R. L. Garnett*, A. Felock, W. K. Ray, R. F. Helm, S. I. Arriola Apelo, and M. D. Hanigan, *Virginia Polytechnic Institute and State University, Blacksburg.*

Excess nitrogen waste excreted from dairy cows causes numerous harmful effects on the environment, such as air and water pollution. Nitrogen efficiency can be improved by feeding low protein diets and supplementing with select essential AA (EAA), as is practiced in the swine industry. However, AA metabolism within dairy animals must be further understood to achieve this goal. The objective of this study was to determine α-S1 casein synthesis responses to the cell signaling inhibitors rapamycin and AICAR and high and low concentrations of essential AA in mammary tissue. Three lactating Holstein cows from the Virginia Tech herd were slaughtered at a processing facility on campus. Mammary tissue from an uninfected rear quarter was collected, and tissue slices (120 ± 30 mg) were prepared and incubated 4 h at 37°C in 5ml of treatment media enriched with [$^2H_5$] Phe. Experiment 1 examined the interaction of 3 concentrations of rapamycin and EAA in a 2 × 3 factorial design. Essential AA were included at either 5 or 100% of normal Dulbecco's Modified Eagle Medium (DMEM) concentrations. Rapamycin was added to the medium at 0, 0.5, or 10 μM. Experiment 2 consisted of a 2 × 3 factorial design with the EAA at 5 and 100% of DMEM and AICAR at 0, 0.4, and 4.0 mM. Experiment 3 tested the interaction between six nonessential AA and protein synthesis rates. Following incubation, samples were homogenized, and a 4.6 pH precipitate was isolated. [$^2H_5$] Phe enrichment of the 34-NLLRFFVAPFPE α-S1 casein peptide was determined in the precipitate via MALDI-TOF-TOF, and α-S1 casein fractional synthesis rate (CFSR) was determined. Experiment 1 revealed no effect of rapamycin, EAA, or their interaction on CFSR. AICAR tended to reduce CFSR. There was no effect of EAA on synthesis rate, nor any interaction between the two factors. These responses were consistent with the marginal changes in mTOR signaling changes caused by these drugs. Experiment 3 revealed no interaction between non-essential AA supply and CFSR. Further study is needed to determine other possible factors regulating CFSR beyond cell signaling and amino acid substrate supply.

Key Words: casein synthesis, rapamycin, AICAR

0789 (M003) Health of Holstein bull calves fed a fermentation extract of *Aspergillus oryzae*. R. M. Townsley*, T. T. Yohe, E. M. Dudash, Y. Roman Garcia, A. R. Gibson, K. M. O'Diam, and K. M. Daniels, *Dep. of Animal Sciences, Ohio State University, Wooster.*

The objective was to determine whether dietary inclusion of a fermentation extract of the fungus *Aspergillus oryzae*, commonly used as a direct fed microbial, would improve measures of health in Holstein bull calves (n = 52) from birth through 1wk post weaning. Calves were randomly assigned to a slaughter age, 4 wk (n = 16) or 8 wk (n = 36), and treatment, control (CON**;** n = 27), or direct fed microbial (DFM; n = 25). Calves averaged 43.2 ± 1.0 kg BW and 2.8 ± 0.3 d of age at the beginning of the experiment. Calves were housed and fed individually; no bedding was used. Calves assigned to DFM were fed 2 g of DFM daily. Liquid DFM was delivered in milk replacer for the first 4 wk of the trial; solid DFM was top-dressed on texturized grain thereafter. Calves were fed nonmedicated milk replacer twice daily (22.0% CP, 20.0% fat DM basis; 680 g/d) and were weaned on consumption of 0.91 kg of grain (20% CP, 2.0% fat; medicated with decoquinate) for 3 consecutive days or on d 45 of the study, whichever came first. Calves had ad libitum access to grain and water throughout the trial. Calf fecal scores were recorded daily, then averaged across treatment. On a weekly basis, DFM calves scoured more frequently than CON. All medical interventions (including oral electrolytes) were recorded. Treatment for respiratory ailments were more frequent in CON than DFM. Medical costs were calculated on a calf basis, then averaged by treatment. Medical costs for calves from 0 through 4 wk ($43.01 ± 2.40) and 5 through 8 wk ($11.18 ± 2.40) did not differ by treatment. For 8-wk calves, jejunal lymph nodes were collected on slaughter for flow cytometric analysis of CD4 and CD8 T cell populations as a measure of immune function. The CD4 cell population as a percentage of total observed cells was greater in DFM calves. Treatment did not affect CD8 cell population as a percentage of total observed cells. Flow cytometric results indicate that DFM may affect the adaptive immune system through effects mediated by CD4 positive cells. In conclusion, calves fed DFM scoured more frequently, but a lesser percentage of DFM calves were treated for respiratory ailments, leading to no effect on medical costs. Interestingly, CD4 cell population of jejunal lymph nodes was greater in DFM calves, which warrants further research.

Key Words: dairy calf, direct fed microbial, T cells

0790 (M004) Fecal score evaluation of pre-weaned dairy calves in group housing. M. Kittell*, J. Augustine, and S. I. Kehoe, *University of Wisconsin–River Falls, River Falls.*

Group housing for pre-weaned dairy calves has gained popularity among farmers because it reduces time and labor. Automatic calf feeders allow calves to receive increased milk intake multiple times a day. However, this increased milk consumption may cause an increase in fecal score, which is the common method for dairy calf managers to identify a sick calf. The purpose of this study was to evaluate whether increased fecal scores in group-housed calves were indicative of illness. A local calf raiser was used to evaluate a total of 61 calves from arrival at approximately 3 to 5 d of age through 3 wk of age. Once a week, a blood sample was analyzed for serum protein and hematocrit concentration to assess dehydration. A fecal sample was obtained and scored using a scale of 1 to 4 with 1 being solid and 4 being watery with little to no solids (Larson et al., 1977). Nasal and ocular discharge were recorded, and the skin tent test was performed. Rectal temperature was taken, and respiration, umbilical area, and overall attitude were evaluated. Weight data and medication records were obtained from the calf grower. Data was analyzed using a multiple logistic regression model in SAS 9.3 (2010). Variables were eliminated using backward stepwise regression to obtain a minimal model containing only significant variables ($P < 0.05$). All variables were eliminated from the model except nasal and ocular discharge and serum protein ($P < 0.001$). These results indicate that a higher fecal score is not a good diagnosing tool in group-housed calves receiving higher amounts of milk. Therefore, additional research is needed to distinguish effective methods for identifying sick calves in group housing with increased milk intake.

Key Words: calves, group housing, health

ANIMAL BEHAVIOR & WELL-BEING I

0791 (M005) Free range pork production system on savanna pasture in Brazil. *L. S. Murata*, F. L. da Silva, L. R. Roos, L. S. Fonseca, I. Fontana, C. A. da Silva Júnior, F. N. Gomes da Costa, C. G. D. Q. Roriz, L. H. N. Ribeiro, A. P. Santana, and S. L. S. Cabral Filho, University of Brasilia, Brazil.*

An alternative pork breeding system to traditional confined pork breeding has been implemented in the Midwest of Brazil on native savanna pasture mainly concerning welfare and product quality to small family farmers. A free-range pork production, separated by solar electric fences, was implemented in a 4.5-ha area on the University of Brasilia's farm in Brasilia, Federal District. The pregnancy and farrowing sectors are run in a cycle system, divided into 25 and 20 paddocks, respectively, both with a management central area. Native pasture is basically composed by *Trachypogon* spp., *Schyzachririum scoparium*, *Paspalum eriantum,* and *Echinolaena inflexa*. Monthly rotation grazing is used, providing a 4-mo pasture recovery period. The maximum density range in pregnancy and farrowing paddocks is 5 and 1 sows, and the available area/paddock is aproximately 1000 m^2 and 280 m^2, respectively. Boars paddocks are composed by eight individual paddocks with 200 m^2 separated by solar electrical and wire-framed fences. The nursering sector has four paddocks with 160 m^2 each and the growing sector has eight paddocks with 80 m^2. T gestation paddock has a collective metallic shelter covered with a straw and plastic roof as well as shade-providing shelters. The farrowing area has an individual shelter similar to the one used for gestation. It contains farrowing sow restraint bars, and females can make a nest with the available provided straw. There is also a shade-providing structure. The livestock is composed of 21 sows and 3 boars in a monthly pork production system, with five groups of females. Artificial insemination is used for reproduction, and the boar's ejaculate is processed at the farm. The semen is collected with the gloved-hand method weekly, and, when needed, later diluted with the commercial BTS diluent. Sows are inseminated three times each heat with 100 mL of diluted semen with $3x10^9$ sperm cells. Ten days before farrow, the pregnant sows are moved to the farrowing paddock. Weaning of piglets occurs after 30 d of lactation. The piglets are slaughtered weighing approximately 23 kg each.

Key Words: behavior, outdoor pork porduction, welfare

0792 (M006) Behavioral laterality, facial hair whorls, and heart rate variability in horses. C. B. Shivley*, T. Grandin, and M. Deesing, *Colorado State University, Fort Collins.*

The objective of this study was to test for an association between facial hair whorl characteristics and behavioral responses to a fear-inducing stimulus as well as heart rate variability in horses. This was a pilot study in which a small sample size was used. Nineteen well-trained riding horses (7 to 30 yr old) were categorized based on their facial hair whorl height (high, medium, or low), lateral location (right or left of midline), and rotation (clockwise or counterclockwise). Each horse was subjected to a novel object test where an umbrella was suddenly opened as a person approached the horse from the front. The turning response (right or left) was recorded. A Polar RS800CX heart rate monitor was used to continuously measure heart rate and heart rate variability. The standard deviation of the inter-beat interval (SDNN) was used for analysis of heart rate variability. Two horses had double facial hair whorls, and analysis was done both including them in the category of the dominant hair whorl and excluding them. Facial hair whorl rotation showed a correlation with turning response to the fear-inducing stimulus with $P = 0.04$ including the double hair whorls and $P = 0.11$ excluding the double hair whorls. Clockwise hair whorls were associated with turning to the right and counterclockwise hair whorls were associated with turning to the left. There were no significant correlations between facial hair whorl lateral location or height and direction turned ($P > 0.05$). All horses showed a decrease in the SDNN after the presentation of the fear-inducing stimulus ($P = 0.0024$). Horses with high facial hair whorls showed a tendency for a greater decrease in SDNN compared to horses with medium/low facial hair whorls ($P = 0.06$). There was no significant correlation between rotation of facial hair whorl or lateral location and heart rate variability ($P > 0.05$). In conclusion, facial hair whorls are associated with turning response and heart rate variability in horses. Facial hair whorls may be used as a noninvasive method to predict how a horse will respond when frightened and how stressful the event will be. Further studies are needed to develop this method for use by horse owners and trainers.

Key Words: facial hair whorls, behavioral laterality, heart rate variability

0793 (M007) Effects of rearing system and stocking density on growth performance, carcass quality, and welfare of male Arbor Acres broilers. W. Chang*, J. Tang, G. Liu, and H. Cai, *Feed Research Institute, Chinese Academy of Agricultural Sciences, Beijing, China.*

This trial was to investigate effects of rearing system and stocking density on growth performance, carcass quality, and welfare of broilers. A total of 936 1-d-old male Arbor Acres

Table 0793.

broilers were randomly allocated to four treatments with six replicates by a 2 × 2 factorial design, including two rearing types (wire floor rearing and litter floor rearing) and two stocking densities (low stocking density of 8 birds/m^2 and high stocking density of 18 birds/m^2). The results showed that during 0~3 wk, high stocking density (HSD) significantly decreased average daily gain (ADG), average daily feed intake (ADFI), and feed/gain (F/G) of broilers than low stocking density(LSD); wire floor rearing (WFR) significantly improved ADG and ADFI than litter floor rearing(LFR). During 4~6 wk, LFR significantly decreased ADG ($P < 0.05$), ADFI ($P < 0.01$) and F/G ($P < 0.01$) of broilers than WFR; HSD lowered ADG ($P < 0.05$), increased ADFI and F/G ($P < 0.01$) than LSD. There was no obvious interaction on growth performance of broilers between stocking density (SD) and rearing system (RS) ($P > 0.05$). HSD significantly decreased eviscerated weight ($P < 0.01$), breast muscle ($P < 0.01$), and thigh muscle weights ($P < 0.05$) of broilers than LSD. There was interrelationship for meat yield between SD and RS ($P > 0.05$), with an exception of eviscerated weight and thigh muscle weight ($P < 0.05$). WFR and LSD groups had higher score of feather damage, pododermatitis, and hockburn; lower foot felt temperature (litter or net) and mortality; and higher uniformity than LFR and HSD groups, respectively. In conclusion, LSD-WFR was the most superior in growth performance, carcass quality and welfare of broilers; oppositely HSD-LFR was the most inferior.

Key Words: broiler, rearing system, stocking density

0794 (M008) Comparison of three acute stressors in horses. A. J. Bachman, A. Berzas, and C. E. Ferguson*, *McNeese State University, Lake Charles, LA.*

Stress in horses can be caused by any number of things: a new pasture mate, trailer ride, unexpected loud noise, or even strenuous exercise. The objective of this study was to test three stressors (air horn, firecracker, and exercise), to determine their effect on heart rate (HR) and time from elevated heart rate to return to baseline heart rate. A total of six horses were used in this study: three mares, two fillies, and one gelding. The horses were used in a crossover design over a 2-m period where each horse received each stressor every 7 d. The horses remained in a stall while the Pre-Stress HR was measured every 30 sec for 5 min to determine baseline. Once baseline was established, the horse was brought to a round pen and exposed to a specific stressor. The exercise stressor required the horse to trot or canter for 10 minutes: 5 min clockwise and 5 min counterclockwise. The air horn and firecracker stressors lasted between 5 and 10 sec during each exposure. Immediately following being exposed to the stressor, the Stressed HR was recorded every 30 sec for 90 sec. The horse was then returned to original stall, and the Post-Stress HR was recorded every 30 sec for 15 min. Statistical differences in treatments were determined using the Proc GLM in SAS. There were no differences between the mean Pre-Stress HR of each of the stressors. The mean Stressed HR for the air horn (89 ± 14) was significantly higher ($P < 0.06$) than firecracker (58 ± 5) but not different from exercise (72 ± 4). There was no significant difference among the stressors' Post-Stress HR means. At the immediate Stressed HR measure, the one with the greatest effect ($P < 0.03$) on HR was the air horn (109 ± 19) compared with exercise (77 ± 4) and the firecracker treatment (66 ± 5). At the second immediate Stressed HR measure (60 sec following end of stimulus) the HR was not different between the air horn (86 ± 14) and exercise (71 ± 4), but both were greater ($P < 0.07$) than firecracker (57 ± 5). There were no differences in the mean Post-stressed HR between treatments. These results indicated that the short-term use of an air horn will elevate a horse's HR greater than 10 min of exercise but only for a short duration. Also, the use of a firecracker to induce short-term stress is not effective.

Key Words: horse, stress, heart rate, air horn, stressors

0795 (M009) Effect of social housing on pre- and post-weaning intake and performance of dairy calves.

E. K. Miller-Cushon*[1], R. Bergeron[2], K. E. Leslie[3], G. J. Mason[3], and T. J. DeVries[1], *[1]University of Guelph, Kemptville, ON, Canada, [2]University of Guelph, Alfred, ON, Canada, [3]University of Guelph, ON, Canada.*

This study investigated how pre-weaning housing environment affects intake and performance of dairy calves during the milk-feeding stage and once group-housed after weaning. Twenty Holstein bull calves were housed either individually (IH; n = 10) or paired and housed in pens (PH; n = 5) from birth until 49 d of age. Calves were offered grain concentrate (23% CP) and milk replacer (26% CP, 16% fat, 150 g DM/L) ad libitum and weaned by incrementally diluting the milk replacer from 39 to 49 d of age. Post-weaning, IH calves were paired within treatment, and all calves were offered a complete pelleted diet (21% CP) ad libitum and followed until 84 d of age. Feed intake was recorded daily and calves were weighed 2x/wk. Data were summarized by week and analyzed in a repeated measures general liner mixed model. Intake of milk replacer was similar between treatments (9.84 L/calf/d, SE = 0.82, P = 0.9). Pre-weaning concentrate intake was subject to a treatment × wk interaction (P = 0.014), with PH calves increasing solid feed intake to a greater extent over time (in wk 5–6, 0.17 vs. 0.051 kg/d, SE = 0.031). During the 10 d of weaning, PH calves had greater concentrate intake than IH calves (0.69 vs. 0.30 kg, SE = 0.11, P = 0.039). Growth was similar between treatments before weaning (1.05 kg/d, SE = 0.10, P = 0.5), but PH calves had greater ADG during the 10 d of weaning (0.67 vs. 0.41 kg/d, SE = 0.07, P = 0.02). Once all calves were pair-housed after weaning, there was no effect of pre-weaning housing environment on intake (3.3 kg/d, SE = 0.15, P = 0.9) or ADG (1.21 kg/d, SE = 0.07, P = 0.2). These results indicate that social housing for dairy calves encourages solid feed intake during the milk-feeding stage, resulting in improved intake and weight gain during the weaning period.

Key Words: dairy calf, social housing, feed intake

0796 (M010) Associations of stall design, behavior, and hygiene of lactating dairy cows.

M. A. Overvest* and T. J. DeVries, *University of Guelph, Kemptville, ON, Canada.*

Free stall standing behavior is typically indexed to improve cow and stall hygiene using stall designs that are often restrictive to the cow. The objective of this observational study was to determine the association of stall design, cow hygiene, and lying behavior in lactating Holstein dairy cows (n = 23; parity = 3.0 ± 1.3; mean ± SD). Cows were part of a group of 40 ± 3 cows, housed in a free-stall barn with 52 free stalls (head-to-head), and designed for free cow traffic to an automated milking system. Each stall was 1.93 m long (from rear of curb to brisket board), 1.22 m wide, and the stationary neck rail was 1.26 m above the stall bedding surface (water mattress bedded with wood shavings), and 1.91 m from the rear curb. Cows were observed for four 2-wk periods. During periods 1 and 3, a swinging PVC neck guard (located 0.92 m from the base of the stall and 2.22 m from the curb) was installed in the free stalls. Cows were hygiene scored (flank, udder, and lower leg; scale of 1 = very clean to 4 = very dirty) on the last 7 d of each period. Stalls were hygiene scored using a grid system (# contaminated 0.15 × 0.15 m squares in a 1.20 × 1.60 m grid). Electronic data loggers were used monitor lying behavior. Data were analyzed in multivariable mixed-effect regression models. Lying duration tended (P = 0.1) to decrease when cows were kept with the neck guard (-0.6 h/d; SE = 0.4), and was decreased (P < 0.05) in primiparous cows (-1.2 h/d; SE = 0.5), with higher production (-0.07 × kg/d; SE = 0.03), and when stalls were dirtier (−9.4 × stall hygiene score; SE = 4.5). Flank hygiene was worse when cows were kept with the neck guard (P = 0.001), in multiparous cows (P = 0.04), when stalls were dirtier (P = 0.002), and tended to be worse when cows spend less time lying down (P = 0.1). Udder hygiene was worse in multiparous cows (P = 0.03), when cows spend less time lying down (P = 0.002), and tended to be worse when stalls were dirtier (P = 0.06). Lower leg hygiene was worse in multiparous cows (P = 0.006), when cows spend less time lying down (P = 0.04), and tended to be worse in earlier lactation cows (P = 0.07). In summary, these results show that cow lying duration may be negatively impacted when free-stall design imposes restrictions on usage and when stalls are dirty. Further, cow hygiene is affected by lying behavior patterns of cows and by the cleanliness of the cow's environment.

Key Words: hygiene, behavior, stall design

0797 (M011) Time budget and rumen development of dairy calves around the time of weaning.

M. A. Overvest*, E. K. Miller-Cushon, and T. J. DeVries, *University of Guelph, Kemptville, ON, Canada.*

The objective of this study was to develop tools to aid in the evaluation of the success of weaning programs for dairy calves, including physiological and behavioral measures and daily time budgets for calves at this stage of life. The study followed 10 ad libitum milk-fed Holstein calves for 24 d: pre-weaning (d 33 to 39 of age), during weaning (d 40 to 49 of age), and post-weaning (d 50 to 56 of age). During weaning, milk replacer was incrementally diluted on d 40, d 43, d 46, and d 49 by 25, 50, 75, and 100%, respectively. Calves were individually housed until weaning was complete (d 49), at which time each calf was paired. Feed intakes were recorded daily. Calves were weighed 2x/wk. Rumination time was observed by live 60-sec scans between 1200 and 1300 h on alternate days beginning on d 34 and ending on d 56. Blood β-hydroxybutyrate (BHBA) concentration was recorded daily, using a

calf-side test, on the same schedule. Electronic data loggers continuously recorded standing and lying behavior for the duration of the trial. A mixed effect regression model provided insight on changes from pre- to post-weaning. Starter DMI increased from pre-weaning to post-weaning (51.7 to 3984.5 g DM/calf/d, SE = 160.0; $P < 0.001$). BHBA increased from pre-weaning to post-weaning (0.003 to 0.133mmol/L, SE = 0.01; $P < 0.001$) as consumption of concentrate increased. Rumination time decreased from pre-weaning to post-weaning (7.9 vs. 2.9 min/h, SE = 1.4; $P < 0.043$). Standing time increased (5.95 to 8.03h/d; SE = 0.16), while both lying time (18.1 to 17.2 to 16.0h/d; SE = 0.16) and lying bouts (21.7 to 18.1 to 16.9 bouts/d; SE = 0.46) decreased from pre-weaning to weaning and again from weaning to post-weaning ($P < 0.001$). The results indicate that these physiological and behavioral measures accurately assess rumen capabilities, daily time budgets, and calf comfort around the time of weaning. Further, BHBA measurements show promise in indicating rumen development in dairy calves.

Key Words: dairy calf, weaning, time budget

0798 (M012) Use of peripartum period cud chewing and activity data for diagnosis of health disorders.

D. N. Liboreiro*[1], K. S. Machado[1], P. Basso Silva[2], M. M. Filho[1], G. Franco[1], A. E. Barreto[1], M. I. Endres[2], and R. C. Chebel[1], *[1]Dep. Veterinary Population Medicine, University of Minnesota, St Paul, [2]University of Minnesota, Saint Paul.*

Objectives of the current experiment were to develop strategies to use peripartum cud chewing and activity for diagnosis of peripartum disorders within 72 h after calving. Holstein animals (nulliparous = 77, parous = 219) were fitted with cud chewing/activity monitors from -17 to 17 d relative to calving. Blood sampled weekly from 0 to 20 d relative to calving were used for determination of β-hydroxybutyrate (BHB) concentration and incidence of ketosis (BHB > 1400 mmol/L). Blood sampled on d 0, 1, and 2 relative to calving were used for determination of total Ca concentration and incidence of sub-clinical hypocalcemia (Ca < 8.5 mg/dl). Cows were examined for retained placenta (RP) and metritis by study personnel. After analyzing cud chewing and activity data according to occurrence of peripartum diseases, cud chewing data from individual cows was used to diagnose disease using the receiver operator characteristics. Formulas involving cud chewing to diagnose disease are not disclosed because of intellectual property considerations. Prevalence of stillbirth, RP, sub-clinical hypocalcemia, metritis, and ketosis were 6.1%, 13.2%, 37.8%, 21.2%, and 7.6%, respectively. The criterion used for diagnosis of stillbirth resulted in sensitivity and specificity of 50 and 79.7%, respectively. There were no criteria that could be used for diagnosis of RP before the day of calving. Two criteria could be used for diagnosis of sub-clinical hypocalcemia on the day of calving. One of the criterion resulted in 66.7 and 61.3% sensitivity and specificity, respectively. The second criterion resulted in sensitivity and specificity of 82.7 and 49.6%, respectively. Metritis could be diagnosed 72 h after calving with a sensitivity and specificity of 75 and 93.1%, respectively. Among cows that were diagnosed with RP within 24 h after calving, the cud chewing criterion resulted in sensitivity and specificity of 70.8 and 75%, respectively. Cud chewing could not be used for diagnosis of ketosis. Activity data was not useful in the diagnosis of any of the health disorders evaluated in this experiment. We conclude that cud chewing data may be used for diagnosis of stillbirth, sub-clinical hypocalcemia, and metritis.

Key Words: transition cow, health disorder, diagnosis

0799 (M013) Effect of stall size, tie-rail position, and chain length on cow injuries and cleanliness in Eastern Canadian tie-stall farms.

V. Bouffard*[1,2], A. M. de Passille[3], J. Rushen[3], E. Vasseur[4], D. B. Haley[5], and D. Pellerin[1], *[1]Université Laval, Québec, QC, Canada, [2]Valacta, Ste-Anne-de-Bellevue, QC, Canada, [3]University of British Columbia, Agassiz, [4]University of Guelph–Campus d'Alfred, ON, Canada, [5]University of Guelph, ON, Canada.*

Lying stall configuration affects cow comfort. Lack of space for the cow may result from old facilities (stall size) and from efforts to keep the cow cleaner (tie-rail position). To evaluate effects of not following recommendations for stall configuration on cow comfort, 40 lactating Holstein cows from each of 100 tie-stall dairy farms (Quebec, $n = 60$; Ontario, $n = 40$) were measured (hip height and hook bone width) and evaluated for neck, knee, and hock injuries, and udder, flank, and leg cleanliness. Data collected about stall configuration included bed length, stall width, tie-rail height and position, tie-chain length, and manger wall height, and these were compared with Canadian recommendations. Data were analyzed using Proc GLIMMIX of SAS with a binomial distribution. Only 21.1% of cows had a tie-chain long enough to meet recommendations. A standard tie-rail forward position ($\geq$ 35 cm compared to the bed length) was observed for 16.8% of cows. Each 10-cm increase of stall width closer to the recommendation decreased odds of neck injury by 11.6% ($P = 0.008$) but increased odds of flank and leg dirtiness by 35.6% ($P = 0.0006$) and 16% ($P = 0.0006$), respectively. Each 10-cm increase in bed length tended to decrease odds of knee injuries by 10.4% ($P = 0.08$) but increased odds of udder dirtiness by 35.6% ($P = 0.02$). Increasing tie-rail height by 10-cm closer to the recommendation increased odds of neck injuries by 22% ($P = 0.008$). Each 10-cm move forward of the tie-rail decreased odds of neck and knee injuries by 41.8% ($P = < 0.0001$) and 17.2% ($P = 0.0001$), respectively, but increased by 20.2% ($P = 0.03$) odds of udder dirtiness. Each 10-cm lengthening of the tie-chain decreased odds of neck (8.3%, $P = 0.02$), knee (9.9%, $P = 0.002$), and hock (8.3%, $P = 0.003$) injuries. A higher than recommended manger wall was not

related to cow injuries ($P > 0.1$) but increased by 3.7% ($P = 0.02$) odds of udder dirtiness. Although recommendations for tie-rail height need further testing, these results suggest that, even if associated with decrease in cleanliness, simple modifications by dairy producers to stall configuration (forward tie-rail position and increased tie-chain length) to meet current recommendations would result in a decrease in neck, knee and hock injuries and increasing cow welfare.

Key Words: tie-stall, injuries, cleanliness

0800 (M014) Evaluation of cow cleanliness and fly avoidance behaviors among cows with docked, switch-trimmed, and switch-intact tails.

E. A. Morabito*, D. T. Nolan, and J. M. Bewley, *University of Kentucky, Lexington.*

Tail docking has become a contentious issue in the dairy industry because of concerns related to pain and inhibition of natural fly avoidance behaviors. The TailWell Power Tail Trimmer (Shoof International LTD, Cambridge, New Zealand) is a cordless drill attachment with circular blades to trim a cows' switch quickly and easily. The objective of this study was to evaluate cow cleanliness and fly avoidance behaviors between 64 cows trimmed with the Tailwell Power Tail Trimmer (T), 89 previously docked cows (D), and 53 cows with intact switches (S). Cow cleanliness was evaluated bi-weekly with separate scores recorded for the flank, leg, and udder using a scoring system ranging from light (L) to very heavy (VH). Individual teat scores were recorded using a scoring system ranging from 0 (no dirt) to 4 (filthy). Fly avoidance behaviors were monitored for 2 min/cow at each sampling. The PROC MIXED of SAS (SAS Institute Inc., Cary, NC) was used to evaluate the effects of tail status, scoring period, herd, and interactions on udder, flank, leg, and teat cleanliness. Stepwise backward elimination was used to remove nonsignificant interactions ($P \geq 0.05$). No significant differences were observed among tail status for flank, udder, or leg scores ($P \geq 0.05$); however, significant differences were observed for scoring period, herd, and the interaction of scoring period × herd ($P < 0.05$). Herd was a significant predictor of teat scores ($P \geq 0.05$), however tail status was not ($P \geq 0.05$). The GENMOD procedure of SAS was used to evaluate fly avoidance behaviors. Cows with docked tails were 2.01 and 2.21 times more likely to have a higher tail swing score than cows with switch-trimmed and intact-switch tails, respectively ($P < 0.01$). The lack of differences among cleanliness supports existing literature suggesting that docking tails does not improve cow hygiene. The observed increase in fly avoidance behavior among docked cows suggests behavioral deprivation for these cows. The Tailwell Power Trimmer provides a way to relieve dairy worker concerns related to intact switches without the perception aspects of tail docking.

Key Words: tail trimming, fly avoidance, cow hygiene

0801 (M015) Effect of reduced hair coat on performance of feedlot steers during summer heat stress.

A. K. Curtis*, B. Scharf, W. J. Sexten, and D. E. Spiers, *University of Missouri, Columbia.*

Heat stress in cattle reduces well-being and performance. The challenge is to develop effective procedures for heat stress mediation over the entire summer period. This necessitates the identification and development of reliable predictors of heat strain in the animal. A 94-d study, using crossbred Angus steers ($n = 36$; average body weight = 284 ± 29kg) was conducted during summer 2013. Animals were stratified by weight, housed in groups of nine among four different pens with ~ 50% shade coverage, and hair scored (1 to 4 scale; with higher values indicating a shorter coat). Hair coat was carefully removed using the standard "torched" procedure from half of the steers, with those remaining being unaltered (average hair score: 1.9). Ambient temperature (T_a) and relative humidity were recorded using Hobo H8 Pro data loggers (Onset Computer, Bourne MA) in sun and shade. Range of T_a was 12.2 to 36.6°C, and calculated temperature humidity index was 54.4 to 85.3. Steers were provided a corn-based feedlot diet and water ad libitum, and core temperature (T_{core}) measured hourly using intraruminal telemetric boluses (Smartstock, Pawnee, OK). Electronic ID tags (Allflex US Inc., Dallas-Fort Worth, TX) connected to a GrowSafe FI system (GrowSafe Systems Ltd., Airdrie, AB, Canada) provided feed intake (FI) data. Respiration rates (RR) were measured at 0800 and 1700 h on select days throughout the study, with measurement frequency increasing with heat events. Data analysis was conducted using ANOVA, (JMP Statistical Software; SAS Institute; Cary, NC) to determine the effect of a reduced hair coat on FI, feed efficiency (FI/ADG), RR, and T_{core}. Analysis revealed no effect of torching on daily FI ($P = 0.85$), but an increase in feed efficiency in non torched versus torched ($P < 0.01$). Analysis of mean daily T_{core} over the entire period by animal and hour of day showed a 0.21°C lower T_{core} value for torched versus non-torched animals ($P < 0.01$). Likewise, maximum daily T_{core} was 0.25°C lower in torched versus non-torched animals, with no difference ($P > 0.10$) in daily minimum T_{core}. Torching appeared to have no significant effect on average daily respiration rates ($P = 0.89$). These results indicate that reducing the hair coat of steers during summer months may offer a cosmetic benefit along a reduction in core temperature due to an increase in cutaneous heat loss. However, overall feed efficiency was slightly reduced as a result of this procedure. Additional studies are needed to determine the reason for this reduction.

Key Words: heat, stress, steers

ANIMAL BEHAVIOR & WELL-BEING II

0802 (W001) Relationship between hair cortisol concentration and previous performance and feeding behavior in holstein bulls fed high-concentrate diets. M. Verdu[*1], A. Bach[2], and M. Devant[3], *[1]IRTA–Dep.t Ruminant Production, Caldes Montbui-Barcelona, Spain, [2]Dep. of Ruminant Production, IRTA, Caldes de Montbui, Spain, [3]IRTA–Dep. of Ruminant Production, Caldes De Montbui, Spain.*

One main hormone produced during stress responses is cortisol. Hair can be used as matrix to measure cortisol levels in beef. Hair specimen could reflect average hormone levels over months and can be used to assess cortisol long-term variations. High cortisol concentrations stimulate breakdown of body tissues to release energy and protein to further support the stress response, and therefore it may impair animal growth. Thus, the hypothesis of the present study was that hair cortisol concentration should be negatively correlated with previous ADG, feed efficiency or feeding behavior parameters. Thirty-seven Holstein bulls (129 ± 2.9 kg BW and 110 ± 2.0 d age) housed in two pens were used to obtain hair samples (1 g) from the forehead by clipping. On d 7, hair was clipped to reflect the new cortisol incorporation in the following hair specimens, which were collected on d 120 and 216 of the study. The relationships between each previous performance and feeding behavior parameters and hair cortisol were evaluated by regression analyses using a fit model procedure of JMP with animal as random effect. Hair cortisol concentration was positively correlated ($P < 0.01$) with ADG ($r = 0.28$), feed efficiency ($r = 0.34$), and coeficient of variation of concentrate intake ($r = 0.36$), whereas hair cortisol concentration was negatively correlated ($P < 0.01$) with average concentrate intake ($r = -0.37$). Hair cortisol concentration tended ($P = 0.10$) to have a negative association with meal size ($r = -0.30$), number of visits ($r = -0.16$), and concentrate eating rate ($r = - 0.21$). In contrast to the hypothesis, the relationship between hair cortisol and ADG and feed efficiency was not negative. Incorporation of cortisol to the hair matrix assumes that blood-borne substances enter the hair through passive diffusion and subsequently become deposited in the hair shaft; however, other possible mechanisms of entry are proposed like the diffusion from sweat or sebum secretions. Probably, hair cortisol concentration needs to be greater to negatively impact ADG and feed efficiency. The negative relationship between meal size and eating rate and hair cortisol concentration may be related with its impact on digestive tract health. In conclusion, weak correlations were obtained between hair cortisol concentration with 3 mo previous data of performance and feeding behavior.

Key Words: bulls, hair cortisol, performance

0803 (W002) Competition in the milk-feeding stage affects post-weaning feeding behavior of pair-housed dairy calves. E. K. Miller-Cushon[*1], R. Bergeron[2], K. E. Leslie[3], G. J. Mason[3], and T. J. DeVries[1], *[1]University of Guelph, Kemptville, ON, Canada, [2]University of Guelph, Alfred, ON, Canada, [3]University of Guelph, ON, Canada.*

This study investigated the effect of competition during the milk-feeding stage on post-weaning feeding behavior and response to a competitive feeding challenge. Twenty Holstein bull calves were pair-housed and provided milk replacer (MR) and grain concentrate ad libitum via either: 1) one teat and feed bucket/pen (competitive feeding: CF) or 2) two teats and feed buckets/pen (non-competitive feeding: NCF). Calves were weaned during wk 7 of life by incrementally diluting the MR. Post-weaning, all pens were managed similarly and offered a complete pelleted diet ad libitum via two feed buckets/pen (non-competitive feeding) in Period 1 (wk 8 and 9) and Period 3 (wk 12 and 13) and one feed bucket/pen (competitive feeding) in Period 2 (wk 10 and 11). Post-weaning feeding times and competitive interactions were recorded 2 d/wk from video. Meal criteria were used to calculate daily meal frequency, meal time, and synchronized meal time (the percentage of meal time when calves within the pen were engaged in simultaneous meals). Data were summarized by week and analyzed in a repeated measures general liner mixed model. Post-weaning, calves raised in CF pens displaced one another more frequently (6.6 vs. 1.5 displacements/d, SE = 1.9, $P = 0.02$) and had fewer overlapping meals than calves raised in NCF pens (34.5 vs. 40.7% of meals, respectively). In Period 1 (non-competitive feeding), calves in previously CF pens had ($P = 0.03$) more frequent meals than calves in previously NCF pens (10.8 vs. 9.8 meals/d, respectively) and tended to have ($P = 0.09$) greater rates of intake (44.3 vs. 38.9 g/min). Likewise in Period 3 (2 buckets/pen), previously CF pens had ($P < 0.04$) more frequent meals (11.3 vs. 9.9 meals/d) and greater rates of intake (87.8 vs. 72.0 g/min). In Period 2 (competitive feeding with 1 bucket/pen), meal frequency and rate of intake were subject to treatment × week interactions ($P < 0.004$), increasing to a greater extent in previously NCF pens compared to previously CF pens. Feeding behavior across treatments was affected by the competitive feeding challenge in Period 2 ($P < 0.04$): feeding time decreased by 18%, meal synchrony decreased by 16%, and displacement frequency increased 1.7x. These results indicate that behavioral responses to pre-weaning competition, such as competitive displacements, degree of feeding synchrony, and rate of intake, may persist once developed.

Key Words: dairy calf, competition, feeding behavior

0804 (W003) Effect of exposure to individual ration components on feed sorting of dairy heifers.

E. K. Miller-Cushon*[1], J. P. Vogel[1,2], and T. J. DeVries[1], [1]*University of Guelph, Kemptville, ON, Canada,* [2]*Dalhousie University, Truro, NS, Canada.*

This study investigated the effect of exposing heifers to individual feed components on extent and pattern of feed sorting on transition to a novel ration. Twelve Holstein heifers (403.3 ± 17.3 d old, weighing 409.8 ± 11.3 kg), consuming a familiar mixed silage-based ration (FMR; 41% corn silage and 59% haylage) ad libitum, were transitioned to a novel total mixed ration (NTMR; 41.6% haylage, 36.5% corn silage, 14.6% high moisture corn, and 7.3% protein supplement, DM basis) according to one of two treatments: direct transition to NTMR (DIR) or exposure to NTMR components individually before receiving NTMR (COM). Heifers were tested in replicates of six and fed individually with automated feed bins. During adaptation (d 1 to 4), all heifers were offered FMR. During transition (d 5 to 12), DIR heifers received NTMR, whereas COM heifers received NTMR components offered separately, in amounts according to NTMR composition (target 15% orts). After transition, all heifers received NTMR (d 13 to 20). Feed intake and feeding time were determined daily. Fresh feed and individual orts were sampled every 2 d for particle size analysis and NDF content. The particle size separator consisted of three screens (18, 9, and 1.18 mm) and a bottom pan resulting in four fractions (long, medium, short, and fine). Sorting activity for each fraction was calculated as actual intake as a percentage of predicted intake. Data were summarized by period and treatment and analyzed in a general linear mixed model. There was no effect of treatment on intake (10.6 kg DM/d, SE = 0.58, $P = 0.46$) or feeding time (172.3 min/d, SE = 4.2, $P = 0.75$) across the study. After transition to NTMR, COM heifers sorted to a greater extent than DIR, sorting against long particles (95.4 vs. 98.9%, SE = 0.5, $P < 0.001$) and for short particles (101.7 vs. 100.6%, SE = 0.4, $P = 0.04$). Heifers fed COM also tended to sort for fine particles more (102.4 vs. 100.7%, SE = 1.0, $P = 0.09$). Differences in sorting resulted in COM heifers tending to have lower NDF intake, as a % of predicted intake (98.9 vs. 100.5%, SE = 0.6, $P = 0.07$). These results suggest that degree of feed sorting in heifers may be influenced by method of transition to a novel ration.

Key Words: dairy heifer, feed sorting, feed presentation

0805 (W004) Relationships of temperament, behavior, and growth of performance tested bulls.

S. A. Lockwood*, H. G. Kattesh, P. D. Krawczel, J. B. Wilkerson, J. D. Rhinehart, D. Kirkpatrick, and A. M. Saxton, *University of Tennessee, Knoxville, TN.*

Flighty cattle can be dangerous to personnel and may threaten the longevity of equipment. The aim of this study was to explore objective criteria for evaluating temperament in bulls while examining relationships between temperament, behavior, and performance. Consigned bulls arrived at the University of Tennessee Bull Testing Station on d -14 ($n = 65$) and were reared into six pens based on age and weight. Bulls (three pens, $n = 30$) were selected to receive dataloggers to measure activity which included: total time lying, total steps taken, number of lying bouts, and lying duration from d 3 to 27 and d 59 to 84 (± 3 d). Pen scores (1, docile to 5, very aggressive) were assigned based on bull reactivity to a human observer on d -1, 27, 55, and 83 (± 3 d). Weight and exit velocity (m/s) were measured along with the time it took the bull to leave the chute once the head gate opened on d 0, 28, 56, and 84 (± 3 d). The average of pen score and exit velocity were used to evaluate overall temperament ratings. A correlation analysis was performed in SAS on temperament, exit velocity, and pen score and their relationship with the behavioral patterns and performance data with moderate and strong correlations of interest ($r > 0.3$, $r < -0.3$). Temperament, exit velocity, time to exit chute, time to cover 1.83 m, and total lying time were repeatable over the testing period ($r = 0.353$ to 0.759, $P < 0.05$) while the order of bulls through the chute showed low repeatability ($r = 0.108$ to 0.307, $P = 0.014$ to 0.394). After d 28, heavier bulls were less active and on d 84, pen score had a negative moderate correlation with bull order through the chute. Based on these data, performance and pen score were better related to behavior than temperament and growth performance.

Key Words: bull, temperament, performance

0806 (W005) The efficacy of bridging stimuli during acquisition of an operant task and the use of food-based positive reinforcement training on unwanted oral investigative behaviors in horses, *Equus caballus*. M. R. LaFollette*, K. A. Cloonan, and K. W. Walter, *Truman State University, Kirksville, MO.*

This study sought to determine the impact of food-based positive reinforcement training (PRT) on frequency and severity of unwanted oral investigative behaviors (UOIB) in horses. It also investigated the influence of various bridging stimuli (BS) on time and number of reinforcements to behavioral acquisition of an operant task. Eighteen horses were used in a randomized complete block design, where they were split into six blocks by age and assigned to one of three treatments at random. Treatments consisted of mechanically produced BS, human-produced BS, or no BS. A standardized training protocol was used to train each individual to touch a target. Lag time between BS and food delivery was minimal. Before and after training, all horses were evaluated for number and type of UOIB (nose, lips, or teeth on skin, clothes, or treat bag) at 10-sec intervals for 5 min. These UOIB were later given a numerical value based on type and summed to evaluate overall severity. These data were analyzed using PROC MIXED of SAS. Treatment did not influence time to behavioral acquisition (TBA) ($P = 0.7682$) or number of reinforcements ($P = 0.8881$). However, the youngest block had the shortest TBA ($P = 0.0599$) and received the most treats per minute ($P = 0.0207$). Before training, the youngest and oldest blocks tended to have fewer UOIB ($P = 0.0692$) and less overall severity ($P = 0.0653$) UOIB compared to the rest of the blocks. Analysis using a two-tailed *t* test showed that, after training, horses had an average of 4.4 fewer UOIB ($P = 0.0311$) as well as a reduction in overall severity of UOIB ($P = 0.0473$). Our data indicates that use of food-based PRT decreased number and overall UOIB, which suggest that proper delivery of food rewards can allow for successful task acquisition without causing UOIB. The lack of treatment influence on TBA could be due to minimal lag time between BS and presentation of the food reward. Future research evaluating if the presence of a BS with a lag time in food delivery influences TBA is recommended.

Key Words: operant conditioning, food rewards, clicker training

0807 (W006) Towards a better understanding of foraging behavior to boost the expression of conditioned preferences for low-quality foods. F. H. Catanese*[1], R. A. Distel[1], and J. J. Villalba[2], *[1]Universidad Nacional del Sur, Bahia Blanca, Argentina, [2]Utah State University–Agricultural Experiment Station, Logan.*

Our objective was to explore the impact of feeding experiences with a low-quality food (LQF) on sheep foraging behavior when the availability of a high-quality food (HQF) is variable. Twenty-four female 2-y-old Merino sheep were randomly split into two groups; one group consumed oat straw (OS, a LQF) for 20 min and immediately after a ration of soybean meal (CS+), whereas the other group consumed OS but the offer of the meal was delayed 5 h (CS-; i.e., control). After conditioning, pairs of sheep from the same treatment were arranged and their dietary preferences were evaluated (15-min tests) in a U-shaped corridor where they faced a choice at each end of the corridor of OS (ad libitum) and HQF (alfalfa pellets [AP, first trial] or corn grain [CG, second trial] in one of six levels of availability: 2, 4, 8, 12, 24, or 32 g/animal). Data from each level of HQF availability was analyzed separately using a mixed-effects model. During both trials OS intake was almost negligible at high levels of HQF and similar between groups (Table 0807). However, during high levels of restriction in HQF availability, OS intake increased abruptly (e.i., nonlinear relationship) and we observed greater intakes for sheep in CS+ than sheep in CS- (Table 0807). Increasing the quality of the HQF (AP to CG) reduced the likelihood of sheep accepting LQF at lower availabilities (e.g., 8 g of HQF; $P < 0.034$). To boost the benefits of a positive previous experience with LQF, restrictions should be placed on the accessibility and/or quality of the HQF (e.g., restricted foraging time, increased stock rate, etc.); otherwise, previous learning would remain silent or its effects over foraging behavior could be minimal.

Key Words: low-quality food, diet selection, sheep

Table 0807. Oat straw intake by pairs of sheep ($n = 6$) previously exposed to a preference conditioning protocol (CS+) or not (CS-) when tested in a U-shaped corridor with one of different levels of availability of a HQF

0808 (W007) Effects of bedding frequency on lying behavior of weaned calves. M. Terré*[1] and A. Bach[2], *[1]IRTA, Caldes de Montbui, Spain, [2]Dep. of Ruminant Production, IRTA, Caldes de Montbui, Spain.*

Twenty-eight Holstein male calves (BW: 79 ± 3.1 kg, age: 78 ± 2.5 d) were used to study whether lying behavior of weaned calves would be modified by bedding frequency. All animals were fed the same pellet concentrate and chopped straw, and they were bedded with sawdust, and kept in individual hutches. At the beginning of the study, 15-kg of sawdust were added to each hutch, and during the first 3 d of the study, 3 kg

of sawdust were added to each hutch (this was considered time 0 and used as covariate in the statistical analyis). Afterward, on Day 4, 6 kg of sawdust were added to all hutches, and thereafter half of the animals were bedded every other day (2B), and the other half every 4 d (4B) with 6 kg of sawdust. The study finished on Day 11 (3 d for the basal time plus 2 periods of 4 d each). Animals were weighed on d 1 and 11 of study, and concentrate intake was measured daily. Lying behavior was monitored by placing a data logger in the right hind leg to record movements at 1-min intervals, and bedding samples were obtained daily to determine the moisture content. Data were analyzed with a mixed-effects model with repeated measures considering lying time or concentrate intake of the basal time as a covariate, and calf and period as random effects. Linear correlations were determined between the moisture content of the bedding, lying time and concentrate intake. Moisture content of the bedding was greater ($P < 0.001$) the third and forth day of each experimental period in 4B than in 2B calves (50 vs. 31 ± 4.8% of moisture, respectively). However, neither lying time (1111 vs. 1105 ± 6.1 min for 2B and 4B, respectively) nor DM concentrate intake (2.72 vs. 2.76 ± 0.084 kg/d for 2B and 4B, respectively) or BW differed between both treatments. A slightly negative relationship was observed between moisture content of the bedding and lying time ($r = -0.23$, $P < 0.001$), and also a slightly negative correlation was found between lying time and DM concentrate intake ($r = -0.26$, $P < 0.001$). In conclusion, sawdust bedding at 50% moisture did not change lying behavior, DM concentrate intake, and performance of weaned calves in a short-period study.

Key Words: bedding, lying behavior, weaned calves

0809 (W008) Effect of oral meloxicam on indicators of pain following band castration in beef calves.

S. Marti[*1], M. J. Jelinski[2], L. C. Dorin[2], E. D. Janzen[3], M. E. Olson[4], B. J. Ralston[5], and K. S. Schwartzkopf-Genswein[1], *[1]Agriculture and Agri-Food Canada, Lethbridge, AB, [2]Veterinary Agri-Health Services, Airdrie, AB, Canada, [3]University of Calgary, AB, Canada, [4]Alberta Veterinary Laboratories, Calgary, Canada, [5]Alberta Agriculture and Rural Development, Calgary, Canada.*

The objective of this study was to evaluate if oral meloxicam could mitigate post-procedural indicators of pain associated with band castration in beef calves. One hundred intact Angus bull calves (BW 299 ± 3.3 kg) were randomly assigned to treatments according to a 2 × 2 factorial design assessing castration method (band castration (B) or sham castration (S)) and provision of a pain mitigating agent at the time of castration (1mg/kg of meloxicam oral suspension (15mg/ml) (M) or non-medicated (N) given an oral saline solution) to yield BM, BN, SM, SN treatments (25 calves/group). Behavioral and physiological indicators of pain were assessed over a 9-wk period post-castration. Animal BW (kg) was recorded weekly to calculate ADG and feed intake (kg/d; FI) daily for all animals over the experimental period. A subsample of 48 calves were randomly selected to obtain more detailed measurements on d 0 and weekly until the end of the study including salivary cortisol (ng/mL), blood cell count (CBC), and gait stride length (cm). In addition, 16 calves (4/treatment) were fitted with data loggers to monitor lying and standing duration (min/d) and number of steps (no./d) taken over a 4-d period post-castration. No differences ($P > 0.05$) were observed in lying and standing duration, stride length or number of steps between M and S calves from d 0 to 6. Similarly, M and S calves did not differ ($P > 0.05$) in BW, ADG, FI, or CBC values over the 63 d study. However, a castration × medication × day effect ($P = 0.03$) was observed for ADG with BM calves tending to have a higher ADG ($P = 0.07$) than BN calves on d 7. Salivary cortisol concentrations were greater ($P < 0.05$) in B than S calves from 60 to 120 min following castration but there was no difference ($P > 0.05$) between M and N calves. Overall, meloxicam administered orally at the time of band castration had little effect on indicators of pain post-castration. However, there was some evidence that ADG was improved in M calves on d 7. More study on the timing of drug administration is required to determine optimal circulating levels relative to the time of the procedure when it may have the greatest benefit.

Key Words: pain mitigation, band castration, meloxicam, beef calves

0810 (W009) Behavior of pigs infected with *Salmonella* and fed diets containing a probiotic or a physiological promoter.

V. F. Buttow Roll[1], E. Barba-Vidal[*2], L. Castillejos[3], X. Manteca[2], and S. Martín-Orúe[2], *[1]Dep. of Animal Science, Faculty of Agronomy Eliseu Maciel, Federal University of Pelotas, Brazil, [2]Animal Nutrition and Welfare Service Dep. of Animal and Food Sciences, Universitat Autònoma de Barcelona, Bellaterra, Spain, [3]Animal Nutrition and Welfare Service, Dep. of Animal and Food Sciences, Universitat Autònoma de Barcelona, Bellaterra, Spain.*

This trial evaluated the effects of a *Bacillus licheniformis* (10^9 CFU/kg of feed; PROPORC; NOREL S.A.) and a physiological promoter based on sodium butyrate (3 kg/t feed; GUSTOR BP70; NOREL S.A.) on the behavior of pigs challenged with *Salmonella* Typhimurium. A total of 72 piglets, weaned at 28 d, were housed in 24 pens and fed three diets: 1) Control diet (CTR), 2) CTR + probiotic (PRO), and 3) CTR + physiological promoter (PHP). After a 1-wk adaptation period, pigs were orally challenged with 10^8 CFU of *Salmonella* Thyphimurium. Behaviors were recorded in the morning and afternoon (0830 to 1030 and 1400 to 1600) for 5 d beginning 2 d before of the challenge (day -2 and -1) and 3 d after the challenge day (Day 2, 3, and 4 post infection, PI). Use of the space (feeder, light, drinker areas), active behaviors (exploration, feeding, drink-

ing, walking, and others) and inactive behaviors (lying ventrally or laterally, and in contact or not with a pen mate) were registered. A repeated measures procedure was used for statistical analysis. No effect of PHP was found. Effects of PRO were observed mostly during the morning. Active behaviors as well as inactive behaviors were higher and lower in pigs fed PRO ($P < 0.008$ and $P < 0.001$, respectively) compared with the other groups. These animals spent less time lying in contact with pen mates ($P = 0.012$), while total time exploring the pen, feeding and other active behaviors, were higher ($P = 0.05$, $P = 0.003$ and $P = 0.03$, respectively). In contrast, the total time lying laterally and ventrally with contact was significantly lower on pigs fed PRO ($P < 0.001$ and $P = 0.008$ compared to CTR and PHP, respectively). Pigs fed the PRO used more the feeding area ($P = 0.02$) and less the lying area ($P < 0.001$). In the afternoon pigs were more active before the challenge than on Day 4 PI ($P < 0.001$). Before inoculation there were significantly fewer pigs lying ventrally in comparison with the d 2 and 4 PI ($P = 0.01$). Positive contacts, exploration, and feeding behaviors were also less frequent on Day 4 PI in comparison with the day before challenge ($P < 0.05$). The use of feeder area decreased ($P = 0.001$) after the challenge. In conclusion the PRO has a positive effect on some behavioral measures, mainly those related to the exploring the pen, feeding and other active behaviors in the morning.

Key Words: probiotics, *Salmonella,* sodium butyrate

0811 (W010) Integrating animal science and human medicine: development of a novel porcine model for calcium oxalate stone formation. B. P. Trojan*[1], S. J. Trojan[2], A. Navetta[1], S. Filleur[1], and T. Nelius[1], *[1]Texas Tech University Health Sciences Center, Lubbock, [2]Texas Tech University, Dep. of Animal and Food Sciences, Lubbock.*

Increased collaboration between animal science Dep.s and medical schools has been highly encouraged in recent years to enhance research funding competiveness. Development of animal models for investigating human health problems has been pivotal for the discovery of treatments for many life-threatening human illnesses. A team of researchers from the Dep. of Animal and Food Sciences at Texas Tech University and the Texas Tech University Health Sciences Center collaborated to develop a porcine model for use in the study and treatment of human calcium oxalate stone formation. Porcine were chosen as the model as they are the most congruent mammal to humans, both anatomically and physiologically, for the study of kidney stone disease. Male, Large White-Chester crossbred pigs ($n = 16$; 19 kg initial BW) were assigned to one of the following seven treatments: 1) 0.8% ethylene glycol administered in drinking water (EG) and 2 µg/kg BW vitamin D dissolved in syrup (Vit. D); 2) EG + 100 mg/kg BW ammonium chloride dissolved in syrup (AC); 3) EG + 5 mg/kg BW gentamicin intramuscularly 3x/wk (GENT); 4) EG + 0.5 mg/kg BW Lasix dissolved in syrup; 5) EG + Vit. D + AC; 6) EG + Vit. D + GENT; and 7) control. Treatments were administered for 28 d; blood was collected and renal panels were obtained on d 0, 14, and 28. Urine was collected on d 0, 14, and 28 and analyzed for pH, Ca, citrate, oxalate, creatinine and P. Renal and bladder ultrasound was conducted intermittently throughout the 28-d period. Animals were euthanized at the end of the study for collection of renal tissue for gross and microscopic analysis of crystal stone formation and inflammation. No crystal deposition was observed in control animals; however, all other treatments developed calcium oxalate stones, confirmed by histopathological analysis of hematoxyin and eosin staining, fluorescent microscopy and stone analysis by infrared spectrum. All treatment combinations examined in this study successfully induced stone formation in pigs. Of the treatment combinations, EG + Vit. D provided the most straightforward model for inducing kidney stone formation and is one that can be employed to study kidney stone disease and mitigation in humans.

Key Words: animal model, animal science, human medicine

0812 (W011) Effects of group size and social rank on welfare and performance of gestating sows in a group-housing system with floor feeding. Y. Li* and L. Wang, *University of Minnesota, West Central Research and Outreach Center, Morris.*

This study was conducted to investigate the interactive effect of group size and social rank on welfare and performance of gestating sows group-housed in pens with floor feeding. Pregnant sows ($n = 152$, parity 1 to 6) were allocated to four large pens (26 sows/pen) and eight small pens (six sows/pen) at 35 d after mating. Both large and small pens provided the same floor space allowance (1.5 m^2/sow). Aggressive interactions among sows during the initial 2 h and during the first meal after mixing were recorded. Rank indices were calculated for each sow based on outcomes of fights, and sows were categorized as high, middle, and low ranking within each pen. Sows were scored for skin lesions at 24 h and 5 wks after mixing. Salivary samples for cortisol analysis were collected from high ranking and low ranking sows during the same periods as assessment of skin lesions. Body weights before mixing, before the subsequent farrowing, and at weaning, litter size and weight at birth and weaning were registered for each sow. Data were analyzed using the PROC MIXED and Glimmix of SAS. There was no interaction of group size and social rank for any variable. Low ranking sows fought less frequently (9.3 vs. 20.7 fights/sow/2h, SE = 3.17; $P < 0.001$) than high ranking sows at mixing, but had similar skin lesions ($P > 0.10$) at 24 h after mixing as high-ranking sows. Low ranking sows sustained more skin lesions ($P = 0.01$) than high-ranking sows at 5 wks after mixing. Low ranking sows and high ranking sows entered gestation pens with similar body weights, but low ranking sows gained less weight (33 vs. 50 kg, SE =

5.6; $P < 0.001$), and had lower weights (250 vs. 268 kg, SE = 5.9; $P < 0.001$) before farrowing than high-ranking sows. There was no difference in cortisol concentration between high- and low-ranking sows. Group size did not affect the number of fights per sow involved, but sows in large pens had more skin lesions ($P < 0.001$) at 24 h and at 5 wks ($P < 0.001$) after mixing than sows in small pens. Neither social rank of the sow nor group size affected litter size or litter weight at birth or at weaning. These results suggest that low ranking sows had poor welfare than high ranking sows in pens with the floor feeding system, as indicated by reduced weight gain and increased skin lesions.

Key Words: group size, social rank, sows

0813 (W012) Grazing and feedlot performance and carcass quality measurements of beef cattle surgically castrated at different stages of maturity with or without analgesia. E. A. Backes*[1], A. C. Brown[1], E. B. Kegley[1], J. T. Richeson[2], H. D. Hughes[2], M. L. Thomas[1], K. Anschutz[1], and J. G. Powell[1], *[1]Dep. of Animal Science, University of Arkansas Division of Agriculture, Fayetteville, [2]Dep. of Agricultural Sciences, West Texas A&M University, Canyon.*

Castration is a common and justifiable management practice used by beef cattle producers; however, it may expose calves to both stress and pain, which may negatively affect animal performance. The objective was to determine the effects of surgical castration at birth or weaning with or without oral analgesic ongrowth performance and carcass quality. This abstract summarizes grazing and feedlot performance, and carcass measurement. Bull calves ($n = 60$) from the University of Arkansas cow/calf unit were allocated randomly near birth to one of four castration methods, consisting of surgical castration near birth or at weaning with or without oral administration of meloicam (1 mg/kg BW). After a 56-d weaning period, calves were transported to West Texas A&M University (WTAMU) for the grazing and feedlot phases. Body weight was determined on arrival and at the end of the grazing phase (start of feedlot phase) and end of the feedlot phase. Calves were allocated to a heavy and low weight group within each treatment on arrival of the feedlot phase. During the 110-d grazing phase, steers were grazed a single group and had access to sorghum × sudan and native pastures consisting of buffalograss (*Buchloedactyloides*) and bluegrama grass (*Boutelouagracilis)*. Throughout the finishing period steers were fed a common feedlot ration. When steers were determined to have reached a suitable degree of finish (1.27 cm backfat), they were harvested at a commercial plant and carcass data were recorded by personnel from the WTAMU Beef Carcass Research Center. Performance and carcass measurements were analyzed using PROC MIXED of SAS, and quality grades were analyzed using Chi-square. Starting (270, 273, 276, and 270 kg, respectively) and ending BW (381, 378, 383, and 374 kg, respectively), ADG, and total gain during the grazing phase did not differ ($P \geq 0.42$) across the four castration treatments. Ending BW (619, 624, 630, and 618 kg, respectively), ADG, total gain during the feedlot phase, and d on feed did not differ ($P \geq 0.50$) between treatments. Carcass weight, fat thickness, color, ribeye area, internal fat, preliminary yield grade, yield grade, and quality grade did not differ ($P \geq 0.17$) across treatments. Therefore, surgical castration performed at either birth or weaning with or without oral analgesia did not affect calf performance during the grazing and feedlot phases and did not affect carcass quality measurements.

Key Words: castration timing, performance, carcass quality

0814 (W013) Evaluation of a disposition scoring system in pen-raised white-tailed deer. K. J. Stutts*, J. L. Lucia, M. J. Anderson, M. M. Beverly, and S. F. Kelley, *Sam Houston State University, Huntsville, TX.*

Pen-raised white-tailed does ($n = 63$) ranging in age from 1.5 yr to 6.5 yr were utilized to evaluate the accuracy of a subjective disposition scoring system for deer by assessing the physiological response to restraint through measurement of serum cortisol concentration. Does were administered annual vaccinations and dewormer while restrained in a drop-floor chute designed for whitetail deer. Following processing and before being released from the chute, blood samples were obtained via jugular venipuncture and serum was harvested to determine cortisol concentration by RIA analysis. Disposition scores ranging from 1 to 5 (1 = docile and 5 = aggressive) were also assigned by independent observers to evaluate deer behavior while restrained in the chute. Pearson correlation coefficients were used to determine the relationship between cortisol concentration and disposition scores, and a one-way ANOVA was utilized to determine if differences existed among mean cortisol concentration for each of the disposition scores. A moderately positive relationship ($r = 0.30$, $P < 0.02$) existed between disposition score and serum cortisol concentration; however, there was no difference in mean cortisol concentration for does receiving a score of 1, 2, 3, or 4 (56.0, 69.7, 69.3, and 54.0 ng/mL, respectively). Does that received a disposition score of 5, indicating the most aggressive behavior while restrained in the chute, had a greater ($P < 0.01$) mean serum cortisol concentration (118.8 ± 13.1 ng/mL) when compared to does receiving a lower numerical disposition score. These results indicate that the disposition scoring system accurately identified does undergoing the greatest physiological stress while restrained in a working chute, but the scoring system requires modification to accurately assess lower levels of stress associated with scores 1 through 4 of the system.

Key Words: deer, stress, disposition

0815 (W014) Objective movement of calf-fed Holstein steers fed in confinement. J. A. Reed[*1], N. May[1], T. McEvers[1], L. A. Walters[1], J. P. Hutcheson[2], and T. E. Lawrence[3], *[1]West Texas A&M University, Canyon, [2]Merck Animal Health, Summit, NJ, [3]West Texas A&M University, Canyon.*

The objective of this study was to determine the impact of zilpaterol hydrochloride (ZH) on movement behavior of calf-fed Holstein steers fed in confinement. The experimental design was a randomized complete block, with a 2 × 11 factorial treatment arrangement of ZH supplementation 0 or 20 d by 11 slaughter dates (254, 282, 310, 338, 366, 394, 422, 450, 478, 506, and 534 d on feed). Steers were fed in 28-d periods; d 1 to 4 included no ZH supplementation, d 5 to 24 included ZH (8.33 mg/kg dietary DM) supplementation, and d 25 to 28 allowed for withdrawal. Animal movement was monitored during each 28 d using IceQube pedometers (IceRobotics, Edinburgh, Scotland, UK), which recorded standing time (mm:ss), lying time (mm:ss), number of steps taken, and number of lying bouts continuously during the 28-d study period. Data collection began at 1200 h on d 1 to remove variation from movement caused by processing the animals at approximately 700 h; data collection ended on d 28 at 2400 h. Data were analyzed as repeated measures using a compound symmetry covariance structure via the GLIMMIX procedure of SAS. Treatment means were generated using the LSMEANS option and separated when significant with the PDIFF option that was adjusted with the Bonferroni correction to reduce the probability of a type-I error $\alpha = 0.05$. Treatment x days on feed interactions occurred ($P < 0.01$) for each outcome variable; they were likely the cause of small sample size per slaughter group and are not likely to be biologically repeatable. No difference ($P > 0.05$) was observed between ZH supplementation treatment groups in the quantity of minutes spent standing (0 d ZH = 565; 20 d ZH = 557), minutes spent lying (0 d ZH = 875; 20 d ZH = 883), or number of steps taken per 24-h day (0 d ZH = 1602; 20 d ZH = 1637). However, the number of lying bouts was different ($P < 0.01$) between treatment groups; cattle supplemented ZH exhibited 10.7 lying bouts, whereas those not supplemented ZH had 11.9 bouts. These results indicate similar objective movement between calf-fed Holstein steers supplemented ZH for 0 or 20 d.

Key Words: zilpaterol hydrochloride, movement, pedometers.

0816 (W015) A competitive and unpredictable feeding environment disrupts feeding and social behavior of pre-partum dairy cows. K. Proudfoot[*1], D. Weary[2], and N. von Keyserlingk[2], *[1]Ohio State University, Columbus, [2]University of British Columbia, Vancouver, Canada.*

Management during the pre-calving period can alter the behavior of dairy cows. The objective was to determine the effect of a competitive and unpredictable feeding environment on feeding and social behavior of pre-partum dairy cows. Sixty-four animals were randomly assigned to treatment ($n = 4$ animals × 8 groups) or control groups ($n = 4$ animals × 8 groups). Each group consisted of three multiparous cows and one primiparous heifer. During a 1-wk baseline period (5 wk before calving) all groups had free access to four Insentec feed bins. From 4 wk before calving until calving, control cows were given ad libitum access to six feed bins. For treatment groups, four non-experimental cows were added to the pen. After 2 wk, treatment groups were moved into a pen with four new cows. Throughout the treatment period morning feeding times were delayed at random 0, 1, or 2 h on alternate days. Cows were excluded if they calved with twins, aborted or calved > 2 wk early. Feeding behavior (intake, feeding time, rate of intake, visits to the feed bins, and intake per visit) and social behavior (total, initiated and received replacements at the feed bins) were collected electronically. Group was considered the experimental unit. Data were analyzed using a mixed model in SAS, including baseline data and parity as covariates, week as a repeated measure (wk 3, 2, and 1 before calving) treatment as the main effect, a week*treatment interaction and group as a random effect. Treatment did not affect feed intake, but decreased time spent feeding (3.9 vs. 4.2 ± 0.1 h/d; $P = 0.003$) and increased feeding rate (82 vs. 63 ± 2 g/min; $P < 0.001$). Treatment groups visited the feeder less often compared to controls (47 vs. 87 ± 3 visits/d; $P < 0.001$), and consumed more feed during each visit (0.39 vs. 0.19 ± 0.01 kgDM/visit; $P < 0.001$). Treatment groups were involved in more competitive replacements at the feeder (30 vs. 22 ± 1 no./d; $P < 0.001$), both initiated (15 vs. 10 ± 1 no./d; $P < 0.001$) and received (15 vs. 12 ± 1 no./d; $P < 0.001$) compared to control cows. In summary, a competitive and unpredictable feeding environment disrupts feeding and social behavior of dairy cows; these effects may be especially problematic for pre-partum cows that are particularly susceptible to disease.

Key Words: close-up, stress, parturition

0817 (W016) Effects of within dyad weight variation on competition, feed intake, and milk production of dairy cows sharing feeding gates. J. R. R. Dórea*[1], A. L. Stanton[2], C. M. Stoffel[2], and L. E. Armentano[2], [1]*University of São Paulo, Piracicaba, Brazil,* [2]*University of Wisconsin–Madison, Madison.*

The goal of this study was to identify the effect of weight variation in cow pairs on animal performance and ingestive behavior under competitive conditions. Twenty-four primiparous and 36 multiparous lactating cows were paired (within parity) to form 30 experimental units (feeding gates). Pairs were fed six diets in five 6 × 6 balanced Latin squares with 21-d periods, using data from the last 5 d. Each pair had access to one gate that allowed one animal to eat at a time, and cows that filched feeds in other gates were excluded during the statistical analysis. Each dyad was categorized based on the difference in weight within dyad. Differences above average (60 kg) were categorized as High. Below average differences in size were categorized as Low. Within cow pair, individual animals were classified by size as either the larger animal in the pair (Large) or the smaller animal in the pair (Small). The effect of size (large/small) and difference (high/low) were tested. For High and Low difference pairs the number of displacement (gate exchange < 1 min) per wk were 55.79 and 90.38 per wk, respectively ($P < 0.05$). An interaction between size and difference was significant for dry matter intake, feeding rate, displacements and milk yield, ($P < 0.05$). In High differences, small cows had greater DMI (% BW) compared to large cows ($P < 0.05$). In Low difference pairs, size did not impact DMI. Milk yield was 4.4 ± 1.1 kg/d lower for Small cows compared to Large cows ($P < 0.05$). For High difference pairs, size was not associated with milk yield ($P > 0.05$). These results suggest that in highly competitive situations, cows close in size have more aggression, poorer welfare, and milk production than animals with a greater difference in weight. This has implications for identifying animals with poor welfare in competitive environments.

Key Words: animal behavior, competition, performance

0818 (W017) Impact of feeding and housing strategy on calf performance and behavior. *S.* H. Ward*, K. Parker, and K. Hart, *Mississippi State University, Starkville.*

Forty-eight Holstein calves were fed either two or three times per day and housed either individually or in pairs (2XI, 2XP, 3XI and 3XP). Calves were randomly assigned to treatments at birth and remained on their treatment until 8 wk of age. At 8 wk of age, calves were moved to a grouped pen and body measures were taken until 10 wk of age. For calves that were on 2XP or 3XP, pairing occurred on d 3 ± 2 d. All calves were fed 3.8L of colostrum within 24 h of birth and then fed whole milk. Calf starter (Startena, Purina Mills, 22% CP) was offered from d 3 and increased by 0.45 kg when less than 0.45 kg was left. DMI and respiration and fecal scores were collected daily. Body weight (BW), hip and wither height, heart girth, and hip width were collected weekly. Play behavior, time spent lying, standing, eating, and drinking were also measured at wk 3, 5, and 7. At wk 8, latency to feed was observed when calves were released into groups. Data were analyzed using the PROC MIXED of SAS (Cary, NC). Separation of means was evaluated with the PDIFF procedure of SAS based on Fisher's F-protected least significant difference test. Significance was declared at $P < 0.05$. There was no effect of treatment on BW or measures or ADG. However, in weeks 6, 9, and 10 calves on 3XP had greater ADG than calves on 2XP (1.15, 1.49, 1.38 vs. 0.72, 0.84, 0.47 kg/d, respectively; $P < 0.05$) and 3XI (1.15, 1.49, 1.38 vs. 0.87, 0.79, 1.19 kg/d, respectively; $P < 0.05$). In wk 6 and 10, 3XP calves had greater ADG than 2XI calves (1.15kg, 1.38kg vs.89kg, 1.06kg respectively). There was no effect of feeding frequency on starter intake, however, calves housed in pairs tended to consume more starter than those housed individually (0.79 kg DM/d vs. 0.84 kg DM/d; $P < 0.07$). Analysis of behavior data indicates no impact of housing type on latency to feed, however, calves fed 3x/day consumed feed within 23.5 min and calves fed 2x/day consumed feed within 37.5 min. Currently, this data demonstrates that, while nutrient values were not different between treatments, both feeding frequency and housing type can impact calf growth and tended to impact intake and latency to feed.

Key Words: dairy calves, housing, feeding behavior

0819 (W018) Communicating farm animal welfare science: Wisconsin dairy producers' attitudes toward and interest in cow welfare. C. Skasa[1], S. Turner[2], and A. L. Stanton*[3], [1]*University of Wisconsin–Eau Claire, Eau Claire,* [2]*University of Wisconsin–Eau Claire, Eau Claire,* [3]*University of Wisconsin-Madison, Madison.*

Farm animal welfare research is gaining momentum in the United States, but few focused assessments of U.S. producer opinions and knowledge about welfare-friendly management practices exist in the literature. By soliciting producer opinions, gaps in producer knowledge and possible strategies to disseminate research-based best practices can be identified. This study of Wisconsin (WI) dairy producers targeted the following: producers' opinions about farm animal welfare and controversial on-farm management practices; their familiarity with farm animal welfare initiatives; and their interest in learning about dairy cattle welfare, including how they currently obtain that information. Surveys were mailed to a computer-generated random sample ($n = 1000$) of WI dairy producers with a response rate of 48.1%. Question topics included impact of management practices on cattle welfare, cattle's ability to experience affective states, familiarity with farm animal welfare initiatives, and accessibility of information about cattle

welfare. Associations between responses and farm size, age, education, and housing type were evaluated with chi-squares test in SAS. Results indicated that farm type, farm size, producer age, and producer education level impacted survey responses. Notably, tie stall farms, smaller farms (1 to 50 head), and producers who identified as university graduates were more likely to disagree with the statement that tail docking is necessary to maintain cow cleanliness ($P < 0.01$). Free stall farms were more likely to agree that milk production is the best indicator of a cow's welfare ($P = 0.05$), as were producers aged 65 and older ($P = 0.02$). Overall, farms that had both free stall and tie stall housing were most familiar with animal welfare initiatives, including extension-sponsored conferences ($P = 0.03$), a university-sponsored welfare-friendly cattle housing guide ($P = 0.01$), and the National Dairy FARM Program ($P < 0.01$). Study results could be used to target welfare education, such as benchmarking information on critical on-farm welfare issues, based on producers' current knowledge and preferred mode of information delivery.

Key Words: welfare, dairy, opinions

0820 (W019) Effect of transportation stress on cytokine gene expression, hematic biometry and blood chemistry in heifers. B. Avila*, J. Kawas, D. Zamora, and H. Fimbres, *Universidad Autónoma de Nuevo León, Escobedo, México.*

Transportation is probably the most stressful event cattle can experience affecting health, performance, meat quality and causing considerable economic losses. The objective of this study was to determine the effect of long-term transport stress on blood chemistry, hematological, and cytokine gene expression measurements. Blood samples from 16 *Bos taurus* x *Bos indicus* heifers from a feedlot located in northeastern México, were obtained by coccygeal venipuncture. Heifers weighed an average of 300 kg. Samples were obtained from eight heifers newly arrived from a 40-h road trip (0 DPA) as they were unloaded and restrained in a hydraulic chute to receive routine weighing and physical check-up, and the other eight heifers were in their 25th day post-arrival (25 DPA). Cytokine gene expression, hematic biometry, and blood chemistry were analyzed. For gene expression, blood samples were stabilized for RNA extraction, and RNA yielded was quantified and standardized. Specific primers were used for the amplification of cytokines TNF-α, IFN-γ, IL-2 and glyceraldehyde 3-phosphate dehydrogenase (GAPDH), the latter used as an internal control gene. Amplified products were analyzed by electrophoresis and quantitative values were calculated for each band using the myImageAnalysis software from Thermo Scientific. Blood chemistry results showed higher concentrations of albumin ($P = 0.013$), amylase ($P = 0.027$), alanine aminotransferase ($P = 0.003$), bilirubin ($P = 0.001$), and cholesterol ($P = 0.013$) in the 0 DPA group. Hematocrit ($P = 0.022$) and hemoglobin ($P = 0.001$) values were lower in heifers at 25 DPA. Cortisol concentration was higher ($P = 0.001$) in the 0 DPA group. On the quantitative gene expression analysis, we observed that the expression of TNF-α was greater ($P = 0.001$) in the 25 DPA group. At the TNF-α amplification two un-specific bands were found, only in the animals of the 0 DPA group. These bands were sequenced, and BLAST analysis suggests that they correspond to bovine lymphotoxin (LT). Literature shows that LT and TNF-α are coded in the same gene, even though, they have different promoters and polyadenylation sites. In conclusion, homeostatic impairment, high stress levels and immunological changes were apparent in recently transported heifers as evidenced by the blood chemistry and hematological measurements, the higher cortisol concentration, the reduction in cytokine TNF-α expression and LT co-expression. Further studies should look into the mechanism that promotes LT expression in animals exposed to transport stress, to probably be used as a biomarker for transport stress.

Key Words: stress, transport, heifers

0821 (W020) Flight speed as predictor of cattle ability to adapt to feedlots. D. R. Soares*[1], J. N. S. G. Cyrillo[2], A. C. Sant'anna[3], T. S. Valente[4], K. S. Schwartzkopf-Genswein[5], and M. J. R. Paranhos da Costa[6], *[1]Bolsista do CNPq– Brasil. Programa de Pós-Graduação em Zootecnia, Faculdade de Ciências Agrárias e Veterinárias, UNESP, Jaboticabal–SP, Brazil, [2]Centro APTA Bovinos de Corte, Instituto de Zootecnia, Sertãozinho-SP, Brazil, [3]Departamento de Zootecnia, Faculdade de Ciências Agrárias e Veterinárias, UNESP, Jaboticabal-SP, Brazil, [4]Programa de Pós-Graduação em Genética e Melhoramento Animal, Faculdade de Ciências Agrárias e Veterinárias, UNESP, Jaboticabal-SP, Brazil, [5]Agriculture and Agri-Food Canada, Lethbridge, AB, [6]Pesquisador CNPq–Departamento de Zootecnia, Faculdade de Ciências Agrárias e Veterinárias, UNESP, Jaboticabal-SP, Brazil.*

The aim of this study was to assess the efficacy of flight speed (FS) as a predictor of cattle ability to adapt to feedlots. Ninety-four animals were studied at the Instituto de Zootecnia research farm in Sertãozinho-SP, Brazil. Cattle were from three herds: 28 Nellore from a Control herd (not genetically selected for maximum post-weaning weights), 26 Nellore from a Selection herd, and 40 Guzerat (animals of both herds were selected based on a maximum differential in yearling weight) were assessed over a 173-d study. Cattle were housed according to their breed (Nellore and Guzerat) in two feedlot pens (68.59 and 105.60 m^2/animal, respectively). Flight speed (FS, m/s) was assessed 1 d after obtaining initial body weight. ADG (kg/d) and bunk attendance (BA, min/d) were used as confirmatory indicators of cattle adaptation to feedlot. ADG was calculated for the entire feeding period (ADGtot; d 1 to

d 169), and also for three feeding phases, defined as initial (ADGin, from d 1 to d 56), intermediate (ADGit, from d 57 to d 113) and the final (ADGfi, from d 114 to d 169). BA was recorded on Days 5, 13, 21, 35, 42, 50, 171, 172, and 173 of the study from 0700 to 1200 h by direct observation using a 10 min interval scan sampling technique. BA was also calculated for the entire feeding period (BAtot, from d 5 to d 173) and for three feeding phases defined as initial (BAin, from d 5 to d 21), intermediate (BAit, d 35 to d 50) and final (BAfin, d 171 to d 173). Regression analysis was used to assess the effect of FS on ADG and BA for the entire feeding period as well as each feeding phase using a model that included the fixed effects of herd and FS as a covariate (linear effect). Flight speed had significant effects on ADGit (ADGit = 0.78- 0.025*FS; R^2 = 0.31; $P < 0.05$), ADGfin (ADGfi = 0.80- 0.016*FS; R^2 = 0.34; $P = 0.08$) and ADGtot (ADGtot = 0.72- 0.015*FS; R^2 = 0.41; $P < 0.05$). No relationship ($P > 0.05$) was observed between FS and BA. The results of this study indicate that FS (assessed within the first d of arrival to the feedlot) has potential to be used as an indicator of cattle ability to adapt to the feedlot, however further studies are needed for a more thorough understanding of this relationship.

Key Words: adaptability, confinement, temperament

0822 (W021) Influence of pen-shade on respiratory rate and panting score in two breed types of growing bull-calves. *A*. Camacho[*1], B. J. Cervantes[2], L. R. Flores[1], J. J. Lomeli[1], J. A. Romo[1], and R. Barajas[1], *[1]FMVZ-Universidad Autónoma de Sinaloa, Culiacan, México, [2]Ganadera los Migueles, S.A. de C.V., Culiacan, México.*

Twenty growing bulls 233 ± 24.9 kg (75% Black Angus blood with remainder of Brahman and Brown Swiss in undetermined proportion, $n = 10$; and Brahman white coated bulls, $n = 10$) were used in an experiment to determine the influence of pen-shade on respiratory rate and panting score in two breed types of growing bull-calves. The experiment was performed during. Bull-calves were blocked by breed type (Angus cross AC type or Brahman BR type) and in groups of five assigned to two category of allotment (pens without shade NS or shaded-pens SH). During 28 alternated days (July and August, 2013), inside of pens air temperature (At), relative humidity (RH), air velocity (Av), and soil temperature (St) were recorded at 0100 and 1400 h, and THI calculated; with a similar schedule respiratory rate (RR) in breaths per min (bpm) and panting score (PS) were visually measured. Animals were fed at 1700 h to minimize the impact of digestive process on heat load during physiological measurements. Data were analyzed by ANOVA and best subset regression. Mean climatic conditions were air temperature 36.4°C (27.6–49.5°C), relative humidity 47.9 (24.7–82.5%), and THI 85.7 (79.1–96.4). RR was higher ($P < 0.01$) for AC than in BR cattle (73.7 vs. 48.7 bpm), and lower ($P < 0.01$) in SH than NS (52.6 vs. 69.8 bpm). Interaction breed x allotments was observed ($P < 0.01$), where BRNS cattle has similar RR than ACSH ($P > 0.10$), mean values were 85.3, 54.3, 62.0, and 43.1 bpm for ACNS, BRNS, ACSH, and BRSH, respectively. PS shown a similar behavior than RR, and its relationship was RR = 33.73 + (24.024 * PS); $r^2 = 0.84$, $P < 0.00001$. General equation for RR = 6.208 + (2.418 At) + (0.1672 St)- (5.043 Shade)- (24.68 Breed type); $r^2 = 0.69$, $P < 0.00001$. And for breed type was AC was RRAC = - 47.3917 + (3.164 At) + (0.2399 St)- (7.169 Shade); $r^2 = 0.72$; $P < 0.00001$; and RRBR = - 17.84 + (1.876 At)- (3.3758 Shade); $r^2 = 0.35$; $P < 0.00001$. Results suggest that panting score could be practical usable in different bred types of cattle, and the benefices of pen-shade helping cattle to cope heat load becomes important in cattle with lower genetic adaptation for confront hot environments.

Key Words: cattle, respiratory rate, pen-shade

0823 (W022) Association among residual feed intake, residual body weight gain, residual intake and body weight gain and temperament of Nellore cattle. C. L. Francisco[*1], A. M. Jorge[2], A. M. Castilhos[1], F. D. Resende[3], J. M. B. Benatti[4], M. B. Silva[1], and R. F. Cooke[5], *[1]Universidade Estadual Paulista–FMVZ, Botucatu, Brazil, [2]Faculdade de Medicina Veterinária e Zootecnia, Universidade Estadual Paulista, Botucatu–SP, Brazil, [3]Agência Paulista de Tecnologia dos Agronegócios–APTA, Colina, Brazil, [4]Universidade Estadual Paulista–FCAV, Jaboticabal, Brazil, [5]Oregon State University–EOARC Burns, Burns.*

A study was conducted to investigate association among residual feed intake (RFI), residual body weight gain (RG), residual intake and body weight gain (RIG) and temperament of Nellore (*Bos indicus*) young bulls ($n = 44$; 387 + 22 kg initial body weight; 22 + 1 mo of age). Animals were evaluated for temperament at feedlot entry (d 0). Individual temperament scores were calculated by averaging steer chute score (5-point scale: 1 = calm, no movement; 5 = violent and continuous efforts) and exit score (calculated by dividing exit velocity results into quintiles; 1 = slowest steers; 5 = fastest steers). Animals were also classified according to temperament type [adequate temperament (ADQ) or excitable temperament (EXC)]. Animals were maintained in individual drylot pens (8 m^2) and individual feed intake was measured during the trial period (d 0 to 109; finishing phase) to determine daily dry matter intake (DMI). Body weights (BW) were measured on d 0 and d 109 to determine the average daily gain (ADG). The DMI and ADG were used to determine the RFI. Residual body weight gain was calculated based on the regression of $BW^{0.75}$ and feed intake. Residual intake and body weight gain was determined from linear combination into RFI and RG. Data were analyzed using PROC MIXED in SAS with fixed effects of temperament; animal was experimental unit.

No differences ($P > 0.05$) were detected for RFI (-0.05 vs. 0.01, for ADQ and EXC steers, respectively; $SE = 0.18$) and RIG (0.04 vs. -0.05, for ADQ and EXC steers, respectively; $SE = 0.20$) between temperament types. However, ADQ steers had greater RG ($P = 0.02$) than EXC steers (0.05 vs. -0.10, for ADQ and EXC steers, respectively; $SE = 0.06$). In conclusion, residual gain is associated with temperament and it is independent of differences in feed intake in Nellore cattle. *Supported by FAPESP#2010/09516–1.*

Key Words: residual feed intake, residual body weight gain, residual intake and body weight gain, temperament.

0824 (W023) Association among peripartum health parameters, cud chewing, and activity.

D. N. Liboreiro[*1], K. S. Machado[1], P. Basso Silva[2], M. M. Filho[1], G. Franco[1], A. E. Barreto[1], M. I. Endres[2], and R. C. Chebel[1], *[1]Dep. Veterinary Population Medicine, University of Minnesota, St. Paul, [2]University of Minnesota, St. Paul.*

Objectives of the current experiment were to evaluate cud chewing and activity of cows with peripartum disorders. Holstein animals (nulliparous = 77, parous = 219) were fitted with cud chewing/activity monitors from −17 to 17 d relative to calving. Blood sampled weekly from 0 to 20 d relative to calving were used for determination of β-hydroxybutyrate (BHB) concentration and incidence of ketosis (BHB > 1400 mmol/L). Blood sampled on d 0, 1, and 2 relative to calving were used for determination of total Ca concentration and incidence of sub-clinical hypocalcemia (Ca < 8.5 mg/dl). Cows were examined for retained placenta (RP) and metritis by study personnel. Data regarding twin calving and stillbirth were recorded. Outcomes measured over time (e.g., rumination and activity) were analyzed by ANOVA for repeated measures using the PROC MIXED. Nulliparous animals spent less time cud chewing than parous animals ($P < 0.01$). There was a tendency for RP to be associated with cud chewing ($P = 0.08$) because from −4 to 10 d relative to calving animals with RP had reduced cud chewing time ($P < 0.01$). Even though there was no association between sub-clinical hypocalcemia and cud chewing time ($P = 0.19$), the interaction between sub-clinical hypocalcemia and days relative to calving was associated with cud chewing time ($P < 0.01$) because on days −16, −13, −11, and 0 relative to calving animals with sub-clinical hypocalcemia had reduced cud chewing time. Concentration of Ca was correlated with cud chewing time ($r = 0.15$; $P = 0.02$). Similarly, ketosis was not associated with cud chewing time ($P = 0.77$) but the interaction between ketosis and days relative to calving was associated with cud chewing time ($P < 0.01$). From 6 to 17 d relative to calving animals with ketosis had reduced cud-chewing time. Concentration of BHB was correlated with cud-chewing time ($r = 0.16$; $P < 0.01$). Nulliparous animals had ($P < 0.01$) greater activity than parous cows. There was a tendency ($P = 0.10$) for animals with stillbirth to have greater activity. There was ($P < 0.01$) an association between RP and activity because from 0 to 11 d relative to calving activity of RP animals was reduced. Although ketosis was not ($P = 0.91$) associated with activity, on d 0 and 1 relative to calving ketotic cows had greater activity and on d 10, 15, 16, and 17 relative to calving ketotic cows had reduced activity. Peripartum disorders are associated with altered cud chewing time and activity in the peripartum period.

Key Words: transition cow, cud chewing, activity

0825 (W024) Animal welfare policies in South Korea.

D. H. Kim[1], J. H. Jeon[2], S. H. Moon[3], M. J. Kim[4], D. M. Ha[1], H. S. Park[5], N. Whitley[5], and S. H. Oh[*5], *[1]Gyeongnam National University of Science and Technology, Jinju, South Korea, [2]National Institute of Animal Science, Suwon, South Korea, [3]Konkuk University, Chungju, South Korea, [4]Seongwoon Livestock Production, Geochang, South Korea, [5]North Carolina A&T State University, Greensboro.*

With the increased global interest in animal welfare, South Korea has implemented laws and policies related to animal production. The goal of this research is to review animal welfare trends in South Korea and introduce the farms that produce livestock with animal welfare in mind. The animal protection laws and policies implemented in South Korea include breeding management, transportation management, slaughter methods, animal welfare, prohibition of animal abuse, and farm regulations. By setting new standards, animal welfare will develop as a leading growth tool in the future livestock industry. In countries with leading livestock industries like the U.S., France, Denmark, and others, certification marks are given to animals produced under strict animal welfare policies to differentiate them from other livestock, and those produced within those certification programs are sold at a relatively higher price. European consumers willingly pay a higher price for products from animals raised under animal welfare certification program guidelines and feel pride in their belief that supporting those products contributes to the good of society. Following these trends, a certification system, which provides legal verification to those farms that comply with the government standard in animal welfare, was stipulated in South Korea. The system went into effect in 2012 with the chicken egg industry. Pigs were included in the system in 2013, and broilers were included in the certification system in 2014. Beginning in 2015, the system will expand annually to include native Korean cattle, beef cattle, dairy cattle, and others.

Key Words: South Korea, animal welfare, policy

0826 (W025) Influence of environmental conditions across day on respiratory rate and panting score of beef cattle in a hot and humidity weather.

A. Camacho*[1], B. J. Cervantes[2], E. X. Murillo[1], M. B. Corona[1], M. A. Osuna[1], and R. Barajas[1], *[1]FMVZ–Universidad Autónoma de Sinaloa, Culiacan, México, [2]Ganadera los Migueles, S.A. de C.V., Culiacan, México.*

Twenty growing bulls 278 ± 11.8 kg (75% Black Angus blood with remainder of Brahman and Brown Swiss in undetermined proportion, $n = 10$; and Brahman white coated bulls, $n = 10$) were used in an experiment to determine the influence of environmental conditions across day on respiratory rate and panting score of beef cattle in a hot and humidity weather. The experiment was performed during August 2013. In groups of five, bulls with same breed were placed in provided or no-shade ground pens (6 × 12 m). During 12 d from 0800 to 1600 h, inside of pens with 1-h intervals, air temperature (At), air relative humidity (RH), air velocity (Av), and soil temperature (St) were measured; one bull in each pen by time and day was randomly selected to respiratory rate (RR) in breaths per min (bpm) and panting score (PS) measurement by direct observation. Data of 12 d were pooled and analyzed by ANOVA. Across experiment, weather conditions were: At 36.30°C (range 25.2 to 53.0), RH 50.30% (range 21.5 to 82.6), Av 3.20 km/h (range 0 to 12), THI 85.93 (range 75 to 98), and St 35.47°C (range 15.7 to 73.9). Mean values of RR and PS were 65.95 ± 1.034 bpm and 1.18 ± 0.037, respectively. At 0800 h RR and PS were 44 bpm and 0.61 with 29.66°C At, 67.86% RH, and 80.35 THI. Mean maximum air temperature (40.65°C), soil temperature (41.10°C), and THI (89.08) were observed at 1300 h, while maximum respiratory rate (72.81 breaths/min) and panting score (1.57) delayed 1 h peaked at 1400 h. Means value of At and THI diminished ($P < 0.05$) at 1500 h; whereas RR, PS were coupled with soil temperature and delayed 2 h more (1700 h) to descend below of climax values ($P < 0.05$). It is concluded that respiratory rate and panting score delays proximately 1 h to reach the highest values after air temperature and THI arrive at its day peak values, and spend around 2 h to decline after air temperature and THI decreases; data suggest that descend of respiratory rate and panting score could be associated with soil temperature.

Key Words: air temperature, cattle, respiratory rate

ANIMAL HEALTH: **MODELS OF ANIMAL IMMUNE STATUS AND PERFORMANCE**

0827 (M016) Gastrointestinal and hepatic tissue fatty acid composition and interleukin-6 concentration in broiler chickens: Effect of maternal dietary n-3 fatty acids. C. J. Bullock, G. Bobe, and G. Cherian*, *Oregon State University, Corvallis.*

Early exposure to nutrients and fetal programming has gained increased attention because of its association with chick quality and viability. In chickens, the 21-d incubational period contributes to over 35% of a bird's life span. During this period, the egg provides polyunsaturated fatty acids (*P*UFA) to the chick embryo. We hypothesized that early exposure of n-3 and n-6 PUFA through egg lipids can alter tissue fatty acid (FA) composition and interleukin-6 (IL-6) production in the progeny chickens during growth. The objectives of the study were to determine: 1) the extent to which maternal (yolk) n-3 or n-6 FA are retained in the duodenum, jejunum, ileum, and liver tissue of the chicken, and, 2) the effect of maternal FA composition on IL-6 concentrations in serum and hepatic tissue in broiler chickens when fed a diet lacking in long chain (> 20-C) n-3 and n-6 FA during growth. Fertile eggs obtained from Lohman-Brown layer hens (n = 75) fed corn-soy diets supplemented with 3.5% yellow grease, sunflower oil or fish oil were incubated. These fat supplements were selected as sources of saturated, n-6 or n-3 FA. Chicks were raised up to d 14 on a commercial diet lacking long-chain n-6 and n-3 FA. Chick tissues (duodenum, jejunum, ileum, liver, and blood) were collected on Day 1, 7, and 14 and were subjected to FA and IL-6 analysis. The egg yolk arachidonic (20:4 n-6) and docosahexaenoic acid (DHA, 22:6 n-3) content was 3.1, 3.6, 1.0 and 1.6, 1.0, and 6.1 for eggs from hens fed yellow grease, sunflower or fish oil diets ($P < 0.001$). The DHA content in duodenum was highest up to d 14 of growth in chicks from fish oil-fed hens ($P < 0.001$). The long-chain n-6 to n-3 ratio was lowest in the duodenum, jejunum, ileum, and liver in chicks hatched from fish oil-fed hens ($P < 0.001$) up to d 14 post-hatch. A significant maternal diet by age interaction was observed for liver and serum IL-6 concentrations ($P < 0.001$). On the day of hatch, chicks from fish oil-fed hens had the lowest liver and serum IL-6 concentrations, whereas at d 14, chicks from fish oil-fed hens had higher liver and serum IL-6 concentrations than chicks from sunflower oil-fed hens ($P < 0.05$). In conclusion, our results indicate that inflammatory pathways and eicosanoid metabolism of broiler chicks can be altered by the maternal dietary ratio of long-chain n-6: n-3 FA.

Key Words: chicken, interleukin-6, n-3 fatty acids

0828 (M017) Sandwich enzyme-linked immunosorbent assay for detection of *Fasciola gigantica* excretory secretory in goats sera. H. R. Metawi*[1] and E. M. Oudah[2], [1]*Animal Production Research Institute, Agriculture Research Center, Cairo, Egypt,* [2]*Faculty of Agriculture, Mansoura University, Egypt.*

Fascioliasis is considerd a major animals health problem. Many immulogical techniques have been developed over years using the different *Fasciola* antigens for diagnosis of parasitic infection and to replace the parasitological techniques, which are time-consuming and usually proved to be inadequate and unreliable. Viable *F. gigantica* flukes were obtained from infected cows at a local abattoir and kept in suitable meduim inside CO_2 incubators to produce excretory/secretory (E/S) antigenes. The pure E/S was collected, and their protein contents were estimated. The bands of sizes 27, 30, 40, 60, and 60/62 were used to obtain suitable antibody probe to be used in isoloting target antigen of E/S origin from infected Egyptian Nubian goats sera. The 40-kilo Dalton immunogenic of E/S origin sandwich enzyme-linked immunsorbent assay is highly specific in detecting *F. gigantica* infection in Egyptan Nubian goats. It also offers a promissing diagnostic tool.

Key Words: Egyptian Nubian goats, *Fasciola gigantica*, sandwich

0829 (M018) Response of beef cows offered a chlortetracycline fortified mineral and either strip or continuous stocked to stockpiled fescue. M. S. Gadberry*[1], D. S. Hubbell, III[2], J. D. Tucker[2], T. Hess[2], P. A. Beck[3], J. Jennings[1], J. G. Powell[4], and E. A. Backes[4], [1]*Dep. of Animal Science, University of Arkansas, Little Rock,* [2]*University of Arkansas Livestock and Forestry Research Station, Batesville,* [3]*Dep. of Animal Science, University of Arkansas, Hope,* [4]*Dep. of Animal Science, University of Arkansas Division of Agriculture, Fayetteville.*

Food and Drug Administration proposed changes to the U.S. feed law addresses judicious use of medically important antimicrobials. Cattle producers grazing Kentucky 31 tall fescue (*Festuca arundinacea*) routinely feed mineral fortified with chlortetracycline (CTC). Available CTC fortified minerals often contain 3.08 g/kg CTC (350 mg CTC/113.4 g mineral consumed). Fescue management may include fall stockpiling for deferred grazing with forage being allocated using either continuous or strip stocking. This project evaluated the effect of CTC delivered in a free choice mineral supplement with either strip stocking (STRIP) or continuous stocking (CONT) on stockpiled fescue. The study design was a 2 × 2 factorial with three 2.4-ha pasture replications per treatment combination. The same mineral package was used for both the no CTC (CTC-) and CTC (CTC+) supplements. The CTC+ mineral contained 3.08 g/kg CTC. Ninety-six pregnant *Bos taurus* cows

were randomly allocated to the 12 pastures. STRIP pasture was allocated at 0.04 ha/d in 4 and 3 d strips. Grazing occurred from December 4 to January 29. The STRIP:CTC- had the least, per cow mineral intake (7.4 ± 0.43 g/d), differing ($P < 0.1$) only from CONT:CTC- and STRIP:CTC+. All other mineral intakes were similar (8.5 ± 0.43 g). Initial rising plate estimated forage allowance was 2513 ± 129.2 kg/ha. Forage utilization was not affected by either grazing method or CTC addition and averaged 47 ± 3.7%. The numerical difference in forage utilization was 44% (CONT) and 49% (STRIP). CTC+ resulted in a 22 kg greater BW change ($P < 0.05$) from the initial to interim weigh date but not interim to final (7 kg less than CTC-). Final BW and BCS were not affected by grazing management or CTC+. External body temperature and thermocirculatory index (TCI, based on rectal, skin, and ambient temperature) at the rump and ear differed between STRIP and CONT ($P < 0.05$) but was not affected by CTC+. CTC+ had a greater skin temperature between the dew claw ($P < 0.1$) at the interim but not final weigh date. CTC+ had no effect on TCI. In conclusion, grazing method did not significantly affect forage utilization, BW, or BCS but resulted in different skin temperature responses. Adding CTC to the mineral primarily resulted in an initial BW gain response without affecting final BW and BCS. Feeding CTC to cattle grazing stockpiled fescue did not result in a sustained benefit for performance or body temperature.

Key Words: chlortetracycline, fescue, strip grazing, strip stocking

---

0830 (M019) Regulation of gene expression and chemotactic and phagocytic function of bovine neutrophils incubated with citrus oil and lipopolysaccharides.

M. Garcia[*1], D. Biswas[1], T. H. Elsasser[2], and K. M. Moyes[1], [1]*Dep. of Animal and Avian Sciences, University of Maryland, College Park,* [2]*USDA/ARS Growth Biology Lab, Beltsville, MD.*

Antibiotic use is coming under increasing public scrutiny due to the possible development of resistant pathogens and risk of residues appearing in the milk. Therefore, new strategies to control or treat mastitis are warranted. Recent studies have shown that citrus derived oil (CO) inhibited growth of major mastitis-causing bacteria. However, the effect of CO on the function of bovine blood neutrophils (BBN) is currently unknown. The objective of this study was to identify the effect of CO and lipopolysaccharide (LPS) endotoxin on BBN by evaluating function and relative expression of genes in vitro. Jugular blood (~150 mL) was collected from 11 healthy Holstein cows in mid-lactation (> 100 DIM). BBN were isolated and incubated with or without 0.01% CO and 50 µg LPS/mL for 2 h at 37°C, 95% humidity, and 5% CO_2. After incubation, BBN chemotaxis and phagocytosis capabilities were determined in vitro, the cell pellet was recovered, and relative gene expression was analyzed via qPCR using the $2^{\wedge-\Delta\Delta Ct}$ method. Three pre-planned non-orthogonal contrasts were evaluated for gene expression. Non-LPS challenged BBN incubated with CO had a 47% increase ($P = 0.03$) in migration in response to IL-8 and a moderate increase in phagocytic capacity (15.9 vs. 14.2%, $P = 0.02$). This effect indicates that the CO was not impairing the function of BBN. However, the pattern of gene expression did not reflect the functional response, where BBN incubated with CO, regardless of LPS challenge, reduced expression ($P < 0.05$, fold-change (FC) $\leq$ -1.57) of several pro-inflammatory genes (IL1B, NFKB, SOD2, TNFA, and TLR2) with the exception of IL8, which tended to be up -regulated ($P < 0.06$, FC = 1.92) when compared to controls. For controls, expression of TLR4, critical for LPS recognition, was downregulated ($P = 0.03$, FC = -1.66) due to LPS although expression of *TNFA* was up-regulated ($P = 0.01$, FC = 2.62). In addition, the anti-inflammatory mechanism of CO at the gene-level does not appear to be mediated by IL10, where IL10 was downregulated ($P < 0.01$, FC = -3.78) in BBN incubated with CO when compared to controls. In conclusion, CO downregulated the expression of pro-inflammatory genes in BBN. However, CO does not appear to be inhibitory for overall BBN function in vitro. Future studies examining the effect of CO on BBN during mastitis in dairy cattle are warranted.

Key Words: neutrophil, citrus oil, genes

0831 (M020) Effect of *Penicillium* mycotoxins on bovine macrophage (BoMac) function.

S. Y. Oh[*1], H. J. Boermans[2], H. V. L. N. Swamy[3], T. K. Smith[1], and N. A. Karrow[1], [1]*Dep. of Animal and Poultry Science, University of Guelph, ON, Canada,* [2]*Dep. of Biomedical Sciences, University of Guelph, ON, Canada,* [3]*Haladi Consultancy Services, Bangalore, India.*

Penicillium mycotoxins (*P*M) are natural contaminants that are commonly found in improperly stored animal feeds. Although exposure to certain PMs has been reported to affect immune function, little data are available for ruminant species. Therefore, in this study bovine macrophages (BoMacs) were exposed to the following PM: citrinin (CIT), ochratoxin A (OTA), patulin (*P*AT), mycophenolic acid (MPA) and penicillic acid (*P*A), and macrophage function was assessed by measuring cytokine gene expression, the production of reactive oxygen species (ROS), and phagocytosis of *Mycobacterium avium* ssp. *paratuberculosis* (MAP), which is the causative agent of Johne's disease. Real-time PCR analysis of pro-inflammatory cytokines interleukin (IL)-1α and IL-6, anti-inflammatory cytokines IL-10 and transforming growth factor-β (TGF)-B, as well as neutrophil stimulating cytokines IL-12 and IL-23 was assessed following 6 and 24 h of PM exposure at concentrations that inhibited BoMac proliferation by 25% (IC25). The mycotoxin treatments altered the gene expression of cytokines at 24 h. Ochratoxin A induced IL-1α expression ($P < 0.05$), while IL-6 expression was suppressed ($P < 0.01$). Mycophenolic acid induced the IL-1α expression

($P < 0.05$) and reduced the expression of IL-12α ($P < 0.01$) and IL-10 ($P < 0.01$). Patulin suppressed the expression of IL-23 ($P < 0.01$), IL-10 ($P < 0.05$), and TGF-b ($P < 0.05$). Neither CIT nor PA affected the expression of these genes. The mycotoxins also affected BoMac intracellular ROS production and phagocytosis at the higher concentrations. Pretreatment with CIT at 300.0 μM increased pathogen associated molecule (*P*AM)-3-induced ROS production, which appeared to contribute to cell death. In contrast, PAT and PA significantly decreased the ROS production at concentrations ranging from 1.3 μM to 10.0 μM and from 31.3 μM to 125.0 μM, respectively; these two PMs simultaneously increased BoMac viability at 10.0 μM and 125.0 μM, respectively, even though they caused the cell death at higher concentrations. Although OTA did not affect the ROS production, an increasing trend in the phagocytosis of MAP was observed from 3.1 to 12.5 μM. In contrast, a decreasing trend in phagocytosis was observed for PAT concentrations from 2.5 to 10.0 μM. These findings suggest that exposure to sublethal concentrations of PM can alter immune function, which could affect innate antimicrobial resistance and immunoregulation.

Key Words: *Penicillium* mycotoxins, bovine macrophages, immunomodulation

---

0832 (M021) The Mycobacterial Diseases of Animals (MDA) Multistate Initiative— A cooperative effort addressing animal diseases. K. E. Olson[*1], V. Kapur[2], P. Coussens[3], and D. H. Lein[4], *[1]KEO Consulting, Schaumburg, IL, [2]Pennsylvania State University, State College, [3]Michigan State University, East Lansing, [4]Cornell University, Ithaca, NY*.

Johne's Disease Integrated Program (JDIP) efforts are well-known and documented. Primary funding was through USDA grants that allowed leveraging of additional public and private resources to expand the effort. The grants have come to an end, so a plan for the future was needed. JDIP addressed many knowledge gaps, but much work remains, so a range of options for the consortium was considered. Primary objectives were to maintain the networking, collaboration and basic infrastructure developed through JDIP, allowing participants to identify, obtain, and share resources needed to address Johne's and other mycobacterial diseases. To this end, a proposal was, developed and later, approved by USDA's National Institute for Food and Agriculture (NIFA) to begin operation as Multistate Initiative: NE1201, Mycobacterial Diseases of Animals (MDA). The multi-state initiative (MI) is focused on two mycobacterial disease complexes— paratuberculosis (Johne's disease; JD) and the tuberculosis complex of diseases (TBc; i.e bovine tuberculosis). The initiative includes five objectives: 1) increase understanding of the epidemiology and transmission of MDA, including predictive modeling; 2) develop and implement new generations of diagnostic tests for JD and TBc; 3) improving our understanding of the biology and pathogenesis of MDA, as well as the host response to infection; 4) develop programs to evaluate and develop new generations of vaccines for JD and TBc; and 5) develop and deliver JD and TBc education and outreach material in electronic and print form for use by producers and other stakeholders. Use trade media, producer organizations, and other outlets to aid in dissemination of information. Projects within each objective, with cross-cutting contributions, are designed to address major animal, human, and societal issues surrounding detection and control of mycobacterial infection, including how these organisms move and spread within cattle, small ruminant, and wildlife populations.

Key Words: mycobacterial disease, Johne's, tuberculosis

0833 (M022) Up-regulation of fetal cardiac genes following persistent and transient bovine viral diarrhea virus infection. *S*. W. Hahm[*], T. R. Hansen, and H. Han, *Colorado State University, Fort Collins.*

Transplacental infection by non-cytopathic (ncp) bovine viral diarrhea virus (BVDV) during early gestation results in persistently infected (PI) fetuses with lifelong viremia. Conversely, infection of ncp BVDV later in gestation (~day 150) or after birth leads to transient infection (TI). We hypothesized that ncp BVDV infection of the dam would alter gene expression related to development of fetal heart and vascular remodeling. Gene expression in the right ventricular heart (RV) of uninfected bovine fetuses was compared to PI and TI fetuses. Naïve pregnant heifers were challenged with 2 mL of ncp BVDV (4.4 log10 TCID50/mL) on d 75 (*P*I fetus; $n = 6$) or Day 175 (TI fetus, $n = 6$) or kept uninfected (Control fetus; $n = 6$). Maternal blood ncp BVDV RNA increased in concentration following PI and TI and then diminished. Fetuses were collected via caesarean section and necropsied on d 190 of pregnancy. To examine fetal cardiac gene expression, quantitative real-time PCR was completed. Data were analyzed using PROC GLM procedure of SAS. BVDV RNA concentration in the RV was greater in PI fetuses when compared to uninfected control and TI fetuses ($P < 0.05$). BVDV was not detected in TI fetal heart because of clearance of virus between d 175 and 190. Atrial natriuretic peptide (ANP) and B-type natriuretic peptide (BNP) act to reduce blood pressure. The mRNA concentrationsfor ANP and BNP were greater ($P < 0.05$) in RV of the TI fetuses, when compared with controls. Vascular endothelial growth factor (VEGF; angiogenic) and cyclin D1 (marker for left ventricular hypertrophy) mRNA concentrations were upregulated ($P < 0.05$) in TI fetuses. Fibroblast growth factor receptor1 (FGFR1; angiogenic) mRNA concentration was greater in RV of PI and TI fetuses ($P < 0.05$). Chemokine ligand 12 (CXCL12) and its receptor, chemokine receptor4 (CXCR4) facilitate fetal cardiac development and may assist in remodeling/repair following acute myocardial infarction. Concentrations of the mRNAs encod-

ing CXCL12 and CXCR4 tended to be upregulated in RV of TI fetuses ($P = 0.0860$, $P = 0.0951$; respectively). Maternal ncp BVDV infection may impaired fetal cardiac development via up-regulation of vascular regulatory, cardiac remodeling, and angiogenic genes regardless of TI or PI. *USDA NIFA AFRI 2008–35204–04652.*

Key Words: bovine viral diarrhea virus, fetus, heart

0834 (M023) OmniGen-AF supplementation inclusion rate independently promotes immune function in a rat model. J. A. Branson*[1,2], D. J. McLean[1], N. E. Forsberg[1], S. A. Armstrong[1], T. H. Schell[1], and G. Bobe[2], *[1]OmniGen Research, Prince Agri Products, Corvallis, OR, [2]Oregon State University, Corvallis.*

Feeding OmniGen-AF (OG; Prince Agri Products, Inc., Quincy, IL), a branded proprietary product, supports immune function in many domestic animals. Targeted profiling of immune-associated genes in whole blood is an established methodology to evaluate the efficacy of feed additives with immune-altering properties. We hypothesized that higher daily inclusion rate of OG than 0.5% may be required to optimize immune function. The objective of this study was to evaluate the effect of dietary OG inclusion rate (0.5% vs. 1.0%) on the expression profile of immune-associated genes. Male CD rats (5/treatment) weighing 180 to 200 g had ad libitum access to a diet with 0 (control), 0.5 (1×), or 1% (2×) of OmniGen-AF for 28 d. At the end of the feeding period, whole blood was collected. RNA was purified from whole blood samples and used to generate cDNA that acted as template in the Rat Innate and Adaptive Immune Responses RT^2 Profiler PCR array (SABiosciences). Using PROC GLM, we compared cDNA abundance of immune-associated genes between control and supplemented groups (0.5 or 1%) with a $P < 0.05$ cut-off value for significance. Of the 79 immune-associated genes that were expressed above the detection limit in all samples, 16 (seven up -regulated) and 13 genes (eight up-regulated) were altered by 0.5% and 1% OG supplementation, most of which (11 with six up-regulated) were altered at both OG inclusion rates. Genes that were up-regulated at both rates include IL13 (0.5%: +3.16, 1%: +3.70-fold-change), IL5 (0.5%: +2.64, 1%: +2.62), Irak1 (0.5%: +2.50, 1%: +1.98), Nod2 (0.5%: +1.83, 1%: +2.02), IFNa1 (0.5%: +1.81, 1%: +2.10), and Cd80 (0.5%: +1.77, 1%: +2.47). Genes that were downregulated at both inclusion rates include TLR3 (0.5%: -2.22, 1%: -2.39), CxCL10 (0.5%: -2.19, 1%: -2.26), STAT1 (0.5%: -2.07, 1%: -1.99), STAT3 (0.5%: -2.05, 1%: -1.92), and NFκb1 (0.5%: -1.84, 1%: -1.75). In conclusion, our results suggest that OG supplementation promotes immune function through various pathways including pathogen recognition, adaptive immune cell activation, and various transcription factors, independent of dietary inclusion rate.

Key Words: gene profiling, immunity, OmniGen-AF

0835 (M024) Effects of betaine on growth performance, carcass characteristics, and meat quality of broilers. J. Ma, W. Chang*, G. Liu, H. Cai, S. Zhang, and A. Zhen, *Feed Research Institute, Chinese Academy of Agricultural Sciences, Beijing.*

This study was to evaluate the effects of betaine on growth performance, carcass characteristics and meat quality of broilers. A total of 240 1-d-old healthy Arbor Acres male broilers were randomly allotted to four groups with six replicates per group and 10 birds per replicate by a single factor completely randomized design. The four diets included a basal diet and three experimental diets supplemented with 0.05, 0.10, and 0.20% betaine, respectively. Birds were slaughtered at 42 dold. The results showed that 0.20% betaine supplementation significantly increased ADG of broilers by 6.53% ($P < 0.05$) but did not significantly affect ADFI and F/G ($P > 0.05$), compared with the control group. Betaine supplementation at the 0.20% level improved breast muscle percentage 9.23% and decreased the values of drip loss 36.36% in breast muscle of broilers ($P < 0.05$). There was no significant difference in dressing percentage, eviscerated yield percentage and thigh muscle percentage between control group and experimental groups ($P > 0.05$). Supplementing betaine of 0.05, 0.10, and 0.20% in diets resulted in significant increase of IMP contents of 13.94, 17.94, and 12.10%, and increase of IMF content of 44.70, 42.92, and 53.14% in breast muscle of broilers, compared with the control group, respectively ($P < 0.05$). The IMF content of 0.20% betaine group was significantly higher than that in 0.05% and 0.10% betaine supplementation groups($P < 0.05$). The IMF content in thigh muscle of broilers in 0.05, 0.10, and 0.20% betaine supplementation group were improved 13.46, 28.53, and 13.75% than that in control group, respectively($P < 0.05$). The content of IMF of 0.10% betaine supplementation group was significantly higher than that in 0.05 and 0.20% betaine group($P < 0.05$). In conclusion, supplementing 0.20% betaine in diet could significantly improve ADG, carcass characteristics, and meat quality of broiler, with an exception of higher IMF content in thigh muscle in 0.10% betaine supplementation group.

Key Words: betaine, carcass characteristic, meat quality

Table 0835.

Treatment	control	0.05% betaine	0.10% betaine	0.20% betaine	*P*–value
ADFI(g/d)	104.26 ± 0.83	104.76 ± 5.85	103.31 ± 4.18	104.13 ± 2.44	0.335
ADG(g/d)	58.39 ± 1.63[a]	60.22 ± 1.47[ab]	57.73 ± 4.22[a]	62.47 ± 1.03[b]	0.029

0836 (M025) Effects of dietary polyphenols on inflammatory processes, nutrient digestibility, and microbiota in the intestine of piglets. A. Fiesel[1], D. K. Geßner[1], B. Eckel[*2], and K. Eder[1], *[1]Institute of Animal Nutrition and Nutrition Physiology, Universität Gießen, Gießen, Germany, [2]Dr. Eckel GmbH, Niederzissen, Germany.*

The weaning period of piglets is a stressful event characterized by an increased occurance of enteric infections and a pro-inflammatory intestinal condition with negative effects on feed consumption and animal growth. Recent studies have shown that polyphenolic compounds exert anti-inflammatory effects in the intestine. This study investigated the hypothesis that feeding the polyphenol-rich dietary supplements grape seed and grape marc meal extract (GSGME) or spent hops has the potential to suppress inflammatory processes in the intestine of piglets. Besides, the influence on nutrient digestibility and fecal microbiota composition should be investigated for the first time. A feeding trial with 48 5-wk-old piglets was performed. The control group received the basal diet mainly based on wheat, barley, and soybean meal; the GSGME group received the diet supplemented with 1% GSGME (AntaOx, Dr. Eckel GmbH, Niederzissen, Germany); and the hop group received the basal diet supplemented with 1% spent hops (AntaPhyt H, Dr. Eckel GmbH). Statistical analysis was done by one-way ANOVA. There were no differences in average daily gains, daily feed intake, and final body weights between the three groups. However, the gain:feed ratio was increased in the hop group ($P < 0.05$) and the GSGME group ($P = 0.15$). Moreover, both treatment groups had lower expression levels of pro-inflammatory genes (e.g., TNFα, IL-1β and IL-8) and nutrient transporters (SGLT1, GLUT2, GLUT5, PEPT1) in the mucosa of duodenum, ileum and colon ($P < 0.05$). In line with this, decreased digestibilities of crude protein and crude fiber have been observed in the hop group ($P < 0.05$). Supplementation of GSGME and hop revealed an increased fecal pH value, lower levels of volatile fatty acids (acetate, propionate, butyrate) together with changes in the fecal microbial composition with a lower amount of *Streptococcus* spp. and Clostridium cluster XIVa ($P < 0.05$). In conclusion, this study confirmed the anti-inflammatory effect of polyphenol-rich dietary supplements that can be a useful dietary strategy during weaning. It is suggested that the improved feed efficiency results from decreased inflammatory processes and might be also due to an interaction with the gut microbiota and their metabolites.

Key Words: grape seed and grape marc meal extract, hop, anti-inflammatory

0837 (M026) Effects of CO_2 and filter pore size on bovine neutrophil chemotaxis. A. M. Barnard*, R. Nebenhaus, S. Polukis, and T. F. Gressley, *University of Delaware, Newark.*

In vitro chemotaxis assays are an efficient and cost-effective way to assess neutrophil (PMN) function, but variations in the procedure may impact assay results. The aim of this study was to evaluate the effects of CO_2 and membrane pore size on chemotaxis of PMN from lactating cows ($n = 9$; 4–163 DIM). Neutrophils were isolated and adjusted to 2×10^6 cells/mL. Media consisted of HBSS supplemented with 5% FBS. The bottom wells of 48-well chemotaxis chambers (Neuro Probe Inc., Gaithersburg, MD) contained media supplemented with 50 ng/mL of complement component 5a (C5a) or 100 ng/mL of Interleukin 8 (IL-8). Polycarbonate membranes with 3, 5, or 8 μm pores separated the bottom and top wells. Neutrophil suspension (50 μL) was added to the top wells, and chambers were incubated at 37°C for 1 h in the presence or absence of 5% CO_2. Negative controls contained no chemoattractant in either well, and positive controls contained 50 ng/mL of C5a in both top and bottom wells. All combinations of cow PMN, CO_2, pore size, and chemoattractant were evaluated in triplicate wells over 6 different test dates. Raw adherence (RawAd) was determined by counting PMN adhered to the bottom of the membrane in five microscope fields per well. Relative adherence (RelAd) was calculated as (RawAd test well)/(RawAd negative control well) × 100%. Data were analyzed using the Glimmix procedure of SAS with the fixed effects of CO_2, pore size, chemoattractant, and all interactions and random effects of date and cow within date. Both RawAd and RelAd were affected by CO_2, pore size, chemoattractant, and CO_2 × pore size ($P < 0.001$), and RawAd was affected by CO_2 × chemoattractant ($P < 0.001$). Both RawAd and RelAd decreased in the presence of CO_2. RawAd increased and RelAd decreased with increasing pore size. For both RawAd and RelAd, chemotaxis to C5a and IL-8 did not differ but both were greater than chemotaxis to controls. The CO_2×pore interaction for both RawAd and RelAd was driven by a reduced increase in chemotaxis with increasing pore size when CO_2 was present. The CO_2 × chemoattractant interaction for RawAd was due to muted effects of C5a or IL-8 on chemotaxis in the presence of CO_2. Of the conditions evaluated, we propose that the use of a 3 μm membrane and incubation without CO_2 may be preferable because this combination resulted in the greatest increase in adherence relative to the negative control.

Key Words: neutrophils, chemotaxis, bovine

0838 (M027) Preliminary evaluation of the effect of a mushroom (*Coriolus versicolor*) probiotic on gene expression in goat blood. K. A. Ekwemalor*, *North Carolina Agricultuiral and Technical State University, Greensboro.*

Gastrointestinal parasites pose a serious threat to the global goat industry due to resistance of parasites to anthelmintic drugs. Oral administration of anthelimintics may activate genes in peripheral blood and impact goat health and production. *Coriolus versicolor* is a mushroom with immunostimulant properties used as a dietary supplement as an immunostimulant. CorPet biomass (Mycology Research Laboratories Ltd, UK) is a mushroom (*Coriolus versicolor*) based feed that is being used as a probiotic in horses and small animals as an immunostimualnt. White-rot fungi such as *Coriolus versicolor* are efficient lignin degraders and have been studied for their ability to ferment different crop residues to produce improved animal feed for ruminants such as goats. Although the impact of white rot fungi on animal feed has been studied the effect of their use as feed supplements on the animal needs further study. The objective of this study was to evaluate the effect of aqueous extracts of CorPet on gene activation in adult Boer goats infected with gastrointestinal parasites. Following initial screening for infection, goats were assigned to three groups of five ($n = 15$). Powdered CorPet was soaked in hot or cold water with stirring. Sterile filtered extracts were prepared. Goats were drenched daily with 10 mL of the hot (treatment I) or cold extract (treatment II) daily for a 4-wk period, and a control group of five age-matched goats received sterile water (treatment III). The groups were reversed for a further 4 wk. Body weight, PCV, fecal sample, and blood were collected in PAXgene tubes. Total RNA was isolated using the Zyomed kit. Haemonchus and coccidi were counted using a 3069 stereo microscope. There was no significant difference between the hot and cold treatment. There was an effect treatment on weight of the animals due to treatment ($P > 0.0041$). The Nanodrop spectrophotometer was used to evaluate RNA concentration and purity. The average concentration and purities of the different treatment groups for each week revealed some variation over time. Administration of Corpet as an oral drench may stimulate gene expression in peripheral blood and may impact rumen microorganisms. Further studies using more samples are needed to assess the impact on diversity and feed efficiency.

Key Words: anthelmintics, immunostimulant, CorPet

0839 (M028) Current colostrums management practices on Jersey farms in Vermont and New York State. K. M. Morrill*[1], M. M. Spring[2], and H. D. Tyler[2], [1]*Cornell University, Ithaca, NY,* [2]*Iowa State University, Ames.*

The objective of this study was to evaluate current colostrum management practices on Jersey farms in New York and Vermont. Colostrum management surveys consisting of seven general farm questions and 24 colostrum management questions were mailed to 75 dairy farms in New York and Vermont in June 2013. A total of 38 farms responded to the survey (50.66%). Of the 38 farms that responded, 10 provided calf serum for IgG analysis. Farms represented conventional (56%), organic (3%), and combinations of conventional and grazing (41%) operations. Farm size ranged from < 100 cows (67%), 100 to 199 (15%), 200 to 500 (10%), 501 to 1000 (5%), 1001 to 2000 cows (3% of respondents). Colostrum collection occurred within 1 h on 16% of farms and within 6 h on an additional 58% of farms. Fresh cows were milked most often in the same parlor as the rest of the herd (69%) and were frequently milked last (52%). Colostrum was transferred to an average of 2.32 containers (SD = 0.47) before feeding. Mean time to first colostrum feeding was 7.79 h (SD = 7.62); 24% of farms surveyed fed calves within 1 h, 33% within 2 h of birth, 35% within 6 h of birth and 8% of calves were fed within 12 h of birth. Mean colostrum consumption within the first 24 h was 3.00 L (SD = 1.11) with a range of < 1 (3% of farms) to > 4.5 L (13% of farms). Colostrum quality was a concern on 55% of the farms and was assessed on 78% of the farms. The most common methods of assessment were to evaluate color and consistency of colostrum; only one farm was using a refractometer to measure colostrum quality. The majority of farms surveyed (82%) would discard unacceptable colostrum. The following conditions led to discarding colostrum on greater than 20% of farms surveyed: mastitis, sick cow, positive for Johne's or Leucosis, watery appearance, or bloody appearance. Only one farm routinely monitored passive transfer in newborn calves. These data suggests that farms in this study are willing to discard colostrum from sick cows or visible altered (bloody); however, colostrum management practices on Jersey farms in New York and Vermont have room for improvement, primarily in timing of feeding, amount of quality colostrum fed within 24 h and assessment of passive transfer.

Key Words: colostrum, management, survey

0840 (M029) Effect of 2,4-thiazolidinedione treatment in milk production and leukocytes phagocytosis after sub-clinical mastitis induction in lactating dairy goats. *S. G. Richards*, L. Robertson, D. Dahl, L. Johnston, C. T. Estill, and M. Bionaz, Dep. of Animal and Rangeland Sciences, Oregon State University, Corvallis.*

Mastitis is one of the most costly diseases for the dairy industry. There is indirect evidence suggesting that peroxisome proliferator-activated receptor γ (PPARγ) regulates milk fat synthesis and may help to prevent mastitis. We postulate that continuous activation of PPARγ in the mammary gland can improve response to sub-clinical mastitis and increase milk fat synthesis. To test this, 25 lactating Saanen goats received either 8 mg/kg BW daily intravenous injections of the PPARγ

activator 2,4-thiazolidinedione (TZD) or saline. Following 1 wk of treatment, half of the TZD and half of the saline treated goats received intramammary infusion (IMI) of 1.7×10^8 CFU/mL of *Streptococcus uberis* (*S. uberis)* in both mammary halves (MTZD and MCTR), while the remaining goats in each group received IMI of saline (CTZD and CTRL). Animals were monitored for 12 d after IMI. Milk was collected daily during the trial to measure yield and composition, including somatic cell count (SCC). Bacteriological analysis of the milk was performed before infusion and 24 h after IMI. Rectal temperature (RT) was assessed daily after IMI. Blood was collected during the trial to assess leukocytes phagocytosis. Body weight and body condition score (BCS) were assessed weekly. Data were analyzed using GLIMMIX of SAS with TZD, IMI, time and all interactions as main effect and goat ID as random. Significance was determined with a Tukey-adjusted $P < 0.05$. Milk SCC increased significantly after IMI in goats infused with *S. uberis,* but the goats receiving TZD had an overall lower SCC. There was a significant decrease in milk yield in mastitis groups but no effect of TZD. There was a decrease in milk fat (mg/d) after IMI in MCTR, while the MTZD group maintained milk fat comparable to non-mastitis groups. The mastitis groups had a much higher percentage of milk protein than non-mastitis groups, but no TZD effect was observed. Compared to 2 d before, after IMI we observed a decrease in % blood neutrophils and increase in % lymphocytes, which was larger in goats infused with *S. uberis*. The phagocytic activity of monocytes increased more in groups infused with saline compared to *S. uberis*. No effect on body weight, BCS, and rectal temperature was observed. The results confirmed successful induction of sub-clinical mastitis, uncovered a positive effect of TZD on SCC and in preventing milk fat depression due to sub-clinical mastitis, but TZD treatment did not affect leukocytes.

Key Words: PPARγ, goat, subclinical mastitis

0841 (M030) Cross-talk between liver and mammary tissue after experimental *Escherichia coli* mastitis in Holstein dairy cows using RNaseq.

M. Bionaz*[1], K. M. Moyes[2], and P. Sørensen[3], [1]*Dep. of Animal and Rangeland Sciences, Oregon State University, Corvallis,* [2]*Dep. of Animal and Avian Sciences, University of Maryland, College Park,* [3]*Center for Quantitative Genetics and Genomics, Dep. of Molecular Biology and Genetics, Aarhus University, Tjele, Denmark.*

Using RNaseq combined with bioinformatics tools, our objective was to identify cross-talk between liver and mammary tissue and key pathways altered during intramammary (IMI) challenge with *Escherichia coli* (*E. coli*). Six cows were inoculated with ~20 to 40 CFU of live *E. coli* into one mammary quarter at ~4 to 6 wk in lactation. Biopsies were performed at -144 and 24 h relative to challenge in liver and at 24 h in both rear quarters (i.e., infected and non-infected) of the mammary gland. Each sample was sequenced using a 100 bp paired-end approach. Sequence reads were aligned to the Bovine genome and the number of reads that mapped to each of the 24,616 Ensembl genes was determined. A generalized linear model was fitted for the read count of each gene and differential expression was assessed using a likelihood ratio test statistic after adjustment for multiple testing (FDR). Ingenuity Pathway Analysis coupled with the Dynamic Impact Approach analysis of differentially expressed genes (overall time effect FDR $\leq$ 0.05, post-hoc $P \leq 0.05$) indicated that IMI induced a large biological response in the liver and mammary tissue with a strong inhibition of metabolism, especially related to lipid, glucose, and xenobiotic metabolism, in the former and induction of inflammatory response/immune cells activation in the latter. Analysis of upstream regulators indicated a prominent role of several cytokines, growth factors, and transcription regulators in the two tissues' transcriptomics adaptation to IMI, clearly lipid-related and inhibited in the liver and inflammatory-related and activated in mammary tissue. The analysis uncovered a substantial cross-talk between the two tissues during IMI with a communication almost unidirectional (i.e., from mammary to the liver) via the induction of the hepatic proliferation, regeneration, and inflammatory response due to a large number of cytokines with an increased expression in the mammary gland and able to interact with highly induced hepatic receptors. The analysis indicated that only three proteins (SPP1, EPO, and GRP) with an increased hepatic expression due to IMI could potentially interact with receptors involved in leukocytes differentiation/proliferation with an increased expression due to IMI in mammary tissue. The larger enrichment of immune cell-related functions in the data from the mammary tissue suggests increased recruitment of active immune-cells to the mammary tissue. The analysis uncovered a large communication from the mammary to the liver to coordinate the inflammatory response with very few factors potentially released by the liver to control mammary gland response.

Key Words: dynamic impact approach, liver, mastitis, RNaseq

0842 (M031) Identifying the major bacteria causing intramammary infections in individual milk samples of sheep and goats using traditional bacteria culturing and Real-time Polymerase Chain Reaction. M. Rovai[1], G. Caja[1], A. Salama[*1,2], A. Jubert[3], B. Lazaro[4], M. Lazaro[3], and G. Leitner[5], *[1]Group of Ruminant Research (G2R), Universitat Autonoma de Barcelona, Bellaterra, Spain, [2]Animal Production Research Institute, Dokki, Giza, Egypt, [3]Laboratori Interprofessional Lleter de Catalunya (ALLIC), Cabrils, Spain, [4]Vacunek, Ibaizabal Bidea 800, Parque Científico y Tecnológico de Bizkaia, Derio, Spain, [5]National Mastitis Reference Center, Kimron Veterinary Institute, Bet-Dagan, Israel.*

Milk provides the major source of income in dairy farms, while one of the main causes of milk production losses is intramammary infection (IMI). Depending on the bacteria type involved, some bacteria cause clinical infection, while the majority of the bacteria cause subclinical with no visible signs of infection. Consequently, to identify infected animals, as well as the bacteria, milk sampling and laboratory diagnosis are needed. Use of DNA based methods such as real-time PCR has increased sensitivity and shortened time for bacteria identification, compared to traditional bacteriology; however, results should be regarded with caution. One-hundred eight lactating dairy ewes (Manchega, 56; Lacaune, 52) and 24 Murciano-Granadina dairy goats were used for identifying the main bacteria causing IMI using traditional bacterial culturing and real-time PCR and their effects on milk performances. Milk samples were taken aseptically from each udder-half for bacterial culture and somatic cell count (SCC) three times throughout lactation. The IMI was assessed based on bacteria isolated in $\geq$ 2 samplings accompanied by increased SCC. Mammary gland infection was caused mainly by *S. aureus* and various CNS species, and resulted in lowering milk yield and decrease of its quality as indicated by coagulation. Prevalence of subclinical IMI was 42.9% in Manchega, 50.0% in Lacaune and 41.7% in goats, estimated milk yield loss being 13.1, 17.9, and 18.0%, respectively. According to bacteriology results, 87% of the identified single bacteria colonies or culture-negative growths were repeatable throughout samplings, and bacteriology and PCR had 100% agreement. Nevertheless, the study emphasized that one sampling may not be sufficient to determine IMI, and therefore, other inflammatory responses such as increased SCC should be monitored to identify true infections. Moreover, when PCR methodology is used, aseptic and precise milk sampling procedure is the key for avoiding false positive amplifications. In conclusion, both PCR and bacterial culture methods proved to have similar accuracy for identifying infective bacteria in sheep and goats. Final methods choice will depend on their diagnosis time and analysis cost according to the farm management strategy (treatment and/or prevention of new infection).

Key Words: intramammary infection prevalence; small ruminant; real-time polymerase chain reaction

0843 (M032) Antibiotic dry-off therapy for intramammary infections in dairy sheep and goats. *M*. Rovai[1], G. Caja[1], A. Salama[*1,2], C. L. Manuelian[1], X. Such[1], M. Cervino[3], and G. Leitner[4], *[1]Group of Ruminant Research (G2R), Universitat Autonoma de Barcelona, Bellaterra, Spain, [2]Animal Production Research Institute, Dokki, Giza, Egypt, [3]Boehringer-Ingelheim España S.A., Barcelona, Spain, [4]National Mastitis Reference Center, Kimron Veterinary Institute, Bet-Dagan, Israel.*

Mammary glands are susceptible to new infections especially at the end of lactation and before parturition and control of subclinical udder infections is still an issue in small ruminants. Intramammary infections (IMI) during the dry period are likely to remain from the previous lactation to the next or develop during this period, which can lead to reducing milk production in the ensuing lactation. Ninety-four lactating dairy ewes (Manchega, 47; Lacaune, 47) and 20 Murciano-Granadina dairy goats were used to evaluate the effectiveness in reducing the prevalence of IMI with a dry-off antibiotic therapy (one syringe/gland of Mamyzin containing 100 mg of penethamate hydriodide, 280 mg of benethamine penicillin, and 100 mg of framycetin sulphate; Boehringer-Ingelheim, Sant Cugat del Vallès, Spain). At drying-off animals were classified into three groups according to the gland bacteria status: 1) N0 (non-infected animals without treatment), T0 (non-infected animals with dry-off therapy), and T1 (infected animals with dry-off therapy). The goat herd was classified into T0 and T1 groups due to the number of available animals. Prevalence of bacterial isolation from milk was determined at the following lactation (15, 40, and 60 DIM in sheep; 20 and 60 DIM in goats). Coagulase negative staphylococci were the most common isolates at dry-off. Incidence of new IMI was determined taking udder halves, previous infection information and results from all samplings after parturition. Rate of new infection was 20 and 18% for N0 and T0 sheep group, respectively. Mammary gland healthy status did not differ between N0 and T0 groups, showing that in this study, dry-off therapy did not protect against new infections in early lactation. Cure rate for the ewes infected and treated at dry-off was 84% after parturition. For goats, the used of antibiotic cured 67% of T1 group while there was no infection found in T0 does. The use of Mamyzin at dry-off showed to be effective to treat infected glands of sheep and goats, reducing IMI prevalence in the subsequent lactation.

Key Words: dry-off therapy, intramammary infection, dairy ruminants

0844 (M033) Tissue protein nitration and peripheral blood endotoxin activity are indicative of the severity of systemic organ compromise in naturally occurring clinical cases of bacterial mastitis in Holstein dairy cows. S. Kahl*, T. H. Elsasser, and G. Sample, *USDA, Agricultural Research Service, Beltsville, MD.*

The objective of this survey study was to determine a relationship between the intensity of tissue protein tyrosine nitration measured in samples of mammary gland, liver, pancreas, and lung compared to endotoxin (LPS) activity estimated in blood. Blood was collected from nine multiparous Holstein cows on confirmation by the State Diagnostic Laboratory of Maryland of mastitis and the relevant causative pathogen. In addition, control blood was collected from 17 healthy animals (cows and steers). Blood LPS activity (BLA) was estimated using an autologous neutrophil chemiluminescence-based assay (EAA, Spectral Diagnostics, Inc., Toronto, Canada) and expressed as a ratio of chemiluminescence of blood samples without and with an added reference quantity of LPS. In accordance with an approved USDA Animal Care Committee protocol, mastitis animals were subsequently euthanized and tissue collected for immunohistochemical (IHC) quantification (pixel density from digital image analysis) of antigens representative of protein tyrosine nitration (PNT) and inducible nitric oxide synthase (iNOS). Resolved pixel densities for pNT and iNOS were compared to a standardized panel of similar tissues previously obtained from healthy animals. Estimated BLA was higher ($P < 0.01$) in cows diagnosed with clinical mastitis than in healthy cows (0.354 ± 0.068 vs. 0.058 ± 0.010). All mastitic cows presented IHC evidence of pNT and iNOS in the designated lobulo-alveolar mammary tissues from both infected and noninfected quarters and peripheral presence of pNT and iNOS in liver, pancreatic islets, and lung alveolae and bronchiolar epithelial cells ($P < 0.03$ vs. control). Across the spectrum of BLA levels, correlation assessments suggested that the greatest levels of tissue pNT were associated with the higher levels of BLA. Given the known relationship between the presence of pNT in pathologic tissues and organ dysfunction, the data here suggest that mastitis generates perturbations in peripheral organs essential to proper metabolic and pulmonary function.

