, 12, and 24 h were 1.13, 15.50, 28.30, 23.8 and 20.3 μg/mL, respectively and total vitamin A concentrations were 0.22, 3.05, 8.34. 8.49, and 11.87 μg/mL for the V-injected animals. For N, serum α-tocopherol concentrations were 1.15, 5.25, 7.18, 7.00, and 8.95 μg/mL; and serum total vitamin A concentrations were 0.25, 0.32, 0.31, 0.30 and 0.39 μg/mL for the five time periods. All post-injection times 24 h and below were significantly different ($P < 0.01$) in favor of V. The basis for differences in bioavailability of the injectable vitamin A forms, notwithstanding similar label concentrations is uncertain and warrants further consideration.

Key Words: vitamin E, vitamin A, injectable, bioavailability

1891 (W350) Individual and additive value of conventional and non-conventional technologies in beef steers housed and fed using a GrowSafe feeding system. A. R. Harding[*1], G. K. Jim[2], C. W. Booker[2], E. J. Behlke[2], S. L. Parr[2], S. J. Hannon[2], T. M. Greer[2], Z. D. Paddock[2], M. L. May[2], L. Burciaga-Robles[2] and C. R. Krehbiel[1], *[1]Oklahoma State University, Stillwater, [2]Feedlot Health Management Services, Ltd., Okotoks, AB, Canada*

This study evaluated the effects of conventional and non-conventional production technologies in cattle. Animals (384 steers, 1101 ± 63 lb.) were utilized in an RCBD. Non-conventional production (NCP) included non medicated supplement and; NCP1:DFM (Sage Biosciences Inc., Edmonton, Alberta); NCP2: enzyme (Sage Biosciences Inc., Edmonton, Alberta); NCP3: Oleobiotec Ruminant (Oleo; Laboratoires Phodé, Terssac, France); NCP4: DFM, enzyme and Oleo. Blended production (BP) systems included BP1: supplement with Rumensin and Tylan (Elanco Animal Health, Guelph, Ontario), DFM, enzyme, and Optaflexx (Elanco Animal

Health) for the last 28 d; BP2: supplement with Rumensin, Tylan, DFM, enzyme, Oleo, and Optaflexx (last 28 d). Controls included a negative control (NEG): non-medicated supplement; and conventional production (CP): supplement with Rumensin, Tylan, and Optaflexx for the last 28 d. Animals were randomized within each production system to receive an implant (Component TE-S with Tylan (Elanco Animal Health), parasiticide (Dectomax; Zoetis Canada, Kirkland, Québec), both, or neither. Cattle were fed an average of 91 d and individual DMI were measured using GrowSafe (GrowSafe Systems Ltd., Airdrie, Alberta). Data were analyzed using the GLIMMIX procedure (SAS Institute Inc, Cary, North Carolina). Carcass adjusted ADG was improved ($P < 0.05$) in the NCP3, BP1,BP2 and CP groups over the NEG cattle. Carcass adjusted G:F improved ($P < 0.05$) in the NCP3, NCP4, BP1, BP2, and CP treatments over the NEG cattle. No differences ($P < 0.05$) were detected in carcass characteristics or animal health variables. Live and carcass adjusted ADG and G:F were improved in implanted animals vs. non-implanted animals ($P < 0.001$). Carcasses of implanted animals were less likely ($P < 0.05$) to grade Canada AAA and more likely to grade Canada AA than non-implanted animals. No performance or carcass differences were noted ($P > 0.05$) for parisiticide treatments. No interactions ($P > 0.05$) were observed between dietary program,implant, or parisiticide and no differences ($P > 0.05$) in animal health were detected for any treatments. The results of this study indicate that Oleo has potential to improve the performance of beef steers but not to the same extent as conventional production practices.

Key Words: feedlot, cattle, technology

1892 (W351) Effects of supplemental bupleurum extract on serum hormone and immune globulin levels in heat-stressed dairy cows.

X. Sun[1,2,3], J. Cheng[1,2,3], N. Zheng[1,3,4], D. P. Bu[3], L. Pan[3] and J. Wang[*1,3,4], *[1]Ministry of Agriculture- Laboratory of Quality & Safety Risk Assessment for Dairy Products (Beijing), Beijing, China, [2]College of Animal Science and Technology, Anhui Agricultural University, Hefei, China, [3]State Key Laboratory of Animal Nutrition, Institute of Animal Science, Chinese Academy of Agricultural Sciences, Beijing, China, [4]Ministry of Agriculture- Milk and Dairy Product Inspection Center (Beijing), Beijing, China*

This experiment was conducted to evaluate the effects of bupleurum extract (BE) on serum hormone and immune globulin levels in dairy cows under heat stress. Forty lactating Holstein cows (75 ± 15 DIM, 37.5 ± 1.8 kg of milk/d, and 1.7 ± 0.4 parity) were randomly assigned to one of four treatments. Treatments consisted of 0 (control), 0.25, 0.5, or 1.0 g BE/kg DM. The experiment lasted 10 wk. Average temperature–humidity index (THI) was more than 72 throughout the experimental period. Blood samples were collected from all of animals via tail vein before the morning feeding on Days 0, 21, 42, and 63. Data were analyzed by MIXED model procedure of SAS 9.2. Compared with controls, cows fed 1.0 g/kg BE had higher thyroxine (T_3) (1.43 vs. 1.16 ng/mL; $P < 0.05$) and prolactin (PRL) (230.50 vs. 188.19 uIU/mL; $P < 0.05$) levels, and 0.5 g/kg BE had the tendence to increase the T_3 (1.27 vs. 1.16 ng/mL; $P < 0.10$) level, but 0.25 and 0.5 g/kg BE had no effect ($P > 0.05$) on PRL level. Serum growth hormone (GH) level was increased (2.17 vs. 1.21 ng/mL; $P < 0.05$) in cows fed 0.25 g/kg BE compared with control cows, and tended to be higher (1.76, 1.69 vs. 1.21 ng/mL; $P < 0.10$) in cows fed 0.5 and 1.0 g/kg BE. Supplementation of BE had decreased the cortisol (COR) levels (48.35, 49.43, 49.86 vs. 64.49 ng/mL; $P < 0.05$), but had no effect ($P > 0.05$) on the levels of thyroxine, Insulin, glucagon, neuropeptide Y, leptin, insulin-like growth factor, and heat shock protein 70. Cows fed 0.5 g/kg BE increased the immunoglobulin (Ig) A content (279.25 vs. 179.78 μg/mL; $P < 0.05$), and IgG level was increased (36.54, 36.14 vs. 27.13 mg/mL; $P < 0.05$) in cows supplemented with 0.25 or 0.5 g/kg BE, while the IgM and tumor necrosis factor-α (TNF-α) levels showed no difference ($P > 0.05$) when compared with the control cows. These findings suggest that BE supplementation could relieve metabolic disorders and enhance immune function in heat-stressed cows.

Key Words: bupleurum extract;serum hormone; immune globulin

1893 (W352) Influence of additional tannins extract level on feedlot performance of finishing hair lambs.

R. Barajas*, E. B. Bonilla, L. R. Flores, J. J. Lomeli and J. A. Romo, *FMVZ-Universidad Autónoma de Sinaloa, Culiacan, Mexico*

Forty eight Pelibuey x Katahdin hair lambs weighing 21.3 ± SD 3.23 kg were used in a 70 d experiment to determine the influence of tannins extract level supplementation on feedlot performance of finishing hair lambs. Animals were blocked by initial weight and in groups of three, lambs were placed in 16 plastic floor elevated pens (1.5 × 1.6 m). In a complete randomized block design, within a block, pens were randomly assigned to four treatments as follows: 1) A 92% concentrate diet (14% CP; 2.07 Mcal of NEm/kg) formulated with corn grain and soybean meal without addition of tannins extract (CTRL); 2) CTRL and supplementation with 0.15% (DM basis) of tannins extract (TE15); 3) CTRL plus 0.3% (DM basis) of tannins extract (TE30); and 4) CTRL added with 0.45% (DM) of tannins extract (TE45). Lambs were fed twice a day. Tannins extract was supplied as a condensed and hydrolyzable tannins-blend obtained from quebracho and chestnut trees (Silvafeed-Bypro; SilvaTeam-Inudor, S.A., Argentina). Results were analyzed by ANOVA for a complete randomized block design, and the influence of TE level on performance variables was explored using polynomial contrasts. Pen was used as the experimental unit. Quadratic responses to TE level

supplementation on final weight and average daily gain were observed ($P = 0.05$), mean values of ADG were 0.214, 0.242, 0.236, and 0.220 kg/d for CTRL, TE15, TE30, and TE45 treatments, respectively. Dry matter intake was not affected by treatments ($P = 0.38$). Feed conversion (feed/gain ratio) responded in a quadratic form ($P < 0.01$) to tannin extract supplementation level, with mean values of 4.61, 4.06, 4.25, and 4.75 kg of DMI/kg of gain, for treatments containing 0, 0.15, 0.30, and 0.45% of tannin extract in dietary DM, respectively. It is concluded, that addition of tannin extract to the diet improves in a quadratic manner the feedlot performance of finishing hair lambs, and the better supplementation level could be between 0.15 and 0.3% of dietary dry matter.

Key Words: feedlot-performance, lambs, tannins

1894 (W353) Supplementation of dairy cows before calving with β-carotene. R. C. Oliveira[1], B. M. Guerreiro[2], N. N. Morais Junior[3], R. L. Araujo[1], R. A. N. Pereira[4,5] and M. N. Pereira[*1,5], *[1]Universidade Federal de Lavras, Lavras, Brazil, [2]Universidade de São Paulo, São Paulo, Brazil, [3]Instituto Federal de Educação, Ciência e Tecnologia do Espírito Santo, Colatina, Brazil, [4]Empresa de Pesquisa Agropecuaria de Minas Gerais, Lavras, Brazil, [5]Better Nature Research Center, Ijaci, Brazil*

The pre-calving supplementation of β-carotene was evaluated. The data set contained 283 Holsteins that received a treatment for > 14 d (29.1 ± 6.9 d). Cows were paired blocked by parity and expected calving date and assigned to a treatment: Beta-carotene (1.2 g/cow/d. Rovimix, DSM) or Control. The same TMR batch was offered to all cows and β-carotene was top dressed per cow once a day. Milk yield was recorded daily and sampled at 30.1 ± 8.3 d post-calving. Frequency distributions were analyzed with GENMOD of SAS using logistic regression for binomial data. Continuous variables were analyzed with MIXED. Within parity, nonparametric estimates of the survivor function for reproductive variables were computed using the product-limit method of the Kaplan-Meier method with LIFETEST. Plasma β-carotene content at the start of the experiment was similar (2.99 µg/mL, $P = 0.59$) and peaked at 3.26 µg/mL on day -15 pre-calving for supplemented cows (2.62 µg/mL for Control, $P < 0.01$). Colostrum density, milk yield, and milk solids content were similar ($P > 0.32$). Milk yield from d 20 to 109 of lactation was 3105 kg for primiparous and 3595 kg for multiparous ($P < 0.01$). Beta-carotene tended to increase milk protein content from 2.90 to 2.96% ($P = 0.09$) and to decrease the proportion of primiparous with a milk fat to protein ratio > 1.4 from 25.8 to 9.7% ($P = 0.10$). The proportion of primiparous with difficult calving, SCC > 200,000 cells/mL, metritis, progesterone > 1 ng/mL at 21 and 42 d, % conception at first service, and % pregnant at 90 and 150 d were similar ($P > 0.46$). There was a trend for decreased incidence of SCC > 200,000 cells/mL in multiparous supplemented with β-carotene (38.9% vs. 28.1%, $P = 0.12$), other variables were similar ($P > 0.21$). Beta-carotene reduced the proportion of multiparous with retained placenta 12 h post-calving from 29.9% to 21.7%, time of placenta release was 392 min (340 to 440) for β-carotene and 490 min (395 to 540) for Control (Median and 95% confidence interval. LogRank $P = 0.05$ and Wilcoxon $P = 0.04$). For primiparous, β-carotene did not determine placenta release (incidence was 15.4%). Responses in the intervals from calving to first estrous, to first service, and to conception were not detected. The pre-calving supplementation of β-carotene increased the plasma content around calving. There was no detectable response in milk yield or reproductive performance. β-Carotene reduced the incidence of retained placenta in multiparous cows.

Key Words: β-carotene, retained placenta, transition period

1895 (W354) Relationship between residual feed intake and mitochondrial function. M. M. Masiero*, M. S. Kerley and W. J. Sexten, *University of Missouri, Columbia*

Crossbred steers were used to determine if mitochondria complex I (C1) differed among residual feed intake phenotypes (RFI) and if C1 subunits (B-RFI) could account for additional differences in DMI. All experiments were analyzed as a completely randomized design. In Exp. 1 ($n = 26$) and 2 ($n = 24$) steers were fed no-roughage corn-based diets. Steers ($n = 13$) were fed an alfalfa haylage (30% diet DM) based diet during growing phase of experiment three and finished using no-roughage corn-based diets. We hypothesized calf DMI was influenced by metabolic efficiency (RFI) and subsequently C1 subunits could describe additional animal to animal DMI variation. Individual DMI was collected using GrowSafe feed intake system and used to calculate RFI and B-RFI. Band RFI was calculated similar to RFI with DMI as dependent and ADG, metabolic mid weight (MMWT) and C1 subunit (Band3) as independent variables. Blood samples were collected during growing phase of all experiments with an additional sampling during experiment three finishing phase to isolate mitochondria from lymphocytes. Complex I quantities were measured using immunocapture. Complex I subunits were separated into bands using gel electrophoresis and three bands were measured by densitometry. Dry matter intake was less and G:F was greater for–RFI compared to +RFI ($P < 0.05$) steers in all experiments. Band-RFI improved coefficient of determination by 17.04, 1.66, 12.65, 7.12, 12.89, and 2.68% compared to regressing intake on ADG and MMWT for experiment one, two, growing phase of three, finishing phase of three, and total period of experiment three using mitochondria measurements of growing and finishing phase of three, respectively. In experiment three, RFI was calculated for growing (d 0 to 70) and finishing (d 71 to 140) phases independently and for the total 140 d period. Residual feed intake correlation was 0.14 be-

tween growing and finishing phases ($P = 0.63$), 0.79 between growing phase and total period ($P = 0.001$) and 0.65 between finishing phase and total period ($P = 0.01$). Using band 3 in regression equations improved agreement of–RFI from 60 to 75% and +RFI from 57 to 83% between growing phase and total period of experiment three. Growing and finishing phases had 40 and 29% agreement of–RFI and +RFI steers, respectively. In conclusion, mitochondrial complexes accounted for additional variation in intake among steers. Adding band 3 to intake regression equations improved coefficient of determination of all experiments. Residual feed intake phenotype may be influenced by age or cattle growing phase.

Key Words: feed efficiency, mitochondria, residual feed intake

---

1896 (W355) Bioavailability of rumen protected choline sources when supplemented at different concentrations. K. J. Herrick*[1], J. A. Davidson[2], F. R. Valdez[1], M. J. Christofferson[1] and S. E. Schuling[3], *[1]Kemin Industries, Inc., Des Moines, IA, [2]Land O'Lakes Purina Feed, Gray Summit, MO, [3]Hubbard Feeds, Inc., Des Moines, IA*

Plasma choline is not an accurate measure of choline supplementation because of extensive liver metabolism. Our objective was to evaluate a method to estimate the bioavailability of rumen protected choline (RPC) products by comparing the response of plasma metabolites involved with choline metabolism. Choline chloride (0, 3, 6, or 9 g/d) was mixed in 2 L of isotonic solution and infused daily into the duodenum of 4 duodenally and ileal cannulated steers (337 ± 23.7 kg BW) to determine a response curve. An additional 6 steers and 2 heifers (322 ± 23.7 kg BW) were used in a replicated 4 × 4 Latin square experiment with 7 d periods to evaluate the RPC products. Both experiments were run concurrently and plasma was collected from all animals for 1 wk before the start of the experiment. Choline chloride was provided using 2 rumen protection technologies (SF and BT; Kemin Industries, Inc.). Treatments provided the following daily amounts of choline chloride: 1) 13 g by SF (LSF), 2) 36.0 g by SF (HSF), 3) 14.5 g by BT (LBT), and 4) 39.0 g by BT (HBT). All treatments were mixed with 0.45 kg of a concentrate mix and individually fed. In both experiments, plasma was collected at 0, 4, and 8 h after feeding on the last day of the baseline and each period. Plasma was analyzed for choline and amino acids. Response curves were determined by regressing plasma choline, methionine, homocysteine, and cysteine against infused dose using the Fit Model procedure in JMP (SAS Institute, 2010). These curves were used to calculate choline chloride delivered by RPC treatments. Plasma and calculated delivered choline chloride were analyzed using the Fit Model procedure in JMP with hour of sampling and treatment as fixed effects and cow as random effect. Plasma amino acids and choline did not differ ($P > 0.05$) between RPC treatments. Calculated delivered choline chloride (4.71, 3.81, 3.37, and 6.25 g/d) did not differ ($P > 0.05$) for the LSF, HSF, LBT, and HBT treatments, respectively. However, the calculated delivered choline chloride for the RPC products was greater ($P < 0.05$) than during the baseline period. This would suggest that the method was appropriate and both of the RPC products were effective in providing a source of choline chloride.

Key Words: rumen protection, choline chloride, bioavailability

---

1897 (W356) Effect of method of flaxseed processing and tannins on the growth performance and carcass fatty acid profile of lambs. E. Castillo-Lopez*, M. Edrosolam, P. J. Shand, D. A. Christensen and G. B. Penner, *University of Saskatchewan, Saskatoon, SK, Canada*

The objective of this study was to evaluate the effect of flax, method of processing, and tannin inclusion on the growth performance of feedlot lambs and the carcass fatty acid composition. Forty Suffolk × Arcott lambs (22 females and 18 males) with an initial BW of 37.7 ± 5.87 kg were assigned to 1 of 2 blocks and within block to 1 of 5 dietary treatments in a randomized complete block design. Treatments (DM basis) were 1) CONT, a diet containing 15% barley silage, 53.6% ground barley, 11.9% canola meal, 6.4% alfalfa dehydrated, 4.0% oat hulls, 3.7% beet pulp, 3.3% fat and 2.1% mineral supplement; 2) FLAX, inclusion of 8.6% flaxseed; 3) FLAX+T, inclusion of 8.6% flaxseed and 4% tannins; 4) EF, inclusion of 20.5% extruded flaxseed; 5) EF+T, inclusion of 20.5% extruded flaxseed and 4% tannins. At the end of the 60 d study, ruminal fluid, blood, longissimus dorsi (LM), and subcutaneous back fat samples were collected and analyzed for fatty acid composition. Fatty acids were expressed as percentage of total fatty acid methyl esters. Data were analyzed as a randomized complete block design using the MIXED procedure of SAS. Treatment did not affect final BW ($P = 0.60$) or ADG ($P = 0.36$) with averages of 55.3 ± 3.10 kg and 324.0 ± 29.75 g/d, respectively. The proportion of saturated fatty acids in ruminal fluid ($P < 0.01$) and plasma ($P < 0.05$) was greatest in lambs fed CONT and CONT had the lowest ($P < 0.01$) proportion of polyunsaturated and omega-3 fatty acids in plasma. The proportions of saturated ($P = 0.93$) and polyunsaturated ($P = 0.15$) fatty acids in LM were unaffected. However, lambs fed FLAX+T, EF or EF+T had the greatest ($P < 0.01$) proportion of omega-3 fatty acids, with a minimum of a 2.3-fold greater concentration ($P < 0.01$) than CONT. The proportion of polyunsaturated fatty acids in subcutaneous fat was greatest ($P < 0.01$) in lambs fed FLAX+T or EF+T. Lambs fed FLAX+T had the greatest ($P < 0.01$) concentration of omega-3 fatty acids in subcutaneous fat with an estimate of 3.13 ± 0.189%: a value 3.3-fold higher ($P < 0.01$) than CONT. Overall, the fatty acid profile of lamb was improved when flaxseed or extruded flaxseed was fed without

affecting growth performance. Tannins had minimal additional effects on carcass fatty acid profile.

Key Words: extrusion, flaxseed, omega-3 fatty acids

1898 (W357) Evaluating the energy and protein requirements for growing Nellore heifers and steers fed two levels of calcium and phosphorus.

L. F. Costa e Silva*[1], T. E. Engle[1], S. C. Valadares Filho[2], P. P. Rotta[1], M. I. Marcondes[3], B. C. Silva[4] and M. V. C. Pacheco[3], *[1]Colorado State University, Fort Collins, [2]Universidade Federal de Viçosa, Department of Animal Science, Viçosa, Minas Gerais, Brazil, [3]Universidade Federal de Vicosa, Vicosa, Brazil, [4]Universidade Federal de Viçosa, Viçosa, Minas Gerais, Brazil.*

An experiment was conducted to evaluate the energy and protein requirements for growing Nellore heifers and steers fed with two levels of calcium and phosphorus. Thirty two Nellore heifers and eighteen Nellore steers were used. Heifers were divided in four groups. Four animals served as baseline reference animals, four were fed at maintenance (MAIN) and twenty four received ad libitum (ADLIB) access to feed. The ADLIB animals were further divided into four groups and assigned to treatments. Treatments were: 1) Ca and P fed at requirements (CaPR) with a 50:50 of roughage:concentrate (R:C) diet; 2) CaPR with at 70:30 R:C diet; 3) 43% of the Ca and 80% of the P requirement (CaPL) with a 50:50 R:C diet; and 4) CaPL with a 70:30 R:C diet. All steers in this experiment were fed CaPR. Half of the heifers and steers were slaughtered at d 50 and the other animals were slaughtered a d 100 of the feeding period while all MAIN animals were slaughtered at d 100. Total feces and urine were collected from all animals 72 h before slaughter. The net energy (NEm) and metabolizable energy (MEm) requirement for maintenance were obtained by exponentially relating the heat production and the metabolizable energy intake, while the net energy requirements for gain (NEg) were obtained using empty body weight (EBW) and EBW gain (EBG). The net protein requirements for gain (NPg) were estimated according to EBG and retained energy (RE). NEm and MEm were 70.1 and 118 kcal/kg $EBW^{0.75}$, respectively. Net protein for maintenance was 1.28 g/kg $BW^{0.75}$and NEg and NPg were estimated using the following equations: $NEg = 0.053 \times EBW^{0.75} \times EBG^{0.6301}$ and $NPg = 137.85 \times EBG – 0.05 \times RE$, respectively. Under the conditions of this experiment, the energy and protein requirements for growth were: $NEg = 0.053 \times EBW^{0.75} \times EBG^{0.6301}$ and $NPg = 137.85 \times EBG – 0.05 \times RE$, respectively.

Key Words: energy, protein, sugarcane

SMALL RUMINANT I

1899 (M365) A simple method to estimate feed required for maintenance of small ruminants.

A. L. Goetsch*[1], R. Puchala[1], A. T. Dolebo[1], T. A. Gipson[1], Y. Tsukahara[1] and L. J. Dawson[1,2], *[1]American Institute for Goat Research, Langston University, Langston, OK, [2]Center of Veterinary Health Sciences, Oklahoma State University, Stillwater*

A simple means to estimate feed required for maintenance by Katahdin (K) sheep and Spanish (S) goats (initial BW = 30.6 ± 0.40 and 21.8 ± 0.27 kg, respectively; 8 mo old) by frequent BW measurement and adjustment of feed offered was evaluated. Ten K and S wethers in 1.05 × 0.55 m pens were fed grass hay (64.1% NDF, 10.4% CP, and 55.4% TDN; DM basis), initially at 58 and 55 g/kg $BW^{0.75}$ (air-dry basis; i.e., ME intake of 427 and 452 kJ/kg $BW^{0.75}$, respectively), at 0800 h for 5 wk. Three times weekly BW was measured at 1300 h in 50-g increments, and hay fed was varied thereafter by 0–5% (i.e., ≤ 40 g/d) to maintain BW. Breed (732 and 538 g for K and S, respectively; SE = 11.5) and wk (625, 653, 632, 623, and 641 g for wk 1, 2, 3, 4, and 5, respectively; SE = 9.4) affected daily air-dry intake (ADI; $P < 0.001$), although breed × wk did not ($P = 0.508$). Variation among days in ADI differed between breeds in wk 2 (SD = 4.68 and 14.5 g; $P = 0.002$) and 5 (SD = 64.6 and 31.1 g for K and S, respectively; $P = 0.044$). Body weights were smoothed using LOWESS and fitted by a segmented polynomial with the middle segment constrained to a flat line. Regression coefficients of the first and third segments and the two join points were estimated using nonlinear regression. The average of the first and second join points was 16 and 28 d, respectively, indicating BW stability between these times. Also, ADI of each wether was regressed against ADG in 2- and 3-d periods based on unsmoothed BW in wk 2–5, 3–5, 2–3, 2–4, 3–4, and 4–5. The only weeks without an intercept different from 0 ($P > 0.10$) were 2–5 and 2–4. Hence, the intercept of wk 2–4 regressions was used to determine feed required for maintenance, with values of 727 and 538 g ADI (SE = 11.6), corresponding to a ME requirement for maintenance of 447 and 426 kJ/kg $BW^{0.75}$ for K and S, respectively. Variability was homogenous between breeds ($P = 0.867$), although intercept SE averaged 6.0 and 12.9 g ADI for K and S, respectively. In conclusion, after 2 wk of adaptation, frequent weighing and change in offered feed for 2 wk may offer a relatively simple means of estimating maintenance feed needs of small ruminants.

Key Words: maintenance, goats, sheep

1900 (M366) Dermal application of PGF2a for estrus synchronization in goats: Preliminary feasibility.

C. E. Ferguson*[1], D. J. Kesler[2], H. Nordberg[1] and J. Veillon[1], *[1]McNeese State University, Lake Charles, LA, [2]University of Illinois, Urbana-Champiagn*

The administration of vaccines and other veterinary products can result in abscesses and scar tissue within the carcass of the animal. The use of PGF_{2a} for estrus synchronization purposes only increases the likelihood of these occurrences. The objective of this study was to test the efficacy of PGF_{2a} dissolved in DMSO, a needle-less, transdermal delivery, compared with intramuscular injections of PGF_{2a}. In this study a total of 16 small cross-bred Spanish breed-type goats were used. The injection group received two 15 mg injections (im) of PGF_{2a} while the transdermal group received two 15 mg administrations dissolved in 2 mL of DMSO (placed between shoulder blades) both 10 d apart. All does were paint marked and exposed to a mature buck for 4 d. Approximately 35 d from buck removal all does were evaluated for pregnancy via ultrasonography. Statistical comparisons were performed in SAS using a chi-square analysis. There were no significant differences between the mean ± SD BCS (1 to 5 scale) for does receiving the injection protocol (1.7 ± 0.7) and does receiving the transdermal protocol (2.0 ± 0.8). Also there were no significant differences in the number of transdermal does displaying estrus (within 4 d) (5/7, 71%) compared with injection does (4/9, 44%). The pregnancy rate was higher ($P > 0.05$) for transdermal does (4/7, 57%) compared with injection does (2/9, 22%), however there was no significant different ($P > 0.05$) in the number of pregnant does from those showing estrus in the transdermal (3/5, 60%) and injection group (2/4, 50%). There was no difference ($P < 0.05$) in the time from last PGF_{2a} to onset of estrus among transdermal (58 ± 13 h) and injection does (42 ± 12 h). A total of 9 out of 16 does (56%) displayed estrus within a 4 d time period where only 19% would be expected randomly. These results suggest that administration of PGF_{2a} via DMSO (transdermal) should produce similar results as im injection for purposes of estrus synchronization. This procedure may result in a method of estrus synchronization without increasing carcass damage to goats.

Key Words: goats, PGF_{2a}, DMSO, estrus synchronization

1901 (M367) *Longissimus* muscle fatty acid profile of crossbred Boer goat kids fed diets containing crude glycerin. M. O. M. Parente*[1], K. S. Rocha[1], H. N. Parente[1], E. M. Ferreira[2], R. D. C. R. E. Queiroga[3], A. S. M. Batista[4], R. M. S. Gomes[1], P. R. O. Silva[1] and J. S. Araújo[1], *[1]Universidade Federal do Maranhão, Chapadinha, Brazil, [2]Escola Superior de Agricultura Luiz de Queiroz- ESALQ/ USP, Piracicaba, Brazil, [3]Universidade Federal da Paraíba, João Pessoa, Brazil, [4]Universidade do Vale do Acaraú, Sobral, Brazil*

Crude glycerin is a co-product of biodiesel production with a high concentration of glycerol. Due to the high production of biodiesel, there is a wide availability of crude glycerin and it is becoming an interesting ingredient for animal nutrition. Most studies focus on the sheep as small ruminants, while limited research exists evaluating crude glycerin in the diet of goat kids. Twenty crossbred Boer goat kids (20.8 ± 2.9 kg of BW at slaughter) were used in a randomized complete block design to determine the effect of partial replacement of corn by crude glycerin on *Longissimus* muscle fatty acid profile. Kids were penned individually for 51 d and fed an isonitrogenous (14.0 ± 0.2% CP, DM basis) diet composed of 70% concentrate and 30% forage (Coastcross Bermudagrass hay). Increasing levels of crude glycerin (80.0% glycerol, DM basis) were 0, 4, 8 or 12% corresponding to the experimental diets G0, G4, G8 and G12, respectively. Total lipids of muscles were extracted, esterified and methylated. Methyl esters were separated by gas chromatography (VARIAN 430-GC, California, USA) using a 60 m capillary column. Orthogonal polynomials for treatment responses were determined by linear, quadratic, and cubic effects. Effects were declared significant at $P < 0.05$, and trends are discussed between $P > 0.05$ and $P < 0.10$. Linear decrease ($P < 0.05$) for linoleic acid (3.57, 2.84, 3.76 and 2.33) and w6:w3 ratio (10.61, 9.71, 7.26 and 7.18 for G0, G4, G8 and G12, respectively) were observed with crude glycerin inclusion. The proportion of capric and eicosanoic acids tended ($P = 0.06$) to increase linearly. Saturated, Monounsaturated and Polyunsaturated fatty acids were not affected by treatments. In conclusion, the partial replacement of corn by crude glycerin cause a little effect on meat fatty acid profile.

Key Words: co-product, meat, quality

1902 (M368) Performance and carcass characteristics of finishing goat kids fed diets containing crude glycerin. M. O. M. Parente*[1], K. S. Rocha[1], H. N. Parente[1], E. M. Ferreira[2], I. G. R. Araújo[1], R. C. Rodrigues[1], R. M. S. Gomes[1] and P. R. O. Silva[1], *[1]Universidade Federal do Maranhão, Chapadinha, Brazil, [2]Escola Superior de Agricultura Luiz de Queiroz- ESALQ/USP, Piracicaba, Brazil*

The crude glycerin (co-product of biodiesel) has the potential to partially replace corn, because glycerol (an 80% constituent of crude glycerin) is converted to propionate in the rumen and acts as a precursor for hepatic glucose synthesis. However, most studies focus on the sheep and beef cattle, while limited research exists evaluating crude glycerin in the diet of goat kids. Therefore, the objectives of this trial were to determine the effects of partial replacement of corn by crude glycerin on performance and carcass characteristics of goat kids. Twenty crossbred Boer goat kids (initial BW of 17.08 ± 2.1 kg and 110 d old) were used in a randomized complete block design according to initial BW and age. Kids were penned individually during 51 d and fed an isonitrogenous (14.0 ± 0.2 CP, DM basis) diet composed of 70% of concentrate and 30% of forage (coastcross hay). Increasing levels of crude glycerin (80.0% glycerol, DM basis) were 0, 4, 8, or 12% corresponding to the experimental diets G0, G4, G8 and G12, respectively. Orthogonal polynomials for treatment responses were determined by linear, quadratic, and cubic effects. Effects were declared significant at $P < 0.05$ and trends are discussed between $P > 0.05$ and $P < 0.10$. Body weight (BW), average daily gain (ADG), G:F, dry matter intake, protein intake and ether extract intake were not affected by glycerin as a replacement for ground corn. Dry matter intake was 0.58, 0.65, 0.54 and 0.59 kg/d while ADG was 106, 106, 90, and 94 g for G0, G4, G8 and G12, respectively. The NDF intake tended ($P = 0.08$) to decrease linearly. Carcass characteristics (hot carcass weight, hot carcass yield and subcutaneous fat thickness) were unaffected by crude glycerin addition. Adding up to 12% crude glycerin to finishing kids does not affect the performance and carcass characteristics.

Key Words: Boer, cost of production, growth

1903 (M369) Effect of reducing dietary cation-anion difference on acid-base balance, plasma minerals level and anti-oxidative stress of female goats. W. X. Wu* and Y. Yang, *College of Animal Science, Guizhou University, Guiyang, China*

Reducing dietary cation-anion difference (DCAD, Na^+K-Cl-S, mEq/kg DM) has been proved an effective way to prevent milk fever in dairy cows. Based on the similar physiological gastro-intestinal tract anatomy and metabolic process between female goats and dairy cows, this study was conducted to evaluate the effects of varying DCAD on fluid

acid-base status, plasma mineral concentration and anti-oxidative stress capacity of female goats. Urinary pH, plasma Ca, P and Mg; and anti-oxidative stress indices of total superoxide dismutase (T-SOD), hydrogen peroxide (H_2O_2), glutathione peroxidase (GSH-Px) and malondialdehyde (MDA) were determined to evaluate the effect. Forty-eight Guizhou black female goats (15 ± 1.9 mo old, 22.3 ± 3.75 kg live weight) were randomly allocated to 4 blocks of 12 goats each and fed 1 of 4 diets that differed in DCAD level. Levels of DCAD were preliminarily designed to be control (+150 mEq/kg DM, CON), high DCAD (+300 mEq/kg DM, HD), low DCAD (0 mEq/kg DM, LD) and negative DCAD (-150 mEq/kg DM, ND), respectively. A commercial anionic salts (Animate) and sodium bicarbonate ($NaHCO_3$) were supplemented to reduce and increase DCAD level, respectively. There was no difference in dry matter intake for 4 groups of goats. Urine pH was aggressively decreased ($P < 0.0001$) with reduced DCAD and there was a strong association between DCAD and urine pH ($R^2 = 0.793$, $P < 0.0001$). Compared with CON and HD, feeding of LD and ND resulted in greater ($P < 0.05$) plasma Ca concentration. Plasma P level was increased ($P < 0.05$) when anionic salts were supplemented. The DCAD alteration did not affect ($P > 0.05$) plasma Mg level. There was no significant ($P > 0.05$) difference in plasma GSH-Px activity and H_2O_2, but anionic salts supplementation in LD and ND significantly increased ($P < 0.05$) plasma T-SOD activity and tended to reduce MDA ($P < 0.1$) over HD and CON. Results from this study indicated that reducing DCAD could decrease urine pH and increase plasma Ca concentration of female goats. Specially, reducing DCAD was helpful to enhance oxidative stress tolerance capability of female goats.

Key Words: dietary cation-anion difference, urine pH, plasma calcium, anti-oxidative stress, female goats

1904 (M370) Effect of dietary linseed supplementation on milk fatty acid profile in dairy goats with different α^{S1}-casein (CSN1S1) genotype.

A. Nudda*, G. Battacone, N. P. P. Macciotta, A. Fenu and G. Pulina, *Dipartimento di Agraria, University of Sassari, Sassari, Italy*

In this study, the effects of dietary supplementation with extruded linseed on milk fatty acid profile of dairy goats with different α-^{s1} casein (CSN1S1) genotype are investigated. A flock of 68 Alpine goats were genotyped by IEF at the CSN1S1 locus. Ten were selected for the experiment: 5 homozygous for the weak *F* allele (*FF*) and 5 heterozygous for a strong allele (*AA or BE*). Goats of each genotype (weak and strong) were allocated into two groups: one was the control (CON) and one was supplemented with 150 g/d of extruded linseed (LIN). The trial lasted 8 wk. Data were analyzed using a mixed linear model that included the period, diet, genotype and diet × CSN1S1 genotype interaction as fixed factors, and the goat as random factor. Results confirmed the lower protein content (-11%) and higher milk yield (+26%) in weak genotype. A significant interaction diet x genotype was found for fat content: it was higher in LIN compared to CON only in the strong genotype (3.4 vs. 4.0%), whereas it did not change in weak genotype (3.3 vs. 3.2%). Goats fed LIN had greater proportions of vaccenic acid (18:1 trans11), CLA c9t11 and 18:3n-3 than goats fed CON. The genotype affected some FA: in particular the weak group showed a higher proportion ($P < 0.05$) of linoleic (2.5 vs. 2.1 g/100 g total FA), CLA c9t11 (0.8 vs. 0.6 g/100 g total FA), C16:1 and C22:4n6, and a lower proportion of stearic (7.4 vs. 8.6 g/100 g FA) compared to strong. Furthermore, the delta9 desaturation ratios were higher in weak CSN1S1 genotypes for C14 and trans11 C18:1. This study evidenced the impact of genetic variants of CSN1S1 on milk fat content and composition. *Acknowledgements: research funded by Fondazione Banco di Sardegna project*.

Key Words: goat milk, α_{S1}-casein, linseed diet by genotype interaction

1905 (M371) GIS hot-spot analysis of pasture utilization of two separate herds of goats over time.

T. A. Gipson*[1], S. P. Hart[1] and R. Heinemann[2], *[1]American Institute for Goat Research, Langston University, Langston, OK, [2]Kiamichi Forestry Research Station, Oklahoma State University, Idabel*

An understanding of pasture landscapes that promotes or hinders efficient utilization is essential for proper management. The objective of this study was to characterize pasture utilization of two separate herds of goats utilizing the same pasture in different years. The study area was a 14.1-ha pasture of predominantly fescue, bermudagrass, panicums, bahia grass, and broomsedge bluestem but was reverting to a wooded area containing predominately pecan, elm, and honey locust sapling-size trees. In year one (Y1), the study area was stocked with 36 Spanish goats, of which 10 were fitted with GPS collars and in year two (Y2), the study area was stocked with 58 Spanish goats, of which 19 goats were fitted with GPS collars. Different goats were used in Y1 and Y2. For the first 2 wk of pasture introduction, goats wore the collars, which recorded a fix every 5 min. An average nearest neighbor analysis yielded a z score of -150.2 ($P < 0.01$) for Y1 and -150.1 ($P < 0.01$) for Y2, indicating highly clustered events for both years. A GIS point-in-polygon (PiP) analysis was conducted for each year using the same grid (1792 10 × 10 m squares) for each year and with unique grid identifiers. Moran's I, a measure of spatial autocorrelation, indicated a peak at 30 m and that value was used in the hot-spot (Getis-Ord Gi* statistic) analysis conducted on the resulting PiP. Based on the resulting z-scores from the hot-spot analysis, each square was classified as very low (VL), low (L), moderate (M), high (H), and very high (VH) usage. Y1 had greater ($\chi^2 = 13.89$, $P < 0.01$) VL and lower VH squares (82% and 1%, respectively) compared with Y2 (80% and 3%, respectively). Hot-spot analysis revealed

two areas of H and VH usage for both years. One of the areas was a small grove of trees that had almost a 100% overlay for both years. The degree of similarity in pasture usage was high as indicated by a Spearman's rank correlation coefficient (0.76; $P < 0.01$) of the square z-scores for Y1 and Y2. Even though the two herds of goats never interacted and were separated by time, their pasture utilization was strikingly similar. Further work is needed to investigate the physical features of the pasture to understand the causes behind this similarity.

Key Words: GIS, GPS, goats

1906 (M372) Model evaluation of methane emission from goats.

M. H. M. R. F. Fernandes[*1], K. T. Resende[2], A. R. C. Lima[1], I. A. M. A. Teixeira[2], B. Biagioli[1] and T. F. V. Bompadre[1], *[1]UNESP, Univ Estadual Paulista, Department of Animal Science, Jaboticabal, Jaboticabal, Brazil, [2]UNESP, Univ Estadual Paulista, Department of Animal Science, Jaboticabal, SP, Brazil*

There have been several attempts to develop mathematical models to predict methane (CH_4) emissions because they can be easily applied in practical situations to estimate diet ME. Because studies evaluating the suitability of different mathematical models available for methane emission prediction in goats are lacking, this study was performed to evaluate 3 empirical models (Blaxter and Clapperton, Moe and Tyrrel, Pelchen and Peters) based on their ease of application, common use and their feasible input variables. The prediction ability of those models was evaluated using a database of two metabolism trials, in which 45 individual measurement of methane emission from goats (averaging 30 ± 2.93 kg BW) was taken using SF_6 technique. Models were evaluated by regressing residual (observed minus predicted) values on the predicted values centered on their mean values. The intercepts of the regression equations were used to estimate mean biases, whereas linear biases were assessed using the slopes of the regression equations. Also, using the same database, an empirical model was developed taking into account the coefficient of determination (R^2), forward selection, and Cp of Mallows. Observed DMI ranged from 280 to 1300 g/d. Observed methane emission ranged from 8 to 22 g/d, which represented methane losses ranging from 3.5 to 11% of dietary GE intake. Results showed a significant mean and linear biases ($P < 0.001$) for all models, showing that these models over predict methane emissions from goats. Moe and Tyrrell model presented the highest linear bias which was −65.5 g/d at the maximum predicted value (86.9 g CH_4/d). Pelchen and Peters model exhibited the lowest magnitude of the linear bias, which was less than 2 g/d at the minimum (11.5 CH_4/d) and -10 g/d at the maximum (27 g CH_4/d) predicted methane values. The linear bias of Blaxter and Clapperton model ranged from approximately 4 g/d (at the minimum predicted values) to -15 g/d (at the maximum predicted values). A simple regression equation was developed using same database. Accordingly, the best-fit linear model that represents goat methane emission was defined as follows ($R^2 = 0.51$, RMSE = 2.23, $P < 0.001$, CP = 11.4): CH_4(g/d) = 4.36 ± 2.07 + 0.17 ± 0.06 × BW (kg) + 0.006 ± 0.001 × DMI (g/d).

Key Words: bias, empirical model, CH_4

1907 (M373) The effect of some herbal plants on plasma metabolites of lactating goats.

K. Rezayazdi[*1], F. Mirzaei[2] and M. Hosseinabadi[3], *[1]Department of Animal Science, Faculty of Agriculture, University of Tehran, Karaj, Iran, [2]Animal Science Research Institute, Karaj, Iran, [3]University of Tehran, Karaj, Iran*

The objective of this study was to investigate the effects of a dried mixture of 7 herbal plants including thyme, mint, oregano, cumin, camel thorn, garlic, and eucalyptus as a natural dietary additive on plasma metabolites of lactating goats. Twenty lactating goats (3 wk after kidding, 2–3 yr old, average BW = 34.45 kg) were used in a completely randomized design with 2 treatments for a 40 d trial. Treatments included (1) a control ration, consisting of barley and alfalfa (50:50 DM basis) without herbal plant mixture, and (2) control ration + 250 mg kg^{-1} body weight per day herbal plant mixture. Amount of basal diet for the 2 groups was 0.5 kg/head/d. Animals had free access to water and green fodder. Blood samples were collected at the end of experiment after morning feeding for determination of plasma glucose, triglyceride (TG), urea nitrogen (BUN), total protein and cholesterol concentrations. Results showed that mean concentration of plasma glucose (60.5 and 57.5 mg/dL), total protein (10.0 and 9.6 g/dL), BUN (21.5 and 24.2 mg/dL) and TG (31.5 and 30.3 mg/dL) were not affected by herbal plants, but cholesterol concentration (73.7 and 59.7 mg/dL was significantly lower in treatment 2 ($P < 0.05$). It is concluded that herbal plant mixture were used in this study significantly decreased cholesterol concentration in plasma of lactating goats.

Key Words: blood metabolites, herbal plants, lactating goat

1908 (M374) Seasonal variation influences the semen characteristics and freezability in Xinong Saanen goat.