Key Words: mastitis, endotoxin, protein tyrosine nitration

0845 (M034) Proinflammatory responses of a hTERT-transformed, immortalized line of cultured bovine mammary epithelial cells (BME). T. H. Elsasser*[1], S. Kahl[1], D. E. Kerr[2], E. Zudaire[3], and F. Cuttitta[3], *[1]USDA, Agricultural Research Service, Beltsville, MD, [2]University of Vermont, Burlington, [3]NIH-NCI, Bethesda, MD.*

Cell Characterization: Primary cultures of BME were generated from healthy mammary glands as described (Vet Immunol Immunopath 101(3–4):191–202, 2004). Towards immortalization, BME from four cows were pooled and transfected with pCI neo-hEST2-HA, a human telomerase segment containing a neomycin/Geneticin resistance selection cassette (Cell 90:785–95, 1997). Cells were grown in DMEM +10%FBS and Geneticin (800 μg/ml) and followed through the ensuing selection growth lag to full proliferation capacity. Following 50+ passages, cells were further subcloned to increase epithelial and decrease myoepithelial cell content; the resulting culture was called ELS-321-Clone2B. For function studies and to achieve hormone and cytokine receptor access by the apical-lumenal polarized cells, cultures experiments were conducted on porous (0.4 μm) hanging well inserts coated with laminin-111. At confluence, cells had the following characteristics: tight junctions (electron microscopic confirmation of desmosomes, EpCAM-1 and E-cadherin immunostaining), expression (immunohistochemical localization) of prolactin receptor PRLr, xanthine oxidase (XO), inducible nitric oxide synthase (iNOS), and cytokeratin-18 (< 10% cells displayed myoepithelial smooth muscle actin). Proinflammatory Modeling: Confluent cells were challenged with 20 ng/ml recombinant bovine TNF-α and 200 ng/ml IL-17a. Media was collected at 0, 1, 4, and 24 h relative to challenge with respective cells on inserts fixed in paraformaldehyde for immunofluorescence analysis of nitrated proteins (PNT) and PRLr. Media content of lactate dehydrogenase progressively accumulated past time 0. The first noticeable cell response to challenge was the redistribution of PRLr followed by a reduction in numbers to < 10% T0 values. Cell pNT content was increased at T4, and progressively increased through T24. The data suggest that ELS-321–2B are well-suited to serve as an in vitro model to characterize BME responses to proinflammatory conditions.

Key Words: mammary, cell, proinflammatory

0846 (M035) A snapshot of multi-toxin contamination in feed— Summary of 37+ Analysis results for 2012–13. A. Yiannikouris*, *Center for Animal Nutrigenomics and Applied Animal Nutrition, Alltech, Nicholasville, KY.*

The large number and structural diversity of mycotoxins has impeded rapid quantification using LC-MS/MS owing to varying extraction efficiencies and interferences from feed and food matrices. Alltech researchers have successfully tackled

these challenges by developing the 37+ Analysis. This novel method provides simultaneous and accurate quantification for more than 37 mycotoxins in feed in a cost-effective manner. This approach normalizes losses during extraction and matrix suppression/enhancement by using labeled mycotoxins as surrogates and internal standards. In this analytical setting, four isotopologues were used to normalize the MS signals of known concentrations of 10 mycotoxin groups. During 2012–13, 3322 feed samples were received from across the world and subjected to the 37+ Analysis. The mycotoxin population followed a Gaussian distribution with measurable concentrations of mycotoxins detected in 99.6% of the 3322 samples (average = eight different mycotoxins/sample), with only 14 samples containing no detectable mycotoxins. The number of mycotoxins per sample at measurable concentrations ranged from 2 to 20, with ~87% of samples contaminated with 3 to 11 mycotoxins. Fumonisins closely followed by trichothecene B were the most prevalent. Trichothecenes, ergot alkaloids and other toxins, such as *Aspergillus* and *Penicillium* toxins found in stored feed accounted for 30% of the balance. Interestingly, hot spots of contamination accounted for 10s to 100s of ppm for certain mycotoxins. For the first time, analysis of the distribution of *Penicillium* toxin as well as potential synergistic compounds such as fusaric acid has been made possible. Mycotoxin concentrations were further interpreted and normalized according to known species-specific sensitivities. The latter were evaluated using principles of toxic equivalent factors used to perform risk assessment for PCBs, dioxins and furans and adapted to mycotoxins. This approach allowed evaluating the toxicological risk associated with levels of mycotoxins found in samples and normalized according to the impact of the distribution of the toxin for mixed animal species. The data showed that trichothecenes B accounted for the highest risk to animal performance or health, followed by aflatoxins (despite only accounting for 2% of mycotoxins found), ochratoxin and *Penicillium* toxins. In conclusion, the 37+ Analysis shows that the spectrum of mycotoxins that naturally contaminates feed commodities is exceedingly broad. For the first time, we are proposing a holistic strategy for accounting and reporting multiple mycotoxin contamination trends that were often neglected using other analytical approaches that focused only on a small number of contaminants.

Key Words: mycotoxin, mass spectrometry, UPLC-MS/MS, feed, contamination

0847 (M036) Identification of immune response markers to OmniGen-AF supplementation in a rat model.

J. A. Branson[*1,2], D. J. McLean[1], N. E. Forsberg[1], S. A. Armstrong[1], T. H. Schell[1], and G. Bobe[2], *[1]OmniGen Research, Prince Agri Products, Corvallis, OR, [2]Oregon State University, Corvallis.*

OmniGen-AF (OG; Prince Agri Products, Inc., Quincy, IL) is a branded proprietary product shown to augment immune function in ruminants and other species. Targeted profiling of immune-associated genes in whole blood is an effective platform for identification of multiple immune response markers to feed additives. The objective of this study was to identify multiple immune response markers that are increased by dietary OG throughout a 28-d supplementation period. We hypothesized that several immune-associated genes in whole blood are consistently up-regulated in a 28-d supplementation period. Fourteen male CD rats weighing 180 to200 g had ad libitum access to a diet containing 0 (control; $n = 5$, only 28 d) or 0.5% OG for 7 ($n = 4$) or 28 d ($n = 5$). Whole blood was collected at the end of the feeding period. RNA was purified from whole blood samples and used to generate cDNA that acted as template in the Rat Innate and Adaptive Immune Responses RT^2 Profiler PCR array (SABiosciences). Using PROC GLM, we compared cDNA abundance of immune-associated genes between control and supplemented groups (7 or 28 d) with a $P < 0.05$ cut-off value for significance. Of the 77 immune-associated genes that were expressed above the detection limit in all samples, six genes were up-regulated after 7 d of OG supplementation with only four genes up-regulated after 28 d of OG supplementation. Of these genes, three were up-regulated on both d 7 (Cd80: +2.40; Irak1: +2.25; Nod2: +2.08-fold-change) and 28 (Cd80: +1.77; Irak1: +2.50; Nod2: +1.83-fold-change). In conclusion, our results suggest Cd80, Irak1, and Nod2 as immune response markers are increased by dietary OG throughout a 28-d supplementation period.

Key Words: biomarker, immunity, OmniGen-AF

0848 (M037) Effects of recombinant bovine somatotropin treatment during the transition period on serum growth hormone and insulin-like growth factor 1 concentrations and liver content of lipid, triglyceride, and glycogen.

P. Basso Silva[*1], D. S. Lobao[2], D. H. Keisler[3], and R. C. Chebel[4], *[1]University of Minnesota, St. Paul, [2]Dep. Animal Science, University of Minnesota, St Paul, [3]University of Missouri–Division of Animal Sciences, Columbia, [4]Dep. Veterinary Population Medicine, University of Minnesota, St. Paul.*

Objectives were to evaluate the effects of treatment of peripartum Holstein cows with recombinant bovine somatotropin (rbST) on serum growth hormone (GH) and insulin-like growth factor (IGF)-1 concentrations and liver total lipid

(TL), triglyceride (TG), and glycogen (GLY) contents. Cows were assigned to one of three treatments at 253 ± 1 d of gestation: CON (0 mg/d rbST, $n = 53$), rbST87.5 (87.5 mg of rbST every 7 d, $n = 53$), or rbST125 (125 mg of rbST every 7 d, $n = 53$). Treatments were given weekly from d −21 to 28 relative to calving. Milk production data was collected weekly until 150 d postpartum. Blood was sampled weekly from d −21 to 21 relative to calving for determination of GH and IGF-1 concentrations. Liver biopsies were performed in a sub-group of cows ($n = 10$/treatment) at −21, −7, and 7 d relative to calving for determination of liver contents of TL, TG, and GLY. Continuous data were analyzed by ANOVA using the PROC MIXED. Treatment did not ($P = 0.75$) affect milk production (CON = 45.9 ± 1.3, rbST87.5 = 45.8 ± 1.4, rbST125 = 47.1 ± 1.3 kg/d) but there was an interaction between treatment and day ($P < 0.01$). Treatment affected GH concentration (CON = 13.0 ± 0.9, rbST87.5 = 16.1 ± 0.9, rbST125 = 18.2 ± 0.9 ng/ml; $P < 0.01$). Concentration of GH of rbST125 cows tended to be higher than rbST87.5 cows ($P = 0.11$), and rbST87.5 ($P = 0.02$) and rbST125 ($P < 0.01$) cows had higher GH concentrations than CON cows. Treatment tended ($P = 0.06$) to affect IGF1 concentration (CON = 84.6 ± 3.5, rbST87.5 = 92.9 ± 3.5, rbST125 = 96.2 ± 3.5 ng/ml). IGF-1 concentration was not ($P = 0.50$) different between rbST87.5 and rbST125 cows, but rbST87.5 cows tended to ($P = 0.10$) and rbST125 cows had ($P = 0.02$) greater IGF1 concentration than CON cows. The interaction between treatment and day ($P = 0.01$) demonstrated that the rbST treatment effect on IGF-1 concentration was observed primarily before calving. There was no effect of treatment on TL ($P = 0.80$) and TG ($P = 0.24$) liver content. Although GLY liver content was not ($P = 0.19$) affected by treatment, rbST125 cows tended to have greater GLY liver content compared to rbST87.5 ($P = 0.10$) and CON ($P = 0.13$) cows at −7 and 7 d relative to calving. Peripartum treatment with rbST increased serum GH concentration during the peripartum period and serum IGF1 concentration prepartum. The increased GLY liver content in rbST treated cows may indicate a more efficient use of fatty acids and sparing of glycogen as a consequence of rbST treatment.

Key Words: transition cow, recombinant bovine somatotropin, metabolism

0849 (M038) Vitamin D signaling enhances expression of antibacterial β-defensin genes in bovine monocytes.

C. D. Nelson*[1], K. E. Merriman[1], and J. D. Lippolis[2], *[1]Dep. of Animal Sciences, University of Florida, Gainesville, [2]USDA, ARS, National Animal Disease Center, Ames*

Vitamin D contributes to immunity of cattle via an intracrine vitamin D pathway that is activated in macrophages in response to recognition of pathogens. The 1,25-dihydroxyvitamin D_3 ($1,25(OH)_2D_3$) that is produced in that pathway activates the vitamin D receptor and regulates the transcription of vitamin D-dependent genes. RNA sequence analysis of $1,25(OH)_2D_3$–treated monocytes compared to control-treated monocytes identified bovine β-defensin 3 (DEFB3) and β-defensin 6 (DEFB6) as potential targets of the activated vitamin D receptor. The DEFB3 and DEFB6 genes encode for small antibacterial peptides and are located on bovine chromosome 27 along with DEFB1, DEFB4A, DEFB5, DEFB7, DEFB10, enteric β-defensin (EBD), lingual antimicrobial peptide (LAP), and tracheal antimicrobial peptide (TAP). The objective of this study was to evaluate the effects of $1,25(OH)_2D_3$ on expression of the β-defensin genes in resting and stimulated monocytes. Peripheral blood monocytes from eight Holstein cows were treated with 0 or 100 ng/mL lipopolysaccharide (LPS) in combination with 0 or 10 nM $1,25(OH)_2D_3$ and cultured for 24h. The mRNA transcripts for each of the β-defensin genes were measured with real-time PCR and normalized to ribosomal protein S9 transcript abundance. The effects of $1,25(OH)_2D_3$ and LPS on expression of each of the β-defensin genes was analyzed with a general linear model that accounted for effects of cow and treatment. In the non-stimulated monocytes, the $1,25(OH)_2D_3$ treatment increased DEFB3, DEFB6, DEFB7, and DEFB10 gene expression ($P < 0.05$; 10 ± 3, 17 ± 8, 4 ± 1, and 5 ± twofold change ± SE, respectively). Similarly, the $1,25(OH)_2D_3$ treatment increased DEFB3, DEFB6, DEFB7, and DEFB10 gene expression in the LPS-stimulated monocytes ($P < 0.05$; 10 ± 3, 60 ± 28, 7 ± 2, and 20 ± sixfold change ± SE, respectively). DEFB1, DEFB4A, DEFB5, DEFB13, EBD, LAP, and TAP were not affected by $1,25(OH)_2D_3$ in either resting or LPS-stimulated monocytes. In addition, LPS treatment alone did not significantly increase any of the β-defensin genes evaluated in this study ($P > 0.05$). In conclusion, $1,25(OH)_2D_3$ induces expression of the DEFB3, DEFB6, DEFB7, and DEFB10 genes in bovine monocytes. Upregulation of these β-defensin antimicrobial genes in response to $1,25(OH)_2D_3$ suggests vitamin D is needed in cattle to support innate host defense mechanisms.

Key Words: vitamin D, innate immunity

0850 (M039) Effects of genotype and transportation stress on cytokine gene expression in steers.

M. A. Sales*[1], M. Ata[1], B. Williamson[1], K. P. Coffey[1], M. L. Looper[2], and C. F. Rosenkrans[1], *[1]University of Arkansas, Fayetteville, [2]USDA-ARS Dale Bumpers Small Farms Research Center, Booneville, AR*.

The objective of this study was to determine effects of transportation stress and single nucleotide polymorphisms (SNP) in the coding sequence of two stress indicators, cytochrome P450 and the prolactin promoter region (C994G and C1286T, respectively), on gene expression of the prolactin receptor (PRLR) and three cytokines: monocyte chemoattractant protein (MCP-1 or CCL2), interleukin-8, and tumor necrosis factor (TNF)-&α. Relative gene expression was quantified

by real-time reverse transcription PCR using custom-made TaqMan assays for each gene of interest (Applied Biosystems, LifeTechnologies, Carlsbad, CA) in peripheral blood mononuclear cells of Gelbvieh x Angus crossbred steers (n = 47; mean body weight = 303 ± 39 kg; mean age = 294 ± 19 d). Three time points relative to transport (T): 27 h before (T−27), and 6 and 20 h after transport (T+6 and T+20, respectively) from Booneville, AR to Stillwater, OK (386 km) were evaluated. Time relative to transport, genotype, and their interaction affected ($P < 0.05$) gene expression. A C1286T x time interaction affected ($P < 0.01$) CCL2 expression: lowest level was in CT steers at T+6. Time affected ($P < 0.01$) PRLR and TNF-&α; expression in both C994G and C1286T genotypes: highest level was at T+20, whereas expression at earlier time points was similar. Genotype affected CCL2 expression on both C994G and C1286T genotypes: expression levels were lowest ($P < 0.0001$) when steers were CT for the C1286T SNP, or CC ($P < 0.01$) for the C994G SNP. Genotype effects on PRLR and TNF-&α expression were evident only in C1286T genotypes: greatest ($P < 0.01$) expression of both genes was in CC steers. Our findings suggest that genotypes at C994G and C1286T SNP sites influence cytokine gene expression and may therefore be used as biomarkers for animal tolerance to shipping stress. Investigating effects of other stressors before and/or after transport on the expression of other stress response genes will help identify critical control points when developing practical and/or therapeutic measures to reduce transport stress.

Key Words: cytochrome P450, cytokine, prolactin

0851 (M040) prevalence and molecular identification of *Cryptosporidium* spp. in lambs on the Huasteca Alta region, State of Veracruz, México. S. S. Gonzalez[1] and I. Vitela-Mendoza*[2], [1]*Colegio de Postgraduados, Montecillo Estado de México,* [2]*Instituto Tecnologico El LLano, Aguascalientes, México.*

Cryptosporidium is a protozoan parasite that causes enteric infection in several mammalian species, including humans. This infection has a major impact in immunocompromised domestic mammals and public health because the parasite oocysts are resistant to environment and can contaminate food and water. In sheep, cryptosporidiosis is presented with mild to severe yellowish diarrhea, plus weight loss, depression, abdominal pain, and eventually the animal may die; usually, it is more common in lambs 1 to 30 d old. Therefore, the objective of this study was to determine the prevalence of *Cryptosporidium* spp., and identify the species of the oocysts in lambs maintained in extensive grazing systems at the Huasteca Alta region, Veracruz, México. From March to June 2012, 210 fecal samples were collected from Blackbelly x Pelibuey lambs 7 to 21 d old from 21 flocks located in seven locations at the Huasteca Alta region. The samples were processed by performing a fecal smear and then dyed by the Kinyoun acid-alcohol resistant staining, and then were observed with a microscope (LCD Digital Leica) at 100 X. A molecular diagnosis was performed using nested PCR to amplify the region of the 18S rRNA gene of the parasite (830 bp), and the positive samples were sequenced. The overall prevalence of *Cryptosporidium* spp. infection in lambs was 19.5%: 10.5% in 7 to 14 d old, and 9% in 15 to 21 d old. The prevalence in flocks ranged from 10 to 40%, and in 62% of them there was at least one infected lamb. In the seven locations positive lambs were detected, and the highest prevalence was observed in Tamiahua (36.67%). The sequenced samples had a homology between 96 and 100% with the 18S rRNA region of *C. parvum*. This is the first report of the presence of *C. parvum* in lambs in the Mexican tropic.

Key Words: *Cryptosporidium*, sheep, genotyping.

0852 (M041) Bacteriological culture and California Mastitis Test results of non-clinical quarters from cows with clinical mastitis. A. Lago[1] and N. Silva-del-Rio*[2], [1]*DairyExperts, Tulare, CA,* [2]*VMTRC, University of California, Tulare.*

The economic value of lactation therapy of subclinical mastitis with antibiotics is generally considered to be limited because of the cost of milk discarded during the withdrawal period. However, the treatment of quarters affected with subclinical mastitis when treating other quarters affected with clinical mastitis does not result in additional discarded milk. The objectives of this study were: a) describe bacteriological culture results of non-clinical quarters in cows affected with clinical mastitis; and, b) validate the California Mastitis Test (CMT) to identify subclinically infected quarters in these cows. A total of 109 cows with clinical mastitis from two dairy herds were identified with clinical mastitis at the general parlor and moved to a hospital pen, where they were milked at a hospital parlor. At the first milking at the hospital parlor, the CMT was performed and a milk sample was aseptically collected for culture from all quarters (clinical and non-clinical). Bacteria were isolated from 52% of the 110 quarters affected with clinical mastitis and from 35% of the other 319 non-clinical quarters. Coliforms (35%), non-agalactiae Streptococcus (25%), and coagulase-negative Staphylococcus (23%) were the bacteria most commonly isolated from clinical quarters. In non-clinical quarters coagulase-negative Staphylococcus (49%), *Bacillus* spp. (21%) and non-agalactiae Streptococcus (13%) were the bacteria most commonly isolated. Of all cows with clinical mastitis, 67% of them had bacteria isolated from at least one of the three non-clinical quarters. If also considering the quarter affected with clinical mastitis, 82% of the cows had at least one quarter infected. The CMT was evaluated for three diagnostic interpretations: identify bacterial growth, identify gram-positive bacterial growth, and identify non-agalactiae streptococci infections. The sensitivity of the CMT was 38, 43, and 29%, and the specificity 71, 70, and 68% for each one of the diagnostic interpretations, respectively. Therefore, the

CMT was not a sensitive enough tool for the identification of subclinically infected quarters in cows with clinical mastitis. The high proportion of infected non-clinical quarters in cows with clinical mastitis may warrant the need to evaluate the efficacy and cost-benefit of treating clinical and subclinical quarters simultaneously.

Key Words: clinical mastitis, subclinical mastitis, California Mastitis Test

0853 (M042) Effect of early feed restriction programs on IgY production of broiler chickens. M. L. Moraes*, F. M. Butzen, M. M. Vieira, C. M. M. Pimente, and A. M. L. Ribeiro, *Universidade Federal do Rio Grande do Sul, Porto Alegre, Brazil.*

It is known that feed restriction increases antibody production in poultry, but very little research exists exploring the after effects of feed restriction on the adaptive immune system. The objective of this experiment was to evaluate the effects of different programs of early feed restriction on IgY production in broiler chickens. A total of 384 Cobb 500 male broiler chicks were randomly assigned to 24 pens at d 1 of age. The study lasted 42 d. After a week adaptation period, four treatments were applied from d 8 to 16: T1– control group, standard diet (SD); T2– quantitative feed restriction (80% of ad libtum feed intake of the SD, according to the breeder management guide); T3– feed restriction by time (SD offered during 8 h/day); and T4– qualitative feed restriction (80% of the limiting nutrients; SD was diluted by the addition of 10% kaolin and 10% rice husk). At d 7 and 21, birds were injected with bovine serum albumin (BSA), and blood samples were collected weekly from d 7 to 42 for assessment of IgY anti-BSA production. There was no effect ($P > 0.05$) of the first BSA inoculation between treatments; however, at 28 d of age, birds in all the three early feed restriction programs had higher IgY anti-BSA than the control group ($P < 0.05$). At d 35, the quantitative and the by time feed restriction groups still showed residual effects of the BSA injection, but no difference ($P > 0.05$) was observed between the four treatments at 42 d. It is concluded that the three different programs of early feed restriction had beneficial effect on the humoral immune system after the restriction program had ended. Overall, the quantitative and the by time feed restriction programs promoted the longer lasting responses.

Key Words: chicken, feed restriction, IgY

0854 (T001) Immune status of dairy heifer calves in the northern plains of Costa Rica. Year III.

J. A. Elizondo-Salazar*[1], J. J. Arroyo-Arroyo[2], J. Sanchez-Salas[3], and J. Heinrichs[4], *[1]Estación Experimental Alfredo Volio Mata, Facultad de Ciencias Agroalimentarias, Universidad de Costa Rica, [2]Universidad de Costa Rica, San José, [3]Cooperativa de Productores de Leche Dos Pinos R.L, San Jose, Costa Rica, [4]Pennsylvania State University, University Park.*

The objective of this study was to characterize the immune status of dairy calves in the northern plains of Costa Rica. The results correspond to total serum protein (TSP) measurements obtained from 657 female calves in 23 dairy farms during the period of August and November 2012. Dam breeds were classified into Holstein, Jersey, Holstein x Jersey crosses, and other. Blood samples were collected between d 1 and 7 of age into serum (red top) Vacutainer tubes, refrigerated overnight, centrifuged, and the serum separated from clot within 24 h of collection. A hand-held refractometer was used to measure STP. For the purpose of this study, failure of passive immunity was considered when TSP concentration was less than 5.5 g/dL. GLM procedure was used to establish differences between parity and breed of the dams. Descriptive statistics were generated to define percentage of failure of passive transfer by breed and parity of the dam. TSP concentration ranged from 2.4 to 10.0, with an overall mean of 5.7 g/dL. Of all the calves evaluated, 44.9% presented failure of passive transfer. Calves born to Jersey and Holstein x Jersey crosses had significantly higher TSP concentrations than calves born to Holstein and other breeds. When considering lactation number of the dam, offsprings born to third lactation cows showed the lowest percentage of calves with inadequate transfer of immunity. The findings of this study suggest that colostrum management practices should be placed to minimize the risk of failure of passive transfer in dairy herds in the northern plains of Costa Rica.

Key Words: total serum protein, immunoglobulins, passive immunity

0855 (T002) Passive transfer of immunity of dairy calves in the central northern region of Costa Rica.

J. A. Elizondo-Salazar*[1], O. A. Vargas-Villalobos[1], L. Noguera-Solera[2], and J. Heinrichs[3], *[1]Estación Experimental Alfredo Volio Mata, Facultad de Ciencias Agroalimentarias, Universidad de Costa Rica, [2]Cooperativa de Productores de Leche Dos Pinos R.L, Alajuela, Costa Rica, [3]Pennsylvania State University, University Park.*

The objective of this study was to characterize the immune status of dairy calves in the central northern region of Costa Rica. The data correspond to total serum protein (TSP) measurements obtained during the period of August and November 2012 in 47 dairy farms. Three hundred thirty-seven female and 127 male calves were sampled. Dam breeds were classified into Holstein, Jersey, Holstein x Jersey crosses, and other. For the purpose of this study, failure of passive immunity was considered when TSP concentration was less than 5.5 g/dL. TSP concentration ranged from 3.0 to 10.0, with an overall mean of 5.7 g/dL. Of all the animals evaluated, 40.5% had failure of passive transfer. When sex of the calves was considered, 39.2% of females and 44.1% of males failed to obtain adequate concentration of TSP, and there were no significant differences (5.8 vs. 5.7 g/dL, respectively) ($P > 0.05$). Calves born to Holstein cows had significantly lower TSP concentrations than calves born to other breeds ($P > 0.05$). When considering calving of the dam, there were no significant differences on TSP concentration of calves; however, offspring born to fourth lactation cows showed the highest percentage of animals with inadequate transfer of immunity. Calves that were allowed to suckle their dams showed a 48.8% failure of passive immunity against 34.1% of calves that were given colostrum by bottle. The findings of this study suggest that colostrum management practices should be placed to minimize the risk of failure of passive transfer in dairy herds in the central northern region of Costa Rica.

Key Words: total serum protein, immunity, passive immunity

0856 (T003) Effects of added spray-dried whole colostrum and spray-dried plasma on veal calf health and performance.

D. Wood, R. Blome, and J. Sowinski, Animix, Juneau, WI.*

The study objective was to evaluate the effects on calf health and performance from supplementing either whole spray-dried colostrum (SDC) or additional spray-dried plasma (SDP) on top of a spray-dried plasma-containing (5.2% plasma inclusion rate, otherwise all-milk) veal starter formula (fed d 1 to 57) and a spray-dried plasma-void veal finisher formula (fed d 58 to 140). Auction-sourced Holstein bull calves ($n = 128$; approximately 1 wk of age) were randomly placed in individual, raised stalls for 10 wk and were then reared as pairs loose-

housed. Treatment pairs were equally placed within each row, i.e., calves in stalls 1 and 2 were fed supplemental WPC/dry fat blend control (WPC), calves in stalls 3 and 4 were supplemented SDP/dry fat blend, and calves in stalls 5 and 6 were supplemented SDC. SDC contained 13% IgG and SDP/dry fat blend was formulated to also contain 13% IgG. Both SDC and WPC were 44.3% CP and 18.1% fat. To be formulated with 13% IgG and 18.1% fat, SDP had to contain 57.3% CP, resulting in SDP-fed calves receiving an additional 200 g of CP over the feeding period verses SDC or WPC. Calves experiencing FPT (< 5.5 g/dL serum total protein) were 70.4, 76.2, and 83.3% of all calves in WPC-, SDP- and SDC-fed groups, respectively. The calves were fed formula and supplemented 25 g/feeding (2x/day) of the respective supplement wk 1, 15 g/feeding wk 2, 10 g/feeding wk 3 through 5, 5 g/feeding wk 6 and 7, and 2.5 g/feeding wk 8 through 20, when slaughtered. Accounting for total solids intake, calves were started on a 25:18 (CP:Fat), increased to 871 g/day of a 21:18 by 21 d age (medicated to d 21) and 1742 g per day of a 20:18 by 53 d age. Calves received no dry feed. Data was analyzed using F-test for variances and student *t* test comparing two means. Calves fed additional SDP outgained ($P < 0.05$) WPC by +2.52 kg d 1 through 53 (SDC was intermediary). SDC tended ($P < 0.077$) to outgain WPC by +8.57 kg d 53 through 140 (SDP was intermediary). SDP and SDC reduced incidences of refusals ($P < 0.05$). SDC tended ($P < 0.082$) to reduce the number of calves treated verses SDP (WPC intermediary). SDC and SDP improved intake. SDP improved 53-d gains.

Key Words: calf, colostrum, plasma

0857 (T004) Holstein calves fed non-saleable milk that was pasteurized or raw had decreased incidence of abnormal feces and hematology measures than calves fed accelerated milk replacer.

L. E. Hulbert[*1], J. A. Noel[2], S. C. Trombetta[1], S. R. Montgomery[1], G. A. Hanzlicek[3], and B. J. Bradford[1], *[1]Dep. of Animal Sciences and Industry, Kansas State University, Manhattan, [2]Kansas State University, Manhattan, [3]Diagnostic Medicine Pathobiology, College of Veterinary Medicine, Kansas State University, Manhattan.*

The objectives were to determine the health and blood parameters before, during, and after weaning of 114 Holstein heifers fed either accelerated milk-replacer (Mrp; 28% CP, 18% fat) or non-saleable milk (3.59 ± 0.28% True-Protein; 4.12 ± 0.37% fat) that was either pasteurized (*P*st) or raw (Raw; refrigerated and fed < 24 h after collection). Calves were randomly assigned feeding treatments at age 0 d. Colostrum (1 L) was fed in less than 14 h after birth (Mrp and Pst = pasteurized colostrum; Raw = raw colostrum). All calves were bottle-fed 1.8 ± 0.20 SD L, 3x/day; all calves were provided fresh water and grain ad libitum throughout the experiment. Calves began step-down weaning at age 5 wk and completed weaning at age 6 wk. Blood samples were collected at ages 3, 5, and 7 wk and were analyzed for complete blood counts (CBC) using a Procyte Idexx Analyzer. In addition, whole blood was tested for bactericide capacity against live *E. coli* 51813 (%Bact). Fecal scores were observed twice daily, on a 1-to-3 scale (FS1 = normal, FS2 = loose, FS3 = scours). The Mrp-fed calves had more ($P < 0.01$) observations (% obs) with FS2 than the Pst- and Raw-fed calves (13.2 vs. 7.32 and 8.9 ± 0.69% obs, respectively), although there were few scouring (FS3; 0.36 ± 0.01% obs) incidences in this experiment. Likewise, Mrp-fed calves had greater hematocrit % compared to the other calves ($P < 0.01$), but Pst- and Raw-fed calves had similar hematocrit % (32.4 vs. 27.9 and 28.4 ± 0.55%, respectively). At age 3 wk, Mrp-fed calves had greater circulating monocytes ($P = 0.02$) compared to the other calves, but there were no differences between Pst- and Raw-fed calves (10.4 vs. 9.2 and 8.2 +0.40%, respectively). Although there were no differences among treatments for % Bact or other hematological measures ($P > 0.10$), all calves had lower neutrophil:lymphocyte, more circulating monocytes and greater % Bact at age 7 wk compared to ages 3 and 5 wk ($P < 0.05$), suggesting that the change in diet from milk or MR to grain influences innate immune and hematological measures. The increased incidence of abnormal fecal scores among Mrp-fed calves and higher hematocrit percentages needs further consideration, especially before age 3 wk. In addition, these findings suggest that raw milk may be adequate for maintaining healthy CBC and fecal score measures on a well-managed, low-disease incidence dairy.

Key Words: milk replacer, pasteurization, calves, hematology

0858 (T005) Effects of Celmanax supplementation to prepartum dairy cows on colostrum quality and the subsequent growth and health of their calves.

C. Campos-Granados[*1], A. Rojas-Bourrillon[1], and C. C. Elrod[2], *[1]University of Costa Rica, San Jose, [2]Vi-COR, Inc., Mason City, IA.*

The objective of this study was to assess the effects of supplementing prepartum dairy cows with a product derived from yeast culture and enzymatically hydrolyzed yeast cell wall (Celmanax (CEL), Vi-COR, Mason City, IA) on colostrum quality and the subsequent health and performance of their calves. Thirty prepartum multiparous Jersey cows were blocked by parity, body condition 21 d before expected calving date and productive and reproductive performance, and randomly assigned within block to one of two treatments ($n = 15$) from 21 d before expected calving date until calving. Rations were top-dressed with CEL at the rate of 0 or 40 g/d throughout the experiment. Calves were fed 3 L of colostrum from their dam within 2 h of birth and then 4 L of whole milk daily through wk 8. Total Ig in colostrum from each cow was evaluated at 25°C from the first milking with a Colostrometer, and a sample was taken for determination of IgG by ELISA.

Approximately 48 h after birth, a blood sample was drawn by venipuncture from each calf for the determination of serum protein by refractometer and IgG by ELISA. Daily feed intake, weekly weight and hip height, and the incidence of pneumonia and scours were recorded. Data were analyzed using mixed models with repeated measures over time. Total Ig in colostrum was significantly increased by CEL treatment ($P < 0.05$; 90.06 ± 23.74 vs. 105.94 ± 17.59 mg/mL for 0 and 40 g/d, respectively) but there was no effect on colostrum yield or IgG content ($P > 0.05$). There was no effect of treatment on birth weight, serum protein, or serum IgG ($P > 0.05$). Average daily gain (382.86 ± 61.20 vs. 410.94 ± 51.22 g/day for 0 and 40 g/day, respectively), hip height increase (1.45 ± 0.33 vs. 1.70 ± 0.31 cm/week for 0 and 40 g/d, respectively), and feed consumption (446.67 ± 9.92 vs. 439.01 ± 6.12 g/day for 0 and 40 g/d, respectively) were not affected by treatment ($P > 0.05$). Odds ratios were calculated and the odds of a calf presenting with scours or pneumonia were 3.5 and 5.0, respectively, times more likely in the calves whose dams did not consume CEL prepartum. CEL supplementation prepartum improved colostrum quality and calf health.

Key Words: immunity, transition cow, calf, health, yeast culture.

0859 (T006) Maternal energy status during mid-gestation affects the immune response in the resultant beef offspring. A. R. Taylor*[1], D. A. Mohrhauser[1], R. Neiger[1], E. J. Blom[1], K. R. Underwood[1], R. H. Pritchard[1], A. E. Wertz-Lutz[2], B. P. Holland[3], and A. D. Weaver[4], *[1]South Dakota State University, Brookings, [2]ADM Alliance Nutrition, Inc., Quincy, IL, [3]Merck, Volga, SD, [4]South Dakota State University, Rapid City.*

Fetal or developmental programming relates the effects of maternal stressors on the developing fetus and potential consequences later in life. Specifically, beef cattle may experience decreased forage availability and quality during gestation, potentially altering nutrient availability and ultimately fetal development. Immune function has major economic implications in the beef industry; however, the understanding of maternal environment on development of the immune system in beef offspring is limited. Therefore, the objective of this study was to determine the effects of maternal energy status during mid-gestation on humoral immune response and tissue morphology of immunologically relevant tissues in beef offspring during the feedlot phase. Beef cows were allotted to one of two treatments: 1) Positive Energy Status (PES; $n = 76$)-fed to maintain BCS 5.0–5.5; or 2) Negative Energy Status (NES; $n = 75$)-fed to lose 1 BCS over the ensuing 91-d mid-gestation period (84 ± 11 d). Following treatment, cows were commingled and managed as a common group through weaning. Calves were weaned, shipped, and allotted into feedlot pens according to gender, dam energy status, and stratified by weight. A subsample ($n = 30$) of calves were subcutaneously injected with 4 mg ovalbumin antigen at d 0 of antigen challenge and again on d 28 of antigen challenge, with blood collected every 7 d from d 0 through d 56 to measure antibody titers. An ELISA was used to determine serum antibody titers in response to the ovalbumin challenge. Additionally, a subsample of calves were harvested following the receiving ($n = 12$) and finishing period ($n = 12$) for histological examination with hematoxylin and eosin stain of lymph nodes, spleen tissue, and gut-associated lymphoid tissue. Ovalbumin data were analyzed as a repeated measures model using the PROC MIXED of SAS (SAS Inc., Cary, N.C.). No morphological differences were observed in tissues. There were no differences ($P > 0.05$) in gender main effects in response to a novel antigen. An anamnestic response was observed over time ($P < 0.05$), which was expected following second exposure to the antigen. There was a difference ($P < 0.05$) between treatments over the sampling period with calves from PES cows having a greater antibody titer of 13.44 compared to calves from NES cows with an antibody titer of 12.38. These results suggest cows in a NES during mid-gestation produce calves with a decreased ability to produce antibodies to a novel antigen and thus a decreased humoral immune response.

Key Words: cattle, fetal programming, immunology

0860 (T007) Comparison of ivermectin and extended-release eprinomectin deworming treatment on stocker and subsequent feedlot performance and carcass characteristics of fall-born Angus heifers. C. A. Clark*[1], B. J. Dedrickson[2], J. L. Sorensen[2], and P. J. Gunn[3], *[1]Armstrong Memorial Research and Demonstration Farm, Iowa State University, Lewis, [2]Merial, Duluth, GA, [3]Iowa State University, Ames.*

The objective of this study was to compare the effects of ivermectin and extended-release eprinomectin on stocker and feedlot performance as well as carcass characteristics. Sixty purebred, fall-born Angus heifers (277 ± 23 kg BW; 4.90 ± 0.34 BCS) were blocked by BCS and BW, and allotted to one of two injectable deworming treatments after 35 d of grazing summer pasture: 1) ivermectin (Ivomec; IVO), or 2) extended-release eprinomectin (LongRange; LR). Concurrent fecal samples were taken at treatment initiation. Heifers were placed back on the same pasture until the pasture was no longer suitable for grazing (total of 63 d). Interim BW was taken 27 d after treatment initiation, and fecal samples, BW, and BCS were taken at grazing termination. At grazing termination, heifers were transported to a feedlot where they remained commingled and fed a finishing ration for 150 d. Upon arrival, heifers were stratified by BW within grazing treatment and allotted to either receive (Ivomec; DWRM) or not receive a deworming treatment at processing (NO). Fecal samples were collected 4 d before transport for slaughter. Carcass data were collect by the Tri-County Steer Carcass Futurity. Binary

and continuous data were analyzed using the GLIMMIX and PROC MIXED of SAS, respectively. Heifer BW and BCS did not differ between treatments throughout the grazing period ($P \geq 0.67$). Although ADG did not differ during the first 27 d, LR heifers had greater overall ADG and increased BW change ($P = 0.01$) during the grazing period. Although fecal egg count (FEC) did not differ at treatment initiation, FEC was greater in IVO (5.138 eggs/g) than LR (0.073 eggs/g) heifers at grazing termination ($P < 0.01$). Final fecal egg counts were nearly undetectable before transport to slaughter and did not differ ($P \geq 0.16$). There were no differences in feedlot performance or carcass characteristics due to grazing period, feedlot period or the interaction between the two treatments ($P \geq 0.09$). Based on data presented in this study, in cattle that have been effectively managed to reduce or eliminate internal parasite infection during a grazing period, there may be no benefit to deworming at feedlot arrival. However, even at extremely low, subclinical levels of infection during the stocker phase, parasites can have a significant impact on performance. These data highlight the importance of parasite control during the stocker phase, even at subclinical infection levels.

Key Words: feedlot, parasite, stocker

0861 (T008) Effect of rumen and fecal inocula from calves fed either milk replacer or whole milk fed on intestinal cells and digestive tract microbiota.

M. Terré*[1], S. Genís[1], C. Yunta[1], A. Bach[2], and A. Arís[1], *[1]IRTA, Caldes de Montbui, Spain, [2]Dep. of Ruminant Production, IRTA, Caldes de Montbui, Spain.*

The objective of this study was to evaluate cell viability and inflammatory status of intestinal cells incubated with rumen and fecal inocula obtained from Holstein calves fed either a milk replacer or whole milk. Liquid rumen and fecal samples were obtained from 10 calves at 5 wk of age. Calves were either fed a milk replacer supplemented with *Enterococcus faecium* at the rate of $1.5x10^9$ cfu/kg (MR), or whole milk (WM). Samples from each group of animals (five animals per group) were pooled, centrifuged, and suspended with PBS at 3%. *Lactobacillus and Bifidobacteria* were quantified by qPCR from the rumen and fecal-pooled samples. The experiment was repeated twice with 10 other calves fed similarly. Jejunum tissue from 12-mo-old bulls was collected at a slaughterhouse to obtain jejunum primary cells and perform further in vitro experiments. Jejunum cells were cultured during 6 h with the fecal and ruminal inocula in 24-well plates at 37°C under a 5% CO_2 atmosphere. After the incubation, the supernatant was recovered to determine LDH activity as a cell damage marker. Cells were washed and lysed with TriZol (Invitrogen) to extract RNA and quantify, by qPCR, the expression of TNFα as an inflammation marker. Data were analyzed with a mixed-effects model considering sample and milk type as fixed effects, and period as random effect. *Bifidobacteria* and *Lactobacillus* contents were greater ($P < 0.05$) in feces (15.6 ± 1.04 and 14.1 ± 0.73 Ct, respectively) than in rumen (21.8 ± 1.04 and 21.8 ± 0.73 Ct, respectively) samples, and *Bifidobacteria* contents tended ($P = 0.10$) to be greater in samples from MR than in those from WM calves (17.1 vs. 20.2 ± 1.04 Ct, respectively). Viability of jejunum cells and the expression of TNFα were similar when cultured with rumen inoculum from MR and WM calves. However, LDH activity was greater ($P < 0.05$) in jejunum cells (less cell viability) when incubated with fecal inoculum from WM (0.50 ± 0.296 mU/mL) than from MR (0.14 ± 0.296 mU/mL) calves. The expression of TNFα was greater ($P < 0.05$) when cells were incubated with MR ($8.8x10^5 \pm 8.89x10^6$) than with WM ($3.2x10^5 \pm 8.89x10^6$) fecal inoculum. In conclusion, fecal inoculum from MR calves improve cell viability and trigger the inflammatory status of intestinal jejunum cells when compared with WM fecal inoculum. These effects might be mediated by the greatest amount of *Bifidobacteria* in the fecal samples from MR calves, which might be favored, by the presence of *Enterococcus faecium*in the milk replacer.

Key Words: jejunum primary cells, milk replacer, whole milk

0862 (T009) The effect of four antiseptic compounds on umbilical cord healing and infection rates in the first 24 h in dairy calves from a commercial herd.

A. L. Robinson*, L. L. Timms, K. Stalder, and H. D. Tyler, *Iowa State University, Ames.*

The objective of this study was to compare the effect of four umbilical dips on the healing rate and incidence of infection of umbilical cords in newborn calves ($n = 60$). Late gestation Jersey cows were monitored at a commercial farm (Sioux Jersey; Salix, IA) and newborn purebred ($n = 30$) and crossbred ($n = 30$) calves were obtained within 30 min after birth. Calves were alternately assigned by birth order to four treatment groups: 7% iodine, 1000 ppm chlorine created using a novel chlorine disinfectant technology (ECAlogix System– Zurex Pharmagra), chlorohexidine, and ZuraLac (Zurex Pharmagra). Before dipping (within 30 min of birth), diameter of the umbilical cords (as an indicator of cord drying and healing) were determined using digital calipers. In addition, as an indicator of umbilical infections, surface temperature of the umbilical stump (along with a reference point at the midpoint of the sternum) was determined using a dual laser infrared thermometer (model 42570, Extech Instruments Nashua, NH). These measurements were all repeated at 24 ± 1 h of age. All data were analyzed using mixed model methods (PROC MIXED, SAS version 9.2). All models included the fixed effects of breed (Jersey or Jersey cross), sex (bull or heifer) and treatment. Fixed effect interactions were not included in the statistical model due to the relatively small sample size. There were no treatment differences ($P > 0.05$) for healing rate of umbilical cords. Initially, mean umbilical cord diameter was 22.84 ± 3.89 mm, and they healed to a mean diameter of 7.64 ± 4.12

mm at 24 h of age. Similarly, there were no treatment effects ($P > 0.05$) on incidence of umbilical infections. Mean surface temperature of the umbilical stump was 33.1 ± 2.2° at birth (1.5 ± 1.6° higher than the sternal reference temperature) and at 24 ± 1 h of age the mean temperature of the umbilical stump was 33.0 ± 4.3° (0.5 ± 1.8° lower than the sternal reference temperature). These data suggest that these dips are equally effective for preventing infections and permitting healing of the umbilical cord when used within 30 min of birth.

Key Words: calves, umbilical cord, umbilical dip

0863 (T010) Relationship between birth weight and calving ease with passive transfer of immunoglobulins in neonatal beef calves.

J. J. Gaspers*[1], G. Stokka[2], B. W. Neville[3], and C. R. Dahlen[1], *[1]North Dakota State University, Fargo, [2]North Dakota State University, Cooperstown, [3]North Dakota State University, Streeter.*

The absorption of immunoglobulins (Ig) found in the colostrum is a passive transfer of immunity that neonatal calves will receive from their dams. Calves that do not receive adequate levels of Ig from their dams can experience increased morbidity and mortality. Primiparous commercial crossbred beef heifers ($n = 53$) were used to evaluate the relationship of Ig absorption from colostrum and passive transfer of immunity on various neonatal traits. Heifers calved in March and April. Females were kept in a dry lot and fed a total mixed ration meeting 100% of NRC requirements through parturition. Onset of the third stage of labor, time to birth, time to stand, and time of first nursing were recorded. Calving ease (CE; 1 = no assistance, 5 = caesarian section), calf vigor (CV), birth weight, and 24-h blood samples for serum Ig were taken from each calf via jugular venipuncture. Mothering score, colostrum samples for colostral Ig, weight, body condition score, udder suspension (1 = broken floor, 9 = very tight), and teat size (1 = very large, 9 = very small) were recorded from the dams. All statistical analyses were conducted using PROC Reg and PROC Corr in SAS. There was a negative correlation between serum IgG and CE ($P = 0.01$), positive correlations between birth weight and CE ($P < 0.001$), and udder suspension and teat size ($P = 0.001$). A tendency for a negative correlation was found between serum IgG and birth weight ($P = 0.11$) and a positive correlation between serum IgG and teat size ($P = 0.10$). After correlations were found, stepwise regression calculations were completed on all significant correlative variables. A linear regression was found between CE and serum IgG ($P = 0.01$), and quadratic regression between birth weight and serum IgG ($P = 0.04$). Difficulties during third stage labor increased as calf birth weight increased. The increases in CE scores were associated with decreased serum IgG found in the calf after 24 h. This depression of serum IgG due to calving difficulty may impair the ability of calves to adequately defend against pathogen exposure and may influence subsequent growth and performance.

Key Words: beef, immunoglobulins, neonate

ANIMAL HEALTH: COW AND HEIFER HEALTH

0864 (W026) Identification of serum innate immunity reactants in transition dairy cows before clinical signs of laminitis. G. Zhang*, D. M. Hailemariam, E. Dervishi, Q. Deng, S. A. Goldansaz, S. M. Dunn, and B. N. Ametaj, *Dep. of Agricultural, Food and Nutritional Science, University of Alberta, Edmonton, Canada.*

Laminitis (LAM) is prevalent in dairy cows and early diagnosis and timely treatment of the disease can lower animal suffering, improve recovery rate, increase longevity, and minimize cow loss. However, there are no indications of disease until it appears clinically, and presently the only approach to deal with the sick cow is intensive treatment or culling. The objective of this study was to identify potential predictive biomarkers of LAM in transition dairy cows. Blood samples were collected from the coccygeal vein once per week before morning feeding from 100 multiparous Holstein dairy cows during −8, −4, disease diagnosis, and +4 wks relative to parturition. Six healthy cows (CTR) and six cows that showed clinical signs of disease (i.e., LAM) were selected for intensive serum analyses. Concentrations of 3 cytokines interleukin-1 (IL-1), interleukin-6 (IL-6), and tumor necrosis factor-α (TNF-α); 3 acute phase proteins (APPs) haptoglobin (Hp), serum amyloid A (SAA), and lipopolysaccharide binding protein (LBP), as well as 3 metabolites lactate, non-esterified fatty acids (NEFA), and β-hydroxybutyrate (BHBA), were measured in serum by ELISA or colorimetric methods. Health status, feed intake, rectal temperature, and milk yield was monitored for each cow during the whole experimental period. Data were processed statistically by PROC MIXED of SAS 9.2. Results showed that cows affected by LAM had greater concentrations of lactate, IL-6, SAA, and LBP in the serum vs. CTR. Most interestingly, enhanced serum concentrations of lactate, IL-6, SAA, and LBP at −8 and −4 wk before parturition were significantly different in cows with LAM as compared with the CTR ones. The disease also lowered the overall milk production and feed intake as well as milk fat and fat:protein ratio. In conclusion, LAM affected serum concentrations of the several parameters related to innate immunity and carbohydrate metabolism that might be serve to monitor health status of transition dairy cows. At this point we are not certain whether these are typical LAM biomarkers or indicators of general disease state. More research is warranted to validate these data.

Key Words: dairy cows, innate immunity, laminitis

0865 (W027) Milk yield and reproductive performance of Holstein cows seropositive for tuberculosis. D. S. Resendiz*, *Universidad Autónoma Agraría Antonio Narro, Torreon, México.*

Bovine tuberculosis is a critical, debilitating and chronic disease of dairy cattle in intensive systems. Studies done in the past have not completely characterized the impact of this disease on productivity of cows. Therefore, the objective of this study was to find out if seropositivity for tuberculosis impairs reproductive performance and milk yield in high milk-yielding Holstein cows. For this purpose 1044 healthy cows and 105 Holstein cows seropositive for tuberculosis were used. Cows tested positive for bovine tuberculosis were from various large commercial dairy operations from the same region. Cows that reacted to an intradermal injection of tuberculin were transferred from their barns to an isolated new dairy facility. Cows free from this disease were placed in the same barn as the seropositive cows, but in an isolated division and served as control animals. The GENMOD, npar1way, and LIFETEST procedures of SAS (SAS Inst., Inc., Cary, NC, USA) were used to assess the significance of treatment on reproductive variables. The reproductive performance of positive reactors was impaired; overall pregnancy per artificial insemination differed ($P < 0.05$) between seropositive and healthy cows (16.9 vs. 20.7). Seropositive animals required 4.52 ± 2.94 services per pregnancy compared with 4.34 ± 2.72 for control cows. The intervals between calving and conception were similar between seropositive (154 ± 78 d) and seronegative animals (150 ± 77 d). Control cows tended ($P = 0.08$) to produce more milk than seropositive cows over a 305-d lactation (10,684 ± 1720 vs. 10,345 ± 1736; three milkings per day, mean ± SD). It was concluded that cows tested positive for bovine tuberculosis exert a mild but significant negative effect on both reproductive performance and milk yield.

Key Words: tuberculosis, bovine, milk

0866 (W028) Behavior of lactating dairy cows under mild and severe heat stress with free access or not to shadow. V. Fischer*[1], E. Forgiarini Vizzotto[1], A. Susenbach de Abreu[1], A. Thaler Neto[2], M. Tempel Stumpf[1], D. Werncke[1], and F. André Schmidt[2], *[1]Universidade Federal do Rio Grande do Sul, Porto Alegre, Brazil, [2]Universidade Estadual de Lages, Brazil.*

In the tropics, during several months of the year, air temperatures are well above the upper critical temperature for lactating dairy cattle. Despite this fact, many dairy farmers still do not provide shade. The objective of this trial was to study the behavior of dairy cows with or without access to shadow under mild (afternoon THI = 74.7) and severe heat stress (afternoon THI = 81.2). Twenty-eight Holstein cows in mid-lactation producing 21 ± 3 L per day were used. Cows were

Table 0866.

Attribute	P > F (interaction)			Heat stress					
				Mild			Severe		
	Heat stress severity	Access to shadow	Heat stress x access to shadow	with shadow	without shadow	P > F	with shadow	without shadow	P > F
Walking (min)	0.0140	0.0001	0.0001	19.6	31.1	0.0323	12.1	52.0	0.0001
Ruminating (min)	0.0001	0.3382	0.0001	175.4	142.3	0.0021	13.1	61.0	0.0001
Grazing (min)	0.3308	0.0001	0.0001	219.0	232.0	ns	257.9	169.2	0.0001
Idling (min)	0.0001	0.1926	0.0436	192.3	201.8	ns	271.0	230.1	0.0243
Lying (min)	0.0054	0.0001	0.0001	158.6	151.8	ns	186.7	50.0	0.0001
Body temperature (°C)	0.0072	0.0001	0.0112	39.6	40.0	0.0298	39.64	40.68	0.0001

split into four groups according to heat stress intensity (mild and severe) and access to shadow (with and without). Behavior of all cows was visually observed from 0600 h to 0900 h for 4 d, and time spent grazing, ruminating, idling, walking, lying, and number of water ingestion bouts were recorded. Body temperature and respiratory rate were recorded at 1800 h. Data was submitted to analysis of variance according to a completely randomized design considering main effects of heat stress severity ($n = 2$), access to shade ($n = 2$) and their interaction. Respiratory rate was greater under severe compared with mild heat stress (100.8 × 72.8, $P < 0.001$) and when no shadow was provided compared with free access to shadow (98.9 × 74.7, $P < 0.001$). Significant interactions were detected for time spent ruminating, grazing, walking, idling, lying, and for body temperature. Shadow was beneficial even under mild heat stress, as cows spent less time walking and spent more time ruminating, but provision of shadow did not improve time spent grazing, idling or lying. Under severe heat stress, provision of shadow helped cows in reducing walking time and allow acceptable values for time spent grazing, idling, and lying besides body temperature, but it was unable to keep ruminating time. Dairy cattle should have free access to shadow independently of severity of heat stress.

Key Words: behavior, heat stress, shadow

0867 (W029) Risk factors for hypocalcemia incidence and their effect on milk yield and reproduction in a grazing Jersey, Guernsey, and Holstein herd in Costa Rica.

A. Saborío-Montero*, and J. M. Sánchez, *Centro de Investigaciones en Nutrición Animal y Escuela de Zootecnia, Universidad de Costa Rica, San José.*

The aim of this study was to determine risk factors for hypocalcemia (blood Ca concentration under 8.0 mg/dl) and its effect on milk yield and reproduction in three breeds of dairy cows under the same feeding, management and environmental conditions. The study was conducted on a dairy farm located in Cartago, Costa Rica, and comprised a total of 152 cows (62 Jersey, 41 Guernsey, and 49 Holstein). Average lactation number for the three breeds was 2.73 ± 1.59. During the close-up period cows grazed kikuyu grass (*Kikuyuocloa clandestina*) (14.8% DM, 23.4% CP, 54% NDF, 0.35% Ca, 0.31% Mg and 3.50% K) and were supplemented with 4 kg/animal/d of a concentrate mixture low in Ca (14% CP, 31% NDF, 0.2% Ca, 0.42% Mg and 1.38% K) and 1 kg of hay (82.3% DM, 5.1% CP, 61.4% NDF, 0.4% Ca, 0.35% Mg and 1.8% K)/d. Cows were fed 1 kg of concentrate (18.6% CP, 0.90% Ca, 0.42% Mg and 1.38% K)/2.5 to 3.0 kg of milk during lactation. Blood samples of cows within 24h from calving were taken from the coccygeal vessels and analyzed for Ca, using atomic absorption spectrophotometry, to establish relationships with productive, reproductive and inherent variables. Results are shown in Table 0867. Milk yield in the previous lactation in Guernsey, BCS at calving in Jersey and calving number in Jersey and Holstein cows were risk factors ($P < 0.05$) for suffering hypocalcemia at peripartum. Likewise, Ca concentration was related ($P < 0.05$) to actual milk yield in the succeeding lactation in Guernsey, and to calving interval in Holstein. These results suggest that Ca concentration at parturition in Guernsey cows could be driven by productive variables and in Jersey and Holstein cows seems to be related to inherent factors. These variables should be studied in a wider population for a better understanding of the causes of hypocalcemia incidence in dairy cattle.

Key Words: dairy cows, hypocalcemia, risk factors

Table 0867. Variables associated with blood Ca concentration in peripartum (calving ± 1d) according to breed

Variable	Ca concentration as association variable				Breed
	Pearson correlation		Linear regression		
	Rho	P	R^2	P

0868 (W030) Activation of innate immunity in transition dairy cows before clinical appearance of milk fever. G. Zhang*, D. M. Hailemariam, E. Dervishi, Q. Deng, S. A. Goldansaz, S. M. Dunn, and B. N. Ametaj, *Dep. of Agricultural, Food and Nutritional Science, University of Alberta, Edmonton, Canada.*

Milk fever (MF) is a metabolic disease of transition dairy cows associated with calcium imbalance at the onset of lactation. Its pathogenesis and etiology still remain unclear. The objective of this study was to identify alterations in innate immunity reactants and carbohydrate and lipid metabolites in the blood of transition dairy cows with or without MF. One hundred multiparous Holstein dairy cows were involved in the study and the experimental period lasted 16 wk from −8 wk before until +8 wk postpartum. Health status, feed intake, rectal temperature, and milk yield was monitored for each cow during the whole experimental period. Blood samples were collected from the coccygeal vain once per week before the morning feeding and stored until analyses at −80°C. Six healthy cows (CTR) and six cows that showed clinical signs of MF were selected for intensive blood analyses. Serum concentrations of lactate, non-esterified fatty acids (NEFA), β-hydroxybutyrate (BHBA), interleukin-1 (IL-1), interleukin-6 (IL-6), tumor necrosis factor-α (TNF-α), haptoglobin (Hp), serum amyloid A (SAA), and lipopolysaccharide binding protein (LBP) were determined. Feed intake, milk production and composition also were collected. Data were processed using the PROC MIXED of SAS 9.2. Results indicated that concentrations of serum lactate, IL-6, TNF-α, SAA, Hp, and LBP were significantly greater in cows with MF than CTR. Most interestingly, serum lactate, TNF-α, SAA, LBP, and Hp in cows with MF were different from CTR cows starting at ~ 4 to 8 wk before diagnosis of disease. Overall feed intake and milk production was lower in MF-affected cows. Interestingly overall milk fat was greater in MF cows vs. CTRs. In conclusion cows affected by MF showed alterations of innate immunity reactants and metabolites related to carbohydrate metabolism weeks before clinical appearance of MF. Since innate immunity is a general non-specific host response to sickness these metabolites might be used to indicate general health status of the transition dairy cows ahead of clinical disease event. More research is warranted to validate these data and better understand etiopathogenesis of MF in transition dairy cows.

Key Words: dairy cow, Innate immunity reactants, milk fever

0869 (W031) Transition dairy cows show blood alterations in innate immunity ahead of occurrence of retained placenta. G. Zhang*, D. M. Hailemariam, E. Dervishi, Q. Deng, S. A. Goldansaz, S. M. Dunn, and B. N. Ametaj, *Dep. of Agricultural, Food and Nutritional Science, University of Alberta, Edmonton, Canada.*

Retained placenta (RP) is defined as failure to expel the fetal membranes from the uterus within 24 h after calving. The incidence of RP in a dairy farm, under normal conditions, averages 7 to 10%. RP results in increased days open, calving to first heat interval, services per conception, and days from calving to first service. The etiopathology of RP is not known and it is of interest to search for contributing factors that induce the disease. The objective of this investigation was to evaluate whether there are alterations in blood variables related to innate immunity and carbohydrate and lipid metabolism in transition dairy cows with placental retention. One hundred multiparous Holstein dairy cows were involved in the study. Seventeen blood samples were collected from the coccygeal vein during the −8 to +8 wk around parturition, once per week before the morning feeding. Six healthy control cows (CTR) and six cows with RP were selected and serum samples collected at −8, −4, time of diagnosis of disease, and +4 wk relative to parturition were analyzed for lactate, non-esterified fatty acids (NEFA), β-hydroxybutiric acid (BHBA), interleukin-1 (IL-1), interleukin-6 (IL-6) and tumor necrosis factor-α (TNF-a), haptoglobin (Hp), serum amyloid A (SAA) and lipopolysaccharide binding protein (LBP). In addition, health status, feed intake, rectal temperature, and milk yield data were monitored for each cow during the whole experimental period. Results revealed that cows with RP had greater concentrations of serum lactate, IL-1, TNF-a, SAA, and LBP in comparison with CTR. Intriguingly, elevated concentrations of all five variables were observed at −8 and −4 wks before the occurrence of RP compared to CTR cows. Cows with RP also had lower feed intake and milk production vs. control animals. However milk composition was not affected by RP. Overall results suggest that serum lactate, IL-1, TNF-a, SAA, and LBP can be used, in the future, to indicate cows that might have health issues during the transition period. More research is warranted to better understand the agent(s) that contribute(s) to RP in transition dairy cows.

Key Words: transition dairy cows, retained placenta, innate immunity

0870 (W032) Hypocalcemia and hypomagnesemia prevalence in a grazing Jersey, Guernsey, and Holstein herd in Costa Rica. J. M. Sánchez* and A. Saborío-Montero, *Centro de Investigaciones en Nutrición Animal y Escuela de Zootecnia, Universidad de Costa Rica, San José.*

The aim of this study was to determine the prevalence of hypocalcemia and hypomagnesemia in Jersey, Guernsey, and Holstein cows at parturition under the same feeding, management and environmental conditions. The study was conducted on a dairy farm located in Cartago, Costa Rica, during a 9-mo period and comprised a total of 152 cows (62 Jersey, 41 Guernsey, and 49 Holstein). During the close-up period cows grazed intensively managed kikuyu grass (*Kikuyuocloa clandestina*) (14.8% DM, 23.4% CP, 54% NDF, 0.35% Ca, 0.31% Mg and 3.50% K) and were supplemented with 4 kg/animal/d of a concentrate mixture low in Ca (14% CP, 31% NDF, 0.2% Ca, 0.42% Mg and 1.38% K) and 1 kg of hay (82.3% DM, 5.1% CP, 61.4% NDF, 0.4% Ca, 0.35% Mg and 1.8% K)/d. Cows were fed 1 kg of concentrate (18.6% CP, 0.90% Ca, 0.42% Mg and 1.38% K)/2.5 to 3.0 kg of milk during lactation. Blood samples were taken from the coccygeal vessels at peripartum (calving ± 1d) and were analyzed for Ca and Mg. The blood thresholds to classify cows as clinically or sub clinically hypocalcemic were less than 5.5 and 5.5 to 8.0 mg/dl of Ca, respectively. A value of 1.8 mg/dl of Mg or lower was set as criterion to classify cows as hypomagnesemic. Results are shown in Table 0870. Jersey cows were more prone to develop clinical hypocalcemia during peripartum than Holstein cows in this herd (OR = 3.48, 95% CI: 0.76–15.9), and Guernsey cows were more likely to suffer hypomagnesemia than Jersey cows during the same period (OR = 8.47, 95% CI: 1.30–55.2). These results suggest that Jersey grazing cows are more susceptible to clinical hypocalcemia and Guernsey to hypomagnesemia. High prevalence of subclinical hypocalcemia found in this study in Jersey, Guernsey, and Holstein cows could comprise cow health and productivity, and more research should be done to better understand Ca metabolism during the transition period in grazing cows.

Key Words: grazing dairy cows, hypocalcemia, hypomagnesemia

Table 0870. Blood calcium and magnesium concentration and prevalence of clinical and subclinical hypocalcemia and hypomagnesemia according to breed

	Ca (mg/dl)		Mg (mg/dl)		Hypocal.(%)		Hypomag.
Breed	Mean	95% CI	Mean	95% CI	Clin.	Subcl.	(%)
Jersey	7,49	7,11–7,87	2,78[a]	2,64–2,92	13	50	2
Guernsey	8,09	7,63–8,56	2,35[b]	2,18–2,52	0	44	12

[a,b] Means in the same column not sharing a common superscript are different ($P < 0.05$).

0871 (W033) Milk and blood selenium concentrations in dairy cattle differ depending on the source of selenium supplementation (sodium selenite, selenium-yeast or l-selenomethionine). L. Vandaele[1], B. Ampe[1], S. Wittocx[2], L. Segers[2], M. Rovers[*2], A. van der Aa[3], G. du Laing[4], and S. De Campeneere[1], *[1]Institute for Agricultural and Fischeries Research (ILVO), Melle, Belgium, [2]Orffa Additives BV, Werkendam, Netherlands, [3]Excentials BV, Werkendam, Netherlands, [4]Ghent University, Belgium.*

Adequate selenium (Se) levels are beneficial for dairy cattle health and fertility. Since many regions in the world have soils with low Se content, supplementation of this trace element is very often warranted. The aim of the present study was to evaluate three different Se sources: sodium selenite (NaSe), selenium-yeast (SeYeast) and L-selenomethionine (SeMet) in their potential to achieve adequate blood and milk Se levels. A feeding trial was set-up with 26 high-producing Holstein Friesian cows. After a 2-wk pre-treatment period without Se supplementation, cows divided in four homogenous groups receiving either no supplementation (Ctrl) or 0.3 mg per kg dry matter (DM) of either NaSe, SeYeast or SeMet for the next 7 wk. Cows were given maize and prewilted grass silage ad libitum, a protein source and a balanced concentrate. Milk and blood serum samples were taken during the pre-treatment period (wk 0) and at wk 3 and 7 after the start of supplementation. Blood serum Se concentrations were analysed by atomic absorption spectrometry. Milk Se concentration was determined by inductively coupled plasma mass spectrometry. Data within each week have been analyzed using ANOVA with treatment as fixed effect. DMI was constant during the trial. Milk production was 29.9kg in Ctrl, 31.6kg in NaSe, 28.3kg in SeYeast and 27.8kg in SeMet cows. Milk composition showed small differences between treatments. The mean blood serum Se and milk Se concentrations during the pre-treatment period were not different between groups (Table 0871). The increase in milk Se concentration between wk 0 and 3 was significantly more pronounced for SeMet in comparison with SeYeast and NaSe, which indicates a better transfer from feed to milk after SeMet supplementation. After 7 wk supplementation Se levels in blood and milk were equally high for SeYeast and SeMet and lower for Ctrl and NaSe. Increase in milk Se content after supplementation is clearly affected by type of Se source.

Key Words: dairy, selenium, transfer

Table 0871. Blood and milk Se in Ctrl, NaSe, SeYeast and SeMet at wk 0, 3, and 7

	Wk	Ctrl	NaSe	SeYeast	SeMet
Blood Se (µg/L)	0	34 ± 10	25 ± 4	35 ± 13	31 ± 10
	3	39 ± 12[a]	63 ± 14[b]	71 ± 13[b]	68 ± 11[b]
	7	23 ± 5[a]	57 ± 12[b]	71 ± 13[c]	69 ± 10[c]
Milk Se (µg/kg)	0	16 ± 2	15 ± 1	14 ± 2	16 ± 2
	3	18 ± 3[a]	26 ± 2[b]	45 ± 6[c]	61 ± 4[d]
	7	21 ± 9[a]	46 ± 15[b]	63 ± 12[c]	75 ± 14[c]

[a,b,c,d] Values with different superscript differ significantly between groups within the same week (row).

0872 (W034) Dynamic of intramammary infections in 3/4 Holstein x Zebu dairy cows from a herd of Minas Gerais State, Brazil. C. V. Ladeira[1], F. N. Souza[1], D. R. Freitas[1], L. G. Ladeira[2], D. S. Rodrigues[2], M. O. Leite[1], L. M. Fonseca[1], C. M. Penna[1], M. A. P. Brito[3], and M. P. Cerqueira[*4], *[1]Universidade Federal de Minas Gerais, Belo Horizonte, Brazil, [2]EPAMIG, Belo Horizonte, Brazil, [3]Embrapa, Juiz de Fora, Brazil, [4]Universidade Federal de Minas Gerais* (*School of Veterinary Medicine), Belo Horizonte, Brazil.*

The aim of the present study was to assess the occurrence of subclinical bovine intramammary infections (IMIs) in 3/4 Holstein x Zebu cattle in a dairy herd from Empresa de Pesquisa Agropecuaria de Minas Gerais (EPAMIG). Thus, composite milk samples (n = 132) from 44 cows were collected in April, July, and September (dry period) for bacteriological examination and somatic cell count (SCC). Bacterial analysis was conducted by culturing 0.01 mL of each sample on 5% ovine blood agar plates and MacConkey agar. The plates were incubated for 48 h at 35°C, which was followed by gram staining, observation of colony morphology and biochemical testing. The cow was regarded as uninfected when the milk SCC was < 200,000 cells/mL and bacteriologically negative. A new IMI was determined when a cow was bacteriologically negative and had SCC < 200,000 cells/mL, and in the next sampling the milk sample was bacteriologically positive and/or have SCC > 200,000 cells/mL, or a different pathogen was isolated. If the same pathogen was isolated in all milk samples, the cow was regarded as chronically infected for that pathogen. A cure occurred when a cow that was regarded as infected became uninfected at the end of experiment (bacteriologically negative and SCC < 200,000 cells/mL). From the 44 cows, 22 (50%) were chronically infected by *S. aureus* (77.27%, n = 17), *Streptococcus* sp. (9.09%, n = 2), coagulase negative staphylococci (CNS; 9.09%, n = 2) and *Corynebacterium* sp. (4.55%, n = 1). Six cows (13.64%) were initially regarded as healthy, and from these cows, four cows (75%) have become infected. Furthermore, three cows (6.82%) have been cured from IMI (two by *S. aureus* and one by CNS) at the end of experiment. Finally, 13 cows (29.55%) have become infected by a different pathogen from that established at the beginning of the experiment (four by *S. aureus* and CNS, two by *Klebsiella* sp., two by *Corynebacterium* sp. and one by *S. aureus* and *Corynebacterium* sp.). From those, five cows (38.46%) have been cured and then, established a new infection by a different pathogen. The percentage of spontaneous cure of *S. aureus* IMI was 18.18%. Thus, this study demonstrated the dynamic of IMIs in a herd that needs a continuous assessment of mastitis pathogens for a comprehensive control of IMIs.

Key Words: mastitis, milk, dairy cattle

0873 (W035) In vitro efficacy of teat disinfectants against *Staphylococcus aureus* strains isolated from bovine mastitis in Brazil. R. P. Santos[1], F. N. Souza[1], C. C. Vasconcelos[2], A. Cortez[2], D. O. Lapinha[1], A. B. Jardim[1], A. F. Cunha[1], M. O. Leite[3], M. R. Souza[3], A. Q. Lana[1], M. B. Heinemann[1], and M. P. Cerqueira[*3], *[1]Universidade Federal de Minas Gerais, Belo Horizonte, Brazil, [2]Laboratorio Veterinario Vidavet, Botucatu, Brazil, [3]Universidade Federal de Minas Gerais* (*School of Veterinary Medicine), Belo Horizonte, Brazil.*

The present study sought to explore the in vitro efficacy of four antiseptics against *Staphylococcus aureus* isolated from milk of dairy cows with mastitis. The efficacy of chlorhexidine (2.0%), chlorine (2.5%), quaternary ammonium (4%), lactic acid (2.0%) and iodine (0.6%) was accessed in concentrations conventionally used as commercial antiseptics before and after teat dipping. We used 50 *S. aureus* strains isolated from milk of 50 different dairy herds located at Minas Gerais, Sao Paulo, Parana, and Rio Grande do Sul States, Brazil. The efficacy of antiseptics were evaluated by incubation of *S. aureus* with the disinfectant at four different times (15, 30, 60, and 300 min). We used 0.8 mL of each antiseptic, 0.2 of sterile milk, and 1.2 mL of a bacteria solution (MacFarland scale 1) for all treatments and testing times. The activity of the antiseptics was accessed by bacteria growth in brain-heart infusion broth and 5% sheep blood agar plates. If there was no bacteria growth in brain-heart infusion broth and blood agar plates, the antiseptic was regarded as efficient. Statistical analysis was performed using Cochran's Q test. We found higher activity of quaternary ammonium (98% at all testing times) and chlorhexidine (84% at 15 min, 90% at 30 min, 94% at 60 min, and 96% at 300 min) against *S. aureus* at all testing times (P = 0.001), followed by iodine (46% at 15 min, 56% at 30 min, 66% at 60 min, and 78% at 300 min) and chlorine (30% at 15 min, 40% at 30 min, 48% at 60 min, and 64% at 300 min). Lactic acid showed the worst results (4% at 15 min, 4% at 30 min, 8% at 60 min, and 14% at 300 min) at all testing times and its use should not be recommended. Due to variation in sensitivity and resistance of *S. aureus* to antiseptics, the appropriateness of a given intervention should be based on efficacy in the specific application.

Key Words: dairy cow, intramammary infection, milking, teat dip

0874 (W036) Profile of clinical and subclinical mastitis pathogens isolated from cows housed on compost bedding. F. V. R. Portilho, S. Favero, G. G. Wanderley, H. Langoni, and J. C. F. Pantoja*, *Sao Paulo State University, Botucatu, Brazil.*

Compost bedding has been increasingly used worldwide. The organic nature of the bedding calls for investigations regarding the role and diversity of pathogens causing intramammary infections in cows housed in this system. The objective of this longitudinal study was to describe the distribution of mastitis pathogens isolated from cows housed on compost bedding. Three farms were visited monthly between May 2013 and January 2014. Farms A, B, and C had 33, 53, and 145 lactating cows and used peanut shell, sawdust, and wood shavings as bedding, respectively. Bedding was cultivated twice a day with new material added to the barn twice a month. Quarter milk samples were collected monthly from a sample of high SCC cows (> 200,000 cells/mL) in each heard and from all cases of clinical mastitis. Pathogens were grouped as environmental streptococci (*Streptococcus uberis*, *Streptococcus dysgalactiae* and *Enterococcus* spp.), CNS (coagulase-negative staphylococci), coliforms (*Escherichia coli*, *Klebsiella* spp. and *Enterobacter* spp.) and others (*Serratia* spp., *Pseudomonas* spp. and *Bacillus* spp.). The average monthly prevalence of subclinical mastitis (based on SCC) per farm was 39.6, 44.0, and 43.5% for farms A, B, and C, respectively. The distribution of culture results for subclinical mastitis (N = 469 quarters) was: negative: 39.4%; *Corynebacterium bovis*: 19.0%; CNS: 10.2%; environmental streptococci: 9.4%; *Staphylococcus aureus*: 6.2%, *Streptococcus agalactiae*: 6.0%; contaminated: 4.9%; coliforms: 3.2%; other: 1.3%, yeast: 0.2%, and *Prototheca* spp.: 0.2%. Culture results for clinical mastitis (N = 128 quarters) were: negative: 34.3%; coliforms: 16.4%; *C. bovis*: 9.4%; *Strep. agalactiae*: 9.4%; contaminated: 8.6%; CNS: 7.8%; environmental streptococci: 7.0%; other: 3.9%, and *Staph. aureus*: 3.1%. The most prevalent coliforms causing clinical and subclinical mastitis were *E. coli* (67% of 21) and *Klebsiella* spp. (74% of 15 cases), respectively. Preliminary results suggest that the distribution of pathogens was similar to those previously reported in Brazil for farms that used other bedding materials such as sand or pasture. *Prototheca* spp.was isolated from one cow on Farm C. *Nocardia* spp. infections were not found and the prevalence of other pathogens of concern such as *Serratia* spp. and *Pseudomonas* spp. was low.

Key Words: milk quality, mastitis, compost bedding

0875 (W037) Risk factors for repeated cases of clinical mastitis during the same lactation. B. dos Santos, G. G. Wanderley, H. Langoni, and J. C. F. Pantoja*, *Sao Paulo State University, Botucatu, Brazil.*

The objective of this nested case-control study was to identify factors associated with the occurrence of repeated clinical mastitis (CM) cases during the same lactation. Between July 2013 and January 2014, a 400-cow herd of Holstein cows was visited monthly for data collection. Quarter milk samples were collected from all CM cases. A repeated case was defined when a cow experienced the second case of CM (regardless of the quarter) within the same lactation. For each repeated case that occurred, three control cows matched by days in milk (DIM) were randomly selected. On the visit day, teat and udder measurements were performed on cases and controls, such as position of the udder floor in relation to the hock, udder depth, teat length and diameter, teat end hyperqueratosis score, ease of milking score, and presence of udder abnormalities (lesions or unbalance). Milk production, parity and the occurrence of further cases of CM were also recorded. The odds of a repeated clinical case were estimated as a function of the variables studied. Data from 68 repeated cases and 171 controls were available. The median time to the first case of mastitis and interval between the first and second cases were 136 DIM and 58 d, respectively. Of the 68 case-cows, 24% had the same pathogen isolated from both the first and second cases, and 57% experienced CM in the same quarter. Parity was associated with the occurrence of a repeated case only in the univariate analysis and was forced into the final model. Cows of first parity were 2.5 more likely to experience a repeated case when compared to cows of parity > 2 (P = 0.04). Ease of milking and udder position in relation to the hock remained in the final model. Cows whose udder was below the hock and cows easy to milk were 6.5 (P < 0.01) and 6.8 (P < 0.01) times more likely to experience a second case of CM when compared to those whose udder was above the hock or difficult to milk, respectively. Results of this study suggest that ease of milking is an important risk factor for repeated CM that should be carefully considered in genetic improvement programs.

Key Words: milk quality, epidemiology, clinical mastitis

0876 (W038) Incidence of retained placenta and the consequences on milk production and reproductive wC. C. Campos, and R. M. Santos*, *FAMEV–UFU, Uberlândia, Brazil.*

Retained placenta (RP) promotes delay in uterine involution and resumption of ovarian activity, besides increasing risk of uterine infections, being the major reason for low fertility of dairy cows. This study aimed to evaluate the effects of parity and calving season in RP incidence, in milk production and in calving to conception interval (CCI), as well as RP effects on these variables. Data were collected at a farm located in Rio Paranaíba city, Minas Gerais state, Brazil during 2012. The herd was composed of 700 Holstein dairy cows producing 32 kg of milk production per day. Calving of 291 cows was registered during the experiment period. To diagnose RP occurrence, cows were observed during calving, and immediately after calving, and those cows that had not eliminated

all of placenta until 12 h after fetal expulsion was considered with RP. The effects of parity and calving season on RP incidence were analyzed by logistic regression, and the effects of parity, calving season and RP occurrence on milk production and on CCI duration were evaluated by analysis of variance, both using SAS program. The incidence of RP in this herd was 13.75% (40/291). The RP incidence was not affected by parity and calving season, however there was a tendency (P = 0.066) of lowest incidence of RP for calving that had occurred during winter. The effects of parity, calving season and RP occurrence on milk production adjusted to 305 d of lactation were not verified (P > 0.05). CCI duration was influenced (P = 0.007) by parity, cows with three or more lactations had higher interval from parturition to conception. The effects of calving season (P = 0.001) and RP occurrence (P = 0.043) were also detected on CCI duration. Calving that had occurred during summer resulted in significant increase on CCI (263.00 ± 107.70) compare to winter (121.02 ± 60.64). Cows that developed RP had an interval from parturition to conception longer than cows without RP (139.64 ± 73.83 vs. 166.30 ± 95.90). The efficacy of RP treatment implemented by the farm could justify the absence of detectable effects of RP occurrence on milk production; however it was not enough to overcome the negative effects of RP on Holstein cows fertility.

Key Words: placenta, postpartum, bovine

0877 (W039) Associations between severity and etiology of clinical mastitis and pregnancy outcomes to first-service in dairy cows. M. J. Fuenzalida*[1], P. D. Carvalho[2], M. C. Wiltbank[2], P. M. Fricke[1], and P. L. Ruegg[1], *[1]Dep. of Dairy Science, University of Wisconsin–Madison, Madison, [2]University of Wisconsin, Madison.*

The objective of this study was to describe associations between the occurrence and severity of clinical and subclinical mastitis with pregnancies per artificial insemination (P/AI) after artificial insemination (AI) at first service. A total of 3164 cows from four commercial dairy farms were enrolled in a prospective cohort study between May 2011 and December 2013. Cows were submitted for first AI, and pregnancy outcomes were determined by using pregnancy-specific protein B (> 0.3ng/mL) and transrectal ultrasonography 32 to 39 d after AI. Clinical mastitis events were categorized as mild (abnormal milk) or moderate/severe (udder affected to animal depression or fever). Subclinical mastitis was defined when SCC exceeded 150,000 cells/mL. Udder health was categorized based on mastitis events occurring within the period from 3 d before to 32 d after first AI as: 1) subclinical mastitis only (SM); 2) clinical mastitis only (CM); 3) subclinical and clinical mastitis (SCM); or 4) no mastitis events. Chi-square tests were used to determine associations between udder health categories and P/AI at first AI. Occurrence of mastitis was associated with reduced P/AI (P < 0.001). As compared to P/AI of healthy cows (48%), cows that experienced SM (41.8%), CM (40.7%) or SCM (30.5%) had fewer P/AI. As compared to healthy cows, the odds of P/AI were 0.8 times as likely in cows that experienced SM (P = 0.005) or CM (P = 0.04) or 0.6 times as likely in cows that experienced SCM (P < 0.001). Among cows that experienced CM, P/AI did not vary based on severity (P = 0.69) or etiology (P = 0.26). As compared to P/AI of healthy cows (48%), cows with CM caused by Gram-negative bacteria (27.8%), Gram-positive bacteria (40.5%) and cases from cows that resulted in no growth (39.8%) had fewer (P = 0.006) P/AI. We conclude that both clinical and subclinical mastitis influenced P/AI and differences in P/AI were observed among etiologies and clinical presentation. *Supported by AFRI Competitive Grant no. 2010–85122–20612.*

Key Words: fertility, severity, pathogen

0878 (W040) Application of probiotics in the vaginal tract modulated bacterial composition in transition dairy cows. B. N. Ametaj*, *Dep. of Agricultural, Food and Nutritional Science, University of Alberta, Edmonton, Canada.*

Uterine infections are highly associated with infertility, which is the main reason for culling of dairy cows. The objective of this study was to test whether intravaginal infusion of probiotics could modify the bacterial composition of the vaginal tract of transition dairy cows. One hundred pregnant Holstein cows were randomly (based on parity, body condition score, and milk yield) assigned to three groups 2 wk before the expected day of parturition (wk 0) as following: 1) a dose of probiotics on wk -2 and -1 and a dose of carrier (sterile skim milk) on wk +1 (TRT1); 2) a dose of probiotics on wk -2, -1, and +1 (TRT2), and 3) a dose of carrier on wk -2, -1, and +1 (CTR). Probiotics were a culture mixture of 3 lactic acid bacteria (LAB) composed of *Lactobacillus sakei* FUA3089, *Pediococcus acidilactici* FUA3138, and FUA3140, which were infused at 10^8–10^9 cfu per dose. Vaginal mucus was collected once a week on wk -2, -1, 0, +1, +2, +3 and +8. Vaginal pH was monitored once a week from wk -2 to +3; vaginal microbiota were monitored by quantitative PCR. At wk +3, compared with the control group, TRT1 increased the gene copy number of *Lactobacillus* group by 3 log (P < 0.01), *L. sakei* by 1.5 log (P < 0.05), and *Enterococcus* spp. by 2.5 log (P < 0.01). Meanwhile, TRT2 increased the number of *L. sakei* by 2.5 log relative to the control group (P < 0.05). No difference was observed among treatment groups in terms of gene copy numbers of total bacteria, *Bacteroides* group, *Bacillus* spp., *Staphylococcus* spp., *Enterobacteriaceae*, *E. coli* and pediocin structural gene pedA. The canonical score plot demonstrated that the gene copy numbers of *Lactobacillus* group discriminated best for TRT1, whereas those of *L. sakei* and *Bacillus* spp. discriminated best for TRT2. The bacterial composition of CTR was not discriminated by any of the bacterial populations determined. No differences were

observed among treatment groups regarding the vaginal pH of periparturient dairy cows. In conclusion, vaginal infusion of probiotics around calving modulated the vaginal microbiota of dairy cows as indicated by alterations in the number of *Lactobacillus* group, *L. sakei*, and *Enterococcus* spp.

Key Words: bacterial composition, dairy cow, probiotics, vaginal tract

0879 (W041) Intravaginal administration of probiotics modulated serum metabolites and milk composition of transition dairy cows. B. N. Ametaj*, *Dep. of Agricultural, Food and Nutritional Science, University of Alberta, Edmonton, Canada.*

Transition dairy cows experience great metabolic fluctuations due to dietary changes and calving-induced stress, which also influence milk composition. Therefore, the objective of this study was to evaluate metabolic responses of periparturient dairy cows administered intravaginally with probiotics around calving. One hundred pregnant Holstein cows were randomly (based on parity, BCS, and milk yield) assigned to three groups 2 wk before the expected day of parturition as following: 1) one dose of probiotic culture on wk -2 and -1 and one dose of carrier on wk +1 (TRT1); 2) one dose of probiotics on wk -2, -1, and +1 (TRT2), and 3) one dose of carrier on wk -2, -1, and +1 (CTR). Probiotics were a mixture of 3 lactic acid bacteria (LAB) composed of *Lactobacillus sakei* FUA3089, *Pediococcus acidilactici* FUA3138, and FUA3140, which were infused at 10^8–10^9 cfu per dose. Blood samples were collected from wk -2 to +3, and milk samples from wk +1 to +5 on a weekly basis. The concentration of serum metabolites and milk components were determined by spectrophotometry, and data were analyzed with SAS 9.2 software. Concentrations of cholesterol in the serum were 108 ± 4, 116 ± 4, and 95 ± 4 mg/dL ($P < 0.01$) in TRT1, TRT2, and CTR, respectively. Concentrations of lactate in the serum were 5.88 ± 0.50, 4.85 ± 0.39, and 3.52 ± 0.35 mmol/L ($P < 0.05$) in TRT1, TRT2, and CTR, respectively. Cows in TRT2 had lower serum NEFA than CTR (452 ± 64 vs. 631 ± 59 μmol/L, $P = 0.05$) but greater BHBA (736 ± 43 vs. 595 ± 43 μmol/L, $P < 0.05$). Treatments had no effect on concentrations of glucose or insulin in the serum. In addition, TRT2 had the highest content of milk lactose (4.39 ± 0.02%, 4.53 ± 0.03%, and 4.44 ± 0.03% in TRT1, TRT2, and CTR, respectively, $P < 0.01$), whereas TRT1 had the greatest content of milk protein (2.99 ± 0.04, 2.93 ± 0.05, and 2.82 ± 0.05% in TRT1, TRT2, and CTR, respectively, $P < 0.05$). No differences were detected in the content of milk fat, total solid content, or SCC. In conclusion, data indicated that administration of probiotics in the vaginal tract of periparturient dairy cows modulated serum concentrations of selected metabolites related to carbohydrate and lipid metabolism as well as milk composition. More research is warranted to understand how intravaginally infused probiotics affect blood metabolites and milk composition.

Key Words: probiotics, serum metabolites, milk composition

0880 (W042) Association among peripartum body condition score and metabolic parameters of Jersey cows and cure of sub-clinical mastitis in the dry period and incidence of sub-clinical and clinical mastitis postpartum. D. N. Liboreiro*, and R. C. Chebel, *Dep. Veterinary Population Medicine, University of Minnesota, St. Paul.*

Objectives were to evaluate the associations among peripartum metabolic parameters and cure of sub-clinical mastitis in the dry period and incidence of clinical and sub-clinical mastitis postpartum in Jersey cows. Cows ($n = 167$) having sub-clinical mastitis within 30 d before drying-off [linear somatic cell count (LSCC) > 4] were considered to be cured if LSCC < 4 within 34 d postpartum. Animals (multiparous = 745, nulliparous = 230) having LSCC > 4 within 34 d postpartum were considered to have sub-clinical mastitis. Clinical mastitis was characterized by change in milk and/or udder swelling (multiparous = 937, nulliparous = 320). Animals received body condition (BCS) and locomotion (LS) scores at -21 and 3 d relative to calving. Blood sampled from -21 to 7 d relative to calving was analyzed for non-esterified fatty acid (NEFA) and blood sampled from 0 to 7 d relative to calving was analyzed for β-hydroxybutyrate (BHB). Binary data was analyzed by logistic regression. Likelihood of cure of sub-clinical mastitis in the dry period had a quadratic association with BCS -21 d relative to calving ($P = 0.03$) and a negative linear association with NEFA concentration from -21 to 7 d relative to calving ($P = 0.07$). Likelihood of incidence of sub-clinical mastitis within 34 d postpartum had a quadratic association with BCS -21 d relative to calving ($P < 0.01$), a negative linear association with BCS loss in the last 21 d of gestation ($P < 0.01$), and a negative linear association with NEFA concentration from -21 to 7 d relative to calving ($P = 0.08$). Likelihood of clinical mastitis in the first 7 d postpartum had a negative linear association with BCS -21 d relative to calving ($P = 0.02$). Similarly, likelihood of clinical mastitis in the first 21 d had a negative linear association with BCS -21 d relative to calving ($P = 0.08$). We conclude from this experiment that BCS -21 d relative to calving, BCS change during the prepartum period, and NEFA concentration in the peripartum period are associated with udder health during the transition period, which is likely a consequence of the association between energy status and immune function.

Key Words: mastitis, transition cow, energy status

881 (W043) Evaluation of the ketone bodies concentration and clinical parameters in dairy cows supplemented with rumen-protected choline during the transition period. R. C. D. Souza[*1], R. C. Souza[1], R. F. Cota[1], J. M. Leão[2], I. B. Fortes[1], and L. S. D. Andrade[1], *[1]PUC Minas, Betim, Brazil, [2]UFMG, Belo Horizonte, Brazil.*

The use of rumen-protected choline (RPC) is a strategy to improve fat metabolism in the liver and reduce the prejudicial effects of negative energy balance in dairy cows during the peripartum. The objective of this study was to evaluate serum levels of ketone bodies and clinical parameters of dairy cows and heifers supplemented with RPC during the transition period (from 21 d pre-partum until 21 d post-partum). Thirty-two lactating F1 Holstein x Gir cows (16 multiparous and 16 primiparous) were blocked by parity and randomly assigned to one of two dietary treatments: addition of 60 g of RPC (AC) as Toplac Transition (Nutrifarma, Maripá, PR, Brazil) and no addition of RPC (NC). Diets contained 60% forage as corn silage and were isoproteic and isoenergetic according to the NRC (2001) model. Supplementation of RPC was done 21 d before expected parturition until 21 d post-partum. Blood samples, of coccygeal vein or artery, were collected 2 h after feeding on the d −21,−14, and −7 pre-partum and on the d 7, 14, 21 post-partum to obtain ketone bodies concentration by the portable electronic method Optium Xceed ™. The clinical parameters were evaluated using the methodology described by Rosenberg (1983). The experimental design used was completely randomized blocks with split plots. Ketone bodies concentration means were compared using Tukey test ($P < 0.05$) and clinical parameters (retained placenta) were evaluated by Chi-square test using the PROC MIXED for SAS. No effect of the use of RPC was observed on the ketone bodies concentration ($P = 0.4262$). However, at times evaluated, the lowest ketone bodies concentration in heifers were at parturition, 0.28 and 0.32 µmol/dl, respectively for animals AC and NC ($P = 0.0001$). No effect of time was observed on the concentration of ketone bodies in multiparous. On partum day, the ketone bodies concentration of AC group was lower in heifers (0.28 µmol/dl) than multiparous (0.57 µmol/dl; $P = 0.0062$). On clinical examination it was observed in the post-partum 16.66% of the AC group with retained placenta and 66% of the NC animals with retained placenta ($P = 0.0360$). Rumen protected choline supplementation to F1 Holstein x Gir multiparous cows reduced the incidence of retained placenta showing that this supplement can improve immunity in cattle. However, no effect was observed of rumen protected choline supplementation on the ketone bodies concentration.

Key Words: rumen-protected choline, ketone bodies concentration, clinical parameters.

0882 (W044) Switching lactating Jersey cows from a high neutral detergent fiber diet to an isoenergetic high soluble carbohydrate diet induces mild inflammation. G. Taasoli[1,2], C. R. Nightingale[*1], F. Kafilzadeh[2], D. Ghadimi[3], J. A. Carroll[4], and M. A. Ballou[1], *[1]Texas Tech University, Dep. of Animal and Food Sciences, Lubbock, [2]Razi University, Dep. of Animal Science, Kermanshah, Iran, [3]MRI, Institute of Physiology and Biochemistry, Karlsruhe, Germany, [4]USDA-ARS, Livestock Issues Research Unit, Lubbock, TX.*

The objective was to investigate whether switching to a high soluble carbohydrate diet induced a systemic inflammatory response in peak lactating Jersey cows. Seven multiparous Jersey cows were selected from a commercial dairy farm. Cows were 71 ± 3 DIM and had an average BW of 407 ± 17.9 kg (mean ± SD). Each cow was individually housed in a 4-by-10-m soil surface pen. All cows received the high neutral detergent fiber (NDF; 33.8% DM)/low non-fiber carbohydrate (NFC; 34.3% DM) diet for 2 wk and then switched to an isonitrogenous/isocaloric reduced NDF (30.2% DM)/high NFC (40.7% DM) diet for 1 wk. The NFC content of the diet was increased by replacing corn distillers products and whole cottonseed with steam flaked barley and canola meal. Feed intake was collected from −7 to 7 d relative to the diet change. Milk yield, milk composition, and peripheral blood samples were collected immediately before switching the diets and 2, 4, and 7 d after the diet change. Blood hematology and plasma haptoglobin, zinc, interleukin-6, and tumor necrosis factor-α concentrations were analyzed. The switch in diet caused a decrease in DMI (19.6 vs. 17.0 ± 0.46 kg/d; $P < 0.0001$). Milk production decreased on d 2 (27.9 vs. 25.5 ± 1.17 kg/d for d 0 and 2 relative to the diet switch, respectively; $P = 0.042$), but had returned to baseline yields by d 7. No differences ($P > 0.473$) were observed in blood hematology, except that hemoglobin concentrations were increased after the diet switch (9.9 vs. 10.9 ± 0.35 g/dL; $P = 0.02$). Plasma haptoglobin concentrations tended to be elevated on d 7 relative to d 0 (62.4 vs. 142.3 ± 23.5 µg/mL; $P = 0.095$). In addition, plasma zinc concentrations were reduced on d 7 relative to d 0 (1.82 vs. 1.42 ± 0.138, mg/L; $P = 0.048$). There were no differences ($P > 0.324$) in the plasma concentrations of either interleukin-6 or tumor necrosis factor-α in plasma after the diet change. These data indicate that switching from a lower NFC diet to an isoenergetic high NFC diet suppressed DMI and caused mild inflammation among peak lactating Jersey cows as evident by the greater plasma concentrations of the positive acute phase protein, haptoglobin, and reduced concentrations of plasma zinc, a negative acute phase metabolite.

Key Words: inflammation, neutral detergent fiber, soluble carbohydrate

0883 (W045) Effects of oral calcium supplementation on body temperature, incidence of uterine diseases, and milk yield in dairy cows. N. Martinez*[1], L. D. P. Sinedino[1], R. S. Bisinotto[1], R. Daetz[1], G. C. Gomes[1], L. F. Greco[1], W. W. Thatcher[1], C. A. Risco[2], and J. E. P. Santos[1], *[1]Dep. of Animal Sciences, University of Florida, Gainesville, [2]Dep. of Large Animal Clinical Sciences, University of Florida, Gainesville.*

Objectives were to determine the effects of oral Ca supplementation (CaS) on the incidence of uterine diseases in dairy cows considered at low (LRM; normal calving) or high risk (HRM; dystocia, twins, stillbirth, retained placenta and/or vulvo-vaginal laceration > 3 cm) of developing metritis. The hypotheses were that oral CaS with boluses containing $CaCl_2$ and $CaSO_4^-$ (each containing 43 g of Ca) during the first 4 DIM maintain blood ionized Ca (Ca^{2+}) concentrations $\geq$ 1.0 mM and reduce the incidence of uterine diseases regardless of risk of metritis. In this randomized complete block design, HRM cows (n = 225) were matched with LRM (n = 225) on the day of calving based on parity. Each pair of matched cows was randomized to one of three treatments: CaS0, no Ca supplementation; CaS2, 2 boluses at 0 and 1 DIM; CaS4, 2 boluses at 0 and 1 DIM followed by 1 bolus at 2, 3, and 4 DIM. Blood Ca^{2+} was measured in a subset of cows (n = 60) before the first bolus administration and 35 min after each dose for the first 4 DIM using a Vetscan Istat handheld analyzer (Abaxis). Rectal temperature and vaginal discharge were monitored in the first 10 DIM. Metritis was defined as fetid, watery vaginal discharge, and puerperal metritis (PuMet) was defined as metritis with rectal temperature $\geq$ 39.5°C. Endometritis was considered as mucopurulent vaginal discharge. Milk yield was evaluated weekly during the first 30 DIM. Cows with at least one corpus luteum in two ultrasounds performed 2 wk apart beginning on 38 DIM were considered cyclic. Data were analyzed using PROC GLIMMIX and PROC GENMOD of SAS. Oral supplementation with Ca during early postpartum increased blood Ca^{2+}concentrations; however, the two regimens of Ca supplementation failed to reduce the incidence of metritis in either HRM or LRM groups.

Key Words: dairy cows, Ca supplementation, metritis

0884 (W046) Blood calcium dynamics after prophylactic treatment of subclinical hypocalcemia with oral or intravenous calcium. C. D. Blanc*[1], M. Van der List[2], S. S. Aly[3], H. A. Rossow[3], and N. Silva-del-Rio[3], *[1]Pacific Rim Dairy, Corcoran, CA, [2]Boehringer Ingelheim, St Joseph, CA, [3]VMTRC, University of California, Tulare.*

Total serum Ca dynamics and urine pH levels were evaluated after prophylactic treatment of subclinical hypocalcemia after parturition in 33 multiparous Jersey/Holstein crossbreed cows. Cows were blocked according to their calcemic status at the time of treatment (Vetscan 200–1000R, Abaxis) [normocalcemic (8.0- 9.9 mg/dl; n = 15), or hypocalcemic (5.0–7.9 mg/dL; n = 18)] and randomly assigned to one of three treatments: Control [no Ca supplementation (n = 11)]; intravenous Ca [Ca-IV (n = 11), 500 mL of 23% Ca Gluconate (10.7 g Ca, Durvet, Blue Springs, MO)]; and oral Ca [Ca-Oral (n = 11), one oral bolus (Bovikalc bolus, Boehringer Ingelheim, St. Joseph, MO) containing $CaCl_2$ and $CaSO_4$ [43 g Ca] two times 12 h apart]. Total serum Ca levels were evaluated at 0, 1, 2, 4, 8, 12, 16, 20, 24, 36, and 48 h after treatment application (Enzymatic Rate/Automated Chemistry Analyzer method, Marshfield lab, WI) and urine pH at 0, 1, 12, 24, 36, and 48 h (on-farm with Oakton pH Testr 20). Overall, total serum Ca levels did not differ with treatment. But Ca-IV cows experienced a sharp increase in serum Ca levels after treatment (Peak = 11.4 mg/dL at 1 h), followed by a steep decline (nadir = 6.4 mg/dL at 24 h). Total serum Ca levels were higher for Ca-IV than control and Ca-Oral at 1, 2, and 4 h after treatment, but lower than Ca-Oral at 20, 24, and 36 h and control at 36 and 48 h. Treatment, time and treatment by time interaction were significant for urine pH. Mean urine pH was lower for Ca-Oral cows (6.69) than for control (7.52) and Ca-IV (7.19) cows. Urine pH levels at 1 h after treatment

[a,b,c] different superscripts indicate differences among treatments (P < 0.05).

were lower for Ca-IV compared to both Control and Ca-Oral. At 12, 24, and 36 h, urine pH levels were lower for Ca-Oral compared to both Control and Ca-IV. This was expected as the oral Ca supplementation used (Bovikalc) is designed as an acidifying agent. Wide fluctuations in blood Ca are observed after prophylactic intravenous Ca supplementation in normo- and subclinical hypocalcemic cows. The implications of these transient changes in serum Ca have still to be determined.

Key Words: hypocalcemia, hypercalcemia, dairy cattle

ASAS UNDERGRADUATE STUDENT POSTER COMPETITION

0885 (T011) Effects of supplementing Holstein heifers with dietary melatonin during late gestation on serum antioxidant capacity and anti-Müllerian hormone of offspring. B. O. Fleming*, K. E. Brockus, C. G. Hart, and C. O. Lemley, *Mississippi State University, Starkville.*

Previously, our laboratory observed an increase in maternal serum antioxidant capacity during late gestation dietary melatonin supplementation. Therefore, the objective was to examine the effects of supplementing melatonin to dams during late gestation on offspring serum antioxidant capacity and anti-Müllerian hormone concentrations. On d 190 of gestation, heifers (n = 20) were blocked by BW and then randomly assigned to one of two dietary treatments: 1). 20 mg of dietary melatonin per day (MEL) or 2). no melatonin supplementation (CON). Dietary treatments were terminated on d 262 of gestation. MEL heifers received 2 mL of 10 mg/mL melatonin in ethanol while CON heifers received 2 mL of ethanol alone. At birth, calves were separated from their dams and given 3.8L of colostrum. Calves were fed 5.7L of whole milk daily and offered 0.9 kg/d of starter grain. Starter was increased by 0.9 kg/d when orts were 0 kg. Calf (n = 18) total antioxidant capacity was determined in serum on wk 0, 1, 2, 3, and 4 of age. Concentrations of anti-Müllerian hormone were determined in female offspring (n = 15) on wk 4 of age. Data were analyzed using the PROC MIXED of SAS. For repeated measures the model statement contained treatment, age, and their respective interaction. Total antioxidant capacity was not different (P = 0.14) between calves from MEL treated dams vs. calves from CON treated. A main effect of age (P < 0.001) was observed for total antioxidant capacity, which was increased at wk 1 of age vs. 0, 2, 3, and 4. Concentrations of anti-Müllerian hormone tended to be increased (P < 0.10) in heifer calves from MEL treated dams (0.82 ± 0.19 ng/mL) vs. calves from CON treated dams (0.35 ± 0.19 ng/mL). In conclusion, the increase in maternal antioxidant capacity following dietary melatonin supplementation did not affect calf antioxidant capacity of serum during early postnatal development. Interestingly, the tendency for increased heifer calf anti-Müllerian hormone concentrations deserves further investigation into offspring ovarian reserves.

Key Words: anti-Müllerian hormone, antioxidant, melatonin

0886 (T012) Effects of electrostatic particle ionization on hog barn air quality, emissions, and pig growth performance. K. N. Card*[1], J. A. De Jong[1], J. M. DeRouchey[1], P. J. Tomlinson[1], M. J. Baumgartner[2], and Z. Liu[1], *[1]Kansas State University, Manhattan, [2]BEI Ag Solutions, Olivia, MN.*

Electrostatic particle ionization (EPI) systems emit negative ions, which in turn create polarized air particles. These polarized air particles attach to conductive or grounded surfaces in the barn. An experiment was conducted to determine the effects of EPI on hog barn air quality, emissions, and nursery pig growth performance. To make the comparison, the EPI system was installed in two identical nursery barns (200 pigs/barn) at the same location. During five 6-wk periods (6 to 23 kg BW) the EPI system was utilized in a single barn for one complete turn and then rotated to the opposite barn to ensure no barn effects would be present (five replications per treatment). Each barn was equipped with three external exhaust fans, and 12 internal attic air inlets. Pigs were allotted randomly between barns at the beginning of each period and measurements were taken every week for the 6-wk period. Dust particles were collected weekly inside the barn and in exhaust air for determination of particle size and average quantity for the turn. Additional measurements included in-barn air hydrogen sulfide and ammonia as well as ADG and final BW. Overall, there were fewer (P < 0.02) in-barn 0.3, 2.5 and 10.0 µ dust particles when the EPI system was active. The EPI system also reduced (P < 0.03) 0.3, 2.5 and 10.0 µ dust particles/m^3 in exhaust fan air. There were no differences for in-barn air ammonia and hydrogen sulfide concentrations. The EPI system tended to improve (P = 0.09) ADG and final BW. In conclusion, EPI was able to reduce airborne dust concentrations in-barn and in exhaust air and tended to improve growth performance.

Key Words: electrostatic particle ionization, emissions, nursery pig

0887 (T013) Effects of different cooling interventions on stationary livestock trailers at a commercial packing plant.

M. Heiller*[1], L. Edwards-Callaway[2], R. Bailey[3], N. Pudenz[4], M. Klassen[4], M. J. Ritter[5], A. Dezeeuw[4], and P. J. Rincker[6], *[1]Iowa State Univeristy, Ames, [2]JBS, Greely, CO, [3]JBS, Marshalltown, IA, [4]Elanco, Greenfield, IN, [5]Elanco Animal Health, Bondurant, IA, [6]Elanco Animal Health, Dahinda, IL.*

The objective was to determine effects of different cooling interventions on trailer temperature (T), relative humidity (RH), and transport losses over 20 min before unloading. Three treatments included: 1) Control (no water or fans), 2) Fan (20 min in front of a bank of fans), and 3) Shower+Fan (5 min of showering using the internal trailer system followed by 20 min in front of a bank of fans). Data was collected using HOBO data loggers placed inside the trailer on arrival at the packing plant on 150 trailers in blocks where all three treatments were represented with 60 min of each other. Data was summarized at time points 0, 5, 10, 15, and 20 min and was analyzed with PROC MIXED in SAS using block as a random effect. Results on trailer T (Table 0887a) indicate that the Control treatment increased numerically over time, the Fan treatment prevented a rise in T, and the Shower+Fan treatment was the coolest ($P < 0.05$) at all time points. RH inside the trailers was similar ($P > 0.05$) in the Control and Fan treatment, but higher ($P < 0.05$) in the Shower+Fan treatment at all time points (Table 0887b). No differences were determined on the incidence of dead on arrivals ($P = 0.87$) or fatigued animals ($P = .077$). Further investigation of the data revealed an interaction ($P = 0.02$) between treatment and environmental temperature where the temperature differences between treatments become greater at higher environmental temperatures.

0888 (T014) Effects of poor maternal nutrition during gestation on gene expression in liver of offspring.

K. K. McFadden*, M. L. Hoffman, K. N. Peck, S. A. Reed, S. A. Zinn, and K. E. Govoni, *Dep. of Animal Science, University of Connecticut, Storrs.*

Poor maternal nutrition during gestation can reduce growth and circulating growth factors secreted by the liver, as well as alter lipid metabolism. However, the mechanisms that lead to these alterations are not well understood. We hypothesized that poor maternal nutrition during gestation would alter expression of key genes involved in lipid metabolism and the somatotropic axis in the liver of offspring. Thirty-six multiparous ewes were individually housed and fed 100, 60, or 140% of NRC requirements beginning at d 31 ± 1.3 of gestation. Lambs were euthanized within 24 h of birth (1 d; $n = 18$) or 3 mo of age ($n = 15$). Lambs from ewes fed 100, 60, or 140% will be referred to as CON, RES, and OVER, respectively. At euthanasia, whole livers were harvested, weighed and tissue samples collected. Total RNA was extracted and gene expression determined by real-time reverse transcriptase (RT)-PCR. Data were analyzed using PROC GLM with significance considered at $P \leq 0.05$ and a tendency at $0.05 < P \leq 0.10$. As previously reported, BW were 13% greater in OVER vs. CON ($P \leq 0.05$). Liver weight was 43% greater in OVER vs. CON ($P = 0.08$) at 1 d when adjusted for BW, but no difference was observed at 3 mo ($P = 0.6$). At 1 d, relative to CON, the expression of sterol-regulatory element binding protein-I (SREBP-I), a regulator of hepatic lipogenesis, was reduced 2.6 ± 0.1 and 3.7 ± 0.1-fold in RES and OVER, respectively ($P < 0.01$). The expression of IGF-I receptor (IGF-IR) was reduced 1.7 ± 0.1 and 2.0 ± 0.2-fold in RES ($P = 0.03$) and OVER ($P = 0.09$), respectively at 1 d relative to CON. Expression of IGFBP-4 was reduced 2.6 ± 0.1 and 1.7 ± 0.1-fold in RES ($P = 0.01$) and OVER ($P = 0.07$), respectively at 1 d relative to CON. Expression of SREBP-I, IGF-IR, and IGFBP-4 were not altered at 3 mo ($P \geq 0.3$). Relative to CON, expression of IGFBP-3 increased 1.7 ± 0.2-fold in OVER ($P = 0.04$) at 3 mo, but was unaltered at d 1 ($P \geq 0.8$). Maternal diet did not affect IGF-I at either time point ($P \geq 0.3$). In conclusion, poor maternal nutrition alters genes involved in lipid metabolism and IGF action, which may contribute to altered growth and increased fat deposition in offspring.

Key Words: liver, sheep, somatotropic axis

0889 (T015) Interleukin-1 β decreases myoblast fusion in vitro. B. E. Sullivan[*1] and S. A. Reed[2], *[1]University of Connecticut, Storr, [2]Dep. of Animal Science, University of Connecticut, Storrs.*

During times of stress, systemic pro-inflammatory cytokine levels are increased, which may prevent optimal growth and development of muscle and/or induce muscle atrophy. Pro-inflammatory cytokines can induce negative responses in muscle by altering the balance of protein synthesis and degradation in established myofibers, or by influencing the proliferation and differentiation of myoblasts. Interleukin-1 β (IL-1β) is a pro-inflammatory cytokine involved in stress and disease responses, but little is known about how IL-1β affects myoblast function. We hypothesized that IL-1β would decrease myoblast proliferation and/or differentiation. To test this hypothesis, C2C12 mouse myoblasts were treated with 0.1 ng/mL or 1.0 ng/mL of IL-1β, or carrier only (control). To determine proliferation rate, myoblasts were plated at $2.6x10^3$ cells/cm^2 and cultured for 48 h in the presence or absence of IL-1β. Cells were pulsed with bromodeoxyuridine (BrdU), fixed, and immunostained. The number of BrdU positive cells was quantified as a percent of total nuclei (identified by Hoescht 33342). To determine if IL-1β affected fusion, myoblasts were plated at $2.0x10^4$ cells/cm^2 in growth media for 48 h, at which time media was changed into differentiation media supplemented with 0.1 ng/mL or 1.0 ng/mL of IL-1β, or carrier only. Cells were immunostained with myosin heavy chain (MyHC) and Hoescht 33342. Fusion index was determined by quantifying the number of nuclei within multinucleated myotubes divided by total nuclei. Finally, to determine the effect of IL-1β on myotube size, myoblasts were cultured for 48 h in growth media and 48 h in differentiation media. Cells were cultured for an additional 48 h in the presence or absence of IL-1β, fixed and immunostained for MyHC. Myotube diameter and fusion index were quantified. All data was analyzed using ANOVA in GraphPad Prism followed by Tukey's test for multiple comparisons. There were no significant effects of IL-1β on proliferation or fiber diameter ($P \geq 0.05$). However, fusion was decreased 13.5% in myoblasts treated with 1.0 ng/mL of IL-1β ($P \leq 0.05$). In conclusion, IL-1β decreases myoblast fusion, but does not affect proliferation or fiber diameter. These results suggest that IL-1β may contribute to poor muscle growth by decreasing fusion of myoblasts into existing myofibers, preventing optimal hypertrophy.

Key Words: cytokine, fusion, IL-1β, myoblasts

0890 (T016) Sperm maturation (capacitation) but not progesterone reduces the abundance of a receptor for oviduct glycans. R. A. Winters[*1], E. Silva[1], and D. J. Miller[2], *[1]University of Illinois at Urbana-Champaign, Urbana, [2]University of Illinois, Urbana.*

As sperm travel through the female reproductive tract they bind to glycan motifs on cells lining the oviduct lumen, forming a sperm reservoir. Near the time of ovulation, sperm are released and travel to the site of fertilization. Our lab has found that a boar sperm protein called lactadherin binds to an oviduct trisaccharide, Lewis^x, to mediate sperm binding to oviduct cells. It has been suggested that sperm release from the oviduct reservoir is partially mediated by an increase in progesterone concentration in the oviductal fluid that would affect sperm capacitation and promote release from oviduct Lewis^x, perhaps by releasing sperm lactadherin. We tested this hypothesis in experiments to define the effect of sperm capacitation and progesterone exposure on sperm lactadherin abundance. Sperm from fertile boars were washed using a Percoll cushion. Treatments consisted of: 1) sperm capacitation for 4 h using mTALP medium containing BSA and sodium bicarbonate, and 2) sperm treatment with increasing concentrations of progesterone (0, 80, 800nM) for 30 min in mTALP. After treatment, sperm protein was extracted using a 0.1% Nonidet P-40 lysis buffer, and samples were submitted to western blot analysis. Experiments were repeated at least twice. Based on western blotting with a lactadherin antibody, two protein bands migrating at 35 kDa and 47 kDa were identified. The greater signal was present at 47 kDa and, based on its migration, it is recognized as lactadherin. The 47 kDa signal (lactadherin) was higher in sperm before capacitation than after capacitation. Based on western blot results, lactadherin concentration was not affected by progesterone treatment; the abundance of the 47 kDa band did not change. In conclusion, two bands were detected by the lactadherin antibody, suggesting the presence of two protein isoforms. Lactadherin abundance on the sperm surface was reduced after sperm capacitation but progesterone did not affect the abundance of lactadherin. The reduction in lactadherin during capacitation may contribute to sperm release from the oviduct. *This project was supported by Agriculture and Food Research Initiative Competitive Grant no. 2011–67015–20099 from the USDA National Institute of Food and Agriculture.*

Key Words: sperm, capacitation, oviduct

0891 (T017) Variations in the expression of triglyceride synthesis genes in pigs provided *Enterobacter cloacae*. S. J. White*[1], J. A. Carroll[2], J. A. Thornton[1], P. R. Broadway[3], J. G. Wilson[1], and J. R. Donaldson[1], *[1]Mississippi State University, Starkville, [2]USDA-ARS, Livestock Issues Research Unit, Lubbock, TX, [3]Texas Tech University, Wolfforth.*

Enteric infections are leading causes of morbidity and mortality among livestock. Weanling pigs are particularly susceptible to infections, primarily due to reduced amounts of adipose tissue. Limited stores of adipose tissue can lead to an insufficient supply of energy during times of nutritional restriction that would be available to mount an effective immune response. Previously, two novel probiotics (*Enterobacter cloacae* JD6301 and JD8715, a genetically altered form that produces extracellular lipids) were found to increase circulating triglycerides in pigs. In this current study, 36 weanling pigs were supplemented with *Enterobacter cloacae* JD6301 or JD8715 for 7 d prior and 3 d afterward relative to an orally inoculated *Salmonella typhimurium* ($1x10^9$ CFU) challenge. To determine if either probiotic altered the production of triglycerides in response to the infection, adipose tissues were collected from four pigs every 24 h in relation to the challenge to evaluate potential differences in lipogenesis. Total RNA was isolated post challenge and analyzed for variations in the expression of genes involved in triglyceride synthesis and compared to control pigs only provided phosphate buffered saline. The data indicate that pigs provided JD8715 had an increase in lipoprotein lipase ($P = 0.027$), and a decrease in the insulin-induced gene 1 ($P = 0.02$), apolipoprotein A1 ($P = 0.04$), and DGAT2 ($P = 0.009$) 1 d post-challenge in comparison to controls. A 16-fold increase ($P = 0.001$) in the insulin-induced gene 1 was also observed on d 3 in pigs provided JD8715 compared to control pigs. Together, these data suggest that providing *Enterobacter cloacae* JD8715 increased the amount of triglycerides available to the pigs, thus potentially improving the availability of energy. Further research is needed to determine how this increase modulates the immune response.

Key Words: pigs, lipids, adipose tissue

0892 (T018) Gene set enrichment analysis of residual feed intake in Hereford cattle. L. D. Kidder*[1], A. Wojtowicz[1], J. F. Taylor[2], C. M. Seabury[3], K. A. Johnson[1], and H. L. Neibergs[1], *[1]Washington State University, Pullman, [2]University of Missouri, Columbia, [3]Texas A&M University, College Station.*

Feed comprises 66 and 77% of the total cost of calf and yearling finishing systems, respectively. Heritabilities for feed intake and feed efficiency (FE, estimated as residual feed intake, or RFI) have ranged from 0.08 to 0.46 in previous studies, highlighting the potential for selection to bring about significant gains in feed efficiency and profitability within the beef industry. The objective of this study was to identify gene pathways significant for FE as measured by RFI through the use of gene set enrichment analysis (GSEA) using single nucleotide polymorphisms (SNPs) as proxies for bovine genes. A population of 847 Hereford cattle (181 purebreds and 666 high-percentage Hereford crossbred animals consisting of 23 females and 824 males ranging in age from 210 to 496 d) from a single ranch were evaluated for a period ranging from 70 to 140 d on feed (DOF). Only 31 animals were fed over 72 d. Average daily gain (ADG), dry matter intake (DMI), initial weight (IW), mid-test metabolic weight (MMWT), and DOF were recorded across the feeding period for each individual. Covariates for the genome wide association study (GWAS) consisted of age, sex, DOF and % Hereford. GWAS was followed by GSEA of SNP data with *Bos taurus* gene sets sourced from GO, KEGG, Panther, Reactome, and Metacyc. Gene sets containing fewer than 10 or greater than 200 SNPs were excluded from the analysis. A total of 19,598 bovine genes were mapped within gene sets, and proxy SNPs were mapped to genes located within 20 kilobase pairs. The null distribution of the GSEA test statistic was approximated using 10,000 random permutations. Genotypes were obtained from the Illumina BovineSNP50 ($N = 361$) and BovineHD ($N = 486$) BeadChips and imputed to 778,000 SNPs using Beagle. The GO pathway GO:0044706 multi-multicellular organism process with 90 genes was significant for RFI with a false discovery rate of 0.061 and a normalized enrichment score of 3.978. There were a total of 51 leading edge genes in GO:0044706. The top 10 genes were: PGR, CORIN, STAT5B, TIMP1, PCSK5, THRB, NR2F2, MMP2, FKBP4, and JUNB. Heritability for RFI was estimated to be 0.49. These results suggest that genetic selection for RFI has potential to dramatically affect the efficiency and, therefore, profitability of beef cattle production.

Key Words: genetics, RFI beef

0893 (T019) pH fluctuations in the hindgut of horses relative to meal feeding. K. M. DeLano*[1], T. L. Douthit[1], A. Reeg[1], N. M. Bello[1], M. E. Gordon[2], and K. Williamson[2], *[1]Kansas State University, Manhattan, [2]Purina Animal Nutrition, LLC, Gray Summit, MO.*

This study assessed changes of pH over time in the equine hindgut relative to meal feeding. Nine quarter horses with cecal cannulae surgically inserted 4 yr before the experiment were utilized. The group was comprised of five geldings and four mares, with ages ranging from 8 to 10 yr old, and body weight between 455 and 590 kg. Horses were housed in heated individual stalls, with ad libitum access to water and white salt blocks. The horses' diet consisted of 1.5% BW prairie grass hay and 0.5% BW concentrate (Omolene 200, Purina Animal Nutrition, LLC, St. Louis, MO), with the concentrate fed in the morning only (0700) and the hay divided into two daily feedings (0700 and 1930). Horses were maintained on this

regimen for three separate 21-d periods. During the last 3 d of each period (d 19 to 21), pH was measured in cecal and fecal samples collected at -1, +1, +4, +8, +12, +16, +20, and +24 h relative to feeding of the concentrate meal. Cecal and fecal pH fluctuations over time were jointly modeled using a general linear mixed model. Hindgut pH dynamics relative to feeding differed between the cecum and the feces ($P < 0.0001$). In the cecum, a decline in pH (approx. 0.363 ± 0.03; lsmean ± SEM) was observed as soon as 4 h after feeding ($P < 0.0001$). Minimum pH values in the cecum were recorded 8 h after feeding, and a return to baseline cecal pH was apparent at 20 to 24 h after feeding. In the feces, a smaller decline was observed (approx. 0.144 ± 0.044) but it did not become apparent until 8 h after feeding ($P = 0.035$). The minimum fecal pH was reached at 12 h after feeding ($P = 0.0055$); by 16 h after feeding, there was no evidence for differences from baseline pH ($P = 1.00$). These results suggest a maximum time lag in pH fluctuations of approximately 4 h between the cecum and the feces. It is necessary to note that more precise lag times could not be quantified with this study design, as measurements were taken every 4 h. Further research is needed to fine-tune predictive ability of fecal pH on cecal pH over time.

Key Words: cecal pH, equine, fecal pH

0894 (T020) Oral supplementation with vitamin E and fertility in young bulls raised in Brazilian midlewest. R. D. Almeida*, L. K. Hatamoto-Zervoudakis, W. A. D. S. Marinho, B. H. Tsuneda, F. A. D. P. D. B. Arguello, J. T. Zervoudakis, M. F. Duarte Junior, P. P. Tsuneda, and T. B. Castaldeli, *Federal University of Mato Grosso, Cuiaba, Brazil.*

The sperm cells are highly susceptible to peroxidative damage, such damage in their sperm membrane occurs due to oxidative stress that is responsible for the reduction in the fertility of sperm. One of the causes of the increase in oxidative stress is increased environmental heat stress and consequent increase in temperature testicular promoting the increase in NADPH oxidase activity and increased availability of transition metals. Dietary deficiencies may also be associated with the decrease in the antioxidant defense mechanisms. Vitamin E is a fat-soluble antioxidant and has the ability to prevent the spread of chain reactions induced by ROS in biological membranes, representing an important defense against oxidative damage caused to the sperm membrane. The objective of this study was to evaluate whether oral supplementation with vitamin E alters bulls fertility and performance of bulls raised in pastures in tropical conditions. We used 16 bulls/Brangus, with a mean of 24 mo and 462.2 kg were randomly divided into two groups: GC = Control group (concentrated supplementation without adding vitamin E), vitamin E group GE = (400UI/animal/day supplemented with vitamin E). The animals were maintained on pasture, and supplemented (4,5 kg/animal) with concentrated feed once a day. During the supplementation period, four samples (days: D0, D30, D60 and D75) were made by electrostimulation. In each collection were evaluated: weight (BW), Diameter (TPER) and Testicular Consistency (TC), Volume (VOL) and Concentration (CONC) of the ejaculate, Motility (MOT) and Vigor (VIG) sperm, Percentage of primary defects (*P*D), Secondary (SD) and Total (TD), Sperm viability (EOS), the Integrity of sperm membrane (HYPO) and Crossomal (POPE). The experiment was conducted in a completely randomized design. Data were analyzed using ANOVA 5%. It was found BW treatment effect ($P = 0.0472$), TPER ($P = 0.0015$), TC ($P = 0.0367$), EVIG ($P = 0.0183$) and a trend effect for SD ($P = 0.0617$). The results obtained in the experimental conditions of this study, it is concluded that oral supplementation with vitamin E, 400UI/day does not altered semen quality, however detracted and testicular characteristics of bulls raised on pasture in tropical conditions.

Key Words: reactive oxygen species, oxidative stress, lipid peroxidation.

0895 (T021) Polymelia in Holstein cattle. K. D. Moss*[1], F. Avila[2], B. M. Marron[3], T. Raudsepp[2], J. Beever[3], M. Neupane[1], S. Parish[1], J. Kiser[1], B. Cantrell[1], and H. L. Neibergs[1], *[1]Washington State University, Pulllman, [2]Texas A&M University, College Station, [3]University of Illinois, Urbana.*

Polymelia is a congenital condition where an animal has more than the normal number of limbs. Previous reports have suggested that polymelia is due to abnormal chromosomal breaks or alternatively due to a mutation found to segregate in Angus cattle. A male Holstein calf was presented to the WSU Veterinary Hospital with scoliosis, a deviated tail, and two additional front legs originating from each scapula. The objective of this study was to determine if polymelia in this Holstein calf was due to the mutation identified in Angus cattle, a gross chromosomal abnormality or potentially another genetic cause. A 10-mL blood sample was taken via the jugular vein for genetic analyses. Five mL of blood was used to prepare a karyotype of the calf to identify chromosomal abnormalities. From the remaining 5 mL of blood, DNA was extracted for genotyping. Genotyping of this Holstein calf for the specific mutation present in Angus cattle was performed using a PCR-RFLP technique. Genotypes were also obtained from the Holstein calf using the Illumina bovine HD BeadChip. A genome wide association study (GWAS) was conducted with the polymelia calf compared with 2800 control Holstein calf samples. The statistical approach used for the GWAS was EMMAX (Efficient Mixed-Model Association expedited) within the SNP & Variation Suite 7 software package (Golden Helix, Bozeman, MT). GWAS data underwent quality control filtering for minor allele frequency (< 1%), SNP call rate (< 95%), and animal call rate (removal of animals with less than 95% of SNPs called). Population stratification was tested

for ($lambda_{GC}$) before GWAS analysis. Loci associated with polymelia were found to be associated when $P < 1x10^{-50}$. The karyotype results showed no evidence of increased levels of chromosomal breaks in the Holstein calf. The PCR-RFLP genotype of the Holstein calf was consistent with a homozygous normal Angus animal. Furthermore, sequencing of the entire coding sequence of the gene mutated in Angus cattle, revealed no additional polymorphisms that might cause the polymelia phenotype. No population stratification was identified ($lambda_{GC}$ = 1.04) in the Holsteins genotyped by the Bovine HD SNP assay. The GWAS association analysis identified three loci associated with polymelia: one locus on BTA13 ($P < 1x10^{-281}$), BTA10 ($P < 2x10^{-110}$) and BTA20 ($P < 2x10^{-52}$). These preliminary results suggest that polymelia may be due to more than one locus and mutations that may cause polymelia are not shared across all breeds.

Key Words: polymelia, genetics, Holstein

0896 (T022) Effect of supplementation of the middle and freezing with vitamin E about the feasibility and quality of frozen bovine semen. R. D. Almeida*, L. K. Hatamoto-Zervoudakis, M. F. C. Filho, J. T. Zervoudakis, P. P. Tsuneda, and T. B. Castaldeli, *Federal University of Mato Grosso, Cuiaba, Brazil.*

The conditions of storing semen induce the formation of free radicals from the oxidation of fatty acids components of the plasma membrane. Those effects are related with the aggression on the plasma membrane and other cellular organelles, caused by oxidative stress, heat shock and formation of intracellular ice crystals. The interception of reactive oxygen species is based in breaking the chain reaction that occurs with free radicals to form oxidation products. This breakdown promoted by certain antioxidants, for example, α-tocopherol (vitamin E), radicals must not result in final products that is, without electrostatic despareado. This work had as purpose to appraise the quality and the feasibility of frozen semen in medium supplemented with vitamin E. Semen collections of 16 bulls Brangus race of reproductive age with proven fertility and healthy were performed. The semen was collected by eletroejaculation method, isolated shock heat, light and previously heated. Immediately after collection each ejaculate obtained was divided into two fractions where each fraction was diluted in one of two treatments being: T1-control (medium without supplementation), T2-medium supplemented with 2.0 mmol/L of vitamin "E". The basic medium used for freezing was tris-yolk sodium citrate, and the methodology used was described by Beconi et al. (1991). The semen was stored in straws of 0.25 and maintained in nitrogen until the time of analysis. For evaluation of sperm viability it was used the method for staining with eosin associated negrosina in thawed semen, cells with membrane lesions present in the nucleus stained by eosin, remaining reddish, the living cells, colorless microscopic reading. In force and motility parameters did not differ between treatments. On sperm viability (eosin/negrosina) had a significant difference between treatments ($P = 0.0031$), where treatment control was superior to treatment with vitamin E, indicating that the inclusion of 2.0 mmol/L was deleterious to sperm viability. More studies should be conducted to find an optimal concentration to ensure a better sperm viability after thawing semen.

Key Words: anti-oxidant, frozen semen

0897 (T023) The effects of cutting height and plant maturity on yield and nutritional value of brome forage. M. A. Woolsoncroft*, S. R. Duncan, A. J. Sexten, and A. K. Sexten, *Kansas State University, Manhattan.*

It is well-known that quality of forage decreases as plants matures. Although some forage quality must be sacrificed to achieve sustainable yields, the purpose of this study is to determine the combination of cutting height and stage of plant maturity that optimizes both quality and forage yield. A brome pasture was divided into 27 plots (3.05 m × 4.57 m) in a completely randomized block design with a 3 × 3 factorial treatment arrangement to determine the effect of cutting height (2.54 cm, 7.62 cm, or 12.7 cm) and plant maturity (boot, bloom, seed) on brome yield and nutritional value. A strip of forage (0.91 m × 3.05 m) was harvested from each plot. One grab sample from each strip was weighed in the field, oven-dried (49°C for 24 to 48 h), reweighed to determine percent dry matter and then calculate plot yield ($kg \cdot ha^{-1}$). A second grab sample from each harvested strip was collected and analyzed for DM, Ash, N, NDF, and ADF. Forage yield was greater ($P < 0.0002$) when brome was cut at 2.54 cm compared to 7.62 cm and 12.7 cm cutting heights. Brome cut at 7.62 cm and 12.7 cm produced similar yields. Cutting height had no effect on any of the nutritional parameters measured. Forage yield was greatest ($P < 0.0001$) for brome that was in the seed stage of maturity, followed by bloom then boot, which produced the lowest forage yield. Dry matter content was greatest ($P = 0.0001$) in the seed stage brome, but lower and similar between bloom and boot stage brome. Ash content was also similar between boot and bloom stage brome with both having a greater ($P = 0.002$) ash content than seed stage brome. Both NDF and ADF increased with plant maturity, with seed and bloom stage brome having a greater ($P = 0.0001$) fiber content than boot stage brome. Crude protein, estimated from N content, was greatest ($P = 0.0001$) in boot, followed by bloom, then seed stage brome, which contained the lowest CP content. Reducing cutting height produced a greater forage yield without negatively impacting nutritional value. More mature brome produced greater yields; however, nutritional value was decreased with increasing maturity. Cutting brome at a reduced cutting height in a younger stage of maturity can lead to better yields without sacrificing nutritional value.

Key Words: brome, plant maturity, cutting height

0898 (T024) Cattle requiring multiple treatments for bovine respiratory disease exhibit decreased capacity to protect against histone cytotoxicity.
J. Matera*, B. K. Wilson, J. Hernandez Gifford, C. R. Krehbiel, and C. A. Gifford, *Oklahoma State University, Stillwater.*

Bovine respiratory disease (BRD) is the leading cause of morbidity and mortality in feedlot cattle. Pneumonia associated with BRD causes significant inflammation and lesions in lung tissue of infected cattle. During acute inflammatory responses, circulating histones increase and contribute to mortality in rodents and humans, yet serum proteins provide protection against histone cytotoxicity in some cases. We hypothesized that cattle experiencing fatal cases of BRD have reduced ability to protect against histone cytotoxicity. Bovine kidney cells (MDBK) were exposed to 0, 50 μg/mL, and 100 μg/mL of histones from calf thymus for 18 h without serum. To assess cell viability, Resazurin was added (0.5%) and cells were incubated for an additional 6 h followed by fluorescent quantification. Because both doses exhibited cytotoxic effects, and work in humans suggests that serum histone levels rise to 50 μg/mL during sepsis, 50 μg/mL was chosen for subsequent studies. At feedlot arrival, serum samples were collected from 37 bull calves, followed by castration and normal feedlot processing procedures. Animals were retrospectively assigned to either Controls (never treated for BRD; CONT; $n = 12$), Recovery (treated once for BRD and recovered; RECOV; $n = 9$), Dead (treated once for BRD and subsequently died; DEAD; $n = 8$), or Chronic (treated four times for BRD; CHRON; $n = 8$). Duplicate wells containing MDBK cells were cultured in 96-well plates as described above except were supplemented with 1% serum from individual animals plus 50 μg/mL histones and duplicate wells with 1% serum alone. Fluorescent values from serum alone were subtracted from values obtained for histone treatment for each animal and analyzed using the GLM procedure of SAS. Results showed that histone treatment reduced cell viability in all groups and treatment group affected serum protective capacity ($P = 0.05$). Serum from CONT, RECOV, and DEAD calves all exhibited a similar ($P > 0.50$) response to histone treatment with values of −591.8 ± 549.9, -1086.9 ± 634.9, and -1193.8 ± 634.9, respectively. However, CHRON calves demonstrated an impaired capacity to protect against histones (-3054.4 ± 673.4) and were reduced ($P < 0.05$) when compared to each of the other groups. Results suggest that calves that require multiple treatments for BRD have reduced ability to protect against cytotoxicity of histones. Understanding the underlying mechanism responsible for protecting against histone cytotoxicity could lead to better identification of animals susceptible to severe cases of BRD.

Key Words: BRD, histones, feedlot, health

0899 (T025) Development of a non-invasive system for monitoring dairy cattle sleep.
J. M. Klefot*, J. L. Murphy, K. D. Donohue, B. F. O'Hara, M. E. Lhamon, and J. M. Bewley*, University of Kentucky, Lexington.*

Lack of sleep in dairy cattle may indicate shortcomings in housing, environment, or increased physiological disturbances. Little research has been conducted to assess sleep in production livestock, primarily because of limitations with monitoring abilities. Consequently, biological understanding of the production circumstances and facility options that affect sleep is limited. The objective of this study was to test a non-invasive system using a three-axis accelerometer monitor to measure head position of the cow to classify sleep, and wake behaviors. The duration of the study consisted of two 24-hour periods of observing four Holstein dairy cows in September 2013 at the University of Kentucky Coldstream Dairy. The three-axis accelerometers were attached to a harness on the side of each cow's neck to determine head and body movement. Human observation of the animals noted the times of active behaviors and very low activity, or sleep behaviors. Wake behaviors were classified as standing and alert. Sleep was classified with the behaviors of lying with no movement and eyes closed with head rested on the ground or flank. The radial signal was extracted from the xyz components of the accelerometer to obtain a motion signal independent of direction. Radial signal features were examined for maximizing the performance of detecting sleep behavior using a Fishers linear discriminant analysis (LDA) classifier. This study included a total of 652 min of high activity behaviors and 107 min of sleep behavior recorded from two cows with usable data. Results from a bootstrapping analysis show an agreement between human observation and the LDA classifier of 93.7 ± 0.7% for wake behavior and 92.2 ± 0.8% for sleep behavior, with a 95% confidence interval. This monitor may be used to help understand options for monitoring sleep in research and production settings.

Key Words: behavior, sleep, accelerometer

0900 (T026) Associative effects of feeding varying levels of soyhulls to lambs consuming grass hay.
K. M. Ulmer*, D. D. Harmon, S. J. Neil, A. K. Revercomb, J. G. Young, L. A. Engel, and M. A. McCann, *Virginia Polytechnic Institute and State University, Blacksburg.*

Soyhulls are routinely utilized as a supplement to forage based diets in ruminants. Previous studies have focused on low and moderate supplementation rates where soyhulls have generally been effective and economical. Recent grain prices have increased pressure on livestock producers to potentially expand their use of soyhulls in situations where higher levels of performance are desired. The objective of this study was to compare the effect of various levels of soyhull supplementation on nutrient digestibility in lambs fed a basal diet of chopped grass hay. Eight St. Croix

cross wether lambs (39 ± 4 kg) were randomly assigned to four diets using a 4 × 4 replicated Latin square design. All lambs were offered a chopped grass hay free choice and supplemented at 0, 1, 2, or 3% of body weight in soyhulls (DM basis). Each period consisted of a 9-d adjustment period followed by a 5-d collection period. Lambs were housed individually and fitted with total fecal collection bags during the adjustment period of each diet. At the conclusion of each collection period and before proceeding to the next adjustment period, lambs were weighed to adjust supplementation levels. During collection periods, daily feed, refusals and feces weights were recorded and samples retained for analysis. Samples were dried, ground, and analyzed for dry matter (DM), crude protein (CP), ash, neutral detergent fiber (NDF) and acid detergent fiber (ADF). Data were analyzed in SAS using the PROC GLIMMIX procedure with a model including diet and period. Linear, quadratic and cubic treatment effects were evaluated using preplanned contrasts. Daily DM intake increased linearly ($P < .01$) with increasing soyhull supplementation. Dry matter digestibility increased quadratically ($P < .01$) as soyhull supplementation increased (56.6, 63.0, 65.4, and 66.4, respectively). Similarly, both NDF and ADF digestibility exhibited a quadratic response ($P < .01$) as dietary soyhull level increased. However, contrary to DM digestibility, NDF and ADF displayed peak digestibility at the 2% supplementation level. Results would suggest that supplementation of soyhulls above 2% of body weight would provide diminishing benefits as compared to lower levels of supplementation. Depression of NDF and ADF digestibilities at the 3% supplementation level contributed to the reduced DM digestibility improvement. Further research is needed to determine if reduced fiber digestibility was the result of increased rate of passage and reduced ruminal digestion.