W. Wang[1], J. Luo[*2] and S. Sun[1], *[1]Northwest A&F University, Yangling, China, [2]Northwest A & F University, Yangling, China*

The aim of this study was to evaluate how season of ejaculate collection influences seminal quality parameters before and after freeze–thawing of Xinong Saanen buck semen. Ejaculates were collected from eight bucks and throughout the four seasons of 1 yr identified in the northern hemisphere (spring, summer, autumn and winter). During the study period, semen was collected at 10-d intervals during each season with an ar-

tificial vagina. Semen samples were evaluated by the combination of traditional and Computer-Assisted Sperm Analysis (CASA) semen assessment methods and sperm quality parameters (motility and morphology) were compared at fresh and after freeze–thawing, respectively. The results demonstrated that season of ejaculate collection influenced ($P < 0.05$) semen quality of Xinong Saanen bucks before freezing. During spring, summer and autumn, the ejaculate subjectively motility; volume; sperm concentration; sperm output and membrane integrity were higher ($P < 0.05$) than in the winter. The CASA also illustrated seasonal variation greatly affected semen motility kinetic parameters. An increase in the curvilinear velocity (CLV); straight line velocity (SLV); beat cross frequency (BCF) and amplitude of lateral head displacement (LHD) was observed during spring, summer and autumn, followed by a significant ($P < 0.05$) decrease during the winter. Furthermore, season of ejaculate collection influenced sperm freezability. Semen characters after freeze–thawing followed a phenomenon similar to that of the fresh ejaculate except in spring. In details, sperm quality was higher ($P < 0.01$) in summer and autumn than in spring and winter, in terms of total motile sperm (MS); rapidly progressive motile sperm (RPMS); CLV; SLV; average path velocity (APV); BCF and LHD base on the CASA. The membrane integrity and acrosome integrity were obtained from summer to autumn were higher ($P < 0.01$) than in spring and winter. Consequently, it can be said that Xinong Saanen bucks have distinct seasonal spermatogenic activity, with better semen quality characteristics being recorded during spring, summer and winter before freezing. Sperm from ejaculates collected during summer and autumn are more suitable for cryopreservation. Thus, it is possible to implement intensive goat breeding strategy with two kidding seasons in 1 yr to produce adequate quantities of goat milk and equalize the need for milk throughout the year, and moreover, the poor semen characteristics emphasize the need in avoiding making use of semen collection for cryopreservation purposes during spring and winter seasons of the year.

Key Words: Xinong Saanen goat, sensonality, semen characteristics, freezability, CASA

1909 (M375) Mean retention time of particulate matter through gastrointestinal tract of growing goat.

R. F. Leite[*1], F. O. M. Figueiredo[2], M. M. Freire[3], V. B. Carvalho[1] and I. A. M. A. Teixeira[1], *[1]UNESP, Univ Estadual Paulista, Department of Animal Science, Jaboticabal, SP, Brazil, [2]Sao Paulo State University, Jaboticabal/SP, Brazil, [3]UFAL, Maceio, AL, Brazil*

The objective of this study was to evaluate mean retention time (MRT) of particulate matter through gastrointestinal tract (GIT) of growing goat of different sex and body weight. A total of 58 Saanen goats (20 intact males, 20 castrated males and 18 females) were housed in individual pens with free access to water. Then, the goats of each sex were randomized in 3 different slaughter BW (around 15, 22, 30 kg). They were fed ad libitum with the same diet (45.4% corn plant hay and 54.6% concentrate comprised), and diet was offered twice daily at 0700 and 1600 h. The animals were slaughter when reached 16.5 ± 0.9; 22.8 ± 1.3; 31.6 ± 1.5 kg of BW. Then, GIT was removed and separated into reticulorumen, omasum, abomasum, small intestine, cecum and colon. The content of each GIT compartment was sampled. To determine the passage rate, we used the ruminal emptying technique of slaughtered animals. The indigestible NDF (iNDF) was used as internal marker. The concentration of iNDF was determined by incubating the samples in rumen-fistulated cattle per 288 h, using Ankom bags (F57). The experiment was analyzed as split plot designed (3 sex and 3 slaughter BW) using PROC MIXED of SAS. The effect of slaughter BW was decomposed into 2 orthogonal polynomial contrasts (linear and quadratic) and the effect of sex was compared by Tukey test. The significance was declared at $P \leq 0.05$. Sex did not influence the MRT for all compartments ($P > 0.05$). On average the reticulorumen retention time was 35.8 h (67% of retention in GIT) and it was similar between sex and BW. As BW increased the MRT in the omasum increased linearly and the MRT in the abomasum decreased linearly ($P \leq 0.05$). It was observed a significant interaction between sex and BW for MRT of omasum and colon ($P < 0.01$). Whereas, females with 22 kg of BW presented lower MRT compared to males (intact and castrated) in the same BW. In conclusion, the increase of BW mainly influenced MRT in the omasum and abomasum compartment. Females present different pattern of MRT for omasum and colon than males.

Key Words: body weight, iNDF, sex

1910 (M376) Goat kids of different genders change the proteic metabolism when subjected to feed restriction.

N. C. D. Silva[1], K. T. Resende[1], I. A. M. A. Teixeira[*1], H. C. Bonfa[2], C. J. Harter[1], F. O. M. Figueiredo[3], R. F. Leite[1] and M. M. Freire[4], *[1]UNESP, Univ Estadual Paulista, Department of Animal Science, Jaboticabal, SP, Brazil, [2]UFV, Universidade Federal de Viçosa, Department of Animal Science, Viçosa, MG, Brazil, [3]Sao Paulo State University, Jaboticabal/SP, Brazil, [4]UFAL, Maceio, AL, Brazil*

The objective of this study was to evaluate the effect of gender and feed restriction on proteic metabolism of 72 Saanen goat kids (24 intact males, 24 castrated males and 24 females) with initial BW of 15.8 ± 0.17 kg. At the beginning of the experiment 6 animals of each gender were slaughtered with 15 kg of BW to estimate their initial body composition, these animals were considered baseline for the comparative slaughter technique. The remaining animals of each gender were distributed into 6 groups of 3 animals subjected to different

levels of feed restriction (ad libitum, 25% and 50% feed restriction). A whole group was slaughtered when the kid fed ad libitum reached 30 kg BW. Protein retention was estimated by the difference between the final and initial body composition. Blood samples were collected from all animals every 10 d, in a total of 7 collections for blood metabolites and 5 collections for hormones profile. In these samples we evaluated total protein, albumin, urea, creatinine, γ glutamyltransferase (GGT), creatine kinase (CK), triiodothyronine (T3) and IGF-I. Data were analyzed as split plot design, using mixed model of SAS. The retention of body protein (kg) was not affected by gender, only showing a linear decrease with the increase of feed restriction ($P < 0.0001$). The total protein, creatinine and CK seric levels increased with the increase of experimental time ($P < 0.05$). When fed ad libitum, urea concentration was highest in females (58.1 mg/dl), followed by castrated males (54.3 mg/dl) and intact males (51.2 mg/dl; $P = 0.0154$). When the goats were subjected to 25% of feed restriction, the difference between genders was no longer observed, however, when subjected to 50% of feed restriction castrated males showed the highest serum urea level (54.02 mg/dl). The GGT activity in intact males was higher ($P < 0.0001$) when they were fed ad libitum (51.31 ± 1.58 U/L) and decreased with the increase of feed restriction. Whereas castrated males fed ad libitumpresented lower activities of GGT compared to those fed restricted and females remained constant at all levels of feed restriction. IGF-1 plasmatic were similar between castrated males and females (81.3 ng/ml), and lower than found in intact males (106.20 ng/ml; ($P < 0.0001$). Intact males showed lower concentrations of T3 compared to females ($P < 0.05$). Despite goats of different gender show similar protein accretion, they act physiologically different when subjected to feed restriction. Males changed their proteic metabolism to keep the protein synthesis.

Key Words: metabolism, sex

1911 (M377) Effects of dietary chromium supplementation on performance, liver and blood metabolites of kids. A. Emami[1], M. Ganjkhanlou[2], A. Zali[2], A. Akbari-Afjani[3] and M. Dehghan-Banadaky[*2], [1]*University of Birjand, Birjand, Iran,* [2]*University of Tehran, Tehran, Iran,* [3]*University of Zanjan, Zanjan, Iran*

This study was performed to determine the effects of supplementing chromium-methionine (Cr-Met) on fattening performance, liver and blood metabolites in Mahabadi goat kids. Thirty-two male kids (BW = 22 ± 2 kg, 4mo) were used in a completely randomized design to one of 4 treatments: control, 0.5, 1.0 and 1.5 mg Cr as Cr-Met/animal/d. The diet was formulated to meet the requirements recommended by NRC with 30% forage (alfalfa and corn silage): 70% concentrate ratio as TMR. The diets were the same, except for top-dress addition of Cr-Met fed in 2 equal meals (0700 and 1700 h) and orts were collected before morning meal. Animals were housed individually for 84 d. Animals were weighed in 21-d intervals. For measuring blood metabolites (glucose and cholesterol), blood samples were collected every 21 d before morning feeding. The end of trial following 16h fasting kids were slaughtered and some of the liver were immediately stored at -20C for assessing moisture, fat and crude protein content. Data considering dry matter intake(DMI), average daily gain (ADG) and blood metabolites were analyzed by Mixed Model procedure and liver metabolites with GLM MODEL procedure and adjust Tukey-Kramer (SAS 9.1). Intake (DMI), ADG, liver metabolites and blood plasma cholesterol were not significantly affected by dietary Cr-Met ($P > 0.05$). However supplementing diet with chromium significantly decreases plasma glucose relative to the control ($P < 0.05$). In conclusion, the results of this experiment indicated that dietary supplementation of Cr-Met failed to affect growth performance, plasma cholesterol and liver metabolites but decreased plasma glucose of Mahabadi goat kids.

Key Words: chromium methionine, blood metabolite, Mahabadi goat kid

---

1912 (M378) Effect of Tasco on fecal egg counts and packed cell volume in meat goats. N. C. Whitley*, S. H. Oh, K. Moulton, R. Franco, S. B. Routh and C. Kyle, *North Carolina A&T State University, Greensboro*

The effect of Tasco on goat gastrointestinal nematode parasite fecal egg counts (FEC) and packed cell volume (PCV) was investigated in two experiments (Exp) using Boer and Boer crossbred goat kids. In Exp 1, female goats at 264 ± 2.5 d of age and 31 ± 0.99 kg BW were artificially infected with 2000 L3 *Haemonchus contortus* every other day for 6 d. At 56 d post-infection, 20 goats were assigned to treatments of Control (Con) or Tasco (TA), $n = 10$/treatment. For Exp 2, 36 naturally-infected, 119 ± 2.4 d old female and castrated male goats at 22.5 ± 0.4 kg were assigned to Con and TA ($n = 18$/treatment). Pre-treatment FEC and BW means were similar. Goats were individually housed in 1.5 × 1.5 m pens with ad libitum water access. A commercially pelleted 17% CP meat goat feed was used. For Exp 1, goats were fed Tasco at 2% feed offered or a similar amount of their daily feed ration (2% BW with coccidiostat) mixed with 20 mL corn oil 2–3 h prefeeding for 14d. For Exp. 2, Tasco was added at 2% DM by the feed company before pelleting (no coccidiostat). Both TA and Con pre-weighed rations were fed daily to allow for 10% orts for 21d. Goats were weighed on d 0 and 21 (Exp 2) and fecal sampled at d 0, 7, and 14 (and d 21 for Exp 2) for FEC by modified McMaster's technique. Percentage PCV was measured in jugular blood samples on d 0, 7, 14, and 21 (d 0 and 14 only for Exp 1). Orts were weighed on d 7 (Exp 1 and 2), and d 14 and 21 (Exp 2). For Exp 1, half the goats regularly left unconsumed Tasco. However, analyzed separately (con-

sumed all vs. part) or together, FEC was not impacted by TA, while PCV was higher ($P < 0.01$) for TA (33.3 ± 0.56%) than Con (30.3 ± 0.58%). For Exp 2, FEC (1820 ± 156 epg), PCV (29.6% ± 0.4%), ADG (0.15 ± 0.02 kg) and FE (0.19 ± 0.02 kg gain/kg feed) were not impacted by TA. Pre-treatment fecal larval identification indicated 84.5% *H. contortus*. Intake was not influenced by TA. Overall, Tasco addition to the diet did not have consistent effects on PCV and FEC in goats and did not impact growth or feed efficiency.

Key Words: goat, parasites, Tasco

1913 (M379) Pharmacokinetic processes of lithium used for food aversion in sheep and goats.

C. L. Manuelian[1], E. Albanell[1], M. Rovai[1], A. Salama[*1,2], G. Caja[1] and R. Guitart[3], *[1]Group of Ruminant Research (G2R), Universitat Autonoma de Barcelona, Bellaterra, Barcelona, Spain, [2]Animal Production Research Institute, Dokki, Giza, Egypt, [3]Laboratory of Toxicology, Faculty of Veterinary, Universitat Autonoma de Barcelona, Bellaterra, Barcelona, Spain*

Conditioned taste aversion (CTA) is a useful management tool to control weeds in commercial crops. Lithium chloride (LiCl) is a safe product used in livestock CTA studies to induce aversion to palatable plants. Despite the use of LiCl in numerous studies, there is a lack of information on the pharmacokinetics that accompany different CTA doses in domestic livestock. This information is needed for using selective grazing in practice, and to avoid any possible soil contamination by excreted Li. With this aim, we studied the kinetics of Li elimination in 2 experiments: 1) Murciano-Grandina lactating goats ($n = 6$) after a single dose of 200 mg LiCl/kg BW; and 2) Manchega dairy sheep, open and dry, after a single dose of 225 mg LiCl/kg BW. For Exp.1, goats were penned in metabolic cages for measuring daily milk yield, water and feed intake. Samples of urine, feces, milk and blood were collected over a period of 168 h. In Exp.2, ewes were maintained as a group in a pen with head lockers, where they were restrained at every sampling time for feces (rectum) and blood (jugular) collection over 192 h. Concentration of Li was measured by graphite furnace Atomic Absorption Spectrometry and data corrected for its basal concentration. Withdrawal period (Wp) was calculated with a statistical tolerance limit of 95% (EMEA/CVMP/036/95). Individual biological half-life ($t_{1/2}$) was calculated using PK Solutions computer program (Farrier, 1997). Results showed that plasma Li concentration reached a maximum at 4 h in lactating goats (14.5 ± 0.8 mg Li/L plasma) and 12 h in dry sheep (17.7 ± 0.8 mg Li/L plasma). Values of $t_{1/2}$ were 30.9 ± 2.1 and 40.3 ± 3.8 h for sheep and goats, respectively ($t = 2.39$; DF = 10; $P < 0.03$). In goats, recovery rate of administered Li was 101.7% at 96 h (urine, 92.4 ± 4.4%; feces, 6.5 ± 1.3%; milk, 2.8 ± 0.4%); however the estimated Wp established in feces was 9 and 11 d for sheep and goats, respectively. In conclusion, Li was fully eliminated in sheep and goats, but needed longer time than reported in other species (i.e., rat and human). LiCl can be used safely to induce CTA for controlling weeds by grazing in organic crops after a waiting period of approximately 1 wk before moving the animals to the crop. *Funded by Plan Nacional I+D+I AGL 2010–22178-C02–01.*

Key Words: conditioned aversion; small ruminants; lithium chloride

1914 (M380) Influence of partial replacement of corn by crude glycerin on water consumption, feed intake and nutrient apparent digestibility.

D. M. Polizel[1], R. S. Gentil[1], E. M. Ferreira[1], R. A. Souza[1], A. P. A. Freire[1], J. A. Faleiro Neto[2], A. V. Pires[3] and I. Susin[*1], *[1]Escola Superior de Agricultura Luiz de Queiroz- ESALQ/USP, Piracicaba, Brazil, [2]Faculdade de Medicina Veterinária e Zootecnia- FMVZ/USP, São Paulo, Brazil, [3]University of São Paulo- ESALQ/USP, Piracicaba, Brazil*

Glycerin is a co-product from biodiesel production and it can improve energy efficiency when replaces corn. Five Dorper x Santa Inês ram lambs (BW 59.7 ± 1.3 kg), cannulated in the rumen, were used in a 5 × 5 Latin Square design to determine the effects of partial replacement of corn by crude glycerin (CG) on water consumption, feed intake and nutrient apparent digestibility. Animals were fed a total mix ration composed of 90% concentrate and 10% coastcross hay. The diets were isonitrogenous (15.9 ± 0.2 CP, DM basis) and the crude protein content was adjusted by increasing soybean meal. Crude glycerin (83.6% glycerol, DM basis) was included in the ration at 0, 5, 10, 15 or 20% (DM basis), corresponding to the experimental diets G0, G5, G10, G15 and G20, respectively. The diet was fed ad libitum, once daily. Every experimental period lasted 19 d. The first 15 d were used to adapt the lambs with the diets and the remaining 4 d were used to determine daily feed intake, water consumption and fecal output. For total collection of feces, harnesses with collection bags were used to avoid contamination of feces by urine. Data were analyzed using the MIXED procedure (SAS Inst. Inc.) and the LSMEANS option was used to generate individual means. Orthogonal polynomials for diet responses were determined by linear, quadratic or cubic effects. CG did not affect ($P > 0.05$) water consumption (4.77, 5.02, 5.01, 5.25, 4.56 L/d), dry matter (1.56, 1.51, 1.45, 1.43, 1.47 kg/d), crude protein (0.25, 0.25, 0.24, 0.22, 0.23 kg/d) and organic matter intakes (1.48, 1.43, 1.36, 1.33, 1.38 kg/d). Crude glycerin decreased ($P < 0.01$) NDF intake (0.29, 0.28, 0.24, 0.22, 0.24 kg/d) and increased ($P < 0.01$) mineral matter intake (0.08, 0.08, 0.09, 0.09, 0.10 kg/d). There was no effect on NDF (55.9, 54.5, 56.3, 56.7, 58.0%) and crude protein digestibilities (82.4, 81.7, 82.8, 81.5, 83.6%), However, DM (83.3, 82.5, 84.2, 85.4, 85.7%) and OM (84.8, 84.0, 85.9, 86.5, 86.8%) digest-

ibilities showed a linear increase ($P < 0.01$). Crude glycerin can replace corn up to 20% of dietary DM increasing DM and OM apparent digestibilities.

Key Words: glycerol, sheep, biodiesel

1915 (M381) Post-weaning performance by intact male F1 Kiko × Boer progeny from does selected based on parasite resistance: 1-yr summary.

L. S. Wilbers*, B. C. Shanks, J. D. Caldwell, K. L. Basinger, W. M. Haslag, J. D. Walker, K. M. Jones and A. L. Bax, *Department of Agriculture and Environmental Sciences, Lincoln University, Jefferson City, MO*

Goats are popular with small landowners and fit into a variety of farming systems. High market prices and continuing parasite challenges have led some producers to consider confinement feeding as a system to improve performance and avoid parasite problems. Therefore, the objective of this study was to evaluate post-weaning performance by intact male F_1 Kiko × Boer progeny from does selected based on parasite resistance. Weaned, intact male F_1 Kiko × Boer progeny ($n = 16$; 10.7 ± 0.59 kg weaning weight; 94.4 ± 2.73 d of age) from two lines of does selected for high resistance to internal parasites (HL; $n = 11$) or for low resistance to internal parasites (LL; $n = 5$) were compared. Animals were confined in a small ruminant barn with full access to a high-concentrate feed ration, water, and mineral supplement. Kid weaning weight, 47-d post-weaning weight, and final weight did not differ ($P \geq 0.19$) across treatments. Weaning to 47 d post weaning ADG, 47 d post-weaning to final ADG, and total ADG did not differ ($P \geq 0.15$) across treatments. Weaning to 47 d post weaning gain, 47 d post-weaning to final gain, and total gain did not differ ($P \geq 0.20$) for HL compared with LL. Therefore, selecting does based on parasite resistance may not influence post-weaning performance of their crossbred male progeny when offered a high-concentrate diet.

Key Words: goats, high-concentrate, parasite resistance

1916 (M382) Effects of thyme oil (*Thymus vulgaris*) on in vitro ruminal fermentation kinetics.

A. D. B. Ribeiro*[1], A. V. Pires[2], I. Susin[3], M. V. Biehl[2], V. N. Gouvea[1], M. V. C. Ferraz Jr.[1], M. L. Day[4], L. H. Cruppe[4], J. A. Faleiro Neto[1] and J. P. C. Thieme[2], *[1]University of São Paulo- FMVZ/USP, Pirassununga, Brazil, [2]University of São Paulo- ESALQ/USP, Piracicaba, Brazil, [3]Escola Superior de Agricultura Luiz de Queiroz-ESALQ/USP, Piracicaba, Brazil, [4]The Ohio State University, Columbus*

The objective of the present study was to investigate the effects of dietary thyme oil (1.25, 2.50 and 3.75 mL/kg DM) or monensin (Rumensin; 20 mg/kg DM) on ruminal in vitro gas production kinetics. Diets were formulated using the Small Ruminant Nutrition System to meet the requirements of growing sheep and were 80% Tifton hay (*Cynodon sp.*) and 20% concentrate DM. Homogenized samples of each diet (1.0 g) were placed into 160 mL serum bottles with 10 mL of rumen inoculum and 90 mL of a buffer solution. Rumen inoculum was collected from 4 fistulated male lambs before the first feed of the day was offered. Each lamb was fed one of the four diets, ad libitum. Six bottles were used per treatment and two additional bottles containing buffered medium, rumen fluid and the feed additives were used as background control. The volume of gas produced was indirectly measured at 2, 4, 6, 8, 10, 12, 15, 18, 21, 24, 36, 48, 72, and 96 h of incubation using the pressure reading technique. To estimate kinetic parameters of gas production data were fitted to the model $Y = A \{1- \exp^{[-b(t-L)-c(\sqrt{t}-\sqrt{L})]}\}$, where Y = cumulative gas production (ml) at time t; A = the asymptotic gas production (ml); b and c = constant rates (h^{-1} and $h^{-1/2}$, respectively); t = incubation time (h) and L = lag time (h). Thyme oil additive at 3.75 mL/kg resulted in similar gas production compared to monensin (194.1 ± 3.3; 197.2 ± 1.1 mL, respectively) and in reduced ($P < 0.05$) gas production compared to either 1.25 mL/kg (209.8 ± 0.9 mL) or 2.50 mL/kg (211.0 ± 0.5 mL) of thyme oil. The fractional degradation rate (FDR) was reduced ($P < 0.05$) in the 2.5 and 3.75 mg/ml thyme oil treatments (0.045 ± 0.0007 h) compared to treatment with monensin (0.049 ± 0.0003 h), while the 1.25 mL/kg treatment (0.047 ± 0.0003 h) did not differ from any other treatment. Lag time was reduced ($P < 0.05$) in the monensin (1.16 ± 0.03 h) compared to the 3.75 mL/kg thyme oil treatment (2.26 ± 0.17 h), however no difference was detected among monensin, 1.25 mL/kg (1.66 ± 0.16 h) and 2.50 mL/kg (1.24 ± 0.17 h) of thyme oil. In conclusion, thyme oil may be an effective alternative to monensin for manipulation of rumen fermentation.

Key Words: thyme oil, rumen gases, sheep

SMALL RUMINANT II

1917 (W358) The effects of live yeast, glucan and mannan on performance, rumen and blood parameters of fattening lambs. O. Canbolat[1], I. Filya[1], V. Akay[*2] and A. Kamalak[3], *[1]University of Uludag, Faculty of Agriculture, Department of Animal Sciences, Bursa, Turkey, [2]Global Nutritech Biotechnology LLC, Richmond, VA, [3]University of Kahramanmaras Sutcu Imam, Faculty of Agriculture, Department of Animal Sciences, Kahramanmaras, Turkey*

The objective of this study was to evaluate the effects of a live yeast (*Saccharomyces cerevisiae* NCYC R618, $4x10^9$ CFU/g), glucan and mannan containing feed additive (Synerall (SYN), Global Nutritech Biotechnology LLC, Richmond, VA) on performance, and rumen and blood parameters of fattening ram lambs. Forty 4-mo old Kivircik ram lambs (29.58 ± 1.6 kg initial BW) were stratified and blocked by BW to 1 of 4 individually fed, isocaloric, isonitrogenous dietary treatments containing 0, 1, 2 or 4 kg SYN per ton of TMR on DM basis. Diets containing cracked barley, wheat and corn grains, sunflower meal, and premix were fed once daily for ad libitum consumption. Lambs were weighed on 21-d intervals, and the study continued 63 d. At the end of the study, rumen fluids and blood samples were collected. Dry matter intake and F:G ratio were similar among treatments ($P > 0.05$). Weight gain during the study was statistically significant among treatments ($P < 0.001$), and was highest in the 2 kg SYN per ton treatment. Daily weight gain was statistically significant among treatments ($P < 0.001$), and was highest in the 2 kg SYN per ton treatment. Rumen pH was statistically significant among treatments ($P < 0.001$), and was highest in the 2 kg SYN per ton treatment. Rumen ammonia N levels were statistically significant among treatments ($P < 0.001$), and was lowest in the 2 kg SYN per ton treatment. Total VFA, acetic acid and propionic acid percentages were also the highest in the 2 kg SYN per ton treatment. Rumen lactic acid levels were statistically significant among treatments ($P < 0.001$), and were lowest in the 2 and 4 kg SYN per ton treatments. Blood glucose levels were statistically significant among treatments ($P < 0.001$), and was highest in the 2 kg SYN per ton treatment. In conclusion, the addition of 2 kg Synerall per ton in fattening lamb diets increased weight gain and improved rumen and blood parameters.

Key Words: Synerall, yeast, glucan, mannan, weight gain, rumen parameters

1918 (W359) Effect of prostaglandin $F_{2\alpha}$ on fertility of ewes treated with a short-term progesterone-based estrous synchronization protocol. C. D. Paul*, *West Virginia University, Morgantown*

Previous studies have shown either no effect or a lower fertility in ewes treated with $PGF_{2\alpha}$ at the end of a short-term progesterone-based estrous synchronization (STPBES) protocol. The objective of this study was to further evaluate the effects of $PGF_{2\alpha}$ when used as a component of STPBES treatments in ewes. Ewes ($n = 423$) from 4 farms located in WV and PA were randomly assigned to receive controlled internal drug releasing devices (CIDR-g, 0.3 g progesterone) for 5 ($n = 243$) or 7 ($n = 180$) days. At insert removal, approximately half of the ewes in each treatment group were randomly assigned to received either 0 ($n = 203$) or 4 ($n = 220$) mL Lutalyse (20 mg dinoprost; $PGF_{2\alpha}$) and were joined with sexually mature rams. Data were analyzed using analysis of variance with the model consisting of the main effects of duration of treatment with CIDR devices, injection with $PGF_{2\alpha,}$ farms, and their interactions and additionally, least square means for treatment effects were determined. The mean estrous response was 82.2 ± 36.9% and was not affected by treatments. Conception rate ($P = 0.01$; 67.1 ± 4.0% vs. 52.9 ± 4.0%), pregnancy rate ($P < .01$; 58.1 ± 3.5% vs. 44.0 ± 3.3%) and proportion of ewes lambing to the first service ($P < .0001$, 45.8 ± 3.8% vs. 33.9 ± 3.9%) were higher in ewes that did not receive $PGF_{2\alpha}$ (CIDR devices alone) than in ewes treated with CIDR devices and $PGF_{2\alpha}$. Conception ($P = 0.01$; 67.1 ± 4.1% vs. 52.9 ± 3.9%) and pregnancy rates ($P < .0001$; 56.0 ± 3.1% vs. 46.2 ± 3.9%) were higher, and proportion of ewes lambing to the first service period ($P = 0.07$, 44.3 ± 3.9% vs. 35.4 ± 3.8%) tended to be higher in ewes treated with CIDR devices for 5 d compared to those treated for 7 d. In conclusion, injection of $PGF_{2\alpha}$ at insert removal in STPBES protocols did not increase estrous response and decreased fertility at the synchronized estrus.

Key Words: prostaglandin, ewes, fertility, progesterone

1919 (W360) Anthelmintic activity of selected aldehydes and ketones against sheep gastro-intestinal nematodes. E. Ortu[*1], G. Sanna[2], A. Scala[2], G. Pulina[1], P. Caboni[3] and G. Battacone[1], *[1]Dipartimento di Agraria, University of Sassari, Sassari, Italy, [2]Dipartimento di Medicina Veterinaria, University of Sassari, Sassari, Italy, [3]Dipartimento di Scienze della Vita e dell'Ambiente, University of Cagliari, Cagliari, Italy*

Ruminant gastrointestinal nematodes cause annually important economic losses to livestock production such as reduction of milk and meat yield. Because the resistance of parasites to conventional anthelmintic products is growing, studies evaluating the effectiveness of alternative products against gastrointestinal nematodes seem interesting. Compounds of botanical

origin are considered as an important source of secondary metabolites with anthelmintic activity. This study was performed to evaluate the nematicidal activity of aldehydes of plant origin such as furfural, 2-hydroxybenzaldehyde and (E,E)-2–4-decadienal and ketones such as 2-undecanone against gastrointestinal nematodes. Fecal samples were collected from the rectum of Sarda dairy ewes and worm eggs were identified by Mc Master technique, while the third stage larvae (L_3) of Strongyle type nematodes were obtained by coproculture after 10 d. Larvaes were identified as Haemonchus contortus (24,7%), Teladorsagia spp.(51,5%) and, Trichostrongylus spp. (23,8%). The larval development assay, by using Cellstar 96-well cell culture plates, was performed to evaluate the effects of the plant origin compounds against L_3 larvaes. For calculation of EC_{50} (mg/mL) inhibition effects, for the tested compounds on L_3 of gastrointestinal nematodes, the motility was assayed at concentration range of 0.28–5.99 mg/mL. Stock solutions were prepared in methanol whereas aqueous solution of tween (0.3% *v/v*) or 0.1 M phosphate- buffered saline solution (PBS) were used for further dilutions or as negative control. Each treatment consisted of 25 L_3 per well and was replicated six times. L_3 were analyzed after 1, 24, and 48 h with an inverted microscope 10x and were ranked into two categories: motile and immotile/paralyzed. The percentages of L_3 paralyzed were corrected by eliminating the natural death-paralysis in the negative control in according to the Schneider-Orelli formula. The 2-undecanone and (E,E)-2–4-decadienal showed the highest nematicidal activity with a $EC_{50/24h}$ = 0.88 and 1.03 mg/mL respectively, while for furfural and 2-hydroxybenzaldehyde this concentration reference was 1.83 and 2.19 mg/mL, respectively. The experimental data revealed in vitro dose- dependent anthelmintic activity. However, the in vitro promising effects against gastrointestinal nematodes have to be carefully evaluated under in vivo conditions.

Key Words: parasite infection, in vitro, sheep

1920 (W361) Ovine footrot gene marker screening in a Katahdin sheep flock. T. Wuliji*[1], J. G. Hickford[2], W. R. Lamberson[3], B. C. Shanks[1] and S. Azarpajouh[1], *[1]Department of Agriculture and Environmental Sciences, Lincoln University, Jefferson City, MO, [2]Lincoln University, Lincoln, New Zealand, [3]University of Missouri, Columbia*

An extensive polymorphism at the DQA2 and DQA2-like loci located within the Major Histocompatibility Complex (MHC) in sheep have been identified and subsequently have been utilized to develop a gene marker testing procedures for footrot resistance. Although hair sheep breeds, such as Katahdin, are reputed to have better disease resistance, no genotypic markers have been reported for footrot resistance. The footrot gene-marker test reports five basic footrot scores (1, 2, 3, 4, and 5) corresponding to alleles of the MHC DQA2 and DQA2-like loci. This gives 15 possible score combinations (1,1; 1,2;... 4,5; 5,5), where 1,1 is claimed to have the highest resistance and 5,5 the lowest resistance to footrot infection. Blood samples were collected on FTA blood DNA collection paper cards from 600 Katahdin sheep and Katahdin crossbred ewes and rams from Lincoln University farms, Jefferson City, Missouri. DNA extraction and the gene marker test were performed at the Lincoln University Gene Marker Laboratory, Lincoln, NZ. Blood samples from 583 sheep with gene marker test results were analyzed. A chi-square test was used to test difference in variant alleles, animal genotypes, and score group distribution frequency. As footrot tolerance genes are assumed to exert a dominant effect, an expressed value for a pair of alleles was derived and animals were grouped into five categorical groups (1 to 5). Variant allelic distributions in 5 score groups were 10.0%, 21.2%, 45.3%, 17.6%, and 5.9%, respectively. Whereas, animals classed into five gene marker score groups were 18.5%, 33.3%, 42.0%, 5.8%, and 0.3%, respectively. Both allelic distribution and genotypic distributions were significantly ($P < 0.01$) different among the five gene marker score groups. The percentage of animals in the footrot tolerance score (1 and 2) was 52%, with a moderate score of 3 was 42%, and with scores of 4 and 5 were 6%. Therefore, by using footrot marker screening, the potential to select a high resistant flock is possible within three to five breeding seasons.

Key Words: Katahdin, footrot, DNA marker

1921 (W362) The effects of gonadotropic stimulation on fertility of progesterone-treated nulliparous ewes bred during seasonal anestrous. A. K. Redhead*, *West Virginia University, Morgantown*

Attempts to breed fall born ewe lambs and yearlings (nulliparous females) during seasonal anestrus have resulted in limited success. Low fertility in these nulliparous females may be related to a deficiency of ram induced gonadotropic release necessary to stimulate sufficient estrogen production to induce estrus. The objective of this study was to evaluate the effects of gonadotropic stimulation on fertility in nulliparous females bred out of season. Nulliparous females (N = 311) from 5 farms throughout WV and PA received progesterone using CIDR inserts (0.38 g progesterone) for 5 d before ram introduction between the months of April and July. At insert removal, females at each farm were randomly assigned to receive a single injection of gonadotropin containing 240 IU eCG and 120 IU hCG (GS: 3mL P.G. 600, Intervet, i.m) or to receive no further treatment (C). Pregnancy diagnosis was conducted using transrectal ultrasonography between Days 25–30 post ram introduction, at which time rams were removed, and a second pregnancy diagnosis was conducted 20–30 d later. Analysis of variance was conducted using the GLM procedures of SAS to evaluate the effects of gonadotropic stimulation, farm and their interaction, and the least square means were computed for reproductive performance variables. Gonadotropin treated females had higher estrous re-

sponse (P = 0.002, 72% ± 3.7 vs. 51% ± 4.0), conception rate (P = 0.0562, 68.3% ± 6.0 vs. 44.5% ± 11), pregnancy to the first service (P = 0.003, 66% ± 4.2 vs. 37% ± 4.4), proportion of females lambing to the first service period (P = 0.0051, 54.5% ± 4.4% vs. 34% ± 4.4%), proportion of females lambing (P = 0.0013, 54% ± 4.4 vs. 34% ± 4.4) and lambing rate (P = 0.0018, 77.6% ± 7.0 vs. 45.1% ± 7.0) than C females. The results of the current study indicate that inadequate gonadotropin stimulation or estrogen production might be limiting fertility in nulliparous ewes bred during seasonal anestrus. Further, supplementation with the gonadotropin combination, P.G. 600 at progesterone withdrawal significantly increased fertility of progesterone-primed nulliparous females when bred outside their normal breeding season.

Key Words: out of season, ewe lambs, yearlings, fertility, P.G. 600, gonadotropic stimulation

1922 (W363) Effects of hair sheep breed on performance response of ram lambs to artificial infection with *Haemonchus contortus*. Y. Tsukahara*, T. A. Gipson, S. P. Hart, L. J. Dawson, Z. Wang, R. Puchala, T. Sahlu and A. L. Goetsch, *American Institute for Goat Research, Langston University, Langston, OK*

Twelve Dorper (D; 4.5 ± 0.44 mo, 31.9 ± 1.75 kg), 18 Katahdin (K; 3.8 mo, 24.3 ± 0.76 kg), and 12 St. Croix (C; 4.5 ± 0.17 mo, 19.7 ± 0.99 kg) ram lambs were used to investigate among and within breed differences in the first year of a centralized test for growth performance and response to artificial infection with *Haemonchus contortus*. Rams were randomly selected from 3 commercial farms in Missouri and Oklahoma. The test at Langston University entailed an adjustment period of 2 wk followed by 8 wk of data collection. Breeds were housed separately in adjacent pens with automated feeders allowing free-choice access to a 15% CP (DM) and 50% concentrate pelletized diet. During adaptation, anthelmintic treatment resulted in low fecal egg count (FEC; < 550/g), after which 10,000 infective larvae were administrated orally. Packed cell volume (PCV) was measured weekly and FEC was determined 4 times in wk 6–8. For analysis, initial BW and FEC were covariates, and the logarithmic transformation ln(x + 2000) was used for mean FEC (MFEC). Variability in MFEC and mean PCV (MPCV) was homogenous among breeds. Breed affected ($P \leq 0.01$) DMI (2.5, 2.2, and 1.9 kg; SEM = 0.10), MFEC (3431, 1273, and 1241 eggs/g, original scale; SEM = 90.7), and MPCV (29.1, 29.7, and 32.9% for D, K, and C, respectively; SEM = 0.68). Residual feed intake (RFI), ADG, and ADG:DMI were similar ($P > 0.05$) among breeds. Rams were categorized into 3 groups within breeds based primarily on MFEC and MPCV (High, Medium, and Low resistance) using the cubic clustering criterion of SAS, which resulted in unbalanced numbers in the groups (5, 5, and 2 for D, 12, 5, and 1 for K, and 8, 1, and 3 for C, respectively). Group means were similar ($P > 0.05$) in ADG, DMI, and RFI but varied ($P < 0.05$) in MFEC (627, 2137, and 3302 egg/g; SEM = 109.7) and MPCV (32.3, 30.2, and 29.2% for High, Medium, and Low, respectively; SEM = 0.72). In conclusion, D appeared less resistant than C or K based on MFEC after an artificial challenge with *H. contortus* larvae in a standardized environment. However, variability in MFEC and MPCV within breed was sufficient to allow assignment to different classes for use in a breeding program to enhance flock resistance.

Key Words: internal parasitism, resistance, sheep

1923 (W364) Effect of sodium butyrate administered in the concentrate on rumen development and productive performance of lambs in intensive production system during the suckling and the fattening periods. S. Cavini[1], S. Iraira[1], A. Siurana*[2], A. Foskolos[1], A. Ferret[1], M. A. Gomez[3] and S. Calsamiglia[1], *[1]Animal Nutrition and Welfare Service, Universitat Autonoma de Barcelona, Bellaterra, Spain, [2]Animal Nutrition and Welfare Service, Department of Animal and Food Sciences, Universitat Autònoma de Barcelona, Bellaterra, Spain, [3]Nutega/Novation, Madrid, Spain*

Sodium butyrate (SB) has been shown to improve growth rate, rumen development and health of calves. In intensive lamb production systems, the fattening period starts after a relative short suckling period, and lambs are fed a high concentrate diet. The aim of this experiment was to determine the effect of supplementing SB in the concentrate on rumen development and productive performance of lambs during the suckling and the fattening periods. During suckling, 66 Ripollesa-breed lambs were distributed with their mothers in 4 pens. Treatments were: control concentrate (CON), and concentrate supplemented with 3.6 g of SB (Butirex C4)/Kg of DM (SBC). At weaning, 9 lambs were slaughtered for sample collection and 10 were use for the herd replacement, and the remaining 47 lambs were distributed into 12 pens for the fattening period. Treatments were: 1) CON-CON for lambs fed CON in both periods; 2) CON-SBC for lambs fed CON in the suckling and SBC in the fattening period; 3) SBC-CON for lambs fed SBC in the suckling and CON in the fattening period, and 4) SBC-SBC for lambs fed SBC in both periods. At 88 d of age all lambs were slaughtered. In both periods, concentrate dry matter intake (DMI), average daily gain (ADG), body weight (BW), hot carcass weight (HCW), dressing percentage (DP), reticulum-rumen weight (RRW), rumen fluid pH, and density, length, width and keratinization of rumen papillae were measured. Feed conversion ratio (FCR) was calculated for the fattening period only. During the suckling period, SBC lambs had higher DMI (69.3 vs. 101.7 g ± 6.25), ADG (232.0 vs. 250.5 g ± 5.84), HCW (8.42 vs. 9.23kg ± 0.196) and DP (49.3 vs. 53.8% ± 1.04) ($P < 0.05$), and tended to have higher rumen papillae length (1.15 vs. 1.68 mm ± 0.168) and lower RRW (303.4 vs. 262.7 g ± 12.8; $P < 0.10$). During the fattening

period, no difference was found among treatments. Results indicate that the supplementation of SB in the concentrate improved rumen development and productive performance of lambs during the suckling period. However, at 3 mo of age, the administration of SB did not improve production in lambs reared in an intensive production system.

Key Words: sodium butyrate, lamb, rumen development, productive performance.

1924 (W365) Nutrients intake and performance of lambs fed diets with two levels of crude protein and concentrate.

R. S. Santos[1], K. G. Ribeiro[*2], O. G. Pereira[3], S. C. Valadares Filho[3], S. D. J. Villela[4], J. L. Silva[1] and P. G. F. Duarte[1], *[1]Federal University of Vicosa, Vicosa, Minas Gerais, Brazil, [2]Universidade Federal de Vicosa, Vicosa, Minas Gerais, Brazil, [3]Universidade Federal de Viçosa, Viçosa, Minas Gerais, Brazil, [4]Federal University of Vales do Jequitinhonha e Mucuri (UFVJM), Diamantina, Brazil*

This study aimed to evaluate the dry matter (DMI), crude protein (CPI) and total digestible nutrients (TDNI) intake, the average daily gain (ADG), daily carcass gain in relation to body weight fasting (CG_{BWF}) and feed conversion (FC) of lambs fed diets containing two levels of concentrate (CONC) and two levels of crude protein (CP). Thirty-two intact Santa Ines x Texel lambs with an average body weight of 19 kg were used. They were distributed in a 2x2 factorial in a randomized block design with four treatments and eight replicates. The diets had 40 or 60% of CONC (plus corn silage as forage source) and 10.0 or 14.4% CP (high or low), in relation to the requirement of 12.5% CP according to the NRC (2007) for lambs with live weight of 20 kg and gains of 200 g/day. Feed was offered ad libitum to the animals at 8 h and 15 h. The offered and leftover feeds were weighed to estimate the daily DMI. The predetermined slaughter weight was 30 kg, when the animals were submitted to a solid fasting period of 16 h, and weighed again to determine the slaughter weight. The durations of the confinement varied from 50 (14.25% CP and 60% CONC) to 106 (10% CP and 40% CONC) days. The data were subjected to analyses of variance and F test at a 10% probability using the statistical program SAEG 9.1. There was no interaction effect on intake of nutrients, but there were independent effects of CP and CONC levels. Higher nutrients intake were recorded for lambs fed the higher CONC or CP levels, whose CP intakes of DM, CP and TDN were, respectively, 972.8 and 821.68, 79.46 and 142.56, and 603.56 and 711.63 g/day. Only ADW was affected by the interaction CP x CONC, with values of 0.090 (10% CP and 40% CONC) to 0.200 kg/day (14.25% CP and 60% CONC). The CP levels affected CG_{BWF} (0.059 vs. 0.106 kg) and FC (7.19 and 5.29) and CONC levels affected CG_{BWF} (0.066 and 0.098 kg) and FC (7.27 and 5.20). We concluded that diets with highest CP or concentrate levels resulted in greater nutrients intake and better animal performance.

Key Words: average daily gain, daily carcass gain, feed conversion

1925 (W366) Milk production, blood glucose, insulin and non-esterified fatty acids concentration in ewes fed diet containing crude glycerin.

D. M. Polizel[1], R. S. Gentil[1], E. M. Ferreira[1], R. A. Souza[1], M. V. C. Ferraz Jr.[2], M. C. A. Sucupira[3] and I. Susin[*1], *[1]Escola Superior de Agricultura Luiz de Queiroz- ESALQ/USP, Piracicaba, Brazil, [2]University of São Paulo- FMVZ/USP, Pirassununga, Brazil, [3]Faculdade de Medicina Veterinária e Zootecnia- FMVZ/USP, São Paulo, Brazil*

Crude glycerin is a glucogenic substrate in ruminants and can decrease symptoms of pregnancy toxemia. The objective in this trial was to determine the effects of partial replacement of corn by crude glycerin (CG) on dry matter intake (DMI), milk yield, milk composition and blood metabolites (glucose, insulin and non-esterified fatty acids) in periparturient ewes. One hundred and eighteen, 90 d pregnant, Santa Inês ewes were used. After lambing, 32 ewes (BW 62.8 ± 1.3 kg) were allotted in a randomized complete block design, defined by pre-lambing diet, sex and offspring number. Diets were isonitrogenous (13.0 ± 0.3% CP, DM basis), composed of 70% concentrate and 30% raw sugarcane bagasse and fed daily, "ad libitum". Crude glycerin (83.6% glycerol, DM basis) levels were zero or 10% (DM basis), corresponding to the experimental diets G0 and G10, respectively. From the second until the eight week of lactation dry matter intake was determined. In the same period, once a week, the ewes were separated from the lambs and mechanically milked after intravenous administration of 10 IU of synthetic oxytocin. Three hours after the first milking, the ewes were milked again and milk production and composition were determined. Glucose and NEFA were measured at -14, −7, 0, 7, 14, 28, and 56 d relative to lambing and insulin at -14, −7, 0, and 7 d. Data were analyzed as repeated measures over time using the MIXED procedure (SAS Inst. Inc.). The LSMEANS option was used to obtain the means. Crude glycerin did not affect ($P > 0.05$) DMI (2.2; 2.2 kg/d) and milk production (168.6; 164.7 g/3 h). However, there was a decrease ($P = 0.01$) in milk fat percentage (8.0 vs. 7.0%). Ewes fed diets with glycerin had decreased ($P < 0.01$) NEFA concentration (0.27 vs. 0.18 mEq/L). Glucose (61.8 vs. 67.6 mg/dL) and insulin (10.8 vs. 15.5 µIU) were not affected by treatments, but there was an interaction between treatment x week ($P < 0.05$). Crude glycerin increased glucose (101.2 vs. 133.7mg/dL) and insulin concentration (10.5 vs. 24.5 µIU) at parturition. Crude glycerin can partially replace corn without affecting DMI, milk yield and milk composition. Crude glycerin improves energy balance of periparturient ewes.