Key Words: soyhulls, associative effects, lambs

0901 (T027) Adding post-extraction algal residue (PEAR) to cattle finishing diets reduces the quantity of fecal volatile chemicals often associated with feedlot malodors.

H. R. Voegele*[1], C. R. Kerth[1], T. A. Wickersham[2], J. C. Hoffman[1], and T. J. Luckemeyer[1], *[1]Texas A&M University Animal Science Dept., College Station, [2]Texas A&M University, College Station.*

Efficiencies of finishing cattle in feedlots have resulted in lower production costs and less expensive beef for consumers. But an increase in the size of feedlots, and resulting waste malodors, along with urban sprawl have brought the public and feedlots closer together and given urgency to finding methods to reduce feedlot malodors. Our objective was to feed post-extraction algal residue (PEAR) to steers to reduce the incidence of fecal malodor chemical compounds. Six steers were fed PEAR (1.25 kg/d, as-fed) along with a 90% concentrate and 10% forage diet for 35 d before harvest. One wk prior and 1 wk after the addition of PEAR to the feed, fecal samples were collected from each steer to produce fecal samples with and without PEAR within the same animal. Fecal samples were stored in an enclosed plastic bag immediately after collection (−80°C) until analyses. Each sample was placed in a 760 mL glass jar submerged in a 60°C water bath, and thawed to 25°C. A 75 µm carboxen/polydimethylsiloxane solid phase microextraction (SPME) fiber was then inserted into the jar and collected for 120 min. The SPME was desorbed in a multi-dimensional GC/MS with dual olfactory ports. All eluted chemicals were quantified as total ion counts (TIC) under the curve of each elution peak corresponding to each chemical identified by the MS library. Simple ANOVA was conducted to determine the effect of adding PEAR to the diet of steers on the relative quantity of fecal aroma chemical compounds. The general classification of amine/amide compounds tended ($P = 0.071$) to be reduced when PEAR was added to the feed. The addition of PEAR reduced the quantity of indole (manure/stench), the butyl ester of acetic acid (acid/burnt aroma), and carbon disulfide (rotten eggs) in fecal samples by 92.5, 80.5, and 97.1%, respectively ($P < 0.02$). Additionally, the quantity of the volatile chemicals dimethyl disulfide (garlic/burnt rubber), ethyl vinyl sulfide (sulfurous), and butyric acid (vomit) in the feces were reduced ($P < 0.05$) to undetectable levels with the addition of PEAR in the feed. The addition of PEAR to cattle finishing diets reduced the quantity of volatile chemicals often associated feedlot malodors.

Key Words: algae, beef, odor

0902 (T028) Treatment response to bovine respiratory disease in beef stocker calves was not positively affected when using isoflupredone acetate as ancillary therapy.

C. E. Crews*[1], J. G. Powell[2], E. B. Kegley[2], J. L. Reynolds[2], and J. A. Hornsby[2], *[1]University of Arkansas, Fayetteville, [2]Dep. of Animal Science, University of Arkansas Division of Agriculture, Fayetteville.*

The objective of this study was to evaluate the use of isoflupredone acetate as ancillary therapy in the treatment of bovine respiratory disease in high-risk stocker calves. Crossbred male beef calves ($n = 192$; BW = 221 ± 3.9 kg) were acquired in two blocks from regional auction markets and were transported to the University of Arkansas Stocker and Receiving Cattle Unit. Calves were observed daily for signs of respiratory illness, and antibiotic treatment was administered if calves displayed signs of illness and rectal temperature was ≥ 40°C. Calves ($n = 72$) requiring antibiotic treatment for respiratory illness were assigned randomly to either treatment 1 (injection of florfenicol) or treatment 2 (injection of florfenicol with isoflupredone acetate). Treatments occurred between d 2 and d 14 of the study. Both treatment groups were rechecked 48 h post treatment to determine treatment efficacy. Blood was collected twice (at treatment and recheck) via jugular venipuncture to evaluate complete blood cell count. Body weights were recorded at d 0, 14, 28, and 46 (block 1) or 42 (block 2). No difference was evident between treatment groups for medical treatment cost ($P = 0.54$) or number of calves requiring a second or third antibiotic treatment ($P \geq 0.61$). Upon

recheck, neutrophils were higher and lymphocytes were lower in calves that received isoflupredone acetate ($P \leq 0.04$) compared to calves that received only antibiotic therapy. Consequently, the neutrophil to lymphocyte ratio was greater ($P < 0.01$) in calves that received isoflupredone acetate compared to those that only received antibiotic therapy. No difference existed in overall white blood cell count at recheck ($P = 0.67$) or body temperature at recheck ($P = 0.43$). Calves that received isoflupredone acetate tended to exhibit greater ($P = 0.09$) ADG between d 14 and 28 compared to calves that were treated with only antibiotic therapy, 1.04 kg and 0.77 kg, respectively. Overall ADG for the entire receiving study was similar ($P = 0.88$) for both treatments. Results indicate that treatment of bovine respiratory disease with isoflupredone acetate as ancillary therapy to an antibiotic regimen does not have a positive effect on overall ADG, and it does not reduce medical treatment cost or the number of repeat treatments.

Key Words: bovine respiratory disease, ancillary therapy, isoflupredone acetate

---

0903 (T029) The effects of stage of production and implant exposure on feedlot performance, carcass characteristics, and relative mRNA gene expression. K. E. Larrabee*, B. C. Bernhard, C. L. Maxwell, B. K. Wilson, S. Roberts, and C. R. Krehbiel, *Oklahoma State University, Stillwater.*

Black-hided heifers ($n = 187$; 362 kg) were used in a 122-d finishing study to determine the effects of a trenbolone acetate-estradiol implant [Revalor 200 (200 mg of trenbolone acetate and 20 mg of estradiol)] on feedlot performance, carcass characteristics, and relative mRNA gene expression when administered at specific stages of production. Treatments included 1) no implant (CON), 2) implantation on d 0 (EARLY), or 3) implantation on d 56 (LATE). A subset of heifers from each treatment were harvested at d 28 and 84 to collect LM samples that were utilized to measure relative gene expression involving myogenesis and intracellular signaling mechanisms. After d 55, ADG (1.68 vs. 1.31 kg) and G:F (0.172 vs. 0.134) were improved for EARLY vs. non-implanted heifers ($P < 0.05$). From d 56 to 122, ADG improved with implantation and was greatest for LATE ($P < 0.05$), while G:F was only improved by LATE ($P < 0.01$). Overall, implantation improved ADG (1.24 vs. 1.04 kg) and G:F (0.136 vs. 0.114) compared to CON heifers ($P < 0.01$), regardless of timing. Dry matter intake was not affected ($P = 0.41$) by implantation protocol. Implantation increased HCW (340 vs. 320 kg), dressing percentage (65.9 vs. 65%), and LM area (92.3 vs. 85.8 cm^2) vs. non-implanted cattle ($P < 0.05$), regardless of timing. Back-fat, marbling score, and REA/HCW ratio were unaffected by treatment ($P > 0.18$), as well as quality and yield grade distributions ($P > 0.21$). The mRNA expression of myostatin and insulin-like growth factor-1 were not affected by treatment at d 28 ($P > 0.18$). At d 84, myostatin was significantly reduced in heifers that had been implanted compared to CON (5.01 vs. 8.06; $P = 0.02$), regardless of timing. Insulin-like growth factor-1 was not affected by treatment ($P > 0.18$), but mRNA expression levels were decreased at d 84 compared to d 28 (31.8 vs. 50.2; $P < 0.05$). The expression of paired box 7 was increased in EARLY cattle compared to CON cattle at d 28 (0.682 vs. 0.467; $P = 0.05$). Paired box 7 mRNA gene expression of EARLY heifers at d 28 was greater than LATE heifers at d 84 (0.682 vs. 0.371; $P < 0.05$). The results of this study suggest that anabolic growth promotants improve cattle performance and production efficiency without altering carcass quality, independent of exposure time. This study also indicates that stage of production has the greatest effect on relative mRNA gene expression.

Key Words: feedlot and carcass performance, gene expression, implantation

---

0904 (T030) The effects of corn silage diets on intestinal morphology in dairy calves. T. J. Pogreba*[1], S. I. Kehoe[1], K. Dill-McFarland[2], and G. Suen[2], *[1]University of Wisconsin–River Falls, River Falls, [2]University of Wisconsin-Madison, Madison.*

A calf's diet in the first few weeks of life is critical for gastrointestinal tract development. Current feed prices are causing producers to experiment with less expensive alternatives. These different feeds may affect the development of the gastrointestinal tract, which can further affect feed efficiency and calf performance. Therefore, evaluating intestinal morphology is an indicator of how well the animal is absorbing nutrients. The objective of the study was to determine the post-weaning effects of calf starter and corn silage fed to pre-weaned dairy calves on jejunal morphology. A total of 45 calves ($n = 15$/trmt) were fed a diet of whole milk with one of the following treatments: 100% calf starter (C), 60% calf starter and 40% corn silage (CC), or 100% corn silage (CS). Nine calves were sacrificed 8 wk after birth. Jejunal samples were collected to compare between the three treatment groups. Samples were preserved in formalin and later phosphate buffered saline until further analysis. Using a cryo-microtome, slices of tissue were made into nine slides per calf and stained with methylene blue. Pictures were taken with a compound light microscope and measured using the ImageJ computer program (NIH, Bethesda, MD). Measurements were recorded including villi length, crypt depth, and villi width. Measurements were averaged per section block and were statistically analyzed using the PROC MIXED in SAS 9.2. Significance was determined at $P < 0.05$ and trends at $P < 0.15$. Least squares means of villi lengths were 97.65, 105.61, and 89.57 µm for treatments C, CC, and CS, respectively ($P = 0.12$). Least squares means of crypt depths were 46.10, 48.58, and 38.69 µm for treatments C, CC, and CS, respectively ($P = 0.03$) and villi diameters were 14.51, 15.38, and 17.17 µm for treatments C, CC, and CS, respectively ($P = 0.69$). Results from the study indicated that the calves fed CS had significantly shorter crypt depths and tended to have shorter villi lengths compared with the other treatments. This may indicate better intestinal development in calves fed either 100% calf starter or a mix of 60% calf starter and 40% corn silage.

Key Words: calves, corn silage, intestine

0905 (T031) The effect of good or poor residual feed intake sires on feedlot heifer performance and carcass characteristics. K. M. Retallick*[1], D. B. Faulkner[2], and D. W. Shike[3], *[1]CalPoly, San Luis Obispo, CA, [2]University of Arizona, Oro Valley, [3]University of Illinois, Urbana.*

Performance and intake data were collected for 90 d on Angus yearling bulls (n = 8) to calculate residual feed intake (RFI) on these potential sires. These bulls were than used as herd sires during the fall breeding season. The Angus x Simmental heifer (n = 84) progeny of these sires were randomly allotted to pens, managed similarly, and fed a common diet. Heifers had intake data collected for 70 d and were weighed every 2 wk for calculation of RFI during this period. Thirty-seven heifers were sired by poor RFI (RFI = 0.64 to 1.35) sires, and 47 heifers were sired by good RFI (RFI = -0.08 to -0.86) sires. The objective of this study was to observe performance and carcass characteristics of feedlot heifers sired by good or poor RFI sires and determine phenotypic feed efficiency correlations between sire and heifer progeny. Data were analyzed using PROC MIXED of SAS with sire RFI classification (poor or good) as a fixed effect and pen a random effect. Individual animal was the experimental unit. Phenotypic correlations were analyzed with the PROC CORR procedure of SAS. Heifer performance did not differ for initial weight, final weight, or ADG. Heifers sired by good (low value RFI) sires had a 0.65 kg/d lower DMI ($P < 0.05$) than heifers by poor (high value RFI) sires. As a result, heifers by good RFI sires had a 0.51 kg/d lower RFI than heifers by poor RFI sires. Heifers by good RFI sires also had a desirable 4.4% increase ($P = 0.21$) in G:F. Hot carcass weight, rib eye area, backfat, and yield grade did not differ. A 28-unit marbling advantage ($P = 0.18$) was given to poor RFI sired heifers. Heifer RFI was correlated to DMI at 0.78 ($P < 0.05$). Heifer RFI and heifer G:F were correlated at -0.27 ($P < 0.05$); however, sire RFI was not significantly correlated to heifer G:F. Sire RFI was correlated to heifer DMI at 0.33 ($P < 0.05$). Sire RFI was correlated at 0.47 ($P < 0.05$) to heifer RFI. The significant correlation of sire RFI to heifer RFI as well as desirable effects on performance and carcass traits assists in the quantification of the advantages of selecting for RFI.

Key Words: sire residual feed intake, heifer performance, feed efficiency

0906 (T032) Feed efficiency and carcass traits for Nellore young bulls fed processed soybean grains. M. C. L. Alves, M. M. Ladeira*, D. R. Casagrande, J. R. R. Carvalho, P. D. Teixeira, L. A. Silveira, A. C. Rodrigues, and L. R. Santos, *Universidade Federal de Lavras, Brazil.*

Use of lipid sources in beef cattle diet is recommended to increase diet energy density, and reduce acetate:propionate ratio and methane production, which may benefit ruminal fermentation and improve feed efficiency. The objective of this study was to evaluate the feed efficiency and carcass quality of Nellore young bulls fed ground soybean or extruded soybean. Sixty animals (average body weight of 320.33 ± 8.12 kg) were used in a completely randomized design. Corn silage was fed as the forage source along with three different types of concentrates, representing the following treatments: no soybean, ground soybean (GSB) and extruded soybean (ESB). Dietary crude protein averaged 13.9%, while soybean diets contained 6.1% ether extract. Animals were allocated to 12 pens based on dietary treatment (four pens/treatment). Animals were weighed at the beginning, after 26 d of adaptation to experimental diets, and at the end of the feedlot to calculate average daily gain after fasting cattle for 16 h. After 88 d on feed, cattle were slaughtered using cerebral concussion and exsanguination followed by recording hot carcass weights. After 24 h of chilling at 1°C, cold carcass weights were recorded, along with measuring subcutaneous fat thickness and longissimus muscle area between the 12th and 13th ribs. The statistical model included the effects of diet with data analyzed using PROC GLM (SAS 9.3). There were no effects of diet on performance and carcass characteristics (Table 0906). The feeding of processed soybeans did not affect feed efficiency and carcass traits for young Nellore bulls. *Funded by Fapemig, CNPq, Capes, and INCT-CA.*

Key Words: extruded, feedlot, lipids, oilseeds

0907 (T033) Supplementing beef cattle finishing diets containing wheat distillers grain with feed enzymes to decrease the ratio of n-6/n-3 fatty acids in meat. Z. He*[1,2], M. He[1], Y. Zhao[1,3], N. D. Walker[4], K. A. Beauchemin[1], T. A. McAllister[5], and W. Yang[1], *[1]Lethbridge Research Centre, Agriculture and Agri-Food Canada, Lethbridge, AB, [2]Key Laboratory for Agro-Ecological Processes in Subtropical Region, Institute of Subtropical Agriculture, The Chinese Academy of Sciences, Changsha, [3]College of Animal Science, Inner Mongolia Agricultural University, Hohhot, China, [4]AB Vista Feed Ingredients, Marlborough, UK, [5]Agriculture and Agri-Food Canada, Lethbridge, AB.*

The objective of this study was to determine the effects of dietary feed enzyme (FE) supplementation on fatty acids (FA, % of total FA) profiles of the pars costalis diaphragmatis (PCD) muscle of beef cattle fed finishing diets with or without inclusion of wheat dried distillers grain with solubles (DDGS). One hundred sixty crossbred yearling steers (initial BW 495 ± 37.9 kg) were blocked by BW and randomized into 16 pens (10 steers/pen). The pens were randomly assigned to one of four treatments: 1) control (CON; 10% barley silage and 90% barley grain-based concentrate), 2) WDG (CON diet substituting 30% wheat DDGS for barley grain), 3) WDGL (WDG diet supplementing with low FE; 1 mL FE/kg diet DM), and 4) WDGH (WDG diet supplementing with high FE; 2 mL FE/kg diet DM). The PCD samples were collected from cattle at slaughter at the end of the finishing period (120 d) with a targeted live weight of 650 kg. Data were analyzed using the PROC MIXED of the SAS (SAS Institute Inc.), considering treatment (diet) as fixed effect. Contrasts were generated to compare the CON and WDG diet. Linear and quadratic orthogonal contrasts were generated to exam the effect of increasing FE in the diet containing wheat DDGS. Concentration of total polyunsaturated fatty acids (*P*UFA) in muscle was greater ($P < 0.01$; 4.52 vs. 3.41), whereas total monounsaturated FA tended ($P = 0.08$; 45.0 vs. 47.1) to be less for steers fed WDG than steers fed CON. In addition, inclusion of wheat DDGS into the diet vs. diet containing no DDGS increased ($P < 0.01$) concentration of conjugated linoleic acids and vaccenic acid (CLA+VA; 1.22 vs. 0.78) and decreased ($P = 0.03$) total trans FA (excluding CLA and VA; 0.98 vs. 1.27), consequently resulted in higher ($P < 0.01$) ratio of n-6/n-3 PUFA (10.95 vs. 7.72). Increasing FE application in wheat DDGS diets linearly decreased ($P = 0.02$) the ratio n-6/n-3 FA (10.95 to 9.23) in muscle without affecting amount of individual or total FA. These results suggest that application of FE in finishing diets containing wheat DDGS may improve FA profiles of beef which could benefit human health.

Key Words: beef, fatty acid, feed enzyme

0908 (T034) Effects of fat level in distillers grain on finishing feedlot performance and carcass traits. V. L. Anderson*[1] and C. L. Engel[2], *[1]North Dakota State University, Carrington, [2]Carrington Research Extension Center, North Dakota State University, Carrington.*

The objective of this study was to evaluate the effects of different corn oil levels in distillers grains (DG) on beef cattle performance during finishing and the effects on carcass traits. Angus sired steers ($n = 182$, 461.97 ± 4.38 kg) were blocked by weight (fall calves and yearlings) and allocated to one of four treatments based on corn oil level in DG: 1) control (CON) no DG, 2) low corn oil (LOW, 5.47%), 3) medium corn oil (MED, 8.05%), and 4) high corn oil (HIGH, 12.96%). Eleven or 12 steers were assigned to each of 16 pens with four replicates per treatment. Steers were fed a corn-based diet (136 Mcal/kg) to appetite formulated to meet or exceed NRC requirements. Steers were weighed after 28 d on feed and at the end of the finishing period which was an additional 41 d for the light blocks and 77 d for the heavy blocks. Steers were marketed in two drafts at Tyson Fresh Meats, Dakota City, NE, with carcass traits evaluated by the same trained grader. Fat level in the ration for the respective treatments was 3.58, 4.02, 4.52, and 5.48, for CON, LOW, MED, and HIGH. DG was included in the finishing diet at 19.4% (DM basis) with sunflower meal (2.44% oil) used in the CON ration. DMI tended to increase linearly with corn oil during the first 28 d on feed ($P < 0.07$) with 12.54, 12.78, 13.11 kg/hd/d consumed by LOW, MED, and HIGH, respectively. Feed intake was affected quadratically during the final finishing period ($P < 0.03$) and over the entire feeding period ($P < 0.05$). There is some suggestion ($P < 0.13$) of linearly improving gain with increasing corn oil during the first 28 d on feed; however, overall ADG was not affected by treatment ($P > 0.27$). Gain efficiency was not affected ($P > 0.26$) by treatment. Marbling score increased linearly ($P < 0.02$) with increasing corn oil. Yield Grade tended to increase linearly ($P < 0.07$) from 2.98 to 3.27 for CON and HIGH, respectively, and REA tended to decrease ($P < 0.07$) with increasing corn oil but other carcass traits were not affected ($P > 0.27$). These data indicate that higher corn oil in DG has some positive effect on feed intake and marbling but does not affect gain or gain efficiency.

Key Words: beef, distillers grain, corn oil

0909 (T035) Effects of zilpaterol hydrochloride feeding time on Nellore bulls performance and carcass characteristics. A. C. R. Dos Santos*[1], M. Caetano[1,2], R. S. Goulart[1,3], S. B. Pflanzer[4], S. Luz e Silva[5], and D. P. D. Lanna[1], *[1]University of Sao Paulo/ESALQ, Piracicaba, Brazil, [2]University of Adelaide, Roseworthy, Australia, [3]MSD Saúde Animal, Sao Paulo, Brazil, [4]University of Campinas/FEA, Campinas, Brazil, [5]University of Sao Paulo/FZEA, Pirassununga, Brazil.*

Nellore bulls (n = 96; initial BW = 377 ± 21.4 kg) were used in a randomized complete block design arranged in a 4 × 2 factorial to evaluate effects of zilpaterol hydrochloride (ZH; 8.33 mg/kg of diet DM basis) on performance and carcass traits. Total days on feed (DOF) were 90 and 117, and there were four periods of ZH feeding (0, 20, 30, or 40 d before slaughter) plus a 3-d ZH withdrawal period for all animals. No interactions between ZH and DOF were detected for the performance or carcass characteristics (P > 0.10). There was a linear increase for G:F (β = 0.0005; P < 0.01), HCW (β = 0.4304; P = 0.03), dressing percentage (β = 0.0541; P < 0.01), and LM area (β = 0.1318; P = 0.01) with length of ZH feeding. Additionally, there was a linear decrease for kidney, pelvic and inguinal fat (β = -0.0384; P = 0.04) when ZH feeding period was increased; however, no difference was noted for 12th-rib fat. In conclusion, Nellore bulls fed ZH had improvements in feed efficiency and carcass traits over controls, and these were independent of DOF. The effects of increasing the length of ZH treatment to 30 or 40 d were relatively small, and this data can be used to find the best economic option based on feed, cattle, and ZH costs.

Key Words: β-agonist, beef cattle, feedlot

Table 0909. Effect of ZH feeding period on Nellore performance and carcass traits

	ZH feeding period

0910 (T036) Influence of calcium depletion and repletion on beef tenderness of steers fed zilpaterol hydrochloride. J. O. Carothers*, D. N. Burton, K. R. Underwood, and R. H. Pritchard, *South Dakota State University, Brookings.*

The objective of this study was to evaluate the influence of manipulating dietary Ca to influence tenderness via the calpain system in steers fed zilpaterol HCl (ZIL). Steers (n = 120; BW 478 ± 18 kg) were blocked by BW, and randomly assigned to one of three treatments 50 d before initiating dietary treatments. Dietary treatments included: 1) Control, conventional finishing diet (sans ZIL); 2) Control diet plus ZIL (6.78 g/T) fed for 20 d; and 3) depleted dietary Ca while feeding ZIL. Cattle on treatments 2 and 3 were changed to diet 1 for 3 d before harvest, which restored dietary Ca for cattle on treatment 3 and accommodated ZIL withdrawal requirements. A subsample of steers were taken to quantify serum Ca levels, and shear force values for strip loins and sirloin butts. Blood was collected from the subsample 24 h before harvest (48 h after cattle treatment 2 and 3 switched to diet 1). Muscles were cut into steaks and aged 14 d. Orthogonal contrasts were used to compare control vs. ZIL (treatment 1 vs. 2 and 3) and Ca manipulations (treatment 2 vs. 3). Feeding ZIL caused increased (P < 0.05) BW (610 vs. 620 kg), ADG (1.32 vs. 1.66 kg), and G:F (116 vs. 152 g/kg) compared to control. Zilpaterol increased (P < 0.05) HCW (373 vs. 392 kg), dressing percentage (63.08 vs. 65.10%) and LMA (82.26 vs. 91.52 cm^2) but did not affect (P > 0.05) marbling score (Small73 vs. Small55) when compared with control. Calcium manipulation did not affect (P > 0.05) live or carcass variables or serum Ca levels (10.6 vs. 11.0 mg/dl). Zilpaterol increased WBSF values (P < 0.05) for 14 d aged strip steaks (5.28 vs. 6.99 kg), while having no effect (> 0.05) on shear force values for sirloin butts (6.24 vs. 6.83 kg). Dietary Ca manipulations did not affect (P > 0.05) shear force values. Manipulating dietary Ca did not adversely affect live performance or carcass traits. Prolonged repletion (3 d) may have been too long to allow for influences on the calpain system to affect tenderness.

Key Words: beef, zilpaterol, tenderness

0911 (T037) Using early ultrasound measurements to predict beef carcass quality grade. J. K. Smith*, M. D. Hanigan, S. P. Greiner, and M. A. McCann*, Virginia Polytechnic Institute and State University, Blacksburg.*

Although many cattle producers have focused selection efforts toward enhancing carcass marbling, a number of pre- and post-weaning management factors often limit the ability of finished cattle to achieve their marbling potential. Enhancing the ability of a feeder to predict finished quality grade (QG) before entry into a finishing program would allow for more strategic utilization of management practices that impact QG,

particularly for cattle with lower likelihood of achieving QG-based retail brand acceptance. The objective of this experiment was to evaluate the ability of early ultrasound measurements collected before finishing to predict finished carcass marbling score (MS) and QG. Serial early ultrasound measurements of ribeye area (REA), 12th-rib subcutaneous fat thickness (SFT) and percent intramuscular fat (IMF) were collected from early- and conventionally-weaned Angus-sired steers ($N = 60$) from three separate calving seasons within a single herd. Ultrasound measurements were collected at the time of early-weaning (EW; 105 ± 18 d of age), conventional-weaning (CW; 210 ± 18 d of age), and again on conclusion of backgrounding (360 ± 60 d of age) immediately before feedlot arrival. Cattle were adapted to a concentrate and corn silage-based ration and finished for 131 ± 34 d at one of two feedlots before being harvested on reaching a common ultrasound predicted SFT of 1 cm. Carcasses were evaluated by a panel of trained analysts to determine MS and QG. Initial screening for factor effects of weaning treatment, sire, and ultrasound predicted REA, SFT and IMF measurements for each of the three time points via the screening procedure of JMP Pro (version 10.0.2; SAS Institute, Cary, NC) indicated that IMF and REA measurements collected at CW and immediately before feedlot arrival explained a significant ($P < 0.05$) portion of the variation in carcass MS. Full four-way factorial regression models were then generated to predict carcass MS ($R^2 = 0.83$; $P < 0.05$) and the probability of achieving a specific QG ($R^2 = 0.95$; $X^2 = 129$; $P < 0.0001$) using the Fit Model procedure of JMP Pro. These results provide evidence that early carcass measurements for REA and IMF can be effectively utilized to explain a major portion of the variation in finished carcass MS and QG. Such information could be utilized to produce models that allow feeders to predict carcass QG at receiving.

Key Words: beef, quality, marbling

0912 (T038) Influence of breed on the sensory meat quality and consumer acceptability in extensively reared beef.

M. E. A. Canozzi[1], L. Sphor[1], C. M. Pimentel[2], J. O. Barcellos[3], C. H. E. C. Poli[1], R. D. Sainz[4], and L. Kindlein[*1], *[1]Universidade Federal do Rio Grande do Sul, Porto Alegre, Brazil, [2]Universidade de Brasília, Brazil, [3]Universidade Federal Do Rio Grande Do Sul, Porto Alegre, Brazil, [4]University of California–Davis, Davis.*

We evaluated the sensory characteristics of meat from different animal types, including cattle (Angus and Brangus) and buffalo raised on pasture, and collected information on socio-demographic determinants of consumer preference. Samples were roasted rib eye, sliced and served in a disordered and monadic manner to 188 untrained tasters. A nine-point hedonic scale was used to assess odor, color, tenderness, succulence and overall appearance. Analysis of variance was conducted using the GLM procedure, considering animal type and socio-demographic characteristics as fixed effects and using the LSMEANS procedure for multiple mean comparisons. Differences ($P < 0.001$) between animal types were observed only for tenderness, with Brangus (7.02) and buffalo (6.82) meat being superior to Angus (6.25). Regardless of the meat origin, age, income, smoking and place of purchase affected the perceived attributes ($P < 0.05$). People aged over 50 yr gave higher mean scores for odor and color ($P < 0.05$), indicative of greater satisfaction and less demanding tastes when compared to other age categories. Most meat was purchased from supermarkets and butchers (82%). The majority (84%) of the panelists reported acquiring chilled rather than frozen meat, which may account for the high juiciness, flavor intensity, flavor, and overall acceptability reported. Despite the variability in the intrinsic characteristics of the meat products, differentiation by the consumer is not easy to determine, with little impact of socio-demographic characteristics on organoleptic perception. The different types of animals did not affect the general visual appearance of the meat as perceived by the consumer. Meat from Brangus cattle and buffaloes raised on pasture was considered more tender by an untrained taste panel than that from Angus cattle raised under the same conditions.

Key Words: beef, quality, palatability

0913 (T039) Evaluation of growth and performance characteristics before entering the feedlot as an indicator for contracting bovine respiratory disease.

S. Miller[*1], M. D. Garcia[2], R. Walker[3], T. Page[1], and K. W. Harborth[1], *[1]Louisiana State University, Baton Rouge, [2]Louisiana State University, Baton Rouge, [3]Louisiana State University AgCenter, Homer.*

The objective of the current study was to evaluate growth and performance traits before entering the feedlot as potential indicator of bovine respiratory disease (BRD) susceptibility. A population of 560 spring-born crossbred steers (2009–11) from the Central Research Station and the Hill Farm Research Station in Louisiana were evaluated for growth and performance before being shipped (2010–12) to a commercial feedlot in Guymon, OK. The growth and performance traits evaluated consisted of birth weight, weaning weight, and hip height. Bovine respiratory disease status was recorded by the feedlot and consisted of animals treated for BRD or animals that subsequently perished due to BRD infection. A total of 24 steers over the 2-yr evaluation period contracted BRD and were subsequently treated or perished in the feedlot. The PROC MIXED model of SAS was utilized to determine if associations between growth and performance traits and BRD status in the feedlot were linked. Fixed variables in the model included year of entrance into the feedlot, farm of origin and BRD status while in the feedlot. Growth and performance traits were fit in the model as random variables. Analyses revealed that no one trait had a significant effect ($P < 0.05$) on BRD status in the feedlot. However, birth

weight did exhibit a genetic trend ($P < 0.09$) in which animals with larger average birth weights (39.84 kg) had a higher degree of BRD incidence in the feedlot than animals with smaller birth weights (37.63 kg) in the utilized population. While no one growth and performance trait was statistically significant ($P < 0.05$), the fixed variable of year was highly significant ($P < 0.0001$) in the statistical model, thus necessitating further evaluation of other environmental and management variables that could be influencing susceptibility of contracting BRD during the feedlot stage of production.

Key Words: bovine respiratory disease, feedlot, growth and performance

0914 (T040) Maximizing profit in a feedlot enterprise using systems analysis thinking and linear programming. K. J. Retallick*[1], T. E. Adcock[1], T. R. Schultz[1], J. M. Bormann[1], R. L. Weaber[1], D. W. Moser[1], and M. D. MacNeil[2], *[1]Kansas State University, Manhattan, [2]Delta G, Miles City, MT.*

Systems' thinking is a management discipline that concerns understanding a complex entity studying the components and interactions between them that form the entirety of that entity. In this case, a system analysis approach was applied to a stereotypical situation of a farmer/feeder. Feedlot enterprises were evaluated using linear programming to maximize profitability from excess feedlot capacity. The hypothetical feedlot analyzed was based on data recorded by Iowa State University Extension. Four alternative beef cattle enterprises: weanlings, yearlings, performance-tested bulls, and beef replacement heifers, were investigated as alternative uses for the excess capacity. An earthen feedlot facility with shelter was modeled. Capacity was constrained by 60,000 linear inches of bunk and a weekly feed holding capacity of 5000 bushels of whole corn. The objective function summed the products of per head profit and numbers of each class of cattle. Results from three alternative scenarios have been presented here. Linear programming models were solved using Microsoft Excel. Simulation 1 involved only the two initial constraints on capacity and maximum profit resulted when 4630 yearlings and 159 performance-tested bulls filled the feedlot. This system assumed both yearlings and performance-tested bulls were turned over twice a year with consistent availability of cattle. In Simulation 2, it was assumed the owner-operator owned 1500 weaned calves, and these were forced into the solution. In this scenario, profit margins were maximized when 3439 yearlings, 26 performance-tested bulls, and the 1500 weaned calves filled the feedlot. Simulation 3 included 200 owned replacement females. This constraint pushed the system to fill the feedlot with 3200 yearlings, 1500 owned weanlings, and 200 owned replacement females. This simulation exercise represents the value of applying both systems thinking and linear programming in real management situations to determine maximum profits with resources available.

Key Words: cattle, feedlot, profit

BEEF SPECIES: COW-CALF AND BULL

0915 (W047) Pregnant beef heifers categorized by residual feed intake measured in adolescence exhibit differential intake and feeding behaviors when fed a restricted diet. C. Fitzsimmons[*1,2], G. Muhire[1,2], F. Paradis[1,2], L. McKeown[1,3], C. Straathof[1], H. Block[4], M. G. Colazo[3], C. Li[1,2], *B. Yaremcio[5], J. A. Basarab[6], and H. Bruce[1], [1]University of Alberta, Edmonton, Canada, [2]Agriculture and Agri-Food Canada, Edmonton, AB, Canada, [3]Alberta Agriculture and Rural Development, Edmonton, Canada, [4]Agriculture and Agri-Food Canada, Lacombe, AB, Canada, [5]Alberta Agriculture and Rural Development, StettlerCanada, [6]Alberta Agriculture and Rural Development, Lacombe, AB, Canada.*

Selection for residual feed intake (RFI) in cattle will bring about changes in metabolism and physiology that are not explicitly known. We appraised feed intake and feeding behavior in heifers, characterized by a range of RFI, when fed two different planes of nutrition from d 30 to 150 of pregnancy. Sixty-nine purebred Angus heifers, with RFIf (RFI corrected for fat, ave = 0.047, SD = 0.7678) measured in adolescence, entered a GrowSafe automated feed intake recording system after confirmation of pregnancy at 30 d post artificial insemination (AI). Heifers were divided randomly yet equally in terms of RFIf, weight at start of test (SOT), and SOT rib and rump fat, into two diet-groups. Heifers received a ration formulated to allow gain of either 0.5 kg/d (L-diet) or 0.7 kg/d (H-diet). Rations were fed until 150 d of pregnancy and were adjusted periodically to account for heifer and fetal growth plus decreasing fall temperatures. Heifer weight, as well as rib and rump fat were measured approximately once every 4 wk, and individual feed intake and feeding behavior was continuously measured by GrowSafe. All weight and fat measurements, feed intake and behavior were analyzed using PROC GLM in SAS 9.0, with RFIf, diet (H- or L-diet), RFIf*diet, and AI (first or second) included in the model. There were no significant differences due to RFIf, diet, or their interaction on SOT weight, or SOT rib and rump fat. By end of test (EOT), significant diet effects were seen on EOT weight, both EOT rib and rump fat, and ADG during the feed trial ($P < 0.01$), with heifers consuming H-diet displaying higher weights and fat measurements, but no effect of RFIf was detected. However, significant diet and RFIf effects were detected in average daily intake, feeding duration and head-down time ($P < 0.05$), where heifers with lower RFIf ate less, had a lower average daily feeding duration and head-down time, than those with higher RFIf. Therefore, regardless of diet consumed and under limiting nutritional conditions, low RFIf pregnant heifers ate less, yet maintained the same growth and body condition when compared to high RFIf pregnant heifers. This result is important as RFIf is typically measured on virgin animals and under ad-libitum conditions. If selection for RFI is to become mainstream in the cattle industry, investigating the performance of high and low RFI animals in different nutritional environments and physiological conditions is important.

Key Words: behavior, cattle, residual feed intake

0916 (W048) Physiological stress response of heifers divergently ranked for residual feed intake following a bovine corticotrophin releasing hormone challenge. A. K. Kelly[*1], A. G. Fahey[2], B. Earley[3], M. McGee[3], and D. A. Kenny[4], *[1]School of Agriculture and Food Science, University College Dublin, Ireland, [2]School of Agriculture and Food Science, University College Dublin, Ireland, [3]Teagasc Grange, Dunsany County Meath, Ireland, [4]Teagasc Grange, Meath, Ireland.*

The objective of this study was to determine whether beef heifers previously ranked on the basis of phenotypic RFI differed in their physiological stress response to an exogenous corticotrophin-releasing hormone (CRH) challenge. Yearling Limousin × Friesian heifers ($n = 86$) were ranked on phenotypic RFI. The 15 highest [mean 0.47 kg/d; high RFI] and 15 lowest [mean -0.53 kg/d; Low RFI] ranking animals were used for this study. To facilitate intensive blood collection heifers were fitted aseptically with indwelling jugular catheters on d -1. To examine the response of the adrenal cortex, a standardised dose of bovine CRH (bCRH;0.3 µg/kg BW) was administered (Day 0). Before heifers undergoing bCRH challenge dexamethasone (20 µg/kg BW) was administered intramuscularly on day -1. Baseline blood samples were collected into tubes containing lithium heparin as an anti-coagulant at −60 and 0 min before the administration of dexamethasone. On Day 0, serial heparinised blood samples were collected at −40, -20, 0, 20, 40, 60, 80, 100, 120, 150, 180, 210, 240, 270, 330, and 390 min relative to the time of CRH administration (0 min) for plasma cortisol and DHEA concentrations. Data were analyzed using a repeated measures mixed models ANOVA (PROC MIXED) in SAS incorporating terms for RFI group, sample time and their interaction, as appropriate. Residual feed intake ranged from -1.27 to 1.87 kg DM/d. (SD = 0.93) representing a mean daily difference of 3.14 kg DM in feed consumed between the most and least efficient animals. Low RFI animals consumed 18% less feed than animals with high-RFI. Least square means for RFI and F:G were higher ($P < 0.05$) for high RFI than for low RFI animals. Neither a RFI × sampling time interaction nor a direct effect of RFI was detected for DHEA, cortisol or cortisol:DHEA concentrations in response to the exogenous bCRH challenge. No difference ($P > 0.10$) in median plasma area under the curve (AUC) for cortisol, DHEA or cortisol:DHEA was observed between the two

RFI groups. The maximum concentration and change in cortisol and DHEA concentrations owing to CRH were not different between the high and low RFI phenotypes. Furthermore, across animals, AUC, maximum concentration or change in cortisol or DHEA concentrations were not associated ($P > 0.10$) with DMI, F:G or RFI co-efficients. These data suggest that the responsiveness of the hypothalamic-pituitary-adrenal axis is unlikely to contribute to appreciable variation in the efficiency feed utilisation of cattle.

Key Words: feed efficiency, stress, cortisol

0917 (W049) Relationship of metabolic hormones, urea, and body composition with feed efficiency in Angus heifers carrying different genetic markers under grazing condition. A. I. Trujillo*[1], A. Casal[1], M. Carriquiry[1], and P. Chilibroste[2], [1]*Facultad de Agronomia, Universidad de la Republica, Montevideo, Uruguay,* [2]*Facultad de Agronomia, Universidad de la Republica, Paysandu, Uruguay.*

The objective of this research was to explore potential physiological indicators of residual feed intake (RFI) in two beef cattle groups carrying simultaneously different genetic markers (GM) associated with low and high RFI (V and C groups, respectively) under grazing conditions. Twelve Angus heifers of each group (aged 369 ± 28 d, 294 ± 37.4 kg of body weight (BW), at the beginning of the experiment) ranked by BW and RFI in a previous feedlot experiment were randomly assigned to four paddocks of an unrestricted high-quality temperate pasture during 57 d. Concentrations of serum IGF-1, leptin, and urea at d 1, 21, and 53, ultrasound subcutaneous fat thickness at d 1 and 56, (SFT), subcutaneous 12/13th rib fat depth, intramuscular fat percentage and eye muscle area at d 40 (SBF, IMF and EMA, respectively) as well as estimation of body composition by the urea dilution technique at d 56 (whole body fat content–BF% and whole body protein content– BCP%) were obtained. Data were assessed using a mixed model. Concentrations of IGF-1 did not differ between GM but tended ($P < 0.078$) to be affected by the interaction between GM and sampling date, being lower in V than in C group at d 1 (274.3 vs. 321.5 ± 22.6 mm/L). Leptin concentrations tended ($P = 0.09$) to be greater for V than C group (2.80 vs. 2.33 ± 0.24mm/L, respectively) and were neither affected by sampling date nor by their interaction. Serum urea concentrations were not affected by GM nor by its interaction with sampling date. The EMA, SFT, SBF, IMF and % BCP did not differ between GM, however estimated BF % and BF:BCP ratio were greater ($P = 0.035$, $P = 0.038$, respectively) in V than in C group (23.7 vs. 20.6 ± 1.29%, 1.64 vs. 1.39 ± 0.12). Leptin concentration and BF % were both negatively correlated ($r = -0.43$ $p = 0.037$ and $r = -0.38$, $p = 0.071$, respectively) with RFI. Our data suggest that leptin concentration and BF % could be used to screen for more efficient females under grazing conditions. Other experiments should be designed to uncover additional indicators underlying variation in RFI under grazing conditions.

Key Words: residual feed intake, beef cattle, pasture

0918 (W050) Effects of maternal plane of nutrition during mid- or late gestation on beef cow performance and progeny performance through weaning. T. B. Wilson* and D. W. Shike, *University of Illinois, Urbana.*

Objectives were to investigate the effects of maternal plane of nutrition during mid- or late gestation on cow BW, BCS, and lactation as well as calf growth through weaning. Spring-calving, multiparous cows ($n = 68$; BW = 631 ± 80 kg) were utilized in a 3 × 2 factorial design that included three planes of nutrition formulated to provide (limit-fed diet = 52% corn silage, 24% soy hulls, and 24% alfalfa haylage): 100% NRC energy and protein requirement (REQ), 70% NRC requirement (70%REQ), or 130% NRC requirement (130%REQ) applied during two stages of gestation: mid-gestation (MID, 196 ± 14 to 113 ± 14 d prepartum) or late gestation (LATE, 92 ± 6 to 9 ± 6 d prepartum). After treatment period, cows were fed a common diet formulated to meet NRC requirements. Treatment period ADG and BCS changes were greater ($P \leq 0.01$) for cows fed 130%REQ than 70%REQ, with REQ being intermediate. There was an interaction ($P = 0.04$) between plane of nutrition and stage of gestation in which treatment was applied for calf birth BW. When treatments were applied during mid-gestation, birth BW was greater ($P \leq 0.04$) for calves born to cows fed 70%REQ compared to calves from cows fed REQ or 130%REQ; however, there were no differences ($P \geq 0.65$) during late gestation. Milk production, at 101 ± 11 d postpartum and weaning (198 ± 11 d postpartum), was not affected ($P \geq 0.19$) by plane of nutrition. Calf weaning BW was not affected ($P \geq 0.17$) by plane of nutrition or stage of gestation in which treatments were applied. Ultrasound backfat at 101 ± 11 d of age was greater ($P \leq 0.04$) for calves born to REQ vs. 70%REQ or 130%REQ cows, yet was not different ($P = 0.12$) at weaning. Ultrasound marbling score was not affected ($P \geq 0.35$) by plane of nutrition, but; was greater ($P \leq 0.01$) for calves born to MID cows at 101 ± 11 d of age. Placing cows on diverging nutritional planes either during mid- or late gestation had profound effects on cow ADG and BCS change and may lead to altered calf body composition through weaning but did not affect calf weaning weight or pre-weaning ADG. There were no effects of an interaction between maternal plane of nutrition and stage of gestation in which treatments were applied, except for increased birth BW of calves born to cows that were nutrient restricted during mid-gestation.

Key Words: beef cow, gestational nutrition, fetal programming

0919 (W051) Effects of prepartum plane of nutrition during mid- or late gestation on beef cow BW, BCS, and preimplantation embryo recovery.

W. C. Meteer*[1], T. B. Wilson[2], P. Cardoso[2], and D. W. Shike[2], [1]*University of Illinois, Champaign,* [2]*University of Illinois, Urbana.*

Objectives were to evaluate potential effects of prepartum plane of nutrition during mid- or late-gestation on BW, BCS, and preimplantation embryo recovery. Spring-calving, multiparous beef cows (n = 60; BW = 657 ± 70 kg) were utilized in a 3 × 2 factorial arrangement that included three planes of nutrition formulated to provide (limit-fed diet = 52% corn silage, 24% soybean hulls, and 24% alfalfa haylage): 100% NRC energy and protein requirement (REQ), 70% NRC requirement (70%REQ) or 130% NRC requirement (130%REQ) fed during two stages of gestation: mid-gestation (Mid, 195 ± 5 to 112 ± 5 d prepartum) or late-gestation (Late, 91 ± 4 to 8 ± 4 d prepartum). After treatment period, cows were fed a common diet formulated to meet NRC requirements. All cows had their estrous cycles pre-synchronized with two injections (14 d apart) of PGF2α beginning 43 ± 4 d postpartum. A 7 d cosync protocol was used to synchronize cows. A 4-regimen of Folltropin (FSH) was administered to induce superovulation and GnRH was given 12 h and 24 h before breeding. Cattle were flushed 84 ± 4 d postpartum, and 7-d embryos were harvested. Cyclicity was accessed by P_4 analysis at 43 ± 4 and 57 ± 4 d postpartum. Statistical analysis was performed using the MIXED and GLIMMIX procedures in SAS. Nutritional plane did not affect (P = 0.61) percentage of cows cycling by 57 ± 4 d postpartum (70%REQ, 15.8%; REQ, 27.3%; 130%REQ, 21.1%). The Logistic model revealed that cows fed nutritional treatments during late-gestation had lower odds for cyclicity than cows fed nutritional treatments in mid-gestation [odds ratio (OR) = 0.18; P = 0.02]. Cows fed 130%REQ had greater ($P \leq 0.03$) BW than REQ and 70%REQ cows, and cows fed 130%REQ and REQ had greater ($P \leq 0.04$) BCS than cows fed 70%REQ at time of breeding. There was a plane of nutrition by stage of gestation interaction ($P < 0.01$) for total embryos recovered. When nutritional treatments were applied during mid-gestation, a greater number of total embryos were recovered from cows fed 70%REQ than from cows fed REQ and cows fed 130%REQ were intermediate; however, when nutritional treatments were applied during late-gestation, a greater number of total embryos were recovered from cows fed 70%REQ and REQ than cows fed 130%REQ. In conclusion, prepartum plane of nutrition during mid- or late-gestation affects cow BW, BCS, and total embryos recovered, but did not affect cyclicity in cows before breeding.

Key Words: embryo, gestational nutrition, reproduction

0920 (W052) Effects of breed, sex, parity, birth year, and birth season on body weight traits for five local cattle breeds and crossbreds in arid region of Punjab, Pakistan.

G. Bilal*[1], M. Moaeen-ud-Din[1], M. Aqeel[1], A. Ijaz[1], M. S. Khan[2], M. Y. Gondal[3], K. M. Khan[3], M. Mukhtar[3], and M. N. Manzoor[3], [1]*PMAS-Arid Agriculture University, Rawalpindi, Pakistan,* [2]*University of Agriculture, Faisalabad, Pakistan,* [3]*Barani Livestock Production Research Institute, Attock, Pakistan.*

The objectives of the present study were to study the effects of breed, sex, parity, year of birth, and season of birth on birth weight, weaning weight, and yearling weight recorded on 796 calves born between 1996 and 2008. This included offspring from five local cattle breeds (Dhanni, Lohani, Dajal, Red Sindhi, Cholistani) and crossbreds (Holstein or Jersey crosses) maintained at Barani Livestock Production Research Institute (BLPRI, Attock, Punjab, Pakistan). The data were analyzed using a mixed linear model with PROC MIXED (SAS). Overall means ± SD (obtained using PROC MEANS) of birth, weaning, and yearling weights were 18.59 ± 2.54 kg, 73.85 ± 19.04 kg and 113.65 ± 30.33 kg, respectively. All three growth traits varied with breed, sex, parity of dam and season of birth and year of birth. However, the birth weight did not vary among seasons (P = 0.16), and weaning weight did not vary between dam parity (P = 0.29). The calves of Lohani cattle (a short stature breed) had the lightest birth weights (16.6 kg) as compared to other breeds and crossbreds (> 18 kg). The heaviest weaning weights (93.0 kg) were found in calves from the Dajal breed, followed by weaning weights for Dhanni (79.9 kg), Cholistani (74.0 kg), Red Sindhi (71.9 kg), and Lohani (66.1 kg). The heaviest yearling weights were found in Dajal calves (147.4 kg), while the lowest yearling weights were found in Lohani calves (98.0 kg). Yearling weights for all other breeds ranged from 111 to 118 kg. Overall, birth, weaning and yearling weights were greater in male vs. female calves. The calves born to first parity cows had lighter birth and yearling weights, and similar weaning weights as compared to calves from later parity cows. Spring born calves had heavier weaning weights (79.2 kg) than summer born calves (71.7 kg). Summer born calves had lighter yearling weight (109.3 kg) than calves born in other seasons (118–120 kg). Additionally, when data were analyzed using a model considering all factors as random, breed explained the most variation for all three body weight traits. The observed between breed variation for growth indicates an untapped potential for beef production. Moreover, results from the present study have useful implications for breed improvement and management decisions for cattle breeds being raised under arid conditions.

Key Words: body weights, cattle breeds, arid region

0921 (W053) Effect of rumen protected carbohydrate supplementation on performance and plasma glucose concentrations in growing heifers. *J.* P. Russi*[1], P. Davies[2], N. DiLorenzo[3], and A. E. Relling[4], *[1]Facultad de Cs Veterinarias, UNLP, La Plata, Buenos Aires, Argentina, [2]INTA Gral. Villegas, General Villegas, Argentina, [3]University of Florida, Marianna, [4]Facultad de Ciencias Veterinarias UNLP, La Plata, Buenos Aires, Argentina.*

The objective of this study was to evaluate the inclusion of a ruminally protected carbohydrate (RUPCA) on performance and blood metabolites in growing heifers. One hundred thirty-five cross-bred heifers (136 ± 14kg) were used in an 84-d experiment. Heifers were blocked according to initial BW and placed (nine per pen) into 15 dirt floor pens (12 × 50 m). Heifers within blocks were randomly assigned to one of three treatments: T0) Control (100% basal supplement), T1) 50% RUPCA and 50% basal supplement, and T2) 100% RUPCA. Diets were (DM basis): 38.8% corn silage, 41.5% dry corn (finely ground), 2% minerals and vitamins mix, and 17.7% supplement (58.1% soybean meal, 39.9% carbohydrates, 2% urea, and 1% minerals). RUPCA and the basal supplement consisted of the same ingredients, differing on the processing of the carbohydrate (i.e., protected or not from ruminal degradation). Heifers had ad libitum access to feed and water during the study. Body weights were measured on d 0, 21, 42, 63, and 84. Dry matter intakes were measured every 7 d from d 21 when the adaptation to the diets finished. Blood samples were taken every 21 d and analyzed for glucose concentration. Back fat on the 12th Rib (BF) was measured on d 1 and 84. Data was analyzed as a randomized complete block design with repeated measures using a mixed model in SAS. There were no significant differences ($P > 0.10$) amongst treatments on initial BW, final BW, or ADG; however, cattle fed T1 had the lowest DMI ($P < 0.01$) and the greatest G:F ratio ($P < 0.02$). There were no differences in glucose concentrations ($P > 0.96$) or BF on d 84 ($P > 0.72$). In conclusion, including RUPCA at a rate of 8.87% of the diet DM improved G:F ratio by reducing DMI and not affecting ADG.

Key Words: carbohydrates, ruminally protected

Table 0921.

	Treatments				
	T0	T1	T2	SEM	*P*–Value
Initial BW, kg	136.5	136.3	136.3	0.5	0.95

0922 (W054) Evaluation of forage soybean, with and without pearl millet, as an alternative forage for developing beef replacement heifers. E. Taylor*[1], P. J. Gunn[2], L. A. Horstman[3], R. L. Atkinson[4], K. D. Johnson[3], and R. P. Lemenager[3], *[1]Purdue University, Lafayette, IN, [2]Iowa State University, Ames, [3]Purdue University, West Lafayette, IN, [4]Southern Illinois University–Carbondale, Carbondale.*

Angus-Simmental beef replacement heifers (n = 90; BW = 366 kg ± 25; BCS = 5.53 ± 0.35) were used to evaluate the effects of feeding forage soybean-based silages on heifer BW, BCS, follicular growth and fertility. At 65 d before timed-artificial insemination (TAI), heifers were allotted by breed, BCS and BW into three replications per treatment to receive one of three diets; 1) alfalfa haylage (CON), 2) soybean silage (SB) or 3) soybean and pearl millet silage (SBPM). All diets were formulated to meet or exceed nutrient requirements (NRC, 2000) of replacement beef heifers with a targeted gain of 0.79 kg/d. Estrous cyclicity status of heifers was determined by two samples of blood taken 10 d apart before initiation of estrous synchronization and analyzed for circulating progesterone concentrations. Heifers were synchronized for ovulation using a 5-d Co-Synch + CIDR protocol and were observed for estrus on 12-h intervals between CIDR removal and TAI. Diameter of the largest antral follicle was determined at time of AI via ultrasonography. Bulls were placed with heifers 10 d after TAI for remainder of the breeding season. Pregnancy diagnosis was accomplished via ultrasonography 35 and 66 d post-TAI, respectively, for TAI and overall breeding season pregnancy. Data were analyzed with the GLIMMIX and PROC MIXEDs of SAS for categorical and continuous variables, respectively. Final BW (avg. 414 kg; $P \geq .10$) and BCS (avg. 5.28; $P \geq .07$) for the heifers were similar among treatments. The proportion of heifers showing estrus before TAI (51%) and interval to estrous in those females that exhibited estrus (55 h) did not differ among treatments ($P \geq .11$). Ovulatory follicle diameter (avg. 11.7 mm) was not different ($P > .31$) among treatments. No differences were noted in pregnancy rate to TAI (avg. = 48%; $P > .19$) or overall breeding season (avg. = 93%; $P > .99$) pregnancy rates. In summary, forage soybean-based silages, with and without pearl millet, are acceptable alternative forages for developing replacement beef heifers.

Key Words: forage, beef, heifer

0923 (W055) Plasma glucose concentration, subcutaneous fat thickness, and puberty attainment in Nellore heifers treated with recombinant bovine somatotropin. G. Nogueira*[1], D. Giraldo-Arana[1], J. S. Souza[1], M. A. Maioli[1], M. C. V. Miguel[1], R. S. Cipriano[2], T. Sayuri Aguiar[3], D. M. Pinheiro[1], and R. F. Cooke[4], *[1]UNESP, Araçatuba, Brazil, [2]UniSalesiano, Araçatuba, Brazil, [3]UNESP, Araçatuba, Brazil, [4]Oregon State University–EOARC Burns, Burns.*

In previous research, we observed that Nellore heifers that attained precocious puberty had greater plasma IGF-I but similar plasma leptin concentrations compared with cohorts that attained puberty later. Hence, this experiment evaluated the effects of bovine ST treatment as an alternative to increase plasma IGF-I concentrations on plasma glucose concentrations, body fat accretion, and puberty attainment of Nellore heifers. Thirty-one heifers were distributed in groups Treated (n = 16; 348 ± 52 d of age; 259 ± 49 kg of initial BW) or Control (n = 15; 356 ± 40 d of age; 260 ± 38 kg of BW). For 10 mo, Treated heifers received 250 mg of sometribove zinc every 14 d, whereas Control heifers concurrently received 2.5 mL of saline. All heifers were maintained on a single pasture and exposed to a teaser bull with a neck-marker device to identify mounted heifers. Ovarian ultrasonography was conducted every 14 d to determine corpus luteum presence. Every 2 mo, rump and back fat thickness were also estimated via carcass ultrasonography whereas blood samples were collected. Heifers were considered pubertal when teaser bull activity was observed and a corpus luteum was detected. Age at puberty and fat thickness were analyzed by unpaired t test, whereas plasma glucose concentrations were analyzed by the Mann Whitney test of GraphPad PRISM. No treatment effects were detected ($P \geq 0.30$) for puberty attainment, nor heifer age and BW at puberty. More specifically, seven Treated heifers (593 d of age and 394 kg of BW at puberty) and seven Control heifers (599 d of age and 411 kg of BW at puberty) reached puberty during the experiment. Back fat thickness was greater ($P = 0.03$) in Control compared with Treated heifers at 22 mo of age (5.0 vs. 4.0 mm, respectively). Rump fat thickness was also greater ($P \leq 0.05$) in Control compared with Treated heifers at 16 mo (5.0 vs. 4.4 mm), 18 mo (5.0 vs. 4.4 mm), 20 mo (5.5 vs. 4.8 mm), and 22 mo of age (5.8 vs. 4.6 mm). No treatment differences were detected ($P = 0.46$) for plasma glucose concentration (90 vs. 89 mg/dL for Treated and Control heifers, respectively). In summary, Nellore heifers administered bovine ST at the experimental conditions utilized herein had decreased subcutaneous fat accretion, but similar plasma glucose concentrations as well as BW and age at puberty compared with cohorts receiving saline.

Key Words: bovine ST, heifers, Nellore, puberty

0924 (W056) Effect of dried distillers grains with solubles and dried citrus pulp supplementation on metabolic and reproductive parameters of Charolais beef cows grazing buffelgrass in Northeastern México. E. Garza Brenner*[1], H. Bernal Barragán[1,2], E. Gutiérrez Ornelas[1,2], F. Sánchez Dávila[1], A. S. Juárez Reyes[2,3], and E. Olivares Sáenz[1], *[1]Universidad Autónoma de Nuevo León, San Nicolás de los Garza, México, [2]Red Internacional de Nutrición y Alimentación en Rumiantes, Durango, México, [3]Universidad Juárez del Estado de Durango, México.*

The objective of this study was to evaluate body weight, body condition and reproductive performance of Charolais beef cows (n = 32) grazing buffelgrass (Cenchrus ciliaris L., 7.0% crude protein (CP) and 56.6% NDF) supplemented with two isocaloric agroindustrial byproducts. Cows were blocked by age, parity, body condition score (initial BCS was 4.75) and body weight, and randomly assigned to individually receive 1 kg/d of either dried distillers grains with solubles (DDGS; 30.3% CP, 2.65 Mcal ME/kg DM), or a 50:50 mixture of DDGS and dried citrus pulp (DDGS:DCP; 17.45% CP, 2.82 Mcal ME/kg DM) during a 30-d breeding period, applying the standard 9-d synchronization protocol utilizing a controlled internal drug-release (CIDR) device and an additional 8-d CIDR resynchronization beginning on the fifth day after artificial insemination. Body weight (BW), and body condition score (BCS) were registered, and blood samples were collected via coccygeal venipuncture on d 0, 9, 16, 24, and 30, and analyzed to determine Urea Nitrogen (BUN, colorimetrically), and plasma Progesterone (ELISA) using commercial kits. Estrus appearance was registered by visual observation, and pregnancy diagnosis was confirmed using transrectal ultrasonography. Data were analyzed using two-way ANOVA (for BW, BCS, BUN and progesterone), and Chi-square test (for reproductive traits). Cows receiving DDGS:DCP were heavier on d 16 (487 vs. 464 kg) and d 24 (500 vs. 485 kg, $P < 0.05$) than those supplemented with DDGS, whereas BCS (mean = 5.0) was not different between treatments ($P > 0.05$). Cows supplemented with DDGS had increased ($P = 0.01$) BUN values on d 9 and 24 (12.8 vs. 8.3 and 11.3 vs. 9.4 mg/dL), compared to cows supplemented with DDGS:DCP. No differences were found between treatments in plasma progesterone concentrations ($P > 0.05$). Cows receiving DDGS:DCP presented 20 estrus, whereas cows receiving DDGS showed 13 estrus ($P < 0.05$). Differences in pregnancy rate (56.2% for DDGS:DCP; 68.7% for DDGS) were not significant ($P > 0.05$) between treatments. In summary, supplementing DDGS:DCP to Charolais beef cows grazing buffelgrass increased body weight and estrus appearance, but not BCS and pregnancy rate compared with DDGS supplementation.

Key Words: beef cows, dried citrus pulp, dried distillers grains with solubles

0925 (W057) Evaluation of anthelmintic resistance of intestinal parasitic nematodes in heifers in south central Nebraska. S. A. Jones[1], C. C. Chase*[1], R. Cortinas[2], D. Griffin[3], L. A. Kuehn[1], K. Shuck[3], K. Whitman[3], R. G. Tait, Jr.[1], and J. W. Keele[4], *[1]USDA, ARS, U.S. Meat Animal Research Center, Clay Center, NE, [2]University of Nebraska Lincoln, Lincoln, NE, [3]Great Plains Veterinary Educational Center, Clay Center, NE, [4]USDA-ARS, Clay Center, NE*

Internal parasitic nematodes impact the livestock industry through losses in reproductive efficiency, rate of gain, carcass quality, milk production, or immune response. The frequent use of anthelmintics with drug formulations in which chemical activity persists for long periods selects for worm resistance and has contributed to parasite resistance to multiple classes of dewormers. We evaluated the effectiveness of two classes of anthelmintics, avermectin and fenbendazole, on fecal parasite load in yearling heifers grazing on irrigated pastures in south central Nebraska. Both of these anthelmintics have been used historically at U.S. MARC. Hence, a reduction in efficacy for these two historically used anthelmintic classes would be indicative of resistance. Spring-born heifers (n = 1015, average BW = 295 kg) were grazed on irrigated, mixed legume and cool season grass irrigated paddocks starting April 15, 2013. Heifers were managed in four pastures and fecal egg counts (FEC) 10% of each grazing group (25 hd minimum) were monitored weekly using a modified Wisconsin fecal floatation technique. When average FEC numbers for the sample reached > 25 eggs per 2 g, heifers in the group were weighed, fecal sampled for FEC (pre-treatment), and randomly assigned to one of three treatment groups (no dewormer; Avermax injectable (avermectin) at 1 mL/50kg BW subcutaneously; or Safeguard 10% Suspension (fenbendazole) at 2.3 mL/45.5 kg BW orally) by age and breed stratification. Treatments occurred July 16, 17, 26, and 27, 2013. Animals were sampled and FEC counts were obtained 2 wk later (post-treatment). The percentage of zeros for FEC was 4.5 for pre-treatment and 39.0 for post-treatment. Because of the high proportion of zero valued FEC, pre-treatment and post-treatment FEC were analyzed assuming a zero inflated negative binomial distribution. The zero inflated negative binomial model fit better than the standard negative binomial for post-treatment FEC (P = 0.0026) but not for pre-treatment FEC (P = 0.363). The effects of pasture (or breed) and treatment interacted ($P = 1.13 \times 10^{-17}$) with treatment having larger effect in pastures with higher FEC pre-treatment. Considering main effects, pasture affected FEC both pre- ($P = 4.44 \times 10^{-17}$) and post-treatment ($P = 9.41 \times 10^{-12}$). Treating animals with either Avermax or Safeguard reduced FEC ($P = 1.25 \times 10^{-94}$), and Safeguard's effect was greater than Avermax ($P = 9.73 \times 10^{-13}$). Treatment with anthelmintics is efficacious and has greater impact when parasitic load is greater. High efficacy of treatment indicates that little or no resistance has accumulated in parasitic nematode populations at USMARC.

Key Words: parasitic intestinal nematodes, cattle, fecal egg counts, resistance, althelmintics

0926 (W058) Effect of an injectable trace mineral on pregnancy rate of virgin heifers when synchronized using the 5-d Co-Synch plus CIDR or 14-d CIDR-PG protocol. C. J. Brasche*[1], J. B. Hall[2], and M. E. Drewnoski[1], *[1]University of Idaho, Moscow, [2]University of Idaho, Carmen.*

This study examined the effect of using a commercially available injectable trace mineral (TMI) on the reproductive performance of virgin heifers. Angus-crossbred heifers (n = 109, BW = 358 ± 3.7 kg) were blocked by weight and randomly assigned to treatment in a 2 × 2 factorial of either TMI containing copper, manganese, selenium, and zinc or no injection (CON) and one of two synchronization protocols, either a 14-d CIDR-PG protocol or a 5-d Co-Synch plus CIDR protocol. The objective of this study was to determine the effects of TMI before fixed time artificial insemination (AI) on conception to AI as well as the effects on overall pregnancy rate after exposure to bulls. Thirty-3 d before AI, heifers receiving TMI were given Multimin90 (0.57 mL/45.5 kg of BW). For the 14-d CIDR-PG protocol, a controlled internal drug release device (CIDR) was inserted 33 d before insemination and removed 14 d later. Prostaglandin (*P*G) was injected 16 d after CIDR removal and heifers were artificially inseminated 73 h later. For the 5-d protocol, a CIDR was inserted 7 d before AI and an injection of gonadotropin-releasing-hormone (GnRH) was given. Five d later the CIDR was removed, and a PG injection was given. A second PG injection was given 5.6 h later, and heifers were artificial inseminated 55 h after the last PG injection. All heifers received an injection of GnRH concurrently with AI and exposed to bulls 9 d post AI. Conception was determined using ultrasonography at 55 and 105 d post-AI. At 105 d post-AI, there was a synchronization protocol by TMI interaction for rate of heifers conceiving to AI (P = 0.04). However, conception to AI within the 5-d Co-Synch plus CIDR protocol (CON 66.0% vs. TMI 52.0%) and within the 14-d CIDR-PG protocol (CON 55.0% vs. TMI 75.0%) did not differ ($P \geq 0.13$) between the CON and TMI. There was no interaction (P = 0.18) between synchronization protocol and TMI for overall pregnancy rate after timed-AI and natural service. However there was significant effect of TMI (P = 0.02) on overall pregnancy rate with heifers receiving TMI (93.0%) having a greater (P = 0.02) pregnancy rate than the CON (83.0%) after AI and exposure to bulls. This data suggests that use of a TMI 30 d before the breeding season may improve reproductive performance of virgin heifers.

Key Words: heifer, injectable trace mineral, reproduction

0927 (W059) Oral suplementation with selenium for young Brangus bulls raised in pasture: seminal quality in fresh and frozen semen. T. B. Castaldeli*, L. K. Hatamoto-Zervoudakis, B. H. Tsuneda, J. T. Zervoudakis, W. A. D. S. Marinho, F. A. D. P. D. B. Arguello, M. F. Duarte Junior, P. P. Tsuneda, and R. D. Almeida, *Federal University of Mato Grosso, Cuiaba, Brazil.*

Cryopreservation stimulates production of free radicals and oxidative stress. The selenium (cofactor of enzyme glutathione peroxidase) acts as antioxidant protecting sperm membrane of lipid peroxidation and against consequent loss of function. The aim of this study was to evaluate oral selenium supplementation on semen quality of fresh and cryopreserved semen from young Brangus bulls raised in pastures in central Brazil. Sixteen Brangus bulls (5/8 Angus, 3/8 Zebu) with 24 mo and 472 kg of body weight on continuous grazing with daily concentrate supplementation by 75 d were used. The treatments were: GC- control (no added selenium in concentrated supplementation), GS- selenium (concentrated with addition of 0.1 mg Se/kg of dry matter intake (DMI)). After collection were evaluated sperm motility (MOT), sperm vigor (VIG), sperm viability (SVIAB), spermatic membrane integrity (SMI) and acrosomal membrane integrity (AMI) and triple stain (TS). Then semen was diluted and cryopreserved in TRIS-egg yolk citrate extender with 4% of glycerol. Thawing was performed in water bath at 37°C for 30 s. After thawing the samples, aliquots to evaluation of MOT, VIG, SVIAB, SMI, AMI, and TS were removed. Experiment was conducted in a completely randomized design. Data were analyzed by ANOVA with significance level of 5%. Supplementation with selenium improved SMI ($P = 0.0480$) in fresh semen (CG 26.71 ± 2.89 vs. 37.45 ± 4.14 GS) and frozen semen (GC 8.75 ± 1.42 vs. GS 9.90 ± 1.59). Selenium supplementation did not alter other parameters evaluated ($P > 0.05$). Studies on selenium supplementation with qualitative and quantitative parameters of bovine semen are rare. Thus, further research should be done to better understand effect of selenium on reproductive function. Oral supplementation with selenium concentration of 0.1 mg/kg DMI for young Brangus bulls raised on pasture does not alter seminal parameters traditionally evaluated in fresh and cryopreserved semen, but improves integrity of sperm plasmatic membrane.

Key Words: antioxidant, cryopreservation, sperm membrane.

0928 (W060) use of vitamin c combined to pentoxifylline and fertility in cattle after cryopreservation. R. D. Almeida*, L. K. Hatamoto-Zervoudakis, M. F. Duarte Junior, J. T. Zervoudakis, P. P. Tsuneda, A. L. C. Rezende Fraga, F. A. D. P. D. B. Arguello, T. B. Castaldeli, and F. M. Wingert, *Federal University of Mato Grosso, Cuiaba, Brazil.*

The process of frozen of the sperm provides a resting state of the cell, reducing energetic expenditures and the production of catabolites, preserving the cell structure and the fertilizing capacity of sperm. In contrast to a loss of quality (40 to 50%) occurs if compared to fresh semen, resulting from cooling processes freezing and thawing. These losses occur due to decreased sperm viability or damage to the functional capacity of the surviving sperm. Vitamin C is considered an antioxidant extracellular fluid, acting by preventing the formation of lipid hydroperoxide in plasma lipoproteins, and protecting the lipids in cell membranes while maintaining their structural integrity and viability during the cryopreservation process. Pentoxifylline is a methylxanthine derivative compound, the same class as caffeine and has the characteristic of inhibiting adenosine cyclic monophosphate (AMP) phosphodiesterase, causing an increase in the intracellular concentration of cyclic adenosine monophosphate (cAMP), activating the adenylyl cyclase which causes the activation of protein kinase-dependent and phosphorylation of sperm proteins, which are essential in initiation and maintenance of sperm movement. The objective of the experiment was to evaluate the use of vitamin C combined with pentoxifylline in the middle of cryopreservation of bovine semen that reduces the damage caused by oxidative stress and preserves sperm quality after thawing. We used 10 Nellore bulls with age/weight average of 31 mo and 632 kg, subjected to a semi-intensive system, raised on pasture *Brachiaria brizanth* cv., kept in sexual rest. One ejaculate was collected by electrical stimulation, which was analyzed after diluted in extender TRIS-citrate-yolk-glycerol (4%), divided into two parts: a part of the control (without additives), and the other supplemented with vitamin C (0.45 mg/mL) + pentoxifylline (1 mg/mL). Afterward, the samples were cooled and frozen and stored until the time of analysis. After thawing, the samples were evaluated for motility and movement characteristics, plasma membrane integrity and acrosome, mitochondrial activity and level of lipid peroxidation (TBARS). The supplementation of cryopreservation did not alter ($P > 0.05$) the mitochondrial activity, acrosomal integrity, and concentration of spontaneous and induced TBARS. Based on the results, it is concluded that the addition of vitamin C + pentoxifylline was not effective in reducing the damage caused by oxidative stress and cryopreservation of bovine semen samples.

Key Words: antioxidant, fertility, oxidative stress

BREEDING AND GENETICS: APPLICATIONS AND METHODS IN ANIMAL BREEDING— BEEF

0929 (M043) Effects of functional polymorphisms on beef carcass merit. W. M. Snelling*, L. A. Kuehn, R. M. Thallman, G. L. Bennett, and E. J. Pollak, *USDA, ARS, U.S. Meat Animal Research Center, Clay Center, NE.*

To develop a resource to identify polymorphisms present in common beef cattle breeds, and relate those polymorphisms to phenotypic differences, low-coverage genomic sequence was obtained on 186 purebred bulls from 15 predominant breeds in the United States and 84 crossbred sons of these bulls. These bulls were influential in the USMARC Germplasm evaluation population (GPE), enabling sequence-derived genotypes to be imputed throughout the population of individuals genotyped with the BovineHD (HD; n = 1027) and BovineSNP50 (n = 8697) platforms. Variants detected from these sequences were classified according to predicted effect on gene function, with 4699 predicted to cause a loss of gene function (LOF); 66,484 non-synonymous (NS) SNP causing an amino acid change in the protein produced by a gene, and 59,092 that may have a role in gene regulation (REG), occurring in annotated non-coding RNA or regions immediately surrounding a gene. Imputed genotypes of 685 purebred genotyped grandsires in the GPE population (18 to 74 bulls per breed) were used to represent each breed to assess diversity and determine breed effects on carcass merit. Relative genetic distances between breeds were consistent regardless of the set of genotypes considered. Brahman was furthest from any other breed, and Hereford the most distant from any other taurine breed. Similar distances were obtained using HD and ND SNP. The mean between-breed distance estimated with REG variants was about 10% higher than HD or NS, and distances using LOF variants were about 30% lower. Heritability estimates from GBLUP considering records of 5990 genotyped carcasses and treating breeds as genetic groups, ranged from 0.49 for ribeye area to 0.59 for marbling score when using only HD genotypes. Similar estimates were obtained in independent analyses using NS and REG, but the LOF estimates were lower, between 0.29 and 0.32. In four-component analyses with different genomic relationship matrices for HD, NS, REG, and LOF, 68% to 76% of additive variance was attributed to HD, and 2% or less to LOF. Contributions of both NS and REG were between 10 and 16% for carcass weight, marbling, and fat thickness. For ribeye area, the REG component was 31% of additive variance, and NS was nil. The GBLUP breed solutions were consistent with breed differences estimated in previous analyses. USDA is an equal opportunity employer and provider.

Key Words: beef cattle, genomic prediction, functional polymorphisms

0930 (M044) Steers' carcass characteristics with different genetic predominance fed with diets containing substitution levels of grain corn by millet grain. R. M. D. Silva*[1,2,3], J. T. Pádua[2], J. J. R. Fernandes[2], R. Z. Taveira[1], R. L. Missio[4], P. S. Pacheco[5], D. A. Fausto[6], and J. Restle[2], *[1]Universidade Estadual de Goiás, São Luis de Montes Belos, Brazil, [2]Universidade Federal de Goiás, Goiânia, Brazil, [3]FAPEG, Goiânia, Goiás, Brazil, [4]Universidade Tecnológica Federal do Paraná, Pato Branco, Brazil, [5]Universidade Federal de Santa Maria, Rio Grande do Sul, Brazil, [6]ESALQ/USP, Piracicaba, São Paulo, Brazil.*

This study aimed to evaluate the crossbred steers' carcass and meat characteristics with European or Zebu genotypic predominance. Considering that commercial animals were used, these animals were divided by genotypic predominance by visual evaluation. Feedlot finished with high diets concentrated percentage (80%), containing different levels of grounded millet grain as replacement for grounded corn grain (0, 33, 66, and 100%). Forty-five steers with European predominance and 44 steers with Zebu predominance, with initial average weight of 317.8 and 320.7 kg, respectively, and average age of 21 mo, were allocated in 16 collective pens. In the total, 89 animals were used from the beginning to the end of the feedlot. For the slaughter evaluation, 6 steers were used from each treatment for carcass evaluation. The animals from each genetic predominance were randomly chosen within of each level of corn substitution by millet grain. The experimental design was completely randomized with factorial arrangement 4 (diets) × 2 (genetic groups– predominance) × 6 (animals). The corn grain replacement by millet grain did not influence significantly slaughter weight (480.4 kg) ($P > 0.05$), hot carcass weight (259.5 kg) ($P > 0.05$), carcass yield (54.1%) ($P > 0.05$), or subcutaneous fat thickness (3.95 mm) ($P > 0.05$). Steers of predominantly European genotype showed significant higher values for slaughter weight (507.6 vs. 453.3 kg) ($P < 0.001$), hot carcass weight (269.6 vs. 249.3 kg ($P < 0.001$), and *Longissimus dorsi* area (65.34 vs. 56.83 cm2) ($P < 0.001$); however, they were lower in carcass yield (53.2 vs. 55.0%) ($P < 0.001$). Millet grain can be used in corn grain substitution for finishing steers since it does not change carcass traits of economic interest. Steers with European predominance are heavier at slaughter, presenting heavier and better carcass conformation.

Key Words: carcass weight, subcutaneous fat, zebu.

0931 (M045) Genome-wide association analysis for beef traits in Marchigiana cattle breed. S. Sorbolini[*1], C. Gruber[2], C. Dimauro[1], G. Gaspa[1], M. Cellesi[1], A. Valentini[2], and N. P. P. Macciotta[1], *[1]Università di Sassari, Italy, [2]Dipartimento per l'Innovazione dei Sistemi Biologici, Agroalimentari e Forestali, Viterbo, Italy.*

Genome-wide association studies (GWAs) are procedures that enable to correlate huge amounts of genetic and phenotypic data to find genomic regions that affect traits of economic importance. Several studies have been conducted for dairy cattle while few reports are available for beef cattle. In this study a GWA was performed on Marchigiana breed cattle, one of the most important beef breeds farmed in Italy. Phenotypes were body weight (BW), average daily gain (ADG), carcass weight (CW), dressing percentage (DP), pH at slaughtering (*P*H), shank circumference (SC) and head weight (HW) measured on 408 Marchigiana young bulls slaughtered between 16 and 24 mo of age. Animals were genotyped with the Illumina 54K bead-chip. Edits were on the call rate (> 0.99), number of missing (> 2, 5%), MAF (> 0.01). Data were analyzed with a mixed linear model that included the fixed effects of herd, date of slaughtering, fixed covariables of age at slaughtering, SNP genotype (coded as 0, 1, 2), and the random effect of the sire to account for population stratification. A permutation test with 10,000 replications for each marker was performed to account for multiple testing. Significant markers (Permutation corrected $P < 0.05$) were 12 for BW, 124 for ADG, 36 for CW, 28 for DP, 9 for pH, 19 for SC, and 41 for HW, respectively. Annotated genes in genomic regions corresponding to significant SNP were derived from the UCSC Genome Browser Gateway (http://genome.ucsc.edu/) using intervals of 500 Kbp (0, 25 Mbp upstream and downstream of the significant region). Among identified genes, some were related to bone metabolism, as the OSTN (Osteocrin), SPARC (secreted protein acid cystein rich), muscle physiology as MEF2C (myocyte enhancer factor 2) and CA3 (carbonic anhydrase III, muscle specific) feeding behavior as HCRTR2 (hypocretin (orexin) receptor 2) and fatty acid biosynthesis as ACACB (acetyl-CoA carboxylase β) and ACAD8 (Acyl-CoA dehydrogenase family, member 8), respectively. Of interest were also some genes that could be related to meat quality as FPGS (folylpolyglutammate synthase) on BTA11, TTPA (tocopherol (α) transfer protein) on BTA 14 and GGPS1 (geranylgeranyl diphosphate synthase 1) on BTA28. These genes are involved in the metabolism of antioxidants such as vitamins A, E and folate that are effective molecules in preventing oxidative stress.

Key Words: GWA, beef traits, Marchigiana cattle

0932 (M046) Estimation of genetic parameters for reproductive traits in a multibreed population of beef cattle. S. O. Peters[*1], K. Kizilkaya[2], D. J. Garrick[3], R. L. Fernando[3], E. J. Pollak[4], M. Enns[5], and I. G. Imumorin[6], *[1]Berry College, Mount Berry, GA, [2]Adnan Menderes University, |Aydin, Turkey, [3]Iowa State University, Ames, [4]USDA, ARS, U.S. Meat Animal Research Center, Clay Center, NE, [5]Colorado State University, Fort Collins, [6]Cornell University, Ithaca, NY.*

Reproductive traits are very important economically relevant traits in beef cattle production, and estimation of genetic parameters for these traits is necessary to optimize selection response and improve profitability of beef production. The objective of this research was to determine genetic parameters for the reproductive traits of heifer pregnancy (HPG), stayability (ST), rebreeding rate (RR) and calving ease (CE) in a multi-breed cattle population. We analyzed a dataset of 10,245 HPG and ST records, 8740 RR records and 11,779 CE records from a large commercial operation in Nebraska that included pedigree information, contemporary groups and sire breed. Hierarchical threshold mixed models based on a probit link specification were used for the bivariate analysis of HPG and ST records and for the univariate analysis of RR and CE with maternal records. The posterior means and 95% posterior probability intervals of additive variance were estimated to be 0.227 ± 0.103 [0.104, 0.418] for HPG and 0.123 ± 0.043 [0.049, 0.215] for ST, and 0.211 ± 0.101 [0.074, 0.449] for RR and 0.216 ± 0.147 [0.04, 0.549] for CE, respectively. Also, the posterior mean and 95% posterior probability interval (*P*PI) of direct maternal variance were estimated to be 0.702 ± 0.229 [0.355, 1.230] for CE. Posterior mean inferences on direct heritability were found to be 0.056 ± 0.019 [0.025, 0.099] for HPG and 0.065 ± 0.021 [0.028, 0.111] for ST, 0.138 ± 0.053 [0.056, 0.254] for RR and 0.08 ± 0.05 for CE, respectively. Posterior mean inferences on maternal heritability were found to be 0.263 ± 0.07 [0.145, 0.417] for CE. The posterior mean of genetic correlation between HPG and ST was low and negative (-0.174 ± 0.289) and insignificant with [-0.665, 0.353] of 95% PPI. The posterior mean and 95% PPI of direct maternal genetic correlation was -0.235 ± 0.132 [-0.509, 0.024] for CE. The low heritability values observed in this study are similar to literature values and the low and negative correlation between HPG and ST indicate that genetic improvement geared towards improving HPG may have antagonistic effect on ST, but this effect is not statistically significant.

Key Words: reproductive traits, genetic parameters, threshold model

0933 (M047) Copy number variation in the genome of Nellore cattle. M. V. A. Lemos[1], M. P. Berton[2], C. Aboujaoude[3], F. Feitosa[4], G. C. Venturini[5], R. L. Tonussi[5], R. Espigolan[5], H. N. Oliveira[2], L. G. Albuquerque[6], and F. Baldi[*7], *[1]State University of São Paulo, Faculty of Agriculture and Veterinary Sciences, Jaboticabal, São Paulo, Brazil, [2]State University of São Paulo, Faculty of Agriculture and Veterinary Sciences, Jaboticabal, São Paulo, Brazil, Jaboticabal, Brazil, Jaboticabal, Brazil, [3]FCAV–UNESP, Jaboticabal, Brazil, [4]UNESP, Jaboticabal, Brazil, [5]Sao Paulo State University (UNESP), Jaboticabal, Brazil, [6]State University of São Paulo, Faculty of Agriculture and Veterinary Sciences, Jaboticabal, Brazil, [7]Universidade Estadual Paulista "Júlio de Mesquita Filho"–UNESP, Faculdade de Ciências Agrárias e Veterinárias, Jaboticabal, Brazil.*

The aim of this work was to study the distribution of CNVRs (regions of copy number variation) in the genome of Nellore cattle. A total of 3022 animals (females and males) finished in feedlot conditions were used. For genotyping, a panel with more than 777,000 SNP markers (High-density Bovine BeadChip) was used. Samples with Call rate lower than 90% were excluded. The PennCNV algorithm (Wang et al., 2007) was used for CNVs detection. To maintain the quality of the samples, samples with LRR (Log R ratio) standard deviation above 0.30, BAF (frequency of allele B) higher than 0.05 and waviness factor higher than 0.01, were excluded from the analyses (Liu et al., 2013), reducing the number of animals to 1561. The regions of CNVs (CNVRs) were generated by overlapping 73,073 CNVs identified by the CNVRuler program (Kim et al., 2012). Initially, different CNVs length were considered with a minimum size of 10kb, 50kb and all sizes, which resulted in 4459, 1365, and 6399 CNVRs, respectively. When all CNV sizes were considered, the average CNVRs length was 36.4 kb, ranging from 0.65 to 1310 kb. There was a higher incidence of CNVRs at BTA1 (483), BTA6 (381), and BTA2 (380). The chromosomes that showed lower incidence of CNV regions were BTA25 (85), BTA27 (104), and BTA28 (117). Considering the CNVs of all sizes, 35.7, 41.0, and 23.3% of the CNVRs were copy gain, copy loss and both (gain and loss in the same region), respectively. The 6399 CNV regions estimated in the present study coverage approximately 8.80% of the bovine genome (UMD_3.1, 2649,685,063 bp). This study confirms the existence of large structural variations in the genome of Nellore cattle and it would support the genetic improvement of this breed and elucidate the genetic mechanisms involved in the expression of productive traits.

Key Words: CNV, CNVR, Nellore

0934 (M048) Seasonality and fresh semen quality from Pantaneira and Nellore bulls raised in Brazilian Pantanal. L. E. S. Silva[1], L. K. Hatamoto-Zervoudakis[*1], A. F. Ramos[2], P. P. Tsuneda[1], F. M. Wingert[1], M. F. Duarte Junior[1], T. B. Castaldeli[1], R. D. Almeida[1], and J. D. O. Moraes[1], *Federal University of Mato Grosso, Cuiaba, Brazil, [2]EMBRAPA–CENARGEN, Brasilia, Brazil.*

Taurine cattle (*Bos taurus*) when subjected to tropical conditions have reduced fertility compared to zebu cattle (*Bos indicus*). The Pantaneira breed (*Bos taurus*) was recently recognized as a Brazilian native breed adapted into climatic conditions of Brazilian Pantanal. However, the seminal parameters of this breed are unknown. Thus, the aim of this work were knowing the seminal parameters Pantaneira breed and evaluate what breed (Pantaneira or Nellore breed) raised on pasture in the southern Brazilian Pantanal region is more adapted to regional climatic conditions. Seven Pantaneiro bulls and three Nellore bulls were used. Semen was collected by electroejaculation. Immediately after collection were evaluated: sperm motility (MOT), vigor (VIG), primary defects (PRIMDEF), secondary defects (SECDEF) and total defects (TOTDEF) semen concentration (CONC), sperm viability (SVIAB) and integrity of acrosomal membrane (ICM). The experiment was conducted in a 2 × 2 factorial arrangement (two breed and two seasons) and data were analyzed by ANOVA and Tukey test, with $\alpha = 5\%$. Seminal parameters in Pantaneira bull are within recommended standards for bovine. SVIAB was lower in winter in both breeds (95.76 ± 1.77% vs. 87.07 ± 4.78%, $P = 0.03$). Nellore bulls showed a higher amount of sperm with SECDEF in summer (2.16 ± 1.09% vs. 0.57 ± 0.31%; $P = 0.02$), and higher percentage of PRIMDEF (61.91 ± 5.92 vs. 26 ± 3.83%, $P = 0.01$) and TOTDEF (62.58 ± 5.63% vs. 27.33 ± 3.91%, $P = 0.03$) in winter. Were not found effects of breed, season, or interaction ($P > 0.05$) in other parameters evaluated. Although Pantaneira breed to be considered a taurine breed (*Bos taurus*), it passed a natural selection process by about 300 yr, adapting to high temperatures in central Brazil and probably has become more resistant to testicular degeneration process. In contrast, Nellore bulls appear to be more sensitive to heat stress by cold. Therefore, it is concluded that Pantaneira breed is most suitable breed to edaphoclimatic conditions in the Brazilian southern Pantanal.

Key Words: sperm morphology, heat stress, fertility

0935 (M049) Sliding window methods to detection of regions under selection in Nellore cattle.

D. F. Cardoso*[1,2], G. C. Venturini[3], D. J. A. Santos[4], R. R. Aspilcueta Borquis[1], A. A. Stella[1], F. Baldi[5], L. G. Albuquerque[1], M. E. Z. Mercadante[6], and H. Tonhati[1], *[1]State University of São Paulo, Faculty of Agriculture and Veterinary Sciences, Jaboticabal, Brazil, [2]Bolsista–Fundação de Amparo à Pesquisa do Estado de São Paulo (FAPESP), São Paulo, Brazil, [3]Sao Paulo State University (UNESP), Jaboticabal, Brazil, [4]Universidade Estadual Paulista, Jaboticabal, Brazil, [5]Universidade Estadual Paulista "Júlio de Mesquita Filho", Faculdade de Ciências Agrárias e Veterinárias, Jaboticabal, Brazil, [6]Centro APTA Bovinos de Corte, Instituto de Zootecnia, Sertãozinho–SP, Brazil.*

The directional selection in bovines lead to genetic differences between breeds or herds because the frequency of alleles range in function of trait selected. A frequency of alleles favorable to selected traits increasing and together also increases the frequency of alleles in adjacent loci. Therefore, mutations under selection are characterized as regions where the allelic frequencies are different from expected under chance or absence of selection. The objective in this study was identify regions under selection in Nellore cattle through of calculate of the difference in allelic frequencies between herds under divergent selection. To this end, we used three experimental herds belongs to Estação experimental de Zootecnia de Sertãozinho-SP, Brazil, two herd selected for higher yearling weight (NeS and NeT) and one herd control (NeC) selected since 1968 to weight near the average. We used 67 animals from NeC, 153 from NeS and 421 from NeT genotyped by the Illumina High Density Bovine SNP BeadChip (777K). After quality control were left 456,816 SNPs. We calculated the frequency of allele B for each SNP in each herd and the allelic difference in this frequency between each pair of herds. Then we adopted the method of comparison between populations described by Hayes et al. (2008) termed sliding window average. This one corresponded with the average of the absolute values of differences to each set of 10 adjacent SNPs, where values that exceeding 0.43 are considered significantly higher than expected in no selection. Although the amount of SNPs used in this study is much higher than that used to determine the empirical significance thresholds, the distribution of differences values here calculated show concordance with its patterns. As expected, a difference above 0.43 was not observed in the sliding window average from NeS-NeT if both herds were selected under same criterion, and intensity would not make sense; the difference between them exceeds the threshold established to predict selection effect on the frequencies. In the NeC-NeS and NeC-NeT sliding window averages there were significant values, 74 and 93, respectively, in chromosomes 3, 4, 6, 7, 12, 16, 18, 20, and 24. The correlation between differences from NeC-NeS and NeT-NeS was high ($r = 0.62$) and the region with max difference between herds contained the PPARGC1A gene, (Bta6). Further, we will analyze the role of genes around the regions considered under selection and also match these results with putative signature selections detected with other methods.

Key Words: divergent selection, SNPs

0936 (M050) Association between copy number variation regions in the Nellore cattle genome and meat tenderness.

M. P. Berton[1], M. V. A. Lemos[2], C. Aboujaoude[2], G. M. de Camargo[3], F. Feitosa[1], G. C. Venturini[4], R. L. Tonussi[4], R. Espigolan[4], D. M. Gordo[1], A. S. C. Pereira[5], H. N. Oliveira[1], L. G. Albuquerque[3], and F. Baldi*[2], *[1]State University of São Paulo, Faculty of Agriculture and Veterinary Sciences, Jaboticabal, Brazil, [2]Universidade Estadual Paulista "Júlio de Mesquita Filho", Faculdade de Ciências Agrárias e Veterinárias, Jaboticabal, Brazil, [3]State University of São Paulo, Faculty of Agriculture and Veterinary Sciences, Jaboticabal, Brazil, [4]Sao Paulo State University (UNESP), Jaboticabal, Brazil, [5]State University of São Paulo, Jaboticabal, Brazil.*

The present study aimed to analyze the association between the copy number variation regions (CNVR) with meat tenderness of 737 Nellore bulls. The animals were finished in feedlot and slaughtered at approximately 2 yr of age. Samples from the *Longissimus dorsi* muscle with 2.5 cm (thickness) were collected to obtain the meat tenderness using a Warner-Bratzler shear force device. A panel with 777,962 SNPs markers (High-Density Bovine BeadChip) was used to genotype the animals. Samples with call rate below 90% were excluded. The parameters used to estimate the CNVs were: Log R Ratio (LRR) and B Allele Frequency (BAF). For quality control, samples with standard deviation values for LRR < 0.30, BAF < 0.05 and waving factor < 0.01 were eliminated. The CNVR were appointed as the CNVs overlaps in the samples, that were located by the CNVRuler software. The shear force data were adjusted for the effects of farm and year of birth, and management groups at birth, weaning and yearling. The model included the state of CNV as a fixed effect and the age of animal at slaughter as a covariate. The average shear force obtained was 5.51 kgf. A total of 4504 CNVRs with an average size of 36.59 kb were detected. There were 10 CNVRs with MAF greater than 0.05, and among them only two significant ($P < 0.05$) associated with meat tenderness (CNVR_1491, CNVR_1130). The CNVR_1491, located on chromosome 7, is in an intergenic region, possibly serving as an indirect marker. This CNVR is between two regions, the first is not characterized, and the second is a pseudogene of transcription factors for heat shock proteins; therefore, the significant *P*-value for this region is an indication that these genes may be influencing this trait. All these LOC regions are "like" regions, areas that have partial or total similarity to genes in other genome regions. The

CNVR_1130, located on chromosome 5, is in theory a intergenic region. There were four regions within this CNVR, two are not characterized and the other two are "like" sequences of the gene associated with butyrophilin protein subfamily 1 member A1, which participates in the formation of fat droplets in milk cattle. Theoretically, this gene may influence the subcutaneous fat thickness and therefore affect meat tenderness. The meat tenderness should be improved in Zebu cattle, and the CNVRs are a tool that can be used to genetic improve this trait.

Key Words: chromosomal region, CNVR, shear force

0937 (M051) An evaluation of 6 years of carcass and feedlot performance in Brahman and Brahman-influenced steers tested by the American Brahman Breeders Association (ABBA) National Carcass Evaluation Program.

A. Royer[*1] and M. D. Garcia[2], [1]*Louisiana State University, Baton Rouge,* [2]*Louisiana State University, Baton Rouge.*

The American Brahman Association has made concerted efforts to improve the carcass quality and composition of Brahman and Brahman-influenced cattle. Thus, the objective of the current study was to evaluate genetic trends for Brahman steer calves that have comprised 6 yr (2004–2010) of the American Brahman Breeders Association (ABBA) National Carcass Evaluation Program. A total of 418 steers were evaluated for growth traits, carcass quality, and composition traits. Steers were fed in Gonzalez, TX, until a desirable harvest weight was achieved. Steers were then transported to a commercial harvest facility where carcass quality and composition traits were collected. Growth and performance traits collected in the feedlot that were evaluated in the current study consisted of entrance weight into the feedlot (INWT), harvest weight (HRVWT) and average daily gain (ADG). Carcass quality and composition traits that were evaluated included hot carcass weight (HCW), ribeye area (REA), marbling score (MARSC), yield grade (YG), dressing percent, and Warner-Bratzler shear force (WBS) analysis for meat tenderness evaluation. The PROC REG procedure of SAS was utilized to determine the average increase or decrease of performance for each trait over the six year evaluation period. Entrance weights into the feedlot in 2004 averaged 239.47 kg and HRVWT averaged 494.35 kg. Entrance weights and HRVWT in 2010 had increased to 292.11 kg and 579.26 kg, respectively. Subsequently, all growth traits evaluated in the current study exhibited a linear increase over the six year evaluation period with INWT increasing 5.5 kg/year, HRVWT increasing 11.1 kg/year and average daily gain increasing 0.17 kg/year. When evaluating carcass quality and composition traits, it was revealed that all traits with the exception of MARSC exhibited a linear increase. Marbling score was the only trait observed not to increase over the six year testing period, decreasing at a rate of 3.7 marbling score units per year, respectively. The carcass traits that exhibited a linear increase over the six year evaluation period included HCW (7.2 kg/year), REA (0.55 cm/year), YG (0.04 units/year), WBS (0.41 kg/year) and dressing percentage (0.10/year).

Key Words: *Bos indicus*, genetic trends, carcass traits

0938 (M052) Relationship of physical characteristics and reproductive status in crossbred Angus replacement heifers.

J. E. Thames[*1], C. M. Turner[1], A. H. Brown, Jr.[2], C. F. Rosenkrans[1], K. Anschutz[2], and J. G. Powell[2], [1]*University of Arkansas, Fayetteville,* [2]*Dep. of Animal Science, University of Arkansas Division of Agriculture, Fayetteville.*

The objective for this study was to measure physical characteristics of developing replacement heifers and to determine if these traits were related to reproductive status at breeding. Contemporary Angus based replacement heifers (n = 89) were managed on pastures containing endophyte infected tall fescue at the University of Arkansas Beef Cattle Research Center near Fayetteville, AK. Measurements that were recorded for each heifer at weaning, yearling, and prebreeding included body weight, pelvic area, hip height, hip width, reproductive tract score, rump fat, back fat, rib eye area, and coat shedding score. A group of heifers (n = 26) were determined to be unsatisfactory for exposure to breeding (NE). Pregnancy status was determined for the remaining heifers (n = 63) following AI and pasture exposure to fertile bulls in a 60-d breeding period. No physical differences were found among the heifers that were exposed and did conceive (EC) (n = 32) compared to heifers exposed that did not conceive (EDC) (n = 31). Mean pelvic height was greater for EC heifers (38.68 ± 4.00) when compared to the NE (35.51 ± 4.00) and EDC (38.00 ± 4.00) heifers (P = 0.056). The NE group had a significantly greater mean coat shedding score than either EDC (P < 0.01) or EC heifers (P < 0.01), with EC heifers having the lowest mean coat shedding score (3.05, 2.62, vs. 2.52 ± 0.91, respectively). The physical characteristics including body weight, hip height, and rump fat that were measured for the NE group displayed an inverse trend to that of coat shedding score. The NE group exhibited lower (P < 0.05) values across all physical measurements compared to EC and EDC heifers. Coat shedding score was further analyzed by dividing the heifers data into two groups, with group one (g1) having coat scores 3 or less and group two (g2) having coat scores 4 or 5. Group one heifers were 10.38 ± 7.23, 21.48 ± 7.78, and 30.18 ± 7.96 kg greater in mean BW when compared to group 2 heifers at weaning, yearling, and prebreeding, respectfully (P = 0.14, P = 0.08, P < 0.01, respectfully). In conclusion, these data indicate that coat shedding score was inversely correlated to physical and ultrasound measurements taken at weaning, yearling and prebreeding. Producers selecting replacement heifers may be able to utilize coat shedding score as another characteristics to assess desirable replacement heifers.

Key Words: replacement heifer, beef cattle, coat shedding

GENOMIC METHODOLOGY

0939 (M053) Signature of selection reveals large difference in selection traits. X. Zhang*[1], I. Misztal[1], M. Heidaritabar[2], J. W. M. Bastiaansen[3], R. Hawken[4], R. Okimoto[4], R. L. Sapp[4], H. H. Cheng[5], D. A. L. Lourenco[1], and W. M. Muir[6], *[1]University of Georgia, Athens, [2]Wageningen University, Netherlands, [3]Animal Breeding and Genomics Centre, Wageningen University, Netherlands, [4]Cobb-Vantress Inc., Siloam Springs, AR, [5]USDA, ARS, ADOL, East Lansing, MI, [6]Purdue University, West Lafayette, IN.*

Selection on animals changes the population-wide frequency spectrum of genes related to the traits under selection. With the aid of single-nucleotide polymorphism (SNP) methods, it is possible to inspect for changes in allelic frequencies directly. To reveal the impact of recent selection on genetic variation, we compared the allele frequencies before and after three generations of selection on an index of three traits in two lines (F and M) sampled from commercial broiler chicken. Line M animals are from a sire line that was selected mainly for growth traits, and line F animals are from a dam line that was selected mainly for reproductive traits. Selection was performed by applying single-step Genomic Best Linear Unbiased Prediction (ssGBLUP). Genotypes were used in this study for allele frequency analysis. The M and F lines consisted of 4922 and 4904 genotyped animals, respectively. After quality control, genotypes included information on 52,742 and 52,639 SNPs in line M and F, respectively. Selection was for an index consisting of body weight at 6 wk, ultrasound measurement of breast meat, and leg score. The average allele frequency change for both lines on autosomes was 0.049. Threshold value for detecting selected regions, where allele frequency changes exceeded expectations under drift were 0.140 and 0.136 for line M and F, respectively. There were 25 and 17 selection regions detected on line M and F, respectively, without any overlap of regions between the lines. Average 4heterozygosity change in line F was greater compared to line M (0.008 vs. 0.003, $P < 0.01$). The putative selected regions between line M and F are different. The results we present indicate that in newly selected populations, the genotype frequencies across chromosomes change differently according to the selection lines even if animals are selected for same traits.

Key Words: SNP, allele frequency change, genomic selection

0940 (M054) Weighted single-step genomic BLUP: an iterative approach for accurate calculation of breeding values and SNP effects. X. Zhang*, D. A. L. Lourenco, and I. Misztal*, University of Georgia, Athens.*

The purpose of this study was to explore options for genome wide association analysis (GWAS) with single-step GBLUP (ssGBLUP). In GWAS by ssGBLUP, GEBV are converted to marker (SNP) effects. Unequal variances for markers are then derived from SNP solutions and subsequently incorporated into a weighted genomic relationship matrix. Improvements on the SNP weights can be obtained iteratively either by recomputing the SNP effects only or by also recomputing the GEBV. Four options were used to calculate the weights: 1) proportional to $2p_i(1-p_i)u_i^2$, where p_i and u_i are frequency and effect of the i-th SNP; 2) proportional to $2p_i(1-p_i)u_i^2$+ constant; 3) weights as in 1, but updating only the top 25 SNP; 4) updating only the top 5 SNP. A simulated data set was used that included 15,600 animals in five generations, of which 1540 were genotyped for 50k SNP. The simulation involved phenotypes for a trait with heritability of 0.5 potentially affected by 5 QTL. Accuracy between TBV and GEBV for genotyped animals in generation 5 was used for evaluation. Comparisons also involved BayesC with deregressed proofs and $\pi = 0.9999$. In single-step, SNP effects were tracked along 10 iterations and weights were equal to 1.0 in the first iteration. Results showed option 3 as the best in identifying simulated QTL without background noise and with precision in most of the regions, as well as BayesC; after two iterations, the accuracy of GEBV reached a plateau and was 0.91 as opposed to 0.88 for BayesC. Testing also included a commercial data set with 200k animals and 15K genotypes for 39k SNP. For one of the traits, Manhattan plots with option 3 and BayesC looked identical showing six large peaks and very small background noise. However, the realized accuracy was 0.16 in the first round and 0.14 in the subsequent rounds, as opposed to 0.19 for BayesC. For the other traits, the accuracy by BayesC was lower and Manhattan plots did not have clear peaks. The option to compute weights for SNP in ssGBLUP with the top 25 SNP gives a good identification of top segments. However, further work is required to compute weights to maximize accuracy for a variety of cases. In addition, a choice for GWAS in single-step approach is based on simplicity and flexibility in case of complex models.

Key Words: weighted SNP, ssGBLUP, BayesC

0941 (M055) Derivation of Bayes and Minimax decision rules for allelic frequencies estimation in biallelic loci. C. A. Martinez*[1,2], K. Khare[2], and M. A. Elzo[1], *[1]Dept of Animal Sciences, University of Florida, Gainesville, [2]Dep. of Statistics, University of Florida, Gainesville.*

In population genetics, allelic frequencies are typically estimated via maximum likelihood (MLE). Under this setting, allele frequencies are treated as unknown fixed parameters. However, population genetics theory indicates that allele frequencies vary at random, thus they should be treated as random variables. The aim of this study was to derive Bayes and Minimax estimators (ME) of allele frequencies for biallelic loci using decision theory. Because an optimal decision rule with uniformly smallest risk rarely exists, an approach is to establish principles that allow ordering of decision rules according to their risk function. Two general methods were used to obtain average risk optimality: the Bayes and the Minimax principles. Briefly, given a loss function and a prior distribution, the Bayes principle looks for an estimator minimizing the posterior risk, while the Minimax principle consists of finding decision rules that minimize the supremum (over the parameter space) of the risk function (the worst scenario). For an arbitrary locus, the sampling model was a trinomial distribution for numbers of individuals for each genotype and the prior was a Beta distribution, chosen because of mathematical convenience, flexibility and genetic interpretation of its parameters. Three types of loss functions were considered: square error (SEL), Kullback-Leibler (KLL), and a quadratic error loss (QEL). The SEL and KLL yielded the same estimator, which was a convex combination of the prior mean and the MLE. Using the Bayes estimator from QEL, a ME was derived by applying a theorem that states that a Bayes estimator with constant risk is also Minimax. The constant risk was obtained by finding appropriate hyperparameter values. This estimator was shown to be equivalent to MLE. The prior associated with this ME was uniform [0, 1]. One consequence of using the previous theorem on the derivation of ME is that the uniform distribution is a least favorable prior, that is, it causes the greatest average loss. Extension to several loci under linkage equilibrium and independent priors was discussed. The estimators derived here have the appealing property of allowing variation in allelic frequencies, which is more congruent with the reality of finite populations exposed to evolutionary forces. In addition, from a Bayesian perspective they permit modeling uncertainty and incorporation of previous genotypic information from the population.

Key Words: allele frequencies, average risk optimality, decision theory

0942 (M056) Adjusting genomic relationship matrices in single-step genomic BLUP for crossbred evaluations. D. Lourenco, and I. Misztal, *University of Georgia, Athens.*

Different breed-specific genomic relationship matrices (GB) were compared to the standard across-breed genomic relationship matrix (G) used in single-step genomic evaluations. Datasets were simulated that resembled a terminal-cross population. Two purebred lines were separated by 50 generations. Three scenarios considered selection based on high EBV, high phenotypes, and no selection. The datasets used for evaluations contained phenotypes and pedigrees for the last 15 generations and genotypes for the last eight generations of purebreds. Data on F1 animals were from a single generation. Number of purebred parents genotyped varied from 3100 to 3300 depending on the scenario, and number of genotyped F1 was 1200. The heritability for the simulated trait was 0.30. Testing involved four genomic matrices: GB1 considered specific allele frequencies (AF) for each pure and crossbred; GB2 used AF for crossbred calculated based on AF from the two purebreds; GB3 and GB4 had AF as in GB2 and GB1, respectively; however, each element was scaled by breed-specific scaling factors. Across-breed and breed-specific correction factors for G and all GB were also used to account for the non-random genotyping caused by selection. The validation was done in F1 animals and parameters of the regression of TBV on GEBV were used to assess the accuracy of evaluations. For G and all GB, coefficients of determination (R^2) and regression were higher when no artificial selection was applied. When no correction factor was used, R^2 for G, GB1, GB2, GB3, and GB4 for EBV selection were 0.33, 0.03, 0.37, 0.37, and 0.03, respectively; for mass selection were 0.23, 0.33, 0.37, 0.38, and 0.33, respectively; for no selection were 0.47 for G and 0.46 for all GB. However, after using breed-specific correction factors, the difference between G and GB was reduced and GB1 and GB4 gave similar results to G (R^2 = 0.40 under EBV and mass selection; R^2 = 0.47 under no selection), while GB2 and GB3 had slightly worse performance. Most unbiased predictions were with G and the correction factor applied, which regressions were close to 1.0 for the purebreds and from 0.65 to 1.0 for the crossbreds; the highest inflation was with the EBV selection and no phenotypes on crossbreds. Breed-specific genomic matrices provide little benefits for genomic evaluations in a terminal cross model. The best performance is with standard G corrected for an average selection across breed types.

Key Words: ssGBLUP, breed-specific, allele frequency

BREEDING AND GENETICS: APPLICATIONS AND METHODS IN ANIMAL BREEDING—DAIRY II

0943 (T041) Genome-wide association study on dairy cow mortality in three U.S. regions. S. Tsuruta[*1], I. Misztal[1], and T. J. Lawlor[2], *[1]University of Georgia, Athens, [2]Holstein Association USA Inc., Brattleboro, VT.*

Cow mortality, from DHI reports, is farmer provided information. The termination code = "dead" is the primary reason given for a cow leaving a herd, particularly late in lactation. This trait can be difficult to interpret because its definition and recording method may differ across farms. Our objective was to do a genome-wide association study (GWAS) on cow mortality and 305-d milk yield for three lactations and determine if there were differences in the genetic architecture associated with these traits in three different regions of the United States. Genomic EBV of cow mortality and 305-d milk yield were estimated with a single-step GBLUP using a threshold-linear model. The SNP file contained 42,503 usable SNP markers for 34,506 bulls obtained from USDA-AIPL. Data consisted of the entire U.S. DHI data for three lactations (10,748,430 animals; 6233,306 records) for cows calving from 1999 to 2008. Three U.S. regions— SE: Southeast (648,991 animals; 293,494 records), SW: Southwest (541,777 animals; 272,934 records), and NE: Northeast (1690,481 animals; 883,887 records)— were selected for regional comparison. Heritability estimate for 305-d milk first lactation yield was 29%. Heritability for mortality within the first lactation was 0.04, 0.06, 0.06, and 0.04 for SE, SW, NE, and U.S., respectively. Genetic correlations between first lactation mortality and 305-d milk yield were 0.14, -0.01, 0.02, and 0.25 for SE, SW, NE, and U.S., respectively. The genome was divided into equal segments of 20 sequential SNPs. As expected, a segment on chromosome 14 was significantly associated with milk production in all regions. The proportion of the total genetic variance for 305-d milk yield, explained by this segment, was 1%, 1%, 3% and 4% for SE, SW, NE region, and total U.S., respectively. Chromosome 14 showed a strong association with first parity mortality for the entire U.S., with the NE showing a strong association for all three parities. Milk components (higher or lower %fat) could be a possible explanation. Within the SE and SW regions, chromosome 14 did not show a significant association for any of the three parities. These results suggest that this farmer-recorded trait on mortality is being interpreted differently and/or there are different traits (genomic segments) responsible for cow mortality in different regions of the country.

Key Words: GWAS, cow mortality, region

0944 (T042) Multiple-breed genomic evaluations by using a reduced pool of SNP-markers. M. Cellesi[*1], N. P. P. Macciotta[1], P. Ajmone-Marsan[2], A. Rossoni[3], G. Marras[1], G. Gaspa[1], and C. Dimauro[1], *[1]Università di Sassari, Italy, [2]Università Cattolica del Sacro Cuore, Piacenza, Italy, [3]Associazione Nazionale Allevatori Razza Bruna, Bussolengo, Italy.*

Large reference populations (RP) of genotyped and phenotyped individuals are required to obtain reliable predictions in genomic selection programs. For small breeds, however, assembling such RPs could result particularly challenging. In this study, a multibreed approach was used to enhance the size of the RP. Data were genotypes of 2054 Italian Holstein and 634 Brown Swiss bulls, respectively, genotyped with the Illumina's 50K BeadChip. Phenotypes were deregressed proofs (DRP) for milk, fat and protein yield. An empirical technique, named Maximum Difference Analysis (MDA), was used to select a restricted pool of SNP-markers significantly associated with the considered trait (T). In each breed, animals were ranked according to a T. The best (B) 10% and the worst (W) 10% individuals were selected and the genotypic frequencies were evaluated. For each SNP, the maximum genotypic frequency in B and, in correspondence, the frequency for the same genotype in W were recorded and the difference between the two frequencies was calculated. A bootstrap procedure was then implemented to derive a posterior probability distribution that was used to declare a SNP positively associated with T. Markers negatively associated with T were detected through the same procedure with the only difference that, for each SNP, the maximum genotypic frequency was recorded in W. A BLUP model was used to estimate marker effects that were then used to calculate genomic breeding values of Brown Swiss younger bulls (50animals). Three datasets were used: all original SNPs, only the MDA selected markers (MDA_SNP) and the MDA_SNP for Brown Swiss plus MDA_SNP obtained for Holstein. MDA selected, for both breeds, around 1500 markers for each trait. Accuracies of genomic predictions (Table 0944) evaluated by using MDA_SNPs in the multi-breed scenario were greater than values obtained with all markers and in the single-breed scenario. Results suggested that the MDA applied to a small genotyped bovine population increases accuracies of genomic predictions of about 10%. A further improvement can be obtained in a multibreed scenario.

Key Words: SNP reduction, multiple breeds, genomic selection

Table 0944. Accuracies of genomic predictions for Brown Swiss

Scenarios	Milk	Fat	Protein
Brown Swiss all SNP	0.21	0.35	0.21
Brown Swiss MDA_SNP	0.31	0.43	0.30
Holstein + Brown Swiss MDA_SNP	0.36	0.43	0.34

0945 (T043) Determination of single nucleotide polymorphisms associated with subclinical ketosis in Jersey cattle. R. T. Fugate*[1], L. H. Dauten[2], G. R. Wiggans[3], and H. M. White[4], *[1]University of WI, Madison, [2]University of Connecticut, Storrs, [3]Animal Improvement Programs Laboratory, Agricultural Research Service, USDA, Beltsville, MD, [4]Dep. of Dairy Science University of Wisconsin, Madison.*

Subclinical ketosis is a fresh cow disorder that is costly in terms of lost milk production and treatment cost. Although treatment and prevention strategies are available, prevention requires targeting animals that are likely to develop the disease. Whole-herd genotyping is becoming more common with commercial dairies, and identification of markers for ketosis predisposition would provide a valuable tool to producers. The objective of this study was to identify single nucleotide polymorphisms (SNP) that are associated with subclinical ketosis in Jersey cattle. Ketotic cows were identified by cowside test using the Precision Xtra meter. Blood and hair samples were collected from 54 Jerseys (ketotic and healthy herdmates on the same day) with < 30 d in milk on New England dairy farms. Mean parity of cows was 2.8, with no difference ($P >$ 0.05) between healthy and ketotic cows; no difference ($P >$ 0.05) also was found for milk yield, 305-d mature-equivalent milk yield (ME_{305}), or ME_{305} from the previous parity. Blood serum was analyzed for concentration of nonesterified fatty acid (NEFA) and β-hydroxybutyrate (BHBA). Hair samples were submitted to the American Jersey Cattle Association for genotyping with the BovineSNP50 BeadChip. Concentrations of NEFA and BHBA were analyzed using the SAS 9.2 PROC MIXED; differences in SNP frequency by ketosis status (healthy or ketotic) was analyzed using the $\chi 2$ test from the SAS 9.2 FREQ procedure. As expected, BHBA concentrations were greater ($P \leq 0.05$) for ketotic cows compared with healthy herdmates (1.63 vs. 0.91 ± 0.17 mmol/L). For NEFA, concentrations tended to be greater ($P \leq 0.01$) in ketotic cows compared with healthy cows (0.45 vs. 0.33 ± 0.05 mmol/L). Of the 54,609 SNP analyzed for each genotype, 1685 were different ($P \leq 0.05$) and 1862 tended to differ ($0.05 < P \leq 0.1$) between ketotic and healthy cows. These data suggest that genotypes from the BovineSNP50 BeadChip could be useful in predicting predisposition for ketosis in Jerseys, but examination of a larger data set is necessary to validate the predictive ability of the identified SNP.

Key Words: ketosis, Jersey, SNP

0946 (T044) Multi-trait, multi-breed conception rate evaluations. P. M. VanRaden[1], J. R. Wright*[1], C. Sun[2], J. L. Hutchison[1], and M. E. Tooker[1], *[1]Animal Improvement Programs Laboratory, USDA-ARS, Beltsville, MD, [2]National Association of Animal Breeders, Columbia, MO.*

Heifer and cow conception rates (HCR and CCR) were evaluated with multi-trait, multi-breed models including crossbred cows instead of the previous single-trait, single-breed models. Fertility traits benefit from multi-trait processing because of high genetic correlations and many missing observations, with 4 million HCR and 14 million CCR lactation records stored since 2003 vs. 66 million daughter pregnancy rate (DPR) records since 1960. Conception rates were previously modeled using multiple binary success records per parity (such as no, no, yes) that are now pre-adjusted for environmental effects and combined into lactation records for simpler multi-trait analysis with the continuous trait DPR. Genetic correlation estimates were 0.45 for HCR with CCR, 0.86 for CCR with DPR, and 0.36 for HCR with DPR. Inbreeding depression per 1% inbreeding was -0.21 for HCR, -0.10 for CCR, and -0.13 for DPR. Heterosis was 1.3 for HCR, 3.2 for CCR, and 1.4 for DPR. Crossbred cows get the combined effects of heterosis and no inbreeding compared to purebreds that may average 6%. Genetic differences among breeds were fairly consistent with phenotypic differences. Holsteins had the highest phenotypic and genetic averages for HCR, while Jerseys were highest for CCR. Evaluations from the new and previous models were correlated by > 0.95 for both HCR and CCR for recent Holstein bulls with > 50% reliability, but were less correlated in other breeds because of additional crossbred daughters and contemporaries. For Holstein sires with > 90% reliability, correlations between single-breed and multi-breed evaluations were 0.986 for HCR and 0.992 for CCR, indicating little change in rank when adding the other breeds. Genetic trend for CCR was more negative with multi-trait processing because of the correlation with DPR. Genetic trends were validated using Interbull tests 1 and 3. The genetic correlations with other countries estimated by Interbull changed little for Holsteins, averaging 0.02 higher for HCR and 0.02 lower for CCR, but were more variable for other breeds. The new model implemented in December 2013 combines data from all breeds and uses DPR as a correlated trait to improve HCR and CCR evaluations.

Key Words: conception, evaluation, multi-trait

0947 (T045) Genome-wide genotyping-by-sequencing (GBS) and association analysis of saturated and monounsaturated fatty acids in bovine milk identifies novel markers in Canadian Holstein cows. E. M. Ibeagha-Awemu[*1], S. O. Peters[2], I. G. Imumorin[3], and X. Zhao[4], *[1]Agriculture and Agri-Food Canada, Sherbrooke, QC, Canada, [2]Berry College, Mount Berry, GA, [3]Cornell University, Ithaca, NY, [4]McGill University, Ste. Ann De Bell, PQ, Canada.*

The effect of bovine milk fatty acids (FA) on human development and heath has fueled concerted efforts towards exploitation of existing heritable variation for genetic improvement. Consequently, genomic regions as well as single markers associated with milk fat traits have been identified in many cattle breeds around the world. Since information on population specific markers of milk FA traits in Canadian Holstein cows is limited, we used the high throughput genotyping-by-sequencing (GBS) SNP mining method and association analysis to determine population specific markers associated with milk saturated FAs (SFAs) and monounsaturated FAs (MUFAs). Fatty acid profiles of 1200 cows from seven herds in Quebec were determined by gas chromatography and SNPs were genotyped by GBS method. Genome wide association analysis (GWAS) with 99,814 SNPs (> 70% call rates, accuracy of imputation score > 50% and MAF > 0.01) out of 515,820 SNPS was accomplished with the single-locus mixed linear model procedure (EMMA) implemented in Golden Helix SNP and Variation Suite v8.0 software (www.goldenhelix.com). Genome wide significance (BH *P*-value < 0.05, range 3.86E-05 to 0.049) was detected between 7 SFAs (C4:0, C6:0, C8:0, C13:0, C14:0, C23:0, and C24:0) and several SNPs located in intergenic, coding, splicing and 3' untranslated (UTR) regions. In particular, 15 significant associations for C13:0 are coding variants located in 15 genes, and 10 for C24:0 are also coding variants with many non-synonymous SNPs. One 3'UTR variant within CHFR (E3 ubiquitin-protein ligase) gene significantly associated with C6:0 and C8:0. Furthermore, genome wide significant (BH *P*-value < 0.05) associations were recorded between several SNPs and two individual MUFAs (oleic acid [C18:1n9c] and trans vaccenic acid [C18:1n11t]), total MUFAs and total SFAs. In particular, a synonymous variant (S25_37873086) within ACHE (acetylcholinesterase) gene significantly influenced both total MUFAs and total SFAs. Minor allele frequencies for all reported significant associations are $\geq$ 0.02. Since most of these associations are being reported for FAs for the first time with only six of the genes known to play a role in lipogenesis, our study has uncovered potential novel SNPs and genes that can be used in improvement of milk SFA and MUFA contents through breeding to ensure quality products for human consumption. Moreover, our results also further confirm the use of the GBS technique for identification of population-based unique SNPs for GWAS and for improvement breeding in dairy cattle.

Key Words: genome wide genotyping-by-sequencing, genome wide association study, saturated and monounsaturated fatty acids

0948 (T046) Peroxisome proliferator-activated receptor γ isoforms alter lipogenic gene networks in goat mammary epithelial cells. H. Shi[1], J. Luo[*2], D. Yao[1], and J. Zhu[1], *[1]Northwest A&F University, Yangling, China, [2]Northwest A & F University, Yangling, China.*

Lactation is a highly demanding lipid synthesis and transport process that is crucial for the development of newborn mammals. Peroxisome proliferator-activated receptor-γ (*P*PARG) was reported to promote adipogenesis and lipogenesis in adipose tissue, its role in the lactating mammary gland is less clear. PPARG is present in two isoforms generated by alternative splicing, PPARG1 and PPARG2. Their roles in ruminant lactation mammary gland have been poorly distinguished. To determine which of these isoforms is more closely associated with the regulation of the lipogenic pathways, their distributions were analyzed and key genes in the mammary lipid network were detected by quantitative PCR (qPCR) after overexpression of the two isoforms in goat mammary epithelial cells (GMEC). Various tissues of goats were collected to assay mRNA expression of PPARG isoforms. The adenovirus pAd-PPARG1 and pAd-PPARG2 were generated. The adenovirus (Ad-GFP) was used as a positive control. GMEC at about 80% conñuence were transfected with adenovirus at the same MOI and cultured in the DMEM/F-12, at 37°C in 5% CO_2. Transfected GMEC were cultured with ROSI or DMSO at 50 μM after 24 h of the initial culture and then harvested at 48 h (24 h later) for RNA extraction. Distribution analysis indicated that expression of PPARG2 was markedly greater in adipose than mammary gland and PPARG1 is the mainly isoform in goat mammary tissue. Both PPARG isoforms could significantly upregulate the mRNA expression of NR1H3, INSIG1, PLIN2, CD36, SCD, AGPAT6, DGAT1 under the treatment with rosiglitazone (ROSI). They had no significant effect on SCAP, PNPLA2 and PLIN3 in absence of ROSI. PPARG1 increased the SREBF1, FASN and ACACA while PPARG2 downregulated these genes expression. In conclusion, the data suggest that both PPARG1 and PPARG2 could largely affect fatty acid metabolism when stimulated. However, de novo lipogenesis in mammary cells appear more closely related to PPARG1 activation, with this nuclear receptor acting through its control of SREBF1 and to some extent NR1H3.

Key Words: PPARG, lipogenesis, mammary gland epithelial cells, goat

0949 (T047) Association between polymorphisms in the IGF-I, GHR and STAT5A genes and the interval from calving to conception and milk production in Holstein cows. L. Hax*, A. Schneider, C. Bespalhok Jacometo, P. Mattei, T. da Silva, G. Farina, and M. Nunes Corrêa, *Federal University of Pelotas, Pelotas, Brazil.*

The aim of this study was to investigate the association of polymorphisms in the insulin-like growth factor 1 (IGF-I), growth hormone receptor (GHR) and signal transducer and activator of transcription 5A (STAT5A) genes with the calving to conception interval (CCI) and milk production of Holstein cows. In this study 308 Holstein cows from a commercial herd in southern Brazil were used. The study evaluated cows between the first and sixth lactation with a CCI no longer than 250 d. The animals were reared in a semi-extensive system being milked twice a day. The CCI and milk production data were obtained from the farm management software. Blood samples were collected for DNA extraction. Genotypes were verified by polymerase chain reaction (*P*CR) using the following primers: IGF-I (TTAAATAATTGGGTTGGAAGACTGC and ACCTTACCCGTATGAAAGGAATATACGT); GHR (TGCGTGCACAGCAGCTCAACC and AGCAACCCCACTGCTGGGCAT); STAT5A (GAGAAGTTGGCGGAGATTATC and CCGTGTGTCCTCATCACCTG). The amplified fragments of IGF-I, GHR and STAT5A were digested with 3U of *Sna*BI, *Alu*I and *Bst*EII at 37°C for 3 h, respectively. The resulting fragments were subjected to agarose gel electrophoresis for subsequent UV visualization. Statistical analyzes were performed using the GLM procedure. A value of $P < 0.05$ was considered significant. The average milk production adjusted to 305 d of lactation and CCI were 5652 ± 1170L and 117 ± 57.8 d, respectively. There was no association between milk production and CCI with the genotypes identified for each gene. The presence of none, one or two alleles had no linear or quadratic association with the evaluated traits for IGF-I, GHR and STAT5A. There was no interaction between the genotypes of each studied gene for milk production and CCI. The low level of milk production suggests that these animals were not subjected to a major metabolic challenge. The somatotropic axis acts regulating metabolism and the reproductive system, and its balance is a result of the metabolic condition of the animal. Thus, it is likely that the function of the studied genes was not impaired in this low challenge condition, therefore without any major changes in the GH/IGF-I axis or folliculogenesis. Under such conditions, the effect of the polymorphisms studied were not observed, as previously shown in studies using high-producing dairy cows. In conclusion, the GHR *Alu*I, IGF-I *Sna*BI and *Bst*EII STAT5A polymorphisms are not good molecular markers for selection of dairy cows for milk production and CCI in semi-extensive production systems.

Key Words: genetic selection, molecular markers, reproduction

0950 (T048) A polymorphism within the prolactin gene is associated with milk production in Holstein dairy cows managed under summer heat stress conditions in northwest México. P. Luna*, *Instituto Tecnologico de Sonora, Ciudad Obregon, México.*

Holstein dairy cows managed in northwest México are exposed during summer to extreme ambient temperature and humidity that lead to heat stress. The physiological response from cows exposed to such weather conditions results from the perturbation of a gene network related to heat stress homeostasis. The prolactin signaling pathway has been proposed as an important mediator of this response in cattle. The objective of this study was to assess the association between a SNP polymorphism (rs110494133-A/G within intron 1) in the prolactin gene (PRL) and performance traits such as average and total milk production in Holstein cattle. The SNP allele frequency was 70% for A and 30% for G. No deviations from Hardy-Weinberg equilibrium ($X^2 = 1.00$, $P > 0.38$) were observed in the cow population. DNA was extracted from blood spotted on FTA cards from 118 cows, and genotyped using the sequenom mass array platform. Genotype to phenotype association analyses were conducted using a mixed effects model that included phenotype as the response variable, genotype as a fixed term, sire as a random term, and days in milk as a covariate. Mean values for milk production, serum prolactin, and rectal temperature were 22.1 ± 0.5 kg/d, 32.2 ± 1.2 ng/mL, and 38.3 ± 0.1°C, respectively. In a previous study, we reported that reduced serum levels of prolactin and increased rectal temperature were associated with lower milk performance, which was remedied by spray cooling the cows. In this study, the genotype term was as a significant ($P < 0.05$) source of variation in predicting milk production. Least square means among genotypes AA, AG, and GG were 24.6 ± 1.3, 21.2 ± 1.5, and 21.2 ± 1.7 kg/d for average milk production, and 7403 ± 13.8, 7397 ± 10.5, and 6241 ± 61.8 kg for total milk production, respectively. The A allele from the SNP in the PRL gene was the most favorable ($P < 0.05$) and increased average milk production (1.2 ± 0.3 kg/d) and total milk production (325 ± 63.5 kg). When the mixed model included serum prolactin or rectal temperature as the response variable instead of milk traits, the genotype term also resulted as a significant predictor ($P < 0.05$). We conclude that a SNP within the prolactin gene appears to be a predictor of lactation performance in Holstein dairy cows managed under summer heat stress conditions common to northwest México.

Key Words: heat-stress, prolactin, polymorphism.

BREEDING AND GENETICS: APPLICATIONS AND METHODS IN ANIMAL BREEDING—POULTRY

0951 (T049) Regulation of microRNAs in necrotic enteritis infected two genetically disparate chicken lines. Y. H. Hong*, *Chung-Ang University, Anseong-si, South Korea.*

Necrotic enteritis (NE) is an acute clostridial disease causing weight depression, loss of appetite, and sudden death. MicroRNAs (miRNA) play a critical role in post-transcriptional regulation by influencing the 3′-UTR of target genes. Using two inbred White Leghorn chicken lines, line 6.3 and line 7.2 showing Marek's disease-resistant and-susceptible phenotypes, respectively, we used small RNA high-throughput sequencing to investigate whether miRNAs are differently expressed in these two chicken lines after inducing necrotic enteritis (NE). The 12 miRNAs, selected from the most downregulated or up-regulated miRNAs following NE induction, were confirmed by their expressions in real-time PCR. Among these miRNAs, miR-215, miR-217, miR-194, miR-200a, miR-200b, miR-216a, miR-216b, and miR-429 were highly expressed in the intestine derived from line 7.2, whereas, miR-1782 and miR-499 were downregulated ($P < 0.05$). In spleen, miR-34b and miR-1684 were the most up-regulated miRNAs in line 6.3 ($P < 0.05$). Notably, five out of six target genes, CXCR5, BCL2, GJA1, TCF12, and TAB3 were differentially expressed between line 6.3 and line 7.2 ($P < 0.05$), and showed suppression in the MD-susceptible chicken line. Their expression levels were conversely correlated with those of miRNA obtained from both HTS and quantitative real-time PCR.

These results suggest that some miRNAs are differentially altered in response to NE, and they modulate the expression of their target genes in the two inbred lines. Collectively, high-throughput analysis of intestinal miRNAs from NE-afflicted inbred chickens showing different disease phenotypes led to the identification of host immunity genes regulated by miRNA. Future studies of the function of these miRNAs and their target genes in the host will lead to enhanced understanding of molecular mechanisms controlling host-pathogen interaction in NE.

Key Words: necrotic enteritis, miRNA, chicken

0952 (T050) Changes in variance of top SNP windows over generations under selection for three traits in broiler chicken. B. D. Fragomeni*[1], I. Misztal[1], D. Lourenco[1], I. Aguilar[2], and R. Hawken[3], *[1]University of Georgia, Athens, [2]Instituto Nacional de Investigación Agropecuaria, Las Brujas, Uruguay, [3]Cobb-Vantress Inc., Siloam Springs, AR.*

The purpose of this study was to determine whether the top SNP windows that explain the most variance are stable over multiple generations of selection in a GWAS analysis using single-step GBLUP. Phenotypes were available for five generations of a pure line of broiler chicken for body weight, breast meat, and leg score. Pedigrees included 297,017 animals, of which 294,632 had phenotypic records over five generations. Genotypes of 57,635 SNP were available for 4922 animals. After quality checks, 41,036 SNP and 4866 animals remained in the genomic file. SNP effects were calculated by a GWAS type analysis using single-step GBLUP approach. In each run, the generations were grouped from 1–3, 2–4, 3–5, and 1–5. The evaluation model included sex and contemporary group as fixed effects, animal additive and maternal permanent environmental as random. In GWAS by single-step GBLUP, genomic breeding values (GEBV) are converted to SNP effects. Variances of SNP effects were derived iteratively in three iterations without re-estimation of GEBV. As individual SNP explained very small portion of the total genetic variation, variances were then calculated for windows of 20 SNP and interpreted as the percentage of the total genetic variance. Ten windows for each trait were identified that explained the largest fraction of the variance in any combination of generations. All the top 10 windows explained at least 0.5% (but less than 2%) of the total genetic variance in all the traits. The variance explained by each window varied greatly among the combinations of generations. In several cases, a window identified as top for one combination of generations explained less than 0.1% variance in the remaining combinations. Top windows of SNP variance in the broiler population are unstable and unsuitable for direct selection. Results in this study could be influenced by many generations of intensive selection in broiler chicken and by a small number of genotypes.

Key Words: genomic selection, genome-wide association study, ssGBLUP

0953 (T051) Relationship between laying frequency and egg sizes in quail. O. T. Abanikannda*, O. N. Ottun, and A. O. Leigh, *Lagos State University, Ojo-Lagos, Nigeria.*

The number of eggs laid by hens during a laying cycle is one of the desirable traits in commercial egg production, and the size of eggs produced by hens determine the quality, grade, marketability, and acceptability of eggs by the consumers. Several factors such as breed, age, weight, and management

Table 0953. Mean ± SE of measured variables

Laying Group	N	HenWt (g)	FeedWt (g)	EggWt (g)	EggLt (mm)	EggWd (mm)	EggSSA (mm^2)	EggVol (mm^3)	EggDens
Low	4	166.40 ± 1.51	30.13 ± 0.84^{ab}	10.08 ± 0.11^{a}	30.39 ± 0.19	24.36 ± 0.14	22.40 ± 0.24	10.19 ± 0.16	1.0525 ± 0.0006^{a}
Medium	3	168.99 ± 0.92	27.30 ± 0.72^{b}	9.64 ± 0.11^{b}	29.92 ± 0.16	24.09 ± 0.14	21.81 ± 0.18	9.79 ± 0.12	1.0522 ± 0.0006^{b}

practices have been reported to influence quantity and quality of eggs produced by quail hens. This study investigates the relationship between quantity and quality of eggs as depicted by the frequency of lay and measurements taken on eggs. After an initial stabilization period, a total of 435 eggs were collected from 17 quail hens over a continuous laying period of 34 d. The hens were classified into three nominal groups as Low (17 to 21), medium (22 to 26) and High (26 to 31) depending on the number of days of lay during the study period. Majority (58.82%) of the hens were in the High laying group, while the Medium and Low laying groups accounted for 17.65 and 23.53%, respectively. Consequently, about two-thirds (66.44%) of the eggs studied were from hens in the High laying group. Parameters studied include Hen Weight (HenWt), Feed Consumed (FeedWt), Egg Weight (EggWt), Egg Length (EggLt), Egg Width (EggWd), Shape Index (ShpInd), Egg Surface Area (EggSSA), Egg Volume (EggVol), Egg Density (EggDens), and Surface Area to Volume Ratio (SSAVol). All statistical analyses (Descriptive, Correlation, Regression, and ANOVA where $Y_{ij} = \mu+\alpha_i+e_{ij}$) were done using Minitab 16 software. A one way analysis of variance (ANOVA) on each of the parameter revealed that only three of the parameters (EggWt, FeedWt and EggDens) were significantly ($P < 0.05$) affected by laying group (Table 0953). There was a significantly ($P < 0.001$) moderate correlation ($r = 0.5$) between ChickWt, FeedWt and EggWt and a highly significant ($P < 0.001$) correlation ($r = 0.99$) between EggWt and EggDens. Hens with lower frequency of lay consumed less feed and had higher egg weight, whereas hens in the middle laying group consumed least and had the least egg weight. Small-sized quail hens consumed moderately, laid least eggs laid but had the heaviest eggs.

Key Words: laying frequency, quail, egg weight

0954 (T052) Phenetic classification of six bird species based on the proximate and mineral composition of their eggs.