Key Words: glycerol, free fatty acids, NEFA

1926 (W367) Apparent digestibility, rumen metabolism and nitrogen balance in lambs fed high-concentrate diets containing increasing levels of ground cottonseed. R. A. Souza[1], R. S. Gentil[1], E. M. Ferreira[1], D. M. Polizel[1], A. P. A. Freire*[1], J. A. Faleiro Neto[2] and I. Susin[1], *[1]Escola Superior de Agricultura Luiz de Queiroz- ESALQ/USP, Piracicaba, Brazil, [2]Faculdade de Medicina Veterinária e Zootecnia- FMVZ/USP, São Paulo, Brazil*

The objective in this trial was to determine the effects of feeding ground cottonseed (GCS) on apparent digestibility, rumen metabolism and nitrogen balance. Five ram lambs, Dorper x Santa Inês (45.2 ± 0.8 kg), cannulated in the rumen, were allotted in a 5x5 Latin Square design. Each experimental period lasted 22 d, 17 d for adaptation and 5 d for sampling. Diets were isonitrogenous (15% CP, DM basis) and composed of 90% concentrate and 10% coastcross hay. Treatments were defined by the levels of GCS inclusion: 0, 7, 14, 21 or 28% (DM basis). Diets were fed ad libitum and total feces and urine were collected. On the last day of sampling, the rumen content was sampled every 2 h during 12 h, starting before feeding. The data were analyzed as repeated measures over time by using the MIXED procedure (SAS Inst. Inc.) The LSMEANS option was used to generate individual diet means. Orthogonal polynomials for diet responses were determined by linear, quadratic, and cubic effects. Apparent digestibilities of DM (80.7, 77.3, 79.2, 76.2 and 74.4%), OM (82.3, 78.8, 80.8, 77.7 and 76.2%), CP (81.4, 80.9, 81.8, 79.3 and 79.7%) and NFC (89.4, 82.6, 84.0, 78.8 and 80.7%) were linearly reduced ($P < 0.05$) and EE (89.7, 93.3, 94.4, 95.0 and 93.7%) was linearly increased ($P < 0.05$) while NDF was not affected. Total SCFA (90.5, 95.7, 96.5, 83.4 and 71.7 mM) and propionate (35.1, 34.5, 36.4, 31.4 and 24.7 mM) had quadratic response ($P < 0.05$) with higher values for the inclusion of 14%. Acetate (47.4, 50.4, 47.8, 43.3 and 38.4 mM) had a linear decrease ($P < 0.05$) and pH (5.4, 5.5, 5.4, 5.6 and 5.7) showed a linear increase ($P < 0.05$). Isobutyrate, butyrate, acetate:propionate ratio and ammonia were not affected ($P > 0.05$). Nitrogen intake and excretion were linearly reduced ($P < 0.05$) resulting in no effect on retained nitrogen ($P > 0.05$). The inclusion of GCS affected negatively DM, OM, CP and NFC apparent digestibilities. Propionate and SCFA were higher with the inclusion of 14% of GCS.

Key Words: co-product, SCFA, rumen ammonia nitrogen

1927 (W368) Intake and performance of finishing lambs fed diets with licuri nut (*Syagrus coronata*) cake. R. L. Oliveira*, J. B. Costa, T. M. Silva, M. S. Borja, M. D. C. Magalhães, A. D. S. Nunes, C. B. D. Pellegrini, W. F. D. Souza and N. G. D. N. Júnior, *Universidade Federal da Bahia, Salvador, Brazil*

The objective of this study was to determine the impact of including licuri nut (*Syagrus coronata*) cake in the diet of crossbred Santa Inês finishing lambs on their intake and performance. Forty-four vaccinated and vermifuge-treated non-castrated lambs aged on average 6 mo and with an average weight of 21.2 kg ± 2.7 were fed equal proportions of roughage (Tifton 85 grass hay) and a concentrate mix composed of corn meal, soybean meal, 1% urea, vitamin-mineral premix, and inclusion of licuri cake at the levels of 0, 8, 16, and 24% in substitution of the soybean meal and corn meal in isonitrogenous diets, these levels being the treatments. Animals were confined in individual stalls for 70 d, fed twice daily, and weighed at the beginning and end of the experiment to calculate weight gain and feed conversion. Samples of feed and orts were collected to determine the intakes of dry matter (DM), crude protein (CP), ether extract (EE), non-fibrous carbohydrates (NFC) and total digestible nutrients (TDN). The data were adjusted to regression analysis, using the SAS 9.1 (2004) statistical software. The increase in the inclusion level of licuri cake led to a linear decrease in DM intake ($\hat{Y} = -21.352\ X + 1312$; $P < 0.001$), with reduction of 39% between the level with 0 and 24% of cake, respectively. Probably this reduction may be was associated with the elevation in NDF content, thereby demonstrating a considerable elevation in ADF representing the accrual in the lignin fraction, linked to decrease in NFC. The decrease in the intakes of CP, NFC and TDN is a consequence of the drop in DM intake. On the other hand, EE intake was quadratically affected ($\hat{Y} = -0.0551\ X^2 + 1.4271\ X + 31.967$; $P < 0.05$), increasing until addition of 12.95% of licuri cake, and reducing from this point. The average daily gain decreased linearly ($\hat{Y} = -0.004x + 0.218$; $P < 0.0001$) as the licuri cake was added. This decrease is mainly related to the drop in CP and TDN intakes. Feed conversion was not affected by the proposed levels. Including licuri cake reduces the intake and performance of the animals and the decision of whether or not to use it in the feeding of lambs will depend on the cost and economic return.

Key Words: intake, sheep, weight gain

1928 (W369) Growth and carcass characteristics of lambs fed high-concentrate diets containing different sources of non-protein nitrogen.

A. P. A. Freire*[1], F. L. M. Silva[1], D. M. Polizel[1], R. A. Souza[1], R. S. Gentil[1], R. C. Araujo[2] and I. Susin[1], *[1]Escola Superior de Agricultura Luiz de Queiroz- ESALQ/USP, Piracicaba, Brazil, [2]GRASP Ind. & Com. LTDA, Curitiba, Brazil*

Nitrate supplements can be used as non-protein nitrogen (NPN) in ruminant diets. The interest in this NPN source is due to its capability of reducing methane emissions. Forty-four Dorper x Santa Inês lambs (initial BW 21.05 ± 2.65 kg and 79 ± 5 d old) were used in a randomized complete block design, according to initial BW and age, to determine the effects of supplementing urea or calcium nitrate on growth and carcass characteristics. Lambs were penned individually during 56 d and fed an isonitrogenous (16% CP, DM basis) total mixed ration composed of 80% concentrate and 20% coastcross hay. The experimental diets were: C (control, with soybean meal), U (1.1% urea), NEN (2.65% non-encapsulated calcium nitrate) and EN (3.0% encapsulated calcium nitrate). Diets containing nitrate were formulated to have the same content of NO^{3-} (DM basis). Urea was added to have the same crude protein equivalent as nitrate. In the first week of feeding a gradual adaptation period was used to avoid toxic effects of nitrate or urea. Data were evaluated using orthogonal contrasts. The first contrast was the C vs. non-protein nitrogen (NPN), the second contrast was U vs. calcium nitrate (U vs. CN) and the third was formed by NEN vs. EN. The control animals had greater ($P < 0.01$) ADG (389, 355, 345, and 346 g for C, U, NEN and EN, respectively) and feed efficiency (gain:feed = 0.286, 0.265, 0.269 and 0.264 for C, U, NEN and EN, respectively) compared with NPN. However, there was no difference ($P > 0.05$) between U vs. CN and NEN vs. EN. Dry matter intake (1.37, 1.35, 1.29 and 1.32 kg/d for C, U, NEN and EN, respectively) and carcass characteristics (dressing percentage, longissimus muscle area, back fat thickness and body wall thickness) were unaffected ($P > 0.05$) by the experimental diets. Lambs fed 2.65% non-encapsulated or 3% encapsulated calcium nitrate have similar performance and carcass characteristics of lambs fed 1.1% urea.

Key Words: calcium nitrate, urea, sheep

1929 (W370) Zilpaterol hydrochloride modify the fatty acids profile of intramuscular fat of feedlot lambs.

H. Dávila-Ramos* and J. C. Robles-Estrada, *Universidad Autonoma de Sinaloa, Culiacan, Mexico*

The objective of this study was to determine the effects of dietary zilpaterol hydrochloride supplementation on fatty acid profile of lambs´s intramuscular fat. Forty crossbred male lambs (37.7 ± 0.67 kg) were used in a 43-d feeding trial (5 pens per treatment in a randomized complete block design). Lambs were fed with finishing diet (2.57 Mcal/kg of ME) containing cracked corn 60%, sudangrass hay 16%, soybean meal 12%, molasses 9.5%, and mineral premix 2.5%, twice daily. Animals were randomly allotted to pens (6 m^2) with full shade and ad libitum water. Treatments were: 1) control, no zilpaterol supplementation (ZIL-0); 2) zilpaterol for 20 d (ZIL-20); 3) zilpaterol for 30 d (ZIL-30); and 4) zilpaterol for 40 d (ZIL-40). Zilpaterol was supplemented at a rate of 0.20 mg/kg of live weight d^{-1} (as zilpaterol hydrochloride, Zilmax, Intervet México, México City). Twenty *Longissimus dorsi* muscle samples (50 g, five per treatment) were collected from left side carcass of twenty crossbred male lambs (Pelibuey × Katahdin, 50.3 ± 3.83 kg final live weight). The muscle samples were frozen (-18°C) and transported to laboratory for fatty acids analysis. Samples were thawed (4°C) and ground to homogenize them. Modified method (Folch et al.,1956) was used for lipid extraction from the muscle samples. The fatty acid composition was determined with gas chromatography (Varian, USA) and column (SP TM-2560 Fused Silica Capilary Column) 100 × 0.25 mm × 0.2 mm filmthickness and flame ionization detector. The results were analyzed with a completely randomized design, comparing means of treatments with orthogonal contrasts and orthogonal polynomials. Zilpaterol hydrochloride supplementation decrease 3.2% ($P = 0.01$) estearic fatty acid, and increase ($P = 0.06$) 3.6% linoleic fatty acid of intramuscular fat. ZIL-30 improved fatty acids profile with respect ZIL-20, reducing the level of estearic fatty acid (4.6%; $P < 0.01$) and increased linoleic (5.2%; $P = 0.06$) and araquidonic fatty acids (1.8; % $P = 0.07$). The results indicated that zilpaterol hydrochloride supply until 40 d reduced ($P = 0.01$; linear component) estearic fatty acid proportion and increased ($P \leq 0.05$) linoleic and araquidonic fatty acids. However, the oleic fatty acid present in greater proportion was not modified by zilpaterol supplementation. Zilpaterol hydrochloride supplementation resulted in increasing the levels of polyunsaturated fatty acids and a reduction in the levels of saturated fatty acids.

Key Words: zilpaterol chlorhidrate, fatty acids, lambs

1930 (W371) Composition of cheeses made from milk of ewes fed with soybean seed or linseed concentrates.

C. F. A. M. Penna*[1], M. I. Simão[2], F. P. Paula[3], M. O. Leite[1], M. P. Cerqueira[1], L. M. Fonseca[3], M. R. Souza[1] and I. Borges[3], *[1]Universidade Federal de Minas Gerais (School of Veterinary Medicine), Belo Horizonte, Brazil, [2]Universidade Federal de Minas Gerais (Veterinary School/UFMG), Belo Horizonte, Brazil, [3]Universidade Federal de Minas Gerais, Belo Horizonte, Brazil*

High solids, fat and protein contents of sheep's milk render it an attractive option for production of exclusive cheeses. However, this activity is still being structured in Brazil. The objective of the present work was to evaluate the composition and yield of cheeses produced with milk obtained from sheeps

fed diets containing soybean seed or linseed. Twenty-eight Lacaune, Santa Inês and crossbreeds sheep were allocated to two equal groups according to the diet. The milk obtained from each experimental group was used for cheese manufacture, and samples of this milk and whey were collected for laboratorial analyses and to complement cheese yield determination. The cheeses were aged for 30 d under low temperature storage (10–12°C), and analyzed for determinations of fat, protein, moisture and total solids contents. The data was evaluated using SNK test at 5% of significance. No influence of the diets on milk and whey composition was found ($P > 0.05$). Similarly, no difference was found for cheese yield and composition in both treatments and the general values observed were: yield of 26.9% (3.77 L/kg), moisture (42.6%), total solids (57.2%), fat (26.2%), protein (22/1%), and fat in dry matter (FDM) (45.8%). It is concluded that choice of the best concentrate to be used for sheep milk production should be based on diet cost, since the option of soybean seed or linseed did not affect cheese yield and composition.

Key Words: cheese composition, diet, cheese yield

1931 (W372) Pregnancy and lambing rates in anestrous ewes bred to a new synchronization protocol and laparoscopic timed artificial insemination (TAI).

S. B. Turner*[1], M. B. Gordon[1], T. Gowan[2], J. A. Small[2] and D. M. W. Barrett[1], *[1]Faculty of Agriculture, Dalhousie University, Truro, NS, Canada, [2]Agriculture and Agri-Food Canada, Truro, NS, Canada*

Reproductive performance in seasonally anestrous ewes is poor even after the application of conventional controlled breeding techniques. Estradiol-17β (E_2) has been shown to synchronize follicular wave emergence in anestrous ewes treated for 12 or 14 d with a medroxyprogesterone acetate sponge. The objective of this study was to determine the effects of an E_2 treatment administered 6 d after CIDR insertion on E_2 concentrations, estrus, pregnancy rates, and lambing rates in ewes bred out of season. Ewes from three farms (Farm A: $n = 22$; Farm B: $n = 48$; Farm C: $n = 28$) received CIDRs (Day −12) followed by an injection of eCG (500 IU; Day 0) at CIDR removal and an injection of sesame oil without (1 mL; Control) or with E_2 (350 µg; Day −6) 6 d before CIDR removal. Treatments were balanced for breed, age, parity, and BCS. Blood samples were taken from half of the ewes on Day −6 and 0 to determine E_2 concentrations. On Day 1 ewes were exposed to rams to observe estrus. Ewes were subjected to laparoscopic TAI on Day 2. Pregnancy was diagnosed by transabdominal ultrasonography on Day 50. Estrus, pregnancy rates, and lambing rates were analyzed using logistic regression. Day of lambing and E_2 concentrations were analyzed using ANOVA. The percent of ewes observed in estrus within 36 h of CIDR removal was similar between treatments (E_2: 24.5%; Control: 34.7%; $P > 0.05$). Pregnancy rates were similar between treatments (E_2: 40.8%; Control: 40.8%; $P > 0.05$) and were higher on Farm C than Farm B (Farm A: 45.5%; Farm B: 22.9%; Farm C: 67.9%; $P < 0.05$). Lambing rates were also similar between treatments (E_2: 34.7%; Control: 34.7%; $P > 0.05$) and were higher on Farm C than Farm B (Farm A: 40.9% Farm B: 16.7%; Farm C: 60.7%; $P < 0.05$). Relative to CIDR removal, ewes lambed earlier on Farm B (Farm A: 141.7 ± 1.3 d; Farm B: 136.6 ± 1.4 d; Farm C: 143.2 ± 0.9 d; $P < 0.05$) and ewes treated with E_2 lambed earlier (E_2: 138.9 ± 1.0 d; Control: 142.2 ± 1.0 d; $P < 0.05$). Concentrations of E_2 were similar between treatments on Day −6 (E_2: 1.5 ± 0.1 pg/mL; Control: 1.6 ± 0.1 pg/mL; $P > 0.05$) and Day 0 (E_2: 1.6 ± 0.1 pg/mL; Control: 1.3 ± 0.1 pg/mL; $P > 0.05$). Differences were mainly observed among farms potentially due to differences in breed, BCS, semen, or management practices. The addition of an E_2 treatment during a CIDR-eCG heat synchronization protocol does not clearly increase pregnancy and lambing rates in seasonally anestrous ewes.

Key Words: anestrus, ewes, controlled breeding

1932 (W373) Effect of supplementation with water-washed neem fruit and/or yeast on the performance and digestibility of west african dwarf sheep.

M. K. Adewumi* and T. O. Ososanya, *University of Ibadan, Ibadan, Nigeria*

This experiment was conducted to determine the performance of rams fed diets supplemented with water-washed neem (Azadirachta indica) fruits with or without yeast (*Saccharomyces cerevisiae*). Sixteen West African Dwarf (WAD) rams with an average weight of 14.41 (s.d = 2.54kg) were assigned to one of four diets with 4 animals per diet in a complete randomized design. The diets were: a total mixed ration (A); B (A plus 5.0 g of baker's yeast per animal per day); C (A plus 5.0% water-washed neem fruit inclusion in the diet); and D (A plus 5.0% water-washed neem fruit inclusion in the diet and 5.0 g of yeast per animal per day). The animals were fed at 5% body weight. At the end of the 56-d feeding trial, three animals per treatment were moved into individual metabolic cages. Average daily gain was higher ($P < 0.05$) in the D (120 g) compared to the other diets. Average daily dry matter intake (g) in C (929.58) and D (958.62) was similar ($P > 0.05$) but higher ($P < 0.05$) than B (839.32). The feed conversion ratio for A (10.05) was similar ($P > 0.05$) to B (11.99) and C (11.61) but higher ($P < 0.05$) than D (7.99). The digestibility of dry matter, crude protein and ash were similar ($P > 0.05$) for A, B and C. However, there was a significant difference between A and D. There was no significant ($P > 0.05$) difference in the digestibility of neutral detergent fibre, acid detergent fibre and cellulose of A and B. The metabolizable energy intake and the digestibility of organic matter was not different ($P > 0.05$) among B, C and D but were higher($P < 0.05$) than A. The nutrients digestibility of D was consistently higher ($P < 0.05$) than A except for ether extract and hemicelluloses components. Water-washed neem fruits significantly ($P <$

0.05) increased nitrogen intake (g) in C (14.02) and D (14.76). Nitrogen retention (g) was higher ($P < 0.05$) for D (11.32) than for A (5.47), B (6.49) and C (8.78), respectively. These results suggest a positive synergic effect of baker's yeast and water-washed neem fruit on the performance characteristics, digestibility and nitrogen retention of WAD rams.

Key Words: baker's yeast, water-washed neem fruit, nitrogen retention

1933 (W374) Effect of crude protein level and zilpaterol supplementation on growth performance and carcass dressing of finishing hairy lambs.

A. E. Angulo[*1], I. C. Perez[1], A. Plascencia[2], H. L. Lopez[1], P. M. Peraza[1], E. I. Gonzalez[1] and F. G. R. Rincon[1], *[1]Universidad Autonoma of Sinaloa, Culiacan Sinaloa, Mexico, [2]UABC, Mexicali, Mexico.*

Forty Pelibuey × Katahdin (37.66 ± 2.2 kg) crossbred intact male lambs were used to evaluate the interaction of two dietary protein levels (15 and 18% CP) and two dietary zilpaterol (ZH) levels (0 and 6 mg/kg of feed) on growth performance and carcass dressing. Lambs were equally grouped by weight into five uniform weight groups and assigned to 5-pen blocks (two lambs per pen). The experiment lasted 30 d. Low protein and high protein diets contained 2.92 and 2.89 Mcal ME/kg, respectively. Treatments were: 1) Low protein-no ZH (LP-0); 2) Low protein-ZH supplementation (LP-ZH); 3) High protein-no ZH (HP-0), and 4) high protein-ZH supplementation (HP-ZH). No interactions were detected between protein level and ZH supplementation. Protein level did not affect ($P > 0.05$) dry matter intake or ADG, but low-protein diets tended to increase ($P = 0.08$) feed efficiency and carcass dressing; however, the latter could be more by the slight difference on energy concentration between LP and HP diets (2.92 vs. 2.89) rather than protein level per se. ZH supplementation did not affect DM intake, but increased ADG (13.8%, $P < 0.05$) and feed efficiency (16.2%, $P < 0.05$) with no effects on carcass characteristics. The Increases on protein level of diet from 15 to 18% did not improve the response to ZH supplementation.

Key Words: zilpaterol clorhidrate, CP level, pelibuey sheep

1934 (W375) Performance of lambs fed with crude glycerin diets.

V. B. Carvalho[*1], J. M. Bertocco Ezequiel[2], R. F. Leite[1], S. F. F. Petrorossi[3], T. R. Delphino[3], H. L. Perez[3], J. R. Paschoaloto[3], M. T. C. Almeida[3], V. R. Favaro[4] and E. H. Fernandes[3], *[1]UNESP, Univ Estadual Paulista, Department of Animal Science, Jaboticabal, SP, Brazil, [2]UNESP, Jaboticabal, Brazil, [3]UNESP, Univ Estadual Paulista, Department of Animal Science, Jaboticabal, Brazil, [4]State University of Sao Paulo, Jaboticabal, Brazil*

The objective of this trial was to evaluate the effect of total corn replacement by crude glycerine (CG) on performance of feedlot lambs. Forty Santa Ines intact males lambs were used with initial BW of 22.9 ± 4.10 kg, assigned in a completely randomized block. Diets consisted of Tifton-85 hay, corn, crude glycerin (83% glycerol), corn gluten meal, corn oil, urea, sunflower meal, soybean hulls and mineral. The diets presented 18% of roughage and 82% of concentrate. Five treatments were used: 0% CG, 7.5% CG, 15% CG, 22.5% CG and 30% CG on dry matter basis. The animals were housed in individual pens with free access to water. The feed intake of animals were adjusted to ensuring 10% daily feed leftovers (ad libitum). The diets were offered twice daily at 0700 and 1600 h with 50% of total in each meal. Weekly before feeding, the animals were weighed to evaluate of BW gain. The DMI, days in feedlot, average daily gain (ADG) and feed efficiency (FE) were calculated at the end of the experiment. The data were analysed using the MIXED procedure of SAS and the treatments were compared using orthogonal contrasts (linear and quadratic) considering 5% significance level. There was no difference treatments among the variables measured ($P > 0.05$). On average, the animals presented 73 d in feedlot and 37.85 ± 1.42 kg final BW. The DMI in average was 1.35 kg d^{-1}, 0.21 kg d^{-1} of ADG and 0.15 kg of FE (kg of gain per kg of DMI). These results indicated that the use of the diets containing high concentrations of glycerin did not affect negatively the dry matter intake and animal performance.

Key Words: byproducts, feed efficiency, feedlot

1935 (W376) Sexual response of anovulatory Dorper X Pelibuey nullip arous and nulliparous and multiparous ewes exposed to males + estrogenized females. M. D. L. A. De Santiago*, *Universidad Autonoma Agraria Antonio Narro, Torreon, Mexico*

The aim of this study was to determine whether the stimulus exerted by the presence of males + estrogenized females, promotes both estrus (EA) and ovulatory activity (OA) in anestrous ewes in northern Mexico, (26°N). The study was conducted in April during the natural sheep anestrous season at this latitude. Sheep ewes (n = 104) were isolated from males 2 mo before the beginning of the experiment. All females were subjected to evaluation of ovulatory activity by transrectal ultrasonography (Aloka SSD- 500) on days -21, -14 and −7, and all of them were classified as anovulatory. To synchronize reproductive activity, each ewe was treated with an intravaginal sponge impregnated with fluorogestone acetate (FGA; Chronogest CR; Intervet) on days −9 to -2. Thereafter, on Day 0, 50 nulliparous and 54 multiparous females were randomly assigned to four experimental groups: two groups of nulliparous (Stimulated Nulliparous, SN; n = 25, and Non Stimulated Nulliparous NSN; n = 25) with similar body weight; 30 ± 1.1 Kg and body condition; 2.9 ± 0.1) and two groups of multiparous (Stimulated Multiparous, SM; n = 24, and non stimulated multiparous; NSM n = 30), with similar body weight; 42 ± 1.0 kg and body condition 3.2 ± 0.1. Males and females were fed with rolled corn, sorghum, wheat and sorghum silage. On March 19 (Day 0) each group of the stimulated females (SN and SM) was exposed to two inactive males (3.0 ± 0.1 BCS; scale 1–4) and 5 estrogenized females, (2 mg estradiol cypionate IM every third day). In the same way, each group of the non-stimulated females (NSN and NSM) was exposed to two inactive males and 5 non estrogenized females. Rams were alternated between groups, and remained in contact during 15 d. Experimental groups were placed at a distance of approximately 100 m from each other. EA was recorded twice daily (AM and PM) and OA by ultrasonographic scanning, observing the presence of corpora lutea, on d 16. EA and OA were compared using Chi^2 test (MYSTAT 12). The percentage of multiparous ewes depicting estrus [SM (63); NSM (60)] was greater ($P < 0.05$) regarding nulliparous [SN (0); NSN (16)]. The same was true with respect to ovulation, favoring ($P < 0.05$) to the multiparous group [SM (75); NSM (57)] with respect to nulliparous [SN (4) and NSN (25)]. Therefore, multiparous ewes depicted a greater ability to respond to male effect than nulliparous, regardless the presence or not of estrogenized females.

Key Words: Ewes, sexual activity, female effect

1936 (W377) Feeding behavior of feedlot lambs fed with high levels of crude glycerin. V. B. Carvalho*[1], J. M. Bertocco Ezequiel[2], R. F. Leite[1], S. F. F. Petrorossi[3], T. R. Delphino[3], M. T. C. Almeida[3], J. R. Paschoaloto[3], H. L. Perez[3], V. R. Favaro[4], E. M. Oliveira[3] and A. P. D`Aurea[3], *[1]UNESP, Univ Estadual Paulista, Department of Animal Science, Jaboticabal, SP, Brazil, [2]UNESP, Jaboticabal, Brazil, [3]UNESP, Univ Estadual Paulista, Department of Animal Science, Jaboticabal, Brazil, [4]State University of Sao Paulo, Jaboticabal, Brazil*

The objective of this trial was to evaluate the effect of crude glycerin (CG) inclusion on feeding behavior of feedlot lambs. Forty Santa Ines intact males lambs were used with initial BW of 22.9 ± 4.10 kg, assigned in a completely randomized block. Diets consisted of Tifton-85 hay (Cynodon dactylon), corn, crude glycerin (83% glycerol), corn gluten meal, corn oil, urea, sunflower meal, soybean hulls and mineral. The diets presented 18% of roughage and 82% of concentrate. The CG used is a byproduct from biodiesel originated from vegetable oils of soybean and sunflower. Five treatments were used: 0% CG, 7.5% CG, 15% CG, 22.5% CG and 30% inclusion of CG on dry matter basis, whereas, the diet with 30% of CG promoted a total replacement of corn. The animals were housed in individual pens with free access to water. The feed intake was adjusted to ensuring 10% of orts (ad libitum). The diets were offered twice daily at 0700 and 1600 h with 50% of total in each meal. Feeding behavior was performed during 48 h by 2 trained observers that made visual observations every 5 min of feeding, drinking, ruminating, resting and other activities. Further, the ruminating efficiency was determined. The means of 2 d were calculated expressed in 24 h. The data were analyzed using the MIXED procedure of SAS and the treatments were compared using orthogonal contrasts (linear and quadratic) considering 5% of significance level. There was no difference treatments among the variables measured ($P > 0.05$). The exception was drinking activity that showed a quadratic response ($P = 0.04$). On average, the animals presented 16.6 min drinking, 234.4 min eating, 428 min ruminating, 535 min resting and 226.8 in other activities. The ruminating efficiency was 325 (min of ruminating/kg DMI). In conclusion, crude glycerin in feedlot lambs influences only time spent drinking.

Key Words: animal nutrition, biodiesel, feed intake

SWINE SPECIES: SWINE SPECIES REPRODUCTION AND MANAGEMENT

1937 (M383) Dietary supplementation with organic or inorganic selenium and pyridoxine in gilts on gene expression in the porcine expanded blastocysts in vivo. D. Bueno Dalto[*1,2], S. Tsoi[3], I. Audet[1], M. Dyck[3] and J. J. Matte[1], *[1]Agriculture & Agri-Food Canada, Sherbrooke, QC, Canada, [2]Department of Animal Science, Universidade Estadual de Londrina, Londrina, Brazil, [3]Department of Agricultural, Food and Nutritional Science, University of Alberta, Edmonton, AB, Canada*

This study aimed to determine the effect of dietary selenium (Se) and pyridoxine supplementation, in gilts, on gene expression in the porcine expanded blastocyst (PEB). Eighteen gilts were randomly assigned to one of the 3 experimental diets: 1) basal diet (natural Se content of 0.2 mg/kg) without supplemental Se or pyridoxine (CONT, $n = 6$); 2) basal diet + 0.3 mg/kg of feed of sodium selenite, and 10 mg/kg of feed of hydrochloride pyridoxine ($MSeB_6$10, $n = 6$); and 3) basal diet + 0.3 mg/kg of feed of Se-enriched yeast, and 10 mg/kg of feed of hydrochloride pyridoxine ($OSeB_6$10, $n = 6$). All gilts were inseminated at their fifth estrus, and sacrificed 5 d after. Both uterine horns were flushed for embryo harvesting. Expanded blastocysts were selected for the porcine embryo-specific microarray: direct comparisons were done for $MSeB_6$10 vs. CONT and $OSeB_6$10 vs. CONT, whereas a reference design comparison were used for $OSeB_6$10 vs. $MSeB_6$10. Data were analyzed according to a randomized arrangement of treatments in blocks with the 3 dietary treatments as the main independent variables. Microarray data were analyzed using FlexArray, with threshold fold change $\geq$ 1.7 and P-value $\leq$ 0.05. CONT had lower blood Se concentration than Se-supplemented gilts ($P < 0.01$), but no differences were found between Se sources ($P = 0.38$). CONT had lower pyridoxine concentrations than $B_6$10 gilts ($P < 0.05$). Plasma glutathione peroxidase (GSH-Px) activity tended to increase during the experimental period ($P < 0.06$), but no treatment effect was detected ($P = 0.57$). $MSeB_6$10 vs. CONT and $OSeB_6$10 vs. CONT respectively showed 24 and 446 differentially expressed genes, whereas the corresponding number was 190 for $OSeB_6$10 vs. $MSeB_6$10. No specific biological processes were affected using Gorilla gene list analysis in $MSeB_6$10, however $OSeB_6$10 stimulated protein folding but not selenoprotein synthesis. Although all associated genes for GSH-Px and other selenoprotein synthesis were found, none of them were differentially expressed in any comparison. Antioxidant genes such as glutaredoxin-3 (GLRX3), peroxiredoxin-4 (PRDX4) and coenzyme Q6 monooxygenase (COQ6) were up-regulated in $OSeB_6$10 vs. CONT, and thioredoxin and thioredoxin domain containing 17 were downregulated in $OSeB_6$10 vs. CONT and $OSeB_6$10 vs. $MSeB_6$10, respectively. GLRX3, PRDX4 and COQ6 expression were validated by real-time PCR. In conclusion, $OSeB_6$10 affects PEB metabolism more markedly than $MSeB_6$10. Although supplements of both Se sources and pyridoxine did not influence GSH-Px -related genes expression in the PEB, they are involved with other antioxidant enzymes regulating antioxidant defense and cell proliferation, at this stage.

Key Words: porcine embryo, selenium, gene expression

1938 (M384) Comparing the growth curves of females and immuno castrated males in commercial conditions. S. López-Vergé[*1], G. Ibanez[2] and J. Gasa[1], *[1]Animal Nutrition and Welfare Service, Department of Animal and Food Sciences, Universitat Autònoma de Barcelona, Bellaterra, Spain, [2]Globosuinos Agropecuária S/A, Paraná, Brazil*

Concerning pigs, intact males grow faster than females; inversely, surgically castrated males perform worse than females. Immuno castration appears as an alternative to surgical castration in pigs, since it features less detrimental effects on growth and guarantees the full preservation of animal welfare conditions. The objective was to compare the growth curve parameters obtained from females and immuno castrated males, reared in commercial conditions. The experiment lasted 105 d and 168 piglets from 6 commercial white genetic lines (28 piglets each) were selected at the end of the nursery period (24.8 kg ± 5.10 kg BW). Animals were allocated to a growing-finishing facility and segregated by sex (males and females). Pigs were fed with up to 6 consecutive different corn-soybean diets in a controlled ad libitum way and ractopamine (10 ppm) was added as a feed additive 28 d before slaughtering. A total of 166 animals finished the experiment (124.4 kg ± 6.20 kg BW). Males were immuno castrated by giving them 2 doses of vaccine Vivax (Zoetis) around 56 and 28 d before slaughtering. Pigs were weighed weekly individually (up to 15 times) and data was adjusted using the double exponential Gompertz model (Live Weight = A*exp(-exp(b-(c*t))); the resulting growth parameters were statistically analyzed by ANOVA. Immuno castrated males had greater ADG (mean values of 1070 vs. 997 g/d, $P < 0.001$) and tended to have a better G:F (441 vs. 428 g of growth/kg feed, $P = 0.076$) than females. Immuno castrated males, compared with females, had greater values for mature live weight (A) (334.3 vs. 272.9 kg; $P < 0.001$), and also maximum growth rate ((A*c)/e) (1249 vs. 1099 g/d, $P < 0.001$), age ((b/c) (155 vs. 141 d, $P < 0.001$) and live weight (118.5 vs. 103.6 kg, $P < 0.001$) at the inflection point (which corresponds to the maximum growth rate with age). In contrast, specific growth rate (c) was higher for females (0.0111 vs. 0.0105, $P < 0.025$) compared to immuno castrated males. It is concluded that Gompertz model was a useful tool to

demonstrate that Immuno castrated male pigs grow faster and more efficiently than females.

Key Words: immuno castrated pigs, growth curve, Gompertz approach

---

1939 (M385) Growth performance of Sarda purebreed suckling piglets reared in smallholder farms.

C. Sulas[1], S. Fele[2], G. G. Fruttero[2], S. B. Gusai[2] and G. Battacone[*1], *[1]Dipartimento di Agraria, University of Sassari, Sassari, Italy, [2]Agenzia LAORE Sardegna, Cagliari, Italy*

The Sarda pig has been recently included in the Italian register of swine native breeds to preserve its genetic diversity and typical productions. Sarda piglets are usually raised on small farms. The most important product is the suckling piglet slaughtered at about 8–10 kg of body weight, used for the preparation of traditional dishes. In this study, a survey was performed to assess growth performances of purebred Sarda piglets during suckling period in smallholder farms. Twenty sows located in two farms, were housed in individual pens before farrowing. Stillbirths, born live, and birth weights for all litters were recorded. All piglets were ear-tagged and weekly weighed until weaning. Animals were grouped according to litter size: medium-small (5 to 8 pigs born alive), and medium-large (9 to 12 piglets). Effects of farm, litter size group and sex on individual average daily gain (ADG) were tested with an ANOVA model. A multiple linear regression model was used to evaluate the influence of age, litter size and sex on body weight. Birth weight of piglets did not differ between farm and litter size category, whereas, males were heavier ($P = 0.039$) than females (1556 vs. 1458 g, respectively). The ADG of the piglets during the suckling time did not differ for sex and farm. Piglets of medium-large litters had a slower growth than medium-small litters (ADG was 108 vs. 124 g, respectively). Results of regression analysis (R-Sq = 0.75) indicate a significant influence of age and litter size ($P < 0.01$) on body weight. Growth performances of suckling pigs were less than that of pigs of most conventional swine breeds. However, profitability of this breed seems strongly linked to the consumers preference for its meat as a key component of originally regional dishes.

Key Words: growth, suckling piglets, Sarda pig breed

1940 (M386) Piglet body weight at weaning: A key success factor for post-weaning performance?

D. Solà-Oriol, S. López-Vergé* and J. Gasa, *Animal Nutrition and Welfare Service, Department of Animal and Food Sciences, Universitat Autònoma de Barcelona, Bellaterra, Spain*

The aim of the study was to evaluate the importance of piglet BW at weaning (WBW) on post-weaning performance and mortality. A total of 4320 male and female crossbreed piglets [Pietrain x (Landrace x Large White)] were used. All the animals were individually weighted at weaning (28 d-old). The selected animals (240 per batch without those corresponding to the percentile 10 and 90) were distributed into 3 BW categories: Low (L; BW < 6.5 kg, $n = 92$); Middle (M; 6.5 kg < BW < 8.5 kg, $n = 216$) and High (H; BW > 8.5 kg, $n = 94$) and allocated in groups of 10 piglets. The same commercial pre-starter diet formulated to contain 10.35 MJ/kg NE, 17.9% CP and 1.32% Lys was offered ad libitum. Feed intake (FI), BW and mortality rate (MR) were weekly monitored to calculate FI and ADG (0 to 14 d post-weaning). Performance data were analyzed with ANOVA by using the GLM procedure of SAS taking into account the WBW category. The initial differences between WBW categories were maintained along the pre-starter period ($P < 0.01$). Lower ADG ($P < 0.01$) but not FI ($P > 0.10$) was observed between WBW categories for the first week post-weaning (H = 99^{b} g/d; M = 115^{a} g/d and L = 122^{a} g/d; $P < 0.01$). For the second week post-weaning, higher ADG and FI was observed for H compared to M and L groups ($P < 0.01$). Overall, higher FI was observed for H than M and L (H = 325^{a} g/d; M = 293^{b} g/d and L = 265^{c} g/d; $P < 0.01$), however, no difference in ADG was achieved (H = 207 g/d; M = 203 g/d and L = 192 g/d; $P > 0.05$). Moreover, higher MR was observed for H than for M and L during the pre-starter period (1.98 vs. 0.2 and 0.3%; $P < 0.05$). The H animals failed to meet the energy requirements during the first week after weaning probably due to a longer anorexia period. After that, H animals start suddenly to eat high amounts of solid feed, following digestive and malabsorptive problems which may explain the higher MR, causing important losses. These results confirmed that in large suckling periods (28 d) the early contact with solid feed may optimize performance and reduce mortality after weaning in pigs with high BW.

Key Words: performance, mortality, weaning, piglet

1941 (M387) Comparison of fecal microbiota among healthy piglets during the weaning transition using barcoded 16S rDNA pyrosequencing.

J. P. Chae, E. A. Pajarillo and D. K. Kang*, *Dep. of Animal Resources Science, Dankook University, Cheonan, South Korea*

The objective of this study is to investigate change in the fecal microbiota of healthy piglets during the weaning transition using barcoded pyrosequencing of the prokaryotic 16S rRNA gene. It is believed that the gastrointestinal microbiome changes over time beginning from birth until adulthood in response to changes in diet, environmental stress and diseases. In particular, the weaning process results in reduced metabolic activity, malabsorption of nutrients, and susceptibility to enteric diseases as a consequence of abrupt separation from the sow before joining other litters in a different environment. Fifteen crossbred piglets weaned on the Day 28 were used in the study. Fecal samples were obtained immediately before

weaning (4 wk of age) and after weaning (6 wk of age), and were subjected to genomic DNA extraction for pyrosequencing analysis. As the piglets underwent the weaning transition a trend toward increased bacterial diversity was observed, based on species abundance as measured by the Shannon-Weaver index. *Firmicutes* (54.0%) and *Bacteroidetes* (59.6%) were the most dominant phyla during pre-weaning and post-weaning, respectively. During the weaning transition a distinct shift from *Bacteroides* sp. to *Prevotella* sp. as the most abundant genus was observed. Additionally, we detected a number of abundant species in the piglet gastrointestinal tract that have not been reported previously. *Clostridium rectum, C. clostridioforme, C. lactatifermentans* and *Butyricimonas virosa* were uniquely detected before weaning while *Roseburia cecicola and Blautia wexlerae*were detected during the post-weaning period only.

Key Words: bacterial diversity, piglets, weaning

1942 (M388) Piglets' early body weight and milk consumption partially explain post-weaning performance.

S. López-Vergé*, D. Solà-Oriol and J. Gasa, *Animal Nutrition and Welfare Service, Department of Animal and Food Sciences, Universitat Autònoma de Barcelona, Bellaterra, Spain*

It's well known that piglets' BW at birth is an important factor determining their subsequent performance. Furthermore, equally important is trying to maximize milk intake during the suckling period. The objective was to assess the influence of the piglets' BW at birth and BW at weaning on pig performance over time. A total of 305 crossbreed piglets [Pietrain x (Landrace x Large White)] from 30 litters were used. All the animals were individually weighed at Day 2 (CF; cross fostering), 27 (weaning), 41 (14 d post-weaning), 62 (35 d post-weaning), 98 (growing) and 173 (slaughter). Piglets were fed ad libitum the same commercial pre-starter, starter, growing and finishing diets. The relationship between the BW at CF and BW at weaning with the BW at the different productive steps until slaughter was analyzed using the CORR procedure of SAS. BW at CF was related with BW at weaning ($P = 0.002$). Considering the Pearson correlation coefficient (r), showed that the BW at weaning was highly related to the BW at 14 d post-weaning [41 d-old ($r = 0.80$, $P < 0.001$)] but its influence was progressively reduced on Days 62 ($r = 0.51$, $P < 0.001$), 98 ($r = 0.19$, $P < 0.001$) and 173 ($r = 0.18$, $P < 0.001$), respectively. The strong relationship between BW at weaning and at 14 d post-weaning resulted in a huge BW difference between the 30% heavier and 30% lighter piglets (at weaning: 8.52 kg vs. 6.43 kg, $P < 0.001$; 14 d post-weaning: 12.17 kg vs. 10.63 kg, $P < 0.001$); difference which were reduced from 32.5% at weaning to 14.5% 2 wk later. The BW at CF also had an effect, but not as strong as BW at weaning, having the best correlation at 14 d post-weaning ($r = 0.40$, $P < 0.001$). Thus, we observed an attenuated effect on Day 27 ($r = 0.36$, $P < 0.001$), 62 ($r = 0.33$, $P < 0.001$), and 173 ($r = 0.27$, $P < 0.001$), respectively. It is concluded that both BW at CF and at weaning, play a significant role on pig BW performance and variability along the productive cycle. However these effects are gradually replaced over time, indicating that new factors become more important explaining BW variability. A higher effect of the BW at weaning was observed at the beginning of the nursing period, but it was diluted later on.

Key Words: performance, correlation, piglet

1943 (M389) Effects of parity and selection for uterine capacity on sow litter performance traits.

B. A. Freking* and J. L. Vallet, *USDA ARS USMARC, Clay Center, NE.*

Selection for 11 generations for uterine capacity (UC) was previously reported to increase litter size in gilts by 1.6 more fully formed pigs at birth compared to an unselected control line (CO) despite averaging 1 less ova shed. Our objective was to characterize litter performance traits in each line from subsequent sow parities following a shift in management scheme to a continuous flow farrowing system that more closely resembles industry conditions. Gilts entered into the system and were farrowed in contemporary groups of a maximum of 19 litters and maintained in this system through four parities if successfully mated in that contemporary group. A total of 203 litters (90 CO, 103 UC; 101 Parity 1, 49 Parity 2, 33 Parity 3; and 20 Parity 4) were analyzed. A mixed model analysis of variance was conducted. Fixed effects of farrowing group, line, parity (1–4), and two-way interactions involving line were fitted. The random effect of sire ($n = 75$) of the litter within farrowing group and line was included in the model. UC line averaged 1.3 ± 0.38 greater ($P < 0.01$) pigs born alive with 0.5 ± 0.14 fewer ($P < 0.01$) stillbirths than CO. Average pig birth weight was similar ($P = 0.99$) between lines, thus the UC line exceeded ($P < 0.05$) the CO line by 1.1 ± 0.38 kg in litter birth weight. UC line averaged 1.6 ± 0.32 greater ($P < 0.001$) pigs weaned than CO. Average pig wean weight was similar ($P = 0.64$) between lines, thus the UC line exceeded ($P < 0.05$) the CO line by 6.0 ± 2.07 kg in litter wean weight. Parity effects were observed as expected from first through fourth parities and no interactions of parity effects were observed with line. Improved reproductive performance of the UC line was maintained in sow litters similar to those previously measured in gilts. Selection for uterine capacity improved fetal survival resulting in increased number born alive with a similar average birth weight. This resulted in an increase in total weaning weight of sows through four parities. USDA is an equal opportunity provider and employer.