O. T. Abanikannda*, O. N. Ottun, and A. O. Leigh, *Lagos State University, Ojo-Lagos, Nigeria.*

Classification is a systematic grouping of organisms into categories on the basis of evolutionary or structural relationships between them, based on their biological similarities and differences. Phenetic classification is the quantification and statistical assessment of characters based on overall or observable similarities rather than on phylogenetic or evolutionary relationships, with an orderly arrangement of organisms in hierarchical series. A total of 240 eggs comprising 40 eggs from each of six species species (chicken, duck, guinea fowl, pigeon, quail, and turkey) were sampled. Proximate composition (moisture content, dry matter, total ash, crude protein, crude fat, and carbohydrate) of the eggs along with mineral analyses (calcium, magnesium, manganese, iron, zinc, and cobalt) were conducted using standard laboratory procedures for proximate and mineral assay. All statistical analyses which included descriptive, analysis of variance and multivariate cluster analyses were done with Minitab Statistical software. Specie was a highly significant ($P < 0.001$) source of variation in all variables measured except for crude fat, Mg and Zn, which were not affected ($P > 0.05$) by specie. The complete linkage method, with squared Euclidean distance and three clusters specified as final partition was used on the standardized variables. Three main clusters were identified with duck, turkey, and quail forming a cluster and joining with chicken and guinea fowl as a second cluster, while pigeon was in the third cluster. This clustering is close to the phylogenetic classification in traditional taxonomy of the three classes (anseriforms, galliforms and columbiforms), and provides a good basis for comparative classification of the six different species of birds.

Key Words: taxonomy, phenetic classification, cluster analysis

Table 0954. Clustering of the six species based on proximate and mineral composition analyses

Step	Number of Clusters	Similarity Level	Distance Level	Clusters Joined	New Cluster	Number of Observation in New Cluster
1	5	97.5304	1.5258	4	3	2
2	4	96.1613	2.3717	2	1	2
3	3	82.2077	10.9930	5	1	3
4	2	63.7853	22.3753	3	1	5
5	1	0.0000	61.7852	6	1	6

0955 (T053) Effect of shell thickness on quail chick pip-out at hatching.

O. T. Abanikannda*, A. O. Leigh, and O. N. Ottun, *Lagos State University, Ojo-Lagos, Nigeria.*

Economic losses incurred by farmers when chicks could not pip out at hatching is a major consideration in commercial hatchery operations. The inability of chicks to come out of an egg shell unassisted has its attendant consequences on the survival and livability of quail chicks. Aside from genetic effect, age and nutritional status of the hen, egg shell thickness is also a major factor. This study was conducted to determine

the effect of egg shell thickness on the on the ability of quail chicks to pip out of the shell at hatching. A total of 593 fertile eggs collected from a farm located in Jos, Plateau State, in the Savannah region of Nigeria, were incubated and hatched. The eggs were weighed and linear measures were taken using digital weighing scale and caliper. The measured variables include, egg weight, egg length, egg width, shell thickness, vertical and horizontal circumference, while shape index, egg density, egg volume, egg surface area, and surface area to volume ratio were computed. All statistical analyses were done using JMP statistical software for the descriptive statistics, correlation, model fitting, and logistic regression. After incubation, 570 eggs hatched, and eggs that were not hatched ($n = 23$) were opened up to determine if the chicks fully developed but could not pip out unassisted. The result revealed that there was no statistical difference ($P > 0.05$) in the mean of all variables studied. A binary logistic regression of the shell thickness on hatching status was not statistically significant ($P > 0.05$), indicating that despite the slight numerical difference in shell thickness of the two groups (Hatched, Not Hatched), it was not enough to invoke a statistical significance probably due to unequal subclass numbers in the two groups.

Key Words: hatchability, quail, egg shell

0956 (T054) Weight changes in quail eggs during incubation. O. T. Abanikannda*, O. N. Ottun, and A. O. Leigh, *Lagos State University, Ojo-Lagos, Nigeria.*

Commercially, quails are mostly raised for their meat and eggs. The eggs are tastier, low in calories and are good sources of essential vitamins, minerals and amino acid, thereby making it a preferred egg compared to other poultry eggs. Chick weight at hatch positively impacted on subsequent productivity indices of quails thereby making it a primary index for the future performance traits of the bird. Differences in chick weight at hatch have been largely influenced by the pre-hatch egg weight and weight loss associated with incubation. Chick weight is primarily determined by initial egg weight and is secondarily determined by weight loss during incubation, shell and residue weight, strain, incubation time and conditions, breeder age and chick sex. This study aims at investigating some egg measures and its influence on chick weight at hatch with a view to statistically predict its chick weight. The eggs used in this study were sourced from a semi-intensively managed poultry farm in Jos, Plateau State in the Savannah region of Nigeria. A total of 987 hatching quail eggs were collected and appropriately labeled for identification purposes and set for incubation. Out of the total eggs set, 606 eggs were hatched and were used for the analyses. Egg weight and egg shell weight were measured with a sensitive (0.00 g) digital scale, while egg length and width were measured with a sensitive (0.00 mm) digital Vernier caliper. Other measures included both the vertical and horizontal circumference of the eggs using a flex graduated tape, 14th day incubation weight of egg and chick weight at hatch. Indices such as shape index, egg density, egg surface area, egg volume, and incubation weight difference were computed. With the exception of shell thickness and shape index, all other variables were highly significantly ($P < 0.01$) impacted on chick weight and were used to model. The statistical model for predicting chick weight at hatch using the 11 variables that significantly influenced chick weight at hatch is given by: $Y = \beta_0 + \beta_1X_1 + \beta_2X_2 + \beta_3X_3 + \beta_4X_4 + \beta_5X_5 + \beta_6X_6 + \beta_7X_7 + \beta_8X_8 + \beta_9X_9 + \beta_{10}X_{10} + \beta_{11}X_{11}$. The model accounted for 31% of the variability in chick weight. The study revealed that egg weight, density, volume, and incubation weight loss were the largest influences on chick weight.

Key Words: quail eggs, incubation, chick weight

BREEDING AND GENETICS: APPLICATIONS AND METHODS IN ANIMAL BREEDING—LIVESTOCK I

0957 (W061) Whole genome association analysis for detecting QTLs related to fat and protein production in buffaloes. H. Tonhati*[1], D. F. Cardoso[1], R. R. Aspilcueta Borquis[1], N. A. Hurtado Lugo[2], G. M. de Camargo[1], L. G. Albuquerque[1], D. J. A. Santos[3], D. C. Scalez[1], and M. C. Nakagawa[4], *[1]State University of São Paulo, Faculty of Agriculture and Veterinary Sciences, Jaboticabal, Brazil, [2]Universidade Estadual Paulista "Júlio de Mesquista Filho", Jaboticabal, Brazil, [3]Universidade Estadual Paulista, Jaboticabal, Brazil, [4]State University of São Paulo, Faculty of Agriculture and Veterinary Sciences, Jaboticabal, Brazil.*

Whole genome association studies are important for the livestock industry because they allow incorporation of the QTL detected in genetic evaluations, thus enabling greater selection accuracy and faster genetic progress. Therefore, this study aims at identifying loci associated with fat and protein production in river buffaloes. A total of 452 animals (57 males and 395 females) were genotyped using the 90K panel Axiom Buffalo Genotyping (Affymetrix). For sample quality control, we established the threshold values for: call rate 0.95 and heterozygosity ± 3 standard deviations. For the marker, we adopted call rate > 0.98, MAF > 0.05, HWE up to 10^{-6}, correlation between markers up to 0.998, plus the elimination of coinciding SNPs and with possible errors of physical positioning in relation to the reference map. The number of SNPs left after quality control was 56,716. Statistical analyses were performed using R scripts and the GenABEL software (Aulchenko et al., 2007). The information used in this studied were the de-regressed breeding values to traits production of fat (FY) and protein (PY), according to Garrick et al. (2009). These data were corrected for population substructure using the principal components obtained by multidimensional scaling of genomic similarity matrix, with residuals weighted by $c+(1-r^2)/r^2$. The significance level of 0.05 was corrected for Bonferroni. The five SNPs with the highest P-value (candidate SNPs) were selected for each trait, and through their genomic coordinates (BTAU_4.0 assembly), the annotation of the closest genes was taken out using the NCBI database (http://www.ncbi.nlm.nih.gov). After population structure corrections, the inflation factors (lambda) were estimated as 1.0014 and 1.0078 for FY and protein PY; within the acceptable range. At the significance level corrected by Bonferroni, only two SNPs were deemed significant for FY and PY. The significant SNPs for both traits were present on chromosome 10. Deiodinase type 2 (DIO2) was the closest gene (~150 Kb). This is the main enzyme that converts Thyroxine (T4) to the active Triiodothyronine (T3) (active form). From the prior knowledge that thyroid hormones directly influence lactation, this gene may explain the greater buffalo hardiness during this phase, adapted to feeding conditions poor in protein.

Key Words: milk quality, buffalo, markers

0958 (W062) Evaluation of single nucleotide polymorphism markers on four pig chromosomes for potential associations with halothane sensitivity phenotypes in a population of Yorkshire-Landrace pigs. K. R. Perry*, C. W. Ernst, J. P. Steibel, and R. O. Bates*, Michigan State University, East Lansing.*

We have previously reported that a proportion of pigs homozygous normal for the RYR1 g. 1843 C > T polymorphism were halothane sensitive and had lower post-mortem *Longissimus dorsi* pH. Pigs from this project (n = 363), which were progeny of Landrace sires and Yorkshire-Landrace F1 dams, were subsequently genotyped for 67 SNPs across four chromosomes (SSC6, SSC10, SSC12, and SSC14). These SNPs were located in or near genes responsible for malignant hyperthermia or myopathies in humans (CACNA1S, CPT2, SCN4 and RYR2) that may influence the stress response in pigs, including multiple SNPs within RYR1. The objective of this study was to determine the association of these SNPs with the halothane sensitivity phenotypes recorded in this population. Pigs were evaluated for limb rigidity (RIGID), limb tremors (TREM), and abdominal discoloration (AD) observed after halothane challenge. Halothane sensitivity was assessed after 60 sec exposure to 5% halothane gas in a closed system delivered at 2 L/min. Pigs were considered to be either sensitive (1) to halothane or not sensitive (0) for each trait. Assays were multiplexed and SNP genotypes collected using Sequenom MassArray. Twelve SNPs were discarded from analysis due to low genotyping call rate (< 90%). Twenty-nine of the remaining 55 SNPs were not in Hardy-Weinberg equilibrium ($P < 0.05$). The three halothane response variables were fit to a generalized linear model that included the fixed effects of sex and SNP, and the random effects of replication and litter. False discovery rate (FDR) was used to determine significance. For the 55 SNPs tested for each halothane sensitivity variable, generally there were few SNPs with P-values less than 0.05. Three SNPs for TREMOR, 1 for RIGID and 1 for AD had P-values less than 0.05. The FDR for all SNPs was greater than 0.25 and therefore it was determined that no SNP significantly associated with any of the three halothane response variables. These results indicate that halothane sensitivity in this population is not controlled by variation in these regions of the swine genome, and other genomic

regions should be investigated to determine the genetic control of halothane sensitivity.

Key Words: pig, halothane sensitivity, SNP

0959 (W063) Growth rate of purebred Berkshire pigs housed in hoop buildings in North Carolina.

S. H. Oh*, N. Whitley, F. McElveen, and H. S. Park, *North Carolina A&T State University, Greensboro.*

This study was designed to estimate growth curves of antibiotic free Berkshire purebred breeding stock reared in hoop buildings at the North Carolina Agricultural and Technical State University Farm. The location features a humid subtropical climate with subtropical summer temperatures and mild winters, and an average annual precipitation of approximately 110 cm. Litters were weaned at 4 wk old, and reared within deep-bedded outdoor hoop houses. Six boars and 21 sows were included in the population. Body weights of a total 124 pigs were collected every 4 wk from birth to 20 wk of age, resulting in 1206 total records. Gompertz growth curves were used to estimate parameters, resulting in 3.681 ± 0.369 as W_0, 0.029 ± 0.002 as m, and 0.006 ± 0.001 as D. Overall average daily gain at 20 wk of age was 0.39 ± 0.11 kg and ranged from 0.16 to 0.64 kg. Average daily gains were 0.38 ± 0.11 kg in boars and 0.40 ± 0.12 kg in gilts. These results were lower than the results reported by others, which may be due to different climates in the test populations and/or due to the closed population used in the present study.

Key Words: Berkshire, growth rate, hoop, outdoor

0960 (W064) Use of the canonical discriminant analysis for selecting a panel of informative markers in 21 Italian sheep breeds.

C. Dimauro*[1], M. Cellesi[1], L. Nicoloso[2], P. Crepaldi[2], N. P. P. Macciotta[1], G. Pulina[3], and F. Pilla[4], *[1]Università di Sassari, Italy, [2]Università di Milano, Italy, [3]Dipartimento di Agraria, University of Sassari, Italy, [4]Università del Molise, Campobasso, Italy.*

SNP markers can be useful to assign individuals to their breed. In the present research, a high density SNP chip was exploited to select a panel of markers useful to verify the origin of 462 individuals belonging to 21 Italian sheep breeds. Animals were genotyped using the Illumina's OvineSNP50 BeadChip and were divided into two groups: the training population (TP) of 420 sheep, 20 for each breed, and the validation population (VP) of 42 animals, two for each breed. SNPs with MAF < 0.20 were discarded and, after data editing, 40,856 markers were used, including 4937 monomorphic SNPs for at least one breed. The canonical discriminant analysis (CDA) was exploited to discriminate among breeds. CDA was first applied at chromosome level and markers with canonical coefficients higher than a fixed threshold were retained. The threshold was obtained through a recursive procedure: the CDA was repeatedly applied by increasing, at each run, the value at which a canonical coefficient is discarded. The procedure stopped when the remaining markers were a pool of linearly independent variables. A genome-wide CDA was then developed with only the selected SNPs, and the effective distance among groups was tested by using the Mahalanobis' distance and the corresponding Hotelling's T-square test. The discriminant analysis (DA) technique was then used to assign the VP to the breed of origin. Finally, the minimum number of significantly discriminant markers was obtained. With a canonical coefficient threshold value of 0.31, 155 linearly independent highly discriminant SNPs were retained. These selected markers provided at Hotelling's T-square test significant separation among all breeds ($P < 0.0000$) and the DA correctly assigned 40 out of 42 VP animals. Among the 155 markers, 46 were monomorphic for at least one breed. The selected markers could be used to develop an assay to routinely track monobreed products. Finally the minimum number of markers able to significantly discriminate all breeds was 48. However, by using this small panel of SNPs, the DA was able to correctly assign only 30 out of 42 VP animals.

Key Words: assignment test, SNP selection

0961 (W065) Genomic differences between Rambouillet sheep selected for high and low reproductive rate.

J. M. Thomson* and J. G. Berardinelli, *Montana State University, Bozeman.*

The Rambouillet sheep selection program at Montana State University began in 1968 with the establishment of the high (HL) and low (LL) reproductive rate lines. Sheep within these lines were selected based on the index of "I" = total number of lambs born in a lifetime/(age of ewe– 1). The lines have significantly differentiated phenotypically for, number of lambs born, number of lambs born per ewe exposed and per ewe lambing, and total kg of lamb weaned ($P < 0.01$) Furthermore, systemic progesterone concentrations during the luteal phase of the estrous cycle differ for HL and LL ewes ($P < 0.05$). Previous research in these flocks has shown differences between the lines for lambing rate, litter size and ovulation rate. Objectives of the present study were to: 1) evaluate if there are genomic differences between lines, and, 2) identify quantitative trait loci associated with each line and candidate genes within these loci. A sample set of 50 and 46 HL and LL sheep, respectively, were genotyped using the Ovine 60K SNP chip. The data for the genotypes were analyzed using the Golden Helix commercial software package. Principal component analysis indicated distinct clusters for the two lines of sheep when the first two eigenvectors were plotted, demonstrating that these lines

are, in fact, genetically different. Using an additive correlation association model and a Bonferroni correction, there were 14 markers that differed ($P < 0.01$). These markers are on chromosomes 1, 3, 9, and 24. The candidate genes that appear to differ include CHP2, ACOT11, NOS1AP, and EGFR. Further analyses and additional samples from each line are needed to better map the differences between the lines. In conclusion it appears that long-term selection for reproductive, a trait known to have low heritability, can be successful in generating animals, at least in sheep that are phenotypically and genetically different.

Key Words: genetic selection, genomics, physiology, reproduction

BREEDING AND GENETICS: MOLECULAR BIOLOGY AND GENOMICS

0962 (W066) Associations of the NCAPG I442M and GDF8 Q204X loci on feed efficiency at the onset of puberty in a beef x dairy cattle resource population. C. Kühn*, P. Widmann, R. Weikard, and E. Albrecht, *Leibniz Institute for Farm Animal Biology, Dummerstorf, Germany.*

Recent studies highlighted the NCAPG/LCORL region, as well as the GDF8 gene encoding myostatin, being associated with genetic modulation of growth in several mammalian species. Specifically, the NCAPG I442M locus had been associated with pre- and postnatal growth in cattle. Furthermore, it had been demonstrated that the highest effect of this genetic variant is expressed at the onset of puberty, which is suggested as the inflection point of the growth curve. Feed costs account for a large proportion of total costs for production in livestock. Thus, including information about feed efficiency in selection decisions would improve the profitability of livestock production. The aim of our study was to evaluate, if the NCAPG I442M or GDF8 Q204X loci had an effect on feed intake and/or feed efficiency at the onset of puberty in cattle. Our study included 176 F_2 bulls from a Charolais x German Holstein resource population generated by multiple ovulation and embryo transfer to virgin heifers that were kept under standardized environmental conditions. After an initial period of 4 mo on a milk replacer diet, the animals were fed ad libitum with concentrate (11.3 MJ ME/kg dry matter, comprising a mixture of barley, molasses chips, soybean extraction meal, molasses, minerals and a vitamin premix) and hay (9.0 MJ ME/kg dry matter). Feed intake was measured daily and body weight was recorded in monthly intervals. For this study, daily dry matter intake, feed conversion ratio and residual feed intake were investigated between d 183 and d 283 of age. Residual feed intake was calculated from daily dry matter intake, metabolic mid weight, and average daily gain. The alleles at the loci NCAPG I442M and GDF8 Q204X were tested for association with daily dry matter intake, feed conversion ratio and residual feed intake. The model fitted year of birth and season as fixed effects, the additive effect of the NCAPG 442M or GDF8 204X allele, and an infinitesimal polygenic animal effect. The analysis revealed that the NCAPG I442M locus was significantly associated with daily feed intake ($P = 0.03$), feed conversion ratio ($P = 0.00012$) and residual feed intake ($P = 0.00001$). In contrast, the GDF8Q204X locus showed only significant effects on feed conversion ratio ($P = 0.04$) and residual feed intake ($P = 0.0005$). Our data indicated that NCAPG I442M is associated with genetic modulation of growth as well as feed efficiency in cattle

Key Words: feed efficiency, cattle, NCAPG

0963 (W067) Association of DNA methylation levels with tissue-specific expression of adipogenic and lipogenic genes in Longissimus dorsi muscle of Korean cattle. M. Baik*[1], T. T. T. Vu[2], M. Y. Piao[1], and H. J. Kang[1], *[1]Dep. of Agricultural Biotechnology, College of Agriculture and Life Sciences, Seoul National University, South Korea, [2]Chonnam National University, Gwangju, South Korea.*

The epigenetic factor such as DNA methylation status may regulate adipogenesis and lipogenesis, affecting intramuscular fat (IMF) deposition of *longissimus dorsi* muscle (LM) in beef cattle. In steers, the LM consists mainly of muscle tissue. However, the LM in Korean cattle steers also contains IMF. We compared the gene expression levels between the IMF and muscle portions of the LM steers after separation of the tissues. Real-time PCR analysis showed that mRNA levels of both adipogenic peroxisome proliferator-activated receptor γ isoform 1 (*P*PARγ1) and lipogenic fatty acid binding protein 4 (FABP4) were higher ($P < 0.01$) in the IMF portion than in the muscle portion of the LM. DNA methylation at specific sites within regulatory regions of gene is known to regulate transcription. We determined DNA methylation levels of regulatory regions of the PPAR γ1 and FABP4 genes by pyrosequencing of genomic DNA isolated from the IMF and muscle portions of the LM. DNA methylation levels of two CpG sites out of three from regulatory region (+144 ~ +225) of PPARγ1 gene were lower ($P < 0.05$) in the IMF portion than in muscle portion of the LM. DNA methylation levels of all five CpG sites from regulatory regions (−9664 ~ −9469) of FABP4 gene were also lower ($P < 0.001$) in IMF portion than in the muscle portion. Thus, mRNA levels of both PPARγ1 and FABP4 genes were inversely correlated with DNA methylation levels of regulatory regions of CpG sites of the corresponding gene. In conclusion, our findings suggest that DNA methylation status regulates tissue-specific expression of adipogenic and lipogenic gene expression in IMF and muscle portions of LM tissues of Korean cattle steers.

Key Words: intramuscular fat, adipogenesis, DNA methylation

0964 (W068) Changes in the cattle cervical transcriptome between estrus and luteal phase. D. Gonzalez-Peña Fundora*, P. Cardoso, M. B. Wheeler, and S. L. Rodriguez Zas, *University of Illinois at Urbana-Champaign.*

During the periestrous phase, the cow cervix undergoes changes associated with hormonal phases that affect the secretions. The cervical mucus fluctuates from fluid and abundant, allowing the sperm transport at estrus, to dense and thick, creating a barrier that minimize pathogen colonization and infection during pregnancy or luteal phase. The corresponding changes in the transcriptome have not be fully characterized.

The objective of this study was to identify the genes that are differentially expressed between the estrus (n = 4) and luteal (7 d postestrus, n = 5) phases in the cervical tissue of synchronized beef heifers. An RNA-Seq platform (Illumina Genome Analyzer II) was used to identify and quantify the transcripts. Single-end reads were mapped to the *Bos taurus* reference genome (Baylor Btau_4.6.1/bos Tau7). In total, 14,419 transcripts from 13,822 genes were tested and 1163 transcripts from 1150 genes were differentially expressed between the luteal and estrus phases (False Discovery Rate adjusted, $P <$ 0.05). Among these, angiotensinogen (AGT) and potassium voltage-gated channel, subfamily F, member 1 (KCNF1) were overexpressed, while cartilage oligomeric matrix protein (COMP) and chloride channel accessory 1 (CLCA1) were under-expressed in the luteal relative to the estrus phase. These results are consistent with known gene functions. AGT produces the enzyme angiotensin II that has been associated with the corpus luteum. KCNF1 regulates the epithelial electrolyte transport and COMP plays a role in cell proliferation, apoptosis, and regulation of cell movement and attachment. Also, the activity of CLCA1 decreases during the luteal phase when mucus thickens. Functional analysis of the differentially expressed genes using DAVID identified six category clusters (enrichment score > 3 equivalent to average category $P <$ 0.001). These categories included cartilage development and condensation, inflammatory responses, defense responses, and sterol-cholesterol biosynthetic. These functional categories suggest that changes during the estrus cycle are associated with changes in molecular pathways that in turn may affect the morphology, function and penetrability of the cervix.

Key Words: RNA-seq, cervix, cow

0965 (W069) Physical and chemical and fatty acid profile in the steers beef with different genetic predominance fed with diets containing substitutions levels of corn by pearl millet.

R. M. D. Silva[*1,2,3], J. T. Pádua[2], J. J. R. Fernandes[2], R. Z. Taveira[1], R. L. Missio[4], P. S. Pacheco[5], D. A. Fausto[6], and J. Restle[2], *[1]Universidade Estadual de Goiás, São Luis de Montes Belos, Brazil, [2]Universidade Federal de Goiás, Goiânia, Brazil, [3]FAPEG, Goiânia, Goiás, Brazil, [4]Universidade Tecnológica Federal do Paraná, Pato Branco, Brazil, [5]Universidade Federal de Santa Maria, Rio Grande do Sul, Brazil, [6]ESALQ/USP, Piracicaba, São Paulo, Brazil.*

This study aimed to evaluate the steers crossbred meat fatty acid profile with European (E) or Zebu (Z) genotypic predominance fed with high concentrated diets (80%) containing levels of ground millet grain in replacement of ground corn grain (0, 33, 66, and 100%). Twenty-four steers of each genetic predominance were feedlot during 96 d and slaughtered at 24 mo of age. The experimental design was completely randomized design with treatments in a 4x2 factorial arrangement using six replicates. The initial pH (6.68) and final carcass pH values (5.9), the final carcass temperature (9.72°C), the fluid loss during thawing (9.7%) and cooking (26.6%), color (3.7 points), texture (3.1 points), marbling (4.5 points), the shear strength of the muscle fibers (8.1 kgf) and moisture (72.9%), crude protein (23.0%), and ether extract content (1.5%) of the meat were not affected by the substitution of corn grain by millet grain ($P >$ 0.05). Meat characteristics were not influenced by genetic predominance, except the marbling, which was higher (4.99 vs. 3.95 points) in European animals. The final pH was correlated with thawing liquid loss (r = -0.36) and meat color (r = -0.62). The replacement of corn grain by millet grain in diet did not affect the steers meat quality ($P >$ 0.05). Increasing the proportion of millet in the diet it linearly increased the arachidic (C20:0), heneicosanoic (C21:0), α linolenic (C18:3 n-3), and di-homo γ linolenic (C20:3 n-6) fatty acids. European bulls meat showed less content of myristic (C14:0), heneicosanoic (C21:0), and γ linolenic (C18:3 n-6) fatty acids. The total concentration of saturated (45.2%), monounsaturated (41.2%), and polyunsaturated (8.7%) fatty acids and monounsaturated/saturated (1.09) and polyunsaturated/saturated (0.18) relationship were not affected by the factors studied. Zebu cattle fed high concentrate produce meat with higher levels of hypercholesterolemic fatty acids that European cattle. The millet grain precentage increase in the diet of European and Zebu crossbred steers improves the ratio between *n-6*/*n-3* fatty acids (0% = 13.90, 33% = 13.79, 66% = 11.67, 100% = 10.58) (P = 0.042). These results indicate that the millet grain used in a complementary way for other strategies, such as providing protected polyunsaturated fatty acids (PUFA) ruminal fermentation, may allow getting a closer relationships ω6/ω3 to the recommended.

Key Words: intramuscular fat, meat tenderness, nutition

0966 (W070) Major loci associated with growth traits on BTA14 in Hanwoo (Korean cattle).

S. W. Lee[*1], K. Y. Chung[1], U. H. Kim[1], B. W. Choi[2], D. Lim[2], Y. M. Cho[2], C. G. Dang[1], H. C. Kim[1], S. H. Yeon[1], H. S. Kang[1], and C. Gondro[3], *[1]Hanwoo Experiment Station, NIAS, RDA, Pyeongchang, South Korea, [2]Animal Genomics & Bioinformatics Division, NIAS, RDA, Suwon, South Korea, [3]University of New England, Armidale, Australia.*

Genome-wide single marker regression using Bovine 50K BeadChip was performed on growth traits from 1012 Hanwoo steers in Hanwoo (Korean cattle). SNPs were excluded from the analysis if they failed in over 5% of the genotypes, had median GC scores below 0.6, had GC scores under 0.6 in less than 90% of the samples, deviated in heterozygosity more than three standard deviations from the other SNPs and were out of Hardy-Weinberg equilibrium for a cutoff p-value of $1E^{-5}$. Unmapped and SNPs on sex chromosomes were also

excluded. A total of 32,696 SNPs were used in this analysis. To test an association between SNP and QTL, single marker regression analysis was implemented in this study. SNP was assumed to be in LD with QTL in close proximity and the effect evaluated was additive effect (QTL allele substitution effect). The Bonferroni-corrected genome wide significant association ($P < 1.5 \times 10^{-6}$) was applied to detect significant SNPs for the GWAS. The GWAS identified one major QTL for body weight at 6, 12, 18, and 23 mo ranging 23Mb to 25Mb on BTA14. The most significant SNP was Hapmap32241-BTC-054753 (24Mb, $P = 1.8 \times 10^{-6}$) for BW6, Hapmap27934-BTC-065223 (25Mb, $P = 1.2 \times 10^{-10}$) for BW12, BW18 and BW23 in Hanwoo. The most significant SNPs accounted for 8 to 10% of additive genetic variance, which is quite large proportion against total additive genetic variance. The Hapmap27934-BTC-065223 has 12.97 kg of allele substitution effect in body weight at 12 mo (BW12). The results revealed that growth traits was affected by major QTL with large effect and many other SNP with small effects with the normal distribution.

Key Words: GWAS, major loci, BTA14

0967 (W071) SNP located on three candidate genes influencing growth, performance and carcass traits in a population of steers sired by Braunvieh, Charolais and Simmental bulls. M. D. Garcia*, S. Mizell, and T. Page, *Louisiana State University, Baton Rouge,.*

The objective of the current study was to evaluate the association of single nucleotide polymorphisms (SNP) on three candidate genes for growth, performance, carcass traits in 39 steers sired by Braunvieh, Charolais, and Simmental bulls. Single nucleotide polymorphisms from three candidate genes including the Thyroglobulin gene (TG), the Adiponectin (ADPOQ) gene, and the Insulin-like growth factor 1 (IGF-1) gene were utilized for association analyses. Single nucleotide polymorphisms were selected utilizing SNP that were evenly distributed and represented the total length of the candidate gene. Of the 67 SNP genotyped, 20 were chosen for TG, 20 for ADPOQ, and 27 for IGF-1. Linkage disequilibrium (LD) was not evaluated in the current study due to the small population size; however, LD will be calculated as the genotyped population becomes larger in future studies. The growth traits that were evaluated included, birth weight (BW), hip height (HH), and weaning weight (WW). Carcass quality and composition traits included marbling score (MS), back fat thickness (BF), ribeye area (REA), hot carcass weight (HCW), and yield grade (YG). The PROC MIXED of SAS was utilized to evaluate associations of the 67 SNPs and measured traits. Sire breed and SNP genotype were fit in the model as fixed effects with performance and carcass traits fit as random effects. Associations between traits and SNPs were reported as significant if $P < 0.05$. Multiple SNP from all three candidate genes were identified as being significantly associated ($P < 0.05$) all traits evaluated in the current study. Association analyses for growth traits revealed seven SNP significantly associated with BW (rs109830314, rs383724494 rs378724414, rs381911082, rs383535987, rs384076273, rs109327701), five with HH (rs110553649, rs132813094, rs210258853, rs109327701, rs137651874), 10 with WW (rs109182502, rs110616947, rs377997897, rs379996188, rs380627374, rs378724414, rs109327701, rs136982429, rs137140434, rs137726884), 10 with BF (rs110501231, rs110616947, rs378567477, rs382644882, rs210258853, rs137140434, rs137374423, rs137601357, rs137662301, rs137726884). Association analyses for carcass quality and composition traits revealed two SNP significantly associated with HCW (rs110501231, rs378567477) four with MS (rs378567477, rs378900777, rs383535987, rs137104571), two with REA (rs109830314, rs137651874), and five with YG (rs379467464, rs382252585, rs386026054, rs378724414, rs137601357). Furthermore, a total of eight SNPs (rs109830314, rs110501231, rs110616947, rs378567477, rs378724414, rs137140434, rs137651874, and rs137726884) representing all three candidate genes were significantly associated with growth, performance and carcass quality and composition traits.

0968 (W072) Single nucleotide polymorphisms in the XKR4 and DRD2 genes influence adjusted birth and 205-d weights of calves grazing endophyte-infected tall fescue. *K. M. Ely*[*1], C. J. Kojima[1], A. M. Saxton[1], and R. L. Kallenbach[2], [1]University of Tennessee, Knoxville, [2]University of Missouri, Columbia.*

Tall fescue (*L. arundinaceum Schreb*.) is the most prevalent forage in the Southeastern United States due to the presence of the endophytic fungus *N. coenophialum*. The fungus enhances the persistence of tall fescue, but decreases the productivity of cow-calf herds grazing it. Single nucleotide polymorphisms in the XK, Kell blood group complex subunit-related family, member 4 (XKR4) and Dopamine Receptor D2 (DRD2) genes both yield the genotypes AA, AG, and GG. The A allele of both XKR4 and DRD2 has shown to increase serum prolactin concentrations in Tennessee beef cattle herds grazing endophyte-infected tall fescue. We evaluated the relationship between genotypes of dam and calf and adjusted 205-d weight (A205) and adjusted birth weight (ABW) in a well-managed fall-calving beef herd in Missouri. The ANOVA model included XKR4 and DRD2 genotype (SAS 9.3, Cary, NC). Genotype and allele frequencies for XKR4 were AA = 0.67, AG = 0.30, GG = 0.04, A = 0.82 and G = 0.18 for the dam; AA = 0.64, AG = 0.34, GG = 0.03, A = 0.81 and G = 0.19 for the calf. Since the G allele was sparsely represented in the

population only AG and AA animals were used for the XKR4 analysis. Genotype and allele frequencies for DRD2 were AA = 0.23, AG = 0.46, GG = 0.31, A = 0.46 and G = 0.54 for the dam; AA = 0.25, AG = 0.50, GG = 0.25, A = 0.50 and G = 0.50 for the calf. Dam genotype for DRD2 influenced ABW such that calves from AA and GG animals had lower ABW than those from AG animals ($P < 0.0001$). This is similar to previous findings in a larger herd of animals from Missouri. The AA genotype for the dam at XKR4 was associated with higher ABW when compared to AG dams ($P = 0.08$). Calf genotype for XKR4 influenced A205, such that AA animals were heavier than AG ($P = 0.05$). The AA genotype for the calf at XKR4 was associated with higher ABW when compared to AG calves ($P = 0.07$). No association was observed between calf genotype for DRD2 on ABW or A205. Similarly, no association was observed between dam genotype for XKR4 and A205. Fall-calving dams are grazing fescue at its peak infection level while in mid-gestation; having a beneficial allele for ABW is important for healthy calf weights. As fall-born calves are grazing endophyte-infected tall fescue before weaning, calf genotype at these loci may influence A205. Taken together with previous work, these results indicate a potential for their use as genetic markers for increased productivity of beef cattle grazing endophyte-infected tall fescue.

Key Words: XKR4, DRD2, fescue toxicosis

BREEDING AND GENETICS: COMPANION ANIMAL NUTRITION

0969 (T055) Influence of velocity on Weimaraner trotting stride mechanics. L. Carlisle[1], M. C. Nicodemus[*1], and K. Slater[2], *[1]Mississippi State University, Starkville, [2]Banfield Pet Hospital, Houston, TX.*

The large size of the Weimaraner assists in the breed performing the tasks of a sporting dog. However, the size may also make the breed more susceptible to hip dysplasia. Nevertheless, the Weimaraner compared to other large dog breeds demonstrates a lower rate of dysplasia, which may be due to the preferred slower speed of this breed and resulting stride mechanics. Although kinematic research has been done on other large breeds, gait analysis of the Weimaraner is lacking, and thus, the objective of this study was to determine the influence of velocity on the trotting stride mechanics of the Weimaraner. Six American Kennel Club (AKC) registered Weimaraner dogs were led by the same handler at a slow (st velocity: 1.2–1.7 m/s) and fast (ft velocity: 1.9–2.3 m/s) trot on even, natural footing. Strides (n = 10) were selected for each dog for each trot based on soundness and correctness of gait, consistency of speed, and noticeable foot placement and lift-off. Stride variables were determined by frame-by-frame analysis with video frames of foot placement and lift-off documented. Stride variables were given as a % of stride. Means (SD) were determined for stride variables and t tests ($P < 0.05$) were performed between velocities. Both trots were produced with a diagonal footfall sequence and a similar stride duration (st-0.53 ± 0.10 msec, ft-0.47 ± 0.07 msec) and frequency (st-1.94 ± 0.13 str/sec, ft-2.12 ± 0.09 str/sec), alternating between periods of diagonal bipedal support (st-88 ± 2%, ft-75 ± 5%) and suspension (st-12 ± 1%, ft-25 ± 3%) with less than half of the stride cycle of each limb spent in stance (Fore: st-44 ± 4%, ft-38 ± 2%; Hind: st-44 ± 5%, ft-38 ± 4%). Although stride length significantly increased with speed (st-0.90 ± 0.02 m, ft-0.99 ± 0.04 m; $P < 0.05$), the diagonal limbs remained paired on contact (diagonal advanced placement: st-0 ± 0%, ft-0 ± 0%). The use of suspension at all velocities and the dependence of stride lengthening to increase velocity are distinguishable characteristics of the Weimaraner from other large breeds studied including the Labrador Retriever and German Shepherd. Understanding of canine locomotion through the analysis of the stride mechanics as was done in this study will assist in the clinical examination of gait and the assessment of veterinary locomotive rehabilitation.

Key Words: kinematics, trot, Weimaraner

0970 (T056) Effects of dietary resistant starch on the fasted plasma metabolome of healthy adult dogs. A. N. Beloshapka[*1], K. L. Pappan[2], and K. S. Swanson[1], *[1]Dep. of Animal Sciences, University of Illinois, Urbana, [2]Metabolon, Inc., Durham, NC.*

Fermentable carbohydrates alter gut microbial activity and metabolite production, with many entering the bloodstream and consequently impacting host physiology. The effects of feeding fermentable carbohydrates, such as resistant starch (RS), on the canine plasma metabolome have not been well-studied. The objective of this study was to use a high-throughput metabolomics platform to identify differences in the fasted plasma metabolome of dogs fed increasing RS concentrations. Seven dogs (mean age = 5.3 yr; mean BW = 20 kg) were randomly allotted to one of three treatments (0%, 2%, or 4% high-amylose maize cornstarch (HI-MAIZE260) in an incomplete Latin square design. Treatments were formulated to be iso-energetic and consisted of graded amounts of 100% amylopectin cornstarch, RS, and cellulose, and fed as a top dressing on the food each day. All dogs were fed the same amount of a basal diet throughout the study and fresh water was offered ad libitum. Blood samples were collected after an overnight fast via jugular venipuncture on the last day of each treatment period (d 21) and were subjected to liquid/gas chromatography and mass spectrometry. A total of 288 named biochemicals were identified in plasma, but few statistical differences were noted among treatments. Compared to the controls, RS consumption appeared to alter amino acid metabolism, marked by increased ($P < 0.10$) plasma N-acetylglutamine, 3-hydroxy-3-phenylpropionate, and α-hydroxyisovalerate concentrations and decreased ($P < 0.05$) plasma kynurenine and kynurenate concentrations. Compared to controls, RS consumption also appeared to alter fatty acid and bile acid metabolism, marked by increased ($P < 0.05$) plasma 2-hydroxyglutarate concentrations and decreased ($P < 0.05$) plasma stearamide, cholate, and 1-pentadecanoylglycerophosphacholine concentrations. While RS supplementation produced some changes on the canine plasma metabolome, large, consistent changes were not observed.

Key Words: canine, plasma metabolome, resistant starch

0971 (T057) In vitro effect of diets added with fructooligosaccharides and differing in their protein content and digestibility on dog fecal microbiota. G. Biagi*, M. Grandi, and C. Pinna, *Dep. of Veterinary Medical Sciences, University of Bologna, Ozzano Emilia, Italy.*

Feeding dogs with diets containing high amounts of low-digestible protein may negatively affect the animal intestinal ecosystem, increasing the presence of undesired proteolytic

bacteria. On the other hand, the administration of prebiotics can enhance the activity of beneficial bacteria residing in the canine intestine. The objective of the present study was to evaluate in vitro the effect of diets differing in their protein content and digestibility, and containing or not fructo-oligosaccharides (FOS), on canine fecal microbiota. There were six treatments: 1) Low-protein diet (LPHD, 23% CP); 2) High-protein diet (HPHD, 30% CP); 3) High-protein low-digestible diet (HPLD, 30% CP); 4) Diet 1 + 1.5% FOS (LPHD+FOS); 5) Diet 2 + 1.5% FOS (HPHD+FOS); 6) Diet 3 + 1.5% FOS (HPLD+-FOS). After enzymatically digestion, the undigested fraction of the diets was added to a canine fecal suspension and incubated for 24 h in an anaerobic cabinet (five bottles per diet). From each bottle, a sample of fermentation fluid was collected at 6 and 24 h of fermentation for microbial counts (by FISH) and chemical analyses. Data were analyzed by three-way ANOVA, with protein level and digestibility and FOS as the main effects. At 24 h, FOS resulted in lower ammonia (36.4 vs. 40.3 mmol/l; $P < 0.001$) and iso-valeric acid (0.52 vs. 1.44% of total volatile fatty acids (VFA); $P < 0.05$) and higher total VFA concentrations (47.1 vs. 32.9 mmol/l; $P < 0.001$). Conversely, LD diets resulted in lower VFA (33.9 vs. 43.1 mmol/l; $P < 0.001$). The presence of FOS induced a shift in VFA production, reducing acetic acid (57.1 vs. 73.8%; $P < 0.001$) and increasing propionic and *n*-butyric acids proportions (20.9 vs. 16.4% and 21.0 vs. 7.5%, respectively; $P < 0.001$). With regard to biogenic amines, putrescine concentrations were increased at 6 and 24 h of fermentation by LD diets (+21 and 22%, respectively; $P < 0.05$) and FOS (+18 and 24%, respectively; $P < 0.01$). After 24 h of fermentation, HP diets resulted in lower counts of lactobacilli and enterococci (-0.5 and -0.7 log cells/ml, respectively; $P < 0.05$), whereas LD diets tended to increase counts of *C. perfringens* (+ 0.2 log cells/ml; $P = 0.07$). Results from the present study showed that diets rich in low-digestible protein may exert a negative influence on the canine intestinal ecosystem, increasing the presence of proteolytic compounds and reducing counts of beneficial bacteria. Conversely, administration of FOS may improve canine intestinal health, reducing proteolysis and enhancing VFA production.

Key Words: dogs, fructo-oligoccharides, dietary protein

0972 (T058) The modified Atwater equation does not accurately predict diet ME value of premium food in adult cats. K. D. Berendt*[1], A. K. Shoveller[2], M. Guevara[2], and R. T. Zijlstra[1], [1]*University of Alberta, Edmonton, Canada,* [2]*Procter & Gamble Pet Care, Mason, OH.*

The diet ME value of pet foods is commonly predicted using the Atwater equation, because routine ME measurements are not practical or not feasible ethically or financially. As such, AAFCO recommends the use of the modified Atwater equation [ME = 3.5 × CP (%) + 3.5 × N-free extract (NFE, %) + 8.5 × crude fat (%)] to predict metabolizable energy (ME) of dog and cat foods, which is then used to calculate daily feeding allotment. Previously, the modified Atwater equation underestimated the measured ME value of dog diets; hence, we decided to study this equation in cats. Twelve domestic shorthair cats were used in a quadruple 3 × 3 Latin square. Initial BW averaged 4.4 ± 0.8 kg and ranged from 3.0 to 5.7 kg. Three premium cat diets varying in predicted glycemic index (GI) based on ingredient composition and starch content (36.8, 30.7, and 23.6% for high, medium, and low GI, respectively) were fed for 10 d, with feces and urine collected quantitatively for the last 5 d. Diet, feces and urine were analyzed for GE to measure diet ME value. Predicted GI and ME value of the three diets were inversely related. The greater ME value of the low GI diet ($P < 0.001$) was associated with its greater fat content (22.9, 22.2, and 15.7% ether extract for low, medium and high GI diet, respectively) and energy digestibility (95, 95.4, and 92.9% for low, medium and high GI, respectively). The modified Atwater equation underestimated measured diet ME values by 12% (11.9, 10.8, and 13.6% for high, medium, and low GI, respectively). The traditional Atwater equation [ME = 4 × CP (%) + 4 × N-free extract (NFE, %) + 9 × crude fat (%)] did predict diet ME values accurately (underestimation of 2.0, 1.5, and 4.6% for high, medium, and low GI, respectively). In conclusion, the modified Atwater equation did not accurately predict diet ME value of diets fed to adult cats. The traditional Atwater equation should be used for premium cat diets.

Key Words: metabolizable energy, Atwater, cat

0973 (T059) Association of idiopathic epilepsy with a novel locus in the Belgian Shepherd. A. M. Oberbauer*, and J. M. Belanger, *University of California–Davis, Davis.*

Idiopathic epilepsy in the Belgian shepherd dog is complexly inherited. The objective was to identify novel genomic loci associated with the expression of generalized seizures in the Belgian Tervuren and Sheepdog. Dogs were classified as cases if they met specific seizure criteria and controls if they were over 7 yr of age and had no other health disorder. DNA from cases ($n = 35$) and controls ($n = 58$) from dogs predominantly unrelated at the grandparent level, were subjected to a high-density genotyping array consisting of more than 170,000 evenly spaced single nucleotide polymorphisms (SNPs). Association analyses were conducted using the software package PLINK. Based on 100,000 permutations and removal of non-informative markers and markers with low call rate, five chromosomal regions reached genome wide significance: chromosomes 5 ($P < .034$), 7 ($P < .015$), 24 ($P < .0003$), 29 ($P < .020$) and 37 ($P < .05$). Chromosome 7 showed four significant SNPs between 46,094,658 and 49,666,725 bp (CanFam 3.1). A Sequenom iPlex analysis was conducted using 34 dogs representing 17 cases and 17 controls. Sequenom Assay Design Suite was used to multiplex 65 SNPS covering the region between 45.03 and 48.06 MB. Three SNPs demon-

strated genome wide significance in three genes: two were intronic SNPs ($P = 0.00001$ and $P = 0.04548$) and the third was a missense SNP ($P = 0.0061$) in a novel gene. The mutation in the novel gene changes the codon from proline to arginine. For the novel gene, a 344-bp region was targeted for resequencing uncovering a second missense SNP within the novel gene. The genome wide analysisconfirmed the previously characterized locus found on chromosome 37 and revealed a second locus segregating for epilepsy on chromosome 7. The missense mutation in a novel gene validates the model of a multifactorial genetic regulation of idiopathic epilepsy for the Belgian shepherd, while also suggesting the existence of a previously unidentified neurological regulatory gene. Taken together, the data support the application of genetic selection to reduce the prevalence of this debilitating disorder.

Key Words: idiopathic epilepsy, canine, genome wide association

0974 (T060) Amino acid and mineral concentrations of whole grains and grain byproducts used in pet foods. A. N. Beloshapka[*1], P. R. Buff[2], and K. S. Swanson[1], *[1]Dep. of Animal Sciences, University of Illinois, Urbana, [2]Nutro Company, Franklin, TN.*

Whole grains may be valuable components of canine diets, due to the functional ingredients, such as dietary fiber and β-glucans, or the amino acids (AA) and minerals they provide; however, the use of whole grains in pet food has not been thoroughly evaluated. Our objective was to measure the AA and mineral concentrations of various whole grains, processed grains, and grain byproducts that may be incorporated into dog food. Thirty-one grain samples, including: rice samples (brown rice, rice, rice bran, and rice flour); barley samples (barley flake, cut barley, ground pearled barley, malted barley, whole pearled barley, pearled barley flakes, and steamed rolled barley); oat samples (groats, ground oatmeal, ground steamed groats, instant oats, oat bran #1, oat bran #2, oat fiber, oat flour, quick oats, regular rolled oats, steamed rolled oat groats, and steel cut groats); and miscellaneous cereals and pseudocereals (conventional hulled millet, conventional whole millet, conventional quinoa, organic spelt hull pellets, potato flake, sorghum, whole wheat, and whole yellow corn) were analyzed. Total essential (0.65 to 7.51% DMB) and individual AA concentrations were highly variable among ingredients tested: Arginine (0.01 to 1.38% DMB), Histidine (0.02 to 0.47% DMB), Isoleucine (0.07 to 0.62% DMB), Leucine (0.15 to 1.49% DMB), Lysine (0.06–to0.88% DMB), Methionine (0.03 to 0.36% DMB), Phenylalanine (0.08 to 0.77% DMB), Threonine (0.05 to 0.66% DMB), Tryptophan (< 0.04 to 0.20% DMB), and Valine (0.09 to 0.96% DMB). Of the ingredients tested, oat fiber had the lowest concentrations of most essential AA and rice bran had the highest concentrations of most essential AA. Calcium, phosphorus, and magnesium concentrations ranged from 0.0 to 2.22% DMB, 0.04 to 2.03% DMB, and 0.03 to 0.88% DMB, respectively, with rice bran having the highest concentrations of all three minerals. Based on our compositional analysis, whole grains and grain byproducts vary greatly in AA and mineral content. Although these ingredients are commonly used in canine diets, more research is needed to test the effects of feeding whole grains to dogs.

Key Words: whole grains, amino acids, minerals

0975 (T061) Metabolic phenotyping using mass spectrometry-based metabolomics: A cross-sectional pilot study of lean and overweight domestic cats. R. E. Cokeley[1], G. R. Seiler[1], and J. W. McFadden[*1,2], *[1]West Virginia University, Morgantown, [2]Johns Hopkins University, Baltimore, MD.*

Overnutrition and sedentary behavior increases adiposity in domestic cats, a consequence of positive energy balance that can be detrimental to health. Adiposity is a risk factor for feline diabetes mellitus, characterized by insulin resistance. Chromatography and mass spectrometry (MS) technologies in the field termed "Metabolomics" may be a means to identify biomarkers for predicting pre-onset insulin resistance. The objective was to evaluate MS, coupled with gas chromatography (GC) or liquid chromatography (LC), techniques to perform metabolic phenotyping in lean and overweight domestic cats in preparation for a large-scale study aimed at identifying predictive biomarkers for feline insulin resistance. To evaluate methods, lean ($n = 6$; ≤ 4.5 kg) and overweight ($n = 6$; ≥ 6.5 kg), adult (2 to 10 y of age), neutered, client-owned male domestic shorthair cats were enrolled in a cross-sectional pilot study. Cats were not diagnosed with diabetes. Plasma samples were collected by a veterinarian following an overnight fast. For GC/MS, plasma metabolites were methanol extracted, derivatized, and analyzed by a GC tandem MS system. For LC/MS, plasma metabolites were chloroform-methanol extracted and analyzed by high pressure LC coupled to an electrospray ionization source of a triple quadrupole tandem MS system. Normalized data were analyzed using Student's *t* test. For metabolomics data, statistics were performed on the log of the normalized, median-scaled data. To validate analytical methods, total free fatty acids (FA) and glucose were determined by colorimetry. Mean weights and ages for lean and overweight cats were 3.9 ± 0.5 and 7.1 ± 1.0 kg ($P < 0.05$), and 4.2 ± 2.6 and 6.8 ± 2.4 y of age ($P > 0.10$), respectively. Untargeted GC/MS analysis detected 40 metabolites including lactate, urea, glycerol, amino acids, citrate, saccharides, saturated and unsaturated free FA, uric acid, vitamin E, and cholesterol. Overweight cats had a nearly two-fold increase in palmitic acid, stearic acid, and oleic acid ($P < 0.05$), results validated by an 83% increase in total free FA ($P < 0.05$). In overweight cats, glucose levels were increased by 38% (MS; $P < 0.05$) and a similar nonsignificant numerical increase when determined by colorimetry. Cholesterol, vitamin E, and glycerol were elevated in

overweight cats ($P < 0.05$). Targeted LC/MS analysis detected 28 sphingolipids including ceramides, monohexylceramides, and dihexylceramides. Of interest, palmitoyl-linked ceramide level was increased 80% in overweight cats ($P < 0.05$); elevated plasma ceramides are associated with insulin resistance progression in humans. In overweight cats, GC/MS and LC/MS methodologies revealed metabolite phenotypes similar to patterns observed in diabetic humans.

Key Words: feline diabetes mellitus, metabolomics, obesity

0976 (T062) Effects of dietary energy restriction on the hunting behavior and home-range size of free-ranging domestic cats. A. N. DeGrave*, S. K. Carignan, and S. E. Kitts-Morgan, *Berry College, Mount Berry, GA.*

Free-ranging cats pose concern for native small mammals and birds due to their reputation as instinctual predators. Hunting and prey consumption may be altered by food amounts received from humans. This study's objective was to determine the effects of dietary energy restriction on hunting behavior and home-range size of free-ranging cats. Eight free-ranging cats (five female, three male) residing at the Berry College Equine Center were blocked by weight and assigned randomly to receive daily ME requirements for adult cats at maintenance (control; $n = 4$) or 80% of daily ME requirements (restricted; $n = 4$). For 11 mo, cats were individually offered commercial cat food daily with additional colored glitter to identify each cat's feces. Cats were fitted with harnesses and GPS units to construct home ranges. Feline feces were dried at 60°C and analyzed for prey teeth, total hair, and cat vs. non-cat hair. No differences in BW ($P = 0.99$) or DMI ($P = 0.66$) occurred throughout the experiment. Home ranges were constructed using 95% kernel density estimation and analyzed by season. While no differences in home-range size occurred during spring or summer, fall home-range was larger ($P = 0.04$) for control cats (7.35 ha; 95% CI 4.72 to 11.43 ha) compared to restricted cats (3.91 ha; 95% CI 2.67 to 5.73 ha). Likewise, winter home-range was larger ($P = 0.04$) for control cats (6.91 ha; 95% CI 4.71 to 10.12 ha) compared to restricted cats (3.92 ha; 95% CI 2.68 to 5.75 ha). Of 306 fecal samples identified by cat, a similar ($P = 0.83$) percentage of feces from control vs. restricted cats contained hair (92.05% vs. 92.9%). There was a tendency ($P = 0.11$) for total hair weight in control-cat feces (0.55 ± 0.058 g) to be greater than total hair weight in restricted-cat feces (0.42 ± 0.057 g). However, restricted-cat feces had a lower percentage (18.1%; $P = 0.003$) of non-cat hair compared to the percentage (33.1%) of non-cat hair in control-cat feces. The percentage (21.85%) of control-cat feces containing prey bones/teeth was greater ($P < 0.0001$) compared to the percentage (6.45%) of restricted-cat feces containing prey bones/teeth. However, there was no difference ($P = 0.82$) in total bone/teeth weight for control-cat feces (0.061 ± 0.008 g) compared to restricted-cat feces (0.065 ± 0.015 g). These results suggest that cats will not expand home-range or increase prey consumption when energy-restricted. It may be possible that further restriction of energy intake might affect home-range size and hunting of free-ranging cats.

Key Words: cats, hunting, energy

0977 (T063) Differences in the cerebral cortex metabolome of young adult and geriatric dogs. M. R. C. de Godoy*[1], K. L. Pappan[2], and K. S. Swanson[3], *[1]Dep. of Animal Sciences, University of Illinois, Urbana, [2]Metabolon, Inc., Research Triangle Park, NC, [3]Dep. of Veterinary Clinical Medicine, Urbana, IL.*

Aging is responsible for chemical and morphological alterations in the brain (e.g., decreased brain mass, increased ventricular size, demyelination, neuroaxonal degeneration, decreased cholinergic activity, etc.) that lead to cognitive decline and neurodegenerative diseases. The longer lifespan of the canine pet population has increased the prevalence of cognitive dysfunction. A better understanding of the brain aging process would aid in preventing or reversing the progression of cognitive decline and improve the quality of life of geriatric dogs. Therefore, the objective of this experiment was to use untargeted GC-LC-MS to assess the impact of age on the metabolome of the cerebral cortex of dogs. Cerebral cortex samples were collected from 12 geriatric (12-yr-old) and 12 young adult (1-yr-old) beagles and stored at −80°C until GC–MS and LC-MS/MS analyses. A total of 239 named biochemicals were identified, with 101 being altered ($P < 0.05$) geriatric and young adult dogs. Prior transcriptomics analysis of these samples showed that 963 genes were altered due to age, with old dogs having increased expression of genes associated with inflammation, stress response, and calcium homeostasis and decreased expression of genes associated with neuropeptide signaling and synaptic transmission. In the current study, the cerebral cortex of geriatric dogs had a relative deficiency of excitatory amino acids, such as glutamate and γ-aminobutyrate (GABA), compared to young adult dogs. In addition, geriatric dogs had increased concentrations of palmitoylethanolamide (PEA), suggesting greater levels of oxidative stress or inflammation in the brain of these animals. Glutathione metabolism also differed ($P < 0.05$) between geriatric and young adult dogs, with the former having greater concentrations of reduced glutathione. A relative hyperglycemia in the cerebral cortex of geriatric dogs seemed to drive elevations in glycolytic pathway intermediates; lactate and sorbitol which, over long periods of time, could drive undesirable pathological events such as protein glycation and aggregation. Overall, the data suggest that the brains of geriatric dogs have reduced neurotransmitter metabolism and increased inflammation, possibly contributing to the altered neural functional capacity and health status of these animals.

Futures studies should investigate whether a metabolic signature of the aging brain may be detected in the plasma or serum of geriatric dogs. Identification of circulating metabolic biomarkers would allow for more frequent sampling using a non-invasive method and be useful in disease diagnosis and the development of nutritional interventions.

Key Words: age, dog, metabolome

0978 (T064) Use of gelatin as a strengthening agent in dry extruded pet food. A. Simmons*[1], C. G. Aldrich[1], T. Zhou[1], M. Remund[1], T. Putarov[2], S. Alavi[1], E. Maichel[1], and C. K. Jones[1], *[1]Kansas State University, Manhattan, [2]Sao Paulo State University, Sao Jose do Rio Preto, Brazil.*

Recent pet food innovations have increased protein and decreased cereal inclusions in diets, which has diminished product durability and negatively changed texture. Low-bloom gelatin is a pure protein that is used to improve some pelleted feeds. The objective of this project was to determine the effect of low bloom gelatin (Pro-Bind Plus 100) on kibble physical properties. Two experiments were conducted on a Wenger X-20 single screw extruder. In Exp. 1, a total of six total treatments were extruded: 0, 5, 10, or 15% gelatin inclusion at 400 RPM and 15% gelatin inclusion at 300 or 500 RPM. Chicken by-product meal was removed to add gelatin and maintain an iso-starch formulation. In Exp. 2, a total of six treatments were extruded: 0 vs. 10% gelatin inclusion; 300 vs. 500 RPM; and 15 vs. 30% hydration ratio, meaning the ratio of water added in the extruder vs. the preconditioner. Extrudates were analyzed for moisture, expansion ratio, specific length, piece density, hardness (TA-XT2, Stable Micro Systems), and pellet durability index (PDI; Holmen NHP 100, Tekpro). Results were analyzed using the GLIMMIX procedure of SAS. Product hardness showed a good positive correlation with PDI. Hardness and PDI improved with gelatin inclusion ($P < 0.05$; 5.15 vs. 9.35 kg; 64.5 vs. 96.9%). It was surmised that the increase in kibble strength and durability was caused partially by the strengthening effect of gelatin on the solid matrix. Lower product expansion also had an important role in increasing hardness and durability, as radial expansion ratio increased at 10% gelatin inclusion ($P < 0.05$; 4.27 vs. 6.65 mm^2/mm^2) but decreased at 5 and 15% gelatin inclusion ($P < 0.05$; 4.27 vs. 3.31 or 2.40 mm^2/mm^2, respectively). Increase in screw speed from 300 to 400 rpm and decrease in hydration ratio from 30 to 15% (impying greater degree of pre-conditoning) led to a slight increase in expansion ratio, suggesting that altering processing parameters may overcome the negative imapct of gelatin on radial expansion. Additionally, specific length (a measure of longitudinal expansion) increased at 15% gelatin inclusion ($P < 0.05$; 42.11 vs. 48.30 mm/g), and as less of the total water content was added in the extruder ($P < 0.05$; 37.62 mm/g vs. 41.16). These results suggest that gelatin had a binding effect on finished product. This binding may be helpful in high protein formulation, especially those reducing the use of functional cereal grain starches.

Key Words: gelatin, pet food, extrusion

CSAS GRADUATE STUDENT POSTER COMPETITION

0979 (M057) Effect of dietary supplementation with linseed oil on the miRnome profile of the bovine mammary gland. R. Li[*1,2], F. Beaudoin[1], X. Zhao[3], C. Lei[2], and E. M. Ibeagha-Awemu[1], *[1]Agriculture and Agri-Food Canada, Sherbrooke, QC, [2]Northwest A&F University, Xi'an, China, [3]McGill University, Ste Ann De Bell, PQ, Canada.*

Linseed is particularly rich in α-linolenic acid (C18:3n3) and its supplementation in diets induces an increase in milk unsaturated fatty acid content (along with decrease in milk saturated fatty acids) with potential milk fat depression. The specific role of microRNAs (miRNAs), important post-transcriptional regulators of gene expression, in this dietary adaption remains unknown. Using next generation sequencing, the miRnome of the bovine mammary gland in response to dietary supplementation with 5% linseed oil on dry matter bases was studied. Thirteen high-producing Holstein dairy cows in mid-lactation were fed a control ration (total mixed ration of corn and grass silages) for 28 d followed by a treatment period (control diet supplemented with 5% linseed oil) of 28 d. Milk component yields including fat (%) were measured on a weekly basis. Mammary biopsies on three cows were performed on d 14 (control period) and on d +7 and +28 (treatment period). Results show a significant decrease ($P < 0.0001$) in milk fat yield (%) during the treatment period (3.02 ± 0.17) as compared to the control period (3.62 ± 0.17). Nine libraries were constructed and subjected to 50bp smallRNA sequencing. A total of 103,796,305 raw reads were obtained and 93,218,009 retained after adaptor trimming and quality filtering. Of these, 69,210,197 (74.25%) were mapped to the bovine genome. A total of 338 known miRNAs (82.6% of mapped reads) were identified with more than one count per million in at least six libraries. Furthermore, 223 novel hairpins encoding for 212 novel miRNAs were identified. Five miRNAs (bta-miR-148a, miR-143, miR-26a, miR-30a-5p, and miR-10b) were most highly expressed, accounting for 54.93% of reads of identified known miRNAs. As compared to d 14 (control period), 10 miRNAs were significantly regulated (five up-regulated: bta-miR-4286, mir-199c, miR-199a-3p, miR-98, and miR-23b-3p; five downregulated: bta-miR-484, miR-96, miR-200a, miR-335, and miR-2299–5p) at d +28 ($P < 0.01$), while no significant regulation was detected at d +7 ($P > 0.01$). About 5541 genes were predicted to be targeted by differentially expressed miRNAs. Function enrichment analysis showed significant enrichment of target genes for functions related with lipid metabolism ($P < 0.01$). In conclusion, our study revealed that several miRNAs were differentially expressed during the milk fat depression introduced by linseed oil supplementation, suggesting that these miRNAs could be important regulators of mammary lipid synthesis. Furthermore, novel miRNAs identified in this study will greatly enrich the bovine miRnome repertoire and also act as targets for further study of bovine mammary gland biology.

Key Words: microRNA, linseed oil, bovine mammary gland

0980 (M058) Effect of co-expression of Lc and C1 flavanoid regulatory genes in alfalfa on nutritive value and ruminal methane production. R. G. Heendeniya Vidanaral[*1], M. Y. Gruber[2], Y. Wang[3], D. A. Christensen[1], J. J. McKinnon[1], B. Coulman[1], and P. Yu[1], *[1]University of Saskatchewan, Saskatoon, Canada, [2]Agriculture, and Agri-Food Canada, Saskatoon, SK, [3]Agriculture and Agri-Food Canada, Lethbridge, AB.*

An alfalfa progeny was developed by transforming Lc and C1 genes which are regulatory genes associated with flavonoid pathway in Zea maize. The transformation objective was to promote anthocyanidin accumulation in alfalfa leaves and stems, thus reducing the extent and rate of protein degradation in the rumen and potentially rumen methane production. The objective of this study was to evaluate the effect of co-expression of Lc and C1 genes on 1) protein, energy and feed milk values, and 2) methane gas production relative to single gene transformed alfalfa and non-transgenic parent plants. Alfalfa samples were collected at late-bud stage from populations of single gene transformed (C1, Lc1, and Lc3), double gene transformed (Lc1C1 and Lc3C1), parental non-transgenic (NT), and a commercial cultivar (AC-Grazeland: ACGL) maintained in growth chambers at the Saskatoon Research Centre, Agriculture and Agri-Food, Canada. Samples were chemically analyzed according to AOAC methods, and energy and protein values were determined using NRC (2001) and CNCPS (v.6.1) models. Fermentation gases were obtained from in vitro batch culture and analyzed by gas chromatography for methane. Rumen degradable protein was higher ($P < 0.01$) by 2% in double gene alfalfa comparing to single gene alfalfa, but no differences ($P > 0.05$) were observed in digestible rumen undegradable protein. In comparison to single gene alfalfa, co-expression of Lc and C1 genes increased ($P = 0.01$) net energy by 50 kcal for both lactation and growth and thereby increasing ($P < 0.01$) the feed to milk conversion efficiency by 80 g of milk per kg of alfalfa dry matter. The double gene alfalfa tended to have lower ($P = 0.07$) total gas production than NT alfalfa and significantly lower ($P < 0.05$) methane production by 3.5 L per kg DM than single gene alfalfa. In conclusion, C1 gene when co-expressed with Lc gene improved the feeding value of alfalfa and reduced in vitro methane production.

Key Words: Lc-C1 transgenic alfalfa, energy and protein, methane

0981 (M059) Predicting milk fat concentration from nutrient content and DCAD of the diet.

L. Fadul-Pacheco*, D. Pellerin, P. Y. Chouinard, and E. Charbonneau, *Université Laval, Québec, Canada*

The farm-gate price of milk in Canada is based on composition, which provides incentive for producers to increase fat content. The objective of this study is to determine the extent to which changes in nutrients and DCAD can predict milk fat percentage. Data recorded by Valacta (Dairy Production Center of Expertise Quebec-Atlantic) for the years 2009 to 2011 was used and originally comprised 3481,705 test-day records (275,758 cows and 3140 herds). Records used for the regression analysis were restricted to those from Holstein cows, between one and 305 DIM, taken during winter months, reducing the number of admissible records for the analysis to 306,191 (134,236 cows and 2658 herds). Lactations were divided into early (1 to 50 DIM), peak (51 to 100 DIM), and established lactation (101 to 305 DIM). Statistical analysis were performed using PROC HPMIXED of SAS with herd and cow (herd) as random effects. Independent variables were included in the final equation when $P \leq 0.05$. The variables used as covariates in the regression were: milk production (kg/day), DIM, and estimated breeding value for fat composition (EBV_FAT). Variables tested to explain milk fat concentration were: NDF from forage + 0.5 x NDF from concentrate (NDF_NRC), NFC, amount of buffers (BUFF; kg/day), amount of fat supplements with more than 80% of palmitic acid (PALM80; kg/day), and DCAD. In the final analysis for the 3 yr, multiple regression in early lactation (n = 24,987; R^2 = 0.44) included, in addition to the covariates, the following variables: NDF_NRC (quadratic) and PALM80. For peak lactation (n = 29,317; R^2 = 0.42) the variables were DCAD, NDF_NRC, BUFF and PALM80. For established lactation (n = 100,706; R^2 = 0.64) NDF_NRC, NFC (quadratic), BUFF and PALM80. All the equations accounted for a significant effect of year. When the regression was split by year, all the variables remained the same, while the DCAD (quadratic) was also added to the model for established lactation in all 3 yr, but with different optimal value (2009: > 330 mEq/kg MS; 2010: 210 mEq/kg MS; 2011: > 380 mEq/kg). In summary, the equations were able to predict up to 64% of milk fat variation based on the combination of different nutrients, especially NDF_NRC (quadratic) and PALM80. Based on the variations in optimal values between years, it could be concluded that the impact of the DCAD on milk fat concentration can be influenced by the nutritional quality of feed ingredients.

Key Words: lactating dairy cows, milk fat, DCAD.

0982 (M060) Evaluation of methane prediction equations for beef cattle fed high forage or high concentrate diets.

P. Escobar[*1,2], K. A. Beauchemin[3], and M. Oba[4], *[1]University of Alberta, Lethbridge, Canada, [2]Agriculture and Agri-Food Canada, Lethbridge, AB, [3]Lethbridge Research Centre, Agriculture and Agri-Food Canada, Lethbridge, AB, [4]University of Alberta, Edmonton, Canada.*

Enteric methane (CH_4) emission is the major contributor to greenhouse gases from beef cattle farms. Many equations are available to predict enteric CH_4 emissions from beef cattle, but the predictions vary substantially amongst equations. The aims of this study were to: 1) construct a database of enteric CH_4 emissions for beef cattle fed forage and grain-based diets from published literature, and 2) identify the most precise and accurate extant CH_4 prediction models for beef cattle fed diets varying in forage content. The database was comprised of treatment means of enteric CH_4 production from in vivo beef studies published from 2000 to 2013. Criteria for selecting data to include in the database were: animal description, intake, diet composition, and measurement of enteric CH_4 production. Missing values were estimated using feed composition tables, nutritional software or by calculation from the diet description. Fifty-one equations that predict CH_4 production from diet composition were evaluated. Precision and accuracy of the equations was evaluated using the concordance correlation coefficient (r_c), bias correction factor (C_b) and root mean square prediction error (RMSPE, g/d), and then ranked highest to lowest based on r_c. Statistical analysis was performed using JMP and SAS. The final database contained 39 studies and 163 treatment means that were divided into two subsets: a subset comprised of data from diets containing 40% or more forage and a subset comprised of data from diets containing less than 40% forage (dry matter basis). Using the complete database, equations with highest r_c were: G (Ellis et al., 2009), IPCC (2006) and J (Ellis et al., 2009), with r_c: 0.71, 0.67, 0.63, C_b: 0.98, 0.98, 0.98, and RMSPE: 55.0, 57.7, 61.4, respectively. For the high forage dataset, equations with highest r_c were IPCC (2006), G (Ellis et al., 2009), and Nonlinear 2 (Mills et al., 2003) with r_c: 0.75, 0.75, 0.71, C_b: 0.96, 0.99, 0.95, and RMSPE: 47.9, 51.7, 52.5, respectively. For the low forage dataset, equations with highest r_c were 9b (Ellis et al., 2007), G and P (Ellis et al., 2009), with r_c: 0.52, 0.48, 0.47, C_b: 0.67, 0.81, 0.81, and RMSPE: 56.0, 64.0, 62.0, respectively. Ranking of extant CH_4 prediction equations for their accuracy and precision differed with forage content of the diet. When used for cattle-fed low-forage diets, extant CH_4 prediction models were generally imprecise and lacked accuracy.

Key Words: beef cattle, enteric methane emission, models

0983 (M061) Non-protein nitrogen improves feed efficiency of growing pigs fed a diet deficient in non-essential amino acid nitrogen. W. D. Mansilla*[1], J. K. Htoo[2], and C. F. de Lange[1], [1]*University of Guelph, ON, Canada,* [2]*Evonik Industries AG, Hanau-Wolfgang, Germany.*

In pig diets the balance between essential amino acids (EAA) and total N should be considered, especially when large amounts of crystalline EAA are supplemented and N levels are reduced. When lowering dietary N, the dietary supply of non-essential amino acids (NEAA) is reduced and the need of N for endogenous synthesis of some NEAA may be increased, requiring N from either catabolism of excess EAA and NEAA or non-protein nitrogen (NPN). The objective of the present study was to determine the effect of supplementing NPN, in the form of ammonium salts, in diets deficient in NEAA-N on performance of growing pigs. In total, 48 gilts (initial BW of 15.2 ± 1.3 kg) were randomly assigned to 4 diets: 1) positive control (PC; 13.39% CP), not deficient in EAA and NEAA-N, and all N was supplied from intact protein (casein and soybean meal) or crystalline EAA; 2) negative control (NC; 10.19% CP), supplying the same amount of potentially limiting EAA as PC, but deficient in NEAA-N; 3) NC with 3 g/kg added ammonium (Low NPN); and 4) NC with 6 g/kg added ammonium (High NPN), the latter containing the same amount of digestible N as PC. Pigs were grouped in two pigs per pen with six pens per treatment. BW gain and feed intake were monitored weekly during 3 wk, and blood samples were taken on d 14 and 21 to determine plasma urea concentration. Wk 1 yielded poor growth performance and was considered a week of adaptation. During wk 2 and 3, BW gain was not affected by NPN ($P > 0.10$), while feed intake tended to decrease with increasing dietary NPN ($P = 0.06$). Gain:feed improved linearly with supplementation of NPN in diets ($P < 0.05$; 0.45, 0.47, and 0.51 for NC, Low and High NPN during wk 2 and 3). Gain:feed for High NPN was similar to that for PC ($P > 0.10$: 0.51 and 0.52 for High NPN and PC; wk 2 and 3). Plasma urea concentration was Low and not different between diets ($P > 0.10$). Dietary supplementation with NPN, in the form of ammonium salts, can improve pig performance when pigs are fed diets deficient in NEAA-N.

Key Words: growth, nitrogen, pigs.

984 (M062) Impact of the fatty acids in the diet on milk fat content: Analysis from a database of commercial farms. H. Mannai*, P. Y. Chouinard, L. Fadul-Pacheco, D. Pellerin, and E. Charbonneau, *Université Laval, Québec, Canada.*

Controlled trials have shown that milk fat content can be affected by dietary fatty acids. The purpose of this study was to evaluate the impact of dietary fatty acids on milk fat content in commercial dairy herds using multiple regression procedure. Data recorded by Valacta (Dairy Center of Expertise, Québec-Atlantic) from 2009 to 2011 were used for the analysis. The fatty acid content in feed ingredients (16:0, 16:1, 18:0, *cis* 18:1, *trans* 18:1, 18:2 and 18:3), not originally in the database, were obtained from CNCPS V6.1, INRA Tables of Feed Composition, and peer-reviewed articles. Test-day records from Holstein cows in early- (1 to 50 DIM) and peak- (51 to 100 DIM) lactation during winter months were used, giving 2491 records over the 3-yr period from 1585 cows and 143 herds. Statistical analyses were performed using the PROC MIXED of SAS with herd and cows (herd) as random effects. Independent variables were included in the final equation when $P \leq 0.10$. The variables used as covariates in the regression were DIM and estimated breeding value for fat composition (EBV_FAT). Variables tested to explain milk fat concentration were: forage NDF + 0.5 × concentrate NDF content (NDF_NRC), NFC content, buffer intake (BUFF), and intake of previously listed individual fatty acids. Multiple regressions for data from early lactation records ($n = 390$; $R^2 = 0.43$) included, in addition to the covariates, the variables 18:0 (quadratic), *cis* 18:1 (quadratic), 18:2, and BUFF. For peak-lactation records ($n = 422$; $R^2 = 0.49$) the variables included were 16:0 (quadratic), 16:1, 18:0 (quadratic), *trans*18:1 (quadratic), 18:2 (quadratic), NFC (quadratic), NDF_NRC (quadratic), and BUFF. The nonlinear relationships observed for several fatty acids retained in the model could be explained by the heterogeneity of fatty acid sources on commercial farms (forages, cereal grains, oil seeds, fat supplements in the form of triglycerides, free fatty acids or calcium salts, etc.), and their interaction with numerous feed ingredients. The current study gives insight into the relationships between individual dietary fatty acids and milk fat content in the context of commercial milk production.

Key Words: dietary fatty acids, milk fat, lactating dairy cows

0985 (M063) Pregnancy and lambing rates in anestrous ewes bred to a new synchronization protocol and laparoscopic timed artificial insemination (TAI). S. B. Turner*[1], M. B. Gordon[1], T. Gowan[2], J. A. Small[2], and D. M. W. Barrett[1], [1]*Faculty of Agriculture, Dalhousie University, Truro, NS, Canada,* [2]*Agriculture and Agri-Food Canada, Truro, NS.*

Reproductive performance in seasonally anestrous ewes is poor even after the application of conventional controlled breeding techniques. Estradiol-17β (E_2) has been shown to synchronize follicular wave emergence in anestrous ewes treated for 12 or 14 d with a medroxyprogesterone acetate sponge. The objective of this study was to determine the effects of an E_2 treatment administered 6 d after CIDR insertion on E_2 concentrations, estrus, pregnancy rates, and lambing rates in ewes bred out of season. Ewes from three farms (Farm A: $n = 22$; Farm B: $n = 48$; Farm C: $n = 28$) received

CIDRs (d -12) followed by an injection of eCG (500 IU; d 0) at CIDR removal and an injection of sesame oil without (1 mL; Control) or with E_2 (350 µg; d −6) 6 d before CIDR removal. Treatments were balanced for breed, age, parity, and BCS. Blood samples were taken from half of the ewes on d −6 and 0 to determine E_2 concentrations. On d 1 ewes were exposed to rams to observe estrus. Ewes were subjected to laparoscopic TAI on d 2. Pregnancy was diagnosed by transabdominal ultrasonography on d 50. Estrus, pregnancy rates, and lambing rates were analyzed using logistic regression. Day of lambing and E_2 concentrations were analyzed using ANOVA. The percent of ewes observed in estrus within 36 h of CIDR removal was similar between treatments (E_2: 24.5%; Control: 34.7%; $P > 0.05$). Pregnancy rates were similar between treatments (E_2: 40.8%; Control: 40.8%; ± $P > 0.05$) and were higher on Farm C than Farm B (Farm A: 45.5%; Farm B: 22.9%; Farm C: 67.9%; $P < 0.05$). Lambing rates were also similar between treatments (E_2: 34.7%; Control: 34.7%; $P > 0.05$) and were higher on Farm C than Farm B (Farm A: 40.9% Farm B: 16.7%; Farm C: 60.7%; $P < 0.05$). Relative to CIDR removal, ewes lambed earlier on Farm B (Farm A: 141.7 ± 1.3 d; Farm B: 136.6 ± 1.4 d; Farm C: 143.2 ± 0.9 d; $P < 0.05$) and ewes treated with E_2 lambed earlier (E_2: 138.9 ± 1.0 d; Control: 142.2 ± 1.0 d; $P < 0.05$). Concentrations of E_2 were similar between treatments on d −6 (E_2: 1.5 ± 0.1 pg/mL; Control: 1.6 ± 0.1 pg/mL; $P > 0.05$) and d 0 (E_2: 1.6 ± 0.1 pg/mL; Control: 1.3 ± 0.1 pg/mL; $P > 0.05$). Differences were mainly observed among farms potentially due to differences in breed, BCS, semen, or management practices. The addition of an E_2 treatment during a CIDR-eCG heat synchronization protocol does not clearly increase pregnancy and lambing rates in seasonally anestrous ewes.

Key Words: anestrus, ewes, controlled breeding

0986 (M064) Effect of duration on feed and energy substrate on the digestive physiology of finishing feedlot cattle. F. Joy*, J. J. McKinnon, S. Hendrick, and G. B. Penner, *University of Saskatchewan, Saskatoon, Canada.*

The objective of this study was to determine the effect of dietary energy substrate and days on feed (DOF) on apparent total tract digestibility, rumen fermentation, short-chain fatty acid (SCFA) absorption and the arterial glucose clearance rate. Eight ruminally cannulated, cross-bred growing heifers were randomly allocated to one of the two dietary treatments. The control (CON) diet consisted of 75.2% barley grain, 9.8% canola meal, 9% mineral-vitamin supplement, and 6% barley silage (DM basis). To evaluate the effect of energy source, a high-lipid byproduct pellet was included to replace 60% of the barley grain and canola meal (HLP). Diets were similar in NEg (5.15 MJ/kg) and CP (13.7% DM). The study consisted of four consecutive 40-d periods with collections occurring in the last 6 d of each period. Dry matter intake did not differ among periods but the HLP group tended to eat less ($P = 0.09$). The ADG was greater for CON ($P < 0.05$) than HLP and ADG decreased with advancing DOF. The ADG of CON was greater than HLP during first and the last periods (Trt×Period; $P = 0.024$). Heifers fed HLP tended to have greater mean ruminal pH (6.10 vs. 5.96; $P = 0.07$) than CON, but pH was not affected by DOF. The CON heifers had a greater digestibility for DM, OM, CP and NDF ($P < 0.05$) and the digestibility for DM, OM, CP, NDF and starch increased with advancing DOF ($P < 0.05$). Crude fat digestibility of CON increased with DOF while that of HLP decreased (Trt × Period; $P < 0.05$). Total SCFA concentration in the rumen was greater ($P = 0.006$) for CON (141.5 vs. 128.08 mM/dL) than HLP and it tended to decrease with DOF ($P = 0.098$). The molar proportion of acetate increased and butyrate decreased with increasing DOF ($P < 0.05$) but propionate was not affected. The rate of SCFA absorption was not affected, but the passage rate of chromium over period was decreased ($P < 0.026$). The arterial clearance rate of glucose was not affected by treatment or DOF. These data suggest that replacing 60% of the barley grain and canola meal with high lipid byproduct pellets negatively affects total tract digestibility and performance. Moreover, regardless of diet, with advancing DOF digestibility increases and SCFA concentration decreases without corresponding changes in SCFA absorption and, as such, these changes do not explain the reduction in G:F with advancing DOF.

Key Words: beef, digestibility, feeding-duration

0987 (M065) A prepartum diet supplemented with rolled canola seed reduced pituitary sensitivity to GnRH in dairy cows during second week postpartum. *R*. Salehi*[1], M. G. Colazo[2], M. Oba[1], and D. J. Ambrose[2], [1]*University of Alberta, Edmonton, Canada,* [2]*Alberta Agriculture and Rural Development, Edmonton, Canada.*

Cows fed a prepartum diet supplemented with rolled canola seed (high in oleic acid, OLA) had longer interval from calving to first ovulation than cows fed diets supplemented with either linola (high in linoleic acid, LA) or flax (high in linolenic acid) (Colazo et al., 2009; JDS, 92:2562). We hypothesized that the delayed ovulation in canola-fed cows occurred through suppression of pituitary LH since adding OLA to culture medium suppressed GnRH-induced LH release from porcine pituitary cells in-vitro (Barb et al., 1995; JAS, 73:1416). To test our hypothesis, pregnant Holstein cows, blocked by BCS, were assigned to 1 of 3 prepartum diets supplemented with canola (high OLA, $n = 10$), sunflower (high LA, $n = 10$), or control (no oilseed, $n = 11$) from 35 d before expected calving date until parturition. The concentrate portion of OLA- and LA-diets contained 0.99 kg rolled oilseeds providing 0.27 kg/d OLA or 0.31 kg/d LA. Average DMI ± S.E. (kg/d) was higher in control (15.30 ± 0.63) than in canola (13.54 ± 0.54), sunflower (13.31 ± 0.57) diets. Blood was sampled during the

first (6 ± 1.00 d, n = 15) or second (9 ± 1.20 d, n = 16) week postpartum, every 15 min for 6 h to measure LH pulsatility. Thereafter, 100 μg GnRH was administrated im and blood was sampled for 4 h to measure induced LH release. Treatments did not affect LH pulsatility during the first and second week postpartum. Mean, minimum, maximum LH, pulse amplitude, and frequency were 0.30, 0.11, 0.82, 0.40 ng/ml, and 4.24 pulses per 6 h, respectively, and they were not affected by treatments or weeks. GnRH-induced LH release was not influenced by dietary treatments during the first week postpartum, but cows fed a prepartum diet high in OLA had lower mean LH (1.70 ± 0.20 ng/mL) than in control (2.40 ± 0.20 ng/mL; P = 0.02) during the second week postpartum, but it did not differ from LA (1.80 ± 0.20 ng/mL; P > 0.05); LA vs. control, P = 0.09. After GnRH administration, diets did not affect LH peak (3.39 ng/ml), interval to peak (47.40 min) or area under curve (7.01 ng/ml per 4h). In summary, although, prepartum diets did not affect pulsatile and GnRH-induced LH release during the first week postpartum, cows fed a prepartum diet supplemented with rolled canola had lower mean GnRH-induced LH than those fed no oilseed.

Key Words: oilseed, prepartum, luteinizing hormone

0988 (M066) Utilization of high lipid byproduct pellet in the finishing diet of feedlot steers to improve carcass traits and reducing feed costs.

F. Joy*[1], J. J. McKinnon[1], P. Gorka[2], and G. B. Penner[1], [1]*University of Saskatchewan, Saskatoon, SK, Canada,* [2]*University of Agriculture in Krakow, Krakow, Poland*

Two studies were conducted to evaluate the rate and timing of provision of a high-lipid high-fiber byproduct pellet (HLP) as a partial replacement for barley grain in diets for feedlot cattle. In study 1, steers (n = 288; BW = 378.4 ± 0.50 kg) were randomly allocated to one of 24 pens, and pens were assigned to one of four treatments. The study period was divided into three equal periods of 49 d each, namely P1, P2, and P3. A barley-based diet (CON; 75.2% barley grain, 9.8% canola meal, 9% mineral and vitamin, and 6% barley silage; DM basis) was compared to a diet where HLP replaced 60% of the barley grain and canola meal, relative to the CON. Steers received the HLP diet for 0 (CON147), 147 (HLP147), the last 98 (HLP98), or the last 49 d (HLP49). Steers fed CON had greater ADG (1.96 vs. 1.83 kg/d; P < 0.01), but DMI was not affected. The HLP147 had greatest DMI and least G:F during P1, but least DMI in P3 (Trt × Period; P < 0.01). Hot carcass weight of CON and HLP49 were the heaviest (P < 0.05), and HLP49 tended to have the greatest percentage of carcasses in yield grade 1 (P = 0.07). Carcass quality grade was not affected. In the second study, steers (n = 264; BW = 441.3 ± 0.19 kg) were randomly allocated to one of 24 pens and fed for 120 d. Diets were similar in composition to study 1 except that the HLP replaced 30% of the barley grain. Treatments included feeding steers the HLP diet for 0 (CON), 120 (HLP120), and the last 60 (HLP60), and the last 60 d along with additional canola oil (HLP60CO). There were no differences for DMI and ADG (12.6 and 2.0 kg/d, respectively). The G:F for HLP120 was less than the other treatments (0.149 vs. 0.158; P = 0.001). Hot carcass weight was greater for CON and HLP60 than HLP120 and HLP60CO (386 vs. 377 kg). The HLP120 tended to have the greatest proportion (P = 0.06) of yield grade 1, with HLP60CO tending to be the lowest (62.5 vs. 37.9%). Carcass quality was not affected. Partially substituting barley grain with HLP in the second half of the finishing period may improve carcass yield grade without negatively affecting growth performance and feed efficiency relative to a barley-based diet.

Key Words: beef, byproduct, pellet, carcass

DAIRY FOODS: **TECHNICAL SESSION 1: CHEESE / YOGURT**

0989 (M067) Physicochemical and sensory characteristics of processed cheese manufactured from goat's milk fed diet supplemented with sunflower seed or sunflower oil. A. G. Mohamed*[1], T. A. Morsy[2], and S. Kholif[2], [1]*National Research Center, Cairo, Egypt,* [2]*National Research Center, Cairo, Egypt.*

Oilseed lipids are important sources of unsaturated lipids. Among oilseeds, linseed, soybeans, and sunflower seed are used both in farms and experimental work. Moreover, the enhancement of unsaturated fatty acids and conjugated linoleic acid (CLA) in milk products is important for human health. The aim of this work was to improve the fatty acid profile of processed cheese by using milk from goats fed with different supplements, namely, sunflower seed or sunflower oil. Fifteen lactating Damascus goats, in early lactation, were divided into three groups using complete randomized design for a 90-d experimental period. The treatments were: 1) control ration consisted of concentrate feed mixture: bersem clover (1:1 dry matter bases); 2) control +50 g/head/d sunflower seed; and 3) control +20 mL/head/d sunflower oil. Pooled milk from each treatment was used in the manufacture of processed cheese. It was manufactured by using cheese base that was prepared by acidifying goats' milk with diluted lactic acid until coagulation. Cheese samples were stored at 7°C for 3 mo. The results demonstrated that experimental additives increased ($P < 0.05$) the total unsaturated fatty acids and CLA in the processed cheese. In all additives decreased ($P < 0.05$) the total saturated fatty acids and omega 6:omega 3 ratio and increased ($P < 0.05$) the polyunsaturated fatty acids contents of the processed cheese fat. Processed cheese flavors, color, and physical properties such as melting index, oil separation, and penetrometer reading were not significantly affected by the experimental treatments. It can be concluded that sunflower seed or sunflower oil addition to lactating goats ration increased the nutritive value of processed cheese.

Key Words: goat's milk, processed cheese, fatty acids profile.

0990 (M068) Fatty acid profile of sheep cheeses that are commercialized in Chile. E. Vargas-Bello-Pérez*, C. Ugalde, P. Toro-Mujica, R. Vera, and C. Aguilar, *Pontificia Universidad Católica de Chile, Santiago, Chile.*

The fatty acid (FA) content of sheep cheeses is an important characteristic for consumers due to its role in human health. In Chile, there is an incipient internal market for sheep cheeses due to the fact that the demand for these cheeses is not widespread; however, its production is expected to be increased in the forthcoming years. The present study was performed to characterize the FA profile of sheep cheeses that are commercialized in Chile. Thirty-two sheep cheeses were collected from supermarkets of five different cities from which 21 were Chilean and 11 imported from Europe (Spain and France). Results showed that C10:0, C14:0, C16:0, C18:0, C18:1 t11, and C18:1c9 represented around 78% of the total FA profile detected in cheeses. Short-chain (C4:0-C6:0) and medium-chain (C8:0–12:0) FA content was lower in Chilean cheeses than European. Saturated, monounsaturated and polyunsaturated FA contents did not differ between cheeses. The n6:n3 ratio was lower in Chilean cheeses than European (2.8 and 5.9). The atherogenicity index was not different between cheeses; however, the thrombogenic index was lower in Chilean cheeses (2.7) than European (2.9). The results indicated that the FA profile of Chilean cheeses was desirable from a human standpoint.

Key Words: cheese, fatty acids, thrombogenic index

0991 (M069) Investigating the impact of distiller's dried grains with solubles on the quality of milk and Swiss cheese. V. Manimanna Sankarlal*, E. D. Testroet, and S. Clark, *Iowa State University, Ames.*

Late blowing in Swiss cheese, a result of unwanted gas production during ripening, is unacceptable to consumers, is impossible to slice, and causes economic loss to manufacturers. Cheese processors have raised concerns that feeding distiller's dried grains with soluble DDGS to cows leads to this defect, in part because of *Clostridium tyrobutyricum*. In this study, the effect of feeding DDGS on composition and quality of milk and Swiss cheese was studied. Thirty healthy mid-lactation ISU Dairy Farm Holstein cows were assigned randomly to one of three dietary treatment groups (10 cows per treatment group): 1) total mixed ration (TMR) with no DDGS; 2) TMR with 10% substitution with DDGS; and 3) TMR with 20% DDGS. One complete milking from all cows within a treatment was collected and pooled for cheese-making trials, twice within each of 3-mo-long treatment periods. Additionally, individual milk samples from three milkings of a day were collected weekly, and proximate analysis was performed on pooled individual milk samples. Cheese milk was filtered, standardized to 0.88 fat:protein, and pasteurized before addition of starter cultures and coagulant. Curds were cut, fore-worked, worked, and post-worked according to a baby Swiss cheese recipe, followed by pressing and brining (10°C, 12 h). The 3.5 kg blocks were vacuum packed and allowed to ripen (10°C, 7 d; then 22°C, 21 d), then cooled (4°C, 60 d). The milk and DDGS were analyzed for *C. tyrobutyricum* using selective media. After incubation up to 48 h in modified RCM lactate medium, tubes containing DDGS did not show gas formation, whereas most of the tubes containing milk showed gas formation, which indicates that DDGS were not the source of *C. tyrobutyricum*. Milk fat content decreased as % DDGS in diet increased ($P < 0.05$). Sol-

ids nonfat, protein, and lactose content of milk of cows fed 10 and 20% DDGS were only slightly higher than from control diet. After ripening (> 60 d), baby Swiss cheese had typical propionic acid Swiss cheese aroma. Regardless of diet treatment, pinholes, slits, and cracks were seen throughout most cheeses. DDGS feeding increased the amount of long-chain unsaturated fatty acids and decreased short-chain and most medium-chain fatty acids. Although feeding cows DDGS modified milk composition and subsequent cheese composition, DDGS alone should not be blamed as a source for *C. tyrobutyricum*or for late blowing in Swiss cheese.

Key Words: *C. tyrobutyricum,* Swiss cheese

0992 (M070) Evaluation of unidentified structural features in hard, aged cheeses and soft, washed rind cheeses by powder X-ray diffractometry.

G. F. Tansman*[1], P. S. Kindstedt[1], and J. M. Hughes[2], *[1]Dep. of Nutrition and Food Sciences, University of Vermont, Burlington, [2]Dep. of Geology, University of Vermont, Burlington.*

Hard, aged cheeses and soft, washed rind cheeses sometimes develop structural features that can be detected visually and texturally by mouthfeel, but which are incompletely characterized. The objectives of this research were to evaluate visible spherical features embedded within the bodies of aged Parmigiano Reggiano and Gouda cheeses, and granular features at the surfaces of three artisanal washed rind cheeses using powder X-ray diffractometry (PXRD). All cheese samples were purchased from local retail sources. Discolored spherical features up to *ca.* 5mm in diameter, which were readily visible against the darker cheese matrix, were extricated from the matrix of Parmigiano Reggiano and Gouda cheeses, defatted in acetone, ground to a powder, and analyzed by PXRD. Samples of the cheese matrix that surrounded the spheres were also prepared similarly and analyzed by PXRD for comparison. Granular features at the surface of washed rind cheeses were scraped off, defatted in acetone, ground, and analyzed by PXRD. The resulting X-ray diffraction patterns were compared with those in a database of over 1 million known crystals to establish crystal identities. The discolored spherical features from both Parmigiano Reggiano and Gouda cheeses diffracted X-rays in a manner characteristic of leucine; however, the surrounding cheese matrix did not diffract X-rays. The formation of numerous large (5-mm diameter) crystalline leucine entities may have important implications for the rheological properties of Parmigiano Reggiano and Gouda cheeses, which warrant further study. The washed rind cheeses exhibited surface grittiness that was perceptible in the mouth. Surface scrapings from three different washed rind cheese varieties yielded X-ray diffraction patterns that were all unique from one another. Two cheeses produced diffraction patterns that could not be identified, whereas the third displayed the presence of calcite crystals. None of the surface scrapings contained appreciable quantities of previously documented cheese crystals such as brushite, tyrosine, or calcium lactate. Due to the outward migration of calcium in washed rind cheeses, it is possible that the unidentified diffraction patterns represent crystalline calcium salts in novel forms that have not been documented. Based on anecdotal reports from cheesemakers and cheese mongers, we hypothesize that these surface crystals are responsible for distinctive visual and mouthfeel characteristics that appeal to consumers of artisanal washed rind cheeses.

Key Words: cheese, crystal, X-ray

0993 (M071) Quality of milk and Minas fresh cheese of pasture cows suplementted with licuri cake.

A. C. C. Ferreira*[1], R. L. Oliveira[2], J. F. Vieira[3], T. M. Silva[2], A. M. Barbosa[2], S. M. P. L. Jaeger[3], and D. D. Amaral[2], *[1]Universidade Federal da Bahia, MI, [2]Universidade Federal da Bahia, Salvador, Brazil, [3]Universidade do Reconcavol da Bahia– UFRB, Cruz das Almas, Brazil.*

This is study aimed to determine the best level of licuri cake for the diets of pasture dairy cows. This was done by the evaluating the quality of milk and Minas frescal cheese. Eight crossbreed cows were distributed in four Latin square simultaneously, on the Farm of Federal University of Bahia (UFBA), Brazil, in August to October 2012. The concentrated feeding consisted of soybean meal, ground corn, mineral salt, ammonia, urea, and licuri cake at 0, 20, 40, and 60% dry matter. Contents of fat, protein, lactose, total solids and solids not fat in milk and cheese were not affected ($P > 0.05$) by licuri cake in the diet (Table 0993). The decrease in the yields of components in the milk is related to the low energy content of the diet and low intake of dry matter. Furthermore, the amounts of fat and protein vary according to race, climate, management, and other factors. The percentage of milk fat had lower values in cows that had given birth at a younger age. In the summer months, the fat content (3.41 to 3.49%) was lower than in the winter months (around 3.7%).

Key Words: byproduct, supplement, ruminant nutrition

Table 0993. Fat content, crude protein, lactose in milk and cheese, and total solids (TS) solid not fat (SNF) in milk from cows on pasture supplemented with licuri cake

	Levels of Licuri cake (% DM)					*P*–Value	
Variable	0	20	40	60	SEM1	Linear	Quadratic
Fat (%)	2,22	2,31,	2,38	2,77	0306	00696	04645
Protein (%)	3,11	3,11	3,11	3,09	0060	08501	09560
Lactose (%)	4,63	4,63	4,64	4,62	0042	09256	08643
TS (%)	10,92	11,00	11,07	11,44	0296	00802	04745
SNF (%)	8,69	8,68	8,68	8,67	0082	08567	09655

Fat (%)	17,20	18,22	19,12	18,41	0298	01835	02528
Protein (%)	23,64	27,33	22,96	23,55	0058	03821	01973
pH	6,45	6,40	6,47	6,40	0754	06322	07385
Humidity (%)	59,94	57,19	58,78	57,86	0054	01544	02123

[1] SEM = standard error of mean. The cheeses were, on average, 18.2% fat and 58.4% moisture. Cheeses of this study can be classified as lean and high humidity. The licuri cake included in the concentrate until 60% of cows grazing did not alter the parameters of milk quality and frescal cheese.

0994 (M072) Microbial stress responses and gene expression during aging of cation-substituted full fat cheddar cheese. B. Ganesan*, S. Muruganandam, and D. J. McMahon, *Western Dairy Center, Utah State University, Logan*

Sodium replacement is a potential alternative to direct Na reduction in foods, wherein an equally salty cheese will attract consumers without the risk of high sodium intake. However bacteria in Cheddar cheese responsible for cheese flavor development may experience a different form of stress and respond differently when Na is, for example, substituted by K. We are yet to understand how salt change is likely to alter flavor formation in cheddar cheese. We proposed to study whether bacteria continue to experience NaCl stress even with Na reduction or with use of different NaCl mixtures with less Na in full fat cheddar cheese containing different fat levels. We investigated how starter bacteria respond to stress from different NaCl combinations during aging of cheddar cheese. To study starter bacterial stress, gene expression studies were done by qPCR targeting six known NaCl stress-related genes (three induced, three repressed by NaCl stress, based on literature) for starter lactococcal subspecies in cheeses with different NaCl combinations. Five cation combinations with different levels of Na replacement– 100% Na (control with 2.2% total salt), 75:25 and 50:50 Na:K, 50:40:10 of Na:K:Ca, and low sodium (0.7% total salt)– were chosen for the analyses. Starter lactococci survived well in response to stress, with initial variations post salting due to cations diminished over aging ($P < 0.05$). Initial responses of the dual enolase genes of lactococci matched known responses from other studies, with *enoA* being induced more by high NaCl and *enoB* repressed by high NaCl ($P < 0.05$), respectively. Expression of *dnaK*, which encodes a molecular chaperone and is known to be induced immediately with acid and NaCl stresses, steadily plateaued and remained high (> 10^6 copies) throughout 6 mo of aging. Initial stress response to other cations varied between the six genes, with only the cheese substituted with 50:40:10 of Na:K:Ca exhibiting lower transcript induction ($P < 0.05$) of all stress response genes. This indicates that Ca even at low levels plays a role in mitigating lactococcal stress. Notably, RNA extracted for gene expression directly from cheeses was devoid of any cross-contaminating genomic DNA, which confirmed that only transcripts were detected. The presence of detectable mRNA even after 6 mo of cheddar cheese aging confirms that lactococci are still physiologically active independent of their exhibiting growth on media plates. This study presents a novel perspective on cation-controlled gene expression through cheese aging.

Key Words: lactococci, cation substitution, gene expression

0995 (M073) Characteristics of yogurt manufactured using reconstituted yogurt cultured milk powder compared to yogurt powder. L. Song*[1], and K. J. Aryana[2], [1]*Louisiana State University, Baton Rouge,* [2]*Louisiana State University Agricultural Center, Baton Rouge.*

For the manufacture of commercial yogurt powder the yogurt has to go through drying process which substantially lowers the yogurt culture counts, so the potential health benefits of the yogurt culture bacteria are deminished or lost. Also, on reconstitution, commercial yogurt powder does not taste like yogurt, it is sour and off-flavored. The objective was to enumerate *Streptococcus thermophilus* and *Lactobacillus bulgaricus* of reconstituted yogurt cultured milk power and reconstituted commercial yogurt powder up to 8 wk and to elucidate their physicochemical and sensory characteristics. Commercial yogurt powder (CYP) was the control and yogurt-cultured milk powder (YCMP) was the treatment. Freeze-dried yogurt starter culture (*Lactobacillus bulgaricus* and *Streptococcus thermophilus* at ratio 1:1) was added to milk powder at 10^7 cfu/g on reconstitution. Microbial and physicochemical characteristics of the reconstituted CYP and YCMP were analyzed daily for the first week and then weekly for a period of 8 wk (at 1, 2, 3, 4, 5, 6, 7, 14, 21, 28, 35, 42, 49, and 56 d) after reconstitution. Three replications of each treatment were conducted. Sensory consumer testing of CYP and YCMP on reconstitution was conducted with 100 consumers of yogurt. Data were analyzed by PROC GLM of SAS. YCMP had 5 log cfu/ml higher counts of *Streptococcus thermopilus* compared to the control (CYP) at 56 d. Also, *Lactobacillus bulgaricus*-counts of YCMP at 28 d was 6.55 log cfu/ml and at 56 d was 5.35 log cfu/ml while the CYP at 28 d onward had no counts. YCMP also had significantly higher apparent viscosity, pH, appearance, sensory color, aroma, taste, thickness, overall liking, consumer acceptability and purchase intent compared to CYP. YCMP had better overall characteristics than CYP.

Key Words: yogurt, powder, reconsituted

0996 (M074) Impacts of different types of exopolysaccharides on the physical and rheological properties of yogurts. U. Pachekrepapol*[1], J. A. Lucey[2], and D. S. Horne[2], [1]*Dep. of Food Science, University of Wisconsin–Madison, Madison,* [2]*Wisconsin Center for Dairy Research, Madison.*

Exopolysaccharides (EPS) produced by some starter cultures are often used to modify yogurt texture. Our goal was to study the impact of different EPSs on yogurt properties. Reconstituted skim milk was inoculated with eight strains of *S. thermophilus*; ST1-UWM (non-EPS producer used as a control) and seven EPS producing strains. Due to the different acid producing ability of each strain, milks were supplemented with different amounts of peptone, and the inoculation rates were var-

ied to achieve a similar acidification rate for all strains. Milks were fermented at 40°C until pH 4.6 was reached. Small amplitude oscillatory rheology was performed to monitor yogurt gel formation. Gel permeability and whey separation were determined. Microstructure of the yogurt gels was studied using fluorescence microscopy. EPS from each strain were isolated for molar mass determination using size exclusion chromatography– multi-angle laser light scattering (SEC-MALLS), and for repeating unit structure determination using nuclear magnetic resonance spectroscopy (NMR-spectroscopy). Gelation pH of each yogurt was significantly different. The yogurt made from the control strain had significantly lower gelation pH (pH ~ 5.10) than yogurts made from EPS-producing strains (pH ~ 5.17 to 5.29). Storage modulus (G′) of the control gel at pH 4.6 (G′ ~ 97 Pa) was significantly lower than the other yogurts made from EPS-producers (G′ ~ 151 to 191 Pa) except the yogurt made from ST-143 strain (G′ ~ 67 Pa). Permeability and whey separation of each yogurt were significantly different with the control yogurt having higher permeability and whey separation than other yogurt gels. The microstructure of the control yogurt showed finer and smaller pore sizes compared to other gels. The yields of EPS produced from each strain varied between 34 and 95 mg dry material/L, with ST-143 being the highest EPS producer. The molar mass of the isolated EPS ranged from 0.13 X 10^6 to 1.74 X 10^6 g/mol. The structures of the repeating units showed that all EPS were different in terms of sugar compositions, linkages and conformations. Since all samples had similar milk composition, heat treatment, and rate of acidification, this study shows that EPS produced during yogurt fermentation modifies the gelation mechanism and physical properties of the yogurt gels.

Key Words: EPS, yogurt, rheology

0997 (M075) Substituting KCl for NaCl in fresh queso fresco. D. L. Van Hekken*[1], D. X. Ren[1,2], and M. H. Tunick[1], [1]*USDA, ARS, ERRC, Dairy & Functional Foods Research Unit, Wyndmoor, PA,* [2]*Institute of Dairy Science, College of Animal Science, Zhejiang University, Hangzhou, P.R., China.*

Reducing the sodium level in cheese is challenging when a signature salty flavor is expected, such as in high-moisture Queso Fresco (QF). Fresh starter-free QF was fine milled and dry salted at different levels of NaCl and KCl to obtain total NaCl levels of 1.5 to 2.0%. The treatments contained 1.5/0, 2.0/0, 1.0/0.5, 1.0/0.75, 1.0/1.0, and 1.5/0.5% NaCl/KCl. Texture profile analysis and small amplitude oscillatory shear analysis were conducted on d 7, and salt intensity levels were evaluated by trained sensory panelists at d 6. Texture profile analysis indicated that the QFs were similar in hardness (16.7 ± 1.8 N) with the 1.0/0.5 QF being the softest and similar in cohesiveness (0.17 ± 0.01) with the 1.5/0/5 QF being the least cohesive. Chewiness was highest in the 1.5/0 QF and lowest for the 1.5/0.5 QF (224 and 144 J, respectively). Increasing the total NaCl in the cheese increased the elastic and viscous moduli although the 1.5/0 QF was higher than the 1.0/0.5 QF and the 1.5/0.5 had the highest values. This suggested that the use of KCl may function differently in the matrix of QF, a weak body cheese that is expected to crumble easily. Five of the six QF had saltiness intensity scores 1.0 to 1.5; the 2.0/0 QF had a score of 2. Panelists selected 2 as the target saltiness for QF. The metallic off-flavor commonly associated with KCl was not an issue at levels used in this study. The replacement of NaCl with KCl in the ranges tested had only slight effects on the textural properties, did influence the viscoelastic properties, and did not match the saltiness intensity of NaCl.

Key Words: sodium, cheese, queso fresco

0998 (M076) Effect of potassium sorbate and sodium benzoate concentrations on growth of cheese starter cultures. D. Olson*, E. Gonzalez, M. Ponce, and K. J. Aryana*, Louisiana State University Agricultural Center, Baton Rouge.*

Potassium sorbate and sodium benzoate are commonly added to foods as antimicrobials. The objective was to determine if varying concentrations of potassium sorbate or sodium benzoate affect the growth of DVS R-604 cheese starter cultures at a 10^{-4} dilution in peptone and M17 broth containing 5% (w/v) lactose. Potassium sorbate and sodium benzoate concentrations used were 0% (control), 0.01%, 0.05%, 0.1%, 0.2%, 0.5%, and 1%. Counts on M17 agar containing 5% (w/v) lactose were performed immediately after inoculation of cheese starter culture and at 1, 2, 3, and 4 d of storage. Immediately after inoculation, concentration of potassium sorbate or sodium benzoate did not affect counts of cheese starter cultures in either peptone or M17 broth containing 5% (w/v) lactose. For cheese starter cultures grown in peptone, the counts after 1 d in the presence of 1% potassium sorbate or 1% sodium benzoate were lower than in the presence of the lower concentrations of these antimicrobials. Also, the decrease of these counts over 4 d of storage was greater in the presence of 0.5% and 1% potassium sorbate or sodium benzoate than in the presence of lower concentrations of these antimicrobials. For cheese starter cultures grown in M17 broth containing 5% (w/v) lactose, the counts increased between 100 and 1000-fold during the first d of storage after inoculation in the presence of potassium sorbate or sodium benzoate at concentrations of 0.2% or less. However, this increase was less than 100-fold in the presence of 0.5% and 1% potassium sorbate and 1% sodium benzoate. Between d 1 and 4 of storage, the counts in M17 broth containing 5% (w/v) lactose decreased between 10- to 100-fold in the presence of potassium sorbate or sodium benzoate at concentrations of 0.2% or less, but this decrease was smaller in the presence of 1% potassium sorbate. Concentrations of 0.5% and 1% potassium sorbate and sodium benzoate were more effective than lower concentrations for decreasing the counts of cheese starter cultures grown in

either peptone or M17 broth containing 5% (w/v) lactose, but this greater effectiveness was observed in different ways in peptone versus M17 broth containing 5% (w/v) lactose.

Key Words: cheese starter culture, potassium sorbate, sodium benzoate, growth.

0999 (M077) Influence of submicronization of sodium chloride on the sensory characteristics of surface salted cheese crackers. *M. Moncada*, C. Sabliov, C. Astete, and K. J. Aryana, Louisiana State University Agricultural Center, Baton Rouge.*

Reducing the particle size of sodium chloride crystal would increase its dissolution rate leading to a more efficient transfer of the ions to the taste buds and hence perhaps a saltier perception of foods. The objective was to evaluate the effect of developed submicro salt on the sensory characteristics of surface salted cheese crackers. The cheese cracker treatments consisted of three different salt sizes (regular, micro, submicro salt) and three different concentrations (2, 1.5 and 1% w/w). A Balanced Incomplete Block Design was used to conduct the consumer analysis of cheese crackers for submicro salt (2, 1.5 and 1%), microsalt (2, 1.5 and 1%) and regular 2% (control as used by industry) using 476 participants in total at wk 1 and 4 mo. At 4 mo, submicro salt treatments (2, 1.5, and 1%) resulted in having significantly ($P < 0.05$) more preferred saltiness scores compared to control (regular 2%). At 4 mo, submicro salt (1.5 and 2%) showed significantly ($P < 0.05$) more preferred just-about-right saltiness scores compared to control (regular 2%). The consumers purchase intent increased by 25% for the submicro salt 1.5% after they knew about the 25% reduction in sodium content of the cheese cracker. The reduction of 25 and 50% salt content in cheese cracker through use of submicro particulated salt did not adversely influence sensory color, aroma, crunchiness, overall liking and acceptability scores, which were the same compared to control (regular 2%) and microsalt treatments (2, 1.5, and 1%). Compared to the micro salt, the sub micro salt particle size was reduced 10 times and yet there was no increase in saltiness of crackers with submicro salt. This may be because instead of taking salt directly it was taken as a surface salting on a product containing protein, fat and other biomolecules which, masked the saltiness of the surface salted cheese crackers. Reduction in sodium chloride particle size by 10-fold may increase its surface area but not the saltiness of surface salted cheese crackers.

Key Words: submicronization, salt, cheese cracker

1000 (M078) Submicronization of sodium chloride and its effect on the physicochemical and microbiological characteristics of surface salted cheese crackers. M. Moncada*, C. Sabliov, C. Astete, and K. J. Aryana*, Louisiana State University Agricultural Center, Baton Rouge.*

Reducing particle size of salt to submicron range increases its surface area. The objective of this study was to develop submicro salt (sodium chloride) by using a nanospray drying method and using the developed submicro salt in surface salted cheese crackers and evaluating their physicochemical, and microbiological characteristics. The sodium chloride solution (3% w/w) was sprayed through the nozzle size of 4 μm with air flow of 125 l/min, pressure of 3800 Pa, head temperature of 95°C and spray percentage of 90%. The processing parameters were optimized to ensure formation of the smallest size submicrosalt, as measured by Scanning Electron Microscopy and Dynamic Light Scattering. The cheese cracker treatments consisted of three different salt sizes (regular, microsalt and submicrosalt) and three different concentrations (2, 1.5, and 1%). The 9 (three sizes x three concentrations) different cheese cracker treatments were tested for salt concentration and sodium content at wk 1. Water activity (A_w), yeast and mold counts, texture-fracturability, and color were determined at wk 1 and 4 mo of storage. Completely Randomized Design (CRD) was used for salt and sodium content and CRD with repeated measures was used for A_w, yeast and mold counts, texture-fracturability, and color. The 80% of the submicro particles produced by the nanospray dryer B-90 was between 500 nm to 1900 nm. Yeast counts and A_w in all treatments increased from 1 wk to 4 mo. Submicrosalt treatments (2, 1.5, and 1%) had positive effect in yeast reduction at 4 mo compared to regular salt (2, 1.5, and 1%). There was no mold growth in all treatments at all times. The L*, b*, C* and h* values in all treatments increased significantly ($P < 0.05$) from 1 wk to 4 mo. The sodium chloride micro and submicro particles maintained low counts in yeasts, no counts in molds and did not adversely influence quality attributes.

Key Words: submicro, salt, cheese cracker

1001 (M079) Influence of various health beneficial spices on some characteristics of yogurt culture bacteria and *Lactobacillus acidophilus* and sensory acceptability of spicy probiotic yogurt. *M*. Sánchez-Vega, and K. J. Aryana**, Louisiana State University Agricultural Center, Baton Rouge.*

Garlic and ginger have a beneficial influence on averting cardiovascular diseases. Onion and turmeric decrease the risk of diabetes and have anticancer properties. *Streptococcus thermophilus*, *Lactobacillus bulgaricus,* and *Lactobacillus acidophilus* are lactic acid bacteria that produce lactase and reduce the symptoms of lactose malabsorption. Earlier work has

shown the influence of spice extracts but the influence of pure spice juice on yogurt culture bacteria is not known. Characteristics of yogurt culture bacteria were measured by suspending freshly thawed cultures into 0.1% peptone water (growth), MRS-Thio broth with oxgall (bile tolerance) and skim milk (*P*rotease activity) with 1% (v/v) of freshly extracted spice juice. Fresh spices were obtained locally and spice juice was extracted using a juice extractor. Bile tolerance was measured by enumeration in presence of bile and protease activity was measured by a spectrophotometric assay. A probiotic blueberry yogurt was made that incorporated 0.05% of individual spice juice. Apparent viscosity of probiotic blueberry yogurt was measured using a viscometer with a helipath and Wingather 32 software. A T-C spindle was used at 20 rpm and 100 data points were acquired per sample. Physico-chemical characteristics of spicy probiotic yogurts containing the three bacterial cultures used were determined. Differences of least square means were used to determine significant differences at $P < 0.05$ for main effects and interaction effects. Consumer acceptability test was conducted using 100 consumers. A nine point scale was used to evaluate overall appearance, color, aroma, taste, texture and overall liking of the product. Results indicated that all spices except turmeric improved the bile tolerance of *L. bulgaricus*. Ginger, turmeric and onion had the best overall influence on the protease activity of *S. thermophilus*. Turmeric improved the protease activity of *L. bulgaricus*. Ginger and turmeric improved the protease activity of *L. acidophilus*. All four spices decreased the pH of the spicy yogurt, while garlic, ginger and turmeric increased the titratable acidity of the spicy yogurt. Onion and ginger increased the apparent viscosity of the spicy yogurt. The control yogurt obtained 80% acceptance and the ginger yogurt obtained 84% acceptance, and both of these yogurts obtained the highest intent of purchase. Ginger can be used in spicy yogurt manufacture for direct consumption while all four spices have potential for a new product line of yogurts for cooking, marinating and dips enabling potential health benefits from both spices and probiotic bacteria.

Key Words: spice, fermented, culture

1002 (M080) Yogurt characteristics as effected by added lactose. B. Mena, and K. J. Aryana*, *Louisiana State University Agricultural Center, Baton Rouge.*

Enrichment of yogurt with lactose addition may increase growth of the yogurt starter culture (*Streptococcus thermophilus* and *Lactobacillus delbrueckii* ssp. *bulgaricus*) and enhance yogurt physicochemical and sensory attributes. The objectives of this study were: to determine the influence of added lactose on 1) the growth of the yogurt starter culture during yogurt´s shelf life, 2) the physicochemical characteristics of yogurt during shelf life, 3) the final lactose content of yogurt during its shelf life, and 4) the sensory attributes of yogurt. Fat-free plain set-type yogurt was manufactured using 0, 1, 3, and 5% w/w added lactose to accomplish objectives 1, 2, and 3. For objective 4, a blueberry yogurt was manufactured using the same lactose levels. Analyses for plain set-type yogurt were done at 7 d intervals during 35 d of storage period. Three replications were conducted. Sensory evaluation was conducted by 100 consumers of yogurt on d 3 of its manufacture. Data were analyzed using PROC MIXED model of SAS 9.3 program. Significant differences between means were analyzed at $\alpha = 0.05$ using Tukey adjustment. Addition of lactose to yogurt at 5% w/w significantly increased growth of *Streptococcus thermophilus* ST-M5 but had no effect on growth of *Lactobacillus bulgaricus* LB-12. Lactose added at 5% w/w showed significantly the highest lactose content during entire storage period as expected, the lowest pH values, and also the highest syneresis values over storage period of 35 d. Lactose addition had no effect on appearance and color of blueberry yogurt. Samples containing added lactose showed significantly higher scores for taste, sourness and sweetness. Lactose added at 3 and 5% w/w had significantly the highest overall liking scores. Acceptability of yogurts and purchase intent markedly increased with the addition of lactose. Added lactose in yogurt manufacture favorably influenced some attributes of yogurt.

Key Words: added lactose, yogurt, probiotic properties, starter culture, lactic acid bacteria

---

1003 (M081) Influence of added lactose on some probiotic properties of yogurt culture bacteria. B. Mena, and K. J. Aryana*, *Louisiana State University Agricultural Center, Baton Rouge.*

Lactose is a source of energy for lactic acid bacteria in dairy fermented products. Acid tolerance and bile tolerance are important probiotic properties. The influence of lactose on acid tolerance and bile tolerance of yogurt culture bacteria is not known. The objective was to determine the influence of lactose on acid and bile tolerance of yogurt starter culture *Streptococcus thermophilus* ST-M5 and *Lactobacillus bulgaricus* LB-12. Acid tolerance was conducted on pure cultures of *S. thermophilus* in M17 broth at pH 2.00 and *L. bulgaricus* in MRS broth at pH 2.00 both at 30 min intervals for 2 h of incubation. Bile tolerance of pure cultures was determined using MRS-THIO broth with 0.3% oxgall for *L. bulgaricus* and MRS broth with 0.3% oxgall for *S. thermophilus*. Dilutions were plated every hr for 12 h. Three replications were conducted. Data were analyzed using PROC MIXED model of SAS 9.3 program. Significant differences between means were analyzed at $\alpha = 0.05$ using Tukey's adjustment. With use of lactose at 3 or 5% (w/v), the *Streptococcus thermophilus* ST-M5 had significantly higher acid tolerance than control at 120 min. In presence of lactose at 3 or 5% (w/v), the *Lactobacillus bulgaricus* LB-12 had significantly higher acid tolerance than control at 60, 90, and 120 min. Lactose, when used at 5% (w/v), significantly improved bile tolerance of *L. bulgaricus* compared to control. With use of lactose at 1%

(w/v), *S. thermophilus* had significantly higher bile tolerance compared to control at 2 h of incubation. Use of lactose at 5% (w/v), favorably influenced acid tolerance of *S. thermophilus* and the bile tolerances of *S. thermphilus* and *L. bulgaricus*.

Key Words: added lactose, acid tolerance, bile tolerance, starter culture

1004 (M082) Evaluation of the perten dough lab for production of imitation mozzarella cheese.

A. Kommineni[*1], S. Patel[1], A. C. Biswas[1], C. Marella[2], and L. Metzger[3], *[1]Dairy Science Dep., South Dakota State University, Brookings, [2]Dairy Science Dep., California Polytechnic State University, San Luis Obispo, [3]Midwest Dairy Foods Research Center, South Dakota State University, Brookings.*

The functional properties of imitation mozzarella cheeses (IMC) are influenced by the equipment and manufacturing procedure used to produce them. To test new formulations a pilot scale twin screw cooker with a batch size of 4.5kg is routinely utilized. However, in situations such as when experimental ingredients are being evaluated, a smaller batch size is desired. The Dough lab (Perten Instruments, Hagersten, Sweden) is a commercial twin screw heating and blending system that is used for dough rheology applications. As compared to a typical pilot scale twin screw cooker the dough lab has a batch size of 600 g. The objective of this study was to compare imitation mozzarella cheese (IMC) manufactured with the Perten dough lab (PDL) to IMC made with a pilot scale Blentech twin screw (BTS) cooker (cheese Therm cooker- Blentech Corporation, Santa Rosa, CA). Initially a typical control IMC was produced in the BTS cooker using a cook temperature of 90°C, a cook time of 4 min and 30s ec and at a stirring speed of 140 rpm. The same IMC formulation was then produced with the PDL using four different stirring speeds (75, 100, 115, and 125 rpm) at a cook time of 4 min and 50 sec and a cook temperature of 90°C. Of the IMCs made in PDL at four stirring speeds, the utilized 115 rpm had similar functional properties as compared to IMC made in the BTS. IMC was then manufactured in triplicate using the PDL operated at 115 rpm stirring speed and samples were analyzed for chemical (Fat, Protein and Moisture) and functional (Texture Profile Analysis (TPA)— Hardness, Melt and Stretch) properties. Method comparison statistics (mean comparison, graphical representation, repeatability) were used to evaluate the agreement between the two methods. The TPA-hardness, schreiber melt and stretch characteristics of the IMCs made with PDL were similar to the IMC produced in the BTS. The results indicate that the Pertain Dough Lab can be used to produce a 600-g batch of IMC that has functionality similar to IMC produced in a pilot scale twin screw cooker.

Key Words: dough lab, twin screw cooker, imitation cheese

1005 (M083) Genome analysis of two *Lactobacillus curvatus* strains that have emerged as dominant non-starter lactic acid bacteria in cheese.

C. J. Oberg[*1], T. S. Oberg[2], J. R. Broadbent[2], M. D. Culumber[1], D. J. McMahon[3], and J. L. Steele[4], *[1]Dep. of MIcrobiology, Weber State University, Ogden, UT, [2]Dep. of Nutrition, Dietetics, and Food Sciences, Western Dairy Center, Utah State University, Logan, [3]Western Dairy Center, Utah State University, Logan, [4]University of Wisconsin, Madison.*

Recent studies concerning cheese microbiology have revealed *Lactobacillus curvatus* becoming an increasingly common component of the non-starter lactic acid bacteria (NSLABs) population in aged cheddar cheese. We recently sequenced the genome of two *Lb. curvatus* strains, WSU1, isolated from aged cheddar cheese manufactured at Utah State University, and LFC-1, isolated from aged cheddar cheese manufactured at the University of Wisconsin–Madison. Whole-genome shotgun sequencing was performed on both isolates and assembled into draft genome sequences. Preliminary genome annotation was performed using the RAST algorithm (rast.nmpdr.org). Initial genetic comparisons between the predicted coding sequences of the two strains showed similar genome content with strain WSU01 having 312 unique predicted proteins, and LFC-1 having 297 unique proteins using a 90% amino acid identity threshold. Both strains have genes encoding enzymes for cellobiose utilization, and the ability to ferment ribose and N-acetylglucosamine. Although both strains have genes for lactose utilization, API sugar panel results showed that only LFC-1 fermented lactose. Further analysis showed that LFC-1 also has genes that encode enzymes for maltose and trehalose fermentation, along with genes for citrate utilization. To understand why *Lb. curvatus* has become a dominant NSLAB in cheddar cheese, genome sequences were analyzed to identify possible mechanisms. Both genomes contain genes for a putative sakacin-like bacteriocin and genes for a propanediol utilization pathway, which converts 1,2-propanediol to propanol and propionic acid. To test for propionate production, both strains were grown to carbohydrate exhaustion in MRS media (*P*H 5.2), after which 50 mM lactate was added. Cultures were incubated under strict anaerobic conditions for 22 d with samples taken after 0, 5, and 22 d and analyzed for propionate using GC–MS. Lactate concentrations were also measured using an enzymatic assay. Results revealed that both WSU1 and LFC-1 produce a fivefold increase in propionate after 22 d. Previous studies on propionate production in other lactic acid bacteria show that lactate was converted to 1,2-propanediol, but lactate in both WSU1 and LFC-1 did not show a decrease in concentration during incubation. This observation opens the possibility that in *Lb. curvatus*, 1,2-propanediol is produced by another pathway and warrants further investigation since high levels of propionic acid have been found in aged cheddar cheese where *Lb. curvatus* is a dominant NSLAB.

Key Words: NSLABs, cheese, genomes

1006 (M084) Use of a water-in-oil-in-water (w/o/w) double emulsion to simulate the full-fat cheese physical properties in a 30% reduced-fat cheese.

L. Liu*[1,2], D. Clayton[2], and D. J. McMahon[2], *[1]Key Laboratory of Dairy Science, Ministry of Education, Northeast Agricultural University, Harbin, China, [2]Western Dairy Center, Utah State University, Logan.*

Reduced-fat cheeses have greater hardness and elasticity than full-fat cheeses because of the reduction in number of fat particles that can interrupt long-range interaction within the casein protein matrix structure of cheese. Our objective was to produce a water-in-oil-in-water ($W_1/O/W_2$) double emulsion as the carrier for butterfat that, when used in the manufacture of cheese, would provide similar physical properties to a full-fat cheese but have 40% less fat. The $W_1/O/W_2$ emulsion was made by making a 1% (wt./vol.) solution of inulin in boiling 0.5% (wt./vol.) NaCl solution, and adding this solution in a 40:60 ratio into anhydrous milk fat (containing 8% (wt./wt.) polyglycerol polyricinoleate) at 50°C using low shear. This formed the primary W_1/O emulsion. The W_1/O emulsion was then mixed with high shear (5000 rpm for 1 min) in a 20:80 ratio with a 2% (wt./wt.) aqueous solution of whey protein concentrate to form the $W_1/O/W_2$ emulsion. A single oil-in-water emulsion was prepared as a control using milkfat emulsified into the whey protein solution and designated as O/W_2. Immediately after emulsion preparation, the control (O/W_2) and double ($W_1/O/W_2$) emulsions were added separately (in triplicate) into pasteurized skim milk at 31°C and then made into cheese FFCON and WOW32, respectively) using a standard procedure for full fat cheddar cheese. Mean (± SE) composition for FFCON cheeses was 354 (± 3) g/kg moisture, 333 (± 3) g/kg fat, 17.2 (± .5) g/kg salt and pH 5.37 (± .02), while for the WOW32 cheese it was 424 (± 6) g/kg moisture, 228 (± 2) g/kg fat, 17.6 (± 0.7) g/kg salt and pH 5.30 (± .02). Rheological properties (at 25°C) were analyzed after 1 mo of storage. Storage modulus (G') and loss modulus (G") for both cheeses were linear over the range of 10^{-3} to 10^{-1} percent strain. The WOW32 cheese was slightly softer ($P < 0.1$) than the FFCON cheese with mean G' between 0.1% and 0.01% strain of 112 kPa and G" of 33 kPa compared to G' and G" of the FFCON cheese of 177 and 52 kPa, respectively. This softening of the WOW32 cheese compared to the FFCON cheese was considered beneficial as normally a 30% fat reduction causes cheese to become firmer. We successfully produced a cheese with 30% less fat and similar (slightly softer) properties to a full fat cheese, with the extra moisture in the WOW32 cheese attributed to moisture coming from the W_1phase of the $W_1/O/W_2$ double emulsion.

Key Words: cheese reduced-fat emulsion

DAIRY FOODS: **TECHNICAL SESSION 2: ANALYTICAL / PROCESSING**

1007 (T065) Incidence of thermoduric bacteria and spores on selected Midwest dairy farms.

K. P. Buehner*[1], S. Anand[2], and A. D. Garcia[1], *[1]Dairy Science Dep., South Dakota State University, Brookings, [2]Midwest Dairy Foods Research Center, South Dakota State University, Brookings.*

Thermodurics can be present in milk even after pasteurization. The objectives of this study were to identify the origin and common species of heat-resistant bacteria occurring during summer and winter on Midwest dairy farms. Bulk tank milk samples were taken from 10 dairy farms along the South Dakota section of Interstate 29 with herd sizes ranging from 650 to 3500 lactating dairy cows. Milk samples were profiled for the prevalence of thermoduric bacteria (TDB) and spore counts (SC). In addition, corn silage samples and swabs of the milking clusters were taken at nine of the 10 dairies to profile the potential sources of TDB and SC. The samples were taken three times during winter (January to March) and summer (June to August), to track seasonal changes in the bacterial flora. During winter the average TDB counts in bulk tank milk were 2.61 log compared to 2.76 log TDB counts in summer. The SC was 1.03 log in winter, which is half the 2.06 log SC present in summer season ($P < 0.0001$). Corn silage sampled in winter contained 7.57 log TDB compared to an increased 10.77 log TDB during summer sampling. Concentrations of SC in corn silage reached an average of 6.3 log in winter compared to 11.81 log for summer ($P < 0.001$). The seasonal effect was evident with an increase in summer counts across the board for TDB and SC both, in the feed and bulk tank. *Bacillus licheniformis* was the predominant species identified in 62.4% of winter (85 total) and 49.4% of summer (83 total) samples. *Bacillus subtilis* made up 9.4% of the remaining winter isolates followed by *Bacillus sonorensis* at 8.2%, conversely, *B. sonorensis* made up 12% of summer isolates followed by *Bacillus pumilus* at 10.8%. *Bacillus licheniformis* is a ubiquitous microbe and was isolated from both TDB and sporeformer categories in all three sample types. There were larger increases in SC than TDB indicating summer conditions potentially increase the ability of sporeforming bacteria to proliferate over TDB. In conclusion, samples from bulk tank milk, milking cluster swabs, and corn silage at each of the 10 sites indicated *B. licheniformis* was the major contaminant regardless of season. In this experiment corn silage was determined as the major source of both TDB and SC over the milking clusters and relative to the levels in bulk tank milk showing significant higher concentrations in summer than winter.

Key Words: spores, thermoduric bacteria, corn silage, *Bacillus*

1009 (T067) Mechanisms and ways for improving heat stability of Micellar casein concentrates.

S. G. Sutariya*, H. G. Patel, and G. H. Meletharayil, *South Dakota State University, Brookings.*

Heat stability of proteins is the major hurdle in designing high protein containing heat stable foods and beverages with long shelf-life. Micellar casein concentrate (MCC) can be an ideal ingredient for such products. As MCC typically has > 90%w/w casein and is devoid of whey proteins, the mechanism of it's heat stability is expected to be different compared to milk powders and MPC. However, little is known about heat stability of MCC solutions, particularly at higher protein concentrates. The objective of the present study was to explore the mechanisms of heat stability of MCC and also investigate the effects of different additives on heat stability of MCC. Aliquot of MCC (12, 14, and 16% w/w protein) were prepared by diluting concentrated MCC retentate with glass distilled water. Experiments were designed with following treatments: 1) no treatment (control), 2) addition of sodium phosphate (SP) at 1, 5, 10, 25, 50 mML^{-1}, 3) addition of sodium citrate (SC) at 1, 5, 10, 25, and $50mML^{-1}$. The time required for visual precipitation or aggregation (generally referred as heat coagulation time (HCT) was measured using oil-bath at 140 and 120°C. The visual observations, calcium-ion activity and particle size were also measured. The HCT of control samples was 49 sec. The colloidal state of casein micelle, calcium activity and voluminosity of casein micelles seemed responsible for poor heat stability of MCC. Addition of SP. and SC at low level (1 mM) improved HCT by 15s compared to control samples., whereas their addition at 5, 10, and 25 mM exhibited significant improvement ($P < 0.05$) in heat stability at all protein concentration showing no aggregation when heated for more than 3 min at 140°C or 120°C. The color was also changed from opaque to translucent. However, increasing level of SP. and SC to 50 mM decreased both HCT and turbidity of samples. The addition of SP. and SC shifted the casein-mineral equilibria leading to decrease in free Ca-ion concentration as well as dissociation of colloidal calcium phosphate from casein micelle and increased negative charges of the casein micelle and hence increased repulsion, which contributed to increase in heat stability of MCC. The results of this study showed significant ($P < 0.05$) improvement in the heat stability of micellar casein concentrate using additives such as SP. and SC, which show promise to make shelf-stable MCC with higher protein content.

Key Words: micellar casein concentrate, heat stability, calcium chelators

1010 (T068) Influence of carboxymethylcellulose molecular weight on physicochemical properties and stability of whey protein-stabilized emulsions. S. Zhang*, and B. Vardhanabhuti, *University of Missouri, Columbia.*

Complexation of protein with polysaccharides at pH near the isoelectric point (*P*I) of protein has been widely used to improve the stability of oil-in-water emulsions. This is attributed to the fact that protein–polysaccharide complex formed a thick, dense and homogenous layer surrounding the droplets to prevent the flocculation. However, little is known about the effect of molecular properties of polysaccharides on emulsification properties of protein. The objective of this study is to assess the influence of carboxymethylcellulose (CMC) molecular weight on physicochemical properties and stability of whey protein-stabilized emulsions. Emulsions containing 5 wt% oil, 0.5 wt% protein and 0 to 0.5 wt% CMC (molecular weights of 270 k, 750 k, and 2500 kDa) were obtained by emulsification of oil with aqueous WPI–CMC solution at pH 7.0 through homogenization at 12,000 rpm for 1 min, followed by ultrasonic processing for 5 min. The emulsions were then slowly acidified to pH 5.2. Droplet size, zeta-potential, and rheological properties of emulsions were measured to characterize their physicochemical properties. Creaming index along with protein surface coverage were used to measure the stability of emulsions. In the absence of CMC, WPI emulsions were prone to flocculation. WPI–CMC emulsion showed improved stability, but was highly dependent on the molecular weight and concentrations of CMC. Addition of less than 0.1% CMC enhanced the adsorption of protein at the interface and increased the repulsion between droplets, resulting in more stable emulsions compared to WPI emulsions. Further addition of CMC did not change the surface coverage of protein, but increased the viscosity of the continuous aqueous phase, further contributing to the stability of emulsions. Emulsions with low molecular weight CMC showed much faster creaming rate than those with high molecular weight CMC during 15 d of storage. This is likely due to combined effects of higher protein surface coverage on the droplets and increased viscosity of the aqueous phase. The flow behavior of emulsions changed from shear-thinning to Newtonian and back to shearthinning, however, the concentrations where these changes occurred were dependent on the molecular weight of CMC. This study demonstrates that complexation of whey protein with high molecular weight CMC improves the surface properties of protein and enhances the repulsion between droplets, contributing to the stability of the emulsions. The outcomes could be applied to improve the stability of food emulsions having pH values near the pI of protein.

Key Words: CMC, molecular weight, emulsion

1011 (T069) Induction of pitting on stainless steel 304 and 316 by *Bacillus sporothermodurans*. S. Gupta[*1], and S. Anand[2], [1]*South Dakota State University, Brookings,* [2]*Midwest Dairy Foods Research Center, South Dakota State University, Brookings.*

Stainless steel (SS) undergoes corrosion in both polished and unpolished regions of dairy evaporators and dryers leading to product quality and economic concerns. The objective of this research was to investigate microbially induced corrosion (MIC) or pitting on SS 304 and 316 by a common milk contaminant; *Bacillus sporothermodurans*. These bacteria and their spores can persist on the SS milk contact surfaces in evaporators and dryers in the form of biofilms and may induce corrosion due microbial metabolic products such as enzymes, exopolymers, organic and inorganic acids and hydrogen sulfide. Many sulfate reducing bacteria (SRB) are active under oxygen stress and contribute to oxygen reduction reactions, thus influencing corrosion. In this study, polished and unpolished SS coupons (1'x1') of grades 304 and 306 were used to form biofilms of a dairy origin strain 10599 of *B. sporothermodurans* (Deutsche Sammlung von Mikroorganismen und Zellkulturen). This strain was found to exhibit sulfate reduction, as well as, proteolytic activities. About 10^7 cfu/mL of the overnight grown culture were inoculated in sterile 11% reconstituted non-fat dry milk (NFDM) in a Petri dish, in which sterile SS coupons were immersed. The incubation was performed at 30°C, being the optimum growth temperature of the culture. The suspension medium (NFDM) was replaced at regular intervals based on its pH drop to 5.0. bacterial counts from the spent media were taken at weekly intervals, while the biofilm counts were taken after every 2 wk to monitor the culture viability. The data were statistically analyzed to compare means. The counts in spent media and biofilms ranged from 10^5–10^6 cfu/mL and 10^2–10^4 cfu/cm^2, respectively. The coupons were examined using scanning electron microscope (SEM) for any corrosion or pit formation. Energy dispersive x-ray spectroscopy (EDS) was used to find the elemental composition of the control SS surface and was compared with that of the pits. From SEM observations and EDS data, it was established that pitting of surfaces for both grades of SS with biofilms got induced from wk 4 onward. These pits were distinct for the two grades; some pits were deep, while others were on the surface with corrosion products deposited over them. Elemental increase in sulphur and oxygen on the pit surfaces further confirmed the induction of corrosion. In conclusion, the biofilms of *Bacillus sporothermodurans* induced corrosion on the surface of stainless steel of both grades.

Key Words: corrosion, *Bacillus,* stainless steel, pitting

1012 (T070) Protective effect of lactic acid bacteria against H_2O_2–induced oxidative stress in Caco-2 cells. S. Liu[1], C. Man[2,3], X. Peng[1], W. Zhou[1], M. Guo[*4], and Y. Jiang[1,2,3], *[1]Dep. of Food Science, Northeast Agricultural University, Harbin, China, [2]Synergetic Innovation Center of Food Safety and Nutrition, Harbin, China, [3]National Dairy Engineering and Technology Research Center, Northeast Agricultural University, Harbin, China, [4]University of Vermont, Burlington.*

Oxidative stress can be defined as an imbalance between production of free oxygen radicals and reactive oxygen metabolism or repair the organism damage. A number of studies indicate that lactic acid bacteria (LAB) possess antioxidant activity due to their ability to regulate the activity of antioxidant enzymes during the cell metabolizing. The objective of this study was to establish a model of oxidative stress in human colon carcinoma cell line, Caco-2 cells, and to compare the protective effect of *Lactobacillus plantarum* NDC75017, *L. plantarum* ATCC14917 and *L. acidophilus* NCFM against hydrogen peroxide (H_2O_2)-induced oxidative stress in Caco-2 cells. The Caco-2 cells were divided into five groups: control group; oxidative stress group; *L. plantarum* NDC75017-protected group; *L. plantarum* ATCC14917-protected group and *L. acidophilus* NCFM-protected group. Caco-2 cells were exposed to 500 μM H_2O_2 in FBS-free DMEM for 30 min to induce oxidative stress, and then the three protection groups were respectively treated with 1×10^7 cfu/ml *L. plantarum* NDC75017, *L. plantarum* ATCC14917 and *L. acidophilus* NCFM suspended in FBS-free DMEM. After 4 h of incubation, the activity of intracellular antioxidant enzymes was measured. Superoxide dismutase (SOD) and catalase (CAT) activity were measured with the commercial kits based on colorimetric method, and the colorimetric reactions were determined at 450 nm and 405 nm, respectively. The data showed that CAT activity increased by 81% in oxidative stress group compared with control group, however no significant difference was observed in CAT activity between oxidative stress group and protection groups. SOD activity decreased by 33% in oxidative stress group compared with control group. All the three strains of the protection groups provided protection ($P < 0.05$) against H_2O_2–induced SOD activity reduction in different degrees, in which *L. plantarum* NDC75017-protected group showed the most significant increase in SOD activity by 44%. The results revealed that when the Caco-2 cell was suffering oxidative stress, the activity of intracellular antioxidant enzymes such as SOD and CAT would increase substantially. Some strains of LAB have positive effects on relieving oxidative stress and regulating intracellular antioxidant enzymes activity. Particularly *L. plantarum* NDC75017, which was isolated from traditional yogurt in Inner Mongolia of China, provided the greatest protection against H_2O_2–induced SOD activity reduction of the three strains, may have potential applications for use in the food industry. *This work was supported by National Science and Technology Project (2011AA100902).*

Key Words: oxidative stress, antioxidant enzyme, lactic acid bacteria

1013 (T071) fatty acid composition of cultured butter with probiotic *Lbc. acidophilus* La-5 produced in winter time. O. Tsisaryk[*1], L. Musiy[1], O. Golubets[2], and S. Shkaruba[2], *[1]Lviv National University of Veterinary Medicine and Biotechnologies, Ukraine, [2]Ukrmetrstandart, Kyiv, Ukraine.*

The objective of our study was to determine the fatty acid composition of sweet butter (SB) and cultured butter (CB) after *Lbc. acidophilus* was added to the starter. Control butter was churned from sweet cream (SB). Starters Flora Danica (*Lac. lactis, Lac. cremoris, Leu. cremoris, Lac. diacetilactis and Lbc. acidophilus La-5*), provided by Chr. Hansen, were used. Four groups of CB were produced: group 1, cream fermented at 30°C for 6 h by Flora Danica (CB1), 1:1 Flora Danica and La-5 (CB2) and La-5 (CB3); group 2, cream fermented at 37°C for 6 h by Flora Danica (CB4), 1:1 Flora Danica and La-5 (CB5) and La-5 (CB6); group 3 (Alnarps Winter method), left for 2 h at 8°Ñ, heated up to 20°Ñ and starter Flora Danica (CB7), 1:1 Flora Danica and La-5 (CB8) and La-5 (CB9) were added and fermented for 8 h, then cooled down to 12°Ñ and left for 10 h; group 4, starter Flora Danica (CB10), 1:1 Flora Danica and La-5 (CB11) and La-5 (CB12) were added to the butter grain. The experiment was replicated three times. Butter samples were stored at 20°C before the fatty acid analysis by GLC. The FAME were separated in a chromatography column (Hewlett-Packard 6890, 100 m × 0,25 mm × 0,2 μm [HP-88] 88%-cyanopropyl aryl-polysilixane, Agilent Technologies). The total content of the trans-9 isomers was 1.22 g in SB, whereas in CB2 the value was the lowest, i.e., 1.02 g/100 g of fatty acids. The total content of trans-11 isomers was the highest in CB2 (7.92 g/100 g) vs. 7.56 g/100 g of fatty acids in the SB ($P < 0.05$). Trans-11 C18:1 content increased from 5.19 in SB to 5.28–5.41% in the CB, the highest value observed for CB2 ($P < 0.05$). The percentage of cis-9,trans-11 CLA was the highest for CB2, CB5, CB6, CB8, when Flora Danica was combined with La-5, and for pure La-5 at 37°C (the optimal inoculation temperature for this strain). The total percentage of unpaired and branched-chain fatty acids was the same for all samples, but the percentage of medium-chain saturated fatty acids (C12-C16) slightly decreased from 37.34% in the SB to 37.0% in CB7 and CB9. CB1 and CB2 possessed the best taste, flavour and texture. Thus, adding La-5 into starter for cultured butter stimulates the 11-trans isomerisation of fatty acid and provides probiotic properties of cultured butter.

Key Words: butter, cultured butter, La-5, fatty acid

1014 (T072) Development of dairy products enriched with healthy lipids. J. Moats[*1,2], M. Epp[2], and D. Christensen[2], *[1]O&T Farms Ltd., Regina, SK, Canada, [2]University of Saskatchewan, Saskatoon, Canada.*

This study investigated the effects of feeding an extruded flaxseed product to dairy cattle on the fatty acid profile and sensory attributes of milk and Havarti cheese. The health benefits associate with certain lipids such as n-3 PUFA have been well documented. However, increasing the availability of these nutrients in dairy products for human consumption remains a challenge due to rumen biohydrogenation. Finding a mechanism for improving the fatty acid profile of dairy products without compromising sensory attributes would prove beneficial to the North American consumer. The hypothesis was: Feeding an extruded flaxseed product to dairy cattle would improve the fatty acid profile of milk and Havarti cheese without compromising sensory attributes. The objectives were: 1) to produce milk with elevated levels of n-3 through dietary means, 2) to produce Havarti cheese from control and n-3 milk, and 3) to evaluate the fatty acid profiles and sensory attributes of the milk and cheese. Six Holstein cows were offered a control diet followed by a treatment diet supplemented with an extruded flaxseed product with 70% flaxseed (LinPRO-R70) at 9% of TMR DM for 28 d. After the 28 d, milk samples were collected for compositional, fatty acid, and sensory analysis. Bulk milk samples were also collected and used to make Havarti cheese. Milk analysis showed a significant difference ($P < 0.01$) in total n-3 in the n-3 milk (1.25% FAME) compared to control milk (0.67% FAME). In a blind triangle test, sensory panelists were unable to identify source of milk indicating they were unable to detect any sensory differences between the control milk and the n-3 milk ($P < 0.01$). After 30 d of ripening, Havarti cheese was sampled for compositional, fatty acid, and sensory analysis. A significant difference in total n-3 ($P < 0.01$) was observed when comparing the n-3 cheese to control cheese. Cheese sensory results indicate that there were no differences in taste, texture or overall acceptability of the n-3 cheese compared to the control cheese. This trial suggests that including extruded flaxseed in the ration of dairy cattle may provide an opportunity for development and marketing of n-3 enriched dairy products.

Key Words: n-3, cheese, extruded flaxseed

1015 (T073) Evaluation of dulce de leche produced with different starches. F. Silva[1], H. Ferreira[2], M. Pinto[3], R. Stephani[2], A. Carvalho[*1], and Perrone[1], *[1]Federal University of Viçosa, Brazil, [2]Gemacom Tech, Juiz de Fora, Brazil, [3]Fedarl University of Viçosa, Brazil.*

Dulce de leche is technologically framed as preserved milk by evaporation and adding sugar. It usually presents creamy or pasty consistency, homogeneous texture, no lumps or flakes, bright caramel brown color, obtained by Maillard reactions and caramelization, peculiar aroma, and distinctive flavor, not too sweet or cloying. It presents good solubility in the mouth, and no perceptible sensory crystals. Starch is one of the main optional ingredients and can be used in its native form or modified. It can contribute to improve consistency and yield due to water retention, or assist in lactose crystallization control, by reducing the perceived appearing of crystals. The aim of this study was to evaluate the composition and properties of dulce de leche obtained with different types of modified starches, added in different concentrations of soluble solids during manufacturing. In this work, formulations of dulce de leche were prepared with different values of soluble solids concentration (39, 48, and 56°Brix). Yield, color, physicochemical composition, texture, crystal formation and sensory evaluation of dulce de leche were evaluated. Starch configures an important optional ingredient to production of dulce de leche, since increase shelf life without changes in texture, composition and yield characteristics of the product. Analysis revealed that the addition of starch reduced the formation of lactose crystals sensorially perceptible in almost all replications over the storage period. Further, dulce de leche with starch presented a good sensory acceptability among the analyzed attributes (color, texture, flavor and overall impression) and only significant difference ($P < 0.01$) was found for color. This was expected as the processes of the Maillard reaction and caramelization are associated with the dimming of the sweet, these reactions are less intense in this treatment.

Key Words: dulce de leche, starch, technology

1016 (T074) Rheological behaviors of edible casein-based packaging films under extreme environmental conditions, using humidity-controlled dynamic mechanical analysis. S. Akkurt[1], L. M. Bonnaillie[2], H. Zhang[1], and P. M. Tomasula[*2], *[1]Rutgers University, Dep. of Food Science, New Brunswick, NJ, [2]Dairy & Functional Foods Research Unit, Eastern Regional Research Center, Agricultural Research Service, USDA, Wyndmoor, PA.*

Thin casein films for food packaging applications possess good strength and low oxygen permeability but low water-resistance and elasticity. Customizing the mechanical properties of the films to target specific behaviors depending on temperature and humidity changes would enable a variety of commercial applications for casein-based films. The mechanical properties of edible films are vitally important to determine possible uses, such as replacement for plastic films. Dynamic mechanical analyses under controlled humidity (DMA-RH) can supply useful information about the mechanical properties and network-structure of hydrophilic protein films, including the storage modulus (E'), loss modulus (E"), deformation (swelling and shrinkage), damping behavior (tan-δ), as well as various transition temperatures and humidities. The dynamic

mechanical properties of solvent-cast (15% solids) calcium-caseinate/glycerol films (CaCas:Gly ratio 3:1) were fully characterized on a broad range of temperature (T = 5–90°C) and humidity (RH = 0–80%) using DMA-RH technology to study behaviors under normal or extreme environmental conditions. Citric pectin (CP, 0.05 to 1 wt.%) was then incorporated into CaCas films as a crosslinker using three different formulations (A, F, G) to examine CP effects on the properties and macrostructure of CaCas/Gly/CP films, and improve the stability of CaCas film under high humidity or temperature. The mechanical properties of casein films were extremely sensitive to formulation, CP content, T and RH, and DMA-RH technology proved a precise and effective tool to characterize composition/properties trends and point out various transition temperatures during T-ramps at 50% RH, and "transition humidities" during RH-ramps at 20°C. Transition-T and RH were considered to correspond to different critical points at which sufficient plasticization with water and/or heat triggered various rearrangements of the CP/protein/water network, until ultimate film-failure at the "melting point." DMA-RH enabled to precisely characterize shifts in E', E'' and tan-δ, as well as shifts in the various transition-T and transition-RH caused by different formulations or increased CP contents. Generally, the addition of CP improved the environmental stability of CaCas films: after addition of 1% CP, the melting-T increased from ~40°C to ~60°C, and the "melting-RH" from ~58% to ~67%, depending on formulation. F films showed the most drastic improvement with increased CP content, while G films appeared stronger and generally more T- and RH-stable at all CP contents. Improving the strength and environmental stability of casein-based films will broaden their possible range of application, such as use in edible food packaging.

Key Words: calcium caseinate, thin films, DMA

1017 (T075) Evaluation of a laboratory-scale batch crystallizer for lactose isolation from deproteinized whey. S. Beckman*, S. Anand, and L. Metzger, *Midwest Dairy Foods Research Center, South Dakota State University, Brookings.*

Accurate replication of industrial-scale lactose crystallizations on a laboratory-scale apparatus has been a challenge for researchers wanting to improve lactose yield from dairy streams. The objective of this experiment was to develop a repeatable method for lab-scale batch crystallization of lactose from concentrated deproteinized whey (DPW). Commercial DPW powder was reconstituted to 60% total solids (wt/wt) in 80°C distilled water and held with agitation for 15 min for complete solubilization of lactose. The 80°C reconstituted DPW solution was immersed in an ice water bath to rapidly (15 min) cool to 50°C. Once the temperature reached 50°C, seed crystals were added (0.027 g per 100 g solution) to the DPW solution, mixed thoroughly, and held at 50°C with agitation for 1 h. After 1 h at 50°C, the solution was split into two portions by weight, and poured into lab-scale crystallizers. The crystallization apparatus consisted of a glass beaker with a PTFE magnetic stirrer and vanes for agitation. Stirring rate was maintained at 100 rpm throughout the cooling profile. The immersed crystallizer temperature was maintained by immersing a coil attached to a recirculation water bath into the bath surrounding the crystallizer. Crystallizers were cooled from 50 to 20°C at a rate of -0.130 ± 0.007°C per min. At the end of crystallization, the crystallizer was decanted and crystals were harvested from the bottom of the beaker for analysis. Recovered lactose crystals were observed microscopically (40×) to determine mean crystal size. Micrographs of lactose crystals were analyzed using image analysis software provided by the manufacturer of the microscope. A minimum of 10 crystals from each micrograph were measured for height, recorded as the length (μm) of the longest side, and duplicate micrographs were analyzed to improve accuracy. Three crystallizations were performed using the same lot of DPW reconstituted to 60% total solids. Results indicated that mean lactose crystal length obtained using this method were 21.36 ± 7.42 μm, with some larger (> 90 μm) crystals present in low numbers. Many small (< 10 μm) crystals were observed (not enumerated), which indicates the presence of secondary nucleation during cooling. The crystal sizes obtained using this method were small compared to what is encountered in industry. Small crystals would be easily lost during subsequent refining steps, decreasing yield. An optimized cooling profile, agitation speed during cooling, and crystal isolation scheme should be considered for future developments of this method.

Key Words: lactose, crystallization, lab-scale

1018 (T076) Dispersibility, suspension ability, solubility, and gelation properties of rehydrated frozen highly concentrated micellar casein. Y. Lu[1], D. J. McMahon[*1], and L. Metzger[2], [1]*Western Dairy Center, Utah State University, Logan,* [2]*Midwest Dairy Foods Research Center, South Dakota State University, Brookings.*

Highly concentrated micellar casein (HCMC), a potential ingredient of protein fortified food, is a gel at cold temperature containing ~20% casein with whey proteins and lactose removed by microfiltration (and diafiltration) of skim milk. Dispersibility, suspension ability, solubility, and gelation properties of rehydrated frozen HCMC were characterized. Thawed HCMC was reconstituted to 3% protein with water or trisodium citrate buffer and adjusted to pH 7 then mixed using 1 min of high shear (7500 rpm) at 4, 12, 20, and 50°C, or 30 min of low shear (800 rpm) at 4, 20, and 50°C, followed by 18 h storage at 4°C. Dispersibility was defined as percentage by dry weight of HCMC that did not pass through a 250-μm sieve. Material that was 100% dispersible was centrifuged for 5 min and tested for suspension ability (using 80 *g*) and solubility (using 20,000 *g*). Protein in the supernatant was measured and

suspension ability and solubility calculated as percent protein that was not sedimented during centrifugation. The HCMC was also rehydrated with cream to obtain casein-to-fat ratio of 0.8 with casein levels from 9.3% to 12.5%, adjusted to pH 7.0, then stirred at 800 rpm for 30 min at 50°C, Gel modulus (G', G'') was measured at 50°C followed by cooling at 1°C/min to 5°C. At temperatures $\leq$ 20°C, HCMC was only partially dispersible in water (e.g., 60% dispersibility using high shear at 4°C), while at 50°C it was 100% dispersible. Mixing at $\leq$ 20°C followed by overnight hydration at 4°C also produced 100% dispersibility. Suspension ability at 50°C was ~90%, while mixing HCMC at $\leq$ 20°C followed by overnight hydration yielded only 50 to 60% suspension ability. Solubility followed a similar trend with HCMC having ~85% solubility at 50°C and only ~30% solubility at $\leq$ 20°C. Mixing HCMC in 60 mM trisodium citrate increased dispersibility, suspension ability and solubility of HCMC at 4°C to 97, 75, and 75%, respectively. Gelation temperature of the HCMC-cream mixture, defined as temperature at which G' = G'' was positively correlated (R^2 = 0.71) with casein level. Gelation occurred at ~35, ~25 and ~15°C with 12.5, 10.5, and 9.5% casein, respectively. This process was reversible with a hysteresis effect observed depending on whether the mixture was being heated or cooled. With a 10.5% casein HCMC-cream mixture exhibiting G' at 15°C of 30 Pa during cooling and 160 Pa during warming.

Key Words: casein, microfiltration, gelation

1019 (W073) Interaction of bovine and caprine milk α-caseins with tea polyphenols.
A. Mora-Gutierrez*, and R. Attaie, *Prairie View A&M University, Prairie View, TX.*

Tea (*Camellia sinensis*) is one of the most commonly consumed beverages. The anticarcinogenic properties of the many phenolic compounds of tea, including catechins, have been shown to inhibit tumor formation in rats. The anticarcinogenic properties of these phenolic compounds have been attributed to their antioxidant activity. However, the antioxidant activity of tea polyphenols may be affected when adding milk to tea. In this work, 7.6 mg/L bovine or caprine milk α-casein and 7.7 μM tea polyphenols (catechin, epicatechin, epicatechingallate, epigallocatechingallate, epigallocatechin and theaflavin) were added to an emulsion of linoleic acid (40 mM) prepared using a borate buffer (0.1 M, pH 8.5) and containing 0.1 M of sodium dodecyl sulfate. Interaction of bovine and caprine milk α-caseins with tea polyphenols in sodium dodecyl sulfate micelles was studied by a lipid peroxidation method. It was found that the antioxidant activities of the smaller catechins (catechin, epicatechin and epigallotocatechin) were higher in the presence of bovine and caprine milk α-caseins. The antioxidant capacity of epigallocatechin was greatly enhanced ($P < 0.05$) by milk α-casein (21.3% by bovine milk α-casein and 25.2% by caprine milk α-casein). The larger and bulkier polyphenols from tea (epicatechingallate, epigallocatechingallate, and theaflavin) did not significantly increase ($P < 0.05$) the lipids protecting effect. These results suggest that bovine and caprine milk α-caseins have the potentials to be used as natural ingredients to increase the antioxidant activity of tea polyphenols.

Key Words: bovine and caprine milks, α-casein, antioxidant activity, tea polyphenols

1020 (W074) Comparison of Jersey And Holstein-Friesian milk composition and coagulation properties.
J. H. Bland*, C. C. Fagan, and A. S. Grandison, *University of Reading, UK.*

Holstein-Frisian milk is increasingly blended with Jersey milk by cheesemakers to improve cheese yield. However, to date, no study has investigated the impact of blending on milk composition and properties. The objective of this study was to compare the composition and milk coagulation properties of Jersey and Holstein-Friesian milk produced in the United Kingdom. In addition, the effect of blending the two types of milk at different ratios (0 to 100% Jersey milk in Holstein-Friesian at 10% intervals), was evaluated. This knowledge could assist cheesemakers in optimising the blending process. Raw bulk milk composition from both breeds was measured every 3 mo over a year ($n = 55$). Significant variations in fat, protein, fat to protein ratio, casein, casein to protein ratio, fat globule size (D(4.3), D(0.5) and span), casein micelle size and titratable acidity were observed ($P < 0.05$). However, no significant difference in lactose, urea, somatic cell count, calcium ions, fat globule surface area mean particles D(3.2) and pH were seen. Blending the milks resulted in a linear trend for all significant variables with the exception of the fat globule volume mean diameter D(4.3) and casein micelle size which followed a quadratic trend ($P < 0.05$), which is believed to be due to change in the mineral balance. Coagulation properties were measured using a C-VOR controlled stress rheometer using raw milk at natural pH. Rennet Coagulation Time (RCT) (min) was defined as at the time at which a firmness of 0.5 Pa was attained, Curd Firmness (CF) (Pa) was taken 10 min after coagulation and Curd Firming Rate (CFR) (Pa min^{-1}) was calculated from the time for the gel to firm from 0.5 Pa to 2 Pa. Mean RCT of Holstein-Friesian was 58.7 min compared to 24.0 min for Jersey milk ($P < 0.001$). CF was 2.01Pa compared to 12.50 Pa and CFR 0.14 Pa min^{-1} compared to 0.49 Pa min^{-1} respectively ($P < 0.001$). CFR increased linearly with increase percentage of Jersey milk ($R^2 = 0.940$, $P = 0.003$) whereas RCT and CF followed a quadratic trend with increased percentage of Jersey milk ($R^2 = 0.9903$, $P = 0.007$ and $R^2 = 0.9965$, $P = 0.001$, respectively). This could be linked to the nonlinear trend found in fat globule volume mean diameter D(4.3) and casein micelle size. This study demonstrates that Jersey milk composition and coagulation properties are more suited for cheese making than Holstein-Friesian and additionally indicated that blending the two milk types gave beneficial synergistic effects for cheese.

Key Words: milk composition, milk coagulation, breed

1021 (W075) Light exposure affects milk acceptability and emotional response of college students.
A. M. Walsh, H. Potts*, and S. Duncan, *Virginia Tech, Blacksburg.*

Off flavors in fluid milk result from light exposure due to poor light-blocking characteristics of packaging materials. Even short periods of light exposure cause light-induced oxidation leading to noticeable differences in flavor. There is no direct evidence that light-induced oxidation affects milk acceptability. In this study, effects of fluorescent light exposure (2000 lux) on fluid 2% milk for periods of 8 and 168 h (7 d; 4°C) were determined on oxidative stability of milk, consumer acceptability of the product, and the resulting emotional response from the sensory experience. Oxidative stability was measured by thiobarbituric reactive substances (TBARS) and riboflavin (Rb) assays. Consumer ($n = 53$) acceptability of the product was reduced, as measured with a 9-point hedonic scale and a check-all-that-apply emotional response scorecard. TBARS assays showed significant in-

creases in oxidation by-products by 168 h (P = 0.006). Rb decreased significantly, with 71% loss by 168 h. Although there was no significant chemical evidence of oxidation by 8 h of light exposure, hedonic scores decreased significantly from 7.20 (like moderately) to 5.85 (below like slightly) (P = 0.008). Acceptability decreased severely by 168 h of light exposure (P = 2.15 E-10) with light-exposed milk scoring only a 3.46 (between dislike moderately to dislike slightly). Light-protected milk maintained a score of 7.0 over the 7 d of refrigerated storage. Emotion term selection reflected the acceptability change; across all milk samples the terms calm, content, good and satisfied were shared ($\geq$ 20% frequency of the term used and < 8% difference in percent frequency between samples compared). Unique terms for 'liked' samples (hedonic score: 6 to 9) included friendly, good-natured, happy, interested, peaceful, pleasant, pleased, quiet, safe, warm, and whole. However, 'disliked' samples (hedonic score: 1 to 4; mostly light-exposed milk samples) exclusively shared the term disgusted. Milk that is protected from light maintains a high quality flavor with positive emotional responses whereas the influence of light degradation causes negative sensory and emotional responses. The emotional and flavor acceptability of milk is particularly important in the 18- to 25-yr-old population focused on in this study. This population is establishing independent selection, purchasing habits, and consumption of products that influence future health and well-being. In the tested population, only 24% reported consuming any milk (whole, 2%, 1%, skim) more than once daily. The selection of milk packaging that protects milk nutrients and flavor quality is important consideration for increasing milk consumption.

Key Words: milk, emotion, oxidation

1022 (W076) Fatty acid compositions of low-fat goat milk ice creams formulated with commercial ice cream mix and 3 different levels of caprine milk fat. C. E. McGhee, B. P. Gupta*, and Y. W. Park, *Fort Valley State University, Fort Valley, GA.*

Low-fat ice cream has been a popular frozen dairy food among the consumers due mainly to health concerns. However, scientific research on nutritional quality of caprine milk ice cream has been very scarce. The objective of this study was to determine fatty acid compositions of three types of low-fat goat milk ice creams. Three batches of three different low-fat caprine milk ice creams were manufactured using skim (0.46%; SIC), 2.0% (2IC) and whole (3.65%; WIC) goat milk by addition of a commercial ice cream mix (0.25% fat) in fluid goat milk. The soft-serve goat ice creams were made using Sani Serv ice cream machine (A5223P, Mooresville, IN), and all experimental fresh ice creams were stored at -18°C in a freezer for 0, 2, 4, and 8 wk. Fatty acids compositions of all experimental ice cream samples were analyzed using a GC–MS (Thermo Electronic TRACE GC Ultra, Austin, TX) equipped with an automatic sampler (Thermo Electronic AS-3000) and a fused silica capillary column (0.25 mm i.d. x 0.25μm × 60 m; SP-2380 Supelco, Bellefonte, PA). The results showed that concentrations of fatty acids C4:0, C6:0, C8:0, C12:0, C14:0, C16:0, C16:1, C18:0, C18:1, C18:3, C24:0 in the ice creams were significantly (P < 0.05 or 0.01) affected by the three different levels of fat treatments, while those of C10:0, C14:1, C18:2, C20:0, C22:0 acids were not influenced by the fat treatment. The C12:0, C16:0 and C18:1 acids were the most abundant fatty acids in the experimental goat ice creams, while C12:0 (lauric acid) revealed the highest concentration among all 16 fatty acids. There were no differences in levels of individual fatty acid between storage periods, where the same trend of storage effect occurred in all 16 fatty acids. The fat level x storage interaction effects were also not significant on fatty acid contents of all three goat ice creams. It was concluded that the highest content of lauric acid among all fatty acids was probably due to the existence of coconut oil in the commercial ice cream mix, which was used in the manufacture of goat milk ice creams in this study.

Key Words: goat milk, ice cream, fatty acids

1023 (W077) Application of non-nutritive natural sweeteners to skim chocolate milk. *X*. E. Li*, K. Lopetcharat, and M. Drake, *Southeast Dairy Foods Research Center, NCSU, Raleigh, NC.*

The additional sugar content of chocolate milk has raised health concerns, and artificial non-nutritive sweeteners have been used to reduce sugar and calories. However, artificial sweeteners lack appeal to parents for purchase of chocolate milk for their children. Natural non-nutritive sweeteners may be viable alternatives to sweeten chocolate milk. The objective of this study was to evaluate stevia or monk fruit extract as the sole or partial sweetener source for skim chocolate milk. Magnitude estimation scaling (MES) with 14 trained panelists was used to create power function curves for the sweet taste of stevia and monk fruit extract in water and skim chocolate milk. The iso-sweetness of 150 mM sucrose chocolate milk, the lowest acceptable sweetness level for young adult consumers in a previous study, from stevia or monk fruit extract were calculated and confirmed by a 2-alternative forced choice (AFC) test with 25 panelists. Due to other taste and flavor attributes of the two natural non-nutritive sweeteners, iso-sweetness from a mixture of sucrose and natural non-nutritive sweetener were also investigated. Chocolate milks (sweetened with sucrose, stevia, monk fruit, stevia:sucrose blend, or monk fruit:sucrose blend) were manufactured and evaluated by young adult consumers (n = 120) for overall and sweet taste liking. Chocolate milks that were sweetened by natural non-nutritive sweeteners alone received lower liking scores compared to chocolate milks sweetened by sucrose or sucrose:non-nutritive sweetener blends (P < 0.05). The results demonstrate that natural non-nutritive sweeteners can be successfully applied in choco-

late milks with no change in liking from sucrose when applied as blends replacing up to 50% of sucrose.

Key Words: chocolate milk, flavor, sugar reduction

1024 (W078) Cross-linking of milk proteins can reduce its susceptibility to plasmin-induced hydrolysis.

H. Bhatt*[1,2], A. Cucheval[2], C. Coker[2], H. G. Patel[3], A. Carr[1], and R. Bennett[1], *[1]Massey University, Palmerston North, New Zealand, [2]Fonterra Research & Development Centre, Palmerston North, New Zealand, [3]South Dakota State University, Brookings.*

Plasmin-induced proteolysis is a major problem in milk and dairy beverages and must be controlled, as it leads to flavor (bitterness) and texture (gelation, sedimentation) defects. Plasmin cleaves proteins at the carboxyl site of lysine-X and arginine-X bonds with a preference for the lysine-X bond. We therefore hypothesized that cross-linking of milk proteins and modification of lysine residues through transglutamination and the Maillard reaction would reduce the susceptibility of milk proteins to the action of plasmin. Lysine residues on the β-casein backbone were cross-linked with glutamyl residues to different extents by transglutamination and lysine-sugar-lysine cross-linking was achieved through the Maillard reaction. The modified systems were then hydrolyzed by plasmin. The extents of cross-linking and the hydrolysis reaction were monitored by quantifying the formation of the different hydrolyzed products, e.g., γ-casein and proteose peptones, using sodium dodecyl sulfate polyacrylamide gel electrophoresis and reverse phase high performance liquid chromatography. Cross-linking of lysine residues with glutamyl residues by transglutamination and lysine-sugar-lysine cross-linking through the Maillard reaction clearly affected plasmin-induced hydrolysis negatively and reduced the susceptibility of b-casein to plasmin-induced hydrolysis. This could have been due to 1) the modification of lysine making it unrecognizable to the substrate-binding pocket of plasmin, and 2) the cross-linking preventing the release of hydrolyzed peptides. In terms of controlling plasmin-induced hydrolysis, it appeared that Effect 1 played a more major role in Maillard reaction cross-linking and that Effect 2 played a more major role in transglutamination. It can be concluded from this study that the cross-linking of proteins may be a useful tool for controlling the plasmin-induced hydrolysis of milk proteins and therefore for minimizing the texture- and flavor-related defects that are caused by the release of hydrolyzed peptides.

Key Words: plasmin, transglutamination, Maillard reaction

1025 (W079) Optimization of γ-aminobutyric acid production of *Lactobacillus plantarum* and determination of flavor substances in γ-aminobutyric acid-enriched fermented milk.

L. Li[1], C. Man[2,3], T. Li[1], Y. Shan[2,3], Y. Deng[1], M. Ding[1], M. Guo*[4], and Y. Jiang[1,2,3], *[1]Dep. of Food Science, Northeast Agricultural University, Harbin, China, [2]National Dairy Engineering and Technology Research Center, Northeast Agricultural University, Harbin, China, [3]Synergetic Innovation Center of Food Safety and Nutrition, Harbin, China, [4]University of Vermont, Burlington.*

Gamma-Aminobutyric acid (GABA) is a nonprotein amino acid with positive physiological properties to animals and human. Two objectives were achieved in this work: 1) optimization of the GABA production of *Lactobacillus plantarum* NDC 75017 isolated from traditional yoghourt in Inner Mongolia of China, and 2) exploration of the flavor variations of GABA-enriched fermented milk by this strain in shelf life. High performance liquid chromatography (HPLC) and o-phthaldialdehyde (OPA) precolumn derivatization were used to determine the GABA concentrations in MRS culture media under different fermented conditions. GABA maximum accumulation increased to 3.004 folds of the original production in the following optimized condition: 75 mM L-solium glutamate (L-MSG), 20 μM pyridoxal 5'-phosphate (*P*LP), 3 mM $CaCl_2$, 3% inoculation in MRS and 48 h fermentation with the initial pH value of 4.5. In the above condition, *L. plantarum* NDC 75017 was cultured to be the starter of GABA-enriched fermented milk and it was stored in 4°C for 21 d. Six typical flavor substances were measured by spectrophotometry and HPLC at 11 point-in-time during the whole storage. Diacetyl increased gradually from 3.226 to 4.975 mg/L. Acetaldehyde went up at first, peaked at the third day with 8.9 g/L and went down slowly to 7.259 g/L at last. Citric acid, pyruvic acid, lactic acid and formic acid contents of fermented milk were stable without significant variations and the concentrations of them at the end of storage were 132.772 mg/L, 10.782 mg/L, 109.268 mg/L and 82.757 mg/L, respectively. Compared to general fermented milk products, lower content of diacetyl and lactic acid but higher concentration of formic acid showed in the GABA-enriched fermented milk and other three flavor substances were similar between them. Results in the present study suggested that the optimized GABA-producing *L. plantarum*NDC 75017 could be the potential starter applied in the manufacture of fermented milk or other dairy products with healthcare functions and unique flavors. *This work was supported by National Science and Technology Project (2011AA100902) and National Natural Science Foundation of China (31171718).*

Key Words: γ-aminobutyric acid, *Lactobacillus plantarum*, fermented milk

1026 (W080) Comparison of odd and branched chain fatty acids profiles of cow, yak, buffalo, Jersey cattle, goat, camel and horse milk fat. L. Ma[1,2], D. P. Bu[2], J. T. Chen[2], and J. Q. Wang[*2], *[1]Inner Mongolia Agricultural University, Huhhot, China, [2]State Key Laboratory of Animal Nutrition, Institute of Animal Science, Chinese Academy of Agricultural Sciences, Beijing, China.*

To unravel the expression profile of odd and branched chain fatty acids (OBCFA) in cow (n = 20), yak (n = 20), buffalo (n = 20), Jersey cattle (n = 20), goat (n = 20), camel (n = 8) and horse (n = 8) milk samples which were collected around the fourth month of lactation for each species from February to April 2013, composition and variation were detected by gas chromatography-mass spectrometry selected scan mode (GC–MS/SCAN) (7890N-5975C, Agilent Technologies Co., Ltd., USA). Descriptive statistics and Duncan's multiple comparison of OBCFA profiles were obtained by SAS 9.1 via GLM model (SAS Institute Inc., Cary, NC). All OBCFA data sets were analyzed by principal component analysis (PCA) using the Unscrambler 9.8 (CAMO SOFTWARE AS, Oslo, Norway) and submitted to further hierarchical clustering using Cluster 3.0 software (USA). Significant differences in milk OBCFA composition of different species were observed. In cow, yak, buffalo and Jersey cattle milk, the highest composition of OBCFA were *iso*-C15:0 and C15:0, in goat milk were C15:0 and *anteiso*-C17:0, while in horse and camel milk were *iso*-C15:0 and *anteiso*-C17:0, respectively. Among various species milk, *anteiso*-C13:0 accounted for the smallest percentage of OBCFA. Total OBCFA composition was highest in yak milk. Most of the individual OBCFA were significantly highest in yak milk, except for *anteiso*-C17:0 which was a little lower than in camel milk. However, most individual OBCFA and the total amount of OBCFA in horse milk were significantly lower than in other species' milk. The cluster analysis result showed that cow, buffalo, Jersey cattle and yak milk samples comprised a major sample cluster, and goat milk added to this group yielded another cluster. Camel and horse milk were in another major cluster. In addition, principal component analysis (*P*CA) result could also be used to group different species according to OBCFA and demonstrate an effective way to distinguish between yak milk and others' milk. It was concluded that milk from different species had its special OBCFA profile.

Key Words: odd and branched chain fatty acids, species milk, gas chromatography-mass

1027 (W081) Detection and comparison of major and trace elements from different species milk by inductively coupled plasma–mass spectrometry. L. Ma, D. P. Bu, J. T. Chen, and J. Q. Wang**, State Key Laboratory of Animal Nutrition, Institute of Animal Science, Chinese Academy of Agricultural Sciences, Beijing, China.*

Milk contains lots of nutrients, such as proteins, lipids, carbohydrates, vitamins and elements. As a complex biological fluid and an excellent source of macro and micro nutrients, milk can play an important way in meeting the nutritional requirements for individuals. The content of nine major and trace elements in cow (n = 20), yak (n = 20), buffalo (n = 20), Jersey cattle (n = 20), goat (n = 20), camel (n = 8) and horse (n = 8) milk samples which were collected around the 4thmonth of lactation for each species from February to April 2013 in China have been determined by inductively coupled plasma–mass spectrometry (ICP–MS) (Agilent 7700X, Agilent Corporation, United States) after microwave digestion. Descriptive statistics and Duncan's multiple comparison of protein contents were obtained by SAS 9.1 via GLM model (SAS Institute Inc., Cary, NC). To check the applicability of the proposed method to the analysis, two certified reference materials available for powder skim milk (GBW10017) and for cabbage power (GBW1001) were analysed to obtain satisfactory results in all cases. The result showed that the contents of major elements (Na, Mg, K, Ca, Fe) and trace elements (Mn, Co, Zn, Se) in different species milk were significantly different. All of the major elements were lowest in horse milk. Much higher concentrations of Mg and Ca were found in buffao milk. The content of Fe was highest in cow milk. Na and K were found highest in camel milk and goat milk, respectively. The concentrations of trace elements (Mn, Co, Zn, Se) were almost higher in cow milk than in other species milk, except for Se, which was a little lower than in buffalo milk. The content of Co was found nearly the same in cow, yak, buffalo, Jersey cattle, camel and horse milk, except for in goat milk, which was a little lower. In addition, Se was not detected in horse milk. It was concluded that the contents of major and trace elements in milk from different species were various and the trace element of Se was not detected in horse milk in this study.

Key Words: major and trace elements, species milk, inductively coupled plasma–mass spectrometry

1028 (W082) Identification of microRNA in fresh milk of cow and goat. D. P. Bu[1], L. Ma[1], X. M. Nan[1], J. J. Loor[2], and J. Q. Wang[*1], *[1]State Key Laboratory of Animal Nutrition, Institute of Animal Science, Chinese Academy of Agricultural Sciences, Beijing, China, [2]University of Illinois, Urbana.*

MicroRNAs (miRNAs) are a class of small RNA molecules (~22 nt) that inhibit translation or induce degradation of pro-

tein-coding mRNAs containing complementary sequences to mRNAs. Recent studies have demonstrated the presence of miRNAs in body fluids such as serum, plasma, saliva, urine and milk. The objective of this study was to identify the differences of microRNA profiles between cow whey and goat whey. Cow whey samples and goat whey samples without milk fat, somatic cells and major proteins were obtained by a series of centrifugations and filtrations. miRNA was isolated and the quantity of RNA measured. Isolated miRNAs were amplified and sequenced by Solexa sequencing technology. After bioinformatics analysis, 381 loci possessed the typical stem-loop structures matched to the known miRNA hairpins and a total of 34 loci with novel hairpins were identified as novel miRNAs in cow whey. In goat whey, a total of 111 microRNAs were obtained, of which 13 were novel microRNAs. Among all the microRNAs detected in cow and goat whey, 29 miRNAs were common between these species. Overall, the miRNA profile of cow whey and goat whey differed significantly.

Key Words: fresh milk, whey, microRNA

1029 (W083) Sodium azide and potassium dichromate not suitable preservative of raw milk for detection β-lactamase by cylinder plate method. Y. Zhang[1,2,3], N. Zheng[1,2,3], F. Wen[1,2,3], S. Li[1,2,3], S. Zheng[1], and J. Wang[*1,2,3], *[1]Ministry of Agriculture– Laboratory of Quality and Safety Risk Assessment for Dairy Products, Beijing, China, [2]Ministry of Agriculture– Milk and Dairy Product Inspection Center, Beijing, China, [3]State Key Laboratory of Animal Nutrition, Institute of Animal Science, Chinese Academy of Agricultural Sciences, Beijing, China.*

Upon selecting the appropriate sample of raw milk, keeping the stability of physicochemical property of β-lactamase relevant compounds is essential for its successful detection and identification in systematic analysis. However, there is no particular standard pre-treatment procedure for detection of β-lactamase in raw milk. This study examined the storage time of refrigeration (4 h, 8 h, 24 h, 48 h) and freeze (1 d, 7 d, 30 d), the temperature (25°C, 40°C, 60°C) and times (1, 3, and 5) of thawing for freeze sample and the kinds of preservative (sodium azide, potassium dichromate, sodium thiocyanate, bronopol, methanol) using cylinder plate method. Milk sample, collected from individual cow and negative for β-lactamase testing by cylinder plate method, was divided into 10 aliquot of the milk sample, two aliquot of the milk sample adding nothing were the control group, eight aliquot of the milk sample adding 4 U/mL β-lactamase were the experiment group. Refrigeration time within 48 h and freeze time within 30 d had no influence on the detection result of β-lactamase, thawing temperature below 60°C and thawing times below five times for freeze sample were also no influence. β-lactamase could not be detected when adding sodium azide and potassium dichromate in raw milk, whereas sodium thiocyanate, bronopol and methanol had no effect, suggesting sodium azide and potassium dichromate were not suitable preservative of raw milk for detection β-lactamase by cylinder plate method.

Key Words: pre-treatment, β-lactamase, raw milk

1030 (W084) Discrimination of reconstituted milk and over-processed milk in pasteurized and UHT milk. H. Wang[1,2,3], N. Zheng[1,3], F. Wen[1,3], H. Wang[2], X. Guo[1,3], S. Li[1,3], and J. Wang[*1,3], *[1]Ministry of Agriculture– Laboratory of Quality and Safety Risk Assessment for Dairy Products, Beijing, China, [2]College of Animal Science and Technology, Yangzhou University, China, [3]State Key Laboratory of Animal Nutrition, Institute of Animal Science, Chinese Academy of Agricultural Sciences, Beijing, China.*

The objective of the present study was to distinguish over-processed milk and reconstituted milk by comparing the heat treatment indicators in raw milk, over-processed milk and raw milk plus reconstituted milk under both pasteurized and ultra high temperature (UHT) conditions. The contents of furosine and lactulose, as well as the ratio of lactulose to furosine were investigated. Lactulose was detected using UV spectrophotometer by enzymatic method (ISO 11285/2004) with modifications and furosine was detected by using high-performance liquid chromatography (HPLC) according to ES ISO 18329/2012. The content of furosine was less than 12 mg/100 g protein, when the milk was pasteurized from pure raw milk; if the content of furosine was more than 12 mg/100 g protein, it can be considered as reconstituted milk when L/F was less than 1, otherwise it could be regarded as over-processed milk when L/F was higher than 1. If it was produced from pure raw milk under UHT conditions, the content of furosine would be less than 140 mg/100 g protein; if the content of furosine was more than 140 mg/100 g protein, it can be considered as reconstituted milk when L/F was less than 2, otherwise it could be regarded as over-processed milk when L/F was higher than 2. Our results suggest that over-processed milk and reconstituted milk in pasteurized and UHT milk might be differentiated by the content of furosine and the ratio of lactulose and furosine (L/F).

Key Words: reconstituted milk; over-processed milk; lactulose/furosine

1031 (W085) Caseinomacropeptide index (cmp), microbiology and protein content of UHT chocolate milk-whey-based drinks in Brazil. F. P. Paula[1], L. M. Melgaço[1], A. B. Jardim[1], C. F. A. M. Penna[2], L. M. Fonseca[1], M. R. Souza[2], M. P. Cerqueira[2], and M. O. Leite[*2], *[1]Universidade Federal de Minas Gerais, Belo Horizonte, Brazil, [2]Universidade Federal de Minas Gerais* (*School of Veterinary Medicine), Belo Horizonte, Brazil.*

Ultra high temperature (UHT) milk-whey-based-drinks are obtained by processing a mix of milk and cheese whey. In Brazil, this may additionally be added of food ingredients, vegetable fat, and other milk derivatives. The intake of this product is popular among children in Brazil, and it is commonly used to replace milk consumption. Consequently, nutritional concerns emerge because of the low protein content due to whey addition. The objective of this work was to evaluate the protein content and microbial contamination, and to estimate the caseinomacropeptide index (CMP) of this beverage. Fifty-six samples of UHT chocolate milk-whey-based drinks from seven dairy plants, and eight production lots each were collected in the city of Belo Horizonte, MG (Brazil) and analyzed for protein content (Kjeldahl), CMP index by high performance liquid chromatography (HPLC) and count of aerobic mesophilic bacteria (total plate count). Descriptive statistics was used. All samples were in compliance with Brazilian standards for aerobic mesophilic countings (< 1.0 CFU/mL). Average CMP index (mg/L), and protein content (g/100 g) for the seven brands are showed in Table 1031. Samples with higher CMP index were correlated with lower protein content (Pearson correlation of -0.7 at $P = 0.07$), as expected. Although protein content results were in compliance with Brazilian legislation, the low levels found in several samples are indicative of potential low protein intake by children with high consumption of this food.

Key Words: milk-whey-based-drinks, caseinomacropeptide index, protein content, microbiology

Table 1031.

Brand	CMP (mg/L)	Protein (g/100g)
A	912.5+	1.15+
B	646.31+	2.06+
C	611.24+	2.93+
D	566.64+	2.04+
E	498.93+	1.73+
F	332.67+	2.93+
G	328.23+	2.49+

1032 (W086) Stability of vitamin a palmitate in raw skim milk and apple juice on exposure to ultraviolet light. M. S. Mohan[*], and F. Harte, *University of Tennessee, Knoxville.*

Vitamin A palmitate is commercially fortified in milk. Earlier studies have indicated that the vitamin A fortified in milk is associated with the casein micelles in milk. Our objective was to study whether casein micelles protect vitamin A palmitate from degradation on exposure to ultraviolet (UV) radiation. For this purpose raw skim milk and apple juice was fortified with vitamin A palmitate (1.4 mM) after dispersing in ethanol (2.44% v/v ethanol in sample) with rotary homogenization at 10, 000 rpm for 3 min. The vitamin A milk and juice samples were then subjected to strong UV radiation (365 nm, intensity at the surface of transilluminator 5300μW/cm^2) for 0, 5, 10, 15, and 20 min. The vitamin A was extracted with hexane and quantified by using a normal phase HPLC at 325 nm. Vitamin A milk samples were subjected to size exclusion chromatography (SEC) and the fractions pertaining to the same peak at 280nm were pooled, then freeze dried and analyzed for vitamin A content. There was rapid degradation of vitamin A palmitate in juice samples, with a reduction of 59% of vitamin A of the initial amount added, on exposure to 20 min of UV light. The vitamin A content was 100%, 97%, 88%, 67% and 41% (± 4%) of the initial amount added, on subjecting to UV exposure for 0, 5, 10, 15, and 20 min, respectively. While the vitamin A in milk samples degraded only 6% over 20 min of UV exposure, with a degradation pattern 100%, 100%, 99%, 97% and 94% (± 4%) of the initial amount added, on subjecting to UV exposure for 0, 5, 10, 15, and 20 min, respectively. The difference in the percentage of vitamin A between milk and juice was especially significant after 15 and 20 min of UV light exposure ($P < 0.01$). The quantification of vitamin A in the SEC fractions indicated that vitamin A palmitate associated only to casein micelles in milk with a recovery of 42% of the initial amount added within the casein section. The results indicate that the association of vitamin A palmitate and casein micelles in raw skim milk samples provide a protective effect to vitamin A palmitate against degradation on exposure to UV light.

Key Words: vitamin A palmitate, ultraviolet, casein, milk

1033 (W087) Effect of abomasal ferrous lactate infusion of dairy cows on milk proteins. A. Wang[*1], A. M. Dietrich[1], S. Duncan[1], K. F. Knowlton[1], and W. Slade[2], *[1]Virginia Tech, Blacksburg, [2]University of North Carolina at Chapel Hill, Chapel Hill.*

Water makes up more than 80% of the total weight of milk. However, the influence of water chemistry on milk quality has not been extensively studied. Heavy metals in bovine drinking water may affect the synthesis of milk and subsequent milk quality. The objective of this study was to determine the in-

teraction of ferrous lactate infusion in dairy cows, representing the intake of iron through drinking water, on qualitative changes in protein composition of their milk. Four ruminally-cannulated cows each received aqueous infusions of ferrous lactate at 0, 200, 500 or 1250 mg of Fe/d in a Latin Square design. A wash-out period (7 d) existed between each infusion period (7 d). Raw milk was collected at d 6 of each infusion period and was homogenized and pasteurized before analysis. two-dimensional electrophoresis (2-DE) coupled with matrix-assisted laser desorption/ionization time-of-flight/time-of-flight (MALDI-TOF/TOF) high-resolution tandem mass spectrometry analysis was applied to characterize the milk proteins. About 56 protein spots were identified and represented the major and minor casein and whey proteins. Although the protein compositions were similar across cows, the intensity of specific protein spots such as α-S1-casein and k-casein showed differences among different cows. Within-cow comparison demonstrated diminished spot intensity and less focusing along the pI gradient for some spots with increasing ferrous infusion. Such variation may indicate that high iron in bovine drinking water affects some cows more than others. Cow D presented the most stable and consistent protein spots both in position and intensity throughout the infusion period. The content of copper and iron in milk from this cow was consistent and was very near the four cow average. In contrast, milk from cow C presented more α-S1-casein spots when consuming high iron-contaminated water then when consuming regular drinking water; the iron and copper concentration in her milk decreased with increasing infusion concentration. However, cow A lost several α-S1-casein spots when drinking high ferrous sulfate concentration water. The iron-binding protein, lactoferrin was observed at both control and high ferrous infusion periods for cows. There is qualitative evidence that iron in drinking water may affect milk proteins differently in different cows.

Key Words: proteins, lactoferrin, iron

1034 (W088) Effect of high hydrostatic pressure processing on in vitro digestion of milk proteins and fats. D. X. Ren[1,2], D. L. Van Hekken[1], M. H. Tunick[1], and P. M. Tomasula[*1], *[1]USDA, ARS, ERRC, Dairy and Functional Foods Research Unit, Wyndmoor, PA, [2]Institute of Dairy Science, College of Animal Science, Zhejiang University, Hangzhou, P.R., China.*

The use of high hydrostatic pressure processing (HPP) is increasing in popularity in the food industry. Its ability to modify milk proteins and fats suggests that it may be useful in creating foods that suppress appetite; however, its effect on the digestibility of proteins and fats is unclear. The objective of this study was to compare the change in clot size with time during in vitro simulated fasting gastro-intestinal digestion of protein and fat for HPP-treated raw whole milk (WP), homogenized raw whole milk (WHP), and skim milk (SP) to that of untreated raw whole (WR) and raw skim milk (SR), and WR and SR milk treated by HTST pasteurization (72°C, 15 s) with or without homogenization. HPP was conducted at 600 MPa (3 min, 21°C). Milk digestion procedures followed the 2012 U.S. Pharmacopeia using simulated gastric fluid (SGF) for 1 h followed by simulated intestinal fluid for 2 h. The average particle size of WR 8.5 ± 0.3 μm remained unchanged with all processing treatments while the average particle size of SR increased from 1.3 ± 0.3 μm to 4.6 ± 0.6 μm with HPP treatment only. The clots that formed on addition of SGF for WR and SR and with the various processing treatments were then followed for 3 h using a light-scattering particle-size analyzer. The clot sizes of processed WR samples were > those for the raw samples but were not different after 3 h. The clot size for SR was < that for SP. after 3 h but the amounts of SR and SP. protein digested were not different ($P < 0.05$). In vitro % protein digestibilities of WR and SR were similar regardless of treatment, ranging from 85 to 90%, except for HPP-treated WR and SR which ranged from 62 to 70%. Free fatty acid release (FFAR) decreased in the order WHP > WR > WP, indicating that WHP was the most digestible due to the increased surface area for enzyme contact and fat breakdown. Stearic and oleic acids, located on the outside of the triglyceride molecule, degraded approximately twice as fast as the other fatty acids. FFAR for WP was 40% < that of WR. Results indicate that HPP processing may possibly be used to moderate in vitro protein and fat digestion of milk.

Key Words: high pressure processing; digestibility; free fatty acids

---

1035 (W089) Effect of storage temperature on the physio-chemical properties of skim milk powders treated with chelators. V. Sikand[*1], P. S. Tong[1], S. Vink[1], and S. Roy[2], *[1]Dep. of Dairy Science, California Polytechnic State University, San Luis Obispo, [2]Dep. of Statistics, California Polytechnic State University, San Luis Obispo.*

The objectives of this study were to determine the impact of storage temperature on functional properties– solubility, opacity and heat stability compared to freshly manufactured skim milk powder (SMP) samples treated with mineral chelators. This study was conducted by adding 5, 15, and 25 mM sodium citrate dihydrate (SCD), sodium polyphosphate (SPP) and disodium EDTA (DSE) to skim milk concentrate (30% total solids) and adjusting the concentrate to 6.65 pH before spray drying. One set of sample bags were stored at room temperature (22°C). The second sets of bags were kept at 37°C for 3 mo. The experiment was repeated twice. Samples were tested for solubility index (SI) and reconstituted to contain 9% TS and tested for opacity by using a Hunter Lab Colorimeter. Heat stability was determined by measuring the heat coagulation time (HCT) at 140°C as the time required for visible flocculation for samples. SI indicated high solubility of all SMP

samples. However, lower values for SI were observed for samples treated with 5mM SPP. and DSE (0.13 mL) as compared to samples treated with SCD (0.3mL). Furthermore, low SI values were observed with an increasing level of chelating agents regardless of chelator type. No significant difference was observed in SI of samples stored at 37°C as compared to SI tested for freshly manufactured samples. A decreased opacity (L* value) or an increase in the lightness of samples was found with increasing levels of mineral chelating salt treatment ($P < 0.001$). Furthermore, lower L* values were observed in samples stored at 37°C ($P < 0.001$) as compared to freshly manufactured samples. Heat stability studies showed that SMP (PH 7.0) treated with 5mM DSE or SCD chelators had higher HS (> 30 min) as compared to the SPP. (16 min). Samples treated with 15mM SPP. showed significantly higher HS (20 min) as compared to SCD or DSE treated samples. Samples showed poor HS (< 5 min) chelator type at 25mM concentration level. Slightly lower HCT values were observed for samples stored at 37°C ($P < 0.001$) as compared to freshly manufactured samples, regardless of any concentration level. The results from this study showed that storage temperature may impact the functional properties.

Key Words: SMP, chelators, solubility, heat stability

1036 (W090) Effect of sunflower oil, vitamin E and selenium inclusion in the diet of dairy cows on the sensory acceptability of milk. L. F. D'Abreu*, C. Rodrigues, A. Saran Netto, J. L. Guimarães, M. A. Silva, and N. D. P. Lopes, *School of Animal Science and Food Engineering, University of São Paulo, Pirassununga, Brazil.*

The objective of the present study was to evaluate the effect of sunflower oil, vitamin E and selenium inclusion in the diet of dairy cows on the acceptance of sensory attributes of milk. Thirty-two Jersey cows in early lactation were divided into four experimental groups in a complete randomized design. The animals were randomly assigned to receive one of the following diets: 1) control (C, $n = 8$); 2) 3.5 mg selenium/kg dry matter (DM) + 3000 IU vitamin E/kg DM (SE, $n = 8$); 3) 4% inclusion of sunflower oil (total diet DM basis) (O, $n = 8$), 4) 4% inclusion of sunflower oil (total diet DM basis) + 3.5 mg selenium/kg DM + 3000 IU vitamin E/kg DM (OSE, $n = 8$). Before sensory evaluation, the milk was pasteurized. Sixty untrained tasters received the samples in complete blocks and used a nine-point hedonic scale for acceptance testing regarding the attributes color, odor, flavor and mouthfeel of milk and a scale of intensity difference of odor and flavor for the test of difference from the control. Data were submitted to ANOVA analysis of variance and Tukey test was conducted to compare means, to the level of 5% of significance using the PROC MIXED of SAS version 9.1. In the test of difference from the control, no difference ($P > 0.05$) between milk from cows fed the C diet and those from cows fed the SE, O and OSE diets was observed for the evaluated attributes- odor and flavor. The acceptability of the commercial milk color was higher ($P < 0.05$) when compared to the other dietary treatments (8.10 *vs*. C = 6.56; SE = 5.73; O = 6.51; OSE = 7.03). The attributes odor, flavor and mouthfeel showed no effect of dietary treatment ($P > 0.05$) in acceptance by the consumer. These results demonstrate the feasibility to produce milk from cows supplemented with sunflower oil, selenium and vitamin E.

Key Words: antioxidants, consumers acceptance, dairy

1037 (T077) Potential bull buyers perceive increased value to their operations when purchasing bulls from the Florida Bull Test. D. D. Henry*, V. R. G. Mercadante, F. M. Ciriaco, P. M. Mercadante, T. Schulmeister, N. DiLorenzo, and G. C. Lamb, *University of Florida, Marianna.*

The primary purpose of the Florida Bull Test is to serve as an educational aid for the improvement of beef cattle production. The test aims to: 1) provide the commercial cow/calf producer a source of bulls that have been tested for animal performance (i.e., ADG, DMI and feed efficiency), that were thoroughly evaluated at the same location, and that have passed stringent health requirements; 2) provide an opportunity for seed stock producers to advertise their breeding programs through testing and marketing bulls; and 3) promote awareness and understanding of the latest animal breeding concepts and tools while showcasing superior beef cattle genetics in Florida. The test standardizes environmental conditions for evaluating postweaning performance. In doing so, it provides useful records for bull consignors to better evaluate breeding programs and creates a local source of performance-tested bulls. Since the inception of the test, 14 annual bull tests have been completed with 1205 bulls tested from more than 14 different breeds. Mean sale average has ranged from $1,283 (in 2001) to $3,274 (in 2013). Before initiation of the 2014 Florida Bull Test sale a survey was conducted among potential buyers on their perception of the value that purchasing a bull may be to their operation. Of the 77 completed surveys, 54% indicated that they had purchased between one and six bulls from previous Florida Bull Test sales. Buyers originated from Alabama (n = 21), Florida (n = 47), and Georgia (n = 9). The primary factors identified by potential buyers when considering to purchase a bull were prioritized as follows: 1) breed, 2) performance and rank in the test, 3) sale price of the bull, 4) phenotype, 5) feed efficiency, and 6) pedigree. The mean perceived increased value per calf sired by bulls purchased from the Florida Bull Test was $58.05, but ranged from $0 to $125 per calf. We concluded that potential buyers value bulls purchased from the Florida Bull Test and these bulls are perceived to increase the value of their offspring at weaning.

Key Words: beef cattle, survey, bull test

1038 (T078) 300-d grazing discovery farm. T. R. Troxel*[1], M. S. Gadberry[1], J. A. Jennings[1], S. M. Jones[1], K. J. Simon[1], J. G. Powell[2], D. S. Hubbell, III[3], and J. D. Tucker[3], *[1]Dep. of Animal Science, University of Arkansas, Little Rock, [2]Dep. of Animal Science, University of Arkansas Division of Agriculture, Fayetteville, [3]University of Arkansas Livestock and Forestry Research Station, Batesville.*

The objectives of the 300d grazing discovery farm were to reduce hay feeding to 60 d or less, 90% net calf crop, average weaning weight of 249 kg and implement management practices common and available to cattle producers. The demonstration pastures consisted of 17.7 ha of common bermudagrass (*Cyndodon dactylon*), two 10.6-ha pastures of toxic endophyte-infected Kentucky-31 tall fescue (*Festuca arundinacea*), 10 ha of Ark-Plus novel-endophyte tall fescue, and 10 ha of Ark-Plus fescue/common crabgrass mix. Red (*T. pretense* L.) and white (*T. repens* L.) clovers were interseeded into fescue pastures. Each pasture contained water sources and were subdivided with electric fence. In yr 1 the cow herd was predominately Balancer females (38 multiparous cows) bred to Balancer bulls with a fall calving season. Two horned Hereford bulls were used in yr 2 to 5. The breeding seasons were approximately November 21 to January 26. The grazing protocol for each yr was fescue/clover in spring, bermudagrass for summer and early fall, fescue/clover for late fall and stockpiled fescue in winter. The primary management practices implemented were rotational grazing, strip grazing stockpiled forages during winter and a short defined breeding and calving season. The length of the grazing season for yr 1, 2, 3, 4, and 5 was 337, 311, 330, 323, and 279 d, respectively, and averaged 316 ± 20.4 d (mean ± SD). The mean mature cow net calf crop for yr 2, 3, 4, and 5 was 90 ± 7.0%; 24% points improvement compared to yr 1. The overall adj. 205-d BW increased ($P < 0.05$) from yr 1 and 2 (190 and 208 kg, respectively) to yr 3, 4, and 5 (225, 222, and 233 kg, respectively). All calves were weaned during the first 2 wk of May. The weaning weight of yr 1 was 213 ± 21.4 kg. The weaning weight goal (249 kg) was achieved for yr 2, 3, and 5 and was 255 ± 39.2, 273 ± 40.4 and 259 ± 31.0 kg, respectively, and was 241 ± 35.7 in yr 4. The average calving season was 59 ± 9.4 d for 5 yr. By incorporating rotational grazing, strip grazing stockpiled forage and a short breeding and calving season a 300 d grazing with acceptable beef cattle performance can be achieved in Arkansas.

Key Words: 300 d grazing, beef cattle, rotational grazing, stockpiled forage, weaning weight

1039 (T079) Case study: Fermentation profile, physical form, and starch digestibility of whole-plant corn silage harvested with novel processing.
L. F. Ferraretto, L. M. Vanderwerff*, and R. D. Shaver, *University of Wisconsin, Madison.*

Samples collected from two self-propelled harvesters (SPFH) at harvest were evaluated for fermentation profile, physical form, and ruminal in situ starch digestibility (StarchD; 12-h incubations on undried, unground samples) in whole-plant corn silage (WPCS). One SPFH was fitted with conventional type rolls with greater roll-speed differential than normal (CRGD). The other SPFH was fitted with intermeshing-disc type rolls (IMDR). The CRGD samples were from three theoretical lengths of cut (TLOC; 1.91, 2.24 and 2.54 cm; 3-mm roll-gap setting) on two hybrid types (leafy [LFY] and dual-purpose [DP]). The IMDR samples were from three TLOC (1.70, 1.91 and 2.54 cm) at two roll-gap settings (1.5 and 2.5 mm) on one hybrid. Unfermented samples were analyzed for processing score (CSPS) and mean particle length (MPL). Fermentation profile and StarchD were measured on fermented samples (30-d; vacuum-sealed bags). Data were analyzed using PROC MIXED of SAS with the Fixed effects of TLOC, hybrids and their interaction or TLOC, roll-gap settings and their interaction for CRGD and IMDR, respectively. For CRGD, CSPS tended ($P < 0.06$) to decrease while MPL increased ($P < 0.001$) with increasing TLOC. Fermentation profile and StarchD were unaffected ($P > 0.10$) by TLOC. Greater CSPS and reduced MPL were observed ($P < 0.05$) for LFY than DP. In addition, LFY had ($P < 0.01$) lower pH and greater total VFA concentrations. Starch digestibility tended ($P < 0.10$) to be greater for LFY than DP (79.9% vs. 71.2%). The difference in DM content between hybrids ($P < 0.01$; 31.2% vs. 35.2% for LFY and DP) may partially explain the differences between hybrid types. For IMDR, CSPS tended ($P < 0.10$) to be greatest for 1.70 cm TLOC. Greatest MPL was observed ($P < 0.05$) at the 2.54 cm TLOC. Measurements of pH were similar ($P > 0.10$) among TLOC, although total VFA concentration was lower ($P < 0.01$) for the 1.91 cm TLOC. A roll-gap set at 1.5 mm increased CSPS and decreased MPL compared to the 2.5 mm setting ($P < 0.001$). Total VFA concentration was similar ($P > 0.10$) and pH lower ($P < 0.01$) for the 2.5 mm treatment. Roll-gap and TLOC setting did not affect ($P > 0.10$) StarchD. Hybrid type and settings for TLOC and roll-gap influenced WPCS physical form and 30-d fermentation profile, while StarchD differed by hybrid type but not TLOC and roll-gap settings.

Key Words: corn silage, processing, starch digestibiity

1040 (T080) Initial assessment of producers' experiences, perceptions and attitudes about mastitis and bulk tank somatic cell count management in the Southeast.
S. M. Schexnayder[1], P. D. Krawczel*[1], M. Fly[1], L. E. Garkovich[2], C. S. Petersson-Wolfe[3], J. M. Bewley[2], S. H. Ward[4], G. M. Pighetti[1], R. A. Almeida[1], M. Arnold[2], S. C. Nickerson[5], A. DeVries[6], and S. P. Oliver[1], *[1]University of Tennessee, Knoxville, [2]University of Kentucky, Lexington, [3]Virginia Tech University, Blacksburg, [4]Mississippi State University, Starkville, [5]University of Georgia, Athens, [6]University of Florida, Gainesville.*

Impacts of mastitis, including reduced quality milk and productivity, negatively affect the profitability and sustainability of dairies in the Southeast (SE). The Southeast Quality Milk Initiative (SQMI), an integrated research, extension, and education project involving six land grant universities in the SE, aims to reduce mastitis and lower bulk tank somatic cell counts (SCC) through cost-effective control strategies. The first aim of this project was to identify social, psychological, and economic barriers limiting adoption of practices known to effectively control mastitis. To address this aim, a qualitative survey was conducted to identify producers' attitudes, their perceptions of control, the normative factors that influence their behavior towards mastitis control, and their attitudes on the ease of use, utility, and cost of associated control practices. In total, thre focus groups (two in Kentucky and one in Virginia) and 18 personal interviews (Producers in Tennessee and Virginia) were conducted. Participants represented a range of farm size (40 to 1200 cows), dairy experience (2 to 55 yr as owner or manager), bulk tank SCC (100,000 to > 600,000/ml; with either decreased or unchanged average SCC in the last 3 yr), and operational types. At each focus group and in personal interviews, a specific set of questions was posed. All content was subsequently reviewed for patterns and similarities. Producer responses were then grouped into key points. Findings summarized here are those that occurred frequently and were emphasized by producers through their input. Main trends are as follows: 1) Shortcomings remain in producer understanding of effects of subclinical mastitis on milk quantity and quality, 2) Producers' long-term objectives drive their investment of time and financial resources into mastitis management, 3) Uncertainty existed on the efficacy and cost-effectiveness of various mastitis control practices, 4) Producers wanted to know the bulk tank SCC that was most cost-effective in terms of the balance among associated costs of labor, management, penalties, and incentives, 5) Culling has been a favored mastitis management practice recently, 6) On-farm demonstrations of effective practices were the preferred means of communication and 7) Frustration resulted when implemented practices failed to control mastitis outbreaks. This information will be utilized to develop strategies for countering non-adoption rationales and form the foundation of a survey subsequently

distributed to approximately 2000 dairy producers in the SE. *This work was supported by a grant award from USDA-NIFA-AFRI (2013–68004–20424).*

Key Words: qualitative survey, mastitis, behavior, dairy production

---

1041 (T081) The status of milk quality at the start of the Southeast Quality Milk Initiative.

G. M. Pighetti[1], C. S. Petersson-Wolfe[2], J. M. Bewley[3], S. C. Nickerson[4], S. H. Ward[5], A. DeVries[6], P. D. Krawczel[*1], R. A. Almeida[1], M. Fly[1], S. M. Schexnayder[1], L. E. Garkovich[3], M. Arnold[3], and S. P. Oliver[1], *[1]University of Tennessee, Knoxville, [2]Virginia Tech University, Blacksburg, [3]University of Kentucky, Lexington, [4]University of Georgia, Athens, [5]Mississippi State University, Starkville, [6]University of Florida, Gainesville.*

The quality of milk produced in the Southeast (SE), based on somatic cell count (SCC) and standard plate count (SPC), is consistently lower than the rest of the United States. Reduced milk quality increases costs while decreasing revenues and efficiency. The combined effect of these factors contributes to the declining dairy industry in the SE. Understanding factors that have the greatest impact on milk quality will provide a background for programs aimed at helping producers improve their operations and was the underlying basis for the establishment of the Southeast Quality Milk Initiative (SQMI). Our overall goal is to enable dairy farmers to move toward production systems compatible with a sustainable industry. To accomplish this, we will integrate outreach, education, and research initiatives focused on improved milk quality, lowered disease costs, and greater revenues on farm. As part of this process, we established the baseline status of milk quality at the start of the project on dairy operations in FL (n = 126), GA (n = 221), KY (n = 753), MS (n = 82), TN (n = 404), and VA (n = 814), which are the partnering states of the SQMI. SCC and SPC bulk tank milk data for 2012 were evaluated from records maintained by state regulatory agencies. At least one SCC and SPC were collected each month from each dairy farm with a Grade A permit and data were summarized using the Timeseries procedure of SAS. Most SPC samples (65%) had < 5000 colony forming units (CFU)/ml and 82% fell within the recommended range (< 10,000 CFU/ml). The SE SCC averaged 324,204 ± 174,083 cells/ml (mean ± SD). The annual mean SCC of individual states ranged from 279,603 ± 160,665 to 417,146 ± 210,692. For herds enrolled in DHIA, which comprised 30–44% of the total herds within a state, annual mean SCC was approximately 50,000 fewer cells/ml. Considerable state-by-state variation occurred in frequency of samples, with SCC > 400,000 cells/ml having the greatest effect evident in the summer months. At this time, 20 to 60% of samples from individual states were > 400,000 cells/ml. In summary, milk quality in the SE lags behind the US as a whole, and hot, humid summers of the region present one of the major challenges to producing quality milk. Continued evaluation of this information will provide a basis to evaluate the success of the SQMI. *This work was supported by a grant award from USDA-NIFA-AFRI (2013–68004–20424).*

Key Words: Mastitis, extension, milk quality

1042 (T082) Hedonic pricing models for Angus bulls sold at auction following performance testing at Oklahoma Panhandle State University.

D. L. Stephens[*1], P. K. Camfield[1], and T. C. Schroeder[2], *[1]Oklahoma Panhandle State University, Goodwell, [2]Kansas State University, Manhattan.*

Selection of a herd sire has always been of paramount importance given the initial financial investment and their contribution and effect on the genetic make-up of a beef herd. Data was collected from the nation's longest consecutively run bull test conducted at the University Farm of Oklahoma Panhandle State University (OPSU). The Bull Test and Bull Sale data utilized were collected from 2008–2013. Performance data were collected over a 112-d test period with data collection occurring at 28-d intervals. The top 70 bulls from each year's test were selected based on a performance index of 1/2 ADG and 1/2 weight per day of age (WDA), and a semen quality and motility score of excellent and sold at auction. Angus bulls were the focus of the study as they represented the vast majority of individuals sold. Three hedonic pricing models were created. The initial hedonic model contained production data that included BW, ADG, WDA, Julian age, final test weight, ultrasound data, and a dummy variable for sale year. The second model utilized production data and added genetic variables in the form of production EPDs (Calving Ease Direct (CED), BW, Weaning Weight, and Yearling Weight) and maternal EPDs (Calving Ease Maternal, Maternal Milk). The third model included the variables from the first and second model with the inclusion of carcass EPDs (Marbling, Ribeye Area [REA] and FAT). Year was significant in all three models however; there was less of an effect on price as more variables were included. In model one, the production factors that were of significance were: ADG ($P < 0.01$), BW ($P < 0.01$) and final test weight ($P < 0.01$). In the second model, ADG, BW, and final test weight retained their significance at the $P < 0.001$ level. The only production EPD that was significant ($P < 0.05$) was CED. In the third model, years, ADG, and BW were still significant ($P < 0.01$). Final test weight ($P = 0.070$) and CED ($P = 0.132$) had substantial changes. The carcass EPD rib eye area had a P-value of 0.057. Producers who are placing bulls on test can utilize the given information to assist with their selection. It cannot go unsaid that while single trait selection can be very detrimental; ADG was significant across all models. The study indicates that performance and growth

are of utmost importance to buyers, followed by birth weight consideration because a live calf is the start to a potentially profitable calf crop.

Key Words: hedonics, Angus, EPD

1043 (T083) Survey of management practices used in the implementation of artificial insemination and estrous synchronization programs in the United States. S. K. Johnson*[1], and G. Dahlke[2], [1]*Kansas State University, Colby,* [2]*Iowa State University, Ames.*

Artificial insemination (AI) and estrous synchronization (ES) remain underutilized tools by US beef producers. Little information is available on actual management practices used by producers who use these technologies and the value they have within their operation. An online survey tool was developed concerning a variety of production practices, synchronization methods and available tools used with AI and ES. A link to the survey was promoted through electronic extension publications, contact lists and cooperating news media. Producers that participated could enter a drawing for AI supplies at the completion of the survey. The survey was accessed by 546 individuals and 425 completed the survey. Responses came from 42 states. Average number of owned cows that were AI was 67 cows (range 0 to 1750) and 34 owned heifers (range 0 to 1500). Respondents represented commercial herds (56%), seedstock herds (67%), having both commercial and seedstock (44%), commercial heifer development (14%), AI Technicians (18%) and DVMs (18%). A majority of producers used AI for both cows and heifers (87%) with 8% use on heifers only and 5% on cows only. The proportion of respondents that always, usually, sometimes, rarely or never ES was 46%, 26%, 28%, 6%, and 4%, respectively. The frequency of use of AI after observed estrus, estrus AI followed by clean-up timed-AI and strict fixed-time AI was 42%, 25% and 34%, respectively and was similar between cows and heifers. A majority of respondents (97%) were familiar with the recommended protocols for synchronization of estrus and ovulation provided by the Beef Reproduction Task Force. Recommendations from these guidelines were generally used by 65% and sometimes or occasionally used by 20%. The estimated difference in value between AI-sired calves and natural service sired calves was highly variable and averaged $465 ± 689 per head. The most common ways that AI contributed to profitability were through value of replacement heifers (60%), seedstock production (46%), reduced calving difficulty (42%), and premium of calves sold at weaning (35%). Sex-sorted semen had been used by 27% of respondents for use in heifers to make heifers (43%), cows to make heifers (47%), or cows to make bulls (8%). Pregnancy rates to sex-sorted semen were reported to be about as expected (61%), better than expected (12%) or worse than expected (27%). Despite improvements in fixed-timed AI protocols, many producers still depend on AI after observed estrus.

Key Words: artificial insemination, estrous synchronization, management practices

---

1044 (T084) Effect of on-farm dairy Beef Quality Assurance (BQA) training on worker knowledge of BQA and welfare-related practices. A. E. Adams*[1], J. K. Ahola[1], M. Chahine[2], A. L. Ohlheiser[1], and I. N. Roman-Muniz[1], [1]*Colorado State University, Fort Collins,* [2]*University of Idaho, Twin Falls.*

A training program in Beef Quality Assurance (BQA) practices, which included BQA core components and guidelines, was developed for use on dairy farms. The objective was to determine if on-farm dairy BQA training has an effect on dairy worker knowledge of BQA and welfare-related practices. Twelve dairies in Colorado and Idaho (six per state) participated in this pilot project, with 3 dairies in each state receiving BQA training. Training was provided to all employees (including owners and managers) on the dairies that received it, was conducted by experts in dairy BQA via Spanish-language materials, and was consistent across all dairies. To gauge knowledge of various BQA and welfare-related practices, dairy employees were administered a brief exam before receiving training, and again immediately after. Scores were compared between the pre- and post-exams using the TTEST procedure in SAS, with a significant improvement in overall test score occurring in both states ($P < 0.0001$). Respondents ($n = 28$) scored an average of 53.1 (out of 100) before receiving training, which improved to 76.0 after the training (mean improvement = 22.9). In addition to improvement in worker knowledge, one dairy added a full-time hoof trimmer to their staff after receiving the BQA training, indicating the training made them realize the importance of lame cow identification and management on dairy cow welfare and BQA. The change in producer perception of the importance of lameness on an operation, as well as improvement in dairy worker knowledge, suggests that BQA training programs have the potential of impacting dairy owner and/or employee behavior in a positive manner. Further research, including a larger sample size and follow-up visits to gauge employee knowledge retention, is needed to investigate the long-term effect of on-farm BQA training on dairy worker knowledge and management practices. A training program that benefits both BQA and welfare practices would be an excellent tool for the dairy industry, and would foster continuous improvement in these areas within the industry.

Key Words: beef quality assurance, dairy cows, training

1045 (T085) Monetary impact of heat stress on dairy and beef industries in the US. B. Scharf*, D. Liu, J. M. Leath, S. A. Kelly, T. X. Nguyen, Y. Shi, M. Schrader, G. D. Martin, P. A. Eichen, and D. E. Spiers, *University of Missouri, Columbia.*

Heat stress continues to be a major economic problem for the livestock industry. Over 10 yr ago, St-Pierre et al. (2003) reported annual economic losses totaling $897 and 369 million for dairy and beef, respectively. Utilizing this publication, economic impact figures were adjusted for 1) inflation using a cumulative rate of 24.78% (US Inflation Calculator), and 2) 2012 USDA figures for the dairy and beef industry inventories by state. For dairy, estimated annual state-by-state financial loss per cow and average farm were calculated. For beef, only estimated loss per cow was found because information on average herd size by state was not available. Annual losses were primarily determined by loss in productivity (i.e., weight gain for beef and milk production for dairy). In terms of economic loss per cow from heat stress, loss to the beef industry is overwhelmed by the dairy industry, with the top 10 dairy states having 25 times greater loss than average loss among the top 10 beef states. Average annual economic losses across all states on a per cow basis for dairy producers was $89.01, while national annual losses for beef producers was only $3.05. Texas had the highest beef loss per cow in 2012 ($19.25), which was nearly double the second highest loss state which occurred in Oklahoma ($10.59). In comparison, the dairy industry showed an annual per-cow losses of $366.85 and $308.03 per animal for Louisiana and Texas, respectively. Of total loss due to heat stress in the contiguous 48 states, the top 10 states account for 85% and 68% of the losses for beef and dairy industries, respectively. Economic losses per farm showed significant variation due to differences both in level of heat strain and average herd size (ranging from 2357 dairy cows per farm in New México to 66 in Missouri). Texas (872 dairy cows per farm), once again had the highest economic losses at $268,601 per farm while the national average per farm was $33,245 (national average of 187 dairy cows per farm). When ranked according to a combination of total economic loss due to heat stress, per-cow losses, and severity of heat stress, Texas, Kansas, Nebraska, and Oklahoma are the states where heat abatement systems would have the largest economic impact.

Key Words: heat stress, beef, dairy, livestock economics

1046 (T086) Phosphorus status of grazing beef cattle in Virginia's Chesapeake Bay watershed. S. J. Neil*[1], K. J. Mize[1], D. D. Harmon[1], J. K. Smith[2], and M. A. McCann[1], *[1]Virginia Polytechnic Institute and State University, Blacksburg, [2]Virginia Tech, Blacksburg.*

Phosphorus is one of the nutrients identified in EPA's TMDL plan for the Chesapeake Bay watershed. Major research and extension efforts in Virginia have focused on reducing P losses from concentrated animal feeding operations, however approximately 400,000 beef cows graze pastures in Virginia's Chesapeake Bay watershed. To better characterize farm P status, fecal, forage and soil samples were collected from beef cattle farms in the watershed. One hundred twenty producers from 11 counties cooperated with sample collection ($N = 166$). Samples were analyzed for total P (TP) and inorganic P (*P*i) using the molybdovanadate yellow and blue methods, respectively. Soil test P values were characterized as low (12%), medium (37%), high (35%), and very high (16%) based on Virginia Cooperative Extension Soil Test guidelines. Phosphorus content of pasture forage grab samples (mean = 0.34%; SD = 0.12) was lowly correlated with soil P ($r = 0.18$; $P < 0.0001$) and fecal TP ($r = 0.15$; $P < 0.0001$). Forage TP levels were compared with Beef Cattle NRC (2001) P requirements for a 545-kg cow (*P*eak milk, 13.6 kg per d). All forage samples were sufficient in P content to meet a dry cow's requirements, while 98% met the requirements for late gestation and 88% met the requirements for peak lactation. Farm mineral supplements were categorized into four levels of P content (< 1.0 [nil], 1.0 to 2.5 [low], 3.0 to 5.0 [medium] and > 6.0% [high]). Forage P content did not affect mineral selection by producers. The mean forage P content of the mineral categories was 0.30, 0.36, 0.32, and 0.40%, respectively. The mean fecal TP (0.56%, 0.65%, 0.79%, and 0.97%, respectively) and Pi levels (0.33%, 0.41%, 0.55%, and 0.68%, respectively) significantly differed between producers that fed a nil and low P mineral, and those that fed mineral in the medium and high categories ($P = < 0.001$ for TP and Pi). Soluble P (defined as Pi/TP*100) tended to increase across mineral categories going from nil to high. All farms surveyed required little or no P supplementation in regard to cow P requirements. These results indicate that reducing mineral P may be capable of limiting soluble P losses from supplementation of beef cattle.

Key Words: phosphorus, beef cattle, Chesapeake Bay

1047 (T087) Assessment of farm nutrient management and phosphorus supplementation practices of beef cattle producers in Virginia's Chesapeake Bay watershed. S. J. Neil*[1], K. J. Mize[1], D. D. Harmon[1], J. K. Smith[2], and M. A. McCann[1], *[1]Virginia Polytechnic Institute and State University, Blacksburg, [2]Virginia Tech, Blacksburg.*

Concerns over the environmental impact and resource usage of agricultural operations have pressured producers to explore nutrient management as an option to improve sustainability and profitability on the farm. The objective of this study was to determine the level of phosphorus supplementation and nutrient management practices among cow/calf producers in Virginia's Chesapeake Bay watershed. Surveys were collected from 67 producers in 10 counties. Total cattle populations (unweaned calves excluded) of sampled farms ranged

from six to 2810 with a mean of 162 (SD = 359). Seventeen percent of producers had no defined calving season, while 21% practiced fall calving, 31% practiced spring calving, and 31% calved in both spring and fall seasons. Nutrient management plans (NMP) are one of the more prevalent strategies currently employed in the Chesapeake Bay watershed in an attempt to minimize whole farm environmental impact and enhance nutrient conservation on the farm by limiting soil erosion and runoff. Fifty-five percent of participants had implemented NMP at the time of survey completion. In relation, twenty-five percent of all producers sampled forage to determine nutrient content. The majority of producers that sampled forage (94%; $\chi^2 = 17.1$; $P < 0.0001$) currently utilized nutrient management plans. Participants ranked criteria for mineral supplement selection. Responses were weighted based on participant designated ordinal ranking of criteria (three for primary, two for secondary and one for tertiary criteria). Interpretation of response distribution suggests that the primary criterion for mineral supplement selection was price (20.6%), followed by local availability (17.8%) and trace mineral content (17.5%). Sixty-nine percent of producers supplemented a commercial complete mineral mix and 22% used a trace mineral salt block. Eighty percent of producers provided a high magnesium (Mg) mineral (> 10% Mg) at some point during the year for an average of 9.5 mo (SD = 3.5). Eighty two percent of participants indicated willingness to reduce mineral phosphorus supplementation levels if forage analyses revealed that feed and forage resources were capable of meeting phosphorus requirements, while 15% indicated uncertainty, and 3% indicated unwillingness. Survey results suggest that producers are willing to monitor and reduce farm nutrient losses if research shows that over-supplementation is a problem. A concurrent study is underway to assess the extent of nutrient over-supplementation on beef operations in Virginia's Chesapeake Bay watershed.

Key Words: phosphorus, beef cattle, Chesapeake Bay

1048 (T088) An economic impact decision support tool for farm specific estimation of not covering horizontal silos storing corn silage.

B. A. Wadsworth*, D. M. Amaral-Phillips, and J. M. Bewley, *University of Kentucky, Lexington.*

In a horizontal silo (i.e., bunkers and trenches), considerable silage is exposed to environmental elements and, if left uncovered, results in significant feed shrink and economic loss. Depending on the silo dimensions and silage density, 25% of the total volume of corn silage may be within the top 1 m of silage. The objective of this project was to create a producer-friendly dashboard tool (SAP America, Inc. Newtown Square, PA) to highlight the cost of not covering a horizontal silo storing corn silage. Farm-specific inputs of the dashboard tool are adjustable by the end user and include silo dimensions, dry matter of the silage, price of shelled corn/bushel, and total cost to cover silage including price of cover and labor. Bunker silage volume was calculated using silo dimensions including: 1) wall height (height of the silage next to the wall), 2) mean width (width of the silo measured half way up the silo), 3) filling ramp length (length of front filling ramp measured horizontally), 4) dome height (height of the silage above the top of the wall), 5) back ramp length (length of the back silage ramp measured horizontally), and (6) wall length (wall length at the top of the silo). Bunker silage volume calculations were generated from Brian Holmes's Investment and Annual Costs of Forage Storage Calculator (www.uwex.edu/ces/crops/uwforage/bunkersilovolume10–18–08.xls) from the University of Wisconsin–Madison. The dashboard tool outputs lost revenues from not covering a silo. This was calculated by silage price per ton (price of shelled corn/bushel × 8), multiplied by dry matter lost, and subtracting the cost of covering silage. To demonstrate model utility, total bunker silage amount was set at 1494 metric tons, dry matter density was 6.35 kg/m^3, price of corn was $5.00/bushel, total price of plastic was $485/horizontal silo, and total labor cost was $100 for covering the silo. With these inputs, the total lost revenues from not covering the silo was $1,100/year. Dairy producers may use this model as a decision support tool to highlight lost revenue from not covering silos.

Key Words: silage covering, economic dashboard, extension tool

---

1049 (T089) A producer assessment of precision dairy farming technology use, usefulness, and pre-purchase considerations.

M. R. Borchers*, and J. M. Bewley, *University of Kentucky, Lexington.*

A survey to identify producer perception of precision dairy farming technologies was distributed in March 2013 through written publications and email. Responses were collected in May 2013 ($n = 109$) and statistical analysis was performed using SAS (SAS Institute, Inc. Cary, NC). Herd size, producer age, and role on the farm were collected and analyzed but significant differences were not found ($P > 0.05$). Producers were asked to indicate parameters currently monitored on their farm from a predetermined list and producers most often selected daily milk yield (52.3%), cow activity (41.3%), and not applicable (producers not currently implementing technologies; 1.2%). Producers were asked to rank the same list on usefulness using a 5-point Likert Scale (1, not useful to 5, useful). Least-squares means were calculated using the GLM procedure of SAS and producers indicated (mean ± SE) mastitis (4.77 ± 0.47), standing heat (4.75 ± 0.55), and daily milk yield (4.72 ± 0.62) to be most useful. Pre-purchase technology selection criteria were ranked using a Likert Scale (1, not important to 5, important) by producers and benefit to cost ratio (4.57 ± 0.66), total investment cost (4.28 ± 0.83), and simplicity and ease of use (4.26 ± 0.75) were found most important. Producers were categorized into United States or an other countries category based on their farm location. Significant differences

($P < 0.05$) were identified between country and the adoption of technologies monitoring: animal position and location, body weight, cow activity, daily milk yield, lying and standing time, mastitis, milk components, rumen activity, and rumination with other countries being higher in all cases. Producers were categorized based on technology use (using technology vs. not using technology) and least-squares means were calculated across technology usefulness with daily milk yield (using technologies: 4.83 ± 0.07, vs. not using technologies: 4.50 ± 0.10) and standing heat (using technologies: 4.68 ± 0.06, vs. not using technologies: 4.91 ± 0.09) differing significantly ($P < 0.05$). Least-squares means were calculated for technology use categories on producer pre-purchase considerations and availability of local support (using technologies: 4.25 ± 0.11, vs. not using technologies: 3.82 ± 0.16) differing significantly ($P < 0.05$). Using this data, technology manufacturers can better design and market technologies for producer needs.

Key Words: producer perception, survey, precision dairy farming technologies

1050 (T090) Sustainable year-round forage production and grazing/browsing management education program. U. Karki*[1], L. B. Karki[2], N. Gurung[1], R. Lemus[3], S. Hart[4], K. Cearley[5], S. Enloe[6], E. Jolley[7], and M/Edmonson[6]. [1]*Tuskegee University, Tuskegee, AL,* [2]*PadmaDal Memorial Foundation, Auburn, AL,* [3]*Mississippi State University, Starkville,* [4] *Langston University, Langston, OK,* [5]*Texas AgriLife Extension Service, Amarillo, TX,* [6]*Auburn University, Auburn, AL;* [7]*Natural Resources Conservation Service, Auburn, AL.*

Pasture-based goat production is becoming popular among the small-scale livestock farmers in the Southern region. However, most farmers have not adopted sustainable forage programs. As a result, they depend on hay and supplementary feedstuff to sustain their herd during times of reduced forage availability. Moreover, there is not much information available on pasture development/improvement and sustainable grazing/browsing management for goats. The goal of this project was to develop a comprehensive education program to increase the productivity, quality, and production duration of pastures as well as to improve the management of existing pastures for sustainable goat production. Project objectives were: 1) to develop training curricula, and 2) to train field-level extension and technical assistance personnel and goat farmers on sustainable year-round forage production and grazing/browsing management. Tuskegee University and PadmaDal Memorial Foundation were collaborating in this project. Other key partners in the project were Alabama Natural Resources Conservation Service, Auburn University, Mississippi State University, Langston University, and Texas A&M AgriLife Extension Service. The project outputs were 1) ready- to-use training curricula in the form of a handbook- sustainable year-round forage production and grazing/browsing management for goats in the Southern Region, which is now freely available to the public at Tuskegee University website: http://www.tuskegee.edu/sites/www/Uploads/files/About%20US/TUCEP/Livestock%20Program/Year- RoundPasture_Handbook.pdf, 2) an educational video to complement the handbook (under review), and 3) trained field-level extension and technical-assistance personnel and extension specialists (22) serving the goat producers in different Southern states and lead goat farmers (4). Short-term impact results showed 29% increase in the knowledge of trainees. The medium-term impact results revealed that majority of the trainees applied the learned skills and knowledge either to educate their clientele more effectively (professionals) or improve their farm operation (farmers).

Key Words: curricula, goats, training

1051 (T091) Assessment of the potential for compost bedded pack barns in sustainable organic dairy farming systems. H. A. Mussell*, J. L. Taraba, K. L. Jacobsen, and J. M. Bewley, *University of Kentucky, Lexington.*

Compost bedded pack barns (CBP) take full advantage of composting and manure management to provide a clean, comfortable environment for cows. Although most CBP research has been conducted on conventional dairy farms, organic dairy farms could also benefit from CBP due to increased cow comfort, natural airflow, and manure storage. To assess the potential for CBP use on organic dairy farms, a survey was distributed to through multiple email lists to organic dairy producers across the United States. Twenty-seven surveys were returned. Mean herd size (mean ± SD) was 95.05 ± 78.71 cows. Mean SCC was 182,250 ± 61,605 cells/mL. Twenty-seven percent of producers housed their milking herds in a straw bedded pack, 23% in free stalls, 23% used a year-round pasture based system, 18% used CBP tilled daily, 5% used CBP that were not tilled daily and 5% used tie stall barns. Fifty percent of herds spent 19 to 23 h on pasture/d. Thirty percent spent an average of 12 h/d on pasture. Twenty percent of herds spent 24 h/d on pasture. The number of months that cows spent in a housing system for 24 h/d ranged from > 4 mo (30%), 3 to 4 mo (15%), < 2 mo (15%) or never in a housing system (30%). Organic dairy producers evaluated how effectively CBP, tie stalls, freestalls, straw-based bedded packs and pasture systems meet the needs of organic dairy herds by using a scale of 1 to 5 (1, poorly meets the needs of organic dairy herds to 5, well-suited for meeting the needs of organic dairy herds). Compost bedded pack barns (4.06 ± 0.64) were the highest ranked system, followed by straw bedded packs (3.84 ± 0.90) pasture based systems (3.39 ± 1.20), and tiestalls (2.72 ± 1.23). Using a scale of 1 to 5 (1, strongly disagree to 5, strongly agree), benefits of the CBP were ranked as shelter (4.47 ± 0.51), cow comfort (4.42 ± 0.69), access to fresh air (4.17 ± 0.99), and ventilation (4.17 ± 1.04). Compost bedded pack barns appear to be a viable housing option for organic dairy farms.

Key Words: compost bedded pack barns, organic, cow comfort

1052 (T092) Development and utilization of the AI Cowculator: A decision-aid application to determine whether to utilize fixed-time artificial insemination (TAI) or purchase herd sires for natural service. V. R. G. Mercadante*[1], D. D. Henry[1], F. M. Ciriaco[1], P. M. Mercadante[1], J. C. Rodgers[2], N. DiLorenzo[1], and G. C. Lamb[1], *[1]University of Florida, Marianna, [2]Zoetis, Florham Park, NJ.*

The development of reliable, efficient and economic TAI protocols has resulted in the opportunity for increased use in commercial cattle production systems. However, producers do not have access to simple decision-aid tools using their own data to determine whether implementing a TAI program or purchasing herd sires is more economically feasible. Therefore, we conducted an experiment to generate an economic model that determined that for every cow exposed to a TAI protocol a cattle producer will gain an additional $49 per cow after weaning. Utilizing this economic model we developed the AI Cowculator smartphone and tablet application for iOS and Android systems. Since inception, the AI Cowculator has been downloaded 1025 times in 38 states and four countries. Features of the application include: 1) a simple calculator to assist producers decide whether to utilize AI or purchase a herd sire. The calculator includes 18 entries divided into three categories (natural service sires costs, herd related costs, and artificial insemination related costs). The output includes a partial budget and provides users an opportunity to email the results to a single email account; 2) a push-pin locator that allows users to locate representatives who perform AI services or suppliers of semen and AI suppliers; 3) a resource icon that allows users to access helpful material for reproduction planning including TAI articles by the Beef Reproduction Task Force, a list of extension documents on beef production and future cattle prices; 4) a gallery of pictures and estrus synchronization protocols recommended by experts in the field; 5) a YouTube icon that provides a demonstration on the use of the AI Cowculator; and 6) a social media icon that directs to Facebook and Twitter pages and allow users to share their results. The AI Cowculator Facebook page is updated weekly with relevant reproductive management information and provides technical assistance to users of the application. Information posted on the AI Cowculator Facebook page has reached more than 5000 users of social media and has been liked by more than 310 people.

Key Words: smartphone application, decision aid tool; artificial insemination

FOOD SAFETY

1053 (T093) Regulatory process for food additives used in animal foods. S. A. Benz[1], R. Christensen[*2], and M. G. Alewynse[2], *[1]Center for Veterinary Medicine, FDA, Woodbine, MD, [2]Nutrition & Labeling Team, Center for Veterinary Medicine, FDA, Rockville, MD.*

Animal food, both livestock feed and companion animal food, is composed of many different ingredients. With recent changes in ingredient availability, there is increasing interest in the use of novel ingredients in animal food. These ingredients may be intended to be a source of nutrients or, like enzymes, may affect the characteristics of the food itself. Under Federal law, ingredients that are not generally recognized as safe (GRAS) for an intended use are considered food additives that must be approved by the Food and Drug Administration (FDA) before they can be used in animal food. The food additive petition (FAP) process is the means to get approval of food additives and it is described in Title 21 of the Code of Federal Regulations Part 571 (21 CFR 571). Within FDA, the Center for Veterinary Medicine (CVM) approves animal FAPs when a firm demonstrates that the ingredient is safe and achieves its intended purpose. In a petition, the safety of the substance at the intended use rate must be addressed for both the animal and the environment. For food producing species, the safety of human food obtained from the animals must also be addressed. When FDA approves a FAP, a regulation in 21 CFR 573 is established addressing the safe use of the substance in animal food. In September 2013, FDA published Guidance for Industry #221 on the Recommendations for the Preparation and Submission of Animal Food Additive Petitions. This draft guidance describes the types of information to be included in a petition, including: the name and all pertinent information concerning the food additive itself; chemical identity and composition of the additive; manufacturing methods and controls; intended use, use level and labeling; data establishing the intended effect (physical, nutritional, or other technical effect); a description of validated analytical methods to determine the amount of the food additive in the food; safety evaluations for the animal and humans consuming animal products; proposed tolerances for the food additive; proposed regulation; and environmental assessment. With the guidance, CVM seeks to provide the animal industry with knowledge of the types of information that are required to establish the safety of the use of an ingredient to help to ensure a safe animal food supply.

Key Words: FDA, food additive, guidance

1054 (T094) Persistence of *Escherichia coli* O157:H7 in feces from cattle fed diets with or without wet distillers grains with solubles. E. D. Berry[*], J. E. Wells, and V. H. Varel, *USDA, ARS, U.S. Meat Animal Research Center, Clay Center, NE.*

Feeding wet distillers grains with solubles (WDGS) to cattle can increase prevalence of *E. coli* O157:H7, but mechanisms for this increase are not fully understood. The objective of these experiments was to examine the persistence of *E. coli* O157:H7 in feces from cattle fed diets with or without WDGS. In the first study, fresh feces from steers fed 0, 20, 40 or 60% WDGS were collected and combined (6 to 8 animals/composite, $n = 8$ separate composites/diet treatment). Feces composites (600 g) were inoculated with a five-strain mixture of streptomycin-resistant *E. coli* O157:H7, incubated at room temperature, and sampled periodically up to 14 d. Feces samples were diluted and plated to determine *E. coli* O157:H7 levels. Compared to levels seen with diets containing WDGS, *E. coli* O157:H7 levels in feces from cattle fed 0% WDGS rapidly decreased ($P < 0.05$), from 6.28 $\log_{10}$ cfu/g on d 0 to 2.48 $\log_{10}$ cfu/g by d 14. From the same initial levels, *E. coli* O157:H7 in feces from cattle fed 20, 40, and 60% WDGS were 4.21, 5.59, and 6.13 $\log_{10}$ cfu/g of feces on d 14, respectively. A second study evaluated survival of *E. coli* O157:H7 in feces from cattle fed 0 and 40% WDGS. Steers were fed in eight pens (75 to 77 per pen; 4 pens/WDGS treatment). Feces were collected from 5 to 6 animals in each pen, both before and after the corn source was switched from high-moisture corn (HMC) to dry-rolled corn (DRC). Feces samples were combined within pen, inoculated, incubated, and analyzed for *E. coli* O157:H7 as described above, and examined in triplicate at 0, 1, 2, 4, and 7 d. Within corn source, *E. coli* O157:H7 persisted at higher levels ($P < 0.05$) in 40% WDGS feces at d 7. For 40% WDGS feces, *E. coli* O157:H7 persisted at higher levels ($P < 0.05$) at d 7 in feces when cattle were fed HMC compared to DRC. Greater persistence of *E. coli* O157:H7 in the feces and environment of cattle fed WDGS may play a role in the increased prevalence of *E. coli* O157:H7 seen in these animals, by increasing the risk for recolonization of animals. This work further suggests potential dietary approaches for reducing the occurrence and numbers of this pathogen in cattle fed WDGS. *USDA is an equal opportunity provider and employer.*

Key Words: *E. coli* O157:H7, distillers grains, cattle

1055 (T095) Characterization of Shiga toxin-producing *Escherichia coli* isolated from feces of cattle in commercial feedlots. T. W. Alexander[*1], T. A. McAllister[1], K. Stanford[2], T. Reuter[2], and E. Topp[3], *[1]Agriculture and Agri-Food Canada, Lethbridge, AB, [2]Alberta Agriculture and Rural Development, Lethbridge, Canada, [3]Agriculture and Agri-Food Canada, London, ON.*

Shiga toxin-producing *Escherichia coli* (STEC) are potential food and waterborne zoonotic pathogens. The objective of this study was to characterize the general population of *E. coli* (EC) in feedlot cattle and determine the proportion that is STEC. Four commercial feedlots with approximately 1,000 pens were sampled over a three-year period. Thirty percent of the pens were randomly selected for study enrollment. Pens were sampled when they had been filled with cattle and again after cattle had been on feed for > 60 days. Sampling consisted of collecting 1 to 2 g of material from 20 fresh fecal pats on pen floors and combining them into a single mixed sample per pen. In total, 291 pens were sampled and processed for EC isolation at both time points. A total of 3,578 EC were isolated and stored after plating pooled fecal pats onto MacConkey agar. Isolates of EC were then screened by multiplex real-time PCR for the virulence genes *stx*1, *stx*2, and *eae*. Isolates positive for *stx*1 or *stx*2 were further characterized for i) variants of *stx* using PCR, ii) susceptibility to 15 antimicrobials using broth dilution, and iii) genetic relatedness after pulsed-field gel electrophoresis (*P*FGE) of Xba1 restricted DNA. In total, 60 (1.7%) isolates tested positive for *stx*1 (N = 27), *stx*2 (N = 30) or a combination of *stx*1 + *stx*2 (N = 3) genes. The most prevalent *stx* variant was *stx*1d, followed by *stx*2a, *stx*2g, *stx*1a, *stx*1a + *stx*2a, and *stx*2b (N = 18, 15, 8, 7, 3, and 2, respectively). Undefined *stx*1 and *stx*2 variants were present in 2 and 5 isolates, respectively. Seasonality and time of isolation did not affect prevalence of total *stx*1 or *stx*2 ($P > 0.05$). However the majority of isolates with *stx*1d (15/18) and *stx*2g (7/8) were detected at > 60 days. Only 10 STEC (0.3%) also tested positive for *eae*. Sampling time point did not affect the prevalence of antimicrobial-resistant STEC ($P > 0.05$). Overall, 69.8% of STEC were resistant to at least one antimicrobial. The most prevalent resistance was to tetracycline which was common to all resistant STEC. From PFGE, 46 subtypes were observed. These data indicate STEC from feedlot cattle are diverse and their prevalence is low among the general population of EC. In addition, the majority of STEC were *eae*-negative, thus unlikely to be associated with outbreaks of hemolytic uremic syndrome.

Key Words: STEC, *Escherichia coli*, cattle

1056 (T096) Development of an ultrasensitive aptasensor for the detection of aflatoxin B1. X. Guo[1,2,3], F. Wen[1,4], N. Zheng[*1,3,4], Q. Luo[2], and J. Wang[1,4], *[1]Ministry of Agriculture—Laboratory of Quality and Safety Risk Assessment for Dairy Products, Beijing, China, [2]College of Animal Science and Technology, Xinjiang Agricultural University, Urumchi, China, [3]Ministry of Agriculture - Milk and Dairy Product Inspection Center, Beijing, China, [4]State Key Laboratory of Animal Nutrition, Institute of Animal Science, Chinese Academy of Agricultural Sciences, Beijing, China.*

Contamination of feed and food by aflatoxin B_1 (AFB_1), one of the most toxic of the mycotoxins, is a global concern. To prevent food safety scares, and avoid subsequent economic losses due to the recall of contaminated items, methods for the rapid, sensitive and specific detection of AFB_1 at trace levels are much in demand. In this work, a simple, ultrasensitive, and reliable aptasensor is described for the detection of AFB_1. An AFB_1 aptamer was used as a molecular recognition probe, while its complementary DNA played a role as a signal generator for amplification by real-time quantitative polymerase chain reaction (*P*CR). Under optimal conditions, a wide linear detection range (5.0×10^{-5} to 5.0 ng mL^{-1}) was achieved, with a high sensitivity (limit of detection (LOD) = 25 fg mL^{-1}). In addition, the proposed aptasensor exhibited excellent specificity for AFB_1 compared with eight other mycotoxins, with no obvious Ct value change. This aptasensor can also be used in quantifying AFB_1 levels in Chinese wildrye hay samples and infant rice cereal samples, demonstrating satisfactory recoveries in the range of 88–127% and 94–119%, respectively. This detection technique has a significant potential for high-throughput, quantitative determination of mycotoxin levels in a large range of feeds and foods.

Key Words: aflatoxin B_1, aptasensor, feed and food safety

1057 (T097) Cytotoxicity induced by ochratoxin A, zearalenone and α-zearalenol: Effects of individual and combined treatment. H. Wang[1,2,3,4], N. Zheng[1,2,3], S. Li[1,2,3], F. Li[4], and J. Wang[*1,2,3], *[1]State Key Laboratory of Animal Nutrition, Institute of Animal Science, Chinese Academy of Agricultural Sciences, Beijing, China, [2]Ministry of Agriculture - Milk and Dairy Product Inspection Center (Beijing), Beijing, China, [3]Ministry of Agriculture - Laboratory of Quality and Safety Risk Assessment for Dairy Products, Beijing, China, [4]College of Animal Science and Technology, Gansu Agricultural University, Lanzhou, China.*

Mycotoxins, a series of secondary metabolites generated from moulds, mainly come from food and feed contaminated in the field, during drying and subsequent storage. Among all

the mycotoxins, ochratoxin A (OTA), zearalenone (ZEA) and α-zearalenol (α-ZOL) have evoked great concern owing to their high occurrence and serious harm to human health. The co-occurrence of OTA, ZEA and α-ZOL was found in animal feed and milk. The previous reports indicated that the co-occurrence of mycotoxins could increase their cytotoxicity. The aim of the present study was to investigate the cytotoxicity of combined mycotoxins of OTA, ZEA and α-ZOL on human Hep G2 cells by using the tetrazolium salt (MTT) assay and the isobologram analysis. Statistical analysis of data was carried out using SAS9.2, statistical software package. Our results demonstrated the significant ($P < 0.05$) cytotoxic effects of the two-toxin combination and the three-toxin combination on Hep G2 cells in a time- and concentration-dependent manner. The IC_{50} (inhibit concentration equal to 50%) values of Hep G2 treated with individual mycotoxin after 24 h, 48 h and 72 h of exposure were 1.86-8.89 μM, 29.48-55.79 μM, 20.91-52.30 μM for OTA, ZEA and α-ZOL, respectively. The combined indexes (CI) were 2.73–7.67 for OTA+ ZEA and 1.23–17.82 for OTA+ α-ZOL after 24 h, 48 h and 72 h of exposure at all inhibit concentration(IC) levels (IC_{10}-IC_{90}), indicated an antagonism. The CIs of ZEA+ α-ZOL were 1.29–2.55 after 24 h and 72 h of exposure (IC_{10}-IC_{90}), indicated an antagonism. The CIs of ZEA+ α-ZOL were 0.74-1.68 after 48 h of exposure, indicated an antagonism (IC_{10}-IC_{40}), additive effect (IC_{50}-IC_{70}) or synergism (IC_{80}-IC_{90}). The CIs were 1.41–14.65 for OTA+ ZEA+ α-ZOL after 24 h, 48 h and 72 h of exposure (IC_{10}-IC_{90}), indicated an antagonism. In conclusion, OTA was more toxic than ZEA and α-ZOL. The combined mycotoxins of OTA and ZEA, OTA and α-ZOL, OTA, ZEA and α-ZOL showed antagonism. And the combined mycotoxins of ZEA and α-ZOL showed antagonism, additive effect and synergism at different concentrations. But the result of combined mycotoxins affected by type of cell used endpoint of cytotoxicity, analysis assay of interaction, and other factors. So interaction of combined mycotoxins should be determined or re-validated in continuously toxicological data.

Key Words: ochratoxin A, zearalenone, α-zearalenol

1058 (T098) Efficacy of various levels of mycotoxin adsorbent to reduce aflatoxin M1 levels in milk of lactation cows fed aflatoxin B1. M. Dehghan banadaky[*1], R. Motameny[2], and S. Parhizkar[3], [1]*Dep. of Animal Science, Faculty of Agriculture, University of Tehran, Karaj, Iran,* [2]*Azad University, Tehran, Iran,* [3]*University of Tehran, Karaj, Iran*.

The aim of this study was to compare the ability of various levels of adsorbent Biotox (Biochem GmbH, Lohne, Germany) to reduce Aflatoxin in milk of Holstein cows. Twenty-four lactating Holstein cows in mid lactation were assigned to one of three treatments ($n = 8$) for 35 d. Diet formulated according to the nutrient requirements of dairy cattle (NRC, 2001). The following treatments were investigated 1- Aflatoxin diet plus 60 g/d/cow of Biotox (Biochem GmbH, Lohne,. Germany), 2- Aflatoxin diet plus 20 g/d/cow of Biotox and 3- Aflatoxin diet without mycotoxin adsorbent (Control). Aflatoxin diet provided 350 μg/d/cow of AFB. Individual dry matter intake and milk yield were recorded daily. Milk samples were collected at each milking time weekly. Blood samples (10 ml) were collected weekly from the coccygeal vein and centrifuged to separate plasma. Quantification of aflatoxin (B1 or M1) in TMR samples, milk and plasma done using microtitre plate enzyme linked immunosorbent assay (ELISA) method. Weekly data were analyzed using the PROC MIXED of SAS as repeated measurement data. Aflatoxin M1 concentrations for the Biotox60, Biotox20 and control (no adsorbent) treatments averaged 338.0, 439.0 and 490.1 ng/kg, respectively. Compared to the control group, AFM1 concentrations in milk were reduced ($P = 0.015$) by the addition of 20 and 60 g/d/cow of Biotox. Aflatoxin M1 excretion via milk, as calculated from milk AFM1 concentration and total milk volume produced, was 9.87, 12.87 and 14.66μg/d/cow in the Biotox60, biotox20 and control treatments respectively. Biotox significantly decreased AFMI excretion in milk ($P = 0.033$). Transfer rate of AF from feed to milk (TR), as calculated from [(excretion of AFM1/AFB1 consumption) × 100] averaged 2.90, 3.85 and 4.22% for the Biotox60, biotox20 and control treatments respectively. Biotox in 60 g/day dose significantly decreased Aflatoxin TR ($P = 0.029$). The results of the analysis of variance on plasma AFM1 showed that treatment did not affect plasma AFM1, but numerical increase in plasma AFM1 of control group showed. Results of the current study indicate that the Biotox was effective in reducing milk AFM1 concentrations, AF excretion, and AF transfer from feed to milk, but this efficacy was improved in higher dosage (60g/day/cow) at least in high polluted diets.

Key Words: aflatoxin, transfer rate, milk

1059 (T099) Inhibitory activity of *Staphylococcus aureus* against *Lactococcus* spp. isolated from artisanal Minas cheese. F. F. Ângelo[1], L. M. Fonseca[*2,3], and M. A. V. P. Brito[4], [1]*Universidade Federal da Paraíba/CTDR, João Pessoa, Brazil,* [2]*Universidade Federal de Minas Gerais* (*School of Veterinary Medicine), Belo Horizonte, Brazil,* [3]*University of Wisconsin-Madison/CAPES Est. Senior 18183-12-3, Madison,* [4]*EMBRAPA Gado de Leite* (*CNPGL), Juiz de Fora, Brazil.*

Production of antimicrobial substances by *Staphylococcus aureus* isolated from food has been reported. Since it is a highly prevalent etiologic agent for mastitis in dairy herds, inhibition of starter culture due to *S. aureus* inhibitory activity is possible during the processing of fermented dairy products, such as cheeses. The objective of the current work was to evaluate the antimicrobial substances produced by samples of *S. aureus* isolated from cow's milk during mastitis occurrence and their effect against strains of *Lactococcus* spp. Individual milk samples,

obtained from 54 herds, were analyzed for *S. aureus* presence and isolated strains were tested for inhibitory activity using the deferred-antagonism assay, with *Corynebacterium fimi* (NCTC 7547) as indicator. Proteic nature of the antimicrobial substances was investigated using protease type XIV from *Streptomyces griseus* (Sigma P-5147). Inhibitory spectrum was tested against nine *Lactococcus* spp. strains, previously isolated from artisanal Minas cheese. Descriptive statistics was used. Antimicrobial activity using the deferred-antagonism assay was detected in 262 (40%) of the 655 *S. aureus* strains tested. All 262 strains were inactivated by a proteolytic enzyme tested, indicating their proteic nature, a characteristic of bacteriocins. From 262 positive strains, 55 were selected based on the diameter of inhibition zone (> 10mm) for inhibitory activity against *Lactococcus* spp. Noteworthy, 42 strains (76%) presented some inhibitory activity against *Lactococcus* spp., and one strain of *S. aureus* presented inhibitory activity against five *Lactococcus* spp. strains. The results indicate that some *S. aureus* strains inhibit samples of *Lactococcus* spp. isolated from artisanal Minas cheese. Additional work is recommended to investigate further implications of this finding.

Key Words: *Staphylococcus aureus*, bacteriocins, mastitis

1060 (T100) Microbiological quality and safety of commercial local yogurt products in Giza Governorate, Egypt.

M. M. Motawee[*1], and S. A. Ibrahim[2], *[1]National Organization for Drug Control and Research, Giza- Egypt, Egypt, [2]North Carolina A&T State University, Greensboro.*

Yogurt is the most popular dairy product in Egypt. The popularity of yogurt can be attributed to its sensory characteristics and nutritional value. The microbiological characteristics of yogurt also contribute greatly to in the quality and shelf life of the final product. Thus, the objective of this study was to examine the microbiological quality and safety of yogurt products available in the local market in Giza Governorate, Egypt. One hundred yogurt samples were collected from local stores and stored in refrigerators prior to microbiological examination which was done within 24 h. Samples were stored under chilled conditions for 14 d at 7ºC ±1 and examined for yogurt culture viability, psychrophic bacteria (*Pseudomonas*), *Salmonella, Staphylococcus, E. coli, Aspergillus, and Bacillus*. The identification of each isolate was molecularly conformed using 16s rRNA. Our results showed that the yogurt culture maintained 6-7 log CFU/ml during the chilled storage. The psychrophic bacteria ranged from 5-6 log CFU/ml, whereas the other tested groups ranged from 2-4 log CFU/ml. The population of the tested bacteria did not change during chill storage. Our findings demonstrated that pathogenic bacteria could survive in commercial yogurt products. However, the presence of yogurt culture could help prevent foodborne illness in consumers. Our research demonstrates the importance of having standardized hygienic quality control practices in place to ensure the highest yogurt quality. Therefore, the implementation of HACCP or an equivalent safety protocol is paramount in preventing future outbreaks of foodborne illness in such popular dairy products in Egypt.

Key Words: yogurt, foodborne, quality.

1061 (T101) Stability of 10 β-lactam antibiotics in raw milk under different storage conditions.

H. Wang[1,2,3], N. Zheng[1,3], F. Wen[1,3], H. Wang[2], and J. Wang[*1,3], *[1]Ministry of Agriculture - Laboratory of Quality & Safety Risk Assessment for Dairy Products, Beijing, China, [2]College of Animal Science and Technology, Yangzhou University, China, [3]State Key Laboratory of Animal Nutrition, Institute of Animal Science, Chinese Academy of Agricultural Sciences, Beijing, China.*

B-lactam antibiotics are used to cure mastitis which inflicts severe economic losses in dairy farming. However, improper use of antibiotics may lead to residues in milk, which could be toxic and dangerous for human health, and may cause allergic reactions and antimicrobial resistance. At present, several methods for detecting the residue of β-lactam require milk samples to be sent back to a testing laboratory and stored until further analysis. In this study, we attempted to evaluate the stability of 10 β-lactam antibiotics, include amoxicillin (AMOX), cloxacillin (CLOX), oxacillin (OXAC), penicillin G (*P*ENG), nafcillin (NAFC), cefoperazone (*P*ER), cephapirin (*P*IR), ceftiofur (TIO), cefazolin (ZOL) and cefalonium (LON) in raw milk under different storage conditions, such as storage temperature and time, thawing temperature, freeze-thaw cycle times, and the addition of preservatives. Raw milk samples were collected from a local farm in Beijing and transported to our lab as soon as possible. Milk samples were spiked with the Maximum Residue Limits (MRL) levels in China and the antibiotic residues were determined by UPLC-MS/MS. Results showed that most of these antibiotics were quite stable (recovery = 90 ~ 120%) under different storage conditions, and their degradation rate increased with the increasing storage temperature and time, thawing temperature and freeze-thaw cycle times. Among the variables, preservatives played a critical role in the stability of β-lactam. The storage of PIR at room temperature for 1 day in raw milk containing preservatives resulted in a degradation rate up to 41.7%. Above all, the milk samples should be stored at -80ºC less than 7 days so that the β-lactam residues can be analyzed accurately.

Key Words: raw milk; β-lactam; storage conditions

1062 (T102) Risk warning of veterinary drug residues in raw milk based on shewhart control chart.

R. Han[1,2,3], N. Zheng[3,4], Z. Yu[2], X. Qu[1,3,4], S. Li[1,3,4], Y. Zhang[1,3,4], X. Zhou[1,3], and J. Wang[*1,3,4], *[1]State Key Laboratory of Animal Nutrition, Institute of Animal Science, Chinese Academy of Agricultural Sciences, Beijing, China, [2]College of Food Science and Engineering, Qingdao Agricultural University, China, [3]Ministry of Agriculture - Laboratory of Quality & Safety Risk Assessment for Dairy Products, Beijing, China, [4]Ministry of Agriculture - Milk and Dairy Product Inspection Center, Beijing, China*.

The aim of this study was to develop a dynamic risk warning method of veterinary drug residues in raw milk. Risk warning methods of veterinary drug concentration above MRLs (C1 risk warning), abnormal detection rates (J-Pn risk warning) and average-standard deviation (X-δ risk warning) were developed based on theory of Shewhart Control Chart. Flumequine and danofloxacin residues data of raw milk from a large dairy company were collected. Fifty raw milk samples were detected in each week and total of 1,000 continuous data of 20 weeks were analyzed. The data were divided into 20 groups according to time series. C1 risk warning was not triggered, because none of samples exceeded MRLs. J-Pn risk warning was used for danofloxacin, because most of samples were not detected. Central line (CL) was calculated with the value of 5.95 and upper control limit (UCL) was 12.82. Control charts indicated that numbers of samples detected in each week were stable and all less than 12.82, so J-Pn risk warning was not necessary in 1-20 weeks. For flumequine, X-δ risk warning was used, because most of samples were detected. The value of CL was 1.5 and UCL was 2.82. Results analyzed by control charts showed average of flumequine in each week were stable and less than 2.82, so X-δ risk warning was not necessary in 1-20 weeks. In this study, abnormality of detection rate and average-standard deviation was also assumed and analyzed.

Key Words: risk warning, veterinary drug residues, Shewhart Control Chart

1063 (T103) Stability of flavonoids in grape seed and grape marc meal extract (GSGME).

M. Würzbach, E. Holl, and B. Eckel[*], *Dr. Eckel GmbH, Niederzissen, Germany.*

A secure food supply is crucial to all consumers. The use of a plant derived component poses a challenge for quality control: environmental factors lead to variations of plant composition, regarding the desired active substances, during the growth period. After harvest the active component should stay stable. The following study investigates the processing and storage stability of plant derived components, using the example of plant derived flavonoids in GSGME (AntaOxE, Dr. Eckel GmbH, Niederzissen, Germany). Flavonoids have shown anti-inflammatory properties and are effective for animal nutrition (Gessner et al., 2013; Fiesel et al., 2013). The stability of flavonoids in GSGME was studied under common processing conditions with different stressors: time of storage (9 mo), standard packaging material and temperature stress to simulate manufacturing processes. Flavonoid content was analysed using the Folin-Ciocalteu-method (Waterhouse, 2003). It was decided to compare storage characteristics in bags which were shut and sewn or open, stored under cool to room temperature (22°C) conditions. Each measurement was taken in triplicate. The samples, with an initial flavonoid concentration of about 86g/kg ± 0.9g/kg, were analysed every 3 mo. To rule out light as a potential influence, some samples were stored in daylight and some in darkness. Heat stability of flavonoids was tested in a cabinet dryer (Heraeus) at different temperatures, ranging from room temperature to 140°C for 4 hr. In the present study, the analysis of the flavonoid content after 3 mo of storage showed a higher concentration (up to 156g/kg ± 1.6g/kg) than before. This increase in flavonoid concentration may be caused by isomerisation. We found no influence of sealing and packaging on flavonoid activity. For the samples stored under daylight conditions, we analysed an increase in flavonoid content of maximum 25% compared to the other groups after 9 mo. For temperatures of 50°C, 75°C and 100°C, the samples showed flavonoid contents above the initial concentration of 86g/kg ± 0.9g/kg. At 120°C and 140°C, the flavonoid content decreased to 70 to 82g/kg. The study showed that both storage up to nine months or temperatures up to 120°C did not lead to a reduction of the initial concentration of flavonoids in GSGME. It even had a positive influence on concentrations. The results indicate that GSGME can be used without any concern with regard to flavonoids. Further studies should be conducted to explain the increase of flavonoids during storage and which molecules are modified during that time.

Key Words: flavonoids, stability, AntaOxE

1064 (T104) Effect of lysozyme or antibiotics on fecal zoonotic pathogens in nursery pigs.

J. E. Wells[*], E. D. Berry, N. Kalchayanand, L. A. Rempel, and W. T. Oliver, *USDA, ARS, U.S. Meat Animal Research Center, Clay Center, NE.*

Lysozyme is a 1,4-β-N-acetylmuramidase that has antimicrobial properties. The objective of this study was to determine the effect of lysozyme and antibiotics on zoonotic pathogen shedding in feces in nursery pigs housed without and with an indirect disease challenge. Two replicates of 600 pigs each were weaned from the sow at 26 d of age (d 0), blocked by litter and gender, and then randomly assigned to one of 24 pens in either a nursery room that had been fully disinfected or a nursery room left unclean after the previous group of pigs. Within a room, pigs were randomly assigned to control diets (C; 2-phase nursery regime), control diets + antibiotics (C + A; chlortetracycline and Denegard), or control diets +

lysozyme (C + Lyso; 100 mg/kg diet). Rectal swab samples were collected on d 0 and 28 of treatment, and enriched and cultured for *Campylobacter* spp. and shigatoxigenic *Escherichia coli* (STEC) O26, O45, O103, O111, O121, O145 and O157. Enrichments from rectal swab samples were also analyzed for presence of enterohemorrhagic *E. coli* (EHEC) virulence genes (*hly*A, *eae*, *stx*1, and *stx*2). Overall, the percentage of samples positive for *Campylobacter* spp., *hly*A, *eae*, and *stx*1/*stx*2 on d 0 were 43.8, 27.4, 25.3, and 14.3%, respectively, and all were different on d 28 (70.6, 17.4, 78.7, and 3.0%, respectively; $P < 0.05$). Room hygiene on d 0 had little effect on d 28 results, except the percentage positives for *hly*A was greater (21.6 vs 13.4%; $P < 0.02$) and for *eae* was less (74.7 vs 82.6%; $P < 0.02$) in unclean compared to clean rooms, respectively. Percentage of samples culture positive for *Campylobacter* spp. was lowest for C + Lyso diet, but similar for C and C + A diets (43.2, 83.7, and 84.8.respectively; $P < 0.01$). Diet had little effect on the EHEC virulence genes *hly*A or *eae* ($P > 0.1$), but there was a tendency for lower percentage of samples positive for *stx*1/*stx*2 in C + A or C + Lyso diet groups compared to C diet (5.8, 1.2, and 2.1%, respectively; $P < 0.07$). The STEC types tested were rarely detected and not affected by time, hygiene or treatment ($P > 0.1$). Thus, lysozyme in the diet can reduce fecal shedding of *Campylobacter* spp. from nursery swine. *USDA is an equal opportunity provider and employer*.

Key Words: antibiotics, lysozyme, swine

1065 (T105) Thermophilic spore forming bacilli: attachment and biofilm formation on stainless steel. M. C. Enes Ribeiro[1], G. Theodore Walsh[2], M. Lucia Gigante[1], and R. Jimenez-Flores[*2], *[1]Faculty of Food Engineering, University of Campinas, Campinas, SP, Brazil, [2]Dairy Products Technology Center, California Polytechnic State University, San Luis Obispo.*

Studies suggest that the spores of thermophilic bacilli possibly bind to the stainless steel surface in greater numbers than vegetative cells. The aim of this study was to evaluate the attachment and biofilm formation by spore-forming bacteria on stainless steel. The microorganisms (CM12, SL12, SL9, CM3, CH7, and SH6) were isolated from milk powder plants in the USA and belong to the collection of cultures at DPTC/Cal Poly. To evaluate the spores attachment and biofilm formation, cleaned stainless steel coupons were used. The experiments were carried out using either whole or fat free UHT milk in order to form a fouling film on the coupons surface. The system was kept at 55°C for 20 hours at 200 rpm. After film formation, the coupons were removed from the matrices and immersed into an aqueous spore solution held at the same conditions to verify the ability of attachment and biofilm formation. Spores were enumerated after heat treatment (80°C/12 minutes) for either 5 minutes or for 20 hours. In addition, a SDS-PAGE gel was performed in order to verify the proteins present in the spores. The effect of the matrices (fat free or whole milk), microorganisms (six different strains), time of exposure (5 minutes or 20 hours), and their interactions on the spores attachment and biofilm formation were evaluated by ANOVA and Tukey's test for comparison between means ($P < 0.05$). Although, the spore strain and the time of exposure significantly affected the attachment and biofilm formation, none of the interactions among the factors were significant. Spores attachment ranged from 3 to 4 log cfu/cm^2. The highest average attachment was observed by SL12 and SH6 (4.01 and 4.08 log cfu/cm^2, respectively), while CM12 and SL9 showed the lowest average attachment (3.42 and 3.52 log cfu/cm^2, respectively). The strains that showed the lowest average attachment (CM12 and SL9) also presented less protein in band density around 25 and 50kDa when compared to the other four strains in the SDS-PAGE. Despite the attachment after 5 minutes was significantly higher than 20 hours, the difference observed was only 0.12 log cfu/cm^2. The results suggest that these matrices did not interfere with the spores attachment and biofilm formation. This could be a strain-dependent characteristic since spores protein may play an important role on attachment. *Acknowledgments: CNPq, CAPES.*

Key Words: dairy, spores, biofilm

1066 (T106) The consumer profile of certified beef in the XXI century. M. E. A. Canozzi[1], J. Magero[1], R. C. T. Mesquita[1], J. O. Barcellos[2], D. Streit Júnior[1], and L. Kindlein[*1], *[1]Universidade Federal do Rio Grande do Sul, Porto Alegre, Brazil, [2]Universidade Federal Do Rio Grande Do Sul, Porto Alegre, Brazil*.

The beef production chain has been reinvented as a consequence of changes in perceptions and importance of its various players. The emergence of the current model, which combines quality and food safety, was in the late twentieth century. It was due to the expansion of the international trade in meats and an awareness of the connection between health crises and animal derived products. These changes in the supply chain and the difficulty of the consumer to judge quality and food safety favored the emergence of the certification processes in the beef market. The aim of this study was to characterize the publications and evaluate the consumer profile of certified beef. A systematic search of descriptive and/or sensory research published between 2002 and 2012 was performed. Three hundred twenty-seven indexed papers were found in the literature on the proposed subject. Only 34 papers were selected for (10.4%) in depth evaluation, based on its importance and meta-analysis methodology. Over these ten years there was a gradual increase in the number of publications. Concerning the spatial distribution of publications, the highest proportion was from the European continent (46.2%), followed by North (23.1%) and South America (15.4%). More than half of the analyzed articles (60.5%) studied traceability, and less repre-

sentative was animal welfare and geographical origin (11.6%/each). There was a predominance of studies on accreditation type most sought or demanded by consumers (35.8%), followed by willingness of the consumer to pay a premium price (33.9%) and the relationship between socio-demographic characteristics and certification type (30.7%). The consumer demand for certified beef in the 21st century increased after the health crises and the quality differential became a relevant point in the buying decision. This process was influenced by social and demographic characteristics.

Key Words: food certification, meta-analysis, traceability

1067 (T107) Identification of horsemeat presence in beef commercial butcheries using the polymerase chain reaction (PCR) technique. G. Aranda-Osorio*[1], B. Alarcón-Zúñiga[1], M. Huerta-Bravo[1], O. Hernández-Mendo[2], and G. Reséndiz-González[1], *Departamento de Zootecnia, Universidad Autónoma Chapingo, México, [2] Colegio de Postgraduados, Montecillo, México.*

The objective of the present study was to determine the presence of horsemeat in beef commercial butcheries through the use of the polymerase chain reaction (PCR) technique. Statistically, horsemeat is not consumed in México, however, the country occupied important places in the world as producer (4º with 64,695 ton) and exporter (4º with 14,026 ton), remaining an important amount (a little more than 50,000 ton) that should be commercialized into the domestic market, thus the question is if some portion of this amount is commercialized as beef in one of the biggest markets in the country, México City. To give answer to this question, there were sampled 22.5% of the Delegational markets of México City (the City is divided in 16 Delegations, each one have different numbers of markets, depending on their size and population). From a completely random design there were selected two butcheries per market, in each butchery, there was asked (bought) for a portion of specific cut of beef, approximately 250 g of "aguayón" (*Biceps femoris*), although it was not always the case. Once the sample was obtained, it was immediately identified and kept on ice for transportation to the meat lab, once arrived to it, the samples were prepared: from the center of the meat cut (to avoid contamination) a subsample of 1 g was deposited in a vial and freeze (-80ºC) until lab analysis. The PCR technique used was based in the methodology reported by Matsunaga *et al.* (1999). Fortunately, the results showed that only 5.5% of the samples were positive to equine. Horsemeat is as nutritious a beef, and has the advantage of being a lean meat, thus less saturated fatty acids, less probability of cardiovascular problems, although, the key point is the fraud to the consumer.

Key Words: DNA identification, meat substitution

FORAGES AND PASTURES: FORAGES AND PASTURES 1: SILAGES AND FORAGES IN DAIRY PRODUCTION SYSTEMS

1068 (M085) The influence of wilting on the quality of *Leucaena leucocephala* silage. T. Clavero[*1], and R. Razz[2], [1]*Universidad Del Zulia, Maracaibo, Venezuela,* [2]*Universidad del Zulia, Maracaibo, Venezuela.*

An experiment was conducted in the northwest of Venezuela in order to evaluate the ensiling properties of *Leucaena leucocephala* using laboratory silos. Factors studied were wilting for 0 and 3 h and ensiling time of 0, 7, 14, 21, and 35 d.The silos were kept in the room set at 25ºC and samples were taken from three silos at each sampling time for chemical analyses. Data were analyzed as a randomized design with a 2 x 5 factorial of wilting and ensiling time, respectively, with three replications. Means were compared by Tukey test. Response variables were: DM, cellulose (C), pH , total nitrogen (TN), ammonia (NH_3) and NH_3/TN. Increasing ensiling time of high moisture *Leucaena* resulted in losses of DM in the silage, unwilted silage contained 52.3% DM at the end of ensiling time while wilting silage showed 59.9% of DM. Ensiling *Leucaena* from 0 to 35 days resulted in decreased ($P < 0.05$) C content in 9.5% for high moisture silage in contrast to 6.5% for wilted. This could have been due to the cumulative activity of plant cell respiration and some facultative bacteria in the fresh ensiled forage. The pH increased ($P < 0.05$) while TN, NH_3 and NH_3/TN decreased ($P < 0.05$) with reduced moisture content of ensiled *Leucaena.* The concentrations of fermentation end-product decreased with wilting, showing that low moisture restricted fermentation. The reduction in TN content in wilted silage was expected due to breakdown of true protein during sun-drying and ensiling process. Wilting resulted in decreased ($P < 0.05$) NH_3 and NH_3/TN when compared to high moisture silage. Concentrations of NH_3 and NH_3/TN in high moisture silage were 35.3 and 24.6% greater, respectively than wilted silage. However, levels of NH_3 were less than 80-100 g/kg TN which is commonly used to represent well fermented silage. All silages in the current experiment achieved satisfactory preservation.

Key Words: *Leucaena leucocephala*, wilting, silage, quality

1069 (M086) Comparison of milk fatty acid profiles of dairy cows grazing cool-season perennial ryegrass or birdsfoot trefoil pasture on a commercial organic dairy farm. R. G. Christensen[1], J. S. Eun[*1], V. Fellner[2], A. J. Young[1], and J. W. MacAdam[1], [1]*Utah State University, Logan,* [2]*North Carolina State University, Raleigh.*

This experiment investigated milk fatty acid (FA) profiles of grazing dairy cows on a commercial organic dairy farm during 2 grazing seasons in 2012 and 2013. Eighteen multiparous cows in mid-lactation were assigned to one of 2 intensively rotated grazing treatments in a completely randomized design: cool-season perennial ryegrass (RGP) vs. birdsfoot trefoil pasture (BFTP). Cows received 2.27 kg of concentrate (flaked barley grain and vitamin and mineral supplement) twice per day following milking. Experiment lasted a total of 10 wk, with 2 wk for adjustment to pasture treatments and 8 wk for data and sample collection. Samples of pasture forages and milk were taken at wk 2 and 6 and were analyzed to determine their FA profiles. In 2012 and 2013, averaged concentration of C18:3 n-3 (42.6 and 53.5 g/100 g) was the greatest in pasture forage FA followed by C16:0 (20.5 and 15.7 g/100 g) and C18:2 n-6 (13.9 and 13.5 g/100 g), respectively. The most noticeable difference of pasture forage FA profiles in 2012 and 2013 was that in 2012 proportion of C18:3 n-3 in RGP increased from wk 2 (39.8 g/100 g) to wk 6 (47.1 g/100 g), whereas its proportion in BFTP was similar at wk 2 and wk 6. In contrast, proportion of C18:3 n-3 in RGP and BFTP decreased from wk 2 (57.3 and 55.1 g/100 g) to wk 6 (51.9 and 49.6 g/100 g), respectively. Concentration of *trans*-11 C18:1 in milk was very low in RGP and BFTP in both grazing seasons, suggesting limited impacts of pasture on the biohydrogenation activity for the pastures tested. Dairy cows grazed on RGP and BFTP showed similar concentrations of *cis*-9, *trans*-11 conjugated linoleic acid in milk fat throughout grazing seasons. Cows grazed with BFTP increased concentration of C22:6 (n-3; docosahexaenoic acid) at wk 6 in 2012 and 2013 compared to those grazed with RGP. However, pasture treatment did not affect ratio between polyunsaturated FA and saturated FA in two grazing seasons. Overall results in this experiment indicate that source of pastures did not affect major milk FA profiles, and some minor changes in FA profiles may have resulted from pasture FA profiles in two grazing seasons.

Key Words: birdsfoot trefoil pasture, lactating dairy cows, milk fatty acids

1070 (M087) Lactational response of Holstein cows to brown midrib or leafy-floury corn silage.