Key Words: pigs, selection, uterine capacity

1944 (M390) Gene expression profiles in muscle of black Iberian pigs supplemented with organic selenium compared with sodium selenite in finishing diets. D. E. Graugnard*, A. C. Smith, M. L. Spry, L. F. Spangler and K. M. Brennan, *Alltech Inc., Nicholasville, KY*

Supplementation with organic Se provides positive benefits through increased bioavailability and absorption compared with inorganic Se. The objective of this study was to evaluate the effect of different sources of Se on muscle gene expression in finishing black Iberian pigs. The finishing experimental period started when the animals reached 80 kg and ended at slaughter at approximately 120 kg. The treatments consisted of a standard finishing diet supplemented with organic Se (0.2 ppm Se as Sel-Plex; SP, Alltech Inc) or inorganic Se (0.2 ppm as sodium selenite; SS). Skeletal muscle samples were obtained at slaughter and stored in RNA later until analysis. Total RNA was isolated from samples (n = 5/trt) using standard methods and was hybridized to the Affymetrix Porcine Genome array. Expression data were statistically analyzed using the GeneSpring GX 10.0 software in which SP. was directly compared to SS using a t test. Statistical differences were declared at $P < 0.05$ without considering a fold change cut-off. Genes differentially expressed were imported into Ingenuity for biological function analysis. Results indicated that 1205 genes (757 up- and 448 downregulated) were differentially expressed ($P < 0.05$) in SP. relative to SS. The biological function analysis resulted in several enriched functions related to muscle development. Among these, positive activation of lipid metabolism, cellular and tissue development (Z score > 2) were the most relevant to the study. Further analysis of the biological functions identified specific genes associated with the regulation of β-oxidation and overall energy metabolism including *CPT1C, SCD5, MYO1B* and *CAST* among others. In addition, upstream molecule analysis indicated that more than 30 genes were controlled by *TGFB1* (Transforming growth factor β 1), which is closely related to Se in the regulation of oxidative stress. In conclusion, this study shows evidence of multiple molecular mechanisms affected by SP. in skeletal muscle of black Iberian pigs that relate to performance and meat quality.

Key Words: Se, swine, gene expression, microarray, muscle

1945 (M391) Neither photoperiod in the farrowing room nor time of weaning affect nursery performance. L. Eastwood, J. Shea and D. Beaulieu*, *Prairie Swine Centre, Inc., Saskatoon, SK, Canada*

Weaning may result in anorexia and reduced growth in pigs especially during the initial 24 to 48 h in the nursery. This study was designed to determine if altering the photoperiod in the farrowing room and/or if weaning at the end of the light or dark cycle would affect performance post-weaning. Twelve farrowing rooms, 13 sows/room, were assigned to one of four treatments approximately one wk before farrowing. Treatments, arranged as a 2 × 2 factorial included 2 farrowing room photoperiods; 16 h light:8 h dark (16L:8D) or 8L:16D, and 2 weaning times; end of the dark or end of the light cycle. Pigs were weaned at 25 (± 1) d of age into nurseries maintained on a 16L:8D regime at time 0 of the dark cycle. Pigs were fed standard commercial diets, in a 2 phase feeding program in the nursery. The phase 1 nursery diet was spiked with ferric oxide pellets for 24 h post-weaning and anal swabs taken at 48 h post-weaning allowed pigs to be designated as "eaters" or "non-eaters". Neither farrowing room photoperiod nor weaning time affected ADG ($P > 0.10$) in the farrowing room (236 g/d; birth to weaning) or nursery (437 g/d, weaning to 54 d of age). On d 0 to 7 post-weaning, there was a tendency for a photoperiod by weaning time interaction for ADFI ($P = 0.06$). The lowest intakes (123 g/d) were observed for pigs who had been on the 16L:8D lighting regime and weaned at the end of the dark cycle. ADFI was similar among the other treatments and averaged 157 g/d. Neither photoperiod nor time of weaning affected the percentage of pigs (34%) identified as "eaters" during the initial 24 h in the nursery ($P > 0.10$). Pigs identified as "eaters" were lighter at weaning (7.26 vs. 7.62 kg BW; $P < 0.01$), but showed improved ADG from d 0 to 7 post-weaning relative to "non-eaters" (187 vs. 141 g/d; $P < 0.01$). Nursery exit weights were similar between "eaters" (19.6 kg) and "non -eaters" (21.0 kg; $P > 0.10$). Farrowing room photoperiod and/or weaning at the end of the dark or light cycle did not affect nursery performance. Pigs exhibiting evidence of phase 1 feed consumption immediately post-weaning were lighter; however they had higher ADG immediately post-weaning than those identified as non-eaters.

Key Words: swine, weaning, photoperiod

1946 (M392) Behavior traits and growth characteristics of newly weaned piglets. M. R. Zukle*, J. E. Naginis and L. A. Pettey, *California State Polytechnic University, Pomona*

Four litters of newly weaned piglets (n = 37; 7.01 kg BW) were used to evaluate the potential correlations between weight of the piglet, behavioral traits, and growth rate in the first 7 d following weaning. Piglets were weaned at an average of 27 d-of-age and moved into an environmentally controlled nursery facility. Littermate piglets were penned together and allowed ad libitum access to feed and water. Room temperature was maintained between 26 and 32°C. Above each pen a video camera connected to a data storage unit recorded all piglet behaviors. Feed and water disappearance and piglet weight were recorded daily. Video files of piglet behavior were evaluated for frequency (FREQ) and amount of time (TIME) involved in the following behaviors: mobile/active, aggression, eating, and drinking. Piglet weaning weight in wk

1 was negatively correlated (r = -0.47) to weight change as heavier piglets tended to lose more or gain less weight than their lighter weight contemporaries. The daily correlation of weaning weight to weight change was numerically the least (r = -0.25) on d 1, and the greatest on d 4 (r = -0.48). Using pen averages, feed intake increased linearly ($P < 0.05$) from d 0 to 7, while water intake increased numerically each day. As expected, FREQ and TIME spent eating and drinking increased linearly ($P < 0.05$) during the first week post-weaning. On d 1, FREQ of eating behavior was not correlated (r = +0.15) to piglet weight change, while FREQ of drinking and aggression were negatively correlated (r = -0.58 and -0.73, respectively) to piglet weight change. On d 2, FREQ of eating and drinking were positively correlated (r = +0.44 and r = +0.72, respectively) to weight change and FREQ of aggression was not correlated (r = +0.25) to piglet weight change. These correlations seem to show that piglets that lost more weight tended to exhibit less inclination towards eating and exhibited more instances of drinking or fighting on d 1. By d 2 to 7, FREQ of eating behavior was positively correlated (r = +0.50) to FREQ of watering behavior and was positively correlated (r = +0.75) to weight change. Data from this study supports previous work where larger piglets tended to lose more weight than smaller piglets post-weaning, which may be due to increased frequency of aggression and water intake on the first day away from the sow.

Key Words: piglet, growth, behavior

1947 (M393) Oxidative stress is higher in replacement gilts than in multiparous sows. J. Lapointe*, C. Roy and M. Lavoie, *Agriculture and Agri-Food Canada, Sherbrooke, QC, Canada*

The recent success obtained in term of increasing the litter size of sows has not correlated with a reduction of replacement rate. There is thus an increased economic demand for gilts with optimal reproductive potential and longevity. Unfortunately, replacement gilts are known to be more susceptible to diseases and less productive than multiparous sows. While it is straightforward to identify the physiological failure which leads to the removal of a gilts from the herd, identification of the underlying molecular reasons for the occurrence of these events continues to be more challenging. Interestingly, reproductive performance, resistance to diseases and longevity could all be largely affected by oxidative stress. To investigate if oxidative stress conditions could account for the poor performance and longevity observed in replacement gilts in comparison to older multiparous sows. Three distinct groups of 15 F1 conventional Yorkshire x Landrace sows were formed based on their similar age and parity. These groups were primiparous gilts (group 1), third parity sows (group 2) and fifth parity sows (group 3). All animals were slaughtered during the post-ovulatory period of the estrous cycle and blood as well as tissues samples were collected and frozen at −80°C. Principal biomarkers of oxidative damage to proteins (Carbonyls) were analyzed in plasma and liver samples using ELISA procedures. Specific mRNA expressions of the major antioxidants glutathione peroxidases 1 and 4 (GPx1, GPx4) as well as superoxide dismutases 1 and 2 (Sod1, Sod2) were monitored in liver and kidney samples by quantitative RT-PCR. Specific enzymatic activities of glutathione peroxydases and superoxide dismutases were measured by spectrophotometric assays. The plasmatic concentrations of protein carbonyls were significantly different between the three groups with the higher concentrations being observed in gilts ($P \leq 0.001$). The mRNA expression levels of GPx1 and GPx4 were also significantly increased in the liver of primiparous gilts when compared to multiparous sows ($P \leq 0.05$) while no differences were observed in kidneys ($P > 0.10$). Sod2 enzymatic activity was found to be higher in the liver of primiparous gilts than fifth parity sows ($P \leq 0.05$). It is well established that the expression and activity of antioxidants increase in response to oxidative stress. Taken together, our results indicate that replacement gilts sustain significantly higher oxidative conditions than multiparous sows. Current findings may contribute to the design of nutritional regimens that will increase the productivity of gilts by counteracting oxidative stress.

Key Words: oxidative stress, gilts, longevity.

SWINE SPECIES NUTRITION

1949 (W379) Effect of porcine digestive peptides as sweet milk whey replacer for piglets diets: preferences, acceptance and performance during the nursery period. J. E. Figueroa[1,2], D. Solà-Oriol[3], R. Davin[*4], E. Borda[5], S. A. Guzmán-Pino[4] and J. F. Pérez[4], *[1]SNiBA, Departament de Ciència Animal i dels Aliments, Universitat Autònoma de Barcelona, Bellaterra, Spain, [2]Universidad de Chile, Santiago, Chile, [3]Animal Nutrition and Welfare Service, Department of Animal and Food Sciences, Universitat Autònoma de Barcelona, Bellaterra, Spain, [4]Animal Nutrition and Welfare Service, Department of Animal and Food Sciences, Universitat Autònoma de Barcelona, Bellaterra, Spain, [5]Bioiberica, Barcelona, Spain*

The aim of the present work was to study the productive performance of nursery pigs when sweet milk whey (SMW) is replaced by porcine digestive peptides (PDP; 620 g/kg of CP, Bioibérica SA, Palafolls, Barcelona, Spain). A total of 240 pigs were randomly distributed after weaning into 2 groups (12 pens/group) depending on the presence of SMW or PDP on their diets. The SMW group was fed a pre-starter (0- 14 d) and starter (15- 33 d) diet with 142 g/kg and 49 g/kg SMW respectively; the PDP group was offered an iso-caloric and iso-proteic diet with 20 g/kg of PDP and 300 g/kg of wheat replacing dairy products. Feed intake and body weight were measured weekly to calculate average daily feed intake (ADFI), average daily gain (ADG) and gain: feed ratio (GFR). A choice test and one-feeder test of 30 min each were performed in another group of animals 3 wk after weaning (36 pen pairs) to evaluate the preference and acceptance for both diets, respectively. Feed intake was recorded by measuring the initial and final weight of the feeders. SMW and PDP diet positions were balance across pig's pairs. Data were analyzed with ANOVA using the GLM procedure (performance values) or the MIXED procedure (preference and acceptance values) of the statistical package SAS. Despite clear differences on feed preference (211 vs. 77 g; $P = 0.039$) and acceptance (287 vs. 192 g; $P = 0.001$) between diets with or without whey respectively, no effects were observed on performance at the end of the nursery period (20.92 vs. 21.13 kg for BW, 0.62 vs. 0.63 kg/d for ADFI and 0.52 vs. 0.53 kg/d for ADG). Despite the reduced preferences and acceptance observed, the use of dairy products appears to be unnecessary if a high valuable protein source is offered during nursery.

Key Words: familiarity, preferences, lactose

1950 (W380) High nutrient intake alters muscular growth and metabolic status of neonatal intra-uterine growth-retarded pigs. F. Han*, L. Chen, L. Che, B. Yu, X. Ding, Y. Luo, S. Bai, D. Chen, Y. Xuan and K. Zhang, *Institute of Animal Nutrition, Sichuan Agricultural University, Chengdu, China*

Intra-uterine growth-retarded (IUGR) neonates have shown an impairment of postnatal skeletal muscle morphology and function. We hypothesized that the growth and development of skeletal muscle of IUGR neonates might be affected by increased nutrient intake during the suckling period. Therefore, we investigated the effects of high nutrient intake (HNI) on the muscular growth and metabolic status of IUGR and normal-birth weight (NBW) piglets. Piglets with a birth weight near the mean litter birth weight (within 0.5 SD) were identified as NBW, whereas those at least 1.5 SD lower birth weight were defined as IUGR. A total of twelve pairs of IUGR and NBW piglets (7 d old) were randomly assigned to two different nutrient-level formula milk groups. After 21 d of rearing, muscle weight and morphology, activities of energy metabolism-related enzymes and muscle protein deposition-related genes involved in the insulin-like growth factor 1/Ak thymoma/mammalian target of rapamycin pathway were determined. The results indicated that semitendinosus and psoas major muscle weights were lighter (-31.7%~37.3%, $P < 0.001$) in IUGR piglets, whereas HNI significantly increased psoas major muscle weight (+31.3%, $P < 0.001$) and length (+17.6%, $P = 0.006$). Likewise, IUGR decreased the cross-sectional areas (-26.4%~40.0%, $P = 0.002$) and myofiber numbers (-20.8%~23.8%, $P = 0.004$) of semitendinosus and psoas major muscle. Furthermore, IUGR piglets with HNI exhibited more myofibers (+25.7%, $P < 0.001$) than those counterpart IUGR piglets, and these alterations in the muscle growth traits of IUGR piglets receiving HNI were accompanied by increasing muscular gene expressions of *insulin-like growth factor 1* (+49.0%, $P = 0.003$), *insulin-like growth factor 1 receptor* (+56.9%, $P < 0.001$), *Ak thymoma* (+60.8%, $P = 0.002$), *mammalian target of rapamycin* (+55.4%, $P < 0.001$), *ribosomal protein s6* (+78.6%, $P = 0.003$), *eukaryotic translation initiation factor 4E* (+75.0%, $P = 0.002$) that are related to muscle protein deposition. Otherwise, IUGR decreased lactate dehydrogenase activity (-13.1%, $P = 0.015$) and activity ratios (-23.0%~26.9%, $P < 0.001$) of lactate dehydrogenase: citrate synthase and lactate dehydrogenase: β-hydroxy-acyl-CoA dehydrogenase, but increased β-hydroxy-acyl-CoA dehydrogenase activity (+16.2%, $P = 0.023$) in longissimus dorsi muscle. Inversely, HNI increased lactate dehydrogenase activity (+14.1%, $P = 0.021$) and activity ratios (+21.8%~39.1%, $P = 0.004$) of lactate dehydrogenase: citrate synthase and lactate dehydrogenase: β-hydroxy-acyl-CoA dehydrogenase, but decreased β-hydroxy-acyl-CoA dehydrogenase activity (-17.1%, $P =$

0.006). In conclusion, the present findings suggest that increased nutrient intake during the suckling period altered muscular metabolic status and improved skeletal muscle growth possibly via regulation of insulin-like growth factor 1/Ak thymoma/mammalian target of rapamycin signaling pathway.

Key Words: intra-uterine growth-retarded pigs, nutrient intake, skeletal muscle

1951 (W381) The inclusion of yeast-derived protein in weanling diet improves growth performance, anti-oxidative capability and intestinal health of piglets. L. Hu, L. Che*, G. Su, Y. Xuan, G. Luo, F. Han, Z. Fang, Y. Lin, S. Xu and D. Wu, *Institute of Animal Nutrition, Sichuan Agricultural University, Chengdu, China*

This study aimed to investigate the effects of yeast-derived protein (YP) on growth performance, intestinal health and oxidative status of weaned piglets. A total of 80 weaned piglets (PIC 327 × 1050, 26 ± 2 d-old) were randomly allocated into 2 groups, 5 pens each group and 8 piglets each pen, receiving control diet and diet with inclusion of 4% YP at the expense of fish meal (YP diet) for a period of 28 d. Piglets had free access to pelleted feed and water. Feed intake was recorded daily and piglets were weighed weekly for calculating ADG, ADFI and G:F. At d 28, blood samples were collected from the cervical vein and centrifuged (3000 ×g, 4°C, 15 min) to separate serum for biochemical assays. Then these piglets were anaesthetized with intravenous injection of pentobarbital sodium (15 mg/kg body weight) and slaughtered. Approximately 2 cm of ileal tissue was collected each piglet and stored at −80°C for real-time RT-PCR. Moreover, the chyme of ileum and colon were removed and stored at −80°C for microbial analysis. Data were analyzed using one-way analysis of variance (ANOVA) procedure of SPSS 20.0 (Chicago, IL, USA) and are reported as means ± SEM. The results showed that piglets fed YP diet had markedly higher overall ADG (470 ± 18 vs. 412 ± 12 g, P = 0.034) and G:F (0.72 ± 0.02 vs. 0.67 ± 0.01, P = 0.001). Serum concentration of urea was significantly decreased (166.58 ± 9.57 vs. 306.34 ± 26.89 mmol/L, P = 0.003) in piglets fed YP diet relative to piglets fed control diet. Moreover, serum activity of glutathione peroxidase (GP_X) was markedly increased (303.31 ± 7.22 vs. 255.54 ± 8.53 umol/L, P = 0.003) in piglets fed YP diet relative to piglets fed control diet. In addition, feeding YP diet significantly increased the DNA copy numbers (log^{10} Cfu/g of digesta) of lactobacilli (8.27 ± 0.13 vs. 7.20 ± 0.17, P = 0.021) and total bacteria (10.44 ± 0.06 vs. 10.26 ± 0.04, P = 0.044) in the colonic digesta of piglets. Furthermore, mRNA expression of the innate immunity-related genes (TLR4, NF-κB1 and IL-6) tended to increase (1.33 ± 0.11 vs. 1.00 ± 0.07, P = 0.057; 1.92 ± 0.15 vs. 1.00 ± 0.21, P = 0.024; 1.45 ± 0.10 vs. 1.00 ± 0.15, P = 0.041, respectively) in the ileum of piglets fed YP diet relative to piglets fed control diet. In conclusion, the diet with inclusion of YP improved growth performance, anti-oxidative capability and intestinal health of weaned piglets.

pamine HCl (RAC; Elanco Animal Health, Greenfield, IN) on growth performance and carcass characteristics. There were 25 pigs per pen and 6 pens per treatment. Pens were randomly assigned to a 2 × 2×2 factorial arrangement in a split-plot design. The whole plot consisted of diets with or without 75 ppm added Zn from d 0 to 45 and the subplots were diets with or without 75 ppm added Zn and with or without 10 ppm RAC from d 45 to72. All diets contained 50 ppm Zn supplied from the premix. No interactions were observed. Addition of 75 ppm Zn during either period or both did not influence pig growth performance or carcass characteristics. Pigs fed RAC had improved ($P < 0.03$) ADG, G:F, final BW, HCW, loin depth, and fat-free lean index compared with pigs fed the control diet. In conclusion, feeding RAC improved the performance of grow-finish pigs; however, additional Zn did not.

Key Words: growing-finishing pigs, ractopamine HCl, zinc

1953 (W383) Postnatal nutrition restriction affects growth and immune response of intrauterine growth restricted piglets. L. Hu, L. Che*, Y. Liu, Y. Xuan, F. Han, Z. Fang, Y. Lin, S. Xu and D. Wu, *Institute of Animal Nutrition, Sichuan Agricultural University, Chengdu, China*

Epidemiological studies and experimental models show that intrauterine growth restriction (IUGR) followed by accelerated postnatal growth is associated with increased susceptibility to diseases in later life. We hypothesized that postnatal nutrition restriction may improve intestinal development and immunity of IUGR neonates. Piglets with a birth weight near the mean litter birth weight (SD 0.5) were identified as NBW, whereas those with at least 1.5 SD lower birth weight were defined as IUGR. Twelve pairs of normal-birth weight (NBW) and IUGR piglets at 7 d of age were randomly assigned to adequate (ANI) or restricted nutrition intake (RNI) for a period of 21 d, which produced 4 experimental groups (birth weight/nutrition intake) as NBW-ANI, IUGR-ANI, NBW-RNI and IUGR-RNI ($n = 6$ per group). The NBW-ANI and IUGR-ANI piglets had free access to formula milk, while the NBW-RNI piglets had same intake of formula milk as IUGR-ANI piglets. To achieve the same degree of nutrition restriction as NBW piglets, the formula milk intake of IUGR-RNI piglets was based on the calculation that the formula milk intake of IUGR-ANI piglets multiplied by the formula milk intake of NBW-RNI piglets and divided by the formula intake of NBW-ANI piglets. At d 28, blood and intestinal samples were collected at necropsy and analyzed for cellular immune response and expression of innate immunity and DNA methylation-related genes. Data were analyzed by SPSS software using the MIXED procedure. The results indicated that both IUGR and postnatal nutrition restriction decreased (-26%, $P = 0.002$) ADG during the experimental period, but there was comparable ADG between IUGR-ANI and NBW-RNI piglets. The relative weight of intestine, heart or brain to body weight was higher (+9%, $P = 0.091$; +23%, $P = 0.025$ and +41%, $P = 0.001$; respectively) in IUGR than that in NBW piglets. Irrespective of body weight, number of peripheral leucocytes, lymphocytes and monocytes were significantly decreased (-25%, $P = 0.006$; -37%, $P = 0.001$ and −82%, $P = 0.009$; respectively) by RNI, whereas the ratio of $CD4^+$ to $CD8^+$ in blood was significantly increased (+27%, $P = 0.034$) by RNI, however, it did not markedly differ between NBW-ANI and IUGR-RNI piglets. Likewise, ileal mRNA expression of innate immunity and DNA methylation-related genes (*TLR-9* and *DNMT1*) were up-regulated in piglets with RNI (+31%, $P = 0.004$ and +57%, $P = 0.001$; respectively), particularly increased in IUGR-RNI relative to IUGR-ANI piglets. In conclusion, the present study indicated that postnatal nutrition restriction may affect systematic and intestinal immune response of IUGR piglets.