S. Y. Morrison*[1], K. W. Cotanch[1], C. S. Ballard[1], H. M. Dann[1], E. O. Young[1], R. J. Grant[1], and C. I. Key[2], *[1]William H. Miner Agricultural Research Institute, Chazy, NY, [2]Healthy Herd Genetics & Nutrition, LLC, Oneida, NY.*

The objective of this experiment was to measure the response of lactating Holstein cows to total mixed rations containing either brown midrib-3 (BMR; Mycogen F2F387) or an experimental leafy-floury hybrid (LF; Healthy Herd Genetics HHG39HF13) bred for improved NDF and starch digestibility compared with similar leafy corn hybrids. Sixteen cows (6 primiparous; 10 multiparous) averaging 130 ± 16 days in milk were assigned to one of two dietary sequences in a crossover design with 28-d periods (21 d adaptation and 7 d collection). Each diet contained 49% BMR or LF corn silage, 9.8% haycrop silage, and 41.2% concentrate mix (DM basis). The BMR silage contained 30.2% DM, 7.3% CP, 41.5% NDF, 60.2% 24-h NDF digestibility, 31.0% starch, and 77.5% 7-h starch digestibility (DM basis). The LF silage contained 31.9% DM, 7.8% CP, 42.6% NDF, 47.5% 24-h NDF digestibility, 30.3% starch, and 73.0% 7-h starch digestibility which was unexpectedly low. The BMR diet contained 17.2% CP, 32.2% NDF, and 24.6% starch, and the LF diet was similar with 17.8% CP, 33.5% NDF, and 23.0% starch. Data were analyzed as a crossover design using the PROC MIXED of SAS with model effects of diet, sequence, and period, with cow within sequence as a random effect. Compared with the LF diet, the BMR diet resulted in greater DMI (29.7, 27.2 kg/d, SE = 0.9; $P < 0.001$), greater SCM yield (47.0, 41.7 kg/d, SE = 1.4; $P < 0.001$), and greater SCM/DMI (1.59, 1.54, SE = 0.04; $P < 0.01$). Chewing during eating and ruminating was greater for the LF versus the BMR diet (89, 84 min/kg NDF intake, SE = 3; $P < 0.001$). Compared with the LF diet, the BMR diet resulted in greater total tract OM and NDF digestibility (81.4, 77.7%, SE = 0.6; 63.8, 55.4%, SE=0.8; $P < 0.001$), although starch digestibility was similar for the LF and BMR diets (99.0, 98.9%, SE = 0.1; $P < 0.001$). Compared with the BMR diet, the LF diet resulted in higher fecal pH (6.92, 6.71, SE = 0.03; $P < 0.001$), lower fecal starch (0.82, 1.15%, SE = 0.09; $P < 0.008$), and lower fecal P (0.53, 0.63, SE = 0.02; $P < 0.001$). The LF hybrid assessed in this experiment constrained DMI and milk production compared with the BMR hybrid. To achieve dietary fermentable carbohydrate content similar to BMR, a LF hybrid will require higher NDF and starch digestibility than the hybrid evaluated in this experiment.

Key Words: leafy-floury corn silage, brown midrib corn silage, dairy cattle

1071 (M088) Production response of lactating cows to diets based on corn or forage sorghum silage produced from first or second harvest.

J. K. Bernard*, *University of Georgia, Tifton.*

The objective of the trial was to compare the production response of lactating Holstein cows to corn or forage sorghum silage produced from two crops. Corn was planted in April and harvested in July (CS1). A second crop was planted in July and harvested in November (CS2). A brachytic dwarf forage sorghum was planted in April, harvested in July (FS1), fertilized, and harvested a second time in November (FS2). All forage was ensiled in plastic bags and stored until the production trial began. Silages contained (DM basis) 8.0, 8.5, 9.0, and 9.5% CP; 39.0, 38.3, 54.2, and 55.1% NDF; 3.55, 2.83. 7.72, and 7.77% acid detergent lignin; and 48.1, 47.7, 31.5, and 29.1 NFC, for CS1, CS2, FS1, and FS2, respectively. Forty-eight mid-lactation Holstein cows (153.5 DIM, 36.5 kg milk, and 3.2% fat) were assigned randomly to one of for diets differing in forage source. Cows were fed individually once daily behind Calan doors for 5 wk. Diets were balanced to provide equal concentrations of protein, fiber, and energy. No differences were observed in DMI, milk yield, or milk composition among treatments: 23.1, 21.1, 21.0, and 19.9 kg/d DMI; 34.5, 34.4, 34.9, and 35.1 kg/d milk; 3.34, 3.22, 3.40, and 3.52% fat; and 2.73, 2.63, 2.61, and 2.65% protein for CS1, CS2, FS1, and FS2, respectively. Concentrations of MUN (mg/dl) were higher ($P = 0.03$) for FS1 and FS2 compared with CS1 and CS2 (16.2, 16.3, 11.6, and 13.9, respectively). Results of this trial suggest that brachytic forage sorghum silage can support similar as corn silage. Forage harvested from the regrowth of brachytic forage sorghum also supported similar performance as the first harvest. The higher MUN observed for diets based on forage sorghum reflects most likely reflects differences in fermentable carbohydrate compared with corn silage diets.

Key Words: corn silage, forage sorghum, milk yield

1072 (M089) Feeding strategy and pasture quality relative to nutrient requirements of grazing dairy cows in the Northeastern U.S.

A. N. Hafla*[1], K. J. Soder[1], A. F. Brito[2], R. Kersbergen[3], F. Benson[4], H. Darby[5], and M. D. Rubano[1], *[1]USDA-Agricultural Research Service, University Park, [2]University of New Hampshire, Durham, [3]University of Maine Cooperative Extension, Waldo, [4]Cornell University Extension, Cortland, NY, [5]University of Vermont, Albans.*

Pasture samples ($n = 229$) collected during the grazing season from 14 organic dairy farms in 2012 (*P*A, ME, NY, NH, VT) and from 11 of the same farms in 2013 (PA, ME, NY, NH) were analyzed for nutritional composition. Frequency analysis was used to determine the proportions of pasture samples that met minimum NE_L, CP, and macro-mineral requirements according to the NRC (2001) model for a 680 kg Holstein, producing

25 kg milk/d with 3.5% milk fat and 3.0% milk protein. The Large Ruminant Nutrition System (LRNS, Version 1.0.24) was used to describe feeding strategies that accompanied grazing on eight of the participating farms. Four farms had moderate conserved feed input (> 20% diet DM not from pasture; MF), and fed corn silage, grass/legume balegae or haylage, and/or a grain mix and dry hay, two farms supplemented pasture with a grain mix (GS), and two farms fed forage only (*P*asture and dry hay; FO). Management and production information used in the LRNS model were specific to environmental conditions, nutrient concentrations of feeds, cow type, and level of production for each farm. If pasture was the only diet component, energy was the most limiting nutrient, with 39% of pasture samples failing to meet the minimum NRC NE_L requirement. Only 7% of pasture samples did not meet the minimum CP requirements. Calcium, P, and S did not meet minimum NRC requirements in 35, 18, and 10% of pasture samples, respectively. Average concentrations of Mg and K were in excess of 156 and 1,113% of dietary requirements. Milk production was observed to be higher on MF farms (23 kg/d), but was comparable on GS and FO farms, averaging 15 kg/d for both. Proportion of DMI from pasture was related to feeding strategy and ranged from 51 to 79% on MF farms, 84 to 96% on GS farms, and 91 to 100% on FO farms. Metabolizable protein provided by the total diet (*P*asture and supplementation) exceeded the requirements at the specified level of production and environmental conditions except for 1 farm (the MF farm with the lowest amount of DMI coming from pasture). Rumen N balance was negative for both GS farms (-18 and -33 g/d). Overall, the forage quality of pastures evaluated was high. Additionally, varying feeding strategies allow farmers to use resources such as pasture, homegrown forages, and grains to meet individual goals of milk production.

Key Words: pasture, grazing, dairy

1073 (M090) Use of biological additives to improve lactic fermentation tropical silages.

L. Bernal[*1], R. Herrera[2], P. Avila[3], H. Jimenez[2], M. Cuchillo[3], and S. D. Martens[4], *[1]La Salle University, Bogotá, Colombia, [2]Corpoica, Bogota, Colombia, [3]International Center for Tropical Agriculture, Cali, Colombia, [4]Saxon State Office for Environment, Agriculture and Geology, Department of Animal Production, Köllitsch, Germany.*

The objective of this study was to assess different biological additives to favor lactic acid fermentation. This trial aimed also to obtain the optimal proportions of sorghum/soybean to ensure good fermentation quality for silage making using a fast in vitro fermentation test (Rostock fermentation test; RFT). Different combinates of a grass (*Sorghum bicolor* L. variety H70) and legume (soybean *Glycine max* variety Panorama 29) were tested against biological additives. Test used sorghum and soybean and their combinations (100/0, 33/67, 67/33, 0/100) with or without biological additives. Inoculates were evaluated for their acidification ability: enzymatic complex from anaerobic rumen fungi (*Orpinomyces* sp), clarified rumen fluid, Lactic acid bacteria (LAB)-epiphytic S738 (from sorghum), LAB-epiphytic S739 (from soybean), LAB from CIAT bacteria collection (S66.7), commercial silage inoculant (SilAll4×4-Brazil) and a control. Fifty grams of fresh minced material and 200ml of distilled water of forage were incubated into sterile glass in triplicate at 37°C for 48 hours and the pH was measured at 0, 20, 28, 44, and 48 hours to determine the dynamics of fermentation. Completely randomized in a 4x6 factorial design was used. Forage inclusion level (four levels) and the type of additive (six additives and control) were arranged. Significant difference ($P < 0.001$) was found at the level of forage inclusion and the additive used ($P < 0.05$). The treatments including biological additives showed lower pH value than control treatment (5.5). Best results were obtained (pH = 3.7) for the sorghum/soybean at 100/0% inclusion, followed by the mixture of sorghum/soybean 67/33 (pH = 4.2) while the pH for the rest of treatments value were above 5.0. The best additive was the bacterial strain (S738) (pH <4.0). The enzymatic complex (pH 5.0), clarified rumen fluid (pH 5.3) and silall4x4 (pH 5.2) have reasonable pH values for ensilability. The highest pH value (5.7) was for soybean 100% ($P < 0.05$). Results show that biological additives such as epiphytic bacterial strains isolated from sorghum have potential to improve fermentability. Larger sorghum inclusion in the mixture facilitated lactic fermentation for silage making.

1074 (M091) Quality evaluation of five varieties of corn for silage production in crop-livestock-forest integration system in the Cerrado region.

M. C. A. Santana[*1], A. A. Pinheiro[1], V. A. Silva[1], J. T. C. Pacheco[1], A. C. Fernandes[1], I. D. Carneiro[1], V. C. Modesto[2], and J. Cavali[3], *[1]Emater, Goiânia, Brazil, [2]UNESP, Jaboticabal, Brazil, [3]Universidade Federal de Rondônia - Unir, Rondonia, Brazil.*

The intercropped of corn within the integrated crop- livestock-forest system can be seen in the establishment of forage with lower costs and diversify, producing silage for animal feed. Thus, we evaluated the qualitative characteristics of five cultivars of maize intercropped with *Brachiaria brizantha* cv. Marandu for silage production in integrated crop-livestock-forest system. The experimental design was a randomized block with three replications and five treatments. Maize cultivars used were: EMGOPA 501, AL Bandeirantes, BRS Caimbé, PL 6880, BRS 1060. To assess the qualitative characteristics were estimated: number of grains per ear; number of kernels per row; number of rows per ear; grain weight per ear and weight of 100 grains. There were no significant differences in the variables studied. The intercropped of forage maize cultivars do not influence on the qualitative characteristics of corn for silage.

Key Words: intercropped, Marandu, tropical region

1075 (M092) Impact of hybrid and growing location on yield and composition of corn plants harvested for silage. D. Bolinger[1], L. Nuzback[*2], and F. N. Owens[2], *[1]DuPont Pioneer, Perrinton, MI, [2]DuPont Pioneer, Johnston, IA.*

Relative effects of hybrid, growing location, and DM at harvest on corn silage yield and composition have not been clearly defined. Their impacts on yield, plant and grain composition at silage harvest, and potential milk yields were examined using corn plants and grain from five Pioneer hybrids grown in each of 15 environmentally diverse Michigan locations in 2013 all harvested at silage maturity. Nutrient compositions were determined at a commercial laboratory; milk yields were predicted from Milk 2006 equations. Relationships were evaluated using regression and GLM procedures of SAS. Whole plant DM, grain DM, starch, and NDF ranged from 24.2 to 47.8, 49 to 76, 17.2 to 39.6, and 37.1 to 49; 24 hour NDF disappearance ranged from 36.3 to 55.6 percent of NDF; DM yield ranged from 8 to 23 metric ton (MT) per hectare while milk ranged from 1444 to 1873 kg per MT. Growing location altered ($P < 0.01$) every measurement. Harvest DM had quadratic effects on milk per hectare and on yields of DM, starch and NDF, each peaking at 41% DM; hence relative nutritional values can be biased if hybrids differ in DM content even when harvested on the same date. Among environmental measures, growing degree days prior to harvest (range 1916 to 2367) was related ($P < 0.05$) negatively to sugar but positively to starch content of plants. Precipitation (36 to 65 cm during the season) was related ($P < 0.02$) positively to yield and milk per hectare but negatively to crude protein content and NDF digestibility. Locations that received less than 41 cm of rain had lower ($P < 0.05$) plant yields and milk per hectare but greater ($P < 0.05$) NDF digestibility (48.3 versus 45.8 percent of NDF) and CP, fat, and prolamin content of grain. Greater plant weight was associated with increased kernel density and yield of milk and DM per hectare. Hybrids with greater drought tolerance had greater ($P < 0.04$) starch content of plants and grain and greater starch availability from grain but lower NDF digestibility. The growing environment and harvest DM generally had greater impact on silage yield and nutritive value than hybrid choice among the corn silage hybrids tested.

Key Words: corn silage, location, harvest

1076 (M093) Impact of corn plant maturation and planting density on nutrient composition and potential milk yield. L. Brown[*1], L. Nuzback[2], B. Redenius[2], P. M. Walker[3], and F. N. Owens[2], *[1]DuPont Pioneer, Bloomington, IL, [2]DuPont Pioneer, Johnston, IA, [3]Illinois State University, Normal.*

Stage of maturity and planting density can alter weight and nutrient composition of corn plants within the silage harvest window and thereby alter both yield and the nutritional value of corn silage. To appraise effects of maturity and plant density on yield and nutrient composition, nine Pioneer silage hybrids (109- to 115-d relative maturity) were planted in a single field near Lexington, IL, with 69000 and 84000 plants per hectare. Duplicate sets of five representative plants were harvested at 3 to 4 day intervals within the silage harvest window (28 to 42 percent DM), weighed and chopped. Duplicate subsamples were dried (48 h at 15 C) and assayed by calibrated NIR procedures for CP, starch, sugars, NDF, and NDF digestibility. Averaged across harvest dates, hybrids differed ($P < 0.01$) in all measurements. The 21 percent increase in plant density decreased ($P < 0.05$) starch content of plant DM by 1.5 percentage points and milk per ton by 2.5 percent, but increased ($P < 0.01$) yields of DM, milk, NDF, digestible NDF, and indigestible NDF per hectare by 7.2, 7.0, 9.0, 8.0, and 10 percent. Across hybrids, linear and quadratic regressions against harvest DM were significant ($P < 0.05$) for starch content, protein content, milk per ton (each increasing at a decreasing rate), and sugar content (decreasing to a plateau). As plant DM percentage increased, yield of DM increased but NDF digestibility declined ($P < 0.01$) slightly (0.09 points for each 1 percentage increase in plant DM. In corn silage test plots, all hybrids typically are harvested on a single date regardless plant moisture content. Among these nine hybrids, ranking for milk per hectare remained reasonably similar across this DM range; milk per ton ranking changed markedly, especially when plant DM was below 34 percent, although rank of the top (a BMR) and bottom hybrids remained similar. In conclusion, increasing planting density increased corn silage yield with some sacrifice in starch percentage. Hybrid ranking for milk per ton differed with harvest DM. To prevent ranking bias, hybrids in silage test plots should be harvested at multiple moisture contents.

Key Words: corn plant maturity, planting density, hybrid ranking

1077 (M094) Gas production and volatile fatty acids of corn stover silage added with yeast culture and fermented apple pomace. C. Rodríguez-Muela*, N. H. Ruiz, P. F. Mancillas-Flores, O. Ruiz-Barrera, A. Corral, C. Arzola-Alvarez, A. Ramírez-Godínez, and E. Santellano, *Universidad Autónoma de Chihuahua, México.*

Silage is a forage conservation method based on fermentation of carbohydrates to produce lactic acid under anaerobic conditions. Solid state fermentation (SSF) is a process of microbiological growth on solid materials under aerobic conditions. With the objective of improving the nutritional value of corn stover through the combination of SSF and silage, three treatments were driven during 28 d using 48 plastic bags as a microsilos each with 2 kg of: (T1) corn stover alone; (T2) corn stover + yeast culture produced by SSF (10% as feed basis) and (T3) corn stover + fermented apple pomace produced by SSF (69% as feed basis). Treatments were added with water to obtain 35% of DM during the ensilage. Gas production (GP) and volatile fatty acids (VFAs) were determined in the samples obtained on 14d of the ensilage, following 96 h incubation in buffered rumen fluid using the in vitro fermentation technique. Data were analyzed by PROC GLM of SAS. Results are shown in Table 1077. The addition of yeast culture and apple pomace increased GP volume ($P < 0.01$) with values of: 58.17 ± 0.69, 63.57 ± 0.69 and 85.96 ± 0.69 ml*0.2g^{-1} MS of T1, T2 and T3, respectively. VFA´s differed between treatments ($P < 0.01$). Acetate-propionate ratio increased from 1.8:1 to 2.4:1 ($P < 0.05$) during the in vitro fermentation. Results may be derived from a change in rumen fermentation. It was conclude that the addition of fermented apple pomace or yeast culture improve GP and VFAs parameters of corn stover silage.

Key Words: yeast culture, silage, corn stover

1078 (M095) Effect of a chemical additive on fermentation and aerobic stability of high-moisture corn. T. C. Da Silva, M. L. Smith*, S. A. Polukis, A. M. Barnard, and L. Kung Jr., *University of Delaware, Newark.*

The objective of this experiment was to evaluate effect of a chemical additive on fermentation and aerobic stability of high moisture corn (HMC). Ground HMC (~63% DM) was untreated, or treated with 2 L of Safesil (SAFE, sodium nitrite, potassium sorbate, and sodium benzoate, Salinity Agro, Halmstad, Sweden)/t of fresh HMC, 3 L of SAFE/t, or 4 L of SAFE/t. Lab silos (7.5 L, 4 silos/treatment/time point) were prepared (density of 672 kg of DM/m^3) and ensiled for 21 and 90 d at 22 ± 2 °C. Data were analyzed as a 4 × 3 factorial arrangement of treatments with main effects of Safesil (4 levels) and days of ensiling (0, 21 and 90 d), and their interaction, using the software JMP, version 10. Numbers of yeasts were similar ($P > 0.05$) among treatments in fresh HMC (log 6.9 to 7.1 log cfu/g) but decreased ($P < 0.01$) substantially after ensiling (< 3.3 log cfu/g). Numbers of yeasts were similar ($P = 0.33$) among treatments after 21 d of ensiling but after 90 d they were lower ($P < 0.01$) in HMC treated with SAFE (< 2 log cfu/g for all levels) compared to untreated HMC (3.22 log cfu/g). Compared to untreated HMC, addition of SAFE to HMC at all levels did not affect the concentrations of organic acids (lactic, acetic, and propionic) or pH at any ensiling time. In contrast, treatment with SAFE markedly decreased ($P < 0.01$) the concentrations of ethanol in HMC after 21 and 90 d (< 0.25% of DM for all SAFE levels) when compared to untreated HMC (1.02 and 0.76% of DM, respectively at d 21 and 90). Treatment with SAFE markedly improved ($P < 0.01$) the aerobic stability of HMC after 30 d (89 h for untreated HMC vs. > 500 h for HMC treated with SAFE at all levels) and after 90 d of ensiling (77 h for untreated HMC vs. > 500 h for HMC treated with SAFE at all levels). This was the first evaluation of Safesil on HMC in North America and it showed that this additive, even when added at a relatively low level (2 L/t) effectively improved the aerobic stability of HMC and reduced concentrations of ethanol without altering the concentrations of organic acids or pH.

Key Words: high moisture corn, fermentation

1079 (M096) The effect of chemical additives with antifungal properties on the fermentation and aerobic stability of corn silage. M. C. Windle*, C. Merrill, M. C. N. Agarussi, L. O. Rosa, and L. Kung Jr., *University of Delaware, Newark.*

The objective of this study was to evaluate chemical additives with antifungal properties on the fermentation and aerobic stability of corn silage harvested at two maturities: 32% DM (LDM) and 38% (HDM) whole-plant DM. At each harvest, plants were obtained from five random locations within the

field and further divided into four piles and treated with a) no additive, b) 1.5 L of Safesil (Salinity Agro, Halmstad, Sweden; active ingredients of sodium nitrite, potassium sorbate, and sodium benzoate)/t of fresh forage, c) 2 L of Safesil/t, or d) 2 L of Crop Saver (CS, CNH America LLC, Racine, WI; 64.5% propionic acid). Each pile was treated with a total volume of 0.03% vol/wt of liquid (water alone for the no additive treatments). Forage from each pile was ensiled in 7.5-L lab silos (packing density of about 220 kg of DM/m^3). Silage data were analyzed as a 2 (maturity) × 4 (additive) factorial arrangement of treatments after 120 d of storage (22 ± 2°C) using the software JMP. At both harvest DM, compared to untreated silage, treated silages had similar ($P > 0.05$) concentrations of lactic and acetic acids, CP, ADF, NDF, starch and pH. Treatment with CS increased ($P < 0.01$) the concentrations of propionic acid silage in silage in both maturities compared to other treatments. In LDM silages, treatment with Safesil did not affect ($P > 0.05$) the concentrations of ethanol but treatment with CS resulted in a higher ($P < 0.01$) concentration of ethanol when compared to untreated silage. In HDM silage, concentrations of ethanol were lower ($P < 0.01$) in a dose dependent manner for silages treated with Safesil but unaffected by CS. Compared to untreated silage, aerobic stability was improved ($P < 0.01$) for both maturities treated with CS (66 vs. 93 h in LDM silage and 59 vs. 116 h for HDM silages). Treatment with Safesil was even more effective resulting in aerobic stabilities ($P < 0.01$; average of > 450 h in LDM silages and average of > 350 h in HDM silages) that were markedly better than both untreated and CS. This study was the first to show that Safesil has the potential to markedly improve the aerobic stability of corn silage in North America.

Key Words: silage, aerobic stability, corn silage

1080 (M097) Effect of *Lactobacillus plantarum* MTD1, potassium sorbate or their combination on production of volatile organic compounds and aerobic stability of corn silage.

M. C. Windle*[1], C. Merrill[1], M. L. Smith[1], S. D. Hafner[2], F. M. Mitloehner[3], R. Franco[3], and L. Kung Jr.[1], *[1]University of Delaware, Newark, [2]Hafner Consulting LLC, Washington, DC, [3]University of California–Davis, Davis.*

Silages have the potential to contribute to poor air quality through emission of volatile organic compounds (VOC), especially ethanol. Silage additives may be useful for reducing VOC production, but few studies have evaluated them for this purpose. The objective of this experiment was to test the effects of a biological and a chemical additive on production of VOC and aerobic stability of corn silage. Whole plant corn (37.5% DM) was chopped, processed and treated with *L. plantarum* MTD1 (LP, Ecosyl, Ltd., Stokesly, UK) at a rate of 1 × 10^5 cfu/g fresh forage basis, potassium sorbate (0.1% fresh forage basis, PS), a combination of LP and PS (LPPS), or distilled water (untreated, CTRL). Forage was packed in 7.5 L bucket silos at a density of about 230 kg DM/m^3, in quadruplicate, and ensiled at 21-23°C for 119 d. Silage data were analyzed by analysis of variance as a completely randomize to design using the software JMP. Measurements with a headspace GC method showed that both PS and LPPS reduced ($P < 0.05$) production of ethanol and ethyl acetate by more than 75% below CTRL. Treatment LPPS also reduced production of three other significant VOCs: 1-propanol, methyl acetate, and valeraldehyde. Lactic acid was slightly elevated by LPPS ($P < 0.01$) compared to other treatments, but the concentration of acetic acid was similar among treatments. Compared to CTRL, the additives had no effects ($P > 0.05$) on CP, soluble CP (% of CP), ADF and NDF. Due to contaminated media, the numbers of yeasts in silage could not be accurately determined and thus are not reported. However, there was a trend ($P < 0.07$) for improved aerobic stability (48, 49, 169 and 218 h, respectively, for CTRL, LP, PS, and LPPS). In conclusion, a combination of *L. plantarum* MTD1 and potassium sorbate appears to be a very effective additive for reducing production of several important VOCs (including the most important compound: ethanol) in corn silage. Potassium sorbate alone appears to have nearly the same effect on overall VOC production.

Key Words: corn silage, inoculant, volatile organic compounds

---

1081 (M098) The effects of strains of yeasts or *Lactobacillus buchneri* 40788 on the fermentation, production of volatile organic compounds (VOCs) and aerobic stability of corn silage.

R. M. Savage*[1], M. C. Windle[1], S. D. Johanningsmeier[2], and L. Kung Jr.[1], *[1]University of Delaware, Newark, [2]USDA-ARS Food Science Research Unit, Raleigh, NC.*

Several yeasts and *Lactobacillus buchneri* 40788 were evaluated for their effects on the fermentation, production of VOCs and aerobic stability of corn silage. Freshly chopped and processed corn plants were treated with a) no additive, b) *Saccharomyces cerevisiae* -1, c) *S. cerevisiae* - 2, d) an experimental yeast known to produce acetaldehyde under aerobic conditions, or e) *L. buchneri* 40788 (LB, 4 x 10^5 cfu/g of fresh forage). Yeasts were inoculated at 1 x 10^6 cfu/g of fresh forage. All microbes were from Lallemand Animal Nutrition, Milwaukee, WI. Silos (7.5 L, forage density of 224 kg of DM/m^3) were ensiled for 70 and 151 d between 21 to 23 °C. Five replicates were opened for each treatment at each time point. Silage data were analyzed by analysis of variance as a 2 x 5 factorial arrangement of treatments with main factors of days of ensiling, inoculation and their interaction. Silages were analyzed for numbers of yeasts, fermentation end products, aerobic stability and VOCs (d 151 only). The VOCs were determined by solid phase microextraction (SPME) coupled to non-targeted, comprehensive two-dimensional gas chromatography-time-of-flight mass spectrometry (GC´GC-ToFMS). Relative to silage with no ad-

ditive, treatment with yeasts did not affect any of the measured parameters. In contrast, when compared to all other treatments, treatment with LB resulted in a higher concentration ($P < 0.05$) of acetic acid (1.58 vs. 0.52 to 0.81% at d 70 and 2.24 vs. 0.94 to 1.22% at d 151) and 1,2 propanediol at both openings, and lowered the concentration ($P < 0.05$) of ethanol (0.37 vs. 1.18 to 1.52%) after 151 d. The VOC profile of corn silage was markedly altered by LB. Approximately, 25% of the volatile compounds detected in corn silage differed in the LB treated silage ($P < 0.0067$). Decreases were observed in several ethyl esters of medium chain fatty acids along with increases in various esters of acetic acid. Aerobic stability was numerically greater for LB than other treatments after 70 d of ensiling and statistically greater ($P < 0.05$, > 450 h) than other treatments (50 to 120 h) after 151 d of ensiling. This is the first study to show that not only does inoculation with LB improve aerobic stability in corn silage, but it has marked effects on VOC compounds.

Key Words: corn silage, volatile organic compounds, *Lactobacillus buchneri*

1082 (M099) Isolation and identification of lactic acid bacteria in forage peanut silage. L. D. Rufino[1], E. S. Leandro[1], K. G. Ribeiro[1], H. C. Mantovani[1], T. C. Silva[1], and O. G. Pereira[*2], *[1]Universidade Federal de Viçosa, Minas Gerais, Brazil, [2]Universidade Federal de Viçosa, Minas Gerais, Brazil.*

Cultivars of *Arachis pintoi* species are widespread in tropical and subtropical areas in Brazil. There are a limited number of reports about the use of tropical leguminous for ensiling process mainly with regard to the autochthonous population of lactic acid producing bacteria (LAB). Therefore, the objective of the present study was to isolate and identify the LAB by the partial sequencing of the 16S rDNA gene in silage of *Arachis pintoi* cv. Belmonte with 0, 3, 7, 14, 28, and 56 days of fermentation. Forage was ensiled in triplicate by vacuum packing the forage in plastic bags and stored at room temperature. Silage samples were mixed with 225 mL of saline solution and serial dilutions were performed. The dilutions were then plated in MRS agar by using Pour plate technique. Plates were incubated at 37°C for 48 h. After incubation period 40 colonies were randomly selected for streak in MRS agar and then incubated at 37°C for 48 h. Selected isolates were tested for catalase, Gram staining and morphology analysis. The isolates characterized as catalase negative and gram positive were selected to be identified by 16S gene rDNA sequencing. The PCR analysis was performed by using GoTaq DNA polymerase kit and a set of primers 1378/P027. The amplified fragment was purified and sequenced. Among the 40 isolates, only 17 isolates had sequences with identity equal to or greater than 97% with sequences already available in GenBank database. From these 17 sequences the *Lactobacillus plantarum, Lactobacillus paraplantarum, Pediococcus pentosaceus,* and *Lactobacillus casei subs. Casei* were detected. The majority of the isolates were identified as *Pediococcus pentosaceus*. The sequence of isolates obtained in the current study was not matched with the sequences of 16S rDNA of *L. plantarum* or *Pediococcus pentosaceus* already available at Genbank. The lack of matching among the sequences of the isolates obtained in this study with the sequences available at Genbank does not mean that they are not from the same specie. Microorganisms are susceptible to constant mutations varying according to the environment conditions. The accumulation of these mutations may be the reason of the difference among the sequences of different strain. *Sponsored by FAPEMIG, CNPq and INCT-CA.*

Key Words: *Lactobacillus plantarum*, legume silage, *Pediococcus pentosaceus*

1083 (M100) Evaluating top losses in Argentine corn silages. L. O. Abdelhadi[*1], G. Marley[2], and J. M. Barneix[3], *[1]Est. El Encuentro, Research & Extension in Ruminant Nutrition, Brandsen, Buenos Aires, Argentina, [2]Sil-All Global Product Manager, Gloucestershire, United Kingdom, [3]Sil-All Argentine Product Manager, Lincoln, Buenos Aires, Argentina.*

The aim of the study was to quantify how much of the quantity and quality is being lost from the top of corn silages when compared with silo mass across Argentina. Fifty corn silages were sampled in Buenos Aires, Santa Fe and Entre Rios provinces. Composite samples (three sub-samples each) were taken in each silo (from 44 to 488 d since the silages were done), from the core (CS: between 50 to 100 cm inside) or the top (TS: within 50cm), refrigerated until freezing and analyzed for pH, DM, OM and Ashes. Measures of packing density was done by sampling site plus particle size separation using the PSP and finally OM losses were calculated as the difference between % and tons found in the top compared with the core. Data were analyzed as RCB design, using each silo as Block (50), within each block the treatment was the sampling location (CS and TS) and ANOVA by variable was obtained using α 0.05. Of total sampled silages 33, 16 and 1 were storage in stack, bunker and pile silos, respectively; most covered using white and black (36) or black (7) standard plastic and seven uncovered. No one used additives or special covering systems for the surface. Results are presented in Table 1083.

From silos which originally had as a mean 8382 m^3, exposed surface averaged 1398 $m^{3,}$ which involved about 291 tons of OM within each silo. Of exposed OM, we estimated that 23.9% is being lost in the top, averaging 69 tons of OM in each of the sampled silages. When we tried to relate OM losses with days after ensiling or packing density, low relationships were detected; suggesting that practices around covering and uncovering were responsible of top losses.

1084 (M101) Corn silage analysis as influenced by sample size. I. M. Malebana[1], D. J. R. Cherney[*2], and W. J. Cox[2], *[1]Agricultural Research Council, Pretoria, South Africa, [2]Cornell University, Ithaca, NY.*

Sampling variability is a major concern when dealing with chopped corn forage that contains as much as 50% grain. Commercial laboratories prefer to minimize the quantity of corn forage that needs to be processed for analysis. Sample size and particle size of chopped forage will influence sampling variability. Our objective was to evaluate the effect of sample size collected for processing, on variability of results of forage analyses. Samples of chopped corn forage were collected from four field replicates of seven corn hybrids, in 8.3 m^2 plots at four sites in NY. The 112 fresh samples collected were mixed and subsampled to produce samples of 50, 100, 150, 200, 400 and 600 g. Subsamples were immediately ensiled in vacuum-sealed polyethylene bags for 30 d. An additional 600 g fresh subsample was immediately dried at 60 °C, and another 600 g subsample was ensiled for 30 d and then evaluated for particle size distribution. The pH of all ensiled samples was < 3.9, indicating proper ensiling. Particle size distribution using the Penn State particle separator was similar to the distribution recommended for corn silage. Crude protein, NDF, ADF, IVTD and NDFD values were analyzed using SAS PROC MIXED. Standard deviations were calculated for each site/species/size combination to evaluate variability due to sample size collected. Ensiled samples (600 g) were not different from fresh samples (600 g) for NDF, but were significantly higher ($P < 0.05$) in ADF and CP, and significantly lower ($P < 0.01$) in IVTD and NDFD. Crude protein, NDF, ADF, and NDFD all decreased quadratically with increased sample size, while IVTD increased quadratically with increased sample size. Standard deviations for all variables decreased quadratically with increased sample size. Based on both actual values and variability, a 400 g sample produced similar results to a 600 g sample, but smaller sample sizes produced both different and more variable values for all parameters evaluated.

Key Words: neutral detergent fiber digestiblity, sampling variation, vacuum-sealed mini-silos

Table 1084.

	Standard deviations (%)				
Size, g	CP	NDF	ADF	IVTD	NDFD
50	0.61	3.09	1.76	2.35	4.88

1086 (M103) In situ degradation characteristics of sorghum silage treated with fibrolytic enzymes. A. Coronado[*1], K. C. McCuistion[1], J. L. Foster[2], G. Schuster[1], and Z. Lopez[3], *[1]Texas A&M University - Kingsville, Kingsville, [2]Texas A&M AgriLife Research-Beeville Station, Beeville, [3]Dow AgroSciences, Knoxville, TN.*

Sorghum (*Sorghum bicolor* L.) silage utilization in beef and dairy cattle diets has increased in recent years due to the increased water efficiency and acceptable feeding values when compared to corn silage. The objective of this study was to determine if fibrolytic enzymes would improve the rate and extent of in situ disappearance of photoperiod sensitive sorghum and hybrid silage varieties with or without the brown midrib (BMR) trait: forage sorghum (FS), BMR forage sorghum (FS-BMR), sorghum-sudangrass (SS), and BMR sorghum-sudangrass (SS-BMR). The experiment was a 4 × 2 factorial design with two replicated periods. Each sorghum silage variety ($n = 4$) was grown, harvested, chopped, and treated with water (control) or a fibrolytic enzyme (50:50 mixture of Cellulase Plus and Xylanase Plus) prior to the ensiling process. Mini-silo buckets were sealed, maintained at 23ºC for 150 d, dried, subsampled, ground to 4 mm, and weighed into duplicate Dacron bags for the in situ trial. An additional silage subsample was taken and stored at -20ºC for subsequent pH determination. Three ruminally cannulated Angus steers (308 ± 24 kg) had ad libitum access to sorghum-sudangrass hay ('Haygrazer'), mineral, and water for 14 d prior to incubation periods. Sorghum silage samples were incubated in situ for 0, 4, 8, 16, 24, 48, or 72 h to determine rate and extent of DM disappearance. Sorghum silage yields were low due to drought. SS yielded the most ($P < 0.01$; 5.3 Mg of DM/ha) compared to SS-BMR (3.8 Mg of DM/ha), FS (3.8 Mg of DM/ha), and FS-BMR (3.7 Mg of DM/ha). All silage reached a pH between 3.1 and 3.5, suggesting that proper ensiling did occur. There were no interactions between treatment and forage variety for DM ($P \geq 0.21$) in the in situ trial. The lag and undegraded residue fraction was not different between varieties ($P > 0.81$). Non-BMR silage had a greater potentially degradable fraction ($P < 0.01$); however, BMR varieties had a

greater wash loss (A; $P < 0.01$) and extent of digestion (ERD; $P < 0.01$). Enzyme treated forage also had a greater A fraction ($P = 0.03$) and ERD ($P = 0.03$), indicating that fibrolytic enzymes can improve silage ruminal degradation. Selecting a sorghum variety containing the BMR trait or using a fibrolytic enzyme can improve silage degradation characteristics.

Key Words: sorghum silage, brown midrib, fibrolytic enzymes

1087 (M104) Effect of ensiling time on fermentation profile and starch digestibility in whole plant corn silage from two different hybrid types.

L. F. Ferraretto[*1], R. D. Shaver[1], S. Massie[2], R. Singo[2], D. M. Taysom[3], and J. P. Brouillette[4], *[1]University of Wisconsin, Madison, [2]Renaissance Nutrition Inc, Roaring Springs, PA, [3]Dairyland Laboratories Inc, Arcadia, WI, [4]Dow AgroSciences, Mycogen Seeds, Indianapolis, IN.*

The objective of this study was to evaluate the effect of ensiling time and hybrid type on fermentation profile, soluble CP (% CP), ammonia-N (% N) and ruminal in vitro starch digestibility (ivStarchD; 7 h incubations on dried and 6 mm ground samples) in whole plant corn silage (WPCS). Samples from 8 hybrids (4 leafy [LFY] and four brown midrib [BMR]; Mycogen Seeds, Dow AgroSciences LLC, Indianapolis, IN) were collected at harvest, vacuum-sealed in plastic bags and ensiled for 0, 30, 120 and 240 d. Samples were stored at room temperature in the dark and immediately frozen to stop the fermentation until processed for analysis. Samples were analyzed for fermentation profile, CP, soluble CP, ammonia-N, starch and ivStarchD at Dairyland Laboratories Inc. (Arcadia, WI). Data were analyzed using Proc Mixed of SAS with the Fixed effects of ensiling time, hybrid type and their interaction. Regressions to determine linear relationships between ivStarchD and ammonia-N and soluble CP contents were performed using Proc Reg in SAS. Contents of DM and starch (DM basis) were unaffected ($P > 0.10$) by ensiling time or hybrid type and averaged 39.3% and 40.0%, respectively. Fermentation profile, ammonia-N, soluble CP and StarchD were similar ($P > 0.10$) between hybrid types. Measurements of pH did not differ ($P > 0.10$) even though lactate, acetate and total VFA concentrations were greater ($P < 0.01$) for WPCS fermented for 30, 120 and 240 d compared to unfermented samples. Gradual increases were observed ($P < 0.001$) from 0 to 240 d for Soluble CP (33.5, 41.2, 48.9 and 54.5% of CP for 0, 30, 120 and 240 d, respectively) and ammonia-N (2.6, 4.6, 6.0, and 7.9% of N for 0, 30, 120 and 240 d, respectively). Likewise, the ivStarchD measurements increased with ensiling time ($P < 0.001$; 50.2, 58.5, 65.8, 71.4% of starch for 0, 30, 120 and 240 d, respectively). Positive relationships between ivStarchD and ammonia-N ($R^2 = 0.67$; $P = 0.001$) and soluble-CP ($R^2 = 0.55$; $P = 0.001$) were observed. Fermentation profile, ammonia-N, soluble CP and ivStarchD were influenced by ensiling time but not hybrid type. Ammonia-N and soluble CP were both good indicators of ivStarchD in WPCS.

Key Words: corn silage, ensiling time, starch digestibility

1088 (M105) Fermentation profile, chemical composition and microbial population in silages of Stylosanthes Campo Grande with microbial inoculant and pelletized citrus pulp.

W. F. D. Souza[1], K. G. Ribeiro[2], S. A. Santos[1], T. C. Silva[2], V. P. Silva[2], and O. G. Pereira[*3], *[1]Universidade Federal da Bahia, Salvador, Brazil, [2]Universidade Federal de Viçosa, Minas Gerais, Brazil, [3]Universidade Federal de Viçosa, Minas Gerais, Brazil.*

We evaluated the chemical composition, fermentation profile and microbial population of silages of Stylosanthes cv. Campo Grande with and without microbial inoculant and different levels of pelletized citrus pulp (0, 3, 6, 9 and 12% fresh forage basis), in different fermentation periods. The plant was harvested at 120 days after sowing, in the flowering stage. Subsequently, this material was chopped in a stationary forage machine and the combinations between the treatments were applied. Treated forages were packed in bag silos that were vacuumed to remove air, heat-sealed, and stored for 1, 3, 7, 14, 28 and 56 d. The microbial inoculant utilized was Sil All C4 (Alltech, Brazil), containing *Lactobacillus plantarum*, *Pediococcus acidilactici, L. salivarius* and *Enterococcus faecium*, at a rate of 1×10^5 cfu/g fresh forage basis. Data were analyzed by analysis of variance as a $5 \times 2 \times 6$ factorial arrangement of treatments with main effects of pelletized citrus pulp (PCP), the presence or absence of inoculant (I), time of ensiling (T) and their interaction, using the procedure MIXED of SAS software, version 9.1. The DM content increased linearly ($P < 0.05$) as the PCP levels were increased. The PCP × I interaction had an effect ($P < 0.05$) on the CP content, with highest values observed in the inoculated silages. Interactions PCP × I and PCP × T affected ($P < 0.05$) the NH₃-N content of silages. The pH and the concentrations of lactic, acetic, propionic and butyric acids were affected ($P < 0.05$) by the PC × I × T interaction. Maximum population of lactic acid bacteria (9.59 cfu/g) was recorded on the first day of fermentation in the non-inoculated silage, whose population decreased linearly over the fermentation period ($P < 0.05$). The population of enterobacteria was greater on the first day after ensiling, but from the fourth day its presence was not detected in all treatments. Interactions PCP × I and PCP × T affected the CP content of the silages, whereas the NDF and ADF levels of the silages were only affected ($P < 0.05$) by the PCP levels. Addition of inoculant and pelletized citrus pulp to Stylosanthes at ensiling increases lactic fermentation and restrict the butyric fermentation, providing better quality silage. Sponsored by FAPEMIG, CNPq and INCT-CA.

Key Words: acetic acid, lactic acid, lactic acid bacteria

1089 (M106) Recombined, late harvested ensiled alfalfa leaves and stems give comparable performance to normally harvested alfalfa silage. R. D. Hatfield*[1], M. B. Hall[1], R. E. Muck[1], W. J. Radloff[1], and K. J. Shinners[2], *[1]U. S. Dairy Forage Research Center, USDA-ARS, Madison, WI, [2]Biological Systems Engineering, University of Wisconsin, Madison.*

Increased use of the perennial forage, alfalfa, on dairy farms could be accomplished by reducing the number of harvests, separately storing leaves and stems, and feeding at a ratio that maintains lactation performance. More use of alfalfa could also decrease the environmental impact of dairies. We compared the impact on lactation performance of normally harvested alfalfa silage (early bud stage) with a blend of separately harvested and ensiled alfalfa leaves and stems obtained from more mature plants (full bloom stage). Forty-four primiparous cows were randomly assigned to one of two diets using a randomized complete block design with a 2-week covariate period followed by a 3-wk experimental period. Lactation performance was measured in the last week of each period. Experimental diets were formulated to provide similar concentrations of crude protein (CP) and neutral detergent fiber (NDF) by blending two whole-plant alfalfa silages (WP), or by blending separately ensiled alfalfa leaves and stems (LS). Urea (0.27%), as diet dry matter (DM), was added to LS to give equivalent CP. Diets were 60% forage, 17.2% CP, 24% starch, 26% ensiled alfalfa, and 34% corn silage on a DM basis. Milk production, energy-corrected milk production, and efficiencies of use of DMI and N did not differ between treatments. Milk urea nitrogen differed between treatments, but by less than 1 mg/dl. This may be due to slightly lower digestibility of LS vs. WP, or to the addition of urea, which likely differed from the soluble protein present in WP. Blending leaves and stems gave similar production performance as normally harvested alfalfa silage, but with the advantage that harvesting alfalfa leaves separate from stems allows large biomass accumulation in the field and fewer harvests.

Key Words: forage, alfalfa, dairy

Table 1089.

Measure	WP	LS	SED	*P*-value
DMI, kg	23.8	23.9	0.62	0.82

1090 (M107) Changes in the structural carbohydrates of corn stover silage added with yeast culture and fermented apple pomace. N. H. Ruiz*, C. Rodríguez-Muela, D. Díaz-Plascencia, O. Ruiz-Barrera, A. Corral, A. Ramírez-Godínez, and C. Arzola-Alvarez, *Universidad Autónoma de Chihuahua, México.*

With the objective of improving the nutritional value of corn stover silage by adding yeast culture or solid-state fermented apple pomace, three treatments were evaluated during 28 d using 48 plastic bags as microsilos each 2 Kg of: (T1) corn stover alone; (T2) corn stover plus yeast culture (10% as feed basis) and (T3) corn stover plus fermented apple pomace (69% as feed basis). Treatments were added with water to obtain 35% (DM). Values for DM, pH, temperature (t), in vitro dry matter digestibility (IVDMD), NDF, ADF, cellulose and lignin were obtained at d 0, 7, 14 and 28 of ensiled time. Data were analyzed by PROC GLM of the SAS. Table 1090, shows the values at 28 d of ensiled. The addition of yeast culture or fermented apple pomace decreased ($P < 0.01$) the pH, increased ($P < 0.01$) the temperature and the DM decreased ($P < 0.01$) across the sampling time. The IVDMD was highest ($P < 0.01$) with the addition of fermented apple pomace. NDF, ADF, cellulose and lignin concentrations decreased with the ensiled time; and the lowest values were shown in T2 and T3. We conclude that the addition of yeast culture or fermented apple pomace improved the nutritional value of silage corn stover.

Key Words: yeast culture, fermentation, silage

1091 (M108) Effects of different additives on chemical composition, fermentation characteristics and aerobic stability of barley silage. Y. Joo[1], D. Kim[1], H. Lee[1], S. M. Amanullah[1], S. C. Kim[*1], and I. H. Choi[2], *[1]Division of Applied Life Science (BK21Plus, Insti. of Agri. & Life Sci.), Gyeongsang National University, Jinju, South Korea, [2]Dep. of Companion Animal and Animal Resources Science, Joongbu University, Geumsan-gun, South Korea.*

This study was carried out to determine the effect of various additives on chemical composition, fermentation quality, and aerobic stability of barley silage. Youngyang barley was grown at Animal Research Unit, Gyeongsang National University, Jinju, South Korea, and harvested at 31% DM. Approximately 500 kg of barley forage were chopped and divided into 4 piles and applied with one of four treatments which were *L. plantarum* (LP, $1.2x10^3$ cfu/g), *L. buchneri* (LB, $1.2x10^3$ cfu/g), fermented persimmon extract (FPE, 1% of fresh forage) and essential oil (EO, 1% of fresh forage). Barley forage was ensiled into 10 L bucket silo in quadruplicate for 0, 1, 3, 7, 48 and 100 day periods. The ANOVA followed by Tukey test was performed using SAS 9.3. The concentrations of CP and ether extract were highest (7.23, 3.83% of DM, respectively, $P < 0.05$) in FPE silage ensiled for 100 days, while crude ash, NDF, ADF and hemicellulose concentrations were highest (51.8, 30.0, 21.8% of DM, respectively, $P < 0.05$) in LB silage. The in vitro digestibility of DM was highest in EO silage (62.5%, $P < 0.05$), while *in vitro* NDF digestibility was highest ($P < 0.05$) in LB (33.7%) and FPE silages (34.5%), respectively. The pH was not affected, but ammonia-N was highest ($P < 0.05$) in EO silage (0.22%), followed by FPE (0.20%), LB (0.17%) and LP (0.13%) silage. The LP silage had highest ($P < 0.05$) lactate but lowest acetate from the early stage of fermentation (3, 7 and 48 d) to the end (100 d), and so happened in the case of lactate to acetate ratio. In contrary, LB silage showed the reverse pattern in lactate and acetate compared to LP silage. Together with acetate (5.17%), LB silage also had highest ($P < 0.05$) propionate concentration (0.42% of DM) and thus resulted in highest aerobic stability (348 h, $P < 0.05$) in this silage. The yeast count was highest (5.25% of DM, $P < 0.05$) in LP silage with concomitant lowest aerobic stability (254 h, $P < 0.05$). The lactic acid bacteria (LAB) were highest (6.45 $\log_{10}$cfu, $P < 0.05$) in EO silage. The mold was not detected in any treatments. In conclusion, LB efficiently improves the aerobic stability, while LP has lowest aerobic stability as well as in vitro digestibility of NDF. On the other hand, FPE and EO substantially improve aerobic stability, preserved protein efficiently as well as improved the in vitro digestibility of DM and NDF.

Key Words: barley silage, additives, aerobic stability, fermentation quality

1092 (M109) Effects of bacterial inoculation on the fermentation and aerobic stability of whole crop soybean silage. B. D. Nkosi[*1], R. Meeske[2], T. Langa[1], T. F. Mutavhatsindi[1], and I. M. Malebana[1], *[1]ARC-Animal Production Institute, Irene, South Africa, [2]Outeniqua Research Farm, Western Cape Dep. Agric., George, South Africa.*

This study was done to evaluate the effects of microbial inoculation on the fermentation and aerobic stability of whole-plant soybean. Soybean cultivars, Pannar [333 g dry matter (DM)/kg, 64.3 g water-soluble carbohydrate (WSC)/kg DM, 177 g crude protein (CP)/kg DM] and Link [268 g DM/kg, 70 g WSC/kg DM and 170 g CP/kg DM] were harvested at R6 growth stage and chopped to 20 mm theoretical length. The materials were treated with or without Lalsil Fresh LB, a heterofermentative lactic acid bacteria (LAB) inoculant. Treatments were produced in a 2X2 factorial design as: 1) pan control (no additive), 2) link control (no additive), 3) Pan Lalsil and 4) Link Lalsil. The treatments were ensiled in 1.5 L anaerobic jars and kept in room for 90 d. Triplicate samples per treatment were collected on d 0, and 90 for determination of chemical composition and fermentation characteristics. Samples of d 90 were subjected to aerobic stability test where 500 g of sample from each jar was loosely packed in an open plastic jar that was covered with two layers of cheesecloth and kept at 28°C. A temperature probe was placed in the geometric centre of the silage mass for each jar and also in the room where the jars were stored to record temperature. The room temperature and the temperature in each jar were simultaneously recorded at 1 h intervals for 5 d and CO_2 production was measured after the 5 d exposure. The CO_2 production and number of hrs silage remained stable were indicators for aerobic stability. The inoculated silage had lower ($P < 0.005$) contents of DM, fibre and lactic acid compared to the control. The pH, ammonia-N and acetic acid content of the inoculated silage were higher ($P < 0.05$) compared to the control. The aerobic stability of silage was improved ($P < 0.05$) with inoculation as indicated by reduced CO_2 production and increased number of hrs compared to the control. The interaction between cultivars and treatments were significant ($P < 0.05$) in all parameters measured, except for the pH and energy content. Further work is needed to test these silages on ruminant growth and nutrient digestion.

Key Words: inoculant, heterofermentation, silage

1093 [Withdrawn]

1094 (M111) Quality and fermentation profile of sugar cane silage treated with chemical and microbial additives. L. L. Cardoso, M. I. Marcondes*, K. G. Ribeiro, O. G. Pereira, T. E. Silva, and D. G. Ferreira, *Universidade Federal de Viçosa, Minas Gerais, Brazil.*

The objective of this study was to evaluate the composition and fermentation profile in sugar cane silage treated with chemical and microbial additives. The treatments consisted of sugar cane silage (SCS); Sugar cane silage with *Lactobacillus buchneri* (SCSLB); Sugar cane silage with *Lactobacillus plantarum* and *Pediococcus pentosaceus* (SCSLPPP); Sugar cane silage with *Lactobacillus plantarum* and *Propionibacterium acidipropionici* (SCSLPPA); Sugar cane silage with 0.5% lime (SCSCaO0.5); sugar cane silage with 1.0% lime (SCSCaO1.0); Sugar cane silage with 0.5% urea (SCSU0.5); sugar cane silage with 1.0% urea (SCSU1.0). Additives commonly used by Brazilian producers were studied. A completely randomized design was used, with eight treatments and four replicates, with inoculants before ensiling. The sugar cane was chopped and ensiled in 20 kg buckets containing Bunsen valves, and opened 180 days after ensiling. It was observed that the sugar cane silage treated with urea markedly increased protein levels and reduced levels of insoluble nitrogen in acid detergent in the silage. However, the concentration of ammonia nitrogen was also increased ($P < 0.05$). Lime 0.5% and urea 0.5% (5.8 and 5.6, respectively) promoted minor gas losses ($P < 0.05$) in relation to the addition of *Lactobacillus plantarum* and *Pediococcus pentosaceus* in the sugar cane silage (9.8% DM). Effluent average production was not affected by treatments ($P > 0.05$), but it can be considered high in comparison to other works using sugar cane silage. Increased dry matter recovery ($P < 0.05$) was observed in the control silage (87.2%) and SCSCaO0.5 (87.2%) compared to SCSLPPP (81.9%), possibly due to increased gas production seen in this treatment. SCSCaO0.5 (9.21% DM) also promoted the highest yield of lactic acid ($P < 0.05$). The addition of 1% lime increased production of propionic and butyric acids ($P < 0.05$). It was found that the inoculation with *Lactobacillus plantarum* and *Propionibacterium acidipropionici* increased ethanol ($P < 0.05$) content (3.55% DM), and the lowest ethanol concentration was observed in SCSCaO0.5 (0.69% DM). Yeast population ($P < 0.05$) was lower in SCSU1.0 (1.4 log cfu/g) compared to SCSLPPP (4.6 log cfu/g), but both did not differ from control (3.9 cfu/g). Therefore, none of the treatments was effective in controlling yeast. It is concluded that the silages studied presented appropriate profile for fermentation, low yeast population concentration, low ethanol concentration and high recovery of dry matter.

Key Words: effluent, ethanol, yeast

FORAGES AND PASTURES II: FORAGES IN BEEF PRODUCTION SYSTEMS

1095 (T108) Reducing winter feeding needs in southern arkansas through the use of best management grazing principles. B. Stewart*[1], P. Beck[1], L. Sullivan[1], M. Sims[1], and J. Jennings[2], [1]*University of Arkansas SWREC, Hope,* [2]*Dep. of Animal Science, University of Arkansas, Little Rock.*

Research is being conducted at the University of Arkansas Southwest Research and Extension Center in Hope, AR, to determine the impacts of best management principles (BMPs) on production and winter feed requirements of spring calving cows (n = 72, BW = 547 ± 33.2 kg) grazing warm-season based pastures (n = 9, 4.7 ha pastures). The BMPs used include rotational grazing to improve pasture utilization; stockpiled bermudagrass, to extend grazing into the fall and early winter; and complementary cool-season annual grass plantings, to provide high quality forage in the spring. This research compares low management (CG, continuous grazing at a moderate stocking rate of 0.8 ha/cow) and intensive management at moderate (MR, 0.8 ha/cow) and high stocking rates (HR, 0.4 ha/cow). Stockpiling was managed by fertilization of 0.25 ha/cow of bermudagrass in early August with 168 kg ammonium nitrate/ha and deferring grazing until November. Pregnancy rate data were analyzed using the Chi-square test and cow performance data were analyzed by ANOVA using the PROC MIXED of SAS (SAS Inst. Inc., Cary, NC). Stockpiled bermudagrass produced over 5,800 ± 500 kg forage DM/ha which was adequate to hold cows grazing these pastures until late February. During calving, from mid-February to mid-April, cows on MR and HR grazed cool-season annuals and stockpiled bermudagrass or fed hay on alternating days. Cows on CG pastures were fed hay an average of 74 ± 7.3 d compared with 43 ± 7.3 d for HR and 0 for MR (P = 0.04). Pregnancy rates at weaning were similar (P = 0.99) across treatments averaging 85%. Growth performance of calves was reduced (P = 0.04) by both rotational grazing and increased stocking rate, with weaning weights of calves from CG (251 ± 9.1 kg) being greater than MR (222 ± 9.5 kg) which was greater than HR (212 ± 7.2 kg). However, total weaning weight per hectare was 68 and 90% greater (P = 0.01) for HR compared with CG and MR, respectively. With rotational stocking there was the opportunity to harvest excess forage as hay in both the moderate (9,418 kg/pasture) and high (2,206 kg/pasture). In this system every year will be different and flexibility of management will be key. Using rotational grazing, stockpiled bermudagrass, and complementary cool-season annual grasses can drastically reduce stored winter feed requirements and simultaneously increase carrying capacity and total net return.

Key Words: bermudagrass, cool-season annuals, cow calf, rotational grazing

1096 (T109) Bale diameter and feeder design effects on hay waste. D. Tomczak, N. E. Mertz, and W. J. Sexten*, *University of Missouri, Columbia.*

Forty-eight mid-gestation spring-calving cows were stratified by BW (583 ± 77.2 kg), BCS (5.4 ± 0.6), and age (5.6 ± 2.5 yr) into 6 pens to evaluate influence of bale diameter and feeder design on hay waste. Tall fescue round hay bales (85.5% DM, 8.22% CP, 66% NDF, 152 cm height) were classified as Small (128.3 ± 3.19 cm), Medium (160.7 ± 6.38 cm), or Large (187.7 ± 3.52 cm) diameter, and placed in hay feeders equipped with cradle chain (CONE) or without (RING) in a 3 x 2 factorial design randomly assigned to a 6 x 6 Latin square. We hypothesized hay waste would increase as initial bale diameter increased in RING and not differ in CONE. Bales were placed on the circular end in round bale feeders (230 cm diameter, 170 cm height) with 16 feeding stations and metal sheeting on top (50 cm) and bottom (60 cm). Small, medium, and large bales were replaced every 2, 3, and 5 d, respectively to ensure ad libitum hay access. Waste was collected daily, and residual forage was collected prior to new bale feeding. CONE (15.8%) reduced ($P < 0.10$) waste as a percent of initial bale weight compared to RING (18.3%). Waste was increased ($P < 0.05$) for large (19.4%) compared to small (14.2%), while medium (17.6%) did not differ ($P > 0.05$) from large or small. Bales were not fed for equal number of days, so data were analyzed as an incomplete 6 x 6 Latin square to evaluate feeder effects relative to access time. Waste was not different ($P > 0.10$) due to increased access time to small in CONE however waste was reduced ($P < 0.05$) as access time increased for small in RING. As access time increased to medium and large waste was reduced ($P < 0.05$). In conclusion, CONE tended to decrease waste. Increasing access time due to increased bale diameter increased waste in all cases, except small CONE.

Key Words: hay waste, bale size, bale feeder

1097 (T110) Forage and shade type effects on stocker heifers' performance. G. Scaglia*, *Louisiana State University AgCenter, Jeanerette.*

In the Gulf Coast region, performance of young cattle is restricted by the nutritional value of perennial grasses and weather conditions (temperature and humidity). Natural shade is often limited because of grazing on reclaimed croplands or due to reduced number of trees in pasturelands. The objective of this experiment was to evaluate the performance of yearling heifers continuously stocked on alyceclover (*Alysicarpus vaginalis* L.) or pearl millet (*Pennisetum glaucum*) for 60 d-grazing periods (early-July to September) with artificial or natural shade. In two consecutive years, 36 crossbred heifers (BW= 323 ± 15 kg) were randomly allotted to 12 paddocks (1.3 ha;

750 kg BW/ha) in a factorial arrangement of treatments with 3 replicates each. Portable shades were built with 6.25 cm pipe and welded into a 3 x 3.5 m frame which held a black woven polypropylene cloth providing 80% shade. These shades were available in half the paddocks while trees provide natural shade to the other half of the paddocks. Alycelover (12 kg/ha) and pearl millet (22 kg/ha) were no-till drilled after two applications of herbicide for weed control. Despite these applications, areas with some crabgrass and johnsongrass were present 30-40 d into the grazing season in all pastures. In July and August, THI (temperature humidity index, an indicator of heat load) was above 76 for the entire day and above 79 from 0600 to 2100. The latter indicates severe heat load which can adversely affect animal performance. Dry matter production of pearl millet (1800 kg DM/ha) was greater ($P < 0.05$) than alyceclover (1050 kg DM/ha). Alyceclover's CP concentration (21%) was greater while NDF (53%), and ADF (41%) concentrations were lower ($P < 0.05$) than pearl millet (11, 63, and 53%, respectively), however, animal gains were not limited by forage mass and nutritional value of either forage. There was no interaction between forage and shade type on ADG ($P = 0.84$). Forage type ($P = 0.029$) affected animal performance. Heifers grazing alyceclover gained more (0.94 kg/d) than those grazing pearl millet (0.80 kg/d). No effect of shade was detected ($P = 0.19$). Heifers with artificial shade gained 0.91 kg/d while those with natural shade gained 0.83 kg/d. As determined by our laboratory before and despite adverse environmental conditions, heifers grazing pearl millet or alyceclover performed better than those grazing bermudagrass (0.60 kg/d). Artificial shades like these are a viable alternative to improve animal welfare when natural shade is not available.

Key Words: alyceclover, pearl millet, shade

1098 (T111) Monensin supplementation levels effects on rumen fluid and blood parameters of steers receiving warm-season grass.

J. M. B. Vendramini*[1], R. F. Cooke[2], A. D. Aguiar[1], O. F. R. Cunha[1], A. C. J. Pereira[3], P. D. S. Ferreira[1], and C. B. Zactiti[1], *[1]UF/IFAS Range Cattle Research and Education Center, Ona, FL, [2]Oregon State University - EOARC Burns, Burns, [3]Elanco Animal Health, Greenfield, IN.*

Variable effects of monensin on performance of beef cattle grazing warm-season grasses have been reported in the literature. Lack of response is generally associated with low levels of monesin; thus increasing monesin levels on the animal diet may be an effective management approach to improve its efficiency and positive effects on beef cattle performance. The objective of this study was to evaluate the effects of levels of monensin on rumen fluid and blood parameters of beef steers (*Bos* sp.) receiving warm-season grass. The experiment was conducted in Ona, FL from July to September 2013. Treatments were three levels of monensin, 10, 20, and 30 ppm and control (no monensin) tested in a 4 × 4 latin square with 10 d adaptation period and 5 d of rumen fluid collection and total DM intake evaluation. Blood samples were collected on d 4 and 5 of the collection period. Ground stargrass (*Cynodon nlemfuensis*) hay (9% CP, 51% IVDOM) was offered daily and adjusted to allow 10% refusals. The steers received 0.4 kg of a concentrate supplement (14% CP and 78% TDN) daily. Total DM intake was similar among treatments ($P = 0.64$, mean = 2.0% BW). There was a linear increase ($P < 0.01$) in propionic acid concentration in the rumen (from 16.9 to 19.4 mol/100 mol) with increasing levels of monensin; however, there was no effect of monesin levels on pH ($P = 0.19$, mean = 6.6), acetic acid ($P = 0.14$, mean = 72.3 mol/100 mol), isobutyric acid ($P = 0.47$, mean = 0.73 mol/100 mol), butyric acid ($P = 0.83$, mean = 8.3 mol/100 mol) and NH4-N ($P = 0.53$, mean = 6.8 mg/dL). In addition, there was no effect of monensin levels on blood glucose ($P = 0.75$, mean = 62.0 mg/dL), insulin ($P = 0.82$, mean = 3.5 uIU/mL), IGF-1 ($P = 0.73$, mean = 12.4 ng/mL), and blood urea nitrogen ($P = 0.83$, mean = 26.4 mg/dL). Increasing levels of monensin alone may not be effective to increase performance of beef cattle receiving warm-season grasses with limited nutritive value.

Key Words: ionophore, monensin, warm-season grasses

1099 (T112) Polymers molecularly imprinted with ergotamine: Recognition properties to template and related alkaloids.

M. B. Kudupoje*[1], E. S. Vanzant[2], A. Yiannikouris[3], K. A. Dawson[3], and K. R. McLeod[2], *[1]Alltech-University of Kentucky Nutrition Research Alliance, Lexington, [2]University of Kentucky, Lexington, [3]Center for Animal Nutrigenomics and Applied Animal Nutrition, Alltech, Nicholasville, KY.*

Alkaloid toxicities negatively impact livestock health and production. Adsorbent technologies may offer effective means to manage alkaloid toxicities. In this study, molecularly imprinted polymers (MIP) were synthesized and evaluated for specificity of adsorption to various ergot alkaloids. Six different noncovalent copolymers were synthesized from styrene and methyl methacrylate functional monomers with a free radical initiator (2,2'-azobis isobutyronitrile) and three different molar ratios (1x, 2x, 4x) of crosslinker (ethylene glycol dimethacrylate) in toluene. Synthesis was performed in the absence (non-imprinted polymer, NIP) or presence of ergotamine template (MIP), yielding products NIP1x, NIP2x, NIP4x, MIP1x, MIP2x and MIP4x. An isothermal adsorption experiment was conducted in triplicates, with product inclusion of 0.01% w/v, using 5 concentrations (range 65 to 1550 ng/mL) of each of three alkaloids (ergotamine, bromocriptine and methylergonovine) in ammonium citrate buffer (*P*H 6.7, 37°C, 90 min). Samples were centrifuged (10,000 *g* for 10 min) and supernatant was analyzed by UPLC-ESI- MS/MS for quantification of unbound alkaloid. Within each alkaloid, adsorption difference between MIP and NIP interacted

($P < 0.05$) with alkaloid concentration and crosslinker ratio. For most comparisons at 1x crosslinker ratio, adsorption was greater ($P < 0.10$) for NIP than MIP. In contrast, for the few differences ($P < 0.10$) detected for 2x and 4x crosslinker ratios, MIP exceeded NIP adsorption. For both MIP and NIP, adsorption was generally greater for 2x and 4x, as compared with the 1x crosslinker ratio. Differences in adsorption between alkaloids varied with alkaloid concentration and product (alkaloid x concentration x product; $P < 0.05$). In most cases, adsorption was seen in the order ergotamine > bromocriptine > methylergonovine. Products with 4x crosslinker ratios gave the greatest adsorption, and therefore those means are used for comparison of products and alkaloids. Averaged across the different alkaloid concentrations, the respective adsorption for MIP and NIP was 91% and 86% for ergotamine, 75% and 69% for bromocriptine, and 26% and 15% for methylergonovine. Differences in adsorption properties among the six products could be explained by differences in functional groups and conformation, which are altered by template or cross linkers. Cross reactivity with related alkaloids exists due to similarities in structure and functional groups. Future in vitro and in vivo studies are required to determine stability of the polymer-alkaloid complexes, and applicability of polymers as adsorbents in livestock to counteract alkaloid toxicoses.

Key Words: adsorbent, MIP, alkaloid

1100 (T113) Silage and hay of Stylosanthes Campo Grande associated or not to corn silage: Nutrient intake and performance of beef cattle.

L. D. Rufino[1], K. G. Ribeiro[1], S. C. Valadares Filho[1,2], R. M. Martins[3], T. F. Bernardes[4], J. A. G. Azevedo[5], and O. G. Pereira[*2], *[1]Universidade Federal de Viçosa, Minas Gerais, Brazil, [2]Universidade Federal de Viçosa, Minas Gerais, Brazil, [3]University of Florida, Dep. of Animal Sciences, Gainesville, [4]Universidade Federal de Lavras, Minas Gerais, Brazil, [5]Universidade Estadual de Santa Cruz, Ilheus, Bahia, Brazil.*

The conservation of stylosanthes Campo Grande as silage or hay is an alternative to the use of corn as it increases the crude protein level of the diet and improves the soil fertility by nitrogen fixation. The nutrient intake and animal performance of Nellore cattle fed diets containing different roughage sources were evaluated. Experimental treatments were: T1 – corn silage (CS); T2 – silage of stylosanthes Campo Grande (StS); hay of stylosanthes Campo Grande (StH); T4 – 50% of CS + 50% of StS; T5 – 50% of CS + 50% of StH. Diets were isonitrogenous (12.5% of CP on DM basis) and consisted of 50:50 roughage:concentrate ratio. A total of 40 non-castrated cattle with initial average body weight of 360 kg were assigned into a completely randomized design with five treatments and eigth replicates per treatment. The experiment was divided into four periods with a 15 d of adaptation followed by three periods of 28 d each totalizing 99 days of experimental period. Means was compared by orthogonal contrasts and the initial body weight was used as a covariate at the statistical analysis of the data. Statistical analysis was performed by using SAS. Animals fed CS had lower ($P < 0.05$) intake of DM, EE, NDFap and NDFi than those fed StS, 50% of CS + 50% of StS, and 50% of CS + 50% of StH. The diet containing CS also decreased ($P < 0.05$) the intake of CP and NFC compared to diets containing StH or StS associated to CS. Despite of the lower DM intake, cattle fed diets containing CS had greater TDN intake ($P < 0.05$) compared to those fed StS. The average daily gain was greater ($P < 0.05$) in cattle fed CS compared to those fed diets with StS or StH as the only roughage source. However, no difference was observed for animal body weight gain ($P > 0.05$) among diets with CS and StS or StH. These data suggests that the mixture of corn silage with silage or hay of stylosanthes seems to be a great alternative to the use of corn silage for diets of beef cattle at the finishing phase. Sponsored by FAPEMIG, CNPq and INCT-CA.

Key Words: average daily gain, feed conversion, legume silage

---

1101 (T114) Evaluation of nutrient intake, in situ disappearance, and fermentation characteristics of fermented Chaffhaye with alfalfa hay and prairie grass hay in steers.

K. K. Guatam, B. S. Obeidat, S. J. Trojan, and M. A. Ballou, Texas Tech University, Dep. of Animal and Food Sciences, Lubbock.*

The aim of this study was to investigate the nutritive value, fermentation characteristics, and in situ disappearance of Chaffhaye and compare it to an isonitrogenous alfalfa and grass hay diets. Each of the three Holstein (mean ± SD, 533 ± 38.2 kg) and 3 Jersey (622 ± 60.5 kg) rumen fistulated steers were arranged randomly in a replicated 3 x 3 latin square design with a 2-wk adaptation period followed by a 1-wk collection period. Isonitrogenous diets consisted of Chaffhaye (fermented alfalfa hay and molasses, Chaffhaye, Inc, Dell City, TX), alfalfa hay diet (92.6% alfalfa hay plus 6.4% cottonseed meal) and prairie grass hay diet (72.9% prairie hay plus 27.1% cottonseed meal). There was no difference ($P > 0.181$) in ad libitum DMI or the intake of CP. There was a tendency ($P = 0.104$) for steers on the grass hay diet to consume more NDF. In situ NDF disappearance at the 12 and 24 hour incubations were greater ($P \leq 0.0001$) for both the Chaffhaye and alfalfa hay diets compared to the grass hay diet, but at the 96-hr incubation the NDF disappearance for the Chaffhaye was greater ($P = 0.024$) than the alfalfa hay. The CP disappearance of the Chaffhaye was greater ($P \leq 0.043$) than the alfalfa hay diet, which was greater ($P \leq 0.003$) than the grass hay diet at the 0, 6, and 24 hour incubations. Furthermore, at the 48 hour incubation the CP disappearance of the Chaffhaye and alfalfa hay was greater ($P \leq 0.001$) than the grass hay diet. Methane production was reduced ($P \leq 0.024$) in the grass hay when com-

pared to the Chaffhaye and alfalfa hay diets. The rumen pH of Chaffhaye fed steers was slightly greater (6.73 ± 0.062; $P \leq 0.040$) than either the alfalfa hay (6.56) or grass hay (6.47) diet. These data indicate that Chaffhaye has an improved NDF digestibility compared to a prairie grass hay diet and that the soluble CP fraction is greater when compared to an isonitrogenous alfalfa hay or prairie grass hay diet.

Key Words: digestibility, forage, neutral detergent fiber

1102 (T115) Ruminal fermentation characteristics of beef steers grazing grass monocultures versus low- and high-tannin grass-legume mixtures.

C. T. Noviandi[1,2], T. J. Bingham[1], J. S. Eun[*1], D. R. ZoBell[1], B. L. Waldron[3], and M. D. Peel[3], *[1]Utah State University, Logan, [2]Universitas Gadjah Mada, Yogyakarta, Indonesia, [3]Forage and Range Research Laboratory, USDA-ARS, Logan, UT.*

Ruminal fermentation characteristics were investigated with 36 Angus crossbred steers grazing 4 treatments: 1) tall fescue (TF) with no fertilizer (TF–NF), 2) TF with N fertilizer (TF+NF), 3) TF-alfalfa mixture (TFALF), and 4) TF-birdsfoot trefoil mixture (TFBFT). Treatments were tested in a randomized complete block design with 3 pasture replicates, 4 paddocks per pasture, and 3 steers per pasture. Replicated 0.47-ha paddocks were grazed with beef steers from May through September in 2013 for total of 16 wk. Steers grazed for 7 d per paddock on a 28-d rotation interval. Pasture forage samples were collected at 4-wk intervals throughout the experiment. Ruminal fluid samples were obtained from all steers using a Geishauser probe at wk 4, 8, 12, and 16 to measure pH and analyze VFA profiles and ammonia-N (NH_3-N) concentration. Concentration of CP in pasture forages was greater ($P < 0.01$) in mixtures than grass monocultures at wk 4 (12.8 vs. 7.89%), but it was similar after wk 4. In contrast, NDF concentration was lower ($P < 0.05$) in mixtures compared with grass monocultures throughout the grazing season. Ruminal pH was maintained at 6.54 or higher and did not differ across treatments. Starting at wk 8, total VFA concentration increased ($P < 0.05$) in steers grazing the mixtures compared to those grazing monocultures. However, the VFA concentration was not different between TFALF and TFBFT. Acetate proportion increased with mixtures at wk 12, but propionate proportion decreased due to grazing mixtures, resulting in increased acetate-to-propionate ratio at wk 12 ($P < 0.05$). Concentration of NH_3-N was highest with TF+NF at wk 8 and 12, whereas at wk 16, it was highest in steers grazing mixtures followed by TF+NF ($P < 0.05$). Steers grazing grass-legume mixtures resulted in enhanced ruminal fermentation evidenced by increased VFA concentration likely due to greater concentration of nonfiber carbohydrates, which may have supported increased growth performance compared to those grazing grass monocultures. Therefore, grass-legume mixtures for grazing steers can replace N fertilization of TF, and thus it can be a sustainable approach to improve pasture utilization for finishing beef steers.

Key Words: grass-legume mixtures, grazing beef steers, ruminal fermentation

---

1103 (T116) Agronomic assessment and beef cattle nutrition suitability of 31 forage type annual crops in the Peace region of Alberta.

T. A. Omokanye**[*1], M. Hobin[1], I. A. Adeyinka[2], and M. Benoit[1], *[1]Peace Country Beef & Forage Association, Grande Prairie Regional College, Fairview, AB, Canada, [2]National Animal Production Research Institute, Shika-Zaria, Nigeria.*

There is increasing use of forage type annual crops for swath grazing, bale grazing and silage for back grounding and finishing beef cattle in the Peace region of Alberta. There is therefore a need for continued effort for recent data (on agronomic adaptation, forage yield and quality, and animal performance) as new forage type annual crop varieties become available for possible inclusion into the forage based cropping systems of the region. A set of 31 annual crop varieties (16 barley, 3 oat, 5 triticale, 3 soybean, 2 field peas, 1 millet and 1 sorghum) were tested in order to identify crop varieties with superior forage yield and quality for beef cattle production. Forage dry matter (DM) yield varied ($P < 0.05$) from 4162 kg ha^{-1} (forage sorghum) to 10769 kg ha^{-1} (AC Ranger barley). Only 6 of the 31 tested crops had > 10.0 t ha^{-1}. Forage crude protein (CP) was unaffected ($P > 0.05$) and was generally > 10.0% for all crops. The 5 legumes included in the test all had significantly ($P < 0.05$) higher forage Ca content than cereal crops. Forage total digestible nutrients (TDN) generally varied ($P > 0.05$) from 60 to 67%. Crops which produced lower DM also had lower CP DM yield (DM x CP%). All crop varieties exceeded the suggested CP, Mg, K and TDN values for a dry gestating beef cow in the mid- and late-pregnancy stages. But the recommended Ca, P and Na values have not been consistently met by all crop varieties. Conducting cluster analysis procedures on the 31 crop varieties tested, using DM yield, forage chemical composition (7 parameters), energy (4 parameters), estimated digestibly (4 parameters), CP DM yield and Ca:P, hierarchical cluster analysis classified the crops into four distinct clusters of 8, 16, 6, and 1 crop varieties with, respectively, excellent, good, regular and poor degree of agronomic adaptation in the region and suitability for beef cattle.

Key Words: annual crop; forage; nutritive value; beef cattle; cluster analysis

FORAGES AND PASTURES III: GENERAL FORAGES AND FORAGE SYSTEMS

1104 (W091) Effect of plant density on nutritional quality of green chopped corn. G. Ferreira[*1,2], D. Carp[2], M. Alfonso[3], and S. Depino[3], [1]Dep. of Dairy Science, Virginia Polytechnic Institute and State University, Blacksburg, [2]CREA Lincoln, Asociación Argentina de Consorcios Regionales de Experimentación Agropecuaria, Lincoln, Buenos Aires, [3]*Forratec Argentina, SA, Chacabuco, Buenos Aires.*

The hypothesis of this study was that seeding corn at high plant densities results in greater concentrations of neutral detergent fiber (NDF) and lower concentrations of starch in corn whole plant. Therefore, the objective of this study was to determine the effect of planting density on whole-plant dry matter (DM) yield and its nutritional quality. The study was performed in a commercial dairy farm located in General Villegas, Argentina. Preceding crop was corn for silage. Total rainfalls during fallow and crop season were 719 mm. Two commercial corn hybrids (Dekalb747 and Duo548) were sown at 60,000, 70,000, 80,000 and 90,000 plants/ha^{-1} in four plots using a no-till corn seeder with a pneumatic dosing machine (TX Mega, Agrometal, Argentina). Plots were composed of eight 50-m rows separated by 52 cm. Corn was sown on October 13, 2012 and chopped on February 1, 2013. Crop was fertilized with 90 kg N and 31 kg P2O5 per hectare. Ten consecutive corn plants, randomly selected from each plot, were manually cut at 15 cm above ground, chopped with a forage chopper (TRF 70, Trapp, Brasil) and weighted to determine DM yield. Nutritional quality of chopped corn was determined by NIRS. Because the resulting densities were inferior and more variable than targeted (likely due to soil temperature variation linked to no-till conditions) statistical analysis was performed by linear regression. Average DM concentration of the chopped corn was 31.1 and 34.5% for the Duo548 and Dekalb747 hybrids, respectively. Plant density did not affect whole plant dry weight ($P > 0.51$) in either hybrid (285 and 252 g DM.plant^{-1} for Duo548 and Dekalb747, respectively). Therefore, DM yield was linearly increased with plant density (slope = 237 kg DM.1000 plants^{-1}.ha^{-1}, $P < 0.01$). Contrary to the hypothesis, plant density did not affect either NDF concentration ($P > 0.25$) nor starch concentration ($P > 0.72$) of chopped corn (47.2 and 50.2% NDF and 27.5 and 21.3% starch for Dekalb747 and Duo548, respectively). Estimated DM digestibility was not affected ($P > 0.24$) by plant density in either hybrid (65.5 and 67.2% for Duo548 and Dekalb747, respectively). We concluded that, with abundant rainfalls (i.e., >700 mm), plant density does not affect nutritional quality of corn. Whether plant density affects nutritional quality of corn under lower rainfall regimes still needs to be elucidated.

Key Words: corn, density, quality

1105 (W092) Assessment of in vitro fermentation characteristics of lactation dairy diets consisting of orchardgrass or birdsfoot trefoil pasture forages with different supplements using continuous cultures. R. G. Christensen[1], A. J. Young[1], J. S. Eun[*1], J. W. MacAdam[1], and B. R. Min[2], [1]*Utah State University, Logan,* [2]*Tuskegee University, Tuskegee, AL*

This study evaluated the effects of feeding 2 different pasture forages [orchardgrass (OG) vs. birdsfoot trefoil (BFT)] combined with 3 supplements [no supplement, ground barley (GB), and forage-concentrate mixture (FCMX)] on in vitro fermentation characteristics. The experiment was performed in a 2 (source of pasture forage) × 3 (supplement) factorial design with 3 independent runs of continuous cultures ($n = 3$). Continuous culture apparatus consisted of 700-mL working volume fermentation vessels to measure major fermentation end-products. Each culture was offered a diet of 15 g DM/d in 4 equal portions at 0600, 1200, 1800, and 2400 h, and the supplements (GB and FCMX) were included at 30% DM of total diets. Culture pH averaged 6.15 and was not different across treatments. Total VFA concentration averaged 39.5 m*M* and did not differ among treatments. Feeding different pasture forages did not influence acetate and propionate concentrations. While acetate concentration was similar across treatments, propionate concentration increased with supplementing GB or FCMX, resulting in a decreased acetate-to-propionate ratio due to the supplementations. Ammonia-N concentration tended to decrease ($P < 0.06$) with BFT compared with OG (9.40 vs. 13.5 mg/100 mL), whereas supplementation resulted in no difference in the ammonia-N concentration, regardless of source of pasture forage. Methane production decreased when fermentors were offered BFT compared with OG (8.50 vs. 10.9 mmol/d), but supplementation did not affect the methane production under OG as well as BFT. The positive impacts of feeding BFT pasture forage with decreased ammonia-N and methane concentrations could have resulted from beneficial effects of condensed tannins (4.46% DM) in BFT which manipulate ruminal fermentation pathways by improving utilization of N and energy substrates. Overall results in this experiment indicate that feeding BFT-based dairy diets did not interfere with in vitro ruminal fermentation, and BFT can be an effective forage source to reduce N excretion and mitigate methane emissions.

Key Words: birdsfoot trefoil, condensed tannins, continuous cultures

1106 (W093) Fatty acid profile and oxidative stability of carcass fat from meat goats fed grass-legume forage diets. B. R. Min[*], *Tuskegee University, Tuskegee, AL*

A series of experiment was conducted at the Caprine Research and Education Unit at Tuskegee University to develop and

demonstrate a profitable and sustainable forage-based goat production system with 6 different forage combinations included annual ryegrass (RG) or RG + legume combinations (e.g. Austrian pea (AP), berseem clover (BC), hairy vetch (HV), RG+AP+HV, and RG+HV+AP+BC)) in the winter of 2011 for the Southeastern United States. Forty-eight crossbred goats (*Capra hircus*; BW= 27.46 kg) were randomly assigned to 12 paddocks with 6 forage combinations with 2 replicates *(n* = 4) during 45 days. After grazing ended, goats were transported to Mississippi State University Meat Lab and were slaughtered according to the USDA guidelines and carcass characteristics were determined. Forage biomass and forage chemical composition were measured from February to May. On each occasion four random quadrates (0.25 m^2) per forage paddock were cut using a hand-clipper. There was a forage sampling time x forage combination interaction ($P < 0.01$) for CP and NDF. Forage CP content was higher in March than February and April, but NDF content continuously increased with time. The RW with HV combinations continued to have greater CP content. Animals on RG and BC combinations grew 18% faster and reached expected slaughter weight in less time when compared to RG pasture system. Goats grazing RG+BC and RG+HV+AP had higher ($P < 0.05$) ADG and carcass weights than other forage combinations. Goats grazed on RG-based diet had higher SFA and polyunsaturated fatty acids (PUFA) in intramuscular fats ($P < 0.01$), but were lower in mescenteric kidney fat and subcutaneous fat ($P < 0.05$) compared to legume forage-based diets, respectively. For goats grazing on RG-based diet had significantly higher ($P < 0.05$) omega-3 and omega-6 fatty acids in intramuscular fat content, but were lower in subcutaneous fat ($P < 0.05$) compared to legume forage-based diets. Mono unsaturated fatty acids (MFA) were not affected by diets. These results indicated that goats receiving RG forage-based diets produced carcasses with more PUFA and higher omega-3 and -6 fatty acids in intramuscular fat from Kiko-crossbred male goats.

Key Words: fatty acids, goats, grass, legume

1107 (W094) Effects of moisture level at baling and Fresh Cut brand plus on quantity and quality of alfalfa hay harvested in large rectangular bales. K. E. Griswold*, R. Almada, A. Lipata, and E. Rodberg, *Kemin Animal Nutrition & Health, Des Moines, IA.*

The effects of baling moisture and Fresh Cut brand plus (Kemin Industries, Des Moines, IA), a propionic acid-based preservative, on quantity and quality of alfalfa hay harvested in large rectangular bales were determined in a split plot design. Baling moisture, low (LM, <15%) vs. high (HM, >20%), was the main plot, and control (NT) vs. Fresh Cut Plus (FC+) applied at recommended levels was the subplot. Weight, mold and yeast counts, and nutrient content were determined for fresh (day of baling) and cured (8 wk after baling) bales using composite samples from 6 cores per bale. Data were analyzed using JMP software with models that included the fixed effects of baling moisture, FC+, and the interaction of moisture by FC+. Significance equaled $P < 0.05$ and trends equaled $0.05 < P < 0.10$. Mold and yeast counts were log transformed prior to analysis. Data are presented on DM basis. The interaction of HM baling and FC+ increased ($P < 0.01$) fresh bale weights (709 vs. 644 kg, respectively) and tended ($P = 0.06$) to increase cured bale weights (719 vs. 635 kg, respectively) compared to all other treatments. In cured bales, mold and yeast counts were lower (4.5 vs. 5.4 and 5.1 vs. 5.8, respectively; $P < 0.01$) for HM vs. LM bales. In fresh bales, mold and yeast counts were not affected ($P > 0.10$) by FC+, but were lower (4.7 vs. 5.2 and 5.3 vs. 5.7, respectively; $P < 0.05$) in cured bales compared to NT. There were no effects or interactions ($P > 0.10$) of baling moisture and FC+ on nutrient content of fresh bales. In cured bales, the baling moisture and FC+ interacted to lower ($P < 0.05$) sugar content (4.62 vs. 6.09%, respectively) and concomitantly increase ($P < 0.05$) lignin (5.42 vs 4.59%), ADICP (2.73 vs. 2.41%), and fat (1.77 vs. 1.66%) content, respectively. In cured bales, FC+ lowered ($P < 0.05$) CP (25.2 vs. 25.7%) compared to NT, and HM baling increased ($P < 0.05$) ADF (29.4 vs. 28.1%), NDF (38.4 vs 36.8%), and ash (14.1 vs. 13.6%) content compared to LM, respectively. However, there were no significant ($P > 0.05$) effects of treatments on feeding value of fresh or cured alfalfa as determined by MILK 2006 software. Overall, these results would suggest that baling at high moisture in combination with FC+ treatment allowed for the harvesting and retention of more high quality alfalfa DM in large rectangular bales compared to baling at low moisture with or without FC+ application.

Key Words: alfalfa, moisture, Fresh Cut plus

1108 (W095) Estimation of macronutrients content in mixed swards by near infrared reflectance spectroscopy. A. I. Roca-Fernández*, P. Castro-García, and A. González-Rodríguez, *Agrarian Research Centre of Mabegondo, La Coruña, Spain.*

Near infrared reflectance spectroscopy (NIRS) is a rapid, non-destructive and inexpensive technique for providing chemical analysis of forage and feedstuffs. The aim of this study was to develop NIRS calibration equations to determine macronutrients (P, Ca, Mg and K) content in mixed swards. Two hundred twenty samples were taken from mixed ryegrass (*Lolium perenne* L. and *Lolium multiflorum* Lam.) and clover (*Trifolium repens* L. and *Trifolium pratense* L.) swards located in a grassland area from Galicia (NW Spain). Reference data that were used for developing calibration equations were analyzed using standard laboratory methods widely applied for determination of macronutrients content in swards samples (*P* was measured colorimetrically as molybdovanado-phosphoric acid and Ca, Mg and K were measured by atomic absorption spectrophotometry). All the samples were scanned with monochro-

matic radiation from 1100 to 2500 nm using NIRSystems 6500 (FOSS Analytical AS, Denmark). Predictive equations were developed using modified partial least squares (MPLS) regression with internal cross-validation and scatter correction using standard normal variate (SNV) and detrend. Cross validation was used to avoid overfitting of the equations. The best equations of MPLS regression for the four macronutrients were obtained by using the second derivative of spectra than using the first derivate. The coefficient of determination in calibration (R^2_c), cross validation (R^2_{cv}) and prediction (R^2_p) and the standard error of calibration (SE_C), cross validation (SE_{CV}) and prediction (SE_P) found for each macronutrient were: P (R^2_c= 0.72 and SE_C= 0.43; R^2_{cv}= 0.61 and SE_{CV}= 0.51; $R^2_{P=}$ 0.70 and $SE_{P=}$ 0.46), Ca (R^2_c= 0.90 and SE_C= 1.44; R^2_{cv}= 0.69 and SE_{CV}= 2.50; $R^2_{P=}$ 0.84 and $SE_{P=}$ 1.35), Mg (R^2_c= 0.76 and SE_C= 0.19; R^2_{cv}= 0.58 and SE_{CV}= 0.26; $R^2_{P=}$ 0.60 and $SE_{P=}$ 0.20) and K (R^2_c= 0.82 and SE_C= 3.46; R^2_{cv}= 0.71 and SE_{CV}= 4.37; $R^2_{P=}$ 0.74 and $SE_{P=}$ 2.98). Taking into account RPD values for validation, calculated as standard deviation of reference data (SD) divided by SE_p, a good quantitative prediction of Ca (RPD= 2.27) and approximately of P, Mg and K (RPD= 1.79, 1.66 and 1.95, respectively) were achieved. Nevertheless, these results might be improved by adding samples to the calibration set.

Key Words: minerals, NIRS, ryegrass-clover pastures.

1109 (W096) Fall harvest management of eastern gamagrass. W. K. Coblentz*[1], M. G. Bertram[2], P. C. Hoffman[3], N. M. Esser[4], and J. S. Cavadini[4], *[1]U.S. Dairy Forage Research Center, Marshfield, WI, [2]University of Wisconsin, Arlington, [3]University of Wisconsin, Madison, [4]University of Wisconsin, Marshfield.*

Recent research has suggested that eastern gamagrass (EGG) may be an effective alternative to chopped straw in the blended diets of dairy heifers and cows. Most extension materials discussing appropriate fall management of EGG recommend avoiding harvest within about 6 weeks of first frost. Using this guideline for central Wisconsin, a final harvest of EGG would need to occur before August 15; however, previous research has shown that single-harvest yields of DM are not maximized by that date because of inadequate accumulation of growing degree days. Our objectives were to evaluate yields of DM, plant persistence, and nutritive value for EGG harvested at 15-d intervals between August 1 and November 1. Residual forage growth was burned each May, and all forages were fertilized with 84 kg N/ha annually. Data collected from 2010 through 2013 indicated that yields of DM increased with linear ($P < 0.01$) and quadratic ($P < 0.01$) effects over harvest dates, peaking at > 7400 kg/ha on both the September 15 and October 1 harvest dates. Overall DM yields varied with year, but were greatest ($P < 0.01$) during the final year (2013) of the trial (7967 kg/ha), thereby suggesting stands were not damaged by fall harvests. Percentage of continuous row coverage also was assessed, but was not affected by harvest date ($P \geq 0.22$). Concentrations of NDF increased from 75.8 to 82.0% across harvest dates, exhibiting both linear and quadratic ($P < 0.01$) effects. Similarly, acid-detergent lignin increased from 4.07 to 5.12% between August 1 and November 1, exhibiting only a linear ($P < 0.01$) effect of harvest date. Crude protein declined linearly ($P < 0.01$) across harvest dates, ranging from 7.69 to 3.67%. Energy density also declined linearly ($P < 0.01$) over harvest dates, ranging from 53.2% TDN on August 1 down to 43.9% TDN on November 1. One-time harvests of EGG during fall allowed for improved yields of DM through October 1, and did not affect stand persistence. For harvests timed between August 1 and November 1, EGG will likely range between 75.0 and 82.0% NDF, and exhibit an energy density of approximately 50% TDN. These characteristics, coupled with the consistent observation that EGG haylage is not sortable by dairy heifers or cows, make EGG a potentially attractive alternative to chopped straw.

Key Words: eastern gamagrass, fall harvest management, DM yield

---

1110 (W097) Fertilization of fall-grown oat with urea or bedded-pack manure. W. K. Coblentz*[1], W. E. Jokela[1], and M. G. Bertram[2], *[1]U.S. Dairy Forage Research Center, Marshfield, WI, [2]University of Wisconsin, Arlington.*

Oat (*Avena sativa* L.) shows promise as a fall-forage option for dairy producers in Wisconsin, and potentially opens a window of opportunity for manure spreading that is not associated with production of corn (*Zea mays* L.). Our objectives were to assess the effects of summer applications of commercial N fertilizer or bedded-pack manure containing wood shavings on the DM yield, N uptake and recovery, and nutritive value of fall-grown oat forages. Research plots were fertilized with either bedded-pack manure (23 or 45 Mg/ha, wet basis; 22.9% DM; 1.9% N, DM basis) or urea (46-0-0) at application rates of 0, 20, 40, 60, or 80 kg N/ha, and then seeded to two oat cultivars (Ogle or ForagePlus). Plots were harvested on two dates (early October or November), which simulated grazing and silage applications, respectively. Climatic conditions differed sharply across years, with growth responses limited somewhat by drought during 2012. During both years, DM yield increased linearly ($P \leq 0.03$) with commercial N fertilization, and yields following applications of urea exceeded ($P < 0.01$) forages receiving bedded-pack manure during 2011, but not during 2012 ($P = 0.85$). Overall DM yields were greater in early November compared to early October during both 2011 (3991 vs. 2257 kg/ha; $P < 0.01$) and 2012 (2753 vs. 1997 kg/ha; $P < 0.01$). Apparent percentage N recoveries by oat forages increased linearly ($P = 0.01$) with urea application rate during 2011, and increased with both linear ($P = 0.01$) and quadratic ($P < 0.01$) effects during 2012. However, apparent N recoveries following applications of bedded-pack manures were es-

sentially nil for both years (overall range = -6.2 to 2.6% of N applied). For 2011, concentrations of water-soluble carbohydrates (WSC) were inversely related to urea application rate, declining from 12.4 to 10.1% as fertilization rate increased from 0 to 80 kg N/ha, which was explained by both linear (P = 0.01) and quadratic (P <0.01) effects of application rate. Similar effects were observed for 2012, when WSC declined from 19.3 to 16.3% across the same urea fertilization treatments. Calculated energy density of fall-oat forages remained very high across all treatments; overall means were 67.0 and 70.1% TDN for 2011 and 2012, respectively. These results indicate that fall-grown oat is an energy-dense forage option, but bedded-pack manures containing wooden shavings provide little immediately available N to support forage production.

Key Words: bedded-pack manure, fall-grown oat, N fertilization

---

1111 (W098) Nutrient composition and in vitro digestibility of cultivated and non-cultivated plant species found within a Southwestern forage production operation. J. D. Allen[*1], L. W. Hall[2], and J. English[2], *[1]Northwest Missouri State, Maryville, [2]University of Arizona, Tucson.*

Nutrient quality of non-cultivated plants in hay or grazing pasture may affect animal feeding behavior, digestive efficiency, forage quality, or a combination of these. Understanding nutritive composition of invasive plants may improve forage and weed management. A 2-year study was conducted to determine the nutrient composition and digestibility of invasive plants growing within the boundaries of 3 alfalfa hay fields and 7 grass pastures (9.75 ha) located at the University of Arizona's West Agriculture Campus and Campus Agricultural Center (Tucson). Multiple whole above-ground samples of cultivated and non-cultivated species were collected at a maturity of mid-bloom for non-grasses (n = 53) and pre-shatter for grasses (n = 13). Samples were analyzed for DM, ash, NDF, ADF, ADL, CP, and IVTD. Species from 21 plant families were sampled, with the grass (*Poaceae*) family having the highest specie count (13), and 9 forb families having only 1 specie recorded. Compared to cultivated alfalfa, forb species had greater (P < 0.01) CP (20.2 vs. 15.5 ± 2.85%), ADL (8.5 vs. 3.0 ± 1.74%), and IVTD (75.1 vs. 67.3 ± 3.28%), and grass species had greater (P < 0.01) NDF (53.8 vs. 45.9 ± 3.76%) but lower (P < 0.01) ADF (25.7 vs. 33.6 ± 1.74%). Seven (7) plant families were represented by at least 3 species: amaranth (*Amaranthaceae*; n = 3), sunflower (*Asteraceae*; n = 7), mustard (*Brassicaceae*; n = 7), goosefoot (*Chenopodiaceae*; n = 5), knotweed (*Polygonaceae*; n = 4), nightshade (*Solanaceae*; n = 5), and grass. Within the 7 families, grasses had greatest NDF but least ADL, ash, and IVTD (54.7, 5.7, 11.9, and 64.3%, respectively; P < 0.01). Nightshade species had greatest CP (23.5%; P < 0.01), amaranth species had greatest IVTD and least NDF (84.0 and 29.3%, respectively; P < 0.01), and mustard species had greatest ADL (10.1%; P < 0.01). Greatest variation was observed with DM (SEM range = 2.47 to 16.98%), and least variation was observed with ADL (SEM range = 0.93 to 4.33%). Predominant species observed affecting grazing behavior or hay production included junglerice (*Echinochloa colonum*), bermudagrass (*Cynodon dactylon*), little mallow (*Malva parviflora*), and Palmer amaranth (*Amaranthus palmerii*). Results indicate the presence of non-cultivated plants growing within Southwestern hay and grazing fields may affect forage nutritive quality.

Key Words: forage, in vitro, invasive plants, nutrient composition

---

1112 (W099) Effects of Marandu pastures heights and sources of energy supplements on the weights gains per animal and per area. A. A. Oliveira[1], M. V. Azenha[*2], S. S. Santana[2], C. H. O. Macedo[2], J. P. R. Costa[2], T. T. Berchielli[2], A. C. Ruggieri[3], and R. A. Reis[2], *[1]Unesp, Jaboticabal, Brazil, [2]University of Sao Paulo State, Jaboticabal, Brazil, [3]Sao Paulo State University, Jaboticabal, Brazil.*

The study aimed to evaluate forage allowance based in sward heights, and energy supplementation from different sources in the weight gain of young Nellore bull yearling in pastures of *Urochloa brizantha* cv. Marandu. Grazing system was continuous with variable stocking (put and take animals) to maintain the sward height during the rainy season. Three pasture heights (15, 25, 35 cm) were combined with three supplementation strategies (mineral mixture, protein/energy supplement based in corn meal, and protein/energy supplement based citrus pulp) distributed in eighteen paddocks (two pasture replications). Both energy/protein supplements contained 19.0% of crude protein, and were supplied at 0.3% of body weight/day. Experiment was conducted from January to April. Forage mass, and animal body weight were determined monthly to calculate the forage allowance. One hundred eight animals (259 ± 20 kg) were grazed for 122 d and weighed at the beginning and the end of the trial. Total dry matter intake was evaluated using modified lignin LIPE (eternal marker), and indigestible neutral detergent fiber (internal marker). The type of supplementation did not influence (P > 0.05) any pasture variable evaluated during the experimental period. To maintain pastures heights it was necessary to adjust the stocking rate that decreased linearly (6.64, 5.03 and 4.08 UA/ha^{-1}) in response to the treatments (15, 25 and 35 cm, respectively). Forage allowance, and dry matter intake increased linearly (P < 0.05) in response to the pasture heights, or forage allowance. Gain per unit of land showed a quadratic response associated to lowest weight gains per unit of land (6.94, 6.38, and 5.37 kg/ha/day) in response to pasture heights (forage allowance), but there was a positive response in individual animal weight gain (0.694, 0.874 and 0.953 kg/day). Protein/energy supplementation increased (P < 0.05) weight gain per area and per

animal. Citrus pulp provided greater ($P < 0.05$) stocking rates (5.4 AU/ha), but corn was similar (5.3 AU/ha) to both mineral (5.0 AU/ha) and citrus pulp. Pasture management at 15 cm during the rainy season resulted in highest stocking rate, and consequently more weight gain per area. However, lowest forage allowance reduced forage intake, average daily weight gain, and final body weight at the end of the rainy season. It was concluded that the pasture energy/protein supplementation (0.3% BW) provides a balance between gain per area, per animal, and low risks to pasture degradation and maximum productivity in the system.

Key Words: beef cattle, supplementation, weight gain

1113 (W100) Effect of sowing date on forage yields and quality of Italian ryegrass in early spring-seeded. K. Kim*, *Livestock Institute, Jeollanamdo, South Korea.*

Because Italian ryegrass (IRG) is generally cultivated by winter cropping on a drained paddy field, the harvest season is overlapped with that of rice in some cases. In addition, people may miss the adequate seedtime for IRG because of the rainy season. Therefore, this research has been performed between October 2012 and July 2013 in Kangjin, Korea, to examine the effect of spring-seeding on the yields and quality of IRG, as an alternative seeding when the adequate seedtime is missed. Using Kowinearly species, five test groups were prepared depending on the sowing date: Control group (sowing date: October 20, 2012, which is an optimum seeding-time), T1 (sowing date: February 15, 2013), T2 (sowing date: February 25, 2013), T3 (sowing date: March 5, 2013) and T4 (sowing date: March 15, 2013), and the IRG was harvested in May 31, 2013. The lodging of vegetative period for control group, T1 and T2 was >70%, while that of T3 and T4 was approximately 50%. The plant height by harvesting for control group showed the highest value of 109.5cm, and for T1 and T2 was 102.2 and 103.0cm, while those for T3 and T4 were 98.6 and 93.3cm, respectively, whereby the difference was statistically significant ($P < 0.05$). The fresh yield per ha was 38.0, 26.5, 21.2, 22.3 and 20.4 ton/ha for control group, T1, T2, T3 and T4, respectively, where the control group showed the highest value and the T1 was significantly larger than those for T2~T4 ($P < 0.05$). The yield for dry matter was 31.3, 27.8, 28.8, 24.4 and 22.3% for the control group, T1, T2, T3 and T4, respectively, which is the similar to the fresh yield. On the other hand, the content of crude protein was 7.9, 8.6, 8.7, 9.4 and 12.3% for the control group, T1, T2, T3 and T4, respectively, where a shorter growing period represents the higher crude protein content. The ADF was 36% for the control group and T1 ~ T3, while that for T4 decreased to 33%. The NDF was 66% for the control group and T1 ~ T3, while that for T4 decreased to 61%. According to these findings, it can be summarized that the Spring-seeding of IRG gives <70% yield compared to that by the adequate seeding. However, the optimum seeding time to maximize the forage yield and quality would be before February 25.

Key Words: Italian ryegrass, early spring-seeded, forage yield, forage quality

---

1114 (W101) Relationship between protein structural characteristics and supply of metabolizable protein to dairy cattle from new cool-season forage corn varieties in Western Canada . *N. A. Khan, S. Abeysekara, D. A. Christensen, X. Huang*, and P. Yu, University of Saskatchewan, Saskatoon, Canada.*

The objective of this study was to find out the relationship between protein inherent molecular structural characteristics of cool-season forage corn and supply of metabolizable protein (MP) to dairy cattle. Six new corn cultivars, including 3 Pioneer (PNR) and 3 Hyland (HL), coded as PNR-7443R, PNR-P7213R, PNR-7535R, HL-SR06, HL-SR22, HL-BAXXOS-RR, were sown in 24 plots on in the research fields of Canada-Saskatchewan Irrigation Diversification Centre (Outlook, SK, Canada). The 24 plots were blocked within 4 fields, and all cultivars were sown in each field (4 block x6 varieties). Whole crop samples were collected after a target of 2160 CHU was achieved. The MP supply to dairy cattle, and energy synchronization properties were modeled by the DVE/OEB system and the NRC-2001 model. The parameters evaluated were protein molecular structures in terms of amide I, amide II, amide I to II ratio, α-helix, β-sheet and α-helix to β-sheet ratio, which were determined using vibrational molecular spectroscopy (VMS). The data analysis were performed using SAS with Proc Mixed and Proc Corr. The Normality test was used Proc Univariate with Normal and Plot options. Multivariate molecular spectral analyses were performed with Statistica (StatSoft Inc., Tulsa, OK). The Tukey method was used for multi-treatment comparison. The significant level was declared at $P < 0.05$. There were no significant differences ($P > 0.05$) among the cultivars in molecular-spectral intensities of protein molecular structures. The amide II had a significant positive correlation with truly absorbable rumen undegraded feed protein (ARUP) ($r = 0.30$; $P < 0.001$), and had a significant negative correlation ($r = 0.18$, $P < 0.05$) with truly absorbable endogenous CP (AECP). Whereas, both amide I and amide II, and protein secondary structures (α-helix and β-sheet) were inversely correlated with rumen available N per insoluble rumen available OM ($r = \sim -0.30$; $P < 0.001$). In summary, protein molecular structure in the new cool-season corn varieties significantly link to the supply of metabolizable protein to dairy cattle.

Key Words: corn varieties, supply of metabolizable protein, protein molecular structures

1115 (W102) Evaluation of agronomic characteristics of five varieties of corn in integrated crop-livestock-forest system. A. A. Pinheiro*, M. C. A. Santana, V. A. Silva, J. T. C. Pacheco, A. C. Fernandes, and I. D. Carneiro, *Emater, Goiânia, Brazil.*

This research aimend to evaluate the agronomic characteristics of five cultivars of maize intercropped with *Brachiaria brizantha*cv, Marandu. The experimental design was a randomized block with three replications and five treatments. Maize cultivars used were: EMGOPA 501, AL Bandeirantes, BRS Caimbé, PL 6880, BRS 1060. To assess the agronomic characteristics were estimated: plant height, ear height, ear number per plant and number of plants per meter. Corn EMGOPA 501 showed higher plant height, since the height of the spike was equal to cultivars EMGOPA 501 and PL 6880. The number of spike was higher in cultivars EMGOPA 501, Al Bandeirantes and BRS 1060. BRS 1060 showed fewer plants per linear meter. Considering the whole plant corn, all cultivars showed agronomic traits suitable for silage production, highlighting the variety EMGOPA 501 for plant height and ear height hence.

Key Words: silage, ear, production

Table 1115. Means of agronomic characteristics of five cultivars of maize intercropped with *Brachiaria brizantha* cv. Marandu

	EMGOPA 501	AL Bandeirantes	BRS Caimbé	PL 6880	BRS 1060	CV (%)
Plant height	2.88^{A}	2.48^{B}	1.74^{D}	2.56^{B}	2.04^{C}	7.75
Ear height	1.80^{A}	1.39^{BC}	0.89^{D}	1.56^{AB}	1.18^{C}	12.28
Ear per plant	1.12^{AB}	1.25^{AB}	1.00^{B}	1.00^{B}	1.60^{A}	30.15
Plant per meter	3.87^{A}	3.32^{AB}	3.73^{AB}	3.87^{A}	3.20^{B}	13.53

Letters in rows differ ($P < 0.05$).

1116 (W103) Non-structural carbohydrates in Marandu-grass pastures under different grazing intensities. M. V. Azenha*[1], L. F. Brito[1], A. A. Oliveira[1], E. R. Janusckiewicz[1], E. Raposo[1], S. S. Santana[1], R. A. Reis[1], and A. C. Ruggieri[2], *[1]University of Sao Paulo State, Jaboticabal, Brazil, [2]Sao Paulo State University, Jaboticabal, Brazil.*

Carbohydrates are the source of available energy for growth and plants survival. This concentration is reduced by occurrence of defoliation and subsequent regrowth. Thus, reduction being directly proportional to the intensity and frequency of defoliation. This study aimed to evaluate non-structural carbohydrate content on Marandu-grass pasture managed under three grazing management heights. The heights of 15, 25 and 35 cm were managed by beef steers grazing under continuous stocking. Evaluations of non-structural carbohydrates occurred from January to November, 2011, at the UNESP, Jaboticabal, SP. Data were analyzed by repeated measurements with grazing intensity, period and interaction as sources of variation in variance analysis using proc mixed from SAS. Root and shoot samples were collected monthly with a steel cylinder of 15 cm diameter and 13.7 cm high. The collected samples were washed and processed for further analysis. The non-structural carbohydrates content in shoots was not affected ($P > 0.05$) by grazing heights, season and interaction grazing height and seasons of the year. In roots, the contents were affected by the seasons and the interaction heights and seasons of the year. Concentrations in roots were lower in summer compared to other seasons evaluated. There was linear fit ($P < 0.05$) of grazing heights only in the autumn. Non-structural carbohydrates showed a linear response ($P < 0.05$) and the highest average values observed for the levels of non-structural carbohydrates in the roots occurred in winter (158.61 g.kg^{-1}), followed by those for autumn (114.13 g.kg^{-1}), spring (101.00 g.kg^{-1}), and finally the lowest place in the summer (47.30 g.kg^{-1}). The decrease of values from winter to spring and summer was probably due to the improvement of weather conditions over the spring and summer months, which should have provided higher dry matter accumulation, which, in turn, demanded more organic reserves supply in order to have formed new tissue. Climatic changes conditions, defined by the seasons, provide changes in the levels of non -structural carbohydrates. Marandu-grass pastures grazed to 15 cm did not show a drastic condition management since it does not affect the reserve compounds from plants, when compared with the other hights studied.

Key Words: reserve compound, roots, shoots.

1117 (W104) Production and quality of alfalfa harvested on different stages of maturity in summer and fall. C. Arzola-Alvarez*[1], R. Copado-Garcia[2], O. Ruiz-Barrera[1], C. Rodriguez-Muela[1], A. Corral-Luna[1], A. Castañeda-Correa[1], H. M. Gaytan-Torres[1], and D. Diaz-Plascencia[1], *[1]Universidad Autónoma de Chihuahua, México, [2]Universidad Autonoma de Nuevo Leon, Monterrey, México.*

Alfalfa is a very important forage for the dairy industry. The objective of this study was to determine the effect of maturity on quality of hay of two varieties of alfalfa ("Cuff-101" and "Excellent Multileaf") in two seasons (summer and fall). The production (t/ha) and quality of forage was characterized through the determination of leaf:stem ratio of biomass and its content of dry matter (DM), crude protein (CP), neutral detergent fiber (NDF), acid detergent fiber (ADF) and lignin over a range of days to harvest (0, 5, 10, 15, and 20 d following Stage 2) within the two seasons. Data were analyzed as a split-plot experiment, the plots arranged factorially in a randomized complete block design, being the alfalfa varieties and season the main effects, and maturity the subplot term. Results indicated season influenced both production and forage quality, so in fall the production of DM was lower ($P < 0.05$). On d 20 in summer a yield of 5.8 t MS/ha was determined and in fall only

4.9 t MS/ha, without differences among varieties ($P > 0.05$). Dry matter crude protein (CP) content of leaves in fall was 35.0% on d 0, and in summer 29.3% ($P < 0.01$). In summer, CP content of leaves was 32.7% and 29.3% in the whole plant, without differences among them ($P > 0.05$), whereas the content of CP on stem was lower than both (22.6%, $P < 0.01$). On d 20 in summer the leaves had 25.4% CP, stems 20.2% and whole plant 23.7% in Excellent Multileaf, compared to 23.5%, 19.1% and 21.6% CP in Cuff-101, respectively, without those differences among varieties being significant ($P > 0.05$). On d 20 it was determined 23.7% CP in fall, whereas in summer 21.6% ($P < 0.01$). NDF and ADF diminished ($P < 0.01$) in fall. In terms of CP, ADF and NDF in leaves, stem and whole plant, it was concluded that a higher quality alfalfa was growth in fall, without differences among varieties.

Key Words: alfalfa, CP, fiber

1118 (W105) Effect of cultivars and planting dates on bioenergy feedstock characteristics of switchgrass (*Panicumvirgatum*) in South Korea.

B. Kim[*1], M. M. Sargolzehi[2], B. Lee[1], D. Ji[1], J. Peng[1], J. Nejad[1], S. Kang[3], D. H. Min[4], and K. Sung[1], *[1]Dep. of Animal Life System, College of Animal Life Science, Kangwon National University, Chuncheon, South Korea, [2]Dep. of Animal Science, College of Agriculture, Ferdowsi University of Mashhad, Mashhad, Iran, [3]Planning and Coordination Division, National Institute of Animal Science, Suwon, South Korea, [4]Dep. of Agronomy, College of Agriculture, Kansas State University, Manhattan.*

The objective of this study was to determine the best performing switchgrass (*Panicum virgatum*) cultivar under three different planting dates as a bioenergy feedstock source in South Korea. Height, yield, energy content and chemical composition of three switchgrass cultivars, Carthage (CT), Cave-in-Rock (CIR) and Forestburg (FB) were measured from 2009 to 2012. Plots were seeded on April 23, May 4, and May 13, 2009 and were harvested once in November each year. The experimental design applied was randomized complete block (RCBD) in factorial arrangement with three replications. Planting date at three levels and cultivars at three levels were used as experimental treatments. Samples were analyzed for dry matter (DM), crude protein (CP), neutral detergent fiber (NDF), acid detergent fiber (ADF), crude fiber (CF), ether extract (EE), ash and total digestible nutrients (TDN). Planting dates did not significantly affect characteristics of CT, CIR and FB cultivars ($P > 0.05$). The NDF value of CT, CIR and FB were 81.19, 81.40 and 80.81% (DM basis), respectively ($P = 0.9318$). Also the ADF value was 45.24, 45.99 and 48.99% (DM basis; $P = 0.3558$) for CT, CIR and FB, respectively. Total dry biomass yields of CT, CIR and FB were 16.85, 15.90 and 4.50 ton/ha/year, respectively ($P < 0.0001$). Significant difference was also observed for height among CT, CIR and FB (177.59, 169.98 and 94.89 cm, respectively; $P = 0.0002$). There were no significant differences in energy content ($P = 0.96$) and chemical composition among varieties ($P > 0.05$). It appears that Carthage and Cave-in Rock are better adapted to South Korea climatic conditions than Forestburg as a biomass feedstock source.

Key Words: South Korea, bioenergy feedstock, cultivar, planting date

1119 (W106) Morphological composition of Piata palisade grass tillers subjected to strategies of intermittent defoliation.

G. O. Rocha[1], F. H. M. Chizzotti[*1], D. M. Fonseca[1], D. N. Junior[1], M. E. R. Santos[2], and B. M. Pereira[1], *[1]Universidade Federal de Viçosa, Brazil, [2]Universidade Federal de Uberlandia, Uberlandia, Brazil.*

It was aimed to evaluate the morphological composition of tillers of Piata palisade grass (*Brachiaria brizantha* cv. Piata) under different combinations of defoliation frequency and severity. The trial was carried out in Vicosa - MG, Brazil, from December 2012 to March 2013. The treatments consisted to combinations of two post-cutting heights (15 and 20 cm) and two pre-cutting frequencies (95% and 100% light interception, LI_{95} and LI_{100}) and were allocated to experimental units (14 m^2) with three replications according to a 2x2 factorial arrangement in a randomized complete block design. Canopy light interception was measured using a canopy analyser LAI 2000 and sward height using a sward stick. The following variables were evaluated: the number of live and dead leaves per tiller, the length of leaf blades and the length of stem. Data were analysed using the mixed procedure of SAS. The number of live leaves was not affected by management strategies ($P > 0.10$), staying on average 4.5 live leaves per tiller. However, the number of dead leaves per tiller was lower ($P < 0.10$) for swards managed with the LI_{95} than those managed with the LI_{100} (1.25 and 1.79, respectively). Additionaly, swards managed with the LI_{95} had lower ($P < 0.10$) stem length (19.15 cm) than those managed with the LI_{100} (27.76 cm). The length of leaf blade also was lower ($P < 0.10$) with LI_{95} strategies than with LI_{100} (18.04 and 27.43 cm, respectively). There were no effects ($P > 0.10$) of two post-cutting heights (15 and 20 cm) on all variables evaluated. The Piata palisade grass managed with the LI_{95} target had lower number of dead leaves and shorter length of stems and leaves, which corresponds to more favorable sward structure to intake by grazing animals. *Funded by Fapemig.*

Key Words: management, pasture, tropical grass

1120 (W107) Chemical composition and in situ dry matter degradability of tropical forages grasses in Northeastern Brazil. S. S. C. Sanches, R. C. Rodrigues, M. O. M. Parente*, I. G. R. Araújo, C. M. S. Galvão, A. L. Silva Júnior, S. Figueredo, R. A. Araújo, I. Rodrigues, and S. S. Mendes, *Universidade Federal do Maranhão, Chapadinha, Brazil.*

Brazil has an area of more than 220 million ha of pasture, and at least 100 million ha are cultivated pastures. Thus, tropical grasslands represent an important resource for the Brazilian cattle industry. The chemical composition and ruminal in situ dry matter (DM) degradability of nine tropical forages grasses in Baixo Parnaíba, Maranhão were evaluated. The forages were harvested at 35 d of growth and the cutting height was 15 cm of soil. One Santa Inês male sheep (BW 63 kg) cannulated in the rumen was used for feed incubation. Samples of 5 grams of each forage were incubated in the rumen in nylon bags. For each time of incubation four bags were used. The experiment followed a completely randomized design in a 3x9 factorial arrangement (three times of incubation – 6, 24 and 96 h and nine species — *Brachiaria humidicola, Brachiaria* hybrid cv. Mulato, *Brachiaria brizantha* cvv. Piatã, Xaraés and Marandu, *Brachiaria ruziziensis*, *Brachiaria decumbens, Panicum maximum* cv. Massai and *Andropogon gayanus*). The *P. maximum* cv. Massai grass presented higher ($P < 0.05$) protein content (7.4%) than *B. humidicola* and *A. gayanus* (3.3 and 3.6, respectively), whereas the NFD, AFD, cellulose and lignin contents didn't differ among grasses. The content of hemicellulose was lower in *P. maximum* cv. Massai, *B. decumbens*, and *A. gayanus* grasses. Higher values of DM disappearance of tropical grasses were found in 96 hours (mean value 36.16, 55.52 and 80.20% for 6, 24 and 96 h, respectively). *B. decumbens* had higher values of effective digestibility (ED) in three passage rates (PR): 67.7, 57.1 and 51.3% in PR of 2, 5 and 8%, respectively. *B. humidicula* and *P. maximum* cv. Massai grasses had the lowest potential degradability, 78.9% and 77.6%, respectively. The nonlinear model was adjusted satisfactorily to data from DM. The coefficients of determination (R^2) obtained for the curves of degradability in both for age degradability were greater than 93%.

Key Words: *Andropogon gayanus*, *Brachiaria* spp., *Panicum maximum*

1121 (W108) Influence of phenological stage on fresh forage, hay and silage on nutritional value of tall wheatgrass. M. Menghini[1,2], H. M. Arelovich*[1,2,3], M. F. Martínez[1], and R. D. Bravo[1], *[1]Dto. Agronomía, Universidad Nacional del Sur, Bahía Blanca, Argentina, [2]CIC, Bahía Blanca, Argentina, [3]CERZOS, Bahía Blanca, Argentina.*

The objective was to compare the nutritional value of two methods of forage conservation and fresh forage (type of forage=TF) of tall wheatgrass (*Thinopyrum ponticum*) in 5 different phenological stages (PhS). The experimental units were 5 m^2 plots randomly distributed upon a uniform stand of tall wheatgrass in a complete randomized design ($n = 3$). Clipping dates were 113, 142, 163, 190 and 211 d after regrowth related to the stages vegetative (V), booting (B), anthesis (A), milk (M) and dough-grain (D) respectively, on standing fresh pasture (P), hay (H) and silage (S). Clipping was mechanical at 10 cm height and dry matter yield (DMY) was measured. Subsamples from each experimental unit were used for: (1) DM determination of P, (2) preparation of H by drying sheltered at environmental temperature (72 h), and (3) preparation of S in PVC cylinders with 2 kg fresh forage carrying capacity (60 d). All materials were analyzed for NDF, ADF, ADL, soluble non structural carbohydrates (SNSC), IVDMD and CP. Data was analyzed by ANOVA and means compared by Tukey ($\alpha = 0.05$). Results are reported in Table 1121. A significant interaction TF x PhS was found for all variables with the exception of CP and ADL. Only A could be an adequate alternative for S. However, at B, A, M and D the H conservation method would preserve an appropriate nutritive value as well.

Key Words: forage conservation, nutritional value, *Thynopirum ponticum*

1122 (W109) Spatio-temporal evaluation of the nutritive value of *Croton cortesianus* and *Leucophyllum frutescens* through in vitro fermentation kinetics.

A. MS.[1], G. C. M.*[*1], G. R. H.[2], D. G. TG.[1], and J. R. A[1], *[1]Universidad Juárez del Estado de Durango, Durango, México, [2]Universidad Autónoma de Nuevo León, Linares, Nuevo León, México.*

The aim of the study was to evaluate, seasonally, two native shrubs which are commonly selected by white-tailed deer in a semiarid and subtropical area of Northeastern México. Foliage from *Croton cortesianus* and *Leucophyllum frutescens* was sampled from Summer 2004 to Spring 2005 in two country sites: China and Linares in the state of Nuevo Leon, México. In vitro gas production was recorded at 3, 6, 9, 12, 24, 48, 72 and 96h. Kinetic parameters such as the asymptotic gas production (B), rate of gas production (*k*) and lag phase (L) were estimated by the exponential model $G = b \times (1 - e^{-k(t-L)})$. Microbial protein synthesis, ME content and in vitro organic matter digestibility (IVOMD) were also evaluated. Data were analyzed according to a completely randomized design with factorial arrangement. The factors were sampling sites, shrub species and seasons. Kinetic parameters significantly varied among shrubs, sites and seasons ($P < 0.001$). The asymptotic gas production (B) ranged from 127 ml of gas/g DM in *C. cortesianus* in summer 2004 in China country to 237 ml of gas/g DM in *C. cortesianus* in spring 2005 in Linares country. The rate of gas production (*k*) was the lowest ($P < 0.05$) in *C. cortesianus* in summer 2004 (0.035%/h) while the highest (0.144%/h) was collected in autumn 2004 in Linares. Values regarding L ranged from 0.05 to 2.89 h, and were superior ($P < 0.05$) in *C. cortesianus* during autumn 2004 in Linares country. Interactions sites x shrub species x seasons were significant ($P < 0.001$) for all kinetic parameters. Microbial protein synthesis measured as purines varied significantly among shrubs and seasons. Mean values ranged from 1.51 to 11.36 µmol, and were lowest ($P < 0.05$) in *C. cortesianus* in spring 2005 in Linares and highest in *L. frutescens* in autumn 2004 in China. The ME content varied from 0.36 to 2.71 Mcal/kg DM ($P < 0.05$). Estimates of IVOMD ranged from 46.4 to 89.7%. *C. cortesianus* had the greatest IVOMD values in summer 2004 in China ($P < 0.05$). Data suggested that although spatio-temporal fluctuations, variables such as the constant rate of gas production, which might indicate nutrient availability for rumen microorganisms (overall mean = 0.079%/h), digestibility (overall mean = 70.2%) and microbial protein synthesis (overall mean = 7.2 µmol) support the nutritive potential of *C. cortesianus* and *L. frutescens* for white-tailed deer in marginal semiarid regions of northeastern México.

Key Words: gas production, native shrubs, semiarid regions

1123 (W110) Reduction of enteric methane emission by using tannin supplementation in grazing goats.

A. C. Ruggieri[*], N. C. Meister, F. O. Alari, V. C. Silva, N. L. Santos, and E. B. Malheiros*, Sao Paulo State University, Jaboticabal, Brazil.*

This study aimed providing condensed tannin (*Schinopsis quebracho*) to reduce methane (CH_4) emission and if it keeps through time. Twelve Anglo Nubian breed goats were used with an average 56 kg of body weight (BW) in Tanzaniagrass (*Panicum maximum*) pasture with access to water and mineral salt managed under intermittent stocking with 11 hours of grazing period during 5 d. The treatments were: control (without tannin-WT) and addition of tannin (AT). Condensed tannin contained 70% (± 2) as guarantee level in powder form was fed (at 6:00 PM) once a day individually for each animal orally 0.31 g per kg of metabolic BW ($BW^{0.75}$). Tannin was provided for 91 d with three collections of methane with intervals of 30 days and period of feces collection to estimate dry matter (DM) intake. CH_4 emission was estimate by technique tracer gas SF_6 (sulfur hexafluoride). Variables for CH_4 emission were analyzed by SAS software in a completely randomized design with two treatments in a split plot in time with two longitudinal factors (5 d and 3 periods) and 6 replications (animals). F-test ($\alpha = 5\%$) was used for comparisons between treatments and orthogonal polynomial contrast for days and grazing cycles. There was no difference ($P > 0.05$) between treatments for g CH_4 emission per animal (21.88 ± 0.8 and 20.52 ± 0.8); kg DM intake (43.07 ± 2.1 and 42.73 ± 2.0) and percentage of loss of gross energy intake (14.65 ± 0.7 and 14.54 ± 0.7) respectively for WT and AT. The higher DM intake was observed ($P < 0.05$) in WT (562 ± 9.2 g / day) treatment compared to AT (510 ± 8.7 g / day). CH_4 emission calculated in relation to $BW^{0.75}$ resulted in larger ($P < 0.05$) amount in WT (1.13 ± 0.04) than AT (0.96 ± 0.4) group. There was not observed ($P > 0.05$) reducing CH_4 emission per animal through time per CH_4/animal (20.66 g ± 0.8, 1.0 ± 22.51 g and 20.42 g ± 1.2) and per $BW^{0.75}$ (1.03 ± 0.04, 07 ± 0.04 and 1.04 ± 0.06) respectively for the period 1, 2 and 3. The similarity in CH_4 production through time is probably due to the amount of tannin provided staying below the required limits for gas reduction and affecting only the fiber digestibility which caused decrease DM intake but no effect on CH_4emission and consequently through time.

Key Words: CH_4; gas emission reduction; tropical pasture

1124 (W111) Nutritive value of buffelgrass-based diets supplemented with dried distillers grains with solubles and dried citrus pulp. N. C. Vásquez Aguilar*[1], H. Bernal Barragán[1,2], R. G. Ramírez Lozano[1], M. Cerrillo Soto[2,3], M. V. Gómez Meza[1], E. Gutiérrez Ornelas[1,2], and M. Guerrero Cervantes[2,3], *[1]Universidad Autónoma de Nuevo León, San Nicolás de los Garza, México, [2]Red Internacional de Nutrición y Alimentación en Rumiantes, Durango, México, [3]Universidad Juárez del Estado de Durango, México.*

The objective of the study was to evaluate the effect of supplementing small amounts of dried distillers grains with solubles (DDGS) or dried citrus pulp (DCP) upon the nutritive value of buffelgrass (*Cenchrus ciliaris* L)-based diets. Twelve experimental diets were formulated using three qualities of buffelgrass: low (3.0% CP, 70% NDF), medium (5.6% CP, 66.5% NDF) and high quality (12.4% CP, 60.8% NDF) and four levels of supplementation (0%, 10% DCP, 10% 50DCP:50DDGS, and 10% DDGS). Utilized DCP and DDGS contained 3.8% and 30.6% CP, respectively. Sample contents of ash, crude protein (CP, Leco), neutral detergent fiber (NDF), hemicellulose, cellulose, lignin, and ether extract (EE) were determined. The in vitro dry matter digestibility (IVDMD; Daisy^{II}, ANKOM), and in vitro gas production (GP) at 0, 3, 6, 9, 12, 24, 48, 72 and 96 h were measured, and fermentation parameters *a*, *b*, and *c* were calculated. Metabolizable energy (ME) content was calculated from the gas production, protein and ether extract content. Each treatment was replicated four times, and results were evaluated according to a 3 x 4 factorial arrangement of treatments, using SPSS software. There were no significant ($P > 0.05$) grass quality x supplement interactions. Ash and protein contents were respectively 30% and 70% less for low- than for high-quality buffelgrass-based diets. Diets made up of high quality buffelgrass had 14% less NDF content, 7% lower hemicellulose, 19% less cellulose and 29% lower lignin content than diets based on low quality buffelgrass (68.1% NDF, 30.9% hemicellulose, 32.5% cellulose, and 4.7% lignin, DM basis). IVDMD was 81.8% for high quality-, and 67.2% for low quality-buffelgrass-based diets, and inversely correlated (r:-0.832; $P < 0.001$) with NDF content. ME content of diets was 26% higher ($P < 0.05$) in high quality-, than in the low quality-grass based diets (1424 Kcal ME/ kg DM). Addition of DDGS increased ($P < 0.05$) 28% the ether extract and 34% the protein content of buffelgrass. Addition of DCP and DDGS to the diet increased in average 5.5% ($P < 0.05$) the IVDMD of non-supplemented buffelgrass (72.5%). In vitro fermentation parameters *a*, *b*, and *c* were neither affected by grass quality nor by type of supplement ($P > 0.05$). In conclusion, quality of buffelgrass determined the nutritive value of diets; supplementing DDGS increased protein and fat content and DCP improved IVDMD.

Key Words: buffelgrass, dried citrus pulp, dried distillers grains with solubles

1125 (W112) Lignin concentration and its correlation with degradability of tropical grasses. A. Vargas Velásquez*, *Universidade de São Paulo, Pirassununga, Brazil*

Lignin inhibits the degradation of structural carbohydrates in the plant cell wall, thus, a precise and accurate method to determine lignin concentration is desirable. The spectroscopic acetyl bromide lignin (ABL) method has recently been receiving more attention by researchers and in this study it was compared to ADL, KL and permanganate lignin (PL). Five species of grasses, *Brachiaria brizantha* cv. Marandú*, Brachiaria brizantha* cv. Xaraés*, Panicum maximum* cv. Mombaça*, Pennisetum purpureum* cv. Cameroon and *Pennisetum purpureum* cv. Napier, harvested at seven maturity stages were used. Three fibrous preparations: NDF, ADF and cell wall (CW) were used to determine lignin concentrations. Protein (N x 6.25) and ash content were determined in the NDF and CW residues. A completely randomized experimental design with duplicate analysis for the lignin assays was used. A randomized block design was used for the in vitro experiment, with rumen fluid blocked by week. Individual treatments were compared by Tukey´s test ($P < 0.05$). Correlation coefficients between lignin methods and in vitro digestibility values were obtained using PROC CORR from SAS. The mean CW values were higher ($P < 0.05$) than NDF values, 768.1 g/kg versus 713 g/kg, reflecting solubilization of pectin and other neutral detergent soluble cell wall oligosaccharides. The ADL method yielded the lowest mean values ($P < 0.05$) of all methods, 95 g/kg versus 107.6, 116.2 and 199.1 g/kg for KL, PerL and ABL, respectively, which may indicate partial lignin solubilization by the acid detergent solution and/or by the 72% sulfuric acid solution. Results obtained by PerL were higher ($P < 0.05$) than those of ADL, possibly due to hemicellulose and pectin oxidation by potassium permanganate. The values for KL were higher ($P < 0.05$) than those of ADL, possibly due to protein contamination. The highest concentrations were obtained by the ABL method. In vitro dry matter degradability showed high negative correlation with lignin content, -0.8505, -0.9130 and -0.8883 when determined by ADL, PerL and ABL, respectively. A proposed correction factor (2.23) applied to the ADL values resulted in a degradability curve similar to the ABL curve. It is interesting to note that this value of 2.23 is very close to the 2.4 value used in the Cornell Net Carbohydrate and Protein System equations $B_2$and C, to estimate carbohydrate fractions, when adjusting lignin content. The ABL method is an easy, fast and convenient method to determine lignin content in forages.

Key Words: lignin, ABL, digestibility

1126 (W113) Chemical characterization and in vitro fermentation activity of tropical legumes.

I. Scull-Rodriguez[1,2], M. A. Cerrillo Soto[*2,3], O. Olao[1,2], M. Guerrero-Cervantes[2,3], A. Juárez-Reyes[2,3], and R. Herrera-Garcia[1,2], *[1]Instituto de Ciencia Animal, San José de las Lajas, Cuba, [2]Red Internacional de Nutrición y Alimentación en Rumiantes, Durango, México, [3]Universidad Juárez del Estado de Durango, México.*

Leguminous species are relevant as feed resources for grazing ruminants in a diversity of agro-ecosystems. Foliage from *Albizio lebecoide, Ormosia panamensis, Centrosema pubescen, C. pubescen* cv Bani*, Pongania pinnata and Albizia lebbeck* from the oriental region of Cuba was chemically characterized and the in vitro fermentation activity evaluated. Plots from various locations at the Rio Cauto's Valley were demarcated and fifteen plants at a vegetative stage were randomly selected. Small leaves and twigs were collected simulating animal grazing. Samples were composite, dried and milled. Chemical composition, in vitro dry matter digestibility (IVDMD), total polyphenols and antioxidative activity using 1,2-diphenyl-2-picrylhydrazyl (DPPH) were determined. Glass syringes were used and gas production recorded at 0, 3, 6, 9, 12, 24, 48, 72 and 96h after incubation initiated. Inoculum from three rumen fistulated sheep fed alfalfa hay and comercial concentrate (70:30) was utilized. Kinetic parameters such as the asymptotic gas production (*b*) and the rate of gas production (*k*) were obtained by the exponential model $G = b \times (1 - e^{-k(t-L)})$. Data related to kinetic parameters *b* and *k,* chemical composition, total polyphenols and antioxidative activity were analyzed according to ANOVA for a completely randomized design. Significant variation ($P < 0.05$) was registered among legume species in all the studied variables. Except for *O. panamensis*, all species had a CP content greater than 15% ($P < 0.05$). Values related to NDF ranged from 51.1% in *O. panamensis* to 59.1% in *C. pubescens* cv bani. Intermediate values were obtained in *P. pinnata* ($P < 0.05$). In vitro dry matter digestibility varied ($P < 0.05$) from 37.3% in *A. lebbek* to 61.5% in *C. pubescens* cv bani. *Centrosema* species exhibited the greatest asymptotic gas production ($P < 0.05$; mean values for *Centrosema*= 182 ml gas/ g DM). Rate of gas production (*k*) ranged from 0.0154% h^{-1} to 0.0549% h^{-1}. *Centrosema* species had superior *k* values as well ($P < 0.05$). Total polyphenols ranged from 1.62% in *A. lebbeck* to 0.29% in both *Centrosema* species ($P < 0.05$). Accordingly, antioxidative activity (overall mean = 92.7%) was greatest in those species containing superior levels of total polyphenols ($P < 0.05$). Among species, *Centrosema* species were of reasonably good quality (CP, 17.7%, IVDMD, 61.5%, DM basis). Moreover, the greatest values regarding the extent (*b*) and rate (*k*) of gas production observed in such species which indicate better nutrient availability for rumen microorganisms, might support their potential in marginal tropical and subtropical regions.

Key Words: legumes, in vitro gas production, chemical composition

1127 (W114) Modeling dry matter production in *Panicum maximum* grasses.

V. L. N. Brandao[1], M. I. Marcondes[2], F. H. M. Chizzotti[*2], and H. Bandeira[2], *[1]Universidade Federal de Viçosa, Minas Gerais, Brazil, [2]Federal University of Viçosa, Brazil.*

The achievement of DM production models for tropical grasses is almost absent in literature, despite the importance for livestock production, especially when considering climate chances, and it has effects on rain and temperature distribution. Models could be used as tools to adjust stocking rate and strategic planning for pasture during the year. The *Panicum maximum* grasses have high DM production (DMP), 30 ton of DM/ha.year on average, and that's why their use is becoming more common in tropical countries. The objective was to determinate a DMP model, using three cultivars of *Panicum maximum* (Mombaça, Colonião and Sempre-verde), and weather variables.A database was used ($N = 180$) based on pre-defoliation criteria as 95% of light interception, and 50% of height residue. Data were collected between December of 2012 and January of 2014. The variables minimum temperature (ºC, MIN), MIN^2, average temperature, maximum temperature, insolation (hours of light/d), precipitation (PCT, mm/d) and fertilizer (FTZ, kg of nitrogen/d) were tested by Stepwise procedure ($P < 0.010$) to determinate the variables that better determinate DMP. Afterwards, the effect of cultivars on selected variables were also tested. The variables MIN^2, FTZ and PCT were chosen by the procedure Stepwise, and they were affected by the cultivars ($P < 0.040$). The intercept was also affected by cultivar ($P = 0.042$). The adjusted equations are: $DMP_{Mombaça}$ (kg/d) = -92.88 + 0.56×MIN^2 + 10.55×FTZ + 3.52×PCT ($r^2 = 0.73$, MSE = 1198, AIC = 566); $DMP_{colonião}$ (kg/d) = -35.44 + 0.42×MIN^2 + 15.67×FTZ + 0.27×PCT ($r^2 = 0.51$, MSE = 1809, AIC = 570); $DMP_{sempre\text{-}verde}$ (kg/d) = -69.33 + 0.46×MIN^2 + 7.03×FTZ + 4.21×PCT (r^2= 0.63, MSE = 1562, AIC = 694). Colonião was the cultivar most responsible to fertilizer, less sensitive to temperature and had the greater DMP, whereas Sempre-verde was the most responsive to precipitation, which shows that their production is more distributed throughout the year in tropical countries. Finally, Mombaça was the most responsive to temperature, with a production strongly affected by weather condition. Nevertheless, despite Colonião having greatest DMP, data from literature shows that it has a small leaf/steam relationship. This variation on morphological components affects their nutritive value, and that's why it's important to develop models capable of stratifying their components for purpose of complementing DMP models. In conclusion, this model is capable to predicting DMP and it is strongly affected by cultivar.

Key Words: Colonião, Mombaça, Sempre-verde

1128 (W115) Productive performance of *Atriplex canescens* forage for 30 years of exclusion and grazing in different seasons of the year in the north of México. E. Suarez*, *UAAAN, Saltillo, México.*

The shortage of forage in rangeland of northern México is becoming more serious every year. Using some shrubs such as saltbush [*Atriplex canescens* (Pursh) Nutt.], can be a feeding strategy because of its high nutritional value. Additionally, its utilization improves ecosystems. Therefore, the use of shrubs improves the productivity of rangelands. The objective of this study was to determine whether the exclusion and/or livestock grazing affect dry matter production of saltbush scrub parvifolio in northern México. Production of dry matter in kg/ha during the four seasons (2012 to 2013) (free-range grazing vs. exclusion) was determined. The plots are distributed in two sites. To collect forage samples quadrant method was used. The data were analyzed using PROC GLM of SAS. The results were a highly significant difference ($P < 0.0001$) was found between the grazing exclusion treatment and the free grazing treatment during every season of the year, for the grazing exclusion site (spring, summer, fall and winter), means of (97.5, 355, 262.5, 95 kg MS/ha, respectively) were found and for the grazing site (65, 274, 144.5, 52.5 kg MS/ha, respectively). Also, a highly meaningful difference between both grazing exclusion and free grazing treatments of ($P < 0.0022$) was found, whose means are (202.5 and 134 kg MS/ha, respectively). With the above we conclude that the shrubs that remained in grazing exclusion can improve the productivity of rangelands and solve the shortage of fodder in times of crisis. On the other hand, where there had been free grazing, the implementation of management strategies to reduce the negative effects of over-consumption of this shrub by livestock is fundamental.

Key Words: forage, chamizo, fourwing saltbush, grazing, exclusion

GRADUATE STUDENT COMPETITION: ADSA DAIRY FOODS DIVISION POSTER COMPETITION

1129 (M112) The effect of native phospholipids on the flavor and flavor stability of bleached cheddar whey. C. Park*, and M. Drake, *Southeast Dairy Foods Research Center, NCSU, Raleigh, NC.*

Off-flavors due to processing of whey protein ingredients negatively influence consumer acceptance of ingredient applications. Previous research has demonstrated that bleaching of Cheddar whey increases lipid oxidation and off-flavors in liquid whey and resulting whey protein ingredients. Due to the high content of unsaturated fatty acids, native phospholipids have a high potential for lipid oxidation. The phospholipid to neutral lipid content ratio in fat free milk is reported to be significantly higher than in whole milk. The objective of this study was to determine the impact that native phospholipids in Cheddar whey have on the flavor and flavor stability of liquid whey. Liquid Cheddar whey was produced from whole milk, reduced fat milk, and fat free milk. The wheys were then fat separated to the same total fat content, pasteurized, bleached (250 ppm hydrogen peroxide) and stored at 4°C for up to 48 h. The wheys were sampled at 0 h, 24 h, and 48 h. The entire experiment was replicated 3 times. Flavor was analyzed by sensory and instrumental analyses. Phospholipids were quantified by UHPLC with an evaporative light scattering detector using hydrophilic interaction chromatography. Fatty acid profiles of the neutral and polar lipids were analyzed by FAME using GC-FID. All wheys increased in the lipid oxidation compounds pentanal, hexanal, heptanal, and nonanal and cardboard flavor from 0 h to 48 h ($P < 0.05$). Liquid whey produced from fat free milk had higher concentrations of hexanal, pentanal, heptanal, and DMTS as well as increased cardboard flavor intensity after 24 or 48 h compared to other wheys ($P < 0.05$). Phospholipids were significantly higher in the whey made from fat free milk compared to wheys made from whole or reduced fat milk ($P < 0.05$). The polar lipid fraction contained higher concentrations of the unsaturated fatty acids 18:1, 18:2, 18:3, and 20:4 and lower concentrations of saturated fatty acids compared to the neutral lipid fraction. These results identify native phospholipids as a major source of off-flavors in liquid whey due to their unsaturated fatty acid profile and susceptibility to lipid oxidation.

Key Words: whey, phospholipids, flavor

1130 (M113) The effect of norbixin destruction or removal on flavor and functionality of 80% whey protein concentrate. Y. Qiu*, T. Smith, A. Foegeding, and M. Drake, *Southeast Dairy Foods Research Center, NCSU, Raleigh, NC.*

The residual annatto colorant (norbixin) in fluid cheddar cheese whey is bleached to provide a neutral-colored final product. Currently, chemical and enzymatic applications are utilized for bleaching liquid whey. These approaches bleach by free radical formation and can cause off-flavors due to lipid oxidation and protein degradation. The objective of this study was to compare three bleaching/norbixin removal methods: hydrogen peroxide (HP), lactoperoxidase (LP), and microfiltration (MF), and their effects on the flavor and functionality of 80% whey protein concentrate (WPC80). Cheddar cheese whey was manufactured from colored, pasteurized milk. The fluid whey was pasteurized and fat separated. Whey was subjected to 1 of 4 different treatments: Control (no bleaching; 50°C, 1h), HP (250 mg hydrogen peroxide/kg; 50°C, 1h), LP (20 mg hydrogen peroxide/kg; 50°C, 1h), or MF (microfiltration; 50°C, 1h). The treated whey was then ultrafiltered, diafiltered, and spray-dried to 80% whey protein concentrate (WPC80). The entire experiment was replicated three times. Proximate analysis, color, functionality, descriptive sensory and instrumental volatile analysis were conducted on WPC80. Norbixin was decreased by 50, 46 and 95% for MF, HP, and LP bleached WPC80 treatments, respectively ($P < 0.05$). The HP and LP WPC80 had higher cardboard flavor and distinct cabbage flavor compared with the unbleached and MF WPC80. Volatile compound results were consistent with sensory results. The HP and LP WPC80 were higher in lipid oxidation compounds (especially heptanal, hexanal, pentanal, 1-hexen-3-one, 2-pentylfuran, octanal) compared to unbleached and MF WPC80. Protein solubility of WPC80 at various pH values was not different ($P > 0.05$). All WPC80 had > 85% solubility at the pH range evaluated. Gelation under all conditions showed similar trends in small strain viscoelastic properties ($P > 0.05$). Based on bleaching efficacy, flavor and functionality results, MF may be a viable alternative to chemical or enzymatic bleaching of fluid whey.

Key Words: whey bleaching, functionality, flavor

1131 (M114) Storage and temperature effects on the solubility, Maillard browning, and sensory characteristics of milk protein concentrates. T. Smith*, R. Campbell, and M. Drake, *Southeast Dairy Foods Research Center, NCSU, Raleigh, NC.*

Milk protein concentrates (MPC) are a relatively young, increasingly important category of dairy ingredients. MPC production in the US increased by 38% between 2008 and 2012. MPC are a highly functional protein, however, solubility and a mild flavor across storage are required for success. The ob-

jective of this study was to determine the effect of storage time and temperature on the solubility, sensory characteristics, and Maillard browning of low (45%) and high (80%) protein MPC. MPC45 and 80 were manufactured in triplicate and stored at low (4ºC), medium (25ºC) and high (40ºC) temperatures for 0, 1, 3, 6, and 12 mo. Solubility was evaluated by measurement of turbidity and protein at pH 7 before and after centrifugation. Maillard browning was determined by measuring furosine levels by high performance liquid chromatography (HPLC). Descriptive analysis and gas chromatography-mass spectrometry (GC-MS) were also performed to evaluate sensory and volatile compound characteristics. Solubility of MPC45 was higher than MPC80 ($P < 0.05$), and a significant decrease in solubility in both MPC 45 and 80 occurred over time and as temperature increased ($P < 0.05$). Furosine increased with storage time and temperature, and this change was higher for MPC80 than for MPC45 ($P < 0.05$). MPC45 were characterized by sweet aromatic/milky and cardboard flavors while MPC 80 were characterized by lower sweet aromatic/milky and higher cardboard flavors, as well as distinct tortilla/grapey flavor. Cardboard, tortilla/grapey and animal flavors increased with storage time and temperature ($P < 0.05$). Key volatile flavor compounds in MPC were o,p,m 2-amino-acetophenone (tortilla), 2 2-methyl-butanal (green/fruity), 1-octen-3-one (earthy/mushroom), and methional (potato brothy), and concentrations of these compounds increased with storage time and temperature. An understanding of storage and environmental effects on MPC lays the foundation for optimizing quality.

Key Words: milk protein, flavor, solubility

1132 (M115) The salt, pH and thermotolerance of a novel nonstarter lactic acid bacterium that might be associated with slit defect in ripened cheddar cheese. F. Ortakci[*1], J. R. Broadbent[1], C. J. Oberg[1,2], and D. J. McMahon[3], *[1]Dep. of Nutrition, Dietetics, and Food Sciences, Western Dairy Center, Utah State University, Logan, [2]Dep. of Microbiology, Weber State University, Ogden, UT, [3]Western Dairy Center, Utah State University, Logan.*

An obligate heterofermentative lactic acid bacteria, *Lactobacillus wasatchii* WDC04 (WDC04), isolated from an aged Cheddar cheese, was studied for salt, pH and thermotolerance. We investigated the pH and salt tolerance of WDC04 in MRS+1.5% Ribose (MRS-R) under conditions that mimic Cheddar cheese ripening. In addition, the thermotolerance of WDC04 was tested in 2% milk to estimate its pasteurization tolerance. WDC04 was inoculated in MRS-R at two different pH levels (5.2 or 6.5), each containing 0, 1, 2, 3, 4, or 5% salt-in-moisture (S/M) levels (w/w). Growth was monitored by OD_{600} measurements every 8 h under anaerobic conditions at 23°C for 60 h. After 48 h, an OD_{600} of 2.0 was reached in all media except for 5% S/M at pH 5.2 which had an OD_{600} of 1.75. At pH 6.5, WDC04 growth rates were similar at S/M levels of 0, 1, 2, and 3% after 24 hr. Growth rates for 0, 1, and 2% S/M levels at pH 5.2 after 24 h were also similar, while growth rates at S/M levels of 4, and 5% at either pH were slower. Two different thermotolerance tests were performed. Milks containing ~$7x10^6$ CFU/ml WDC04, was heated at 72°C for 15 s followed by a cooling by placing in a water bath at 31°C (set temperature for cheesemaking) for 2 h. In the second heat treatment, WDC04 inoculated milks were heated at 63°C for 30 min with samples collected at 0, 15 and 30 min intervals followed by incubation at 31°C for 2 h. Samples were plated on MRS-R agar in triplicate. There was a 4-log reduction of WDC04 after the 72°C for 15 s heat treatment with $9.2x10^1$ CFU/ml after cooling to 31°C. However, there were no detectable colonies (<10^2CFU/ml) when heated for 30 min at 63°C. This suggests that WDC04 is maybe sufficiently thermoduric for some cells to survive HTST pasteurization but perhaps not LTLT pasteurization. It also appears that WDC04 is able to grow in the same environment that occurs during Cheddar cheese ripening, high S/M (2.5 to 4.5%) and low pH. The ability to survive pasteurization and grow under cheese ripening conditions allow WDC04 to be considered a NSLAB, placing it in a position to be involved with late gas production and slit defect in ripened Cheddar cheese.

Key Words: nonstarter lactic acid bacteria, salt, pH, and thermotolerance

---

1133 (M116) Role of protein interactions on microstructure and rheological properties of Greek-style yogurt. G. H. Meletharayil[*1], H. A. Patel[2], and S. G. Sutariya[1], *[1]South Dakota State University, Brookings, [2]Dairy Science Dep., South Dakota State University, Brookings.*

Disposal of acid whey is a major concern for the manufactures of Greek-style yogurt (GSY) because of its potential environmental impact. An alternate way of preparing GSY is to eliminate de-wheying step by using functional milk proteins and manipulating process-induced protein interactions. The objective of this study was to investigate the influence of micellar and non-micellar casein to globular proteins ratios on the properties of GSY prepared using this alternate process. GSY (7.5% w/w proteins, 15% w/w total solids) were prepared with either milk protein concentrates (MPC) as a source of micellar casein or carbon-dioxide treated milk protein concentrate (T-MPC) as a source of non-micellar caseins. Whey protein concentrates (WPC) and de-proteinized whey was used to adjust the globular protein and total solids level respectively. The casein to whey ratio was adjusted to 4:1, 2.3:1 and 1.5:1. All samples were pre-adjusted to pH 6.5 before heating at 90°C/10 min. Acid gels were prepared using Glucono-δ-lactone to obtain final pH 4.4 after 4 h of incubation at 30°C. The soluble (serum) phases obtained by centrifugation of heated and unheated milk samples at 25,000g/1h were characterized using sodium dodecyl

sulfate polyacrylamide gel electrophoresis (SDS-PAGE). Microstructure and rheological characterization of acid gels were performed using confocal laser scanning microscopy (CLSM) in the fluorescence mode and small amplitude oscillatory rheology (1% strain, 0.1Hz frequency), respectively. ANOVA was used to test the results and statistical significance at $P < 0.05$ was determined, using the statistical software SAS. SDS-PAGE results indicated significantly higher proportion ($P < 0.05$) of soluble disulfide-linked aggregates in serum phase of heated milks prepared from T-MPC. Gels prepared using T-MPC as a source of non-micellar casein had significantly higher ($P < 0.05$) elastic modulus (G') (e.g., 1.12 x 10^3 Pa) compared to gels prepared using MPC (e.g., 6.59 x 10^2 Pa). Acid gels containing T-MPC in different ratios with globular proteins had a significantly higher ($P < 0.05$) G' than acid gels prepared with MPC and WPC. CLSM images revealed that T-MPC gels had smaller, well-connected aggregates with uniform, homogenous pore sizes, which strongly supported the results of rheological characterization. It can be concluded that T-MPC as a source of non-micellar casein is an ideal ingredient to alter the ratio of non-micellar to globular protein ratio and thereby increase the gel strength of Greek-style yogurts. This invention is patent pending and can be used to produce protein structures having different gels strengths suitable for commercial applications.

Key Words: Greek-style yogurt, carbon dioxide, rheology

1134 (M117) Assessment of consumer perceptions and preferences regarding fluid milk at the beginning and end of printed code date. M. E. Paterson*, *Iowa State University, Ame.s*

The objective of this study is to understand consumers' expectations and actual sensory perceptions about fluid milk at the beginning and end of code. Eleven sessions were carried out ($n = 103$). Sessions began with explanation of consent form and the experiment process, then panelists filled out a survey about demographics and milk purchasing and consumption behaviors. Consumers were blindly served two pairs of milk samples (2% within 2 to 3 days of production (fresh) and 2% with 2 to 3 days to end of code (end); skim (fresh and end) and asked to indicate preference and the level of acceptability for each sample using a seven-point scale. All samples tasted by consumers were simultaneously evaluated by a panel of eight judges who were trained to evaluate milk quality attributes on a 15-cm line scale. All milk was from the same source, processed on the same timeline for each session; milk was stored in the warehouse until transport to the sessions. Eighty-five participants (82%) indicated they check for the farthest out code date more than half the time they shop. However, upon tasting, consumers did not have a preference for 2% fresh milk over 2% end, or for skim fresh over skim end ($P > 0.05$). These findings were in agreement with their acceptability scores, which were 4.7 for skim fresh, 4.6 for skim end, 5.1 for 2% fresh and 5.1 for 2% end ($P > 0.05$). Trained panelists did not detect a difference in lacks freshness flavor in skim fresh (1.9 cm) or skim end (1.3 cm). Trained panelists also did not detect a difference in cooked, feed, flat, foreign or oxidized flavors for 2% or skim milk samples. Trained panelists detected a significant difference in lacks freshness flavor of 2% fresh (2.3 cm) and 2% end (0.3 cm) ($P < 0.05$). When the one off-flavored batch of 2% fresh milk was removed from analysis, trained panelists could not distinguish a difference in lacks freshness between 2% fresh (1.0 cm) and 2% end (0.4cm) ($P > 0.05$). After tasting and receiving an educational message about the meaning of code dates, 83% of consumers stated the information would impact their future purchases. These results confirm that although many consumers go out of their way to buy the freshest milk, they cannot distinguish fresh milk from milk at the end of code. Additional research must be conducted to confirm impact of educational messages about code date on purchasing behavior.

Key Words: milk, sensory, code-date

1135 (M118) Performance of cross-linked and calcium-reduced milk protein concentrate ingredients in model high-protein nutrition bars. J. C. Banach*[1], S. Clark[1], L. Metzger[2], and B. P. Lamsal[1], *[1]Iowa State University, Ames, [2]Midwest Dairy Foods Research Center, South Dakota State University, Brookings.*

Milk protein concentrate (MPC) and micellar casein concentrate (MCC) have the potential to be the major protein source in high-protein nutrition bars. However, MPCs are known to produce bars that harden too quickly and also result in a crumbly texture. Less is known about the performance of MCC in bars. The objective of this study was to evaluate the performance of transglutaminase (TGase) cross-linked MPC and MCC, and calcium-reduced MPC in high-protein bars. MPC and MCC retentate were treated with TGase at 0.3 units (low; MPC-L and MCC-L) and 3.0 units (high; MPC-H and MCC-H) per g protein. Controls (MPC-C and MCC-C) were not treated with the enzyme. Separately, CO_2 was injected during MPC ultrafiltration to produce calcium-reduced MPC. Retentates were spray-dried to produce ingredients with 72 to 78% protein. Bars were prepared by hand pressing dough containing 30% protein, 8.9% HFCS, 20.7% glycerol, 11% maltitol syrup, and 17.6% palm oil into molds (ID = 21 mm, H = 13 mm) and water activity sample cups. Model bars were stored at 32°C for up to 42 days, during which texture, color, water activity, moisture content, and pH were evaluated. Bar hardness and fracturability were determined with compression, after which a sieve analysis was used to evaluate crumbliness. Data, separated via Tukey's adjusted p-value ($P < 0.05$), are the average of two bar preparations. On day 0, no statistical difference was detected for fracturability and hardness between bars ($P < 0.05$) and crumbliness reduced when cross-linked ingredients were compared with their respective controls ($P < 0.05$). Throughout storage, bars formulated with a commercially

produced native MPC80 were less crumbly and maintained a larger geometric mean diameter after compression. A high-level of TGase helped maintain cohesiveness in MPC-H and MCC-H compared with their controls through day 16 and day 28, respectively ($P < 0.05$). Sample moisture content on the day of preparation was the same ($P > 0.05$), whereas water activity was different ($P < 0.05$). A significant increase ($P < 0.05$) in water activity was seen ~24 h after preparation, but after the initial increase it remained stable within each batch. Moisture content and pH remained fairly constant during storage, while visual color change was apparent within the samples. TGase treated and calcium-reduced milk protein ingredients have altered performance in high-protein nutrition bars, which potentially could lead to improved commercial feasibility.

Key Words: milk protein concentrate, micellar casein concentrate, protein bar

---

1136 (M119) The effects of post-exercise consumption of a kefir beverage on performance and recovery during intensive endurance training. K. V. O'Brien*, *Louisiana State University, Baton Rouge.*

This study was designed to determine whether kefir accentuates the positive health benefits assessed by measures in fitness and/or body composition, as a measure of cardiovascular disease risk as well as the biomarker c-reactive protein (CRP). Thirty-eight adult males and females aged 18 to 24 yr were assigned to one of four groups: 1) endurance training + control beverage (ETC), 2) endurance training + kefir beverage (ETK), 3) active control + control beverage (ACC) or 4) active control + kefir beverage (ACK). The E groups (ETK and ETC) completed 15 weeks of structured endurance training. The AC groups (ACK and ACC) maintained their usual exercise routine. Additionally, each group was assigned to either a kefir (ETK and ACK) or a calorie/macronutrient matched placebo (ETC and ACC) beverage that was consumed twice per week. The kefir beverage and the control beverage were developed and manufactured in the Louisiana State University Creamery and were identical in ingredients used with the only difference being the fermentation of the milk used in the kefir beverage. Pre/post measures included: body mass and composition, waist hip ratio and 1.5 mile run. Serum CRP was measured using an ELISA (Alpco Diagnostics, Salem, NH). A MANOVA was used to identify significant interactions and significance was set at $P < 0.05$. RESULTS: There was a significant time x training group interaction ($P = 0.0124$) with the E groups (ETK and ETC) experiencing an average of 4.11% improvement in 1.5 mile time. There were no significance interactions among groups with respect to all other outcome variable with the exception of serum CRP. Serum CRP increased over time ($P = 0.103$). However, there was also a trend for a time x kefir effect($P = 0.0778$). The ETK and ACK groups experienced less (21.18%, 5.45%) of an increase when compared to the ETC and ACC (22.36%, 64.71%). The endurance training was effective in improving 1.5 mile times and kefir supplementation may have been a factor in attenuating the increase in CRP that was observed over the course of the intervention period. This preliminary study suggests that kefir may be involved in improving the risk profile for cardiovascular disease as defined by CRP.

Key Words: kefir, endurance training, cardiovascular disease

1137 (M120) Manufacture of high protein yogurts with low-Ca MPC. A. Kommineni*[1], C. Marella[2], A. C. Biswas[1], and L. Metzger[3], *[1]Dairy Science Dep., South Dakota State University, Brookings, [2]Dairy Science Dep., California Polytechnic State University, San Luis Obispo, [3]Midwest Dairy Foods Research Center, South Dakota State University, Brookings.*

The purpose of this study was to evaluate and compare the effects of high protein yogurt produced with calcium reduced milk protein concentrate (low-Ca-MPC) and regular milk protein concentrate (MPC). The yogurt properties studied were viscosity, syneresis and quantity of acidifying agent required for the yogurt. Reduced Ca MPC was manufactured from ultra and dia-filtration process of skim milk that was injected with CO2 prior to and during the ultra-filtration process. Three different high protein yogurt formulations containing 8% protein were prepared with regular MPC (T-1), low-Ca-MPC with the pH neutralized to 6.7 (T-2) and low-C-MPC at pH 5.9 (T-3). The MPC was the primary source of protein contributing approximately 97% in the all the formulations and the remaining 3% was coming from de-proteinized whey which was used for balancing the lactose content of each formula. All three treatments were manufactured in triplicate from three replicates of low-Ca MPC and regular MPC. Each yogurt formulation was heat treated to 93°C, held for 6 min and then cooled to 45°C. The formulations were then acidified with Glucono-delta-Lactone (GDL) at 45°C and then incubated for 2 hrs. The amount GDL required to reach a pH of 4.6 for 30g of yogurt was 0.7g, 0.6g and 0.55g respectively for T-1, T-2 and T-3. The T-3 yogurt formulation required 21% less GDL to reach the same pH due to the lower initial pH of the T-3 formulation. The T-2 yogurt formulation also used 14% less GDL than T-1 even though the initial pH of both the formulations was same. The undisturbed low-C yogurt formulations (T-2 & T-3) had approximately 40% higher viscosity than the control T-1 formulations. However after stirring all yogurt formulations had similar viscosities. The control yogurt formulation T-1 also had 10% higher syneresis than T-2 and T-3 yougurts. These results indicate that, the use of low-Ca MPC reduces both syneresis and amount of acid required to ferment yogurt.

Key Words: low-Ca MPC, calcium, yogurt, MPC

1138 (M121) Effect of titanium dioxide, annatto, and homogenisation on the translucency of reduced-fat cheddar cheese. R. A. Ibanez[*1,2] and P. L. H. McSweeney[1], [1]*University College Cork, Ireland,* [2]*University of Wisconsin–Madison, Madison.*

The appearance of cheese is greatly influenced by its composition. Low fat content is usually related to an increase in translucency. Many alternatives have been proposed to modify translucency of cheese, such as the addition of ingredients or through the modification of manufacturing protocols. Colorimetric methods have been used extensively to determine the degree of translucency. The Kubelka-Munk index (K/S) measures the relationship between the reflectance of a thin layer of sample above black and white backgrounds, which indicates the reflectance of a sample of infinite thickness. A method based on the measurement of L* values and the application of K/S was proposed to investigate the effect of titanium dioxide, annatto and homogenisation on the translucency of reduced-fat Cheddar cheese during ripening. Three reduced-fat Cheddar cheeses were manufactured in parallel experiments. For titanium dioxide, levels of 0, 20 or 40 g of TiO_2/100 kg were added to cheesemilks. For annatto, levels of 0, 8.25 and 16.50 ml/100 kg were added to cheesemilks. Cheesemilks were also homogenised at 0, 10 or 20 MPa, using a two stage homogeniser (4:1 ratio) at 40°C. L* values and K/S were obtained with a colorimeter at 20°C for all experimental cheeses during six months of ripening. A high correlation was observed between K/S and L* values (r>0.90). Titanium dioxide, annatto and homogenisation significantly ($P < 0.05$) modified K/S values compared to the control. Ripening significantly increased translucency (i.e., reduced K/S) for all treatments ($P < 0.05$). An increase in K/S was observed when TiO_2 was added ($P < 0.05$). A reduction of the K/S value was observed following addition of annatto ($P < 0.05$). An increase of K/S was observed when milk was homogenised ($P < 0.05$). However, no differences in K/S values were found between homogenisation pressures of 10 and 20 MPa. These results suggest that K/S is a useful tool to determine changes in the translucency of Cheddar cheese. Addition of titanium dioxide and homogenisation reduced translucency. On the other hand, the use of annatto increased translucency in experimental cheeses.

Key Words: translucency, L* value, Kubelka-Munk

1139 (M122) Effects of supplemental garlic (*Allium sativum*) powder and probiotics on diarrhea and immunoglobulin response in pre-weaned dairy calves. T. W. Kekana*, *University of Venda, Thohoyandou, South Africa.*

This study was carried out to investigate the effects of feeding Garlic powder or Probiotics or both on diarrhoeal incidence and immunoglobulin response of pre-weaned Holstein calves. Sixteen Holstein calves (BW = 34.5 ± 1.65 kg) were randomly assigned at birth to 4 treatments to evaluate the effects of garlic powder or probiotics, or both on feed intake, diarrhea, serum glucose and immunoglobulin (IgG) in Holstein calves. The treatments were: C (control, no additive); G: supplemented with 5g/d garlic powder; P: supplemented with 4 g/d probiotics (total viable count: 1.3 x 107 cfu/g) and G+P: supplemented with 5 g/d garlic powder and 4 g/d probiotic. Calves were given colostrum for the first 3 d of life followed by a standard whole milk feeding until weaning at 42 days. A commercial calf starter was offered ad libitum starting at 4 d of age until the end of the study. Fresh water was available throughout the study. Intake of whole milk and starter feed were measured daily and body weights were taken weekly. Blood samples were collected to determine glucose and IgG concentrations. Garlic and probiotics were diluted in milk and fed daily from day 4. Starter DMI tended to be higher ($P < 0.10$) in G+P calves compared to Control calves. Calves fed G and G+P had higher ($P < 0.05$) IgG than C and P calves (28.0 and 27.5 vs. 23.5 and 25.5 g/l: respectively). Calves fed C and G had lower ($P < 0.05$) final BW (56.0 kg) compared to G+P (60.3 kg). Garlic, P and their combination (G+P) did not affect ($P > 0.05$) serum glucose and body temperature. Calves in G+P and P groups had lower ($P < 0.05$) fecal score, days of diarrhea and days fed electrolytes compared to C and G calves. The results suggest complementary effects of the combined garlic powder and probiotics when fed to calves during the first 42 days of life. Improved starter feed intake and final body weight in group G+P suggest high concentrations of ruminal volatile fatty acid for a stimulated rumen development. Additionally, higher serum IgG in G+P may indicate an improved intake of nutrients responsible of immunity modulation and regulation.

Key Words: garlic powder, probiotics, IgG, Holstein calves

1140 (M123) Development of an application for touch-screen devises to capture defined calving-related events in dairy herds. A. A. Barragan*, J. D. Workman, and G. M. Schuenemann, *Dep. of Veterinary Preventive Medicine, Ohio State University, Columbus.*

Calving-related losses (survival, health, and productivity) and welfare practices have become known challenges for the dairy industry worldwide. Furthermore, management practices have been associated with this problem. It is common to observe large within- and between-herd variation in recording calving-related events and personnel performance (*P*P) over time. Successful identification of factors affecting stillbirth and personnel performance at the herd level can be challenging due to their multi-factorial nature. The objective was to assess a user-friendly mobile application (APP) for touch screen devises to aid in decision-making about calving-related events in dairy herds. The APP was developed to capture, identify, and rank risk factors (e.g., dystocia, PP, work shift transition, BCS, colostrum management) affecting stillbirth according to their contribution weights. Novel components of the APP included: 1) Login screen for individual herds, 2) Capture of selected calving-related events for both dam and calf (e.g., parity, breed, BCS, hygiene of perineum, calving ease, sex of calf, presentation, personnel), 3) Rolling list of active cows with an alarm to monitor calving progress and time in labor, 4) Rolling list of active calves (single or multiple) within 24 h after birth, 5) Colostrum management practices (quality, quantity, time of administration, calf vigor, birth weights, and personnel), and 6) Connectivity to dashboard to process data in real time. Using data from dairy herds, the APP accurately captured (100%) and integrated multiple calving-related events with PP (accounting for the effect of work shift transition), and ranked within-herd risk factors for stillbirth due to herd management. Dairymen, consultants, and veterinarians often trouble-shoot stillbirth within-herd; however, the lack of meaningful records using defined events makes it difficult to implement corrective practices. Comprehensive assessment of several events occurring in real time around-the-clock will likely reduce calving-related losses (stillbirth) while improving herd productivity and welfare.

Key Words: app, calving management, dairy

1141 (M124) Effects of dietary crude protein levels during a twelve-week period on late-lactation dairy cow performance. M. A. Quaassdorff*[1], T. Barros[1], J. J. Olmos Colmenero[2], M. J. Aguerre[1], S. J. Bertics[1], and M. A. Wattiaux[1], *[1]University of Wisconsin–Madison, Madison, [2]University of Guadalajara, Tepatilan, México.*

The objectives were to determine the effects of feeding four dietary CP levels on late-lactation dairy cow performance, and whether there were any treatment by week interactions. One

hundred twenty-eight late-lactation Holstein cows (736 ± 18 kg BW; 224 ± 54 DIM) were used in a 16-pen study with 8 cows per pen, and fed a TMR once per day for 12 weeks (*P*en = experimental unit). Treatments which included diets characterized by 11.8, 13.1, 14.6, or 16.2% CP (DM basis) were randomly allocated to pen for the entirety of the experiment. Rations consisted of approximately 67% forage (half corn silage; half alfalfa silage); and soy hulls (SH) replaced soybean meal (SBM) to achieve the desired dietary CP levels for each treatment. Pen-level data presented were covariate-adjusted and included DMI, milk yield (MY) and composition (biweekly), BW (final minus initial), and body condition score (BCS); (every 3 wk). There was no treatment by week interaction for any variables except MY ($P < 0.01$) and true protein % ($P < 0.01$), but there was a linear effect on DMI, MY, true protein %, fat yield (FY) and true protein yield (PY). No measured variables differed between treatments 14.6 and 16.2% CP except for true protein %. DMI, MY, FY and PY were lower on treatment 11.8% than other treatments. There was a quadratic effect ($P < 0.01$) for BW change, with the highest BW gain observed on the 14.6% CP treatment, but there was no difference in BCS. Results suggest that there was essentially no difference in late-lactation cow performance when diets of 14.6 or 16.2% CP were fed.

Key Words: soy hulls, soybean meal, protein nutrition

1142 (M125) Patterns of circulating serotonin (5-HT), calcium, and glucose in lactating Jersey and Holstein dairy cows. S. A. E. Moore*, J. Laporta, and L. L. Hernandez, *University of Wisconsin-Madison, Madison.*

Dairy cows are challenged to maintain calcium (Ca) and glucose homeostasis during the transition period. Serotonin (5-HT) is a monoamine, which modulates Ca and glucose homeostasis in rodents. Serotonin was positively correlated with Ca and glucose status in dairy cows on d1 of lactation. However, the pattern of circulating concentrations of 5-HT over the course of a 305-d lactation is unknown. In this longitudinal study, we examined the metabolite patterns of 5-HT, Ca, and glucose on two commercial dairy farms in southcentral, Wisconsin. Cows sampled on farm 1 were multiparous Jersey cows ($n = 30$, avg lact = 3.2), which calved within a 23d period and on farm 2 were multiparous Holstein cows ($n = 35$, avg lact = 2.8), which calved within a 20-d period. Blood samples were collected daily during the transition period (d-5 through d10 relative to parturition) and on d30, 60, 90, 150, and 300. Data was analyzed using PROC MIXED and correlations were estimated using PROC CORR in SAS. Overall, there was a time effect ($P < 0.0001$) and a farm and time interaction ($P < 0.0003$). Near parturition, 5-HT decreased as compared to pre-partum by 57.8% ($P < 0.0001$) and 29.6% ($P = 0.056$) on farm 1 and farm 2, respectively. Transition period 5-HT nadir was observed at d2 on farm 1 (879 ± 215 ng/ml), and d1 on farm 2 (1064 ± 186 ng/ml). Serotonin was recovered to 1637 ± 211 ng/ml by d5 on farm 1, with a second decrease of 25.8% ($P = 0.11$) on d7. Farm 2 showed a 5-HT recovery to 1577 ± 184 ng/ml by d5 and subsequent decrease of 34.7% ($P = 0.02$) by d9. Furthermore, 5-HT increased markedly on both farms near peak lactation (d60, 90, 150) and decreased at d300. Calcium decreased compared to pre-partum levels by 35.3% ($P < 0.0001$) and 10.9% ($P < 0.0001$) on farm 1 and 2, respectively. Calcium nadir was observed at d1 on farm 1 (1.79 ± 0.06 mmol) and farm 2 (2.29 ± 0.06 mmol). Serotonin and Ca were positively correlated on farm 1 ($r = 0.24$; $P < 0.0001$) and farm 2 ($r=0.15$; $P = 0.0003$). No significant correlation was detected between 5-HT and glucose. These results show that 5-HT concentrations change dynamically through the transition period and this change is positively correlated with circulating Ca patterns. Further research should be aimed at discerning how 5-HT affects Ca in different dairy breeds.

Key Words: calcium, serotonin, transition period

1143 (M126) Ruminal degradability and intestinal digestibility of protein and amino acids in canola meal. N. Jayasinghe*, K. F. Kalscheur, J. L. Anderson, and D. P. Casper, *Dairy Science Dep., South Dakota State University, Brookings.*

Differences in processing by different plants may result in canola meal (CM) with varying nutritional composition. The Dairy NRC (2001) estimated CM to be 35.7% rumen undegradable protein (RUP) with an intestinal digestibility of 75% when DMI was set at 4% of BW. Seven CM samples were obtained from different processing plants and 1 soybean meal (SBM) to evaluate the variability in ruminal degradability and intestinal digestibility of CP. Dacron bags containing 5 g of each feed were incubated in the rumen in duplicate for 0, 2, 4, 8, 12, 16, 24 and 48 h using three ruminally cannulated lactating cows. The rate of passage was calculated at 6.6%/h. The A fraction (rapidly degradable CP) varied from 26.6% to

Table 1143.

TDP, %	98.2^{a}	89.3^{bc}	89.1^{c}	90.1^{bc}	89.4^{bc}	90.8^{b}	89.3^{bc}	85.1^{d}	0.73

[a-c] Means in rows with different superscripts differ significantly ($P < 0.05$)

17.8%, respectively, for CM10 and CM5 ($P < 0.05$). The B fraction (slowly degradable CP) was highest for CM5 (79.9%) and lowest for CM12 (62.4%), whereas the C fraction (undegradable CP) was highest for CM12 (14.6%) and lowest for SBM (0.6%). The rate of degradation of B fraction, Kd (%/h) was highest for SBM (11.1%/h) and lowest for CM12 (4.0%/h). The RUP (% of CP) was highest for CM12 (53.8%), whereas lowest for SBM (31.0%), while the IDP (measured by pepsin-pancreatin digestion) ranged from 94.5% for SBM to 71.6% for CM10. The total digestible protein (TDP) was highest for SBM (98.2%) and CM ranged from 85.1% to 90.8% for CM12 and CM10 ($P < 0.01$), respectively. The mean ruminal and intestinal digestibilities of CM are in agreement with NRC, however considerable variation exists between CM processing plants.

Key Words: canola meal, rumen degradability, intestinal digestibility

1144 (M127) Estimate of serum immunoglobulin G concentration in Jersey calves using refractometry. M. M. Spring*[1], K. M. Morrill[2], A. L. Robinson[1], and H. D. Tyler[1], *[1]Iowa State University, Ames, [2]Cornell University, Ithaca, NY.*

Previous data from our lab demonstrated that refractometry could be used to estimate serum IgG in Holstein calves; data suggested that a % Brix cut-point of 7.8 should be used to identify failure of passive transfer in 1 day old Holstein calves. The objective of the present study was to validate the use of refractometry to determine serum IgG concentrations and evaluate failure of passive transfer in Jersey calves. Blood samples (n = 108) were obtained from 1-3 day old Jersey calves and centrifuged at 3,300 x g for 20 minutes at 25°C. The serum was analyzed for %Brix and refractive index (nD) using a digital refractometer and IgG concentration was determined by radial immunodiffusion. The mean serum IgG concentration for all calves was 23.7 mg/ml (SD = 12.2), with a range of 2.2 to 65.0 mg/ml. Mean serum %Brix for all calves was 8.8 (SD = 1.1), with a range of 6.5 to 12.0. Mean serum nD for all calves was 1.34596 (SD = 0.00173), with a range of 1.34280 to 1.35110. Serum %Brix and nD were positively correlated with IgG concentration (r = 0.74 and 0.73 respectively; n = 107). Regression analysis was used to determine cut points for 10, 12, and 14 mg IgG/mL and diagnostic characteristic test characteristics were calculated to determine the sensitivity and specificity of refractometry to identify failure of passive transfer (serum IgG < 10mg/mL at 24 h old). The % Brix were 7.1, 7.3, and 7.6 and the nD cut-points were 1.24332, 1.34271 and 1.3448, respectively. The 7.3% Brix and 1.34271 nD cut-point resulted in the greatest percentage of samples being correctly classified (92.59 and 93.52%, respectively) and the best combination of diagnostic test characteristics. Our data suggest that a digital refractometer is an acceptable, rapid and low cost method to estimate immunoglobulin G in Jersey calf serum but that breed-specific cut points may need to be utilized.

Key Words: passive transfer, refractometer, jersey, validate

1145 (M128) Examination of pre-milking teat disinfectant contact times using the excised teat model. B. D. Enger*, L. K. Fox, J. M. Gay, and K. A. Johnson, *Washington State University, Pullman.*

Use of pre-milking teat disinfectants is a common practice used to aid in the control of mastitis which is the most common and expensive disease in the U.S. dairy industry. Effectiveness of pre-milking teat disinfectants in reducing pathogen load on teat skin is influenced by the duration these disinfectants remain on the teat skin, although this has not been adequately investigated. The objective of this study was to determine the percentage reduction in mastitis pathogen load, four environmental and four opportunistic (n = 8), on teat skin with disinfectant contact times of 15, 30, and 45 sec. Three commercially available disinfectants were tested: 0.25% (A) and 0.5% (B) iodophor, and 1% H_2O_2 (C). Excised teats, collected from an abattoir, were washed, dried, hung from a dowel rod, dipped in 70% isopropyl alcohol and allowed to dry. Once dry, teats were dipped in challenge solution of approximately 10^7 colony forming units/ml of a pathogen. After 5 minutes, teats were dipped with desired disinfectant and rinsed with quench solution upon achieving test contact time. Rinse was serially diluted, plated, incubated for 18-48 hr, and enumerated. Main effect differences were observed within dips, contact times, and

species ($P < 0.0001$). Dip A percentage log reduction across all species was 28% at 15 sec, 35.7% at 30 sec, and 39.2% at 45 sec, SE ± 1.7%. Dip B, percentage log reduction was 36% at 15 sec, 41.2% at 30 sec, and 43.8% at 45 sec, SE ± 1.7%. Dip C, the least efficacious disinfectant, had log reductions of 26% at 15 sec, 25.5% at 30 sec, and 28% at 45 sec, SE ± 1.7%. In summary percentage log reductions across all pathogens and dips at 15, 30, and 45 sec were 30% ± 0.97%, 34% ± 0.97%, and 37% ± 0.96% respectively, all significantly different from one another ($P < 0.05$). The relationship between duration of contact time and percentage log reduction demonstrates the importance of allowing adequate contact time to maximize pathogen reduction and reduce the risk of mastitis.

Key Words: mastitis, teat disinfectant, contact time

1146 (M129) The effects of feeding an algae supplement on milk yield, milk components, and dry matter intake.

M. E. Weatherly*[1], A. M. Gehman[2], A. M. Lisembee[2], J. D. Clark[1], D. L. Ray[1], and J. M. Bewley[1], *[1]University of Kentucky, Lexington, [2]Alltech, Inc., Nicholasville, KY.*

Feeding docosahexaenoic acid (DHA) via algae supplementation could increase milk polyunsaturated fats. The objective of this study, conducted at the University of Kentucky Coldstream Dairy, was to determine the effects of feeding cows *Schizochytrium* sp. Microalgae (SP-1, Alltech, Inc., Nicholasville, KY) on milk fat and DHA content, dry matter intake, and milk yield. Eight multiparous, mid-lactation, Holstein cows were housed in a tie-stall barn and fed a basal ration 2X. Cows were blocked by milk production and DIM and assigned to 1 of 4 treatments: 0, 100, 300, or 600 g of algae per day for 28 d. Milk samples were composited by week and analyzed for fat and DHA composition. Dry matter intake and milk yield were recorded daily and averaged by week. The PROC MIXED of SAS (SAS Institute, Inc., Cary, NC) was used to evaluate fixed effects of week, treatment, and their interactions on milk fat percentage and DHA content (g/d), milk yield (kg/d), and DMI (kg/d), with block within treatment as subject repeated by week. Stepwise backward elimination was used to remove non-significant interactions ($P \geq 0.05$). All main effects were kept in each model regardless of significance level. Week affected milk yield ($P < 0.01$) but treatment did not ($P = 0.30$). Milk yield (mean ± SE) for periods 1 to 4 was 30.44, 29.10, 25.10, and 25.21 ± 4.58 kg, respectively. Treatment and week affected fat percentage ($P = 0.02$). Fat percentage was greater ($P < 0.05$) for cows on treatments 0 and 100 (4.20 and 3.54 ± 0.18%, respectively) than cows on treatments 300 and 600 (2.52 and 2.52 ± 0.18%, respectively). Treatment, week, and the interaction of treatment × week affected DMI ($P < 0.01$, $P < 0.01$, and $P = 0.02$, respectively). Dry matter intake decreased across time across treatments until wk 4. Treatment and the interaction of treatment × wk affected milk DHA ($P = 0.03$ and $P = 0.02$, respectively). DHA content in milk was greater ($P < 0.05$) for cows on treatment 300 and 600 (3.30 and 5.18 ± 0.66 g/d, respectively) than cows on treatment 0 and 100 (0.00 and 0.39 ± 0.66 g/d, respectively). This data suggests supplementing lactating dairy cows with high-DHA microalgae may allow for the incorporation of polyunsaturated fats, including DHA, into milk; however, decreases in milk fat percentage and DMI may limit on-farm application.

Key Words: algae, milk fat, DHA

1147 (M130) Rumen morphology measurements in periruminant Holstein bull calves fed a fermentation extract of *Aspergillus oryzae*.

T. T. Yohe*, E. M. Dudash, K. M. O'Diam, and K. M. Daniels, *Dep. of Animal Sciences, Ohio State University, Wooster.*

Age and diet not only affect calf BW, they can impact rumen growth and development too. A fermentation extract of *Aspergillus oryzae* has previously been utilized as a direct fed microbial (DFM) to increase rumen bacterial numbers and promote starter intake in calves. Effects of feeding an extract of *A. oryzae* on rumen morphology in periruminant calves are largely unknown. Objectives were to determine if age and dietary inclusion of an extract of *A. oryzae* affect: organ size, muscle and sub-mucosal thickness of rumen tissue, and papillae area in periruminant Holstein bull calves. Individual calves ($n = 52$) were randomly assigned to a slaughter age, 4 wk ($n = 16$) or 8 wk ($n = 36$), and treatment, control (CON**;** $n = 27$) or DFM **(**n = 25). Calves were housed and fed individually; no bedding was used. Liquid DFM was delivered in milk replacer (2 g per day) for the first 4 wk of the trial; solid DFM (2 g per day) was top-dressed on grain thereafter. Calves were fed non-medicated milk replacer twice daily (22.0% CP, 20.0% fat DM basis; 680 g/d) and had ad libitum access to texturized grain (20% CP, 2.0% fat) and water. Treatment and the interaction of treatment and age did not affect full or empty rumen weights. However, full and empty rumen weights were greater at 8wk (5.29 ± 0.21and 1.31 ± 0.04 kg, respectively) than 4 wk (1.81 ± 0.30 and 0.52 ± 0.06 kg, respectively). Muscle thickness (894.15 ± 69.50 μm, 4 wk; 1098.58 ± 47.64 μm, 8wk) and sub-mucosal thickness (247.57 ± 43.48 μm, 4 wk; 583.67 ± 29.80 μm, 8 wk) were both affected by age, but not by treatment or interaction. Lastly, within the cranial ventral region of the rumen of 8-wk-old calves (4-wk samples not measureable), treatment had no effect on papillae area (6.52 ± 0.39 mm^2, CON; 6.65 ± 0.41 mm^2 DFM). In summary, dietary inclusion (2g/d) of an extract of *A. oryzae*did not affect rumen morphological development when supplemented animals were compared to cohorts not fed DFM. It is possible that the dose used here was not high enough to elicit treatment effects. Evaluation of other measures of performance, such as calf growth, may add further information on the efficacy of this DFM in periruminant calf diets. A higher dose of DFM may yield different effects.

Key Words: dairy calf, rumen, direct fed microbial

1148 (M131) Response of dairy cows supplemented with antioxidants and/or chelated trace minerals to intra-mammary bacterial challenge.

R. O. Rodrigues*[1], M. O. Caldeira[1], G. I. Zanton[2], and M. R. Waldron[1,3], [1]*University of Missouri, Columbia,* [2]*Novus International, Inc., St. Charles, MO,* [3]*Nutrition Professionals, Inc., Chilton, WI.*

The effects of chelated trace minerals (TM) of Zn, Cu, and Mn (Minitrex, Novus International, St. Charles, MO) and dietary antioxidant (Agrado Plus, Novus International) supplementation on responses to experimental mastitis in lactating cows were evaluated. Sixty cows were blocked by parity, expected date of parturition, and initial BW. Cows were individually fed a basal diet formulated according to NRC (2001) from d -39.3 ± 4.6 prepartum until d 38 postpartum. Treatments were top-dressed as: 1) Negative control – no TM nor antioxidant (NEG), 2) TM provided with 100% sulfates without antioxidant (ITM), 3) TM provided with 100% sulfates with antioxidant (ITMAOX), 4) TM provided 50% of sulfates and 50% of chelated TM without antioxidant (OTM), and 5) TM provided 50% of sulfates and 50% of chelated TM with antioxidant (OTMAOX). Treatments were iso-mineral except NEG; all were iso-methionine. Animals were vaccinated against *Escherichia coli* (Enviracor J-5, Pfizer Animal Health) at drying-off, -27.3 ± 4.6, and 14 d from parturition, and against rabies (IMRAB, Merial) at parturition. On d28 after calving, the right front quarter of each animal was infused with 1.74 x 10^4 CFU of *E. coli* P4:O32 diluted in 5 mL of sterile PBS and the contralateral quarter with the same volume of sterile PBS. Blood and milk samples were collected regularly during the experiment. Primiparous had higher rabies titers concentrations on d14 compared to multiparous cows, but no difference between parities on d28 (parity x time, $P < 0.001$). OTMAOX showed the highest rabies titer concentrations compared to other treatments on d14 (treatment x time, $P = 0.04$). Higher milk yield was observed for the first 3 days post-infusion in primiparous compared to multiparous cows (parity x time, $P < 0.05$). *Escherichia coli* CFU were higher in infected quarters of multiparous cows (parity x quarter, $P = 0.03$). Milk SCC were higher in AOX and OTMAOX in response to challenge than in other treatments (treatment, $P = 0.01$). Additionally, SCC in primiparous peaked earlier and higher compared to multiparous cows (Parity x time, $P = 0.004$). Blood GSH:GSSG peaked at 48 h post-infusion ($P = 0.01$). Blood GSH:GSSG in OTMAOX was highest in primiparous, but lowest in multiparous cows ($P < 0.05$). Antibody titer and SCC recruitment results suggest OTMAOX may have improved some aspects of peripartal immune function. Additionally, the earlier and elevated milk SCC in primiparous cows may have limited the severity of *E. coli* infection, thereby allowing for increased DMI and milk production.

Key Words: *Escherichia coli*, mastitis, supplementation

GRADUATE STUDENT COMPETITION: **ADSA PRODUCTION, PhD**

1149 (M132) Effect of feeding diets with different type of carbohydrates on dry matter intake, rumen fermentation, and productivity of lactating dairy cows. X. Gao*, J. Mewis, and M. Oba, *University of Alberta, Edmonton, Canada.*

The objective of this study was to investigate the effect of feeding different types of carbohydrates on DMI, rumen fermentation, and milk production of lactating dairy cows. Our hypotheses were that both high sugar and high starch diets will decrease rumen pH compared to a basal diet, but a high sugar diet has higher DMI and milk fat yield than a high starch diet. Six ruminally cannulated peak-lactating dairy cows (DIM = 75 ± 12.2; BW = 630 ± 59.2 kg) were used in a replicated 3 × 3 Latin square design with 21-d periods. Cows were fed diets consisting of 35.5% barley silage and 64.5% concentrate mix on a DM basis. Control diet (CON) contained 27% starch, 4% sugar and 28% NDF, high starch diet (STA) supplemented with additional steam-rolled barley grain contained 32% starch, 4% sugar and 26% NDF, while high sugar diet (SUG) supplemented with sucrose contained 27% starch, 9% sugar and 26% NDF. All diets were formulated to contain 17% crude protein. Although DMI was not different among these three diets, mean rumen pH of STA and SUG diets was lower than CON diet (6.29 and 6.23 vs. 6.38; $P < 0.01$). However, there was no significant difference between STA and SUG diets. In addition, duration of rumen pH < 5.8 was not different between STA and SUG diets, but it tended to be longer for SUG diet than CON diet (117 vs. 30.1 min/d; $P = 0.08$). Concentrations of total VFA and NH_3-N in rumen fluid were not different among the treatments. However, compared with CON, STA and SUG diets had lower acetate proportion (62.0 vs. 59.6 and 59.4 mol / 100 mol; $P = 0.01$), but there was no difference between STA and SUG diets. Although DMI, milk yield, milk component yields and milk fat concentration did not differ among the treatments, concentrations of milk CP (3.14 vs. 3.08 and 2.97%; $P < 0.01$) and MUN (16.2 vs. 13.3 and 14.9 mg/dL; $P < 0.01$) were higher for SUG diet compared with STA and CON diets. These results suggested that feeding high sugar and high starch diets to lactating dairy cows might decrease rumen pH without affecting DMI or milk fat yield, but that high sugar diet may increase milk CP content.

Key Words: sugar, starch, milk production

1150 (M133) Propionate is a dominant inducer of bovine cytosolic phosphoenolpyruvate carboxykinase gene expression. Q. Zhang*, S. L. Koser, and S. S. Donkin, *Purdue University, West Lafayette, IN.*

Expression of cytosolic phosphoenolpyruvate carboxykinase (PCK1) is a critical control point for gluconeogenesis. Indirect evidence suggests that increased feed intake after calving and diet modification that increase rumen propionate production, the primary precursor of gluconeogenesis in ruminants, induces PCK1 mRNA. Our objective was to determine the direct effects of propionate on regulation of bovine PCK1 promoter activity and the relationship to hormones known to modulate glucose metabolism. The full length proximal promoter of bovine PCK1 from -1238 to +221 relative to transcription initiation and nested 5' truncation deletions at -815, -409, -281 and -85 to +221 were ligated to pGL3 Firefly Luciferase Reporter Vector and transfected into rat hepatoma H4IIE cells. The pGL3-Basic (*P*romoterless) and pGL3-Promoter (SV40 promoter driven) vectors served as negative and positive controls for the experiment. Renilla Luciferase Reporter Vector was cotransfected to normalize transfection efficiency. At 5 h after transfection, cells were exposed to either 2.5 mM propionate (PRO), 100 nM insulin (INS), 1 mM 8 Br-cAMP (cAMP), 5 μM dexamethasone (DEX), or the double and multiple combinations of PRO, INS, cAMP and DEX for 23 h. Promoter activity was expressed as the ratio of firefly luciferase to renilla luciferase and data were analyzed using the PROC MIXED of SAS 9.3. All bovine PCK1 promoter constructs were capable of driving firefly luciferase expression. Propionate induced ($P < 0.001$) expression of all PCK1 promoter constructs compared with no treatment control. The induction by propionate was greatest for the -1238 to +221 promoter construct (up to 6-fold) and similar for the other four PCK1 promoter constructs (about 3-fold). Activity of the -1238 to +221 PCK1 promoter was not altered by cAMP and DEX alone but was induced (3-fold) by their combination ($P < 0.01$). Induction of the -1238 to +221 PCK1 promoter construct with cAMP and DEX, was repressed by 24% in response to INS and PRO prevented this effect ($P < 0.0001$). The data demonstrate an inductive effect of propionate on bovine PCK1 promoter activity that is dominant to the repressive effect of insulin. Furthermore, the effect of propionate to induce PCK1 appears to be independent of the actions of cAMP and dexamethasone to also induce bovine PCK1 transcription.

Key Words: cytosolic phosphoenolpyruvate carboxykinase, propionate, hormones

1151 (M134) Slow-release urea, rumen-protected methionine, and histidine: Effects on expression and activation of the mTOR signaling pathway in skeletal muscle of dairy cows receiving a diet deficient in metabolizable protein. *F*. Giallongo[*1], H. Sadri[2], A. N. Hristov[1], J. Werner[3], C. Parys[4], B. Saremi[4], H. Sauerwein[2], and C. Lang[5], *[1]Dep. of Animal Science, Pennsylvania State University, University Park, [2]Institute of Animal Science, Physiology & Hygiene Unit, University of Bonn, Germany, [3]Animal Resource Program, Pennsylvania State University, University Park, [4]Evonik Industries AG, Hanau, Germany, [5]Dep. of Cellular and Molecular Physiology, Penn State College of Medicine, Hershey.*

The mammalian target of rapamycin (mTOR) signaling pathway is mediated by two functionally distinct multi-protein complexes, mTORC1 and mTORC2. The mTORC1 is a nutrient sensor, in particular of amino acids, activating protein synthesis by phosphorylation of ribosomal protein S6 kinase (S6K1) and eukaryotic initiation factor 4E-binding protein (4E-BP1). The mTORC2 responds to growth factors but is largely nutrient insensitive and phosphorylates protein kinase B (Akt) on Ser473, resulting in activation of cell growth, and survival. We hypothesized that supplementation of diets deficient in metabolizable protein (MP) with slow-release urea or rumen-protected (RP) Met and His will affect the gene expression of key factors of the mTOR pathway, in particular of mTORC1, and will alter their activation by phosphorylation in skeletal muscle of dairy cows in support of protein synthesis. Sixty Holstein cows were blocked based on DIM and milk yield and within block randomly assigned to 1 of 5 diets in a 10-wk experiment (including the first 2 wk as covariate period): MP-adequate diet (AMP); MP-deficient diet [DMP; 5% below MP requirements (NRC, 2001)]; DMP supplemented with slow-release urea as Optigen (Alltech Inc.; DMPO); DMPO supplemented with RPMet (Mepron; Evonik Industries AG; DMPOM); and DMPOM supplemented with RPHis (Balchem Corp.; DMPOMH). Muscle biopsies were collected from *Longissimus dorsi* during the last wk of the experiment. The mRNA abundance of the following target genes was quantified by qPCR: mTOR, S6K1, and 4E-BP1. Western blotting was used to assess total (t)- and phosphorylated (*P*)-S6K1 (Thr389), t-Akt and p-Akt (Ser473), p-mTOR (Ser2481), and p-S6 (Ser240/244). Data were analyzed by the PROC MIXED of SAS. The mRNA abundance of the target genes was not affected by the treatments; treatment effects were limited to p-mTOR and p-S6: p-mTOR values in DMPO were decreased when compared against DMP ($P = 0.03$) and also tended to be lower ($P = 0.07$) in DMPOMH than in DMPOM. The p-S6 values in DMPOM tended to be greater ($P = 0.07$) than in DMPO. There was also a trend ($P = 0.09$) for decreased p-S6 in DMPO versus DMPOM and DMPOMH. In conclusion, supplementation of the DMP diet with slow-release urea, or RPMet and RPHis, respectively, altered the phosphorylation status of mTOR-associated signaling proteins in muscle. No such effects were observed when comparing the AMP and DMP diets, thus indicating specific effects of the supplements.

Key Words: rumen-protected amino acid, mTOR, dairy cow

1152 (M135) Attenuation of the integrated cortisol response following administration of oral firocoxib in preweaned calves prior to cautery disbudding. M. L. Stock[*1], R. Gehring[2], S. T. Millman[1], C. Wang[1], L. W. Wulf[3], L. A. Barth[1], and J. F. Coetzee[3], *[1]Iowa State University, Ames, [2]Kansas State University, Manhattan, [3]Pharmacology Analytical Support Team, Iowa State University College of Veterinary Medicine, Ames.*

Perioperative analgesic effects of oral firocoxib following cautery disbudding were investigated in preweaned calves. Twenty Holstein calves (55.2 ± 5.8 kg) approximately 35 d old were orally administered firocoxib, a non-steroidal anti-inflammatory prostaglandin blocker, using a dose of 0.5 mg/kg ($n = 10$) or whey protein placebo ($n = 10$) in a randomized clinical trial. All animals received a cornual nerve block using a local anesthetic prior to disbudding. Pain biomarkers including ocular temperature determined by infrared thermography, pressure algometry measuring mechanical nociception threshold, and heart rate were evaluated following cautery disbudding at 2, 4, 7, 8, and 24 hr. Blood samples were collected over 96 hr and analyzed for plasma cortisol and substance P concentrations by radioimmune assay. Additionally, ex-vivo prostaglandin E_2 (PGE_2) concentrations were determined over the same 96-hr study period using an enzyme immunoassay. Data were analyzed using a linear mixed effects model with repeated measures. An attenuation of the integrated cortisol response (mean ± LSM) as calculated as area under the effect curve was greater in placebo treated calves (1611.1 ± 249 nmol.h/L vs. 1114.2 ± 181 nmol.h/L) ($P = 0.058$). A significant decrease in cortisol concentrations (mean ± LSM) was observed in firocoxib treated animals at approximately 48 hrs after disbudding (11.3 ± 1.9 nmol/L vs. 22.8 ± 2.8 nmol/L) ($P = 0.0013$). Additionally, a significant inhibition ($P < 0.01$) of ex vivo PGE_2 concentration was observed from 12 to 48 hr following disbudding in calves treated with firocoxib. These data support the potential for firocoxib to be used to provide analgesia after cautery disbudding in calves; however, further investigation of its perioperative analgesic effects is warranted.

Key Words: disbudding, welfare, NSAID

1153 (M136) Effect of storage temperature on the bacterial growth and pH levels of bovine colostrum. C. Cummins[*1,2], I. Lorenz[2], and E. Kennedy[3], *[1]Teagasc, Animal and Grassland Research and Innovation Center, Moorepark, Fermoy, County Cork, Ireland, [2]School of Agriculture, Food Science & Veterinary Medicine, University College Dublin, Belfield, Ireland, [3]Teagasc, Moorepark, Fermoy, County Cork, Ireland.*

Storage of colostrum is a convenient practice that ensures supplies are readily available should they be needed, however storage temperature may affect colostrum quality. The objective of this study was to investigate the effect of storage temperature on bacterial growth and pH levels of colostrum. The study took place at Teagasc Moorepark Research Farm, Cork, Ireland. Colostrum from six Holstein-Friesian cows (³3rd lactation) was collected from March 5 to 12, 2013, at the first scheduled milking post-calving (<9hr post-calving). Immediately after collection samples were separated into 100-ml aliquots, which were replicated and stored in separate temperature-controlled units at one of three temperatures: 4°C, 13°C and 20°C. Aliquots were removed and frozen at 0, 6, 12, 24, 36, 48, 60 and 72 hr post storage. Consequently, they were defrosted at 4°C to determine total bacterial count (TBC) using serial dilution. Dilution rate ranged from 1:10,000 (lowest expected) to 1:10,000,000 (highest expected). Diluted samples (1ml) were incubated at 32°C for 48 hr on 3M petrifilm aerobic count plates. Subsequent recordings were obtained using a 3M Petrifilm Plate Reader. Duplicate TBCs were prepared and an average was calculated. Simultaneously, aliquots were measured for pH using an OHM Delta 2105.2 datalogger (www.lennox.ie). Calibration was carried out before each test period and the probe was cleaned weekly using product guidelines. Data was tested for normality using PROC UNIVARIATE in SAS (v9.3) displaying positively-skewed data, thus a log transformation was performed. Transformed data was analysed using a mixed model (PROC MIXED; SAS v9.3). The model included treatment, time and their interactions. Significant differences between treatments were seen in TBC once colostrum was stored for ³12 hours. Storage at 20°C had significantly higher TBC from 12 hours than storage at both 13°C and 4°C ($P < 0.001$), while TBC of colostrum kept at 13°C for $\geq$ 24 hours was significantly greater than colostrum kept at 4°C ($P < 0.001$). Additionally, colostral pH was significantly lower from 24 hr in colostrum kept at 20°C compared to 13°C and 4°C ($P < 0.001$). Furthermore, from hour 60 of storage the pH of colostrum stored at 13°C was significantly lower than that kept at 4°C ($P < 0.01$). Analysis revealed that a LogTBC >7.5 cfu/ml resulted in a pH drop to < 6.5. Further research is warranted to determine if this affects passive transfer of immunity in calves. It is clear however that stored colostrum should be refrigerated ($\leq$ 4°C) to minimise bacterial proliferation and maintain pH.

Key Words: colostrum, storage, bacteria

1154 [Withdrawn]

1155 (M138) The effect of prepartum housing on metabolic and reproductive health in dairy cows. C. L. Miltenburg[*] and S. J. LeBlanc, *University of Guelph, ON, Canada.*

The determinants of metabolic and reproductive health disorders and the degree to which housing and management can influence health are only partially understood. The objective of this randomized controlled study was to determine if a prepartum housing strategy of providing non-competitive feeding and lying access improves metabolic health and immune function and reduces reproductive disease. Forty-eight Holstein cows of all parities were randomly assigned to a close up treatment group of 6 to 10 cows in 1 pen with either 80% cows to stalls and 90 cm of feeding space/cow or 120% stocking density and 45cm of feeding space/cow for 3 weeks before expected calving. Pen size and bunk space were adjusted to maintain space per cow as animals were removed for calving. Weekly coccygeal blood samples measured non-esterified fatty acids (NEFA), beta-hydroxybutyrate (BHB), calcium, glucose, albumin, aspartate aminotransferase (AST), bilirubin and haptoglobin from 3 weeks before to 5 weeks after calving. Neutrophil phagocytosis and oxidative burst were assessed at -2, -1, 1, 2, 3 and 5 weeks relative to calving. A modified glucose tolerance test to assess insulin resistance was performed 1 week before calving. Liver biopsies were performed at weeks +1 and +3 to assess liver triglyceride content and gene expression. Vaginoscopy was used to identify cows with purulent discharge (*P*VD) and uterine and cervical cytobrush samples were collected to assess endometritis and cervicitis as well as uterine gene expression at weeks +3 and +5. There were no interactions of treatment with time. Cows in the crowded treatment had significantly lower mean albumin ($P = 0.05$) and bilirubin ($P = 0.01$) but had greater BHB ($P = 0.01$) and NEFA ($P = 0.05$). At 5 weeks postpartum, 7% of cows had PVD and 33% of cows were diagnosed with endometritis based on > 5% neutrophils. There was no significant effect of treatment on endometritis. Cows that had endometritis at week 5 tended ($P < 0.1$) to have lower average glucose and bilirubin and higher albumin concentrations throughout the study period. These results indicate that metabolic and reproductive health is more complex than can be explained solely by exposure to what is understood to be optimal access to feeding and lying space.

Key Words: endometritis, transition, crowding

1156 (M139) Intake, milk production, ruminal, and feed efficiency responses to DCAD in lactating dairy cows. M. E. Iwaniuk* and R. A. Erdman, *University of Maryland, College Park.*

Previous meta-analyses (Hu and Murphy, 2004, J. Dairy Sci. 87:2222) of the effects of dietary cation anion difference (DCAD) in lactating dairy cow diets utilized studies conducted after the development of the DCAD concept. Dietary buffers such as $NaHCO_3$ and K_2CO_3 increase DCAD and have been used in lactating dairy cow diets for several decades. However, most published studies on buffer feeding were conducted prior to the development of the DCAD concept. Our objective was to determine the intake, milk production, ruminal, and feed efficiency responses to DCAD using previous studies with dietary buffer addition and more recent studies that focused on DCAD as dietary treatments. The database consisted of 44 articles that were published between 1965 and 2011. The studies included 196 dietary treatments, and 89 treatment comparisons that varied in DCAD. For studies that lacked analyses of one or more of the dietary cations (Na, K, or Cl), ion percentages were estimated from ingredient composition using the 2001 Dairy NRC Software. Two basic models were used to evaluate DCAD responses using the NLPROC MIXED in SAS 9.2: 1) A simple linear model: Y = A + B*(DCAD) where A = intercept and B = the increment (slope) in performance per unit DCAD (meq/kg diet DM); and 2) a nonlinear model: $Y = A + M(1\text{-}e^{(K \times DCAD)})$ where M = maximal increment in performance from DCAD and K = the rate constant. In both models, study was designated as the random effect. DCAD effects best described by the linear model included milk fat percent, fat yield, rumen pH, NDF digestibility, and FCM/DMI where a 100 meq/kg increase in DCAD resulted in respective increases of 0.10% ($P < 0.001$; RMPSE = 0.01), 35 g/d ($P < 0.001$; RMPSE = 5), 0.033 pH units ($P < 0.001$; RMPSE = 0.001), 1.5% NDF digestibility ($P < 0.001$; RMPSE = 0.4), and 0.0013 FCM/DMI units ($P < 0.001$; RMPSE = 0.005). DMI, milk yield, and 3.5% FCM were best described by the nonlinear model where the maximal responses were 3.05, 2.88, and 6.57 kg/d, respectively ($P < 0.001$). The DCAD concentration at which 80% of the maximal response occurred was 456, 207, and 617 for DM intake, milk yield, and 3.5% FCM, respectively. These results suggest that DCAD has significant effects on intake, milk production and composition, digestion, and feed efficiency in lactating dairy cows.

Key Words: DCAD, meta-analysis, dairy cows

1157 (M140) Hepatic metabolomics and transcriptomics in prepartal dairy cows supplemented with Smartamine M and MetaSmart during the transition period. K. Shahzad*[1], J. S. Osorio[2], D. N. Luchini[3], and J. J. Loor[1], *[1]University of Illinois, Urbana-Champaign, Urbana, [2]University of Illinois, Champaign, [3]Adisseo S.A.S., Alpharetta, GA.*

Supplementation with Smartamine M (SM) and MetaSmart (MS) during the transition period improves postpartal dry matter intake, milk production, and blood neutrophil immune function. In the current study we used metabolomics and transcriptomics to provide a more holistic view of the adaptations induced on the liver by dry period nutrition. Liver from cows fed a control high-energy diet without (OVE) or with SM or MS were used. Metabolomics was performed via LC-MS and GC-MS (Metabolon Inc.) and transcriptomics using a whole-transcriptome bovine microarray (Agilent). From a total of 313 biochemical compounds identified, metabolomics analysis ($P \leq 0.10$) revealed a total of 20, 21, and 48 compounds affected by SM vs. OVE, MS vs. OVE, and SM vs. MS, respectively. Comparing profiles in SM vs. OVE revealed that compounds up-regulated belong to the pentose, sterol, inositol, and purine metabolism pathways, while down-regulated compounds belong to secondary bile acid, arginine and proline, purine and pyrimidine, and eicosanoid metabolism pathways. In MS vs. OVE, the compounds up-regulated belong to primary bile acid, pyrimidine, and lysolipid metabolism, while compounds down-regulated were linked with glycolysis, gluconeogenesis, urea cycle, sphingolipid, and pyruvate metabolism. Liver of MS vs. OVE cows had lower hydroxybutyrate and lactate concentration. The transcriptomic analysis of these groups resulted in 922 (SM vs. OVE), 1,573 (MS vs. OVE) and 1,033 (SM vs. MS) differentially expressed genes (DEG, P £0.05). Bioinformatics analysis using the Dynamic Impact Approach (DIA) that SM vs. OVE resulted in a marked impact and activation of 'fatty acid biosynthesis', 'cyanoamino acid metabolism', 'O-glycan biosynthesis', and 'glycosaminoglycan biosynthesis'. In MS vs. OVE, however, among the top-5 most-impacted pathway there was marked inhibition of 'phenylalanine, tyrosine, and tryptophan biosynthesis' and 'phenylalanine' metabolism. 'Cyanoamino acid metabolism' and 'taurine and hypotaurine' metabolism were highly-impacted and activated pathways in MS vs. OVE. Unique responses in SM vs. MS included a marked activation of 'fatty acid biosynthesis', 'glycosphingolipid metabolism', 'valine, leucine, and isoleucine biosynthesis', and 'sulfur metabolism'. Preliminary data interpretation suggests MS and SM induce distinct changes on the metabolome and transcriptome phenotype of the prepartal liver. The functional relevance of such changes remains to be determined.

Key Words: systems biology, metabolic profiling, bovine liver

1158 (M141) Detection of subclinical milk fever and ketosis in fresh dairy cows using rumination time, lying time, reticulorumen temperature, and neck activity. A. E. Sterrett*[1], B. A. Wadsworth[1], R. J. Harmon[1], M. Arnold[1], J. D. Clark[1], E. P. Aalseth[2], D. L. Ray[1], and J. M. Bewley[1], *[1]University of Kentucky, Lexington, [2]Earl P. Aalseth, Jr. Dairy Consulting, PLLC, Lake Stevens, WA.*

The objective of this study, conducted at the University of Kentucky Coldstream Dairy, was to evaluate changes in rumination time (RU), lying time (LT), reticulorumen temperature (RT), and neck activity (NA) around subclinical hypocalcemia (SHC) and ketosis (SKET) events. Fresh cows (90 Holstein, 19 crossbred, and 11 Jersey cows) were assigned HR Tags (SCR Engineers Ltd., Netanya, Israel), IceQubes (IceRobotics, Edinburgh, Scotland), and DVM boluses (DVM Systems, LLC., Boulder, CO) ≥ 14 days pre-partum. The Milpro P4C (Milkline, Gariga di Podenzano, Italy) system measured milk yield (MY). Blood calcium was measured on 3, 7, and 14 DIM to determine SHC (≤ 1.8 mmol/L). Milk KetoTest (Elanco, Greenfield, IN) and blood Precision Xtra (Abbott Laboratories, Abbott Park, IL) beta-hydroxybuterate tests were analyzed on 3, 7, and 14 DIM to determine SKET (both tests ≥ 1.2 mmol/L). Mean RU, LT, RT, NA, and MY were recorded and summarized for each cow day for the first 7 DIM. The GLM Procedure of SAS (Cary, NC) was used to evaluate the relationship between SKET or SHC presence and RU, LT, RT, NA, and MY. LSMeans NA was less in cows with SHC than cows without SHC (210.30 ± 6.40 and 253.81 ± 3.93, respectively, $P < 0.01$). LSMeans RT was less for cows with SHC than cows without SHC (38.58 ± 0.05 and 39.01 ± 0.03 °C, respectively, $P < 0.01$). No difference was observed for RU (316.99 ± 8.35 and 299.90 ± 5.12 min/d for SHC and non- SHC cows respectively, $P = 0.08$), MY (48.57 ± 1.64 and 50.83 ± 1.14 kg/d for SHC and non- SHC cows respectively, $P = 0.26$), or LT (10.66 and 9.97 h/d for SHC and non-SHC cows, respectively, $P = 0.03$). LSMeans LT was greater for cows with SKET than cows without SKET (10.26 and 9.58 h/d, respectively, $P = 0.04$). LSMeans NA was greater for cows without SKET compared with cows with SKET (258.86 and 236.73, respectively, $P < 0.01$). No difference was observed for RT (38.91 ± 0.04 and 38.93 ± 0.04 °C, for SKET and non-SKET cows respectively, $P = 0.72$), RU (307.11 ± 4.88 and 295.84 ± 8.14 min/d, for SKET and non-SKET cows respectively, $P = 0.24$), or MY (51.64 ± 1.09 and 49.03 ± 1.65 kg/d for SKET and non-SKET cows respectively, $P = 0.19$). These parameters may be useful for identifying fresh cow diseases.

Key Words: ketosis, hypocalcemia, fresh cow

1159 (M142) Effects of stage of gestation and feeding regime on intake and apparent total tract digestibility in Holstein × Gyr dairy cows. P. P. Rotta*[1], S. C. Valadares Filho[2], T. E. Engle[1], L. F. Costa e Silva[1], M. I. Marcondes[3], F. S. Machado[4], T. R. Gionbelli[5], B. C. Silva[5], and F. A. S. Silva[3], *[1]Colorado State University, Fort Collins, [2]Universidade Federal de Viçosa, Dep. of Animal Science, Minas Gerais, Brazil, [3]Universidade Federal de Viçosa, Brazil, [4]EMBRAPA, Juiz de Fora, Brazil, [5]Universidade Federal de Viçosa, Minas Gerais, Brazil.*

Two experiments were conducted to determine the effects of stage of gestation (SG) and feeding regime (FR) on DMI and apparent total tract digestibility (ATTD) in Holstein × Gyr dairy cows. Exp. 1: 20 multiparous Holstein × Gyr cows with average initial BW of 495 ± 10.4 kg and age 5 ± 0.3 of yr were used in this experiment. Cows were individually fed a corn silage-concentrate based diet (93% and 7% DMB, respectively). In order to allow cows ad libitum access to feed, feed delivery was adjusted to allow approximately 5% orts daily. Dry matter intake was evaluated at 122, 150, 178, 206, 234 and 262 d of gestation. Overall, DMI decreased ($P < 0.05$) as days in gestation increased. The decrease in DMI may be associated with reduction in ruminal volume caused by the rapid increase in fetal size during late gestation. Exp. 2: 44 multiparous Holstein × Gyr cows with average initial BW of 480 ± 10.1 kg and age of 5 ± 0.5 of yr were allocated to 1 of 2 FR. Feeding regimes consisted of: 1) ad libitum intake (ADLIB; $n = 20$) and maintenance intake (MAIN; $n = 24$). Maintenance intake was considered as 1.15% of BW. Cows were individually fed a corn silage-concentrate based diet (93% and 7% DMB, respectively) as a total mixed ration, twice a daily. Apparent total tract digestibility was evaluated every 28 d beginning at 122 d of gestation through day 262 by collecting 24 h fecal excretion for the last 5 d of each 28 d period. Within feeding regime, DM digestibility decreased ($P < 0.05$) as days in gestation increased. An interaction ($P < 0.05$) existed for DMI and OM apparent digestibility between FR and SG on days 150 and 178 of gestation. Cows fed at MAIN had greater ($P < 0.05$) DM and OM apparent digestibility than cows fed ADLIB. However, DM and OM apparent digestibility were similar ($P > 0.05$) for FR at 122, 206, 234 and 262 d of gestation. These data indicate that FR and days in gestation can influence ATTD.

Key Words: dairy cattle, digestibility, pregnancy

1160 (M143) Description of high cow premix recipes in California dairies. Y. Trillo*[1], A. Lago[2], and N. Silva-del-Rio[1], *[1]VMTRC, University of California, Tulare, [2]DairyExperts, Tulare, CA.*

The objective of this study was to describe high cow premix (HCP) recipes prepared in 13 California dairies ranging in size

from 1,000 to 6,000 cows. Records from a consecutive twelve month period, starting from Jan-June 2012, were extracted from the feeding management software FeedWatch 7.0. The variables included were: date, drop number, recipe, ingredient, loading sequence, target weight, as-fed weight, tolerance level, and mixer wagon capacity. Descriptive statistics were conducted with SAS 9.3. Throughout the study period, HCP recipes were prepared on farm at least 90% of the days (n = 3) or less than 70% of the days (n = 5). The median number of HCP recipe prepared per day were one (n = 5), two (n = 7) or four (n = 1). The median number of ingredients included daily in the HCP recipe was four to six (n = 7) and seven to nine (n = 6). The number of ingredients included in HCP recipe varied over time within dairy in three (n = 3), two (n = 5), one (n = 4) or zero (n = 1) ingredients. The most commonly used ingredients in HCP recipes were canola meal (n = 13), whole cotton seed (n = 11), dry distillers grains (n = 8), corn gluten meal (n = 8), almond hulls (n = 6), wheat middlings (n = 6), molasses (n = 5) and rolled corn (n = 5). Forages were also included in the HCP [straw (n = 5), alfalfa hay (n = 1)]. Other ingredients used less frequently were slow release non-protein nitrogen (n = 3), beet pulp (n = 2), rice grain (n = 2), cotton meal (n = 2), safflower (n = 2), whey (n = 2), soybean meal (n = 2), bypass fat (n = 1), ground wheat (n = 1), and soyhulls (n = 1). All dairies but one added the mineral-vitamin mix in the HCP. The ingredients most frequently added first were straw (n = 4), cotton seed (n = 3), canola meal (n = 3), almond hulls (n = 1), mineral-vitamin mix (n = 1) and wheat middlings (n = 1). The ingredients added most frequently last were molasses (n = 5), whey (n = 2), mineral-vitamin mix (n = 4), beet pulp (n = 2), soybean (n = 1) or corn gluten meal (n = 1). Ingredients with assigned tolerance level >10% of admissible deviation from target were mineral-vitamin mix, molasses, and straw (n = 1) and mineral-vitamin mix (n = 1). The frequency of HCP recipes prepared over 10% of the mixer wagon capacity (based on weight) was over 90% in four dairies. There is a large variation in HCP ingredients and preparation across dairies in California.

Key Words: dairy cattle, high cow premix, feeding management software

1161 (T117) Body weight adjustments for feeding status and pregnant or non-pregnant condition in beef cows.

M. P. Gionbelli*[1,2], M. S. Duarte[1], S. C. Valadares Filho[1,2], E. Detmann[1,2], M. L. Chizzotti[1,2], T. R. Gionbelli[1], F. C. Rodrigues[1], D. Zanetti[1], and M. G. Machado[1], [1]*Universidade Federal de Viçosa, Minas Gerais, Brazil,* [2]*Instituto Nacional de Ciência e Tecnologia– Ciência Animal, Viçosa, Minas Gerais, Brazil.*

Dataset from 49 multiparous Nellore cows (32 pregnant and 17 non-pregnant) averaging 451 ± 10 kg was used to develop a set of equations and relations for body weight (BW) adjustments in pregnant or not pregnant cows. Cows were fed a corn silage based diet and weighed every 28 days (0700 h, before feeding) to obtain BW, and reweighed at the same time following day after 16 h fasting to obtain shrunk body weight (SBW). Pregnant cows were separated into four groups of 8 cows and harvested at 136, 189, 239 and 269 days of pregnancy (DOP) to obtain the empty body weight (EBW) and the weight of components related to pregnancy. A set of linear and non-linear equations was tested, based on theoretical suppositions, to establish the relationships between the BW, SBW and EBW of pregnant and non-pregnant cows as function of DOP. The pregnant compound (PREG) was defined as the weight genuinely related to pregnancy, that includes the gravid uterus minus the non-pregnant uterus plus the accretion in udder related to pregnancy. The PREG was deducted from the SBW or EBW of a pregnant cow to estimate the non-pregnant weights (SBW_{np} and EBW_{np}). Results are shown in Table 1161. There was no accretion in udder weight up to 238 days of pregnancy. We conclude that the weight related to the pregnancy can be estimated in a live cow allowing estimate non-pregnant EBW and SBW of a pregnant cow and calculates the body gain of only maternal tissues. *Funded by INCT-CA, CNPq, FAPEMIG.*

Key Words: *Bos indicus*, gestation, gravid uterus

1162 (T118) Changes in performance and immune response in dairy calves offered milk replacer or raw milk.

C. Yunta[1], A. Bach[2,3], and M. Terré*[1], [1]*IRTA, Caldes de Montbui, Spain,* [2]*Dep. of Ruminant Production, IRTA, Caldes de Montbui, Spain,* [3]*ICREA, Barcelona, Spain.*

The objective of the present study was to compare intake, growth performance, and immune response in dairy calves fed milk replacer (MR) or raw milk (RM). Seventy dairy female Holstein calves were randomly assigned to either MR or RM treatments and were offered 750 g/d of MR or RM respectively from days 15 to 56 and 375 g/d from 56 to 63 d of life. All the calves were weaned at d 63 and starter feed was offered ad libitum throughout the study. Daily milk and feed intake was recorded from d 2 to 63. Animals were weighed weekly and blood samples were collected at d 14, 28, 42 and 56 to determine glucose and insulin concentrations. Immune response was evaluated in blood samples collected at 35 d of age by measuring TNFa after an in vitro lipopolysaccharide (LPS) challenge in blood. Also, at d 7, 21 and 35, 1-ml of ovoalbumin was injected to calves and blood samples were collected at day 7 and 56 to measure antibody titers against

Table 1161. Summary of equations used to adjust BW of pregnant and non-pregnant cows

Estimated variable	Predictors	Relation
Non-pregnant cows		
SBW_{np}	BW	$SBW=0.8084\times BW^{1.0303}$
EBW_{np}	SBW_{np}	$EBW_{nP=}0.8424\times SBW_{np}^{1.0122}$
Pregnant cows		
SBW	BW	$SBW = 0.8084\times BW^{1.0303}$
SBW_{np}	SBW and PREG	$SBW_{nP=}SBW–PREG$
PREG	If DOP ≤ 238: GU_{dp} If DOP > 238: GU_{dp} and UD_{dp}	If DOP ≤ 238: $PREG = GU_{dp}$ If DOP > 238: $PREG = GU_{dp} + UD_{dp}$
Gravid uterus accretion due to pregnancy (GU_{dp})	GU and UT_{np}	$GU_{dp} = GU–UT_{np}$
Gravid uterus (GU)	DOP or DOP and body condition score (BCS)	$GU = 0.2243\times BCS^{0.3225}\times e^{((0.02544–0.0000286\times DOP)\times DOP)}$, or $GU = 0.2106\times e^{((0.03119–0.00004117\times DOP)\times DOP)}$
Non-pregnant uterus (UT_{np})	SBW_p and GU	If DOP≤238: $UT_{nP=}0.0012\times(SBW–GU+0.6)$ If DOP > 238: $UT_{nP=}0.0012\times(SBW–GU+0.6–2)$
Udder accretion due to pregnancy (UD_{dp})	UD_{np} and DOP	$UD_{dP=}UD_{np}\times e^{((DOP–238)\times 0.0109)}–UD_{np}$
Non-pregnant udder (UD_{np})	SBW_p and BCS	$UD_{nP=}SBW_{np}\times 0.00589\times BCS^{0.2043}$, or If DOP ≤ 238: $UD_{nP=}(SBW–GU_{dp})\times 0.00589\times BCS^{0.2043}$ If DOP > 238: $UD_{nP=}(SBW–GU_{dp}–2)\times 0.00589\times BCS^{0.2043}$
EBW	EBW_{np} and PREG	$EBW = EBW_{np}+PREG$
EBW_{np}	SBW_{np}	$EBW_{nP}= 0.8424\times SBW_{np}^{1.0122}$

ovoalbumin. Data were analyzed using a mixed-effects model with repeated measures. Data from insulin and insulin to glucose ratio were previously transformed to reach a normal distribution. No differences were found in milk or feed intake, ADG or gain to feed ratio between treatments. Plasma glucose concentrations did not differ between treatments but, plasma insulin concentration was greater ($P < 0.05$) in MR compared with RM calves (1.36 vs 0.78 ± 0.053 μg/L) as it also was the ratio insulin to glucose (0.12 vs 0.07 ± 0.535). Immune response to the in vitro LPS and the in vivo ovoalbumin challenges were similar in both groups. However, RM calves needed to receive antibiotic treatments (24%) fewer times ($P < 0.05$) than those fed MR (37%). In conclusion, even no significant differences were found in intake or growth performance, the lower insulin to glucose ratio and the decrease in the number of antibiotic treatments in RM calves compared with those fed MR, suggested an improvement on glucose metabolism, and a potential benefit on calf health when feeding RM to calves compared with feeding MR.

Key Words: calves, performance, raw milk

1163 (T119) Comparison of albumin depleted and whole serum samples for biomarker identification.

J. K. Grubbs*, C. K. Tuggle, J. C. M. Dekkers, and S. M. Lonergan, *Iowa State University, Ames.*

Serum is a highly complex mixture of proteins with a vast range in concentrations. Ease and accessibility make serum an ideal fluid for biomarker identification. Eight proteins represent over 90% of the protein content of serum. Albumin alone often comprises over 50% of total protein content in serum. Presence of high abundance proteins like albumin has long been a hurdle to proteomic researchers in establishing suitable biomarkers for disease states and other biological statuses. Historically, albumin and other high abundance proteins have been removed from serum prior to biomarker studies. The purpose of this project was to investigate the impact of albumin removal on porcine serum protein profiles and protein spot abundance variation across samples. Serum samples from eight pigs were used; half of each sample was kept as whole serum while the other half was depleted of albumin using a commercially available kit designed to remove 95% of the albumin. Depleted and whole serum samples, for a single pig, were then compared using two dimensional difference in gel electrophoresis for a total of eight comparisons run in duplicate. Among the 236 protein spots identified, 167 were changed in abundance ($P \leq 0.05$) between depleted and whole serum. Of these differences, 87 protein spots were increased in the albumin depleted serum while 76 spots were increased in the whole serum. The 87 spots found to be increased are a result of a shift in protein profile due to the removal of albumin. While some of these changes in protein profile could be linked directly to the location of albumin on the gel, most spots were not co-localized with albumin. Albumin is known to interact with many proteins, thus albumin depletion procedures may alter abundance of such proteins and increase the overall variation within the serum. These data indicate that for serum protein biomarker discovery in animal production, it may be prudent to investigate technologies and methods that allow use of whole serum over depleted serum. These data also show that using gel based proteomic approaches may be one of the technologies that ameliorates the need to deplete high abundance proteins from serum. *This project was supported by Agriculture and Food Research Initiative Competitive Grant no. 2011-68004-30336 from the USDA National Institute of Food and Agriculture.*

Key Words: residual feed effciency, serum, albumin

1164 (T120) Comparison of radial immunodiffusion and enzyme-linked immunosorbant assay for quantification of bovine IgG in colostrum and plasma.

A. M. Smith, S. L. Gelsinger*, C. M. Jones, and A. J. Heinrichs*, Pennsylvania State University, University Park.*

Radial immunodiffusion (RID) is the standard quantification method for bovine IgG in colostrum and plasma. Recent studies have published ELISA IgG values; however, RID and ELISA measurements have not been compared. Heating colostrum to 60°C for 30 min does not decrease IgG concentration measured by RID; use of ELISA has not been tested. This study's objective was to compare ELISA and RID values in plasma and in colostrum before and after heating. Colostrum ($n = 58$) and plasma ($n = 99$) were collected from individual cows and calves and frozen prior to IgG assessment. Colostrum was diluted 1:10 for RID and 1:1,000,000 for ELISA. Two dilution series were created for each sample and duplicated within each assay. Values were accepted when coefficients of variation (CV) were ≤ 10.5% among duplicates from a single dilution series and < 15% among 2 series from the same sample. Samples were retested until acceptable CV were acquired. The effect of heat-treatment was tested by heating 20 mL aliquots of each colostrum to 60° C for 30 min, then cooling, freezing, and retesting using the same dilution factors. Plasma samples were tested by RID without dilution and by ELISA at 1:500,000. Requirements for CV were identical to those used for colostrum. Proc Corr and Proc Mixed in SAS were used to determine correlation coefficients and effect of heat on colostrum IgG quantification, respectively. Mean (± SD) IgG concentration of colostrum before heating was 39.7 mg/mL (± 22.7) and 81.2 mg/mL (± 29.7) by ELISA and RID, respectively; and 19.2 mg/mL (± 12.8) and 76.8 mg/mL (± 34.6) after heating. Heat treatment reduced colostral IgG concentration when measured by ELISA ($P < 0.01$) but not by RID ($P = 0.73$). Correlation coefficients (P - value) were 0.20 (0.14) and 0.27 (0.03) for unheated and heat-treated colostrum, respectively. Fat and non-IgG protein in colostrum may interfere with assays and may be a cause for low correlation. Mean (± SD) plasma IgG concentration was 11.4 mg/mL (± 7.9) by

ELISA and 15.2 mg/mL (± 9.1) by RID. Relative to colostrum, plasma results were more strongly correlated (r = 0.55; $P < 0.01$); however, direct comparisons of ELISA and RID values merit caution. Results from ELISA were < RID for colostrum and plasma, and colostrum IgG decreased during heat-treatment when measured with ELISA. Further research is needed to determine effects of heat-treatment on colostrum IgG.

Key Words: IgG

1165 (T121) Effect of fish oil and thyme on nutrient digestibility, chewing activity, and rumen metabolites of Mahabadi goat kids. A. Hozhabri[1], M. Ganjkhanlou[1], A. Zali[1], A. Emami[2], A. Akbari-Afjani[3], and M. Dehghan-Banadaky[*1], *[1]University of Tehran, Iran, [2]University of Birjand, Iran, [3]University of Zanjan, Iran.*

This study was carried out to determine the effects of supplementing fish oil and thyme on nutrient digestibility, chewing activity and rumen metabolites in Mahabadi goat kids. Twenty-eight goat kids (BW = 17.8 ± 2.8 kg, 4 to 5 mo of age) were randomly assigned to 4 treatments: (1) basal diet (BD), (2) BD + 0.2% thyme essence, (3) BD +2% fish oil, and (4) BD + 2% fish oil and 0.2% thyme essence (DM basis of concentrate). Diets were formulated to meet the requirements recommended by NRC with forage (alfalfa and corn silage): concentrate ratio of 30:70 in TMR form. Animals were kept in individual pens with self-mangers for 94 d. Chewing activity in two 24-h periods was evaluated. During the last 7 d of the experiment, fecal samples were collected every morning around feeding time and acid insoluble ash (AIA) content was used as an internal marker to determine the apparent digestibility of nutrient digestibility. Ruminal fluid samples were taken from the rumen at 3 h after the morning meal the last day of the experiment to determine rumen concentration of ammonia nitrogen (NH_3-N) and VFA. Rumen contents were sampled 5 times during the trial to measure ruminal protozoa and pH. Protozoa counts were determined using light microscopic numeration with a hemocytometer. Protozoa and pH data were analyzed by MIXED model procedure and rumen nutrient digestibility, chewing activity, NH_3-N and VFA with GLM model procedure and adjusted Tukey-Kramer. Addition of fish oil decreased NDF digestibility, and increased ether extract digestibility versus the control ($P < 0.05$). Rumen liquor pH was not affected by treatments (6.11, 6.33, 6.20. and 6.23 respectively for treatments 1-4). Ruminal ammonia concentration decreased by 0.2% thyme essence ($P < 0.05$). Addition of thyme increased acetate concentration and acetate to propionate ratio ($P < 0.1$). It was also found that diets 2 and 3 significantly decreased protozoa count compared with diet 1 ($P < 0.05$). Time to eat (minutes per day) was not affected by treatments ($P > 0.05$), but chewing time significantly decreased by with diet 2 ($P < 0.05$). The results of this experiment indicate that supplementation of goat kid diet with fish oil and thyme changed nutrient digestibility and rumen metabolites.

Key Words: fish oil, nutrient digestibility, thyme essence

1166 (T122) Effect of heat treatment and bacterial population of colostrum on passive transfer of IgG. S. L. Gelsinger[*], and A. J. Heinrichs, *Pennsylvania State University, University Park.*

Heat treatment of colostrum has been shown to increase apparent efficiency of IgG absorption (AEA) in newborn dairy calves. It has been hypothesized that this may be partially due to reduction in bacteria that occurs during heat treatment. This study's objective was to test the effect of bacteria concentration in unheated and heat-treated colostrum on IgG absorption. Colostrum treatments were created by pooling colostrum from individual cows to create a single batch. Half of the colostrum was heated to 60° C and held for 30 min before cooling and rebottling (heat-treated). The remaining half of the colostrum was rebottled without heating (unheated). Half of each treatment was frozen immediately after bottling. Remaining heat-treated colostrum was inoculated with 20 mL of unheated colostrum. Remaining unheated and inoculated heat-treated colostrum were stored at 20° C for 60 and 72 h, respectively, to achieve similar final bacteria populations and subsequently frozen until needed for feeding. Samples were collected from each colostrum treatment for IgG and bacteria analysis prior to freezing. Bull calves ($n = 104$) were randomly assigned to treatment at birth. Plasma samples were collected 48 h after birth and assessed for IgG concentration. Data were analyzed using the PROC MIXED in SAS. Initial SPC was 4.59 log cfu/mL and reduced to 2.79 log cfu/mL following heat treatment. High bacteria treatments of unheated and heat-treated colostrum contained 8.65 and 8.56 log cfu/mL, respectively. Mean AEA (48-h plasma IgG concentration) was 31.25% (20.7 mg/mL) and 15.86% (10.4 mg/mL) in calves fed unheated colostrum of low and high bacteria concentration, respectively; and 37.27% (24.0 mg/mL) and 13.94% (9.3 mg/mL) in calves fed heat-treated colostrum of low and high bacteria concentration, respectively. Bacteria level significantly reduced AEA and 48-h plasma IgG concentration ($P < 0.01$). No effect of heat treatment was observed for 48-h IgG concentration or AEA ($P = 0.42$ and 0.36, respectively); however, there tended to be an interaction between bacterial population and heat treatment for AEA ($P = 0.08$). Slicing the interaction indicated a tendency of heat-treatment to increase 48-h IgG concentration and AEA in low bacteria colostrum treatments ($P = 0.10$ and 0.07, respectively). In this study, concentration of bacteria in colostrum had greater effect on calves' ability to absorb IgG than heat treatment of colostrum.

Key Words: IgG, calf, colostrum

1167 (T123) Effect of omega-3 fatty acids and thyme essence on carcass traits of Mahabadi kids.

A. Hozhabri[1], A. Zali[1], M. Ganjkhanlou[1], A. Emami[2], A. Akbari-Afjani[3], and M. Dehghan-Banadaky[*1], *[1]University of Tehran, Iran, [2]University of Birjand, Iran, [3]University of Zanjan, Iran.*

This study was carried out to determine the effects of supplementing long-chain fatty acids of fish oil and thyme on carcass traits in Mahabadi goat kids. For this aim, twenty-eight Mahabadi goat kids (average initial BW of 17/8 ± 2/8 kg, 4-5mo) were randomly assigned to four treatments: 1) control (basal diet), 2) 0.2% thyme essence, 3) 2% fish oil and 4) 2% fish oil +0.2% thyme essence.Animals were kept in individual pens with self-mangers for 94 d. Diet was formulated to met the requirements recommended by NRC with forage (alfalfa and corn silage): concentrate ratio of 30:70 in TMR form. Kids were weighed after 10 d of adaptation and at 21 d intervals after feed restriction and slaughtered at the end of the trial by Iranian traditional procedure . The area of the 9, 10, 11, 12 and 13 ribs together with the adjoined section of spinal column was used to estimate the amount of bone-free meat, fat and bone in the carcass. The meat, fat and bone were weighed after separation and the bone-free meat component stored at -20 °C for the chemical analysis. Data were analized by GLM procedure of SAS 9.1 and tukey test ($P \leq 0.05$). Addition of 2% fish oil increased fat depth over 12 rib ($P < 0.05$). Dressing percentage, eye muscle area, carcass length, liver and kidney weight, abdominal and kidney fat were not affected by treatments ($P > 0.05$). Percentages or weights ribs dissected muscle, fat and bone, and percentages of wholesale cuts of the carcass were not affected by fish oil and thyme essence ($P > 0.05$). The results of this experiment indicate that supplementation of goat kid diet with fish oil and thyme did not influence carcass traits but, fish oil increased back fat thickness.

Key Words: thyme essence, fish oil, carcass traits

1168 (T124) Effect of stage of pregnancy, maternal feeding level and fetal sex on fetal gut length in Holstein×Zebu cows.

T. R. Gionbelli[*1], P. P. Rotta[1], C. M. Veloso[1,2], M. P. Gionbelli[1,2], S. de Campos Valadares Filho[1,2], M. A. Novaes[1], J. V. Souza[1], J. S. Santos[1], L. C. Lacerda[1], and C. S. Cunha[1], *[1]Universidade Federal de Viçosa, Minas Gerais, Brazil, [2]Instituto Nacional de Ciência e Tecnologia–Ciência Animal, Viçosa, Minas Gerais, Brazil.*

Lower gut development at birth is suggested as one hypothesis for explain the lower development during the whole life of calves from cows that were low fed throughout gestation. These calves can have lower absorption of immunoglobulin right after birth and consequently lower immune capacity and be more susceptible to diseases that can impair the normal development. Forty-one nonlactating multiparous Holstein × Gyr cows, pregnant from the same Gyr bull, were used in an experiment to assess the effect of stage of pregnancy, maternal feeding level and fetal sex on fetal gut length. Cows were fed either HIGH (ad libitum, $n = 18$) or LOW(DMI restricted to 1.15% of BW in DM basis, $n = 23$) feeding level of the same diet (93% corn silage and 7% concentrate). Fetal sex was confirmed by ultrasonography at 55 days of gestation. Cows were separated at random into four groups, which were harvested at 100, 200, 240 and 270 days of gestation ($n = 4/5$, 5/6, 5/6 and 4/6 for HIGH/LOW fed cows at 100, 200, 240 and 270 days, respectively) with at least two cows gestating same sex fetuses being harvested at each time. At harvest, fetuses were collected and dissected and gut was emptied and separated into small and large intestine, which were measured. Data were analyzed in a 2×2×4 factorial with two feeding level, two fetal sex and four stages of pregnancy. There were no significant interactions ($P > 0.19$) among feeding level, fetal sex and days of pregnancy on gut length. Small intestine and total gut length were not affected by feeding level ($P = 0.86$ and 0.75, respectively) and fetal sex ($P = 0.87$ and 0.71, respectively). Large intestine was longer ($P = 0.049$) in female (134.9 cm) than in male fetuses (123.4 cm) but was not affected by feeding level ($P = 0.16$). Fetal small and large intestine and total gut length increased ($P < 0.001$) as the pregnancy age increased but were not different between 240 and 270 days of gestation ($P = 0.64$, 0.78 and 0.62, respectively). The average fetal gut length was 431, 976, 1272 and 1361 cm at 100, 200, 240 and 270 days of gestation, respectively. The results suggest that female fetuses have longer large intestine than male fetuses, although the explanation for this finding is still inconclusive and requires further studies.
Funded by INCT-CA, CNPq and FAPEMIG.

Key Words: fetal programming, gut development, maternal nutrition

1169 (T125) Intrauterine position affects fetal weight and crown-rump length throughout gestation.

Y. D. Jang[*], Y. L. Ma, and M. D. Lindemann, *University of Kentucky, Lexington.*

To investigate the effect of intrauterine position on fetal growth throughout gestation, data from 64 gilts ($n = 784$ fetuses) that were slaughtered at assigned days of gestation (d 43, 58, 73, 91, 101, and 108; $n = 8$, 11, 11, 12, 11, and 11, respectively) on a project to evaluate fetal mineral deposition were used. Placental units were removed from the uterus, and position, sex, weight, and crown-rump length (CRL) of each fetus were recorded. Fetuses were classified into 5 categories for absolute intrauterine position: the ovarian end (OE) of the uterine horn, next to the ovarian end (NOE), the middle (M), next to the cervical end (NCE), and the cervical end (CE). Fetuses at the OE and NOE of the uterine horn were heavier (108.6, 109.3, 101.9, 103.6, and 105.0 g for OE, NOE, M, NCE, and CE, respectively; $P = 0.06$) and longer (12.8, 12.6, 12.2, 12.1, and 12.3 cm; $P < 0.01$) than those in the M at d

58 of gestation. Fetuses at the OE of the uterine horn were also heavier and longer than those at M and NCE at d 101 (1078.9, 1015.6, 945.5, 890.6, and 956.2 g, and 28.4, 27.4, 26.8, 26.3, and 26.8 cm; $P < 0.01$) and 108 (1410.3, 1453.4, 1318.0, 1254.1, and 1407.9 g, and 31.6, 31.4, 30.6, 30.1, and 31.1 cm; $P < 0.01$) of gestation. Fetuses at the CE were intermediate in weight and length. Male fetuses were heavier than female fetuses at d 43 (16.9 vs. 15.9 g), 58 (109.4 vs. 101.1 g), 73 (350.9 vs. 331.7 g), and 108 (1410.6 vs. 1298.6 g) of gestation ($P < 0.05$) and longer than female fetuses at d 58 (12.5 vs. 12.3 cm; $P = 0.06$), 73 (18.9 vs. 18.5 cm; $P < 0.05$), 101 (27.4 vs. 26.8 cm; $P = 0.07$), and 108 (31.1 vs. 30.5 cm; $P < 0.05$) of gestation. Fetal weight was highly correlated with CRL at all gestational ages (r = 0.778 to 0.955; $P < 0.01$). These results indicate that the absolute intrauterine position affects fetal growth such that each end of the uterine horn has heavier fetuses than the middle, and that male pigs grow faster than female pigs even prior to birth.

Key Words: fetal growth, gestation age, intrauterine position

1170 (T126) Milk diet but not quercetin intake affects postprandial glucose metabolism in neonatal calves. J. Gruse[1], S. Görs[1], W. Otten[1], J. M. Weitzel[1], S. Wolffram[2], C. C. Metges[1], and H. M. Hammon[*1], *[1]Leibniz Institute for Farm Animal Biology (FBN), Dummerstorf, Germany, [2]Institute of Animal Nutrition and Physiology, University of Kiel, Germany.*

The hypothesis was tested that the flavonoid quercetin, which exerts effects on glucose metabolism in several species, influences postprandial glucose uptake in neonatal calves and that this effect depends on milk diet. Twenty-seven new-born male German Holstein calves were randomly assigned to two feeding groups receiving same amounts of either colostrum (C; $n = 14$) or a milk-based formula (F; n = 13) with same nutrient density as C, but no biologically active factors during the first two d of life. From d 3 to d 7, all calves were fed milk replacer at 12% of BW (150 g powder/L). From d 2 on, groups were subdivided each into a treatment group receiving 150 µmol/(kg BW × d) quercetin as quercetin aglycon with milk and a control group without additional quercetin. On d 7, calves were tube-fed their morning meal (4% of BW) mixed with 10 mg/kg BW [$^{13}C_6$]-glucose and the daily quercetin dose. Immediately afterwards, an intravenous bolus dose of [6.6-$^2H_2$]-glucose (5 mg/kg BW) was applied through a jugular vein catheter. Blood samples were taken to measure plasma ^{13}C and ^2H glucose enrichments and to calculate rates of glucose appearance ($Ra_{i.v.}$ resp. Ra_{oral}) and fractional first pass splanchnic uptake (FPU) of glucose. Additional blood samples were taken to determine plasma concentrations of glucose, insulin, glucagon, noradrenaline and adrenaline. Data were analysed either by General Linear Model or by PROC MIXED of SAS with feeding, quercetin, and time as fixed effects. Plasma concentrations of glucose, insulin, glucagon, and adrenaline were greater ($P < 0.05$) in C- than in F-fed calves. Recovery of decreased adrenaline to basal concentrations was faster ($P < 0.05$) when quercetin was fed. Glucose FPU and Ra_{oral} were greater ($P < 0.05$) in F- than in C-fed calves, but were not affected by quercetin. Results underline the importance of colostrum feeding during the first days of life on postprandial glucose metabolism and indicate that quercetin does not have a major effect on glucose metabolism neither in C- nor in F-fed neonatal calves.

Key Words: quercetin, glucose first-pass uptake, calf

1171 (T127) Ontogenic gene expression profiles in pig hepatogenesis. J. Kwintkiewicz[*1], T. J. Caperna[1], T. G. Ramsay[1], H. D. Guthrie[1], C. C. Talbot[2], L. L. Schreier[1], and L. A. Blomberg[1], *[1]USDA-ARS-BARC, Beltsville, MD, [2] Johns Hopkins School of Medicine, Baltimore, MD.*

Liver is a key organ required for development and growth, whether fetal or post partum. Selection for greater litter size in swine has resulted in increased variability in piglet weight/litter, and greater weight piglets thrive better postnatally. To better understand hepatogenesis, comprehensive ontogenic gene expression profiling was performed to determine baseline expression patterns associated with liver development. Liver was collected from the greatest weight fetus of four distinct unilaterally hysterectomized:ovariectimized gilts at prenatal day (PND) 37, 50, 70, and 110. Total RNA was isolated, mRNA amplified and subjected to microarray analysis (Agilent). Three comparisons were performed: PND50 vs. PND37, PND70 vs. PND50 and PND110 vs. PND70; only genes whose expression, between at least two time points, was ± 1.5 fold with $P < 0.05$ were characterized further. A total of 6061 annotated genes exhibited altered expression: 648 down- and 341 up-regulated at PND37 vs. PND50; 666 down- and 1399 up-regulated at PND70 vs. PND50; and 1564 down- and 1443 up-regulated at PND110 vs. PND70. Thirty-five transcripts were selected for validation by absolute quantitative PCR; they clustered into five functional categories: 1) hematopoietic and early liver function, 2) extracellular matrix, 3) hepatocyte function, 4) biliary function, and 5) transcription factors. To examine changes elicited following parturition, liver was collected from greatest weight piglets at post partum day (*P*PD) 1 ($n = 3$) and 2 ($n = 4$) and analyzed along with fetal samples. The expression of hematopoietic genes (e.g. coproporphyrinogen oxidase) was high at PND37 and declined by mid-gestation. Similarly, the expression of markers of undifferentiated hepatoblasts (e.g. Cbp/P300-Interacting Transactivator 1) was high in early gestation and decreased below the detection threshold post partum. In contrast, the abundance of extracellular matrix genes (e.g. hevin) peaked perinatally. Hepatocyte serum or enzyme transcripts increased gradually with a maximum induction at PPD2 vs. PND37 (e.g alcohol

dehydrogenase, a 2,266-fold increase). Likewise, the expression of inhibin beta B, involved in biliary duct morphogenesis, increased 188-fold. Transcription factors (e.g. hepatocyte nuclear factors) exhibited small variation during gestation but were significantly elevated perinatally. More impressive was the up-regulation (79-fold) of Kruppel-like factor 9 at and beyond PND 110 vs. earlier time points. The study identified commonalities and differences of expression profiles to those observed in other species; this should help scientists navigate new routes of investigation in liver cell function in swine. Future studies will examine dysregulation of these genes in runt or slow growing pigs.

Key Words: liver, development, pig

1172 (T128) Production of bioactive porcine mutant myostatin propeptide/Fc fusion protein in *Escherichia coli*. S. B. Lee*[1], S. K. Park[2], and Y. S. Kim[1], *[1]University of Hawaii, Honolulu, [2]National Institute of Animal Science, RDA, Suwon, South Korea.*

Skeletal muscle mass is negatively regulated by myostatin (MSTN), implying that MSTN inhibition would be a potential approach to increase skeletal muscle mass of meat producing animals. The activity of MSTN is suppressed by MSTN propeptide (MSTNPro), the N-terminal region of unprocessed MSTN that is cleaved off during post-translational MSTN processing. The objective of current study was to produce a mutant form of porcine MSTNPro fused to the Fc region of pig immunoglobulin G (*P*MSTNProM-Fc) in *E. coli* in order to examine its potential as an agent to enhance muscle mass in pigs. The *pMSTNProM-Fc* cDNA was constructed and cloned into pMAL-c5x vector downstream of the maltose-binding protein (MBP) gene, then was transformed and expressed in soluble forms in *E. coli*. For each L of cell culture at 4°C for 7 days, about 13 mg of soluble MBP-pMSTNProM-Fc protein was purified by amylose-resin affinity chromatography. Further purification by protein A agarose affinity chromatography yielded about 0.64 mg/L culture of MBP-pMSTNProM-Fc protein. MBP-pMSTNProM-Fc inhibited MSTN bioactivity in a dosage-dependent manner in an in vitro gene reporter assay. The capacity of MBP-pMSTNProM-Fc to inhibit MSTN was comparable to those of MBP-pMSTNPro produced in *E. coli* and commercially-available murine MSTNPro produced in an eukaryotic system. Results from the current study show that Fc fusion to MBP-pMSTNPro does not affect the bioactivity of MBP-pMSTNPro, and the production of bioactive, mutant form of pig MSTN propeptide/Fc fusion protein is possible in *E. coli*.

Key Words: myostatin propeptide, pig, Fc fusion protein

1173 (T129) Short- and medium-term changes in performance and metabolism of dairy calves offered different amounts of milk replacer. C. Yunta[1], M. Terré[1], and A. Bach*[2,3], *[1]IRTA, Caldes de Montbui, Spain, [2]ICREA, Barcelona, Spain, [3]Dep. of Ruminant Production, IRTA, Caldes de Montbui, Spain.*

The objective of the present study was to compare the intake, growth, and glucose metabolism of dairy calves fed 4, 6 or 8 L/d of milk replacer (MR). One hundred and twenty female calves were randomly assigned to one of the 3 groups (4L, 6L, and 8L) differing only in the quantity of MR offered. Daily MR and feed intakes were recorded. Calves were weighed at days 0, 35 and 63. Average daily gain (ADG) at day 35 (ADG35) and at day 63 (ADG63) as well as gain to feed (GtoF) were calculated. A glucose tolerance test (GTT), consisting of 180 mg of glucose per kg of BW infused into the jugular vein of 15 heifers per group, was performed at days 42 and 86 of life. Blood samples were collected at -5, 0, 4, 8, 12, 18, 25, 35, 35 and 60 min relative to glucose infusion and glucose and insulin levels were analyzed. Area under the curve (AUC), clearance rate (CR), insulin to glucose rate (ItoG) and insulin sensitivity were calculated. Data were analyzed using a mixed effects model with repeated measures. Total DMI was greatest ($P < 0.05$) for 8L calves (1,010 ± 22 vs 950 ± 23 g/d), but 6L and 8L calves consumed less starter feed ($P < 0.05$; 205 ± 21 g/d) than 4L calves (400 ± 22 g/d). Calves on 8L had the greatest ($P < 0.01$) ADG35 (757 ± 20.1 g/d) followed by 6L (566 ± 19.8 g/d) and 4L calves (476 ± 20.4 g/d); but ADG63 did not differ among treatments. Allowance of MR did not affect GtoF ratio. Glucose AUC or CR did not differ between treatments. However, calves on 8L produced more ($P < 0.005$) insulin (2,365 ± 211 µU/mL x 60min) than 6L (1,353 ± 219) or 4L (1,300 ± 219) calves. Calves on 8L, had an ItoG (177.5 ± 20.76 µU/mg) that was almost 2-fold greater ($P < 0.05$) than in 4L (93.1 ± 21.17) and 1.5-fold greater ($P < 0.05$) than in 6L (113.6 ± 21.17) calves. Insulin sensitivity tended ($P = 0.07$) to be less in 8L (3.38 ± 0.30 mL/min x µU/mL per kg of BW) than in 4L or 6L calves (3.43 ± 0.30). We concluded that offering 8 L/d of MR elicits a decrease in starter feed intake and tends to decrease insulin sensitivity of calves.

Key Words: calves, enhanced-feeding, metabolism

1174 (T130) Stabilization of intestinal mast cells at weaning improves performance of early-weaned pigs. A. Mereu[1], M. G. Tedo[1], J. Charve[1], A. J. Moeser[2], and I. R. Ipharraguerre*[1], *[1]Lucta S.A., Montornés del Vallés, Spain, [2]North Carolina State University, Raleigh.*

Previous work showed that weaning stress causes gut barrier dysfunction partly by triggering the release of corticotropin releasing factor (CRF) and thereby inducing the degranulation of intestinal mast cell (MC). This study investigated the

hypothesis that attenuating the weaning-induced activation of the CRF-MC axis via administration of a MC stabilizing agent (cromolyn) may improve gut permeability and piglet performance after weaning. Twenty piglets (Large White x Landrace x Pietrain) were weaned (20 ± 1 d of age; 6.4 ± 0.4 kg of BW) and injected intraperitoneally with saline (control, n = 10) or 20 mg/kg BW of sodium cromolyn (CR, n = 10) at – 0.5, 8 and 16 h relative to weaning. Piglets were housed individually and fed *ad libitum* a pre-starter diet from 0 to 14 d postweaning followed by a starter diet until the end of the study on d 35. Body weight and feed intake were measured weekly; the plasma concentration of CRF and MC tryptase (MCT) was measured on d 2; and the plasma recovery of lactulose and Co-EDTA (*P*ermeability markers) was assessed 1 h after intragastric infusion on d 2 and 35. On d 35, 8 pigs/treatment were sacrificed and their intestines were collected for later analyses. Performance data were analyzed with a mixed-effects model with repeated measures in time in which pig was treated as random effect and treatment, week, and their interaction as fixed effects. All other variables were analyzed with the same model without repeated measures. Plasma concentration of CRF, MCT, and permeability markers and mucosal morphology of the ileum were not affected by treatments. Although not significant, CR pigs had 15% more granulated MC in the ileum than control pigs (66.3 vs. 51.7 ± 0.10 cells/mm^2; $P < 0.20$). On average, CR pigs consumed more feed (369 vs. 313 ± 13.6 g/d; $P < 0.01$), gained more BW (283 vs. 234 ± 11.7 g/d; $P < 0.01$), and grew more efficiently (0.60 vs. 0.40 ± 0.07; $P < 0.05$) than their control counterparts. As a result, pigs on the CR group were 1.4 kg heavier than those in the control group by d 35 (16.5 vs. 17.9 ± 0.17 kg; $P < 0.01$). In conclusion, interventions capable of moderating the weaning-induced activation of the CRF-MC axis may contribute greatly to improve pig performance after weaning.

Key Words: stress, gut permeability, growth

1175 (T131) The effect of essential oil/botanical product on growth and performance of calves fed milk replacer.

B. L. Miller[*1], T. Earleywine[2], W. S. Bowen Yoho[3], and T. E. Johnson[3], *[1]Land O'Lakes–Purina Feed LLC, Gray Summit, MO, [2]Land O'Lakes Animal Milk Products, Shoreview, MN, [3]Land O' Lakes, Inc., Webster City, IA.*

In two separate trials, the growth and performance of calves fed milk replacer (MR) containing an essential oil/botanical product were examined. Eighteen (18) and thirty-two (32) 3 – 10 d old Holstein bull calves with average initial weights of 43.3 kg (SD = 1.62 kg) and 47.6 kg (SD = 2.50 kg) were shipped from Wisconsin to the Land O' Lakes Research Facility for trials 1 and 2, respectively. Calves were randomly assigned according to body weight (BW) and blood gamma globulin to either a control or experimental milk replacer. The experimental MR in both trials was the same as the control with an essential oil/botanical product (Digestarom, Micro-Plus Konzentrate; Stadtoldendorf, Germany) included at 0.05% active ingredient. Calves on trial 1 were fed to provide 680 g DM/d of a 22% protein/20% fat MR during d 1 to 35 in 2 feedings at 0600 and 1515h. Days 36 to 42, calves were offered 340 g DM/d in one feeding at 0600h. Calf starter (20% CP, as fed basis) was fed ad libitum. Calves on trial 2 were fed a 27% all milk protein/10% fat MR to provide 816 g DM/d during d 1 to 7, and 1135 g DM/d during days 8 – 42, in 2 feedings. Calves were offered 567.5 g in one feeding at 0600 h during days 43 - 49. Calf starter (22% CP, as fed basis) was fed ad libitum. Data were analyzed by PROC MIXEDs of SAS. For trial 1, calves offered no essential oil/botanical product tended to be inferior in total weight gain ($P = 0.12$) and MR consumption ($P = 0.11$) when compared to calves offered an essential oil/botanical product. Calves receiving an essential oil/botanical product were numerically higher ($P > 0.05$) in total starter consumption when compared to calves receiving no essential oil/botanical product. For trial 2, while there was no statistical difference ($P > 0.05$) in total body weight gain, calves fed an essential oil/botanical product were numerically higher in total body weight gain when compared to calves fed no essential oil/botanical product. Calves offered an essential oil/botanical product were superior in feed efficiency ($P = 0.07$), hip height gain ($P \leq 0.01$), and heart girth gain ($P < 0.05$), when compared to calves offered no essential oil/botanical product. Essential oil/botanical product improved calf growth and performance.

Key Words: calf, milk replacer, essential oil

1176 (T132) The effects of feeding strategy and housing management on intake and growth performance of Holstein calves from birth through weaning.

H. M. Gauthier[1], S. E. Williams[*1], D. M. Shenk[1], C. S. Ballard[1], K. M. Morrill[2], and H. M. Dann[1], *[1]William H. Miner Agricultural Research Institute, Chazy, NY, [2]Cornell University, Ithaca, NY.*

Forty-eight Holstein calves with an average birth weight of 42.5 ± 0.4 kg were used in a randomized block design to evaluate feeding strategy and housing management from birth through weaning (wk 8). Calves were fed 675 g of colostrum replacer (≥ 180 g IgG; The Saskatoon Colostrum Co. Ltd.) within 2 h of birth. Serum total protein averaged 5.6 ± 0.1 g/dL at 2 d of age. Treatments were: 1) fixed feeding of milk replacer at 770 g DM/d from birth through 15 d of age and 900 g DM/d thereafter split into 2 feedings with calves housed in individual hutches (FI; n = 16), 2) ad libitum feeding of milk replacer with calves housed in individual hutches (AI; n = 16), and 3) ad libitum feeding of milk replacer with calves housed as a group of 4 in group hutches (AG; n = 16). Milk replacer was 24% CP and 20% fat and fed at 14% solids. Calves received water and a 23% CP starter concentrate ad libitum. Weaning occurred over a 6-d period with FI calves fed 450 g DM/d and AI and AG calves fed 900 g DM/d for 3 d

followed by 450 g DM/d for 3 d. Intake was measured daily. Body weight was measured weekly. Data were analyzed with the PROC MIXED of SAS with the experimental unit defined as a group of 4 calves with data expressed on a per calf basis. When calves were individually housed, ad libitum feeding resulted in greater intake, average daily gain, and feed efficiency than fixed feeding. Intake and body weight gain were not affected by housing when calves were fed ad libitum. However, the AG calves had a better feed efficiency than AI calves suggesting that there may be benefits to group housing and the social interaction it provides the calves although the mechanism is unclear.

Key Words: calves, growth performance, milk replacer

Table 1176.

	Treatment				*P*-value	
	FI	AI	AG	SE	FI vs. AI	AI vs. AG
Milk replacer intake, kg DM	40.6	59.7	54.8	3.4	<0.01	0.35

1177 (T133) The impact of in utero heat stress and nutrient restriction on progeny body composition.

J. S. Johnson[*1], M. Abuajamieh[1], M. Sanz Fernandez[1], J. T. Seibert[1], S. K. Stoakes[1], A. F. Keating[1], J. W. Ross[1], J. T. Selsby[1], R. P. Rhoads[2], and L. H. Baumgard[1], *[1]Iowa State University, Ames, [2]Virginia Tech, Blacksburg.*

We demonstrated that in utero heat stress (IUHS) alters future tissue accretion in pig progeny. Whether this results from reduced maternal feed intake (FI) or the direct effect of heat stress (HS) is not clear. Study objectives were to compare the rate and quantity of tissue accretion in growing rats exposed to differing in utero environments. On gestation d 3, pregnant Sprague Dawley rats were exposed to either thermoneutral (TN; constant 22°C; $n = 4$), HS (cyclical 34ºC nighttime and 30°C daytime; $n = 4$), or pair-fed to HS-counterparts in TN conditions (*P*FTN; constant 22ºC; $n = 4$) until d 19 of gestation. HS increased ($P < 0.01$) dam rectal temperature (1.3ºC) compared to TN and PFTN conditions, and reduced FI ($P < 0.01$; 14.1 vs. 21.0 g/d) compared to TN controls. Litter size was similar ($P > 0.96$; 10.9 pups/litter) for all treatments and pup birth weight was reduced ($P < 0.04$; 29.7%) in HS dams versus TN controls. At d 26 of life, two male pups per dam [n = 8 in utero TN (IUTN); $n = 8$ IUHS; $n = 8$ in utero PFTN (IUPFTN)] were selected, and initial body composition was determined using dual-energy x-ray absorptiometry (DXA). Following the initial scan, all offspring were individually housed in TN conditions (21.8 ± 0.1°C) and DXA analyses were repeated on d 46 and 66 of life. In utero treatment did not alter ($P > 0.81$) offspring BW, FI (18.6 g/d) or ADG (5.8 g/d) from d 26 to 66. Body fat content and total adipose tissue were increased ($P < 0.01$) in IUPFTN (19.8% and 39.6 g, respectively) compared to IUTN and IUHS offspring (17.9% and 35.9 g, and 17.6% and 34.1 g, respectively). IUPFTN offspring had reduced ($P < 0.01$) body lean tissue compared to IUTN and IUHS counterparts (77.9 vs. 79.8 and 80.1%, respectively). Body composition did not differ between IUHS and IUTN offspring. In utero treatment did not alter body ash content. From d 26 to 66 the adipose to lean tissue accretion ratio was greater ($P < 0.01$; 19.2%) for IUPFTN compared to IUHS offspring. Epididymal fat pad weight was increased ($P < 0.04$; 21.6%) in IUPFTN versus IUHS offspring. In summary and in contrast to pigs, IUHS did not appear to impact body composition; however, IUPFTN rats likely experienced prenatal imprinting that altered the future hierarchy of tissue accretion.

Key Words: in utero heat stress, rat, tissue accretion

1178 (T134) Weight, height and relative accuracy indicators as a management tool for reducing age at first breeding and calving of dairy heifers.

M. Duplessis[*1,2], R. Lacroix[2], R. I. Cue[3], D. E. Santschi[2], and D. M. Lefebvre[2], *[1]Université Laval, Département des Sciences Animales, Québec, Canada, [2]Valacta, Ste-Anne-de-Bellevue, QC, Canada, [3]McGill University, Dep. of Animal Science, Ste-Anne-de-Bellevue, QC, Canada.*

In Québec, Canada, age at first calving occurs on average at 27 mo, whereas the target is 22 to 24 mo to maximize herd profitability. The aim of this study was to generate indicators (such as heifer weight and height at 15 and 24 mo, and age at which optimal weight for breeding is attained i.e. 55% of mature weight) and their respective relative accuracy (RA) using a growth predicting model based on random regression. Weight and height data records from 1995 to 2012, respectively measured by chest girth, and height at the withers on Holstein (HO), Jersey (JE), and Brown Swiss (BS) dairy heifers were obtained from Valacta database (DHI agency, Ste-Anne-de-Bellevue, QC, Canada). Heifers with less than two records were excluded from the analysis. For each heifer, weight at 15 and 24 mo were computed using a second degree polynomial equation for which individual parameters were obtained from random regression using R (v1.15.2) and nlme package. For height, a non-linear mono-molecular random regression model was used. Age at optimal breeding weight was calculated by the square root of the second degree polynomial equation. Relative accuracy was calculated as the prediction error variance, relative to an RA of 99% when a heifer was measured routinely every 3 mo, starting at 2 mo of age. Table 1178 shows the mean, standard deviation (SD) of the five indicators described above, RA and mature weight. It is possible to observe that,

Table 1178. Indicators with their respective relative accuracy (RA, %)

Indicators	Holstein			Jersey			Brown Swiss		
	Mean	SD	RA	Mean	SD	RA	Mean	SD	RA
Weight at 15 mo (kg)	425	34	87	297	26	92	379	36	87
Weight at 24 mo (kg)	627	39	43	429	27	60	560	43	67
Height at 15 mo (cm)	134	4.8		122	4.0		130	5.3	
Height at 24 mo (cm)	143	5.9		131	4.0		140	6.2	
Age at optimal breeding weight (mo)	13.6	1.4		12.7	1.4		14.5	1.7	
Mature weight	710	65		470	64		670	61	

on average, dairy heifers in Québec, Canada could be bred at 13.6 mo, the optimal age for a first calving at 24 mo. These indicators could be calculated on an individual-heifer and on a herd-level basis, and used on farm as a management tool for reducing age at first breeding and at first calving.

Key Words: dairy heifers, age at first breeding, age at first calving

1179 (T135) Growth and health of pre-weaned Holstein dairy heifers fed Proternative SF in combination with Levucell. S. D. L. Gadeken[*1], A. D. Garcia[2], F. Díaz-Royón[2], T. Erickson[1], and A. Aguilar[3], *[1]South Dakota State University, Brookings, [2]Dairy Science Dep., South Dakota State University, Brookings, [3]Lallemand, Martinsville, IN.*

The objective of this experiment was to evaluate the effects of grain starter supplemented with two live yeast-cell products on health and growth of pre-weaned Holstein heifers. In July 2013, sixty newborn heifers from a local dairy were blocked by weight and serum protein concentration (SPC). A texturized calf starter was prepared with half of the batch used as control (NS). The other half was yeast-supplemented (YS), to contain in each 1.14 kg of starter, 10 billion colony forming units (CFU) of Proternative SF (*Saccharomyces cerevisiae boulardii),* and 10 billion CFU of Levucell SC (*Saccharomyces cerevisiae*I-1077), both from Lallemand Animal Nutrition (Milwaukee, WI). The starter was formulated with cracked corn, whole oats, protein pellets, liquid fat, molasses, corn gluten feed, Bio-Mos (Alltech Inc., Nicholasville, KY), and Deccox (Zoetis, Inc. Kalamazoo, MI). Blood SPC was measured at birth with a refractometer (Misco #PA202X, Cleveland, OH). Growth was assessed on d 0, 30 and 60 d using an electronic scale, measuring tapes, and a hipometer. Calves were individually housed in polypropylene hutches until weaned at d 60. Two liters of farm-pasteurized milk (UV Pure) were bottle-fed twice daily. Starter was fed daily to 6d old calves at d1. Starter intake and individual orts were measured. Drinking water was constantly available. An SPC of 6.5 g/dL observed in both NS and YS calves suggested high passive immunity transfer, as it is strongly correlated with IgG concentrations. This exceeded the concentrations of 5.5 g/dL SPC considered excellent by the dairy industry. There was a trend for higher starter DMI (11%) in calves fed YS(1.14 kg vs. 1.01 kg for YS and NS, respectively) (P = 0.09). Weight gains (70.3 kg vs. 69.6 kg, P = 0.68), whither heights (86.4 vs. 86.9cm, P = 0.77), hip heights (91.9cm vs. 91.4cm, P = 0.59), and hip widths (27.5cm vs. 27.4cm, P = 0.58) were not different between YS and NS, respectively. Three animals were removed from the experiment due to hernias or reduced motility; no significant respiratory problems or diarrhea were observed. Under the conditions of this experiment, calf growth was not different between treatments. This can be attributed in great part to the very high SPC result of excellent colostrum feeding program which may have negated the beneficial impact of yeast supplementation.

Key Words: heifers, calves, growth, *Saccharomyces*

GROWTH & DEVELOPMENT II

1180 (W116) Effect of incubation temperature on the proliferation and differentiation of pig preadipocytes in primary culture. A. E. Bohan*, J. Bartosh, and T. D. Brandebourg, *Auburn University, Auburn.*

Better understanding molecular mechanisms governing the proliferation and differentiation of pig preadipocytes may provide insight into the regulation of adipose tissue development in vivo. Primary cultures of pig preadipocytes have served as a useful tool for investigating these mechanisms. However, to date, such cultures have generally been maintained at 37°C while normal body temperature in pigs is 39.2°C. This raises questions concerning the physiological relevance of culturing primary pig preadipocytes at 37°C. The objective of this study was to investigate the effect of culture temperature, 37 vs. 39°C, on the proliferation and differentiation of pig preadipocytes in primary culture. The effect of temperature on preadipocyte proliferation was determined using the MTT, resazurin, and cell count assays as markers for proliferation. Preadipocyte number was increased 30 to 50% when cultures were incubated at 39 vs. 37°C based upon cleavage of the tetrazolium salt, MTT ($P < 0.001$), reduction of resazurin ($P < 0.001$), and daily cell counts ($P < 0.001$). Differentiation was monitored on d 8 after induction morphologically, enzymatically, and by measuring the mRNA abundance of key adipogenic transcription factors via real-time PCR. Glycerol-3-phosphate dehydrogenase (GPDH) activity was higher in differentiating cultures maintained at 39°C than in cultures differentiated at 37°C ($P < 0.01$) in agreement with increased lipid accumulation observed in these cultures as measured by Oil Red O staining suggesting that cultures maintained at 39°C differentiated to a greater degree than those maintained at 37°C. Finally, the effect of temperature on gene expression was investigated. Expression of peroxisome proliferator-activated receptor gamma (*P*PARγ; $P < 0.01$), CCAAT/enhancer binding protein α (C/EBPα; $P < 0.01$), bone morphogenic protein 2 (BMP2; $P < 0.05$), bone morphogenic protein 4 (BMP4; $P < 0.05$), and adiponectin ($P < 0.001$) were higher while mRNA expression of CCAAT/enhancer binding protein beta (C/EBPβ; $P < 0.01$) was lower in cultures differentiated at 39°C versus those differentiated at 37°C. Collectively these data indicate that culturing primary preadipocytes at 37 rather than 39°C decreases their proliferation rates and suppresses their adipogenic potential. Furthermore the observation that incubation temperature influences gene expression in primary cultures of pig preadipocytes raises the possibility that studying porcine adipocyte hyperplasia at temperatures below physiological body temperatures may confound the ability to extrapolate observations concerning the underlying mechanisms regulating proliferation and differentiation of primary cultures of pig preadipocytes to the live animal.

Key Words: adipocyte, primary culture, pig

1181 (W117) Effects of maternal nutrient restriction on muscle satellite cell activity. J. S. Raja*, M. L. Hoffman, K. N. Peck, K. E. Govoni, S. A. Zinn, and S. A. Reed, *Dep. of Animal Science, University of Connecticut, Storrs.*

Postnatal muscle growth is altered by poor maternal nutrition during gestation. Satellite cells are myogenic precursor cells that contribute to postnatal muscle growth. Satellite cell activity can be evaluated by the expression of several transcription factors that are critical for proper myogenesis. Pax7 is expressed in quiescent and active satellite cells. Expression of MyoD is increased in active and proliferating satellite cells and terminal differentiation is marked by expression of myogenin. We hypothesized that poor maternal nutrition during gestation would alter the temporal expression of Pax7, MyoD and myogenin in satellite cells in vitro. Multiparous ewes ($n = 23$) were housed individually and fed 100% or 60% NRC requirements beginning at d 31 ± 1.3 of gestation. Lambs from control-fed (CON) or restricted-fed (RES) ewes were euthanized within 24 h of birth (d 1; $n = 12$) or were maintained on a control diet until 3 mo of age ($n = 11$). Satellite cells were isolated from the semitendinosus muscle at necropsy and cryopreserved until further use. Satellite cells were cultured in growth media for 24, 48 or 72 h before immunostaining for Pax7, MyoD and myogenin. Hoechst dye was used to visualize nuclei. The percent of immunopositive cells was calculated as the number of immunopositive cells divided by total nuclei. Data were analyzed by PROC PROC MIXED of SAS. After 24 h of culture, the percent of cells expressing MyoD was 5-fold greater in RES lambs at birth (58.40 ± 12.08%) than cells of CON lambs (11.68 ± 17.08%; $P = 0.03$). After 48 h of culture, there was a greater percentage of cells expressing myogenin in RES lambs at birth (63.25 ± 14.00%) compared with cells from CON lambs (17.57 ± 17.08%; $P = 0.04$). However, after 72 h of culture the percent of satellite cells expressing myogenin in RES lambs at birth (40.07 ± 14.00%) was approximately 50% less than cells from CON lambs (83.98 ± 17.08%; $P = 0.05$). There were no differences in the percent of Pax7 immunopostive cells at birth, or any factors in cells from lambs at 3 mo of age ($P > 0.05$). In conclusion, restricted nutrient availability during gestation alters the temporal expression of myogenic regulatory factors in the offspring and is suggestive of precocious differentiation.

Key Words: muscle, satellite cells, poor maternal nutrition

1182 (W118) Effects of milk replacer and multivitamin-mineral supplementation on performance of heat stressed dairy calves. S. Blair*[1], C. C. Williams[1], B. F. Jenny[1], M. Thomas[1], V. Morgan[1], and T. Earleywine[2], [1]*Louisiana State University AgCenter, Baton Rouge,* [2]*Land O'Lakes Animal Milk Products, Shoreview, MN.*

Seventy-one neonatal Holstein calves (40 female; 30 male) were used in a randomized block design with a 2x2 factorial arrangement of treatments to evaluate the effects of milk replacer (MR) alone or in combination with a multivitamin and electrolyte supplement on growth performance and mitigation of heat stress in southeast Louisiana. Milk replacer treatments consisted of Land O'Lakes Herdmaker Supreme (20% CP, 20% fat; CON) and Land O'Lakes Warm Front (27% CP, 10% fat; WF). Supplemented calves received either 0 or 20 ml Palamountains Calf Boost (CB) in MR once daily in the morning feeding. Calves were offered MR treatments beginning on day 2, and all milk replacer was mixed at 15% solids. Calves consuming CON were fed 2.28kg MR twice daily. Calves on WF were fed 2.72kg MR twice daily for the first three wk of life, and 3.86kg twice daily until weaning. Water and calf starter (20%CP) were offered ad libitum beginning on d 2. Beginning on d 42, MR feeding was reduced to 1 time per day for all treatment groups to decrease MR intake by 50%. On d 49 calves were weaned. Calves remained in their hutches until d 56 to determine immediate post weaning performance. Body weight, hip height, wither height, hip width, and body length were recorded weekly, and grain and water intakes were measured twice daily. Average rectal temperature, respiration rates, and fecal scores were recorded three times weekly at both 0800 h and 1600 h. All data were analyzed using the PROC MIXED of SAS. There was a main effect of MR, with calves fed WF showing greater body weights and increased hip height, wither height, and body length ($P < 0.05$). There was no significant effect of CB on growth or intake measurements. Calves fed WF consumed less grain than CON calves ($P < 0.05$) until the end of wk 7, but showed no difference at wk 8. Calves consuming WF also showed higher fecal scores ($P < 0.05$), but well within normal ranges for healthy calves. All calves consumed more water as age increased ($P < 0.05$), with no interactions of sex or treatment. There was no significant effect of MR or CB on temperature or respiration rates ($P > 0.05$). These data indicate that MR feeding management may improve growth performance in neonatal dairy calves, but multivitamin mineral supplements may not provide any additional benefit.