Key Words: pigs, intestine, innate immunity

1954 (W384) Effects of dietary omega-3 polyunsaturated fatty acids on growth and immune response of weanling pigs. Q. Li, J. H. Brendemuhl, K. Jeong and L. Badinga*, *University of Florida, Gainesville*

The recognition that *omega*-3 polyunsaturated fatty acids (*n*-3 PUFA) possess potent anti-inflammatory properties in human models has prompted studies investigating their efficacy for animal growth and immunity. The objective of this study was to examine the effect of feeding an *n*-3 PUFA-enriched diet on growth and immune response of weanling piglets. Newly weaned pigs (averaging 27 ± 2 d of age and 8.1 ± 0.7 kg of BW) were assigned randomly to receive a control (3% vegetable oil, $n = 20$) or *n*-3 PUFA-supplemented (Omega, $n = 20$) diet for 28 d after weaning. Diets were formulated to be isocaloric (3.3 Mcal/kg of diet) and isolysinic (14 g Lys/kg of diet). A diet × gender × week interaction was detected ($P < 0.04$) for body weight. Female pigs consuming the *n*-3 PUFA-enriched diet were lighter ($P < 0.01$) at wk 4 post-weaning than their counterparts fed the vegetable oil-supplemented diet. Newly weaned pigs gained more weight ($P < 0.01$), consumed more feed ($P < 0.01$) and had better G: F ($P < 0.01$) between d 14 and 28 than between d 0 and 14 post-weaning. Peripheral IGF-1 concentration decreased ($P < 0.01$) between d 0 (87.2 ± 17.0 ng/mL) and 14 (68.3 ± 21.1 ng/mL) after weaning and then increased again by d 28 (155.2 ± 20.9 ng/mL) post-weaning. In piglets consuming the vegetable oil-enriched diet, plasma TNF- α concentration increased ($P < 0.04$) from 37.6 ± 14.5 to 102.9 ± 16.6 pg/mL between d 0 and 14 post-weaning and remained high through d 28 (99.0 ± 17.2 pg/mL) post-weaning. The TNF-α increase detected in the piglets fed vegetable oil was not observed in the piglets fed *n*-3 PUFA (d 0 = 33.0 ± 17.2

pg/mL; d 14 = 29.1 ± 21.7 pg/mL; d 28 = 36.7 ± 21.4 pg/mL). With the exception of blood platelets and eosinophil cells, dietary *n*-3 PUFA had minimal effects on hematological characteristics. Fecal consistency scores improved ($P < 0.01$) with increasing weeks after weaning, but were similar between the two dietary treatments. Results indicate that weaning induces considerable immune stress on piglets and that this stress can be mitigated by dietary supplementation of *n*-3 PUFA.

Key Words: *n*-3-PUFA, growth, immunity, pig

TEACHING/UNDERGRADUATE AND GRADUATE EDUCATION

1955 (W385) Examining demographics and student interests in an introductory animal science course. D. A. Nichols* and M. R. Hay McCammant, *Kansas State University, Manhattan*

Over the past 9 yr, the Department of Animal Sciences and Industry at Kansas State University has seen tremendous growth in undergraduate programs (2005 n = 704, 2013 n = 1197). One of the courses impacted by enrollment growth is ASI 102, Principles of Animal Science (2005 n = 263, 2013 n = 438). This course is required for Animal Sciences & Industry majors and is a service course to students in the Colleges of Agriculture, Business Administration and Arts & Sciences. Over 9 yr, surveys were given to the students enrolled in ASI 102 during the Fall semester, examining demographics and student interest. These questions examined gender, ethnicity, age, residency, and both primary and secondary specie of interest. Gender distribution has held relatively steady over the years with 61% of the class being female in 2005 and 68% female in 2013. Age distribution held steady with 61% of the class being ages 17–18 yr of age in 2005 and 63% in 2013. Subtle changes in student ethnicity have been shown as the class went from being 92% White/Non-Hispanic to 85% White/Non-Hispanic with the most significant growth in both the Black/Non-Hispanic population (1% in 2005 to 5% in 2013) and the Hispanic/Spanish American/Latin/Mexican population (2% in 2005 to 6% in 2013). The change in residency came from the increase of out-of-state students (18% in 2005 to 23% in 2013), while international students remained 1% each year. Student primary specie of interest in 2005 showed that the most popular specie was beef cattle at 37% of the class, with companion animals close behind at 31%, then horses at 29%, swine or sheep (these were combined because of bubble sheet limitations) at 2% and dairy cattle at 1%. In 2009, the percentage of students with a primary specie interest in companion animals (35%) surpassed those with a beef cattle interest (34%). Companion animals continue to be the most popular species of interest with 39% of the students reporting them as their primary species of interest in 2013, however, beef cattle have held steady at 34%. When students were asked about their secondary specie of interest, horses consistently were the most popular (36% in 2007 and 31% in 2013). Survey results have been extremely useful to categorize students. Examining demographics has allowed us to identify student interest and focus on areas of the course that need greater clarification and emphasis.

Key Words: undergraduate, demographics, teaching

1956 (W386) Development of a science education experience for adolescents based on stress physiology and a growing interest in smartphone technology. P. A. Eichen*, B. Scharf, G. D. Martin, R. Mott and D. E. Spiers, *University of Missouri, Columbia*

Interest in STEM (i.e., Science, Technology, Engineering, and Mathematics) education is increasing among all age groups. In a recent survey of Missouri beef and dairy producers, 98% indicated willingness to use technology to improve management of heat stress in their herds, with about 80% having access to wireless internet and 60% having smartphones. In contrast, only half thought understanding heat stress was important, while 90% of extension livestock specialists noted it is a significant issue. This discrepancy suggests the need for education on this important topic at an early age. To this end, a 2-d "Science Boot Camp" for pre-college students was developed several years ago to stimulate interest in environmental stress issues. A brief survey of the students participating in this camp showed that 90% agreed that science is important, and science education can benefit everyone. In contrast to producers, a majority of the teens had wireless internet and smartphones. Building on the results of this event, we have developed at the University of Missouri a 4-d science camp for adolescents in 2014 (Summers@Mizzou, "The Stress of Life,"). The goal of the camp is to increase understanding and appreciation of science research through experiential learning. A smartphone heat stress app for livestock (i.e., ThermalAid) has been developed in our laboratory, along with a website thermalnet.missouri.edu. It is incorporated into the camp to illustrate the real-world value of science. Students will be introduced to research methods, and then use state-of-the-art technologies (e.g., ThermalAid, iPads, and iButtons) to collect data on themselves under different environmental conditions. They will then learn to statistically analyze and interpret the results. This information, along with data from cattle at the University research farm, will be incorporated into a final determination of the impact of stress. Students will work in teams to collect videos throughout the camp to be combined with their results into a final presentation. Developing and presenting these videos will give them an opportunity to practice presentation skills, apply new information they have learned, and gain confidence in working with others. Entry and exit surveys will be administered, to assess students' views on science and technology and the life skills they developed throughout this camp. Future projects will build on the educational discoveries of this camp.

Key Words: heat stress, education, technology

1957 (W387) Student assessment through a survey instrument of a horse management laboratory course. M. C. Nicodemus* and T. L. Bova, *Mississippi State University, Mississippi State*

Inclusion of a hands-on laboratory to the Mississippi State University horse management course, ADS 3223 Horse Management, was done in the spring of 2008, and due to it's popularity, this year the course offering will be expanded to both the spring and summer semesters. With course expansion, an understanding of the course impact on students is needed to determine areas that should be explored in future laboratories, and thus, the study objective was to assess through the application of a survey instrument the effectiveness of a horse management laboratory course in developing student's horse handling abilities. Students (n = 35) enrolled in ADS 3223 Horse Management were given a researcher-developed, 19 forced-choice question survey instrument at the beginning (B) and end (E) of the semester. Each question described a horse management activity that students rated 1 to 5 for their ability to perform. A score of 5 indicated the student had a perceived high proficiency level for performing all aspects of the described activity. The average score for each question was determined and compared using a one-way ANOVA to determine the impact of the course on handling abilities ($P < 0.05$). While all questions indicated students believed their abilities had improved through completion of the course, a significant impact on skill level according to students' scores was seen in the following areas: basic handling of European (B: 3.2, E: 4.2) and pony (B: 3.3, E: 4.5) breeds and performance-related handling of society-type (B: 2.4, E: 3.4) breeds ($P < 0.05$). Students were acclimated to various breeds through laboratory activities. The highest score given at the end of the semester was associated with the most common laboratory activity, catching, haltering, and leading of adult, well-trained horses (4.75), while the lowest score was associated with an activity not covered in laboratories, handling untrained, young horses (2.7). At the end of the semester, students were able to select suggested future topics to be covered in which training younger horses was the most popular topic (35%). While this topic is covered in another course, the majority of the students were all upperclassmen (70%) that were not taking another equine course that same semester (80%), nor had they taken another equine course in past semesters (55%), and thus, topics not covered proficiently in this course may leave these students lacking in those particular horse handling skills.

Key Words: horse management, survey

1958 (W388) Educational outcomes of an online course: Pharmaceutical use in cattle. E. Blythe*, *West Texas A&M University, Canyon*

Objective: To assess the effectiveness of a distance-based, online course entitled "Pharmaceutical Use in Cattle" by measuring the cognitive knowledge of agricultural science students (n = 27) as felt in their confidence level to explain; legal and regulatory issues that affect responsible pharmaceutical use and food safety principles, basic pharmacokinetics, veterinary drug informatics and classes of pharmaceuticals used in the therapeutic treatment of disease states in cattle. The course goal is to provide any interested animal science, dairy science, meat science, agricultural education, and pre-veterinary medicine student an opportunity to obtain knowledge and skills that can positively impact educational, veterinary and economic outcomes by applying drug knowledge resources to beef and dairy cattle operations. Methods: Quantitative and qualitative methods were utilized to assess the effectiveness of the curriculum. A one group, pre-post, quasi-experimental design was used to evaluate the confidence level and application skills of the students. A 5-point Likert scale was used to measure confidence levels. Improvement in confidence is expressed by standard deviations and confidence intervals. Results: Cognitive post-course scores improved significantly over the pre-course scores on all 11 survey questions. The analysis for each question indicated an increase in the cognitive measure as a result of completing the course curriculum. The reflective commentary on how students will utilize concepts learned in the course was positive. Students reported that increased knowledge in all topic areas would enhance their ability to; implement patient safety and food safety principles, serve as the basis for educating others under their supervision, and ultimately benefit the end consumer and industry. Additionally students reported; increased awareness of the depth of drug control regulations, the desire to demystify drug use in cattle, desire to strengthen working relationship with their attending veterinarian, and improve overall herd health, quality and performance. Students also reported applying what they learned to their personal cattle, to the job market, competitive internships and graduate thesis work. The large majority of students reported a near complete lack of self-awareness on the many facets of pharmaceutical use in cattle before this class. Conclusion: This online course can be used to increase the confidence level of the student's cognitive knowledge and skills after completion of the curriculum. The online offering of this course is an effective method to educate any interested agricultural science students in the United States on topics specific to pharmaceutical use in cattle.

Key Words: cattle, pharmaceuticals, education

1959 (W389) Using community engagement to enhance student learning in animal science: Farm to fork-at home and abroad. T. Montgomery*, *University of Wisconsin-Platteville, Platteville*

Community engagement in the animal sciences takes many different forms. Our Pioneer Academic Center for Community Engagement (PACCE) was founded as a way to help faculty from all across campus to engage students with community

partners to increase learning opportunities that involve problem-solving. PACCE projects are funded through segregated student fees and allow each faculty member to design projects that will engage students without a significant financial burden on the course. Many disciplines, such as engineering and business, have community partners looking for the specific expertise of the course and the students within. Animal science courses have historically been less able to attract community partners and so we have had to seek them out more intentionally and controversy exists as to whether this approach compromises the engagement process. Surveys and interviews were conducted in animal science, agribusiness, and agriculture engineering technology to determine if differences in approach to finding community partners changed the experiences and outcomes for faculty, students, and community partners in the different disciplines. From on-farm projects creating standard operating procedures to exploring ice cream flavors for a local business to doing community service during study abroad experiences (such as Ghana and Romania), students that engage in these activities have an increased investment in the course, a greater sense of civic responsibility, and an overall awareness of how they fit into the larger community regardless of discipline. Community partners felt equally engaged throughout the projects. Struggles for faculty include finding time to organize these projects as well as garnering acceptance from colleagues that these projects are worthy of the same weight as grant-writing and research publications.

Key Words: community engagement, study abroad, farm to fork

1960 (W390) An animal handling course for today's animal science student. A. P. Fidler*, *University of Arkansas, Fayetteville*

An increasing number of students with limited exposure to animal husbandry and plans to practice companion animal veterinary medicine are enrolling as Animal Science majors at the University of Arkansas. Without adjusting the curriculum to reflect the needs of the incoming student body, the department is at risk of graduating students lacking the knowledge and skills expected of an Animal Science graduate. Chief among those is the general livestock husbandry principles and practices which previous generations of animal science students might have been expected to already have become familiar with before matriculation. Simultaneously, the knowledge base and technologies continues to grow in a number of animal science disciplines, necessitating their inclusion into courses in our curriculum, often at the expense of the more time-consuming and logistically difficult live animal handling laboratory experiences. To address this disparity, a course has been developed at the University of Arkansas to provide animal science students with the opportunity to learn and practice safe and humane animal handling, restraint, and husbandry procedures of a variety of domestic species. The course utilizes live animal demonstrations and hands-on activities with cattle, horses, sheep, swine, dogs, cats, and laboratory rodents. Students learn methods of safe, effective, and humane handling and restraint as well as typical husbandry procedures which may be performed by an animal scientist. Examinations combine a written portion to test comprehension of basic principles as well as a practical portion to test ability to perform basic procedures. Students are thereby given the opportunity to learn, practice, and demonstrate animal handling knowledge and skills that may be lacking in their previous experience or academic history.

Key Words: handling, husbandry, student

1961 (W391) Experiential learning experience for undergraduate students in livestock and fisheries work in India. S. Robinson, M. Shelby, C. Prakash, O. Bolden-Tiller and N. Gurung*, *Tuskegee University, Tuskegee, AL*

The Tuskegee University (TU), as a collaborating partner, for the Agricultural Innovation Partnership project funded by USAID in India with Cornell University as the lead institution, was responsible for developing new and enhancing existing animal science courses at select Universities in India for advanced learning to prepare market ready students to improve their employability with market knowledge and market access as well as to develop curricula to address the needs of small and landless farmers to improve their livelihood. Three faculty members and two undergraduate students from TU travelled to India in December of 2012. The project partners in India were Sardar Vallabhbhai Patel University of Agriculture and Technology (SVPUA&T) in Meerut, India, Banaras Hindus University (BHU), Varanasi, India and Assam Agricultural University in Guwahati, India. Over the project period, the team assisted with the development of new curriculum and revised the existing curriculum in animal science and veterinary science programs, diplomas, certificate programs and experiential learning programs. Based on our work, the BHU launched a program for Bachelor of Veterinary Science and Animal Husbandry (B.V.SC. and A.H) effective July 13, 2013. Two other short courses were successfully completed in the hygienic production of milk-based desserts and vegetable processing at BHU. Since 2010, several faculty exchange visits have been made between Tuskegee University and SVPUA & T and BHU. The faculty members from India spent several weeks in the US for developing new curricula and improving the exiting one. In addition to the curricula development for the Indian universities, The TU students visited numerous fish markets, both dry and wet, becoming sensitive to the challenges faced in post-harvest processing, value addition and marketing for such markets in India. Further, TU students observed first-hand various challenges facing animal production systems in rural India. Students prepared white papers describing their international experiences with comparisons of challenges faced by

limited resource producers in rural America (Alabama Black Belt). Collectively, these experiences provided and continue to provide a platform for enhanced intellectual consideration in their training subsequent to the program.

Key Words: experiential learning, undergraduate students, livestock, fisheries

1962 (W392) *Fine Focus*: A new international journal for undergraduate microbiology research.

J. L. McKillip*, *Ball State University, Muncie, IN*

The American Association for the Advancement of Science (AAAS) recently disseminated a call to action underscoring the need for a re-evaluation of undergraduate biology education. Development of creative student-centered research into existing curricula is a major theme of this announcement, as well as 'community-based participatory research.' Ball State University is well positioned to take advantage of many of these rapidly evolving objectives in undergraduate science education, largely due to an established track record of excellence through our Biotechnology Certificate Program, an active Chapter of Sigma Xi (the Scientific Research Society), and the only ASM chapter in Indiana. This proposed immersive learning course utilizes the skill sets of 12 undergraduates in four departments to develop a peer-reviewed journal that will publish findings of undergraduate microbiology research internationally. This journal, entitled *Fine Focus*, will be the first of its kind, and will be produced in print form and electronically. Participating students gain a multitude of experiences through collaborations with professionals from ASM National and other professional coalitions. Such experiences will include acquisition of a working knowledge on scientific writing, editing, peer review, graphic design, and advertising, as they relate to dissemination of microbiological research data through an academic journal with international scope. Students will leave the course having also established permanent professional contacts in varied subdisciplines of microbiology worldwide. To be successfully implemented, contemporary undergraduate research in the biosciences must incorporate not only the bench skills, and experimental design principles, but the other vital aspects of doing original research, including professional dissemination. It is this unique niche that *Fine Focus* will fill. Our proposed work here is the first undergraduate journal specifically in microbiology. In a time when limited research budgets prevent undergraduates from attending national conferences to present their data, a venue such as *Fine Focus* allows interested students the opportunity to see their research efforts to fruition and learn about the entire research process at the same time.

Key Words: undergraduate research, microbiology, immersive learning, peer-review

PHYSIOLOGY AND ENDOCRINOLOGY: INTERRELATIONSHIPS BETWEEN ENVIRONMENTAL, METABOLIC AND PHYSIOLOGICAL PROCESSES I

1963 Non-targeted plasma metabolomic profile at early and late lactation in parity 1 dams with diverging body composition at weaning. L. A. Rempel* and J. R. Miles, *USDA, ARS, U.S. Meat Animal Research Center, Clay Center, NE.*

Following Lactation is an extremely energy demanding event, impacting naïve dams to a greater extent as they are still physiologically immature. The objective of the current study was to determine if a unique plasma metabolome exists at early and late lactation from first parity gilts having similar body measurements and litter sizes post-farrow (PF) with divergent body condition measurements at weaning. Farrowing data, body composition traits (bodyweight, backfat thickness, and loin eye area), and a plasma sample were collected PF (2.7 ± 1.45 d) and 1d prior to weaning (WN) from composite Landrace-Duroc-Yorkshire gilts bred with Yorkshire semen. Twenty-seven gilts were identified from 68 first parity farrowings with similar farrowing ages (P = 0.9442), PF body weight (P = 0.6789), PF backfat thickness (P = 0.8549), and litter size ($P \geq 0.2263$). Dams were fed to appetite from d3 PF through WN. Of the 27 dams, 10 with the greatest (Hi) and 10 with the least (Lo) body weight loss ($P < 0.0001$; 26.1 ± 1.90 kg and 8.6 ± 1.48 kg, respectively) and backfat thickness loss (P = 0.0094; 4.7 ± 0.86 mm and 1.3 ± 0.67 mm, respectively) had plasma samples submitted for non-targeted profiling by UPLC-MS and GC-MS techniques. Raw spectral data was processed using XCMS package in R to generate feature detection and alignment followed by grouping of features into compounds. Samples were blocked by time of collection (PF and WN) and body condition loss (Hi and Lo) and ANOVA was performed on each compound in R with a Benjamini-Hochburg false discovery rate adjustment. Several compound changes ($P \leq 0.05$) in the metabolome occurred from PF to WN under both detection techniques (UPLC-MS, 112; GC-MS, 59). While changes ($P \leq 0.05$) in compounds between Hi loss and Lo loss also occurred, the prevalence was much less (UPLC-MS, 21; GC-MS, 11). Interestingly, the interaction of time by body condition loss yielded unique compound profiles for both detection techniques (UPLC-MS, 16; GC-MS, 20). Of the 36 compounds significant for interactions, 11 compound signatures may prove to be relevant as predictors for animals that will or won't lose excessive weight and backfat thickness during the course of lactation. Further investigations into the specific identities and validation of all significant compounds will provide potential nutraceuticals to offset intensive depletion of energy stores in young dams during lactation. *USDA is an equal opportunity provider and employer.*

Key Words: gilts, lactation, metabolome

ASAS EARLY CAREER WINNER

Small RNA expression and function during oocyte maturation and embryo development in the pig. B. J. Hale, C.-X. Yang, E. C. Wright, and J. W. Ross* *Department of Animal Science, Iowa State University, Ames.*

Following germinal vesicle breakdown (GVBD), the genome of an immature oocyte becomes transcriptionally inactive and changes in mRNA and protein abundance rely on interactions with the surrounding cumulus oophorus and cellular processes occurring within the oocyte and early embryo prior to the maternal to zygote transition. Thus, molecular events regulating oocyte recruitment and maturation may have a significant impact on the developmental ability of subsequent embryos. MicroRNA (miRNA), in addition to several RNA binding proteins, have a demonstrated ability to regulate both mRNA and protein repertoires through their ability to confer post transcriptional gene regulation (PTGR). To better understand the biological roles of miRNA in the pig oocyte during meiotic progression and during early embryonic development, we characterized expression patterns of miRNA and other small RNA molecules using deep sequencing. Following mapping of our sequencing reads to the pig genome, we identified the expression of several hundred miRNA in cumulus cells, oocytes and in the 4- to 8-cell stage and blastocyst stage embryos following in vitro fertilization. In addition to miRNA, we were able to identify the expression patterns of other small, non-coding RNA, such as piwi-interacting RNA (piRNA), and siRNA. Based on total small RNA expression in the oocyte and the ability of those small RNA to map to intronic and exonic regions of mRNA, we were able to predict mRNA that may be subject to small RNA mediated PTGR in the oocyte. We have also pursued the characterization of miRNA, including MIR21 and its target, programmed cell death 4 (PDCD4), during in vitro maturation and the implications of MIR21 inhibition for developmental competency. We have demonstrated a temporal relationship between MIR21 and PDCD4 protein abundance exists and can be altered during in vitro maturation by prematurely elevating MIR21 abundance or through the use of MIR21 antagonists. We have also further characterized expression of dead end homolog 1, an RNA binding protein with the potential to interact with specific mRNA and spare those molecules from miRNA mediated PTGR, during follicle development, in vitro maturation and during early embryo development. *These projects were supported by USDA National Institute of Food and Agriculture grant no. 2008-35205-05309 and 2008-35205-18712.*