Key Words: calf milk replacer, multivitamin-mineral supplement, heat stress

1183 (W119) Effects of milk replacer feeding frequency on growth and performance of neonatal Holstein calves. M. Thomas*, C. C. Williams, B. F. Jenny, S. Blair, C. F. Hutchison, C. Burke, E. L. Chartier, M. Orellana, and A. H. Dolejsiova, *Louisiana State University AgCenter, Baton Rouge.*

Fifty-seven neonatal Holstein calves (40 female; 17 male) were assigned to one of three treatments at day 2 of age to study effects of milk replacer feeding frequency on growth, performance, and health. Treatments consisted of 1X, with total amount of reconstituted milk replacer fed at 0600 h; 2X, with total amount of reconstituted milk replacer divided into 2 equal amounts and fed at 0600 h and 1700 h; and 3X, with total amount of reconstituted milk replacer divided into three equal amounts and fed at 0600 h, 1200 h, and 1700 hp Calves were housed in individual hutches and fed milk replacer until abrupt weaning at 42 d of age. Total daily amount of milk replacer offered was equal to 1.5% of birth weight and reconstituted to a total volume of 10% birth weight. Water and an 18% crude protein calf starter were offered ad libitum beginning on d 3 throughout the duration of the trial. Calves remained in their hutches until day 56 to determine immediate post weaning performance. BW was determined at birth and weekly throughout the trial. Wither height (WH), hip height (HH) and hip width (HW) were measured on d 7, 14, 28, 42, and 56 of age. Feed intake, water intake, and fecal scores were recorded daily. Effects of treatment, week, and their interactions were analyzed using the PROC MIXED of SAS (Cary, NC). There was no effect ($P > 0.05$) of treatment on BW, HH, HW, or WH. There was a week effect ($P < 0.01$) for BW, HH, HW, and WH as well as grain and water intake, with all calves increasing intake and growth throughout the duration of the study. There was no effect ($P > 0.05$) of treatment on fecal scores, with scores being similar and within the normal ranges for healthy calves throughout the project. Overall, milk replacer feeding frequency did not show any significant effects on growth or performance of these Holstein dairy calves.

Key Words: dairy calves, milk replacer, feeding frequency

1184 (W120) High energy diet enhances intramuscular adipogenesis in Hanwoo steers distributed to breeding value for meat quality. K. Y. Chung*, S. W. Lee, U. H. Kim, S. C. Jang, Y. M. Cho, E. M. Lee, S. M. Lee, and H. S. Kang, *Hanwoo Experiment Station, NIAS, RDA, Pyeongchang, South Korea.*

High energy diet has been used for enhancing intramuscular adipose tissue in high quality beef cattle. Estimated breeding value (EBV) was used as a selection method to determine high quality beef group. The aim of this experiment was to determine the effect of high energy diet on the high and low

beef group distributed by EBV for carcass quality grade. We hypothesized that adipogenic gene expressions and adipose carcass traits are increased in high EBV groups when fed a high energy diet. A 2 x 2 factorial arrangement (High EBV, Low EBV, and High energy diet, control diet) in a completely random design was used to feed 26 Hanwoo steers. Two steers were fed in same pen and 13 pens were used for treatment. Blood sample was drawn once a month at the beginning from 11 to 28 month. Longissimus Dorsi (LD) muscle was collected within 10 min of harvest for analysis of mRNA SCD, PPARγ, GLUT4, MHC1, MHC2X abundance. Overall ADG and DMI were not different between high energy diet and control diet ($P > 0.05$). Serum glucose and triglyceride concentrations were increased ($P < 0.05$) by high EBV group from 22 to 28 month old. Serum NEFA levels were greater ($P < 0.05$) in 24 mo old at high EBV group and steady decreased at 28 mo old. Marbling score and yield grade were not affected by high energy diet and EBV ($P > 0.05$). Real-time quantitative PCR revealed that the mRNA content of PPARγ and SCD of high EBV group increased ($P < 0.05$) as compared to low EBV group. The mRNA level of GLUT4 and MHC1 tend to increase ($P = 0.08$, 0.09) when control diet fed at high EBV group. These data indicate that high energy diets increased serum glucose and triglyceride concentrations of high EBV-steers at final fattening period. Although there are no interaction between diet and EBV levels, adipogenic gene expressions in high EBV-steers were greater than those in low EBV-steers. The selection of EBV for meat quality affected serum glucose level and adipogenic gene expression of feedlot Hanwoo steers.

Key Words: Hanwoo, EBV, adipogenesis

1185 (W121) Impact of the sires on puberty onset in Nellore heifers.
M. V. C. Ferraz Jr.*[1], A. V. Pires[2], D. D. Nepomuceno[2], A. D. B. Ribeiro[1], M. V. Biehl[2], J. P. C. Thieme[2], E. M. Moreira[1], J. A. Faleiro Neto[1], and J. R. S. Gonçalves[3], *[1]University of São Paulo– FMVZ/USP, Pirassununga, Brazil, [2]University of São Paulo– ESALQ/USP, Piracicaba, Brazil, [3]Experimental Station Hildegard Georgina Von Pritzelwitz, Londrina, Brazil.*

In Brazil the main breed of beef cattle is Nellore, where it represents 70% of the national herd. Since the late onset of puberty one of the principal problems associated with this breed. The aim of this study was to evaluate the expected progeny differences (EPDs for scrotal circumference) of sires and its effect on puberty in Nellore heifers. The daughters of 12 sires (143 calf heifers) were used. After weaning at 210 days of age, the animals were mantained in cultivated pasture of Brachiaria ssp. with mineral supplement and water ad libitum. The heifers were weighed, and the puberty onset was assessed monthly from 12 to 30 mo (by ultrasonography - corpus luteum detection). The sires were classified in precocious and non-precocious groups according to the positive (PEPD, $n = 8$) or negative (NEPD, $n = 4$) EPD to scrotal circumference. Continuous variables were analyzed by PROC MIXED, and variables with binomial distribution were analyzed by GLIMMIX procedure, both through SAS 9.3. Heifers that were NEPD daughters had the puberty onset heavier ($P = 0.009$) and older ($P = 0.013$) than the PEPD daughters (weight: 317.0 ± 10.6 vs 294.8 ± 8.7 Kg; age: 644.7 ± 59.3 vs 593.5 ± 62.7 days; for NEPD and PEPD, respectively). The percentage of pubertal heifers at 14, 18, 26 and 30 months of age, not were different between NEPD and PEPD (14 months of age: 11.1 vs 8.2%; 18 months of age: 26.7 vs 30.6%; 26 months of age –66.7 vs 73.5%; 30 months of age: 93.3 vs 92.8%, for NEPD and PEPD, respectively). We can conclude that there is genetic heterogeneity to onset puberty in Nellore breed. Furthermore, the results reveal the importance of the use of proven sires for sexual precocity. Financial support: FAPESP.

Key Words: sexual precocity, Nellore, sire

1186 (W122) Microarray studies in high and low rfi cattle reveal a potential role for gonadotropin releasing hormone (GnRH) in regulating feed efficiency.
S. D. Perkins*[1], C. Foradori[1], A. K. McNeel[2], L. A. Kriese-Anderson[1], and T. D. Brandebourg[1], *[1]Auburn University, Auburn, [2]USDA, ARS, U.S. Meat Animal Research Center, Clay Center, NE.*

Residual feed intake (RFI) is a heritable feed efficiency measure. Mechanisms underlying variation in feed efficiency are currently poorly understood. To address this issue, two divergent cohorts consisting of High (H) and Low (L) RFI individuals were created by assessing RFI in forty-eight Angus-sired steers during a 70 d feeding trial to identify steers with divergent RFI. Microarray studies using the Affymetrix Bovine Genome Array were then conducted on hypothalamic tissue (HT) RNA samples harvested from H and L RFI steers. The test diet was 50% sorghum-sudan silage, 50% grain (2.9 Mcal ME/kg DM). While on test, feed intake was recorded daily with BW and hip heights recorded at 14 day intervals. Ultrasound measurements of rib eye area (REA) and backfat (BF) were recorded initially and prior to harvest. Carcass and growth data were analyzed using a mixed model with RFI level (L, H) as the independent variable. The lsmeans for RFI were -1.25 and 1.51 for the L and H cohorts ($P < .0001$). Dry matter intake was higher for the H individuals versus the L steers ($P < .0001$) while on test BW gain was not different between the two groups ($P < 0.73$). Of the 24,000+ probes included on the Affymetrix Bovine Genome Array, 891 were found to be significantly different ($P < 0.05$) with 149 of these being highly different ($P < 0.01$) between high and low RFI. Pathway analysis of the data set using Ingenuity Pathway Analysis software revealed that the pathways most heavily represented in the differentially expressed genes were consistent with the known functions of the central nervous

system, specifically; increased cellular movement (important for synapse formation and neuronal communication), cell-to-cell communication and cellular development ($P = 1.34x10^{-24}$, $9.54x10^{-20}$,$3.14x10^{-17}$, respectively). In terms of canonical pathways, dendritic cell maturation and interleukin signaling ($P = 3.56x10^{-6}$ and $5.24x10^{-6}$, respectively) were identified as differentially activated by RFI status of particular interest and warrant further investigation. Furthermore, GnRH signaling (including GnRH agonist and GnRH signaling) was predicted to be to be greater in H steers. These findings are consistent with targeted gene expression assays using real-time PCR where GnRH mRNA abundance was lower in the arcuate nucleus of L steers**.** These data support the hypothesis that differences in hypothalamic neuropeptide gene expression underlie variation in feed efficiency in steers while the gonadotropin axis may also influence feed efficiency.

Key Words: RFI, steer, feed efficiency

1187 (W123) Microbiota diversity is inversely related to adiposity in Mangalica pigs. J. W. Broady, L. Wang, A. G. Moss, T. D. Brandebourg, and E. Schwartz*, *Auburn University, Auburn.*

Alabama is at the epicenter of an obesity epidemic representing a critical threat to public health by precipitating increased risk to stakeholders for diabetes, heart disease, stroke, arthritis, and certain cancers. Several studies in humans and in mice have demonstrated a strong interaction between the composition and diversity of gut microbiota, inflammation, and obesity. To address the connection between these parameters, we used the Mangalica pig as a model organism given the extreme, early onset, hyperphagic obesity displayed by this breed. A growth trial was conducted where obese and lean groups were created by either allowing ad libitum access to feed or restricting energy intake to 65% of ad libitum levels. Throughout the trial longitudinal analyses of the bacterial composition of the fecal microbiota was performed using denaturing gradient gel electrophoresis (DGGE). Circulating glucose was measured in whole blood samples taken from pigs following fasting or administration of an oral glucose dose. Body composition was determined at regular intervals using ultrasound and subcutaneous adipose tissues (SC) harvested at the end of the trial to facilitate gene expression studies. As animals aged and increased in adiposity, a general reduction in the overall diversity in the gut bacteria was observed with several other changes in specific bacterial taxa as indicated by DGGE analysis. At mature weight, obese pigs exhibited 2.5-fold greater SC mass ($P < 0.001$) but no differences in muscle mass ($P < 0.39$) compared to lean counterparts. Obese pigs exhibited severe fasting hypoglycemia and impaired glucose tolerance following oral glucose challenge suggesting development of insulin resistance. The mRNA expression of interleukin-6 (IL6) and tumor necrosis factor-α (TNF-α) were 4.72- and 3.74-fold higher respectively in the SC of obese versus lean Mangalica as measured by real-time PCR ($P < 0.01$). These data provide evidence that obese Mangalica pigs indeed develop a metabolic phenotype consistent with insulin resistance and this is associated with a proinflammatory shift in gene expression in SC. Furthermore, these data suggest that obesity is inversely correlated with diversity in gut microbiota. These findings will inform the design of therapies aimed at manipulating gut microbiota and/or inflammation in the treatment of obesity.

Key Words: microbiota, obesity, mangalica

1188 (W124) Muscle hypertrophy induced by myostatin inhibition is suppressed by rapamycin administration. D. Choi*[1], J. Yang[1], S. K. Park[2], and Y. S. Kim[1], *[1]University of Hawaii, Honolulu, [2]National Institute of Animal Science, RDA, Suwon, South Korea.*

Recent studies have shown that myostatin (MSTN), a skeletal muscle specific negative growth factor, may regulate skeletal muscle mass through the mTOR pathway. The mTOR pathway is known to be blocked by rapamycin (RAP), thus it was hypothesized that muscle hypertrophy induced by MSTN inhibition would be blocked by RAP treatment. This study was designed to examine the effect of RAP administration on muscle growth in MSTN-propeptide transgenic mice, a hypermuscular phenotype by MSTN inhibition. 5 wk old male heterozygous MSTN-propeptide transgenic mice and wild-type littermates were administered with 0 or 3 mg/kg body weight of RAP intraperitoneally every other day for 4 wk. At the end of RAP treatment, animals were sacrificed, and gastrocnemius, plantaris, and soleus muscles were dissected, weighed, and snap-frozen for later analysis. Body weight gain of transgenic mice was greater ($P < 0.01$) than that of wild-type mice. RAP suppressed ($P < 0.05$) body weight gain about 40% in both genotypes. Soleus, plantaris, and gastrocnemius muscle weights of transgenic mice were greater ($P < 0.05$) than those of wild-type mice. RAP suppressed ($P < 0.05$) muscle growth in both genotypes, but the extent of suppression was greater in transgenic mice than in wild-type mice (6.6% vs. 18.6% in plantaris, and 20.7% vs. 24.8% in gastrocnemius). When the expressions of MyoD and myogenin were analyzed by real time PCR, expressions of these myogenic regulatory factors were not affected by either genotype or RAP administration. The current result of suppressing muscle growth by RAP in MSTN-propeptide transgenic mice supports that the mTOR pathway is involved in the regulation of muscle growth by MSTN.

Key Words: myostatin, rapamycin, mTOR pathway

1189 (W125) Poor maternal nutrition during gestation reduces mesenchymal stem cell (MSC) proliferation in offspring. S. M Pillai[*1], M. L. Hoffman[1], K. N. Peck[1], E. V. Valley[1], T. D. Crenshaw[2], S. A. Zinn[1], and K. E. Govoni[1], *[1]Dep. of Animal Science, University of Connecticut, Storrs, [2]University of Wisconsin, Madison.*

Poor maternal nutrition may alter bone and adipose development in offspring by diverting MSC from osteoblast to adipocyte lineage. To determine if poor maternal nutrition during gestation alters bone and adipose development and function of MSC in offspring, 36 ewes were fed 100%, 60%, or 140% of requirements (NRC, 1985) beginning at d 31 ± 1.3 of gestation. Lambs from ewes fed 100% (CON), 60% (RES) and 140% (OVER) were euthanized within 24 h of birth (d 1; n = 18) or at 3 mo of age (n = 15). At necropsy, the left tibia and femur were collected for MSC culture and mineral analysis, and backfat thickness and BW were measured. The MSC were isolated from bone marrow at d 1 and cultured (α- MEM + 10% fetal bovine serum + 0.5% penicillin streptomycin + 0.25% Amphotericin-B). Proliferation of MSC was determined by bromodeoxyuridine assay. Gene expression was quantified using real-time RT-PCR. Data were analyzed using PROC MIXED in SAS. As previously reported, BW were 13% greater in OVER than CON at 1 d and 3 mo ($P \leq 0.05$), but not different in RES ($P > 0.1$). Maternal diet did not affect ($P > 0.2$) bone length, area, mineral content and mineral density at d 1 or at 3 mo. Backfat thickness was reduced 50% in RES compared with CON at 3 mo ($P = 0.01$). Compared with CON, MSC proliferation was reduced 51% and 58% in RES ($P = 0.07$) and OVER ($P = 0.03$), respectively in the presence of serum and reduced 27% and 44% in RES ($P = 0.11$) and OVER ($P = 0.05$), respectively without serum. Expression of markers of MSC commitment to adipocyte and osteoblast cell lineages were evaluated. *P2Y purinoceptor 14* was reduced 1.7 ± 0.1-fold in OVER ($P = 0.09$) and *P2Y purinoceptor 1* was reduced 1.7 ± 0.1-fold in OVER ($P = 0.09$) vs. CON. Whereas *C/EBPβ, Msh homeobox 1, Protein delta homolog 1, P2Y purinoceptor 2* were not affected by maternal diet ($P >$ 0.3). Studies are in progress to determine if maternal diet alters differentiation of MSC into osteoblasts and adipocytes. In conclusion, poor maternal nutrition reduces the proliferation of MSC in offspring which may contribute to altered bone and adipose tissue development.

Key Words: mesenchymal stem cells, proliferation, sheep

1190 (W126) Regulation of key markers of lipid metabolism by short chain fatty acids in differentiated pig adipocytes. H. Yan[*1], and K. M. Ajuwon[2], *[1]Purdue University, West Lafayette, IN, [2]Dep. of Animal Sciences, Purdue University, West Lafayette, IN.*

Short chain fatty acids (SCFA), primarily acetate, propionate and butyrate, are the major carbohydrate fermentation end products of in the gut. Previously, we had demonstrated that inulin, a fermentable fiber, alleviated high fat diet induced fat mass accumulation, and that this was accompanied by increased expression of acyl CoA oxidase (ACO), a marker of peroxisomal fatty acid oxidation, decreased expression of fatty acid synthase (FAS) and alteration in the gut microbial community structure to favor increased level of butyrate-producing bacteria. Although gut microbial structure is highly associated with SCFAs production, direct effect of SCFAs on lipid metabolism is still unclear. Therefore, we examined, by RT-PCR, the effect of SCFAs administration on markers of lipid metabolism in differentiated pig adipocytes. Increasing concentrations of SCFAs (μM to low mM) led to an upregulation of expression of acyl CoA oxidase (ACO) and sterol regulatory element binding protein 1c (SREBP-1c), which play a key role in fatty acid synthesis. Furthermore, butyrate, but not propionate and acetate, significantly reduced ($P < 0.05$) the expression of fatty acids synthase (FAS) and carnitine palmitoyl transferase 1α (CPT1α). Butyrate, but not propionate and acetate, significantly increased ($P < 0.05$) adiponectin and glucose transporter type 4 (GLUT4) expression and led to decreased leptin expression. This study showed that SCFAs, especially butyrate, may exert direct influence on lipid metabolism and adipokine expression profile in adipocytes. Results are consistent with previously observed in vivo effects of fermentable fiber on metabolic markers in pig adipose tissue and suggest that in vivo fiber effects may be partly mediated by SCFA produced during fiber fermentation.

Key Words: SCFA, adipocyte, metabolism

1191 (W127) Relationship among efficiency measures, economic value and feedlot performance assessed in growing phase of Nellore cattle. A. M. Castilhos[1], C. L. Francisco[*1], A. M. Jorge[1], R. H. Branco[2], M. E. Z. Mercadante[2], S. F. M. Bonilha[2], C. M. Pariz[1], and D. C. Rivaroli[1], *[1]Universidade Estadual Paulista–FMVZ, Botucatu, Brazil, [2]Centro APTA Bovinos de Corte, Instituto de Zootecnia, Sertãozinho-SP, Brazil*.

Data from 6 yr of studies (2007–2012) were compiled using 357 Nellore bulls (212 + 38 kg BW; 279 + 29 d of age) to evaluate the relationship among efficiency measures, current economic value and feedlot performance. Dry matter intake (DMI) was recorded for two different ways: using a GrowSafe automated feeding system (GrowSafe Systems Ltd., Air-

Table 1191.

	RFI		RIG		RG		
Variable	Low	High	Low	High	Low	High	SEM
Profit, $/steer·d^{-1}	0.72^{b}	0.56^{c}	0.48^{d}	0.77^{a}	0.38^{e}	0.77^{a}	0.03
ADG, kg/d	1.04^{bc}	1.05^{b}	1.00^{c}	1.08^{ab}	0.89^{d}	1.10^{a}	0.02
DMI, kg/d	6.40 ^{c}	7.46^{a}	7.49^{a}	6.46^{c}	7.00^{b}	6.75 ^{b}	0.12
Final BW, kg	330.39^{a}	333.88^{a}	335.63^{a}	329.91^{a}	334.66^{a}	328.39^{a}	59,39

^{ab} $P < 0.05$

drie, Alberta, Canada) or individual pens. Efficiency measures evaluated were: residual feed intake (RFI), residual intake and BW gain (RIG) and residual BW gain (RG). Residual feed intake was calculated as the residuals from the regression of total DMI on $BW^{0.75}$ and ADG. Residual gain was calculated as the residuals from the regression of total ADG on $BW^{0.75}$ and DMI. Residual intake and BW gain was determined from linear combination into RFI and RG. Animals were classified for each efficiency measure as Low (< 0.5 SD mean), Medium (within ± 0.5 SD), and High (> 0.5 SD mean) groups. Economic value included was profit ($/steer.d^{-1}), calculated from the economic data from 2006 to 2012. Feedlot performance variables were ADG (kg/d), DMI (kg/d), and final BW (kg). Profit for all groups differed ($P < 0.05$), with the exception between $High_{RIG}$ and $High_{RG}$ groups ($P = 0.98$) which had the highest profitability (Table 1191). When the groups were analyzed separately, within each of efficiency measures, the profit increased ($P < 0.0001$). Final BW was similar among all groups of efficiency measures ($P = 0.78$). Body weight gain was not different between groups $High_{RFI}$ and Low_{RFI} ($P = 0.64$), Residual feed intake groups had lower gain only compare to $High_{RG}$ group ($P = 0.01$). The $High_{RIG}$ and $High_{RG}$ increased approximately 8% and 23% ($P < 0.0001$) compared to Low_{RIG} and Low_{RG}, respectively. Among all the groups Low_{RFI} and $High_{RIG}$ had lower DMI ($P < 0.01$) and reduced by approximately 14% compared to $High_{RFI}$ and Low_{RIG}, respectively. Therefore, residual intake and body weight gain is a recommended measure to increase profitability and reduce dry matter intake of Nellore cattle.

Key Words: efficiency measures, Nellore cattle, profit

1192 (W128) Retinoic acid alters expression of key genes during differentiation of bovine intramuscular preadipocytes. J. Kim*[1], K. Chung[2], S. Chang[2], and B. J. Johnson[1], *[1]Texas Tech University, Lubbock, [2]Hanwoo Experiment Station, NIAS, RDA, Pyeongchang, South Korea.*

Retinoic acid has been shown to be important in regulating mammalian tissue development, such as, proper bone formation, growth, energy metabolism, and cell differentiation. Retinoic acid has been reported to be a potent inhibitor of adipocyte differentiation by binding to the retinoic acid receptor (RAR) or retinoid X receptor (RXR). The objective was to determine the effect of RAR agonist (retinoic acid) and RAR antagonist (LE540) on gene expression during differentiation of bovine intramuscular preadipocytes. Intramuscular (IM) adipose tissue was collected between the 10th and 13th from longissimus muscle and cultured in growth media consisting of DMEM, 10% fetal bovine serum, and antibiotics at 37°C under a humidified atmosphere of 95% O_2 and 5% CO_2. Upon reaching confluence, the growth medium was replaced by a differentiation medium consisting of DMEM and 10 μg/mL insulin, 25 nM hydrocortisone, 10 μM oleic acid, 5 μM ciglitizone, and antibiotics with treatments The treatments were: 1)control, 2)10 μM all-trans retinoic acid (RA), and 3)10 μM LE540 (synthetic RA antagonist; Waco Co.). Real-Time RT-PCR was used to measure the quantity of C/EBPβ, PPARγ, SCD, and SMAD3 mRNA relative to the quantity of ribosomal protein subunit 9 (RPS9) mRNA in total RNA isolated from cultured bovine IM adipocyte cultures. Addition of RA reduced ($P < 0.05$) PPARγ and SCD mRNA levels compared to control IM adipocytes. However, addition of LE 540 increased expression of PPARγ and SCD mRNA ($P < 0.05$) levels in bovine IM adipocytes. Relative level of C/EBPβ mRNA was inhibited ($P < 0.05$) by LE540 during differentiation. Results of this study indicated that retinoic acid inhibits bovine IM preadipocyte differentiation by downregulation of PPARγ or SCD. However, treatment of RAR antagonist induces adiopogenic gene expressions during IM preadipocyte differentiation.

Key Words: bovine intramuscular adipose cell, marbling, retinoic acid

1193 (W129) Role of G protein-coupled estrogen receptor-1 and matrix metalloproteinases 2 and 9 in the effects of Estradiol-17β on proliferation, protein synthesis and protein degradation in bovine satellite cell cultures. E. Kamanga-Sollo, B. C. Reiter, K. J. Thornton*, M. E. White, and W. R. Dayton, *University of Minnesota, St. Paul.*

In feedlot steers, Estrogen (E2) and combined E2 and trenbolone acetate (TBA) (a testosterone analog) implants enhance rate and efficiency of muscle growth; and, consequently, these compounds are widely used as growth promoters. Although the positive effects of E2 are well established, the mechanism(s) involved is not well understood. Combined E2/TBA implants result in significantly increased muscle satellite cell number in feedlot steers. Additionally, E2 treatment stimulates proliferation of cultured bovine satellite cells (BSC). The ability of

E2 to stimulate satellite cell proliferation is significant because satellite cells provide nuclei needed to support postnatal muscle fiber hypertrophy and are crucial in determining the rate and extent of muscle growth. To identify the mechanism(s) involved in E2-stimulated muscle growth, we have focused on identifying the receptors involved in the effects of E2 on BSC proliferation, protein synthesis and protein degradation. Our previous studies have shown that silencing expression of estrogen receptor 1 (ESR1) or epidermal growth factor receptor (EGFR) suppresses E2-stimulated BSC proliferation. Studies in nonmuscle cells have shown that binding of E2 to G protein-coupled estrogen receptor (GPER)-1 results in activation of matrix metalloproteinases 2 and 9 (MMP2/9) resulting in proteolytic release of heparin binding epidermal growth factor-like growth factor (hbEGF) from the cell surface. Released hbEGF binds to and activates EGFR resulting in increased proliferation. To determine if GPER-1 and MMP2/9 are involved in the ability of E2 or IGF-1 to affect BSC, we have utilized specific inhibitors to inhibit the activity of GPER-1 and MMP2/9 and assessed the impact of this inhibition on the effects of E2 on proliferation, protein synthesis and protein degradation rates in BSC cultures. Treatment of BSC cultures with G36, a GPER-1 specific inhibitor, or with an inhibitor of MMP2/9 activity completely suppressed E2-stimulated proliferation and protein synthesis ($P < 0.05$) but had no effect on the ability of E2 to suppress protein degradation. Our results show that both GPER-1 and MMP2/9 are necessary for E2-stimulated proliferation and protein synthesis in BSC cultures.

Key Words: bovine, satellite cell, muscle, estradiol-17β

1194 (W130) The effect of pre-weaning feeding and housing strategy on calf growth performance and behavior following post-weaning housing transition.

H. M. Gauthier[*1], H. A. Tucker[1], S. E. Williams[1], D. M. Shenk[1], C. S. Ballard[1], K. M. Morrill[2], and H. M. Dann[1], *[1]William H. Miner Agricultural Research Institute, Chazy, NY, [2]Cornell University, Ithaca, NY.*

The objective was to compare the effects of pre-weaning housing and feeding strategy on post-weaning growth performance and behavior after housing transition. Forty-eight Holstein calves were fed 770 g DM/d from birth through 15 d of age and 900 g DM/d thereafter split into 2 feedings and housed in individual hutches ($n = 16$; FI), or fed ad libitum acidified milk replacer and housed in either individual hutches ($n = 16$; AI) or group hutches with 4 calves/hutch ($n = 16$; AG). Milk replacer was 24% CP and 20% fat, fed at 14% solids. Following weaning (wk 8), calves were moved to a separate housing area (wk 10) and housed in 3.05 × 3.66 m pens with 4 calves/pen. Calves were weighed before transit (FI = 79.2 ± 3.4 kg; AI = 89.7 ± 4.2 kg; AG = 88.1 ± 4.2 kg) and weekly thereafter. Behavior of individual calves ($n = 36$) for the first 5 h following transit and pen introduction was observed using 5-min scan sampling and averaged across pen. Calves were offered free choice chopped hay (16.1% CP; 58.7% NDF) and pelleted grain (25.7% CP; 29.8% NDF) daily. Dry matter intake was measured daily. Data were analyzed as a randomized block design using the PROC MIXED of SAS. Total DMI was greater ($P = 0.02$) for AI (mean ± SE; 5.85 ± 0.12 kg DM/d) compared to AG (5.29 ± 0.12 kg DM/d) and tended ($P = 0.06$) to be greater than FI (5.40 ± 0.12 kg DM/d). Average daily gain over the 2 wk period tended ($P = 0.08$) to be greater for FI (1.20 ± 0.08 kg BW/d) than AI (0.97 ± 0.08 kg BW/d) or AG (0.90 ± 0.08 kg BW/d). Feed efficiency was not altered ($P = 0.12$) by pre-weaning housing and feeding strategies averaging 6.16 ± 0.53 kg DMI/kg gain for AI, 5.67 ± 0.53 kg DMI/kg gain for AG, and 4.38 ± 0.53 kg DMI/kg gain for FI. Time spent in contact with another calf was greater ($P = 0.02$) for AG (85.4 ± 8.8 min) compared to AI (27.1 ± 8.8 min) and FI (40.0 ± 8.8 min). Housing and feeding strategy pre-weaning did not alter time spent standing ($P = 0.55$) or lying ($P = 0.55$) post-weaning. These data suggest post-weaning compensatory gain occurs with fixed intake feeding when compared to ad-libitum feeding.

Key Words: post-weaned calves, performance, behavior

1195 (W131) The effect of two sources of soy protein concentrate and hydrolyzed soy protein modified on growth and performance of calves fed milk replacer.

*B. L. Miller[*1], T. Earleywine[2], W. S. Bowen Yoho[3], and T. E. Johnson[3], [1]Land O'Lakes–Purina Feed LLC, Gray Summit, MO, [2]Land O'Lakes Animal Milk Products, Shoreview, MN, [3]Land O' Lakes, Inc., Webster City, IA.*

Fifty-one (51) 3- 10 d old Holstein bull calves with an average initial BW of 50.1 kg (SD = 1.63 kg) were shipped from Wisconsin to the Land O' Lakes Research Facility. Calves were randomly assigned according to BW and blood γ globulin to one of three 20% protein/20% fat non-medicated milk replacer (MR) diets offered in a 17.6% solution. The objective of this study was to evaluate calf performance and growth when fed MR containing one of two sources of soy protein concentrate or hydrolyzed soy protein modified as a protein source. Treatments were as follows: soy protein concentrate source 1 (SPC 1; Solae Profine F, Solae, Aarhus, Denmark); soy protein concentrate source 2 (SPC 2, Solae Danpro A, Solae, Aarhus, Denmark); hydrolyzed soy protein modified (HSPM). Calves were fed to provide 680 g DM/d during Days 1– 7, 907 g DM/d during Days 8– 14, 1134 g DM/d during Days 15– 21, and 1361 g DM/d during Days 22– 28, in 2 feedings at 0600 and 1515 h. Calf starter was not offered during this 28 d trial. Data were analyzed by PROC MIXEDs of SAS. Total weight gain, MR consumption, feed:gain, and scour scores did not differ ($P > 0.05$) among treatments. The three soy protein sources fed in this study can be interchangeably employed in calf milk replacers as all support calf growth and performance equally.

Key Words: calf, milk replacer, hydrolyzed soy protein modified

1196 (W132) The effect of various fat levels and fat sources on growth and performance of calves fed milk replacer.

T. Earleywine*[1], B. L. Miller[2], W. S. Bowen Yoho[3], and T. E. Johnson[3], *[1]Land O'Lakes Animal Milk Products, Shoreview, MN, [2]Land O'Lakes–Purina Feed LLC, Gray Summit, MO, [3]Land O' Lakes, Inc., Webster City, IA.*

Seventy-one (71) 3- to 10-d-old Holstein bull calves with average initial BW of 45.6 kg (SD = 1.95 kg) were shipped from Wisconsin to the Land O' Lakes Research Facility. The objective of this study was to examine the growth and performance of calves fed milk replacer (MR) varying in fat level and fat source. Calves were randomly assigned according to BW and blood γ globulin to their respective MR diet offered in a 15.0% solids solution. Calves were assigned to 1 of 3 diets: 22% crude protein (CP), 20% fat with lard as the primary fat source; 22% CP, 15% fat with medium-chain triglycerides (MCT) as the primary fat source; 22% CP, 15% fat with lard as the primary fat source and supplemented with 8 g essential fatty acids per calf daily (EFA; Neotec4™, Provimi North America, Inc., Brookville, OH). Calves were fed to provide 680 g DM/d in 2 feedings at 0600 and 1515 h. Calves were offered 340 g DM/d in one feeding during the last week. Calf starter (20% CP, as fed basis) was fed ad libitum throughout this 42 d trial. Data were analyzed by PROC MIXEDs of SAS. There were no statistical differences ($P > 0.05$) in total BW gain, starter feed intake, or feed:gain among treatments. Calves fed a 22:20 MR with lard as the primary fat source consumed less ($P < 0.05$) MR compared to calves fed a 22:15 MR with lard as the primary fat source and supplemented with EFA. Milk replacers with MCT as the primary fat source may allow for a reduction in fat levels while supporting equal calf performance and growth.

Key Words: calf, milk replacer, medium-chain triglyceride

1197 (W133) Use of biometric measurements to predict age and body weight of bovine fetus.

T. R. Gionbelli*[1], M. P. Gionbelli[1,2], M. S. Duarte[1], S. C. Valadares Filho[1,2], F. C. Rodrigues[1], M. G. Machado[1], D. Zanetti[1], B. C. Silva[1], and F. A. Villadiego[1], *[1]Universidade Federal de Viçosa, Minas Gerais, Brazil, [2]Instituto Nacional de Ciência e Tecnologia–Ciência Animal, Viçosa, Minas Gerais, Brazil.*

Fetal biometric measurements that can be achieved by ultrasonography were used to develop equations to predict fetal age and fetus body weight in *Bos indicus* cattle. Dataset from 32 purebred Nellore fetuses from 130 to 272 d of gestation, obtained from cows fed corn silage based diet at various feeding levels, was used. Cows were hand mated, with day of mating considered as day zero of pregnancy. Fetal weight and biometric measurements were taken at slaughter and biometrics measurements were (all in cm): body length (BL), thoracic circumference (TC), height at shoulder (HS), height at rump (HR), cranial eyes circumference (CEC) and cranial neck circumference (CNC). Nonlinear equations ($y = ax^b$) were fitted to the data and results are shown in Table 1197. Generated functions were evaluated regressing observed values in function of predicted. The joint hypothesis that $\beta_0 = 0$ and $\beta_1 = 1$ was tested and the results shown good fit for all functions generated ($P > 0.70$). However, these regressions do not predict fetal ages accurately in early gestation, thus should not be extrapolated beyond the scope of these data (130 to 272 d of gestation). The results suggest that the gestational age and fetal body weight can be estimated from biometric measurements of fetus using ultrasonography in live cows or directly in fetuses from cows that were slaughtered without specified gestational age. *Funded by INCT-CA, CNPq and FAPEMIG.*

Key Words: biometric measurements, fetal growth, gestation

Table 1197. Functions to predict fetus body weight and fetal age from biometric measures of fetus[1]

	Predicting fetal age (days)			Predicting fetus body weight		
Biometric predictor measure	Function	r^2_{xy}	*P*-value	Function	r^2_{xy}	*P*-value
Body length, cm	$y = 14.3 \times BL^{0.6516}$	0.960	0.998	$y = 0.000155 \times BL^{2.701}$	0.981	0.708
Thoracic circumference, cm	$y = 16.89 \times TC^{0.6588}$	0.964	0.999	$y = 0.000263 \times TC^{2.769}$	0.974	0.864
Height at shoulder, cm	$y = 24.21 \times HS^{0.5536}$	0.975	0.999	$y = 0.001 \times HS^{2.367}$	0.975	0.985
Height at rump, cm	$y = 26.42 \times HR^{0.5322}$	0.983	0.999	$y = 0.00192 \times HR^{2.209}$	0.958	0.944
Cranial eyes circumference, cm	$y = 10.45 \times CEC^{0.8215}$	0.953	0.999	$y = 0.000041 \times CEC^{3.412}$	0.946	0.884
Cranial neck circumference, cm	$y = 9.97 \times CNC^{0.8478}$	0.970	0.995	$y = 0.000073 \times CNC^{3.314}$	0.962	0.689

[1] The r^2_{xy} value is for observed values regressed in function of predicted. *P*-value is the significance value for testing the joint hypothesis that $\beta_0 = 0$ and $\beta_1 = 1$, wherein *P*-values greater than 0.05 means that the H_0hypothesis was accepted.

HORSE SPECIES I

1198 (T136) Glucose-insulin homeostasis and characterization of proteins involved in glucose uptake signaling in equine skeletal muscle. R. C. Avenatti*, K. Malinowski, and K. H. McKeever, *Rutgers Equine Science Center, New Brunswick, NJ.*

The objective of this study was to test the hypothesis that glucose-insulin homeostasis, and activation of AMP-activated protein kinase (AMPK), the protein kinase Akt, and the Akt substrate protein of 160 kDa (AS160) in equine skeletal muscle are altered by acute, exhaustive exercise and by aging. Unconditioned aged (n = 6; 22.6 ± 2.25 yr) and young (n = 6; 5.5 ± 2.8 yr) Standardbred mares were assessed for glucose-insulin homeostasis via frequently sampled intravenous glucose tolerance test (FSIGTT). All mares underwent a single bout of submaximal exercise. Plasma insulin and glucose concentrations were measured via radioimmunoassay and enzyme-electrode interface, respectively. Mid-gluteal muscle biopsies were taken pre-exercise, and at 0, 4, 24, and 48 h post-exercise. Muscle samples were analyzed via western immunoblotting for changes in activation of AMPK, Akt and AS160. Minimal model analysis of FSIGTT and repeated measures ANOVA were utilized to analyze data. Null hypothesis was rejected when $P < 0.05$. FSIGTT results indicated that there was no difference between young and aged mares for insulin sensitivity (SI), glucose effectiveness (SG), acute insulin response to glucose (AIRg) or disposition index (AIRg x SI) ($P > 0.05$). Area under the curve for both insulin (AUCi) and glucose (AUCg) were not different between young and aged mares ($P > 0.05$). In response to acute exercise, young mares displayed elevated insulin concentrations at 2 ($P = 0.009$) and 4 ($P = 0.007$) h while aged mares displayed elevated insulin at 30 ($P < 0.001$) and 60 ($P = 0.001$) minutes post-exercise. Neither age nor exercise caused a significant change in AUCi ($P > 0.05$). Glucose concentration was elevated at 2 h post-exercise in young mares ($P < 0.001$), while in aged mares glucose remained elevated only until 60 min post-exercise ($P = 0.037$). Exercise caused an increase in AUCg in young ($P = 0.007$) and aged ($P = 0.031$) mares, however there was no age effect on AUCg ($P > 0.05$). Neither age nor exercise altered total protein concentrations or phosphorylated protein concentrations of AMPK, Akt or AS160 ($P > 0.05$). In conclusion, age alone is not sufficient to alter insulin sensitivity in horses, but does alter glucose-insulin dynamics in response to exercise. Also, a single bout of submaximal exercise was not sufficient to alter activation of proteins believed to be involved in glucose uptake in skeletal muscle at the time points measured. The comparative literature suggests that these proteins are important for endocrine- and exercise-related glucose uptake and energy homeostasis.

Key Words: aging, exercise, muscle

1199 (T137) Splanchnic extraction of phenylalanine in adult thoroughbred mares fed two different levels of threonine. S. Tanner, T. Barnes, K. Cybulak, and K. L. Urschel*, *University of Kentucky, Lexington.*

Previous studies in horses examining the effects of amino acid (AA) intake on whole-body protein synthesis have used intravenous phenylalanine isotope infusion and the resulting calculations required estimates of splanchnic phenylalanine extraction that were derived from other species. Threonine is believed to be the second limiting AA in some equine diets. The objectives of the study were to determine splanchnic extraction of phenylalanine, validate an oral infusion of [1-^{13}C]phenylalanine, and test the effects of threonine supplementation on whole-body protein synthesis in horses. Six thoroughbred mares were fed timothy hay and a low threonine concentrate supplemented with isonitrogenous amounts of either threonine (+THR) or glutamate (+GLU), which were top dressed on the concentrate portion of the diet. Threonine intakes were 119 (+THR) and 58 mg/kg/d (+GLU) and diets exceeded NRC recommendations for all nutrients, including threonine (33 mg/kg/d). Each horse received each diet twice for 7d; studied once with an oral infusion and once with an intravenous infusion of [1-^{13}C]phenylalanine, for a total of four study periods per horse. On d 6 of receiving each diet, blood samples were taken before and 90 min after the AA supplemented concentrate meal. The next day, a 2-h primed, constant intravenous infusion of [^{13}C]sodium bicarbonate and a 4-h primed, constant infusion of [1-^{13}C]phenylalanine, either oral or intravenous, were used with blood and breath sampling to measure blood [^{13}C]phenylalanine and breath $^{13}CO_2$ enrichment. Data were analyzed in the PROC MIXED of SAS with threonine intake, route of infusion and the interaction as the fixed effects. Baseline and post-feeding plasma concentrations of glutamate, serine, glycine, threonine, and methionine were affected by diet ($P < 0.05$). Phenylalanine flux, intake, from protein breakdown, oxidation, and non-oxidative disposal were not affected by diet ($P < 0.05$). Splanchnic extraction was 26 ± 5% and 27 ± 3% for the +THR and +GLU diets, respectively. This was the first study to use oral administration of [1-^{13}C]phenylalanine in horses and this technique offers a less invasive alternative to the intravenous infusion method. Threonine does not appear to be a limiting AA in our diet, as phenylalanine kinetics were not affected by supplementation; however differences in plasma AA concentrations in response to threonine supplementation suggest that this AA can affect the metabolism of other AA. *This project was supported by Agriculture and Food Research Initiative Competitive Grant no. 2012–67015–19448 from the USDA National Institute of Food and Agriculture.*

Key Words: splanchnic extraction, equine, amino acids

1200 (T138) Effects of a docosahexaenoic acid-rich algae supplement on plasma amino acid levels in healthy, mature horses after prolonged treatment with dexamethasone. R. A. Williams[1], K. L. Urschel[2], R. E. Schaeffer[1], and K. M. Brennan*[1], *[1]Alltech Inc., Nicholasville, KY, [2]University of Kentucky, Lexington.*

Dexamethasone (DEX) is used to treat inflammation and off-label as a calming agent in performance horses. Long-term treatment with DEX reduces insulin sensitivity (SI) and can impair other insulin-activated pathways such as protein synthesis. We previously reported that supplementation with docosahexaenoic acid (DHA)-rich algae increased SI during prolonged DEX treatment in healthy horses. The objective of this study was to determine the effect of a DHA-rich algae supplement on plasma amino acid levels in healthy, mature horses after prolonged treatment with DEX. Eight healthy, mature horses were used in a balanced, crossover design of two 56-d periods. In each period, horses were fed a basal diet (CON), or diet + 152 g/d of a DHA-rich algae (15% CP; Algae SP-1, Alltech Inc., (ALG)) providing 21.1 g/d DHA for 28 d, after which blood was sampled (*P*re-DEX) and 0.04 mg DEX/kg BW/d administered orally; treatment continued for 21 d, then blood was sampled (*P*ost-DEX). Plasma AA concentrations were determined every 30 min during a 2-h insulin infusion. Plasma amino acid concentrations were analyzed using PROC MIXED using repeated measures analysis, with pre-DEX baseline as a covariate. Diet had no effect on plasma amino acid concentrations with the exceptions of Lys, Met, Ala and Gln ($P < 0.05$). A treatment by DEX interaction ($P < 0.01$) occurred for Glu, Ser, Asn, Gly, Gln, His, Thr, Ala, Pro, Tyr, Val, Met, Leu, Phe and Lys. Within each of the CON and ALG treatments, all horses received the same diet during both the pre- and post-DEX periods and therefore the increase in plasma amino acid concentrations in response to DEX in the CON horses suggests either an increase in rates of protein degradation or a decrease in rates of protein synthesis in response to prolonged DEX administration. Daily ALG feeding appeared to mitigate these changes in plasma amino acid concentrations. Additional research is necessary to identify the mechanism of this algae effect, although we hypothesize this is due to the previously reported increased SI with ALG.

Key Words: horse, amino acid, dexamethasone, docosahexaenoic acid

1201 (T139) Evaluating the expression of microRNA miR-1 and miR-133 in the muscle of horses fed a docosahexaenoic acid-rich algae supplement after prolonged dexamethasone treatment. M. L. Spry, A. C. Smith, D. E. Graugnard, R. E. Schaeffer, and K. M. Brennan*, *Alltech Inc., Nicholasville, KY.*

MicroRNAs (miRNAs) are small noncoding RNAs that bind to the 3' untranslated (3'UTR) region of genes and are responsible for inhibiting translation or promoting mRNA degradation. Two well characterized muscle-specific miRNAs are miR-1, and miR-133. MiR-1 decreases myoblast proliferation and increases differentiation, whereas miR-133 has an opposing effect promoting myoblast proliferation while decreasing differentiation. It is known that skeletal muscle breakdown and an increase in circulating amino acids are associated with the decreased insulin sensitivity after prolonged dexamethasone (DEX) treatment. In horses there is an association between an increase in miR-1 and miR-133 levels and diseases involving muscle breakdown. Supplementing diets with DHA-rich algae (Algae SP-1, Alltech Inc., (ALG)) improves insulin sensitivity and decreases plasma amino acid levels in horses after prolonged DEX treatment. The objective of this study was to determine the effect of Algae SP-1 supplementation on miR-1 and miR-133 expression in healthy, mature horses ($n = 5$) before and after DEX treatment using a balanced, crossover design of two 56-d periods. In each period, horses were fed a basal diet (CON), or diet + 152 g/d of ALG for 28 d and muscle was sampled (*P*re-DEX). DEX was then administered (0.04 mg/kg BW/d, orally) for 21 d while dietary treatments continued. On d 49 of dietary treatments (*P*ost-DEX), muscle was sampled and microRNA was measured using TaqMan MicroRNA Assays (Applied Biosystems). The relative quantification (RQ) was expressed as a ratio of the target microRNA to control microRNA normalized to a pooled control (CON, pre-DEX) using the delta-delta Ct ($^{\Delta\Delta}$Ct) method. There was no effect of diet, DEX or diet*DEX interaction on skeletal muscle miR-1 and miR-133 expression. Novel techniques used for miRNA evaluation could be useful to help relate changes in gene expression to physiological status, however further studies are needed.

Key Words: microRNA, horse, dexamethasone, docosahexaenoic acid

1202 (T140) The effects of abrupt dietary alterations on equine cecal pH. A. Reeg*[1], T. Douthit[1], K. M. DeLano[1], M. E. Gordon[2], M. M. Raghavendra Rao[2], and K. Williamson[2], *[1]Kansas State University, Manhattan, [2]Purina Animal Nutrition, LLC, Gray Summit, MO.*

Feeding starch in quantities exceeding 3.4 g/kg BW to the equine has been shown to exceed small intestinal capacity for digestion (Potter et al., 1992). This leads to fermentation of starch in the cecum resulting in a buildup of acidic products and decline in pH. Two consecutive 22-d experiments separated by 2 d of rest were conducted to identify whether abruptly feeding 1% (3.1 g starch/kg BW) and 1.25% (3.88 g starch/kg BW) BW concentrate during experiments 1 and 2, respectively, without hay would elicit a more profound decrease in cecal pH, as compared to the baseline diet. Nine cecally cannulated 8- to 10-yr-old quarter horses, 5 geldings and 4 mares, ranging in BW from 455 to 591 kg, were utilized. Baseline diets

for both expt. consisted of 0.5% BW concentrate (Omolene 200, Purina Animal Nutrition, LLC, Gray Summit, MO; 1.55 g starch/kg BW) fed at 0700 and 1.5% BW native prairie grass hay divided into two feedings (0700 and 1930) for 21 d. On d 22 of both experiments the concentrate meal was increased to 1% (Exp. 1) and 1.25% (expt. 2) BW and fed without hay. Cecal pH was measured from d 19 to 22 of both experiments at -1, +1, +4, +8, +12, +16, +20, and +24 h relative to feeding concentrate. ANOVA was performed with mixed models (SAS 9.3, 2011) and least square means compared using Fisher's LSD ($P < 0.05$, LSM ± SE). Complete randomization with either repeated measures (Exp. 1) or a split-plot design (expt. 2) was utilized. In both experiments, there was a time effect ($P < 0.0001$) on cecal pH. Exp. 1 cecal pH at +1 (7.2 ± 0.046) and +12 (6.8 ± 0.046) h on d 22 was decreased ($P < 0.05$) when compared to mean responses at +1 and +12 h during baseline feeding (7.4 ± 0.046 and 7.02 ± 0.046, respectively). In Exp. 2 cecal pH was decreased ($P < 0.05$) only at +12 h (6.8 ± 0.041) on d 22 when compared to mean values at +12 h during baseline feeding (7.0 ± 0.041). Throughout both experiments, post-prandial cecal pH was characterized by a decline at +4 h, reached a minimum value at +8 h, and increased by +12 h. However, the primary variation between baseline and d 22 was a more rapid rise in pH from +8 to +12 h.

Key Words: equine, starch, cecal pH

1203 (T141) Utilizing fecal pH to predict cecal pH in the equine. C. J. Douthit*[1], T. Douthit[1], A. Reeg[1], N. M. Bello[1], M. E. Gordon[2], and K. Williamson[2], *[1]Kansas State University, Manhattan, [2]Purina Animal Nutrition, LLC, Gray Summit, MO.*

Cecal cannulation is commonly used for direct assessment of dietary manipulation on cecal pH in equines. However, analysis of fecal material is considered one of few viable methods for monitoring digestive health in intact horses. In this retrospective study, we assessed the association between fecal pH and cecal pH in an attempt to develop a predictive equation for cecal pH. Nine cecally cannulated quarter horses were utilized. The group was comprised of 5 geldings and 4 mares, between the ages of 8 to 10 yr and body weight ranging from 455 and 590 kg. Horses were housed in heated individual stalls with ad libitum access to water and white salt blocks. Horses were fed 1.5% BW prairie grass hay split into twice daily feedings (0700 and 1830) and 0.5% BW concentrate (Omolene 200, Purina Animal Nutrition, LLC, Gray Summit, MO) which was fed in the mornings only (0700). Horses were maintained on this diet for 3 separate 21-d periods. Cecal and fecal pH were measured on d 19 to 21 of each period at -1, +1, +4, +8, +12, +16, +20, and +24 h relative to feeding the concentrate meal. Given inherent animal-to-animal variability in the pH dynamics of the cecum and rectum over time, the minimum cecal pH after feeding was collected for each animal-day combination and modeled as a function of the corresponding minimum fecal pH using a general linear mixed model. Analysis revealed evidence for an association ($P = 0.03$) between minimal cecal pH and minimal fecal pH. The estimated rate of change for minimum cecal pH per unit increase in minimum fecal pH was 0.131 with 95% confidence interval [0.011, 0.251]. The prediction equation for estimated cecal pH was $Y = 0.131*X + 5.8969$, where X is the observed fecal pH. However, the amount of predictive variability was considerable, likely due to multiple factors contributing to cecal pH, including feed composition, animal weight, and physiological state, which can alter the transit time of digesta from cecum to rectum. Our data indicates that fecal pH appears to have limited usefulness in predicting cecal pH.

Key Words: cecal pH, equine, fecal pH

1204 (T142) Comparison of ultrasound transducers to determine rump fat thickness in mature horses at maintenance. K. J. Stutts*, J. L. Lucia, M. J. Anderson, M. M. Beverly, and S. F. Kelley, *Sam Houston State University, Huntsville, TX.*

Rump fat measurements are utilized to assess changes in subcutaneous fat thickness when conducting feeding trials in horses. Commonly, these measurements are taken using a transducer that is designed for use in the rectum to evaluate the reproductive tract. This study was conducted to determine if measurements obtained using a rectal transducer were comparable to measurements obtained using a transducer designed to measure carcass characteristics. Rump fat measurements were obtained from 30 mature horses (368 to 552 kg and 5 to 10 yr) that were part of a feeding trial. Measurements were taken at 28-d intervals for a period of 154 d at a point half way between the points of the hip (Tuber coxae and Tuber ischiadicum) and 6 cm from the midline of the horse with the transducer positioned perpendicular to the midline of the horse. Images were taken with an Aloka SSD 500V real-time ultrasound machine (Corometrics Medical Systems, Wallingford, CT) equipped with a 17.2-cm, 3.5-MHz linear transducer (carcass probe) and a 6-cm, 5-MHz linear transducer (rectal probe). All measurements using the carcass probe were conducted by a certified technician who captured images that were analyzed at the Centralized Ultrasound Processing Lab (Ames). All measurements using the rectal probe were conducted by a non-certified employee using on-screen diagnostic tools on the scanner. Longissimus muscle (LM) area between the 17th and 18th ribs and fat thickness three-quarters the length ventrally over the LM were also obtained using the carcass probe. Least squares means for rump fat thickness (RFT) and LM fat thickness (LMFT) were calculated using the GLM procedure of SAS. Pearson correlation coefficients were used to determine the relationship between RFT and LMFT. Mean RFT was greater ($P < 0.01$) using the rectal probe (1.27 ± 0.39 cm) compared to the carcass probe (1.00 ± 0.36 cm); however, there was a strong, positive relationship between the two measurements

(r = 0.76, P < 0.01). Measurements using both the rectal (r = 0.48) and the carcass (r = 0.33) probes also had a positive relationship (P < 0.01) with LMFT with a greater correlation observed between LMFT and RFT measurements using the rectal probe. These data validate the utility of the rectal probe to measure RFT in horses. Although measurements were different between the rectal and carcass probes, measurements obtained using the rectal probe accurately assessed changes in RFT and exhibited a greater correlation to changes in fat thickness over the *longissimus* muscle.

Key Words: horses, ultrasound, rump fat

1205 (T143) On-farm tapeworm testing in horses.

N. C. Whitley*[1], R. Kaplan[2], K. Moulton[1], S. B. Routh[1], R. Franco[1], and R. K. Splan[3], *[1]North Carolina A&T State University, Greensboro, [2]University of Georgia, Athens, [3]Virginia Tech, Middleburg.*

The incidence of tapeworm infection in horses was investigated on nine farms in North Carolina and one in Virginia. Two of the North Carolina farms were used in three replicates. A total of 602 horses at least 1 yr of age were used (321 individuals, 281 were replicates; 157 females, 164 males) in the summer, fall, and winter seasons. Individuals averaged 12.1 ± 0.4 yr of age and 541.8 ± 7.0 kg body weight. Animals were treated with commercial horse anthelmintics containing ivermectin and praziquantel (Zimecterin Gold; n = 412; eight farms including those replicated; and Equimax™; n = 190; four farms) as labeled for BW measured by equine weight tape plus 15% with doses rounded up to the nearest 22.7 kg (50 lb). At treatment (d 0) and 24 hlater (d 1), fecal samples were collected after defecation for tapeworm fecal egg count (FEC) using the Modified McMasters technique with a sensitivity of eight eggs per gram (epg). Descriptive statistics were used to report data. On d 0, 1.4 ± 0.01% of horses were positive for tapeworm eggs, whereas on d 1, 20.6 ± 1.7% were positive. Positive horses were found on 30% of farms on d 0 and 60% of farms on d 1. This data suggests that tapeworm infections are common on horse farms, but that most horses do not have infections or have undetectable infections. Furthermore, these data demonstrate that sensitivity of detection for tapeworms via fecal exam is greatly increased by testing 1 d after treatment.

Key Words: tapeworms, horses, FEC

HORSE SPECIES II

1206 (W134) Trotting stride variables of the North American Akhal-Teke Horse. M. C. Nicodemus[*1] and J. Beranger[2], [1]*Mississippi State University, Starkville,* [2]*American Livestock Breeds Conservancy, Pittsboro, NC.*

Although the population is less than 350 horses placing it on the threatened breed list of the American Livestock Breed Conservancy (ALBC), the Akhal-Teke Horse of North America is as a source and a reservoir for genetic diversity for the ancient breed as it includes bloodlines that are unique. Preservation of the breed and its distinctive characteristics such as its smooth and elastic gaits is of top priority to the ALBC and the Akhal-Teke Association of America, and to accomplish this, a better understanding of the breed is needed. Therefore, the objectives of this study were to measure and describe the stride timing found in the trot of the Akhal-Teke Horse of North America. Subjects (n = 6) were selected through the direction of the ALBC and the Akhal-Teke Association of America based on bloodlines and performance history. Each horse was filmed at 60 Hz being ridden under saddle by a rider familiar with the horse at a trot with hoof contact and lift-off documented using frame-by-frame analysis. Means (SD) were determined for 10 strides for each horse with variables given as % of stride and variability of measurements indicated using the coefficient of variation (CV) expressed as a % of mean. The trot was performed in a diagonal footfall pattern that alternated between periods of unipedal (Hind: 10 ± 1%, CV 6%; Fore: 10 ± 2%, CV 19%) and bipedal (Diagonal: 80 ± 2%, CV 3%) supports. The trotting velocity (4.34 ± 0.15 m/s, CV 3%) was achieved using a stride length of 2.96 ± 0.25 m (CV 8%), rate of 1.47 ± 0.11 strides/s (CV 7%), and duration of 683 ± 49 ms (CV 7%) with the limbs spending the majority of the stride in the swing phase (Fore: 55 ± 2%, CV 6%; Hind: 54 ± 2%, CV 4%). The diagonal limbs moved as couplets, both at hoof contact (Advanced Placement: 5 ± 1%, CV 15%) and lift-off (Advanced Lift-Off: 5 ± 1%, CV 19%), creating a 4-beat rhythm. Coupling, rather than pairing of limbs, was similar to the stride timing reported in previous research for Dutch Warmblood and Standardbred horses, but the unpairing of diagonal limbs occurred at dissimilar velocities. In addition, the absence of suspension that has been reported for other trotting breeds such as the Dutch Warmblood and Morgan horse was also produced at a velocity distinctive from the other breeds suggesting velocity may account for the uniqueness of the trot of the Akhal-Teke Horse of North America.

Key Words: Akhal-Teke

1207 (W135) Development of an objective on-farm equine temperament scoring system. J. N. Foley[*1], J. L. Lucia[2], and K. W. Walter[1], [1]*Truman State University, Kirksville, MO,* [2]*Sam Houston State University, Huntsville, TX.*

To evaluate interest in development of an objective equine temperament scoring system (TSS), an online survey was distributed via hyperlink to faculty at three public universities and their equine interest groups and social media pages. Of 123 respondents, 71.4% were familiar with existing TSS, 81.1% of those familiar with existing TSS felt they did not accurately represent the horse's temperament, and 70.5% were interested in an improved TSS to replace subjective scales currently used on equine websites (equinenow.com and horsetopia.com most frequently cited). Existing TSS rank the horse from 1 to 10 (1 = calm, 10 = spirited), however no further clarification is provided. To assess equine temperament more objectively, 27 horses were utilized in a two phase test. Phase 1 incorporated 10 min of isolation while tied. Frequency of vocalization, defecation, urination, lateral movements, forelimb pawing, and blatant pulling on lead were recorded and used to develop a 0 to 6 scoring system (score assigned based on frequency of aforementioned behaviors). Phase 2 tested willingness to cross an unfamiliar obstacle. Horses were allowed 1 min to cross the obstacle. If the obstacle was refused, horses were trotted in a 5 m circle for 1 min. This procedure was repeated up to 5 times, and horses were assigned a score from 0 to 6 based on time required to cross with little resistance or fear. For both phases, vital signs of heart rate (HR), respiration rate (RR), and rectal temperature (RT) were evaluated immediately before and after each test. Blood samples were taken via jugular venipuncture and later analyzed for cortisol concentration utilizing a commercially available ELISA kit. Pre-test values of HR, RR, RT and cortisol concentrations were subtracted from post-test values to calculate the difference. Pearson's correlations were analyzed for all variables within phase, and Spearman's rank test performed to compare phases. Strong positive correlation existed between difference in cortisol and assigned score in both phase 1 and 2 ($r \geq 0.61$; $P < 0.001$). A strong positive correlation between assigned score in both phases and difference in vital signs (HR, RR, RT; $r \geq 0.4387$, $P \leq 0.02$) was noted. However, there was no correlation between phase 1 and phase 2 scores ($r = 0.25$, $P = 0.20$). This suggests each phase successfully evaluated different aspects of equine behavior using clearly defined 0 to 6 point scales, and both phases could be used together to evaluate equine temperament.

Key Words: behavior evaluation, equine, temperament scoring

1208 (W136) Cooling of equine semen at 16°C for 36 h with the addition of cysteine in different concentrations. R. A. De Oliveira[1], L. S. Murata[*1], M. A. D. O. Viu[2], and M. L. Gambarini[2], *[1]University of Brasilia, Brazil, [2]Federal University of Goiás, Goiânia, Brazil.*

Equine semen manipulation during the cooling process reduces sperm viability and fertility in consequence to, among others, membrane lipid peroxidation, because of the high content of polyunsaturated fatty acids, which makes cells highly susceptible to free radicals and reactive oxygen species. The objective of the present study was to evaluate the effect of in vitro addition of cysteine in four concentrations (0, 1, 1.5, and 2.5 mM) for cooling spermatozoa of 12 stallions at 16°C for 36 h. Evaluated variables were motility, vigor, viability and plasmatic and acrosomal membrane integrity in four different moments (0, 12, 24, and 36 h). With the exception of acrosomal integrity, it was verified a reduction in motility, vigor and plasmatic membrane integrity in all samples, during cooling. In the evaluations at 36 h of cold storage, motility (mot) and viability (viab) were greater in groups treated with 1 mM (mot:46,5 ± 6,1/viab:76,5 ± 6,9) and 1.5 mM (mot:46,0 ± 4,6/viab:76,9 ± 3,7) cysteine, respectively, compared to control (mot:35,5 ± 18,4/viab:68,1 ± 13,4) and 2.5 mM (mot:39,7 ± 12,4/viab:66,0 ± 17,2) ($P < 0.05$). As for vigor (vig) and plasmatic membrane integrity (plasm), 1 mM cysteine (vig:3.6 ± 0.5/plasm: 57.2 ± 9.5) showed greater results compared to control (vig:3.2 ± 1.1/plasm:54.1 ± 11.8), 1.5 mM (vig:3.5 ± 0.6/plasm:52.2 ± 13.3) and 2.5 mM (vig:3.2 ± 1.1/plasm:55.8 ± 12.5) ($P < 0.05$). Regarding acrosomal membrane integrity, in general, there was no loss of integrity (70.5 ± 10.4; 69.4 ± 4.4; 68.0 ± 7.2 and 70.3 ± 0.5), control, 1 mM, 1.5 mM and 2.5 mM, respectively. The concentration of 1 mM cysteine was more effective for the protection of sperm cells in the commercial system of passive cooling at 16°C for 36 h, with greater values for motility, vigor, viability and plasmatic membrane integrity.

Key Words: antioxidant, cooled semen, stallion

1209 (W137) Administration of bioactive proteins to mature horses improves gait kinematics. J. Coverdale*, and J. M. Campbell[2], *[1]Texas A&M University, College Station, [2]APC, Inc., Ankeny, IA.*

Thirty mature quarter horses (439 to 684 kg and 5 to 22 yr) were utilized in a randomized complete block design to evaluate the effect of a supplement consisting of a proprietary blend of bioactive proteins on gait kinematics. These bioactive proteins are isolated from plasma. Horses were blocked by age and BW and randomly assigned to treatment within block for the 28-d trial. Treatments consisted of a commercial pelleted concentrate administered with no supplement (CON), 240 g/d of a pelleted supplement containing 66 g of bioactive proteins (Low; Lifeline, APC, Inc.), or 240 g of a pelleted supplement containing 132 g of bioactive proteins (High; Lifeline, APC, Inc.). Concentrate was fed at 0.5% BW (as-fed) daily in addition to ad libitum coastal bermudagrass hay. Each horse was exercised by a single assigned student 5 d/wk focusing on horsemanship skills at the walk, trot, and canter approximately 60 min/d. Gait kinematic analysis was performed on d 0, 14, and 28 with video footage collected and analyzed using gait analysis software (EquineTec). Horses were trotted in hand for three passes over a 10 m flight path while wearing reflective markers at each joint of the right limbs. Stride length was measured as distance the right foreleg traveled during the swing phase. Additionally, range of motion (ROM) of the knee was determined using the difference between the maximum and minimum angles observed during each frame of the swing phase. All data were analyzed using PROC GLM of SAS. Mean stride length of the front limb tended to increase linearly at d 14 as increasing levels of bioactive proteins were added to the diet ($P = 0.07$). Similarly, at d 28 stride length of the front limb increased linearly with increasing inclusions of bioactive proteins ($P = 0.05$). Stride length at the trot of the hind limb tended to increase at d 14 ($P = 0.10$) and increased linearly at d 28 ($P = 0.02$) with increasing levels of bioactive proteins. When evaluated at the trot, knee range of motion increased linearly at d 14 and d 28 with increasing levels of bioactive proteins in the diet ($P < 0.01$). In conclusion, supplementation of bioactive proteins in mature, exercising horses resulted in improved gait kinematics.

Key Words: bioactive proteins, gait, horse, stride, supplement

1210 (W138) The effect of skim milk as an equine semen extender. M. L. Freitas, C. S. Bouéres, F. J. G. De Oliveira, L. S. Murata*, and R. A. De Oliveira, *University of Brasilia, Brazil.*

Cryopreservation constitutes the best method to conserve the genetic material of great zootechnic value stallions. However, the expenses of this procedure are high, becoming an obstacle to the spread of this biotechnology. One possible way to reduce spending on the process of cryopreservation is to search for alternative and less onerous extender media. The current study aimed at comparing the commercial semen extender (control group) to UHT skim milk (treatment group) used during centrifuging for subsequent cryopreservation of equine semen. After thawing of semen, parameters such as computerized spermatic kinetics and acrosome and plasmatic membrane integrity using fluorescent dyes were assessed. No differences ($P > 0.05$) were observed in what concerns to total sperm motility (42.71 × 38.29%); progressive sperm motility (12.29 × 7.86%); plasmatic membrane integrity (53.43 × 60.14%) and acrosomal membrane integrity (93.29 × 93.71%) between the control and the treatment groups. Considering that UHT skim milk has a much lower cost than the commercial semen extender, this may henceforth skim milk is an

option for extending equine semen, which decreases the expenses of the equine semen cryopreservation process.

Key Words: equine, sperm, UHT skim milk

1211 (W139) Reproductive activity in quarter horse mares with artificial light. J. A. Ramírez-Godínez*, J. Delgado-Laphond, A. Flores-Mariñelarena, and E. Santellano-Estrada, *Universidad Autónoma de Chihuahua, México.*

The objective was to determine the effect of artificial light during the winter on the reproductive activity in quarter horse (QH) mares in México. Sixty seven QH mares, 5 to 12 yr old with an average weight of 480 ± 20 kg, and body condition between 5 and 7 were randomly divided into a control group (G0, n = 15), exposed to natural light and an artificial light group 1 (G1, n = 52), exposed to artificial light to complete 16 h light from November 15 to February 15. Both groups were alternately monitored (every other day) with a teaser stallion to assess the presence of estrus, and the reproductive tract ultrasounded to monitor follicular growth and ovulation. Means for days to estrus, ovulation, pregnancy, services per conception and size of the ovulatory follicle were compared between treatments using the GLM procedure of SAS. The effect of treatments on ovulation rate per month was analyzed by Chi Square ($\chi 2$ test) using the FREQ procedure of SAS. The use of artificial light accelerated ($P < 0.001$) the onset of estrus, ovulation and gestation considerably. The average time from exposure of artificial light to onset of estrus was 47 ± 3.21 d ($P < 0.001$) in G1 and 105 ± 6.13 d in G0, and to ovulation 81.6 ± 3.7 d with artificial light (G1) and 134.5 ± 7.0 d control group (G0). The highest rate of ovulations ($P < 0.1$) occurred in February (0.46) in G1 and in April (0.66) in G0, respectively. Diameter of the ovulatory follicle was similar ($P > 0.05$) in mares in the control group (40.7 ± 1.11 mm) than under artificial photoperiod (41.7 ± 0.58 mm). The interval from the onset of artificial light to pregnancy was 96.54 ± 4.46 d (G1) and 141.28 ± 8.53 d with natural light (G0; $P < 0.001$). The services per conception (SPC) were similar ($P < 0.05$) between treatments (1.6 ± 0.123 SPC for artificial photoperiod and 1.7 ± 0.236 SPC for controls, respectively). The use of artificial light from November to February in QH mares accelerated the presence of estrus and the ovarian activity (ovulation) which resulted in a higher proportion of earlier gestations in the year.

Key Words: estrus, ovulation, mares

1212 (W140) Composition of follicular fluid and serum, ovarian dynamics, and IGF-1 concentrations following n-3 fatty acid supplementation in mares. S. E. Buist*[1], M. J. Schmidt[1], D. M. Grieger[1], C. A. Blevins[1], S. K. Webel[2], T. L. Douthit[1], L. Murray[1], and J. M. Kouba[1], *[1]Kansas State University, Manhattan, [2]JBS United, Baylis, IL.*

The effects of a marine-derived n-3 fatty acid supplement on ovarian dynamics and follicular fluid and serum composition were evaluated during the estrous cycle in mares. Fifteen mares were assigned to a control diet (CONT, n = 7) or a fish oil-enriched diet (FO, n = 8) providing 18.48 g eicosapentaenoic acid (EPA) and 10.08 g docosahexaenoic acid (DHA) daily. Follicular activity was determined via transrectal ultrasonography at the initiation of the treatment diet. Estrous cycles were synchronized in all mares concurrently with initiation of treatment diets using a progesterone and estradiol protocol. Following ovulation post-synchronization, mare monitoring continued through the second estrous cycle. Ovarian activity, timing of ovulation, and presence of a corpus luteum were recorded. Mares were scanned during the third estrous cycle until a 35-mm follicle was detected, at which time hCG was administered. A transvaginal ultrasound-guided follicular aspiration (TUGA) was performed on the largest preovulatory follicle 14 to 16 h post-hCG. Follicular fluid was analyzed for fatty acids, estradiol 17-β, LH, progesterone, $PGF_{2\alpha}$, PGE_2, and IGF-1 concentrations. Serum samples were collected at the onset of treatment diet and every 2 wk until termination of the study to determine fatty acid concentrations. Additional serum samples were obtained before hCG administration and before TUGA procedure for measurement of IGF-1. Arachidonic acid (ARA), EPA, docosapentaenoic acid (DPA), and DHA in mare serum and EPA, DPA, and DHA in follicular fluid were increased ($P < 0.01$) in the FO group. Serum IGF-1 was decreased ($P < 0.05$) in the FO group immediately before aspiration. Concentrations of IGF-1 were decreased ($P < 0.05$) in follicular fluid in the FO group compared with controls. No other differences in follicular fluid hormone concentrations were detected. Follicular growth rate, ovulation interval, and timing of ovulation were similar between groups. These data indicate that in addition to incorporation into serum, dietary n-3 fatty acids can also be incorporated into follicular fluid, and may have an inhibitory effect on serum and follicular fluid IGF-1 concentrations in the cycling mare.

Key Words: mare, n-3, follicular fluid

INTERNATIONAL ANIMAL AGRICULTURE: **INTERNATIONAL ANIMAL PRODUCTION**

1213 (T144) Handbook for livestock research on smallholder farms in developing countries.

A. L. Goetsch*, *American Institute for Goat Research, Langston University, Langston, OK.*

Resources for on-station livestock research in many developing countries are limited, and it is common for researchers to have little direct interaction with smallholders. On-farm research offers considerable attributes, which include attention to most significant production constraints, opportunities for meaningful studies, and greater adoption by smallholders of advantageous technologies. However, few researchers perform on-farm livestock research, at least partially because of inadequate training and knowledge of the design and conduct of on-farm experiments, statistical analyses and interpretation of resultant data, and preparation of reports suitable for peer-reviewed journals. Thus, a publication has been developed as a resource for training in methods of applied livestock research, with special attention to treatments, design, implementation, analysis, interpretation, and peer-reviewed articles. The target audience is junior to mid-level professionals (e.g., MSc) and graduate students in developing countries. In addition to US participants in the publication project, there are foreign collaborators and evaluators from Ethiopia, India, China, Jordan, México, Israel, and Japan. Major sections of the publication include: introduction; on-station vs. on-farm research; topic identification; protocols; experimental design; treatment considerations; experiment implementation; statistical analyses; dissemination with an emphasis on preparation, review, and revision of scientific manuscripts; and literature cited. Furthermore, a key component is the design and analysis of numerous example study scenarios, such as: farmer research groups– missing data, nature of the data; individual smallholder households– household animals on one treatment, household animals on each treatment, missing data and household animals on one vs. each treatment, households with subplots; group or village as fixed vs. random; studies in different seasons or years; year-round performance monitoring– continuous and categorical variables; and crossovers, switchbacks, and Latin squares. There are also comparisons of P values from different analyses (e.g., SAS GLM and MIXED and GenStat). Appendices contain the relevant statistical analysis statements and inputs, results, and simulated data sets. Workshops based on the publication were held during 2013 and 2014 in Kenya, Ethiopia, China (two sites), Jordan, Malawi, México, and India (two sites) to create awareness of the resource, train junior researchers, and receive feedback for publication enhancement, with well over 200 attendees. After external peer-review in fall 2014, hardcopies will be distributed and the publication made available free on the Institute's website (www2.luresext.edu).

The project was supported by the USDA Foreign Agricultural Service (grant/agreement no. 58–3148–2-175).

Key Words: applied research, livestock, small holders

1214 (T145) Reproductive performance in United Kingdom Holstein dairies by geographic region.

J. Hildon[1], C. Vergara*[2], and H. Lopez[2], *[1]Genus ABS, Stapeley, UK, [2]ABS Global, DeForest, WI.*

Our objectives were to compare reproductive indicators from Holstein dairies in three regions of The United Kingdom and establish benchmarks for the 20% most efficient herds. Data from 30,112 cows and 95,326 inseminations recorded on Dairy Comp 305 software were evaluated from January to December 2014 from 111 dairies in Region 1 (R1[North; n = 16 herds]), Region 2 (R2[West; n = 52]), and Region 3 (R3[South; n = 43]). Analyses were conducted with the PROC MIXED using herd as the experimental unit. Mean herd size (R1 = 252 ± 126; R2 = 267 ± 119; R3 = 284 ± 156), mean daily milk production in kilograms (R1 = 27 ± 3; R2 = 27 ± 4; R3 = 28 ± 5), days for voluntary waiting period (R1 = 40 ± 5; R2 = 42 ± 4; R3 = 40 ± 4), days for pregnancy diagnosis (R1 = 37 ± 5; R2 = 37 ± 4; R3 = 35 ± 5), days to reenrollment (R1 = 15 ± 4; R2 = 15 ± 4; R3 = 14 ± 4), conception rate for inseminations after natural estrus (R1 = 37%; R2 = 36%; R3 = 34%), insemination risk (R1 = 53%; R2 = 56%; R3 = 56%), pregnancy rate (R1 = 19%; R2 = 19%; R3 = 20%), and percentage of cows pregnant by 100 DIM (R1 = 49%; R2 = 50%; R3 = 53%), by 150 DIM (R1 = 69%; R2 = 72%; R3 = 75%) and by 300 DIM (R1 = 88%; R2 = 91%; R3 = 89%) did not differ among regions. The percentage of cows bred after synchronization was lower ($P < 0.05$) for R3 (7%) than R1 (12%), and R2 (10%) but conception rate did not differ (R1 = 29%; R2 = 28%; R3 = 28%). The 20% most efficient operations had mean pregnancy rate of 24%, mean daily milk production of 27 ± 4 kg, days to pregnancy diagnosis of 33 ± 5, days to re-enrollment of 12 ± 3, insemination risk of 61%, conception rate for inseminations after natural estrus of 39%, percentage of cows bred after synchronization of 7%, conception rate for inseminations after synchronization of 33%, and percentage of cows pregnant by 100 DIM of 61%, by 150 DIM of 83%, and by 300 DIM of 96%. The percentage of cows bred after synchronization was lower for the South region but no other regional differences were detected in reproductive parameters in United Kingdom dairies.

Key Words: fertility, reproduction, estrus

1215 (T146) Crossbreeding effects for body weight and carcass characteristics in a three-breed diallel cross. D. Norris[*1], L. Tyasi[2], and J. Ng'ambi[1], *[1]University of Limpopo, Polokwane, South Africa, [2]University of Limpopo, Sovenga, South Africa.*

A 3 × 3 complete diallel mating system involving three chicken breeds, namely Potchefstroom Koekoek (P), Venda (V) and Ovambo (O), was used to estimate crossbreeding genetic effects (heterosis, maternal effects and combining abilities) for growth and carcass characteristics. Nine genetic groups consisting of 25 chickens per group were produced which were reared from hatch to 10 wk of age. Body weights were recorded at hatch, 4, 8, and 10 wk of age while meat quality analysis (color, pH and tenderness) of the breast meat was done at slaughter age (10 wk). Meat tenderness was determined using the Instron-Warner-Bratzler Shear Force (WBSF). Potchefstroom Koekoek (P) was heavier at all different growth stages among the purebreds, while the Venda had the lowest weights at all different growth stages. The highest level of heterosis (30 and 21%) was observed in the V X P cross at 8 and 10 wk, respectively. The P x V cross showed positive estimates of maternal effects except at 10 wk of age. High and positive general combining ability (GCA) was observed in the Potchefstroom Koekoek (P) breed. The P x V showed positive effects of specific combining ability (SCA) at hatch, 4, 8, and 10 wk of age. With respect to meat characteristics, the Pochefstroom Koekoek breed had higher values of a* (redness) and b* (yellowness) color indicators in comparison to the other chicken breeds. Potchefstroom Koekoek and P x O breed had higher values of pH at 2 h and 24 h after slaughter. The pH declined in all the nine genetic groups at 2 h to 24 h, except for the P x O, which increased. The O x P had the highest shear value (74.80) while the lowest shear force (43.62) was observed in the P X V genotype. The P X V and its reciprocal cross, V X P could be further evaluated for other characteristics such as egg production and used as base for improved indigenous chicken production. It may be worthwhile to also consider developing a composite chicken breed based on these two breeds.

Key Words: crossbreeding, heterosis

1216 (T147) Total bacteria counting profile of raw milk in minas gerais state according to the storage system. A. G. Fernandes[1], L. M. Fonseca[*2,3], M. P. Cerqueira[2], M. O. Leite[2], M. C. P. P. Oliveira[2], R. M. Longo[2], G. C. Ribeiro[2], C. F. A. M. Penna[2], and M. R. Souza[2], *[1]Ministry of Agriculture, Belo Horizonte, Brazil, [2]Universidade Federal de Minas Gerais* (*School of Veterinary Medicine), Belo Horizonte, Brazil, [3]University of Wisconsin–Madison/CAPES Est. Senior 18183–12–3, Madison.*

The microbial contamination of milk is influenced by several factors and it is one of the major hindering problems for milk quality improvement in Brazil. The objective of the present work was to evaluate total bacteria counting of milk collected in different storage systems. A total of 1080 samples of milk from three regions of Minas Gerais State (Triângulo Mineiro, Sul, and Leste) were analyzed for total bacteria counting, during a 12-mo period. The samples were randomly selected from three storage systems, individual bulk tank milk, collective bulk tank milk, and cans. The last two storage systems are exceptionally allowed in Brazil under specific conditions. Each storage system was represented by 360 samples, which were preserved with azidiol, and sent to the laboratory for analysis in up to 72 h, using insulated boxes with reusable ice. All samples were evaluated by flow cytometry in the official federal net of laboratories for milk quality analysis in Brazil. Data were analyzed using general linear model and Tukey test for pairwise comparison. Collection system was the major factor correlated to the milk quality, with average countings of 5.38, 5.89, and 5.75 log CFU/mL for milk stored in bulk tank milk, collective bulk tank milk, and can, respectively. Non -compliance to the current standard of 600,000 CFU/mL was found in 47.6% of the samples, with 32.2, 61.1, and 49.7% non-compliant samples from bulk tank milk, collective bulk tank milk, and can, respectively. Considering recommended international standards, only 18.1% of the samples were in the range of up to 100,000 CFU/mL, comprising 28.6, 8.3, and 17.2% for, respectively bulk tank milk, collective bulk tank milk, and can storage. Milk quality was correlated to the seasonal variation ($P < 0.05$), with 53% of the samples above the limit of 600,000 CFU/mL during the rainy season. Regional differences were also observed. It is concluded that collecting systems, and regional and seasonal differences must be considered for strategic action by the dairy industries towards microbial quality improvement of raw milk.

Key Words: Brazil, microbial contamination, milk quality

1217 (T148) Reproductive performance in Chilean holstein dairies by geographic region. F. Arias[1], H. Lopez[2], R. Krauss[1], and C. F. Vergara[*1,2], *[1]ABS Chile Ltda, Santiago, Chile, [2]ABS Global Inc., DeForest, WI.*

Our objectives were to compare reproductive indicators from Holstein dairies in the three main productive areas of the Chilean Valley and establish benchmarks for the 20% most efficient herds. Data from 24,319 cows and over 70,000 inseminations recorded in DC305, Afi-farm, and Dairy Plan were evaluated from January to December 2013. Data included 30 dairies located in: Central Area (C [fifth, sixth, and Metro Regions]; n = 12 herds]) in dry lots and free-stall housing; South-Central Area (SC [seventh and eighth Regions]; n = 6 herds]) with free-stall and grazing systems; and South Area (S [ninth and 10th Regions]; n = 12]) with free-stall and grazing systems. Analyses were conducted with the PROC MIXED of SAS using herd as the experimental unit. The regions did not differ ($P > 0.05$) by mean (SD) herd size (C = 592 ± 315; SC = 940 ± 1612; S = 989 ± 815), days open in pregnant cows (C = 137 ± 19; SC = 135 ± 19; S = 144 ± 15), days in milk (C = 203 ± 17; SC = 209 ± 39; S = 210 ± 31), and days to first breeding (C = 71 ± 5; SC = 73 ± 10; S = 79 ± 4). Similarly, pregnancy risk (C = 19%; SC = 17%; S = 16%), insemination risk (C = 53%; SC = 48%; S = 46%), all services conception rate (C = 37%; SC = 37%; S = 38%), and removal rate by 60 d in milk (C = 7%; SC = 7%; S = 5%) were not different among regions. The S region had lower ($P < 0.05$) mean (SD) daily milk production in kilograms (25 ± 4) in comparison to the SC (34 ± 5) and C region (36 ± 5). The C region had more ($P < 0.05$) days of voluntary waiting period (51 ± 3) than regions SC and S (48 ± 4 and 47 ± 3, respectively). The 20% most efficient operations based on pregnancy risk ranking had a voluntary waiting period of 52 ± 3 d, mean pregnancy risk of 21%, insemination risk of 56%, and all services conception rate of 40%. They achieved 50% pregnant by Day 100 in milk, and mean (SD) days open and days in milk of 126 ± 8 and 184 ± 16, respectively. Conception rates for first insemination (40% vs. 35%) and for the first lactation (44% vs. 37%) were higher ($P < 0.05$) for the 20% most efficient herds. The 3 regions evaluated differed only in milk production level and voluntary waiting period. The most efficient herds had higher pregnancy risk, insemination risk, and conception rates; especially for first insemination and first lactation cows.

Key Words: fertility, reproduction, estrus

1218 (T149) In vitro fermentation and digestion characteristics of shrubs *Leucophyllum frutescens* and *Zanthoxylum fagara* browsed by white-tailed deer (*Odocoileus virginianum Texanus*). A. MS.[1], C. S. MA*[1], G. C. M.[1], G. R. H.[2], and R. L. RG.[3], *[1]Universidad Juárez del Estado de Durango, México, [2]Universidad Autónoma de Nuevo León, Linares, México, [3]Universidad Autónoma de Nuevo León, San Nicolás de los Garza, México.*

Native vegetation in northeastern México is mainly composed by shrubs and small trees, which are browsed by white-tailed deer. The aim of the study was to determine, seasonally, the in vitro fermentation profiles of *Leucophyllum frutescens* and *Zanthoxylum fagara.* Foliage was sampled from summer 2005 to spring 2006 for a total of four consecutive seasons in two country sites: Linares and Los Ramones in the state of Nuevo Leon, México. In vitro gas production was recorded at 3, 6, 9, 12, 24, 48, 72, and 96 h. As inoculum, rumen fluid from fistulated sheep was utilized. Microbial protein, ME content and in vitro organic matter digestibility (IVOMD) were also evaluated. Data were analyzed according to a multi-factorial arrangement being sites (2), shrubs (2) and seasons (4) the factors. Kinetic parameters significantly varied among shrubs, sites and seasons. The asymptotic gas production (B) ranged from 149 mL of gas/g DM in *L. frutescens* in summer 2005 in Los Ramones to 273 mL of gas/g DM in *Z. fagara* in winter 2006 in Linares country. The rate of gas production (c) was the lowest in *L. frutescens* in spring 2006 (0.028%/h) while the highest (0.104%/h) in *Z. fagara* collected in summer 2005 in Los Ramones. Values regarding lag phase (L) ranged from 0.64 to 2.07 h; in general, this variable was superior during spring seasons in both sites. Interactions sites x shrub species x seasons were significant ($P < 0.001$) for all kinetic parameters except for L. Microbial protein synthesis measured as purines varied significantly among sites, shrubs and seasons. Mean values ranged from 2.76 to 10.91 µmol, the latter was registered in *L. frutescens* collected in spring 2006 in Linares. The same scenario was registered with the ME content where values varied from 0.66 to 2.60 Mcal/kg DM. Estimates of IVOMD ranged from 56.8 to 93.1%. In general, highest digestibility values were registered in *Z. fagara*. Significant interactions related to IVOMD were registered as well. Data suggested that regardless spatiotemporal variations, variables such as constant rate of gas production, ME and microbial protein synthesis support the nutritive potential of the studied shrub species specially during the summer and autumn seasons for white-tailed deer.

Key Words: gas production, semiarid regions, white-tailed deer

1219 (T150) Characterization of goat foraging and body condition in Jhadol Block, Udaipur, India.
M. Valentine*, *Cornell University, Ithaca, NY.*

India contains 125.7 million goats, 14.6% of the global goat population. Smallholder farmers own the majority of Indian goats, and animal productivity ranks far below goats' genetic potential. Our objective was to characterize the feeding practices of goat owners and the nutrition of goats in the Jhadol Block of the Udaipur District in Rajasthan, India. Sixty-four goat owners were surveyed in 10 villages of the Jhadol Block. The questionnaire focused on various aspects of the livestock system including socio–economic characteristics, livestock management, goat consumption and physical assessment of goat condition. The survey was broken into general household data, goat husbandry practices, goat diet composition, feeding habits, feed shortage mitigation, crop residue use and lactation. Most interviewees received the majority of their income as wage laborers and subsisted on their own land. Mean household landholdings were 0.52 ha with SD ± 0.248. Households owned from 1 to 22 goats with an average of 6.59 ± 4.12 goats. The highest level of education averaged 7.03 ± 3.75 yr, and 65.6% of households had electricity. Linear regression models and bivariate tables were used to compare data. Goat health was assessed using body condition scoring, which was measured by applying a five-point palpation and observation-based scale. Body condition was related to socio–economic factors, geographic location, and management practices. Body condition was significantly correlated with the household and village, in addition to whether the household cultivated forages (P = 0.0076) or lopped tree branches in the rainy season (P = 0.0385). The target population was also stratified by how many of the three local seasons (rainy, winter and summer) households took goats foraging outside of the home as a way to characterize goats' feeding regiment. Number of seasons foraged was compared to household parameters such as number of persons, number of goats, education and land. Seasons foraged was correlated with the total number of goats (P = 0.0105) and total number of other livestock owned (P = 0.0196). Aspects of the semi-extensive goat system in the Udaipur district were characterized to better understand household characteristics and practices that contribute to sound nutritional management practices and healthier goats. Information generated from these analyses advances knowledge of goat farming systems in rural Rajasthan, where there is currently limited published information to support caprine management or direct future caprine research initiatives.

Key Words: India, goat systems, semi-extensive farming

1220 (T151) Characterization of cattle manure value chains in South-Central Vietnam.
K. C. McRoberts[1], D. Parsons[2], C. F. Nicholson[3], L. V. Nam[4], and D. J. R. Cherney*[1], *[1]Cornell University, Ithaca, NY, [2]University of Tasmania, Hobart, Australia, [3]Pennsylvania State University, University Park, [4]Hue University of Agriculture and Forestry, Vietnam.*

Cattle manure value chains play an important role in smallholder crop-livestock systems in south-central Vietnam. Lowland cattle farmers sell manure through a network of chain participants to pepper, coffee, dragon fruit, and rubber farms in the Central Highlands and south coast. This study describes cattle manure value chains originating in two representative lowland communes, Nhõn Khánh (NK) and An Chấn (AC). Semi-structured interviews with value-chain participants between April and September 2013 collected information from lowland farmers (n = 101), manure collectors and traders (n = 27), rubber companies (n = 2), highland farmers (n = 50), and dragon fruit farmers (n = 20) about cattle management, manure-related labor, manure transactions, and fertilizer and manure use. Lowland cattle owners were selected using stratified random sampling. Farmer interviews identified subsequent value chain participants. Most farmers interviewed reported manure sales (AC = 78%, NK = 92%), and reported sales of 62% of farm manure with SD ± 26%. Farmers prepared manure for sale by drying it on the ground or in cakes for approximately 4 d. Dry manure (89 ± 3% DM, 18.7 ± 5.6% OM, 1.27 ± 0.37% N, and 0.59 ± 0.27% P_2O_5) was bagged and sold to local manure collectors who arranged transfer to highland farmers, south coast farmers, or traders. Manure was sold by the bag (bag volume in AC = 20.4 L, NK = 46.6 L). Sale price in farmer-reported transactions was \$34.19 ± 4.95/m^3 in AC and \$24.31 ± 3.88/m^{3}in NK. Preliminary analyses suggest annual farmer revenue of \$116 ± 102 in AC and \$120 ± 93 in NK, thus providing an important source of supplementary income. Manure not sold was composted and used for crop fertilization. Farmers reported most manure sales between February and August (during NK and AC dry season) when demand exists for organic amendments in the highlands. From NK, approximately 80% of manure sold flowed to Gia Lai Province and 20% to Đắk Lắk Province in the Central Highlands. From AC, 70% flowed to Gia Lai, 10% to Đắk Lắk, and 5% to Đắk Nông. 15% flowed to dragon fruit farmers in Bình Thuận Province late in the year. Before application, highland farmers purchasing manure often prepared a 45-d compost with manure and other amendments including potassium, urea, coffee pulp, and a commercial probiotic. This study generated descriptive information about manure value chains in Vietnam that can inform analysis of value chain dynamics via simulation modeling.

Key Words: cattle manure, value chain, Vietnam

1221 (T152) Selenium concentration in blood, milk and urine in grazing jersey herds in Costa Rica.

A. Saborío-Montero*[1], M. Alfaro-Cascante[1], F. Granados-Chinchilla[2], and A. Molina-Alvarado[1], *[1]Centro de Investigaciones en Nutrición Animal y Escuela de Zootecnia, Universidad de Costa Rica, San José, [2]Centro de Investigaciones en Nutrición Animal, Universidad de Costa Rica, San José.*

The aim of this study was to determine the concentration of selenium (Se) in blood, milk and urine in grazing Jersey cows. The study was conducted on four commercial dairy herds in the highlands (≈ 2250 m of altitude) of Cartago, Costa Rica. Cows were intensively grazing kikuyu grass (*Kikuyuocloa clandestina*) and daily supplementation consisted of concentrate according to milk yield (1 kg concentrate:3 kg of milk). Blood samples were taken from the coccygeal vessels, milk samples were collected during milking from the milk yield measure container and urine was obtained using rubbing stimulation. A total of 102, 139, and 87 samples of blood, milk and urine respectively were collected and analyzed. Atomic absorption spectrophotometry was used to determine Se concentration. Soil was sampled in each farm to determine Se and sulfur (S) concentration and their associations with average Se in blood, milk and urine. A soil borer was used to obtain 20 subsamples per sample; those subsamples were collected drilling the soil surface to a depth of 10 cm. Se an S concentration in soils was analyzed using atomic absorption spectrophotometry and $Ca(H_2PO_4)_2 \cdot H_2O$ 0.008M 10:25 extraction, respectively. Average blood, milk and urine Se concentration are shown in Table 1221. Se in soils of farms 1, 2, 3, and 4 were 98, 78, 144, and 345 µg/kg respectively, S concentration in soil was 74, 35, 57, and 32 mg/L in the same order. No association was obtained between average Se concentration in the animal fluids and the soil Se or S concentration. Se concentration in blood was correlated to Se concentration in milk ($r = 0.31$, $P < 0.01$). Differences between Se concentrations in milk among herds suggest that it could be related to supplementation on each farm. Results also indicate that high values of selenium in urine in some of the farms could imply a poor utilization or excessive supplementation of this mineral with associated economic costs. More research should be done in a wider population to support these findings.

Key Words: Jersey cows, selenium, soil

Table 1221. Selenium concentration in blood, milk and urine in four grazing Jersey herds

Herd	Se in blood (µg/L)	Se in milk (µg/L)	Se in urine (µg/L)
1	41.12	32.61[a]	200.27[ab]
2	108.11	66.57[b]	263.05[a]
3	69.44	32.94[a]	47.48b[c]
4	41.44	22.35[a]	28.35[c]

[a, b] Means in the same column not sharing a common superscript are different ($P < 0.05$)

LACTATION BIOLOGY I

1222 (M144) relationship between dry period length and production and reproduction in grazing Jersey and Holstein cows in Costa Rica. J. M. Sánchez*[1], A. Saborío-Montero[1], and A. Córdoba-Roldán[2], [1]*Centro de Investigaciones en Nutrición Animal y Escuela de Zootecnia, Universidad de Costa Rica, San José, Costa Rica,* [2]*Programa de Transferencia Tecnológica, Cooperativa de Productores de Leche Dos Pinos, San José, Costa Rica.*

The aim of this study was to evaluate relationships between dry period length (DPL) of Jersey and Holstein grazing cows and succeeding productive and reproductive performance. The study was conducted on 29 dairy herds in the highlands of Cartago, Costa Rica. The predominant pasture grass on the farms was kikuyu (*Kikuyuocloa clandestina*) and cows were supplemented with 1 kg of a grain mixture/2.5 to 3 kg of milk. A total of 4792 completed lactations (Jersey n = 3000, Holstein n = 1792) were registered from 2009 to 2012. DPL in Jersey (mean = 75.6 d, 95% CI: 74.1–77.0 d) differed (P < 0.001) from Holstein (mean = 80.7 d, 95% CI: 78.2 to 83.2 d). In Jersey cows the DPL was inversely correlated with actual milk yield (-0.23, P < 0.001) and 305-d milk yield (-0.27, P < 0.001). Open period length in Jersey cows (mean = 120 d, 95% CI: 117 to 123 d) differed (P < 0.001) from Holstein (mean = 150 d, 95% CI: 145 to 154 d). Jersey cows with DPL less than 58 d produced more 305-d milk (mean = 5583 kg, 95% CI: 5480 to 5687 kg, P < 0.001) than cows with a DPL greater than 73 d (mean = 5208 kg, 95% CI: 5086 to 5331 kg). Cows in both those dry groups produced less (P < 0.01) milk than cows with a DPL of 58 to 73 d DPL (mean = 5949 kg, 95% CI: 5885 to 6012). Jersey cows with DPL greater than 73 d had shorter (P < 0.001) lactation length (mean = 305 d, 95% CI: 299 to 310 d) than those below that threshold (mean = 324 d, 95% CI: 321 to 327 d). Calving interval for Jersey cows with DPL less than 58 d (mean = 403 d, 95% CI: 398 to 409 d) was greater (P < 0.05) than those with DPL between 58 and 63 d (mean = 392 d, 95% CI: 388 to 397 d). 305-d milk yield was greater (P < 0.01) in Holstein cows with DPL between 55 and 63 d (mean = 7620kg, 95% CI: 7434 to 7807 kg) than those with DPL less than 55 d (mean = 7162kg, 95% CI: 6964 to 7361kg) or higher than 86 d (mean = 7066kg, 95% CI: 6830 to 7301kg). Open period in Holstein cows was greater (P < 0.01) in those with DPL greater than 86 d (mean = 163d, 95% CI: 153 to 173d) compared to those cows with DPL between 55 and 86 d (mean = 144d, 95% CI: 138 to 150d). These results suggest that in grazing Jersey and Holstein cow herds milk yield and reproduction performance could be influenced by DPL.

Key Words: dry period length, grazing cows, dairy cows

1223 (M145) Effect of insulin on mRNA expression of genes related to milk synthesis in primary bovine mammary epithelial cells cultured in vitro. T. Qin[1], H. Y. Wang[1], D. P. Bu*[2], and H. B. Zhu[1], [1]*Embryo Biotechnology and Reproduction Laboratory, Institute of Animal Science, Chinese Academy of Agricultural Sciences, Beijing, China,* [2]*State Key Laboratory of Animal Nutrition, Institute of Animal Science, Chinese Academy of Agricultural Sciences, Beijing, China.*

The crucial role for mTOR in the regulation of milk protein synthesis in the bovine mammary gland has been reported, but the molecular events associated with regulation of milk fat synthesis remain unknown. This study was conducted to examine the potential role of insulin in the presence of two lactogenic hormones, hydrocortisone and prolactin, on milk protein and fat synthesis. Primary bovine mammary epithelial cells cultured in vitro were treated in three different ways (no hormones (NH, control), 50 ng/mL hydrocortisone and 200 ng/mL prolactin (FP), or 100 ng/mL insulin, 50 ng/mL hydrocortisone and 200 ng/mL prolactin (IFP)). Expression of 17 key genes involved in four pathways were detected by real-time PCR. Statistical significance was evaluated by unpaired t test analysis with SAS 9.0 software. Significance was declared at P < 0.05. Results showed that IFP group significantly increased the mRNA level of β-casein (CSN2), κ-casein (CSN3), Acetyl-CoA carboxylase (ACACA), fatty acid synthase (FASN) and Sterol Regulatory Element Binding Protein1 (SREBP1) compared to NH and FP groups (P < 0.05). Relative to the other groups, IFP group significantly up-regulated the expression of signal transducers and activators of transcription 5B (STAT5B) and E74-like factor 5 (ELF5) in JAK-STAT5 pathway, as well as Phosphatidylinositol 3-kinase (*P*I3K), Protein Kinase B (AKT1) and Eukaryotic initiation factor 4E (EIF4E) in PI3K/Akt/mTOR signaling pathway (P < 0.05). But the IFP hormone combinations had no effect on TSC1, TSC2 or RHEB transcription in AMPK signal pathway (P > 0.05). The results demonstrated that insulin may stimulate milk protein synthesis by JAK-STAT5 and PI3K/Akt/mTOR signaling pathways, and stimulate milk fat synthesis by PI3K/Akt/mTOR and SREBP signaling pathways in bovine mammary epithelial cells cultured in vitro. This research indicated insulin has an important role in milk protein and fat synthesis as the other two lactogenic hormones, hydrocortisone and prolactin.

Key Words: insulin, bovine mammary epithelial cells, real-time PCR

1224 (M146) Conjugated linoleic acid (CLA) trans-10, cis-12 decreases ACC-α gene expression in lactating mammary gland by decreasing specific transcripts from different promoters. D. E. Oliveira[*1], D. E. Bauman[2], and K. J. Harvatine[3], *[1]Santa Catarina State University, Lages, Brazil, [2]Cornell University, Ithaca, NY, [3]Penn State University, State College.*

Transcription of acetyl-CoA carboxylase α (ACC-α) is initiated from multiple promoters in a tissue-specific fashion and mammary expression of ACC-α is decreased during CLA-induced and diet-induced MFD. The effect of *trans*-10, *cis*-12 CLA and a low forage and high oil diet on regulation of the different ACC-α isoforms in mammary tissue was investigated. Nine mid-lactation cows were arranged in a 3 × 3 latin square design with 14-d experimental periods. Treatments were Control, 3 d i.v. infusion of *trans*-10, *cis*-12 CLA (CLA-MFD), and feeding a low forage, high oil diet (Diet-induced MFD). Milk fat yield was decreased 38% percent by the low forage and high oil diet and by 24% percent by CLA. Mammary biopsies at the end of each treatment were taken. Quantitative real-time reverse transcriptase PCR assays were developed for ACC-α specific promoters of interest. Data were analyzed using the PROC MIXED of SAS to test expression of individual ACC-α promoters I, II, III (exon 5A) and a well described splice variant (-24NT). The geometric mean of 3 housekeeping genes was calculated and used as a covariant in the model. Differences in expression of individual ACC-α promoters was declared significant at $P < 0.05$ and trends at $P < 0.1$. There was no treatment effect on expression of ACC-α transcript from promoter I. Compared to Control, ACC-α promoter II transcript were reduced 32.9% with diet-induced MFD treatment ($P = 0.005$) and tended to be decreased 18.5% by CLA treatment ($P = 0.06$). Transcript from promoter III (exon 5A) was reduced 26.4 and 35% for CLA-induced and diet-induced MFD treatments ($P = 0.0001$), respectively, compared to Control. Transcript for the -24NT splice variant was reduced by 25.8% during det-induced MFD in comparison to control ($P = 0.03$), but CLA treatment was not different from control. Promoters II, III, and -24NT splice variant transcript of ACC-α are decreased during diet induced milk fat depression demonstrating a promoter specific role of bioactive fatty acids in ACC-α gene expression.

Key Words: acetyl-CoA carboxylase promoters, gene expression, conjugated linoleic acid

1225 (M147) Conjugated linoleic acid (CLA) affects in different ways acetyl-CoA carboxylase α (ACC-α) transcripts from different promoters in mammary and adipose tissue from lactating ewes. E. Ticiani[1], M. Urio[1], A. P. Povaluk[1], M. V. Camera[1], R. Ferreira[2], L. C. Miletti[1], K. J. Harvatine[3], and D. E. Oliveira[*1], *[1]Santa Catarina State University, Lages, Brazil, [2]Santa Catarina State University, Chapecó, Brazil, [3]Penn State University, State College.*

Feeding *trans*-10, *cis*-12 CLA to lactating ewes reduces milk fat by down-regulating gene expression of enzymes involved in lipid synthesis in mammary gland. An example is acetyl-CoA carboxylase α (ACC-α), a key enzyme in the de novo fatty acid synthesis pathway. ACC-α is encoded by mRNAs transcribed from three promoters, PI, PII and PIII, characterized as tissue-specific in the ovine genome. This study evaluated the effects of a rumen-unprotected *trans*-10, *cis*-12 CLA supplement fed to crossbred Lacaune/Texel lactating ewes, on gene expression of different mRNA transcripts of ACC-α. Twelve ewes arranged in a completely randomized design received for 15 d one of the following treatments: Control (forage + 1 kg of concentrate) and CLA [forage + 1 kg of concentrate + 28 g/d of CLA (29.9% *trans*-10, *cis*-12)]. The CLA supplement (an oil mixture) was orally dosed. Mammary gland and adipose tissue biopsies were taken on Day 15. Subsequently RNA was extracted, cDNA synthesized and quantitative real-time reverse transcriptase PCR analysis conducted. Data were analyzed by PROC MIXED using ribosomal protein S18 housekeeping gene as a covariate in the model. Compared to Control, in the mammary gland CLA reduced by 29.1% ($P = 0.037$) transcript from PIII with no changes on transcripts from PI and PII ($P > 0.05$). In the adipose tissue, transcript from PI was increased by 379.8% ($P = 0.028$) in the CLA treated group when compared to Control. There was no treatment effect on transcripts from promoters II and III in the adipose tissue. Overall, our results suggest that *trans*-10, *cis*-12 CLA downregulates ACC-α gene expression by decreasing expression from promoter III in mammary tissue and increases ACC-α gene expression by increasing expression promoter I in adipose tissue.

Key Words: adipose tissue, gene expression, mammary gland

1226 (M148) Effect of different hormones on â-casein and lactoferrin expression in mammary epithelial cells. *W. Q. Li[1,2], J. Q. Wang[*1], D. P. Bu[1], and X. M. Nan[1], [1]State Key Laboratory of Animal Nutrition, Institute of Animal Science, Chinese Academy of Agricultural Sciences, Beijing, China, [2]College of Life Science, Henan Agricultural University, ZhengZhou, China.*

An inverse relationship in expression patterns for lactoferrin (LTF) and caseins occurs throughout the lactation cycle: when LTF expression is high, casein expression is low and vice versa. The objective of this study was to investigate the effect of different hormones on β-casein (CSN2) and LTF expression in mammary epithelial cells. Primary bovine mammary epithelial cells were treated with eight kinds of induction mediums to induce expression of CSN2 and LTF, including group A dexamethasone&prolactin&insulin (1 μg/mL, 5 μg/mL, 5 μg/mL), group B dexamethasone&prolactin&insulin (1 μg/mL, 10 μg/mL, 5 μg/mL), group C β estradiol (5 μg/mL), group D 10 ng IGF-I, group E 100 ng IGF-I, group F 200 ng IGF-I, group G 400 ng IGF-I, group H 1000 ng IGF-I. Materials administered in groups C-H did not include dexamethasone&prolactin&insulin. Relative mRNA expression of CSN2 and LTF was detected at 24h after induction by qPCR. Data was analyzed by One-way ANOVA and pearson correlation procedure of SAS 9.0. The results showed that 100ng IGF-I was the most suitable inducing material for β-casein ($P < 0.05$) and no significant difference of LTF expression among groups was observed ($P > 0.05$). Correlation coefficient of CSN2 and LTF expression was -0.277. It was concluded that CSN2 expression in bovine mammary epithelial cells depended on hormone and IGF-I, but not LTF. More research is needed to explore the relationship between β-casein and lactoferrin.

Key Words: β-casein, lactoferrin, mammary epithelial cell

1227 (M149) Effects of methionyl-methionine on milk protein synthesis in bovine mammary gland. J. X. Yang[1], H. Y. Liu[1], C. H. Wang[1], Q. B. Xu[*1], and J. X. Liu[2], [1]*Institute of Dairy Science, Zhejiang University, Hangzhou, China,* [2]*Zhejiang University, Hangzhou, China.*

This study was conducted to evaluate effect of methionyl-methionine (Met-Met) on milk protein synthesis in cultured lactating bovine mammary tissues. Mammary tissues were obtained from three lactating Holstein dairy cows and incubated in DMEM/F12 for 72 h. Triplicate isolated cultured mammary tissues were treated with conditional medium containing certain essential amino acid (AA) for 3 h before treatment exposure. The concentration of Met-Met was adjusted through replacing the medium Met with Met-Met at ratios of 0, 5, 10, 15, 20, and 25%, respectively. After incubation with experimental medium, tissues were collected for determination of α_{s1} casein expression by RT-qPCR and western blot. The AA absorption was determined by the change of free AA concentration in the medium. The mRNA abundance of AA transporters, mTOR and JAK2-STAT5 signaling pathway were measured for the control and optimal ratio of Met-Met treatment. Replacement of Met-Met for single Met significantly increased α_{s1} casein expression, with the highest expression at 15% of Met-Met substitution. Compared with the control, mRNA abundance of AA transporters including ATB (0, +) and CAT1 was increased, and AA absorption were significantly improved in 15% Met-Met group ($P < 0.05$), in which the mRNA abundance of mTOR, S6K1, 4E-BP1, JAK2 and STAT5 ($P < 0.05$) was also increased. From these results, it is indicated that Met-Met promoted milk protein synthesis and AA absorption in cultured bovine mammary tissues, and mTOR and JAK2-STAT5 signaling pathways may be involved in the Met-Met-stimulated milk protein synthesis.

Key Words: αs1 casein, bovine mammary gland, methionyl-methionine

1228 (M150) Effect of bta-miR-145 overexpression and down-expression on the other microRNA expression in primary bovine mammary epithelial cells. W. Q. Li[1], D. P. Bu[*1], J. Q. Wang[2], and X. M. Nan[1], [1]*State Key Laboratory of Animal Nutrition, Institute of Animal Science, Chinese Academy of Agricultural Sciences, Beijing, China,* [2]*State Key Laboratory of Animal Nutrition, Institute of Animal Science, Chinese Academy of Agricultural Sciences, Beijng, China.*

MicroRNA research has made great progress. MicroRNA overexpression by mimic or down-expression by inhibitor is a common method to study the function of microRNA. However, it is unknown that whether overexpression or inhibition of a certain microRNA affects other microRNAs expression or not. This study was performed to evaluate the effect of bta-miR-145 overexpression or down-expression on other microRNAs expression. Bta-miR-145 mimic (150pmol/well) or inhibitor (300pmol/well) was transfected in primary bovine mammary epithelial cells in 6-well plates. After 24h transfection, expressions of bta-miR-145, bta-miR-214, bta-miR-181a, bta-miR-21 were detected by RT-qPCR method. Relative quantification (ΔΔCt) method was used to analyze the data. The geometric mean of 5SrRNA and U6 was used to normalize the expression of microRNAs. All data were tested by one-way ANOVA program of SAS 9.1. The results showed that the overexpression effect of bta-miR-145 was achieved in cells by its mimic, and inhibiting effect of bta-miR-145 was achieved by its inhibitor. In addition, bta-miR-181a and bta-miR-145 had the same expression trend, while bta-miR-214 and bta-miR-145 had the opposite expression trend. And bta-miR-21 expression was almost not affected by bta-miR-145

overexpression and down-expression. It was concluded that one kind of microRNA overexpression or inhibition would cause expression change of other microRNAs. It is suggested that system biology views should be take to explain the related biological problems.

Key Words: bta-miR-145, overexpression, down-expression

1229 (M151) Stearic acid alters microRNA profiles in bovine mammary gland epithelial cells. Y. G. Chai[1], X. M. Nan[1], D. P. Bu[*2], J. J. Loor[3], and J. Q. Wang[2], *[1]State Key Laboratory of Animal Nutrition, Institute of Animal Science, Chinese Academy of Agricultural Sciences, Beijing, China, [2]State Key Laboratory of Animal Nutrition, Institute of Animal Science, Chinese Academy of Agricultural Sciences, Beijing, China, [3]University of Illinois, Urbana.*

MicroRNAs (miRNA) are important regulators of cellular processes. The objective was to study whether the addition of stearic acid would alter the microRNA profile of bovine mammary epithelial cells. Cells were cultured and passaged in DMEM/F12 basic medium with 10% fetal bovine serum. For experimental assays, cells at 80% confluence were cultured in lactation medium (containing insulin, epidermal growth factor, transferring, hydrocortisone, progesterone and fatty acid free bovine serum albumin) with or without stearic acid (SA) for 24 h. A customized microarray containing 672 bovine miRNA was used to investigate their functional roles in bovine mammary gland epithelial cells in response to supplemental stearic acid (SA). Total miRNA expressed in the control and SA incubations was 157 and 165. Seventeen of 165 miRNA were differentially expressed with SA, and 12 (bta-miR-452, bta-miR-30c, bta-miR-362–5p, bta-miR-181a, bta-miR-194, bta-miR-2368, bta-miR-2893, bta-miR-2888, bta-miR-2374, bta-miR-29c, bta-miR-19a, and bta-miR-2411) were verified by real-time PCR. Using TargetScan, PicTar, GO and KEGG for functional analyses revealed that gene targets of miRNAs affected by SA are associated with regulation of transcription and mTOR signaling. This study provides novel data on miRNAs responsive to fatty acid in vitro.

Key Words: stearic acid, microRNA, lactational response

1230 (M152) The peroxisome proliferator-activated receptor γ (PPARγ) agonist thiazolidinedione (TZD) does not overcome *trans*-10, *cis*-12 conjugated linoleic acid (CLA) inhibition of milk fat synthesis in lactating dairy ewes. E. C. Sandri[1], E. M. Sandri[2], M. V. Camera[1], A. P. Povaluk[1], M. Urio[1], E. Ticiani[1], K. J. Harvatine[3], and D. E. Oliveira[*1], *[1]Santa Catarina State University, Lages, Brazil, [2]Santa Catarina State University, Chapecó, Brazil, [3]Penn State University, State College.*

Peroxisome proliferator-activated receptor γ (PPARγ) is regulated by ligand activation and regulates lipid synthesis pathways, but a functional role for PPARγ in diet-induced MFD in vivo has not been established. This study evaluated the effect of PPARγ agonist thiazolidinedione (TZD) on milk fat synthesis and its interaction with *trans*-10, *cis*-12 CLA. Twenty-four lactating ewes (60 ± 0.45 kg of BW) were randomly assigned one of the four treatments (n = 6/treatment) for 7 d: Control (100 mL/d of saline); TZD (IV 4 mg of TZD/kg of BW per d in 100 mL of saline); CLA (oral dose of 27 g/d of rumen-unprotected CLA (oil mixture: 29.9% *trans*-10, *cis*-12), and TZD+CLA (TZD infusion initiated 1 d before CLA dosing). Milk was sampled and analyzed for fat, protein and lactose concentration. Compared to control, fat content was 22.3% lower in CLA (6.14 vs. 4.77%, P = 0.05), tended to be 20.7% lower in TZD+CLA (6.14 vs. 4.87, P = 0.06), and did not differ between control and TZD (6.14 vs. 6.70%, P = 0.39). Compared to TZD, fat content was 28.8% lower in CLA (6.70 vs. 4.77%, P = 0.008) and 27.3% in TZD+CLA (6.70 vs. 4.87%, P = 0.01). Fat content did not differ between TZD+CLA and CLA (4.87 vs. 4.77%, P = 0.87). Treatments did not affect the concentration of milk protein and lactose (P > 0.05). In conclusion, TZD did not stimulate milk fat synthesis and was not able to overcome CLA inhibition of milk fat synthesis, indicating that PPARγ does not mediate CLA-induced MFD

Key Words: milk fat depression, lipid synthesis pathway, peroxisome proliferator-activated receptor γ

1231 (M153) Fatty acid synthase is essential for milk fat formation in goat mammary gland. J. Zhu[1], J. Luo[*2], Y. Sun[1], and H. Shi[1], *[1]Northwest A&F University, Yangling, China, [2]Northwest A & F University, Yangling, China.*

The inevitable role of fatty acid synthase (FASN) on fatty acid metabolism has been a validated concept for a quite long period of time. However, the details of its effect on milk fat formation remain to be unclear. This study explored the potential role of FASN in regulating milk fat accumulation and secretion in lactating goat mammary gland epithelial cells (GMECs). Using quantitative real-time PCR, we detected that FASN was predominantly expressed in fat, small intestine and mammary

gland tissues among 10 different tissues (subcutaneous fat, small intestine, mammary gland, lungs, rumen, muscle, spleen, liver, kidney and heart) collected from three Xinong Saanen dairy goats at mid-lactation period. In addition, we also found a much higher expression level of FASN gene at mid-lactation mammary gland compared with dry-off period (17.9-fold) from three Xinong Saanen dairy goats. These results indicated the potential role of FASN in lactation. Using designed shRNA targeting FASN sequence to construct adenovirus vector with BLOCK-IT system, the effect of shRNA on mRNA expression of GMECs were determined after 48-h incubation of infected GMECs. Inhibition of FASN by C75 (10 ng/uL) and shRNA mediated interference, with the adenovirus as infection vector, markedly reduced cellular triglyceride (TAG) content by decreasing the expression of genes related to TAG synthesis (glycerol-3-phosphate acyltransferase, GPAT; 1-acylglycerol-3-phosphate O-acyltransferase, AGPAT6; diacylglycerol acyltransferase 2, DGAT2) and enhancing the expression of lipolysis related genes (adipose triglyceride lipase ATGL; hormone-sensitive lipase, HSL) (except ATGL response to shRNA treatment) in GMECs. Consistent with the markedly decreased expression of the genes related to lipid droplets formation and secretion (tail-interacting protein 47 gene, TIP47; adipose differentiation-related protein, ADRP; butyrophilin 1a1, BTN1A1; xanthine oxidoreductase, XOR), cellular lipid droplets were also reduced sharply after incubation with C75 or Ad-shRNA investigated by Oil red O staining method. The results provided evidence of FASN's essential role in TAG synthesis and secretion in GMECs. Hence, FASN may be future essential for goat milk fat formation.

Key Words: fatty acid synthase, milk fat, mammary gland epithelial cells, dairy goat

LACTATION BIOLOGY II

1232 (W141) Daylength affects simultaneously mammary epithelium integrity and mammary epithelial cell exfoliation in milk. M. Boutinaud[*1], A. Bondon[1], P. Debournoux[1], J. Couedon[1], M. Johan[1], A. Narcy[2], and C. Hurtaud[1], *[1]INRA, Saint Gilles, France, [2]INRA, Nouzilly, France.*

Some of the mammary epithelial cells (MEC) responsible for milk synthesis are exfoliated into milk during the lactation process. MEC exfoliation into milk could play a role in mammary epithelium integrity. A trial was performed to study the effects of daylength and type of diet on milk calcium content. Calcium is known to play a role of cement for tight junction closure between epithelial cells. The aim of this study was to identify a potential effect of daylength and dietary anion-cation differences on mammary epithelium integrity and MEC exfoliation in milk. A trial was performed according to a Latin square design using 8 dairy cows averaging 103 ± 44 DIM with two treatments in a factorial arrangement with 4 periods of 14 d. The cows received 2 levels of dietary anion-cation differences (DCAD; 0 mEq/kg DM for D0 and 400 mEq/kg for D400) and 2 d lengths (8 h of light/d for short days and 16 h/d for long days). The cows were only exposed to solarium lights providing UVA and UVB. Once per period, milk was collected to purify MEC from milk after centrifugation and immunocytochemical sorting. MEC exfoliation was evaluated using the determination of MEC concentration in milk. The percentage of apoptotic MEC was determined by flow cytometry after TUNEL labeling. Epithelium integrity was monitored using the determination of blood lactose sampled 1 hbefore morning milking, and the ratio Na:K in milk. Blood prolactin concentrations from samples collected at 0700 h and 1400 h were determined by RIA. Data were analyzed using PROC MIXED. There was no significant interaction between daylength and DCAD level. Milk yield did not vary with any treatments averaging 32.7 kg. d^{-1}. DCAD treatment did not affect any of the parameters. Blood lactose and Na:K ratio were higher with short compared with long days ($P < 0.05$) indicating that mammary epithelium integrity was more disrupted with short days. More MEC and more apoptotic MEC were exfoliated in milk with short days compared to long days (338 vs. 227 · 10^6 exfoliated MEC per day, for respectively short and long days; $P < 0.05$). As expected blood prolactin concentration was lower with short days ($P < 0.05$). Taken together these results suggest that MEC exfoliation could be induced by low prolactin concentration during short days.

Key Words: mammary epithelial cell, mammary epithelium integrity, photoperiod, feeding

1233 (W142) Serotonin receptors expression in caprine and ovine mammary gland by real time PCR-RT. A. Suárez-Trujillo[*1], A. Argüello[1], M. A. Rivero[2], J. Capote[3], and N. Castro[1], *[1]Dep. of Animal Science, Universidad de Las Palmas de Gran Canaria, Arucas, Las Palmas, Spain, [2]Dep. of Morphology, Universidad de Las Palmas de Gran Canaria, Arucas, Las Palmas, Spain, [3]Canarian Agronomic Science Institute, La Laguna, Tenerife, Spain.*

The role of serotonin (5-HT) as a feedback inhibitor of lactation in humans, mice and cows has been previously reported. This action is mediated by 5-HT receptors, which are expressed in the mammary tissue. The 5-HTR subtype 7 is expressed in the three quoted species, but in bovine, subtypes 1B, 2A, 2B and 4 have been also found. The aim of this study was to identify the 5-HTR (subtypes 1A, 1B, 1D, 1E, 1F, 2A, 2B, 2C, 3A, 4, 5a, 6 and 7) expression in the goat and sheep mammary gland using Real Time PCR-RT. Lactating Holstein cows, Majorera dairy goats and Canarian dairy ewes were used to obtain hypothalamus and mammary gland samples. The sampling was performed immediately after slaughter. Samples were kept in RNA later, and subsequent RNA extraction was performed using a combination between TriPure reagent (Roche, Barcelona, Spain) and E.N.Z.A. total RNA kit (Omega, Nordic Naturals, inc) protocols. cDNA synthesis was conducted using iScript cDNA synthesis kit (BioRad, Madrid, Spain). The primers used in this study were obtained from published data (1B, 1F, 2A, 2B, 2C, 4, 5a and 7) or were designed using bovine CD sequences from GeneBank (1A, 1D, 1E, 3A and 6). Hypoxanthine phosphosibosyltransferase I (HPTR1), Ribosomal Protein (S18), β-Actin and Glyceraldehyde 3-Phosphate Dehydrogenase (GAPDH) genes were utilized as internal control. Hypothalamus samples were used as positive control to evaluate the primers in the three studied species. Real Time PCR was performed at 57.5°C of annealing temperature for all primers. The receptors found in bovine mammary gland were in agreement with previous studies. Receptors 1B, 1E, 2A, 2B, 4 and 7 were found in the three species. Additionally, receptors 1D and 5a were observed in goats and sheep. Moreover, 1A and 1F subtypes were only detected in ovine mammary gland. Nevertheless, subtypes 2C, 3A and 6 were found neither bovine, nor caprine or ovine mammary gland. In conclusion, the same 5-HTR subtypes previously described in cows are expressed in caprine and ovine mammary gland. In addition, in caprine mammary gland were identified two more (5-HTR_{1D} and 5-HTR_{5a}), and the most number of 5-HTR were found in ovine mammary gland. Further studies will be necessary to study more in deep the role of serotonin as inhibitor of lactation in small ruminants.

Key Words: serotonin receptors, goat, sheep

1234 (W143) Immortalization of a primary bovine mammary epithelial cell line by the SV40 large T-antigen gene. H. Hu[1,2,3], N. Zheng[1,2,3], W. Dai[1,2,3], H. Gao[1,2,3], and J. Wang[*1,2,3], *[1]State Key Laboratory of Animal Nutrition, Institute of Animal Science, Chinese Academy of Agricultural Sciences, Beijing, China, [2]Ministry of Agriculture–Milk and Dairy Product Inspection Center, Beijing, China, [3]Ministry of Agriculture–Laboratory of Quality & Safety Risk Assessment for Dairy Products, Beijing, China.*

In this study, we report an immortalized cell line expression of SV40 large T-antigen established from a Chinese Holstein primary mammary epithelial cell (CMECs) cultured in vitro. The plasmid that carried the SV40 large T-antigen sequence was introduced into mammary epithelial cells by retroviral mediation. Following injection, cells were cultured under puromycin for selection and 10% resistant cells remained after two wk. Four immortalized bovine mammary epithelial cell colonies were obtained, but only a single colony was surpassed over 50-passage and was designated CMEC-H. The obtained clone was characterized with respect to their morphogenetic behavior, long-term proliferative potential, and differentiation characteristics. The immortalized mammary epithelial cells grew in close contact with each other and exhibited the typical "cobblestone" morphology characteristic with obvious boundary that were more homogeneous than in the primary mammary epithelial cells. And the homogenously polygonal of immortalized cell was maintained from passage 1 to 50. The population growth rate between immortalized cells at passage 5 or 50, doubled in number within 36 h, was not significantly different but was faster than in the primary cells. The typical and representative karyotype of CMEC-H was counted at 100 chromosomes, which was more than the normal diploid chromosome number 60. The telomerase expression of CMEC-H had consistently demonstrated the presence of telomerase activity as an immortalized cell line, but the cell line failed to induce tumor formation in nude mice. The immortalized epithelial cell expressed epithelial cell markers, including cytokeratins CK7, CK8, CK18, and CK19. The gene and protein expressions of caseins (α_{S1}-casein, β-casein, and κ-casein) indicated that the immortalized CMEC-H maintained the milk protein synthesis function of epithelial cells. We conclude that CMEC-H may become a valuable reagent for studying the secretion mechanism of mammary gland.

Key Words: bovine mammary epithelial cell, immortalization, SV-40 large T-antigen

1235 (W144) Color measurement as potential tool for determination of colostrum quality in primiparous and multiparous dairy cows. J. J. Gross[*], E. C. Kessler, and R. M. Bruckmaier, *Veterinary Physiology, Vetsuisse Faculty University of Bern, Switzerland*

Instruments for on-farm determination of colostrum quality like refractometers and densimeters are increasingly used in dairy farms. The colostrum color is also supposed to reflect its quality. A pale or mature milk like color is associated with a lower colostrum value compared to a more yellowish and darker color. The objective of this study was to elucidate the relationships between color measurements (CIE L* = from white to black, a* = from red to green, b* = from yellow to blue) and colostrum quality as assessed by two common on-farm instruments and composition in colostrum in cows and heifers. Thirteen primiparous and twelve multiparous cows were milked for the first time exactly 4 h post-calving. Colostrum was analyzed for total IgG by ELISA and for fat, protein and lactose by a FTS Infrared Milk Analyzer (Bentley Instruments Inc., Chaska, MN, USA) (Previously validated for use with colostrum). A Brix sugar refractometer (BRIX) and a Kruuse colostrum densimeter (DENS) were used to assess colostrum quality at 20°C. For color measurements of colostrum samples, a calibrated spectrophotometer (Microflash 200d, Data-color International) was used. In primiparous cows, the total IgG concentration was poorly correlated with L*, a*, and b* (r = -0.13, 0.02, and 0.12; $P > 0.05$), while in multiparous cows correlations were higher (-0.40, 0.32, and 0.06, resp., $P > 0.05$). While DENS did not correlate with color measurements, BRIX was closely correlated with L* (r = -0.68, $P < 0.01$), and b* (r = 0.55, $P < 0.0001$) in primiparous and for b* in multiparous cows (r = 0.52, $P < 0.001$). Milk fat concentration was correlated with a* (r = 0.42, $P < 0.001$, and r = 0.44, $P < 0.001$, for primi- and multiparous cows) and b* (r = 0.27, $P < 0.05$, and r = 0.43, $P < 0.01$), while milk protein concentration was more correlated to b* (r = 0.53, $P < 0.0001$, and r = 0.30, $P < 0.05$). Highest correlations were found between milk lactose percentage and b* in primiparous (r = -0.59, $P < 0.0001$) and multiparous cows (r = 0.56, $P < 0.0001$). In conclusion, the color measurements via spectrophotometer were closest correlated with milk fat, protein and lactose concentrations in colostrum but only to a lesser extent with total IgG concentration colostrum of primiparous cows. An implementation of color measuring devices in automatic milking systems might be a potential instrument also to access colostrum quality besides detecting abnormal milk.

Key Words: colostrum, color, quality

1236 (W145) Effect of milk yield genotype on gene expression in liver and adipose tissue from periparturient Holsteins. W. J. Weber[1], M. Carriquiry[2], S. C. Fahrenkrug[1], and B. A. Crooker[*1], *[1]University of Minnesota, St. Paul, [2]Universidad de la República, Montevideo, Uruguay.*

Multiparous cows from unselected (stable milk yield since 1964; UH; $n = 5$) and contemporary CH; $n = 6$) Holsteins that differed in milk yield (6200 and 11,100 kg milk/305 d) were fed the same diet ad lib, milked 2x/d, and exposed to the same management and environmental conditions. Liver and adipose biopsies were collected at -14, 3, 14, and 35 d in milk (DIM). RNA was extracted and expression of 38 genes (focused on the somatotropic axis, glucose and lipid metabolism) and 12 possible internal control genes determined by digital multiplexed analysis (nanoString nCounter). Expression was normalized to the positive control and the geometric mean of 5 internal control genes. Data were transformed (square root) and analyzed by repeated measures using PROC MIXED (SAS) with DIM as the repeated effect. Means differed when $P < 0.05$. Expression of 23 genes in liver and 20 in adipose was altered by DIM. Liver and adipose expression of 6 and 8 genes was greater in CH and of 8 and 7 genes was greater in UH, respectively. There were line by day interactions for IGFBP2 and IGF-ALS in liver and DGAT2, HNF4a, IGF2 in adipose. Hepatic GHRtot and GHR-1A were greater in UH than CH. GHR-1A decreased at 3 but recovered by 14 DIM. Adipose GHRtot was greater in CH. Hepatic IGFBP2 was greater in CH than UH, increased at 3 DIM and although decreasing, remained increased through 35 DIM. Hepatic IGF-ALS was greater in UH, decreased at 3 DIM in both lines and returned to prepartum values by 14 and 35 DIM in UH and CH, respectively. Hepatic FGF21 was greater in CH than UH and peaked at 3 DIM in both lines. FGF21 was not detected in adipose. DGAT1 was similar in UH and CH liver and greater in CH adipose. Liver DGAT1 increased at 3 DIM but was not altered by DIM in adipose. DGAT2 was similar in UH and CH liver and greater in UH adipose. Liver DGAT2 decreased through 35 DIM in both lines. Adipose DGAT2 decreased at 3 DIM and recovered by 35 DIM in UH but not in CH cows. Results are consistent with a prolonged postpartum reduction in hepatic sensitivity to somatotropin and in triglyceride synthesis from de novo fatty acids in adipose of contemporary Holsteins.

Key Words: gene expression, liver, adipose

1237 (W146) Comparative glycolysis and Krebs cycle metabolism of the bovine and murine mammary gland determined with [$^{13}C_6$]glucose and mass spectrometry. L. J. Juengst[*1], E. E. Connor[2], R. L. Baldwin, VI[2], and B. J. Bequette[1], *[1]Dep. of Animal and Avian Sciences, University of Maryland, College Park, [2]USDA-ARS, Bovine Functional Genomics Laboratory, Beltsville, MD.*

The compositions of bovine and murine milk differ significantly with respect to the proportions of lactose, protein, and fat. To better understand the metabolic origins of this difference, we interrogated the crossroads of glycolysis and the Krebs cycle in the mammary gland of cows and mice using a glucose stable isotope (^{13}C) tracer approach in vitro. Mammary tissue was collected from mid-lactation dairy cows ($n = 4$) and Day 15 of lactation mice ($n = 6$) then sliced to form explants (0.5 mm thick, 100 to 150 mg). Explants were incubated for 3 h (5% CO_2) at 37°C in DMEM containing a 50:50 mix of unlabeled and [$^{13}C_6$] labeled glucose at 2.5, 5, 7.5 or 10 mM concentrations. Following incubation, explants were rinsed in PBS and stored at −80°C. Intracellular metabolites were extracted and derivatized for determination of ^{13}C-isotopomer enrichments employing gas chromatography-mass spectrometry. Alanine, glutamate, and aspartate ^{13}C-isotopomer enrichments were monitored as representative surrogates of their Krebs cycle counterparts pyruvate, α-ketoglutarate, and oxaloacetate, respectively. These data provided the inputs to calculate glycolytic and Krebs cycle fluxes. In bovine mammary tissue, increasing media glucose concentration increased glycolytic flux as represented by an increasing contribution of glucose to pyruvate flux. However, the proportion of pyruvate derived from glucose catabolism reached a plateau (44 to 46%) at 7.5 mM glucose. Similarly, in murine mammary tissue, glycolytic rate increased with increasing media glucose concentration, though no plateau was attained and glucose contributed to 43% of pyruvate flux at the highest glucose concentration. Krebs cycle flux was assessed by the relative activities of pyruvate dehydrogenase (PDH) vs. pyruvate carboxylase (PC) based on [^{13}C] tracer kinetics. For bovine mammary explants, PDH flux activity increased to a maximum at 5.0 mM glucose whereas PDH vs. PC activities of murine mammary tissue was not responsive to glucose concentration. The current study suggests that the dairy cow mammary gland shifts from high anapleurotic flux rates into the Krebs cycle to energy-producing (oxidative) fluxes with increasing glucose concentration whereas the murine mammary gland maintains a more rigid metabolic balance, and thus is less adaptive to glucose availability.

Key Words: bovine, murine, mammary metabolism

1238 (W147) Is there a core microbiome in bovine milk samples from healthy quarters with somatic cell counts of less than 200,000 cells/mL?. S. L. Brooker*[1], J. E. Williams[1], S. M. Reynolds[1], K. M. Yahvah[1], L. K. Fox[2], and M. A. McGuire[1], *[1]University of Idaho, Moscow, [2]Washington State University, Pullman.*

Recent analysis has shown that healthy bovine milk contains a commensal bacterial community. Rigorous data are not available on the bacterial community structure in bovine milk, thus it is unknown whether there is a 'core' microbiome within healthy bovine milk. Quarter milk samples were collected from nine Holstein cows that had at least two low SCC quarters (< 200,000 cells/mL). Characterization of the microbial community was performed by culture independent 454 pyrosequencing of amplicons from the V1-V3 region of the 16S rRNA gene to determine relative abundance. Cows were selected only if milk from at least two quarters was below 200,000 SCC. The relative abundance data show that most healthy quarters have bacterial communities that include *Clostridium* spp. (5 to 75% relative abundance), *Pelomonas* spp. (10 to 35% relative abundance), *Duganella* spp. (< 5% relative abundance), *Turicibacter* spp. (0 to 10% relative abundance), and *Sporacetigenium* spp. (0 to 45% relative abundance), with all samples having a large influence from unclassified bacterial spp. (5 to 55% relative abundance). The Shannon and Chao diversity indices of the bacterial communities between cows were not different ($P > 0.1$) suggesting similar distribution of community membership. Analysis by PCoA using the Bray dissimilarity matrix showed strong clustering based on the relative abundance of *Clostridium* spp., which was a major contributor in all healthy quarter samples. No clustering based on SCC was apparent among the samples. Clustering of healthy quarters within cow was also not discernable suggesting a high variation in the bacterial community even between quarters of the same cow. These results propose a highly variable bacterial community exists in bovine milk even between healthy quarters within a cow. Though there appears to be no obvious 'core' set of bacterial members, the variation present could account for similar functional roles within quarter milk bacterial community. This work was supported by the Idaho Agricultural Experiment Station, NIH grants P20 RR15587 and P20 RR016454 and the Institute for Bioinformatics and Evolutionary Studies (IBEST) at the University of Idaho.

Key Words: milk, bacteria, microbiome

1239 (W148) Impact of machine milking on teat dimensions. J. F. Guarin*[1,2], D. J. Reinemann[3], and P. L. Ruegg[1], *[1]Dep. of Dairy Science, University of Wisconsin–Madison Madison, [2]Grupo de Investigación Biogénesis, Facultad de Ciencias Agrarias, Universidad de Antioquia, Medellin, Colombia, [3]Dep. of Biological Systems Engineering, University of Wisconsin–Madison, Madison.*

The objective of this study was to determine associations between machine milking and changes in teat dimensions. A total of 1751 teats from 445 cows from the University of Wisconsin dairy herd were measured pre and immediately post-milking. The difference in teat length (Length), barrel width (Barrel) and teat tip diameter (Tip) before (PRE) and after (POST) machine milking was determined. Absolute change (Delta) on teat dimensions was calculated as POST-PRE measurements. Relative change (DeltaMeasureREL) was calculated as POST-PRE/PRE and expressed as percentage. Additional covariates included: Milk flow peak (PeakFlow), and parity (1, 2 or $\geq$ 3). Descriptive statistics were determined using PROC UNIVARIATE, FREC, GLM, and LOGISTIC of SAS version 9.3. Means and SD for Pre-milking Length, Barrel, and Tip were 44.3 ± 8.3, 23.9 ± 3.7, and 19.6 ± 2.3 mm, respectively. Means for PRELength were different for parity ≥ 3 (46.6 mm) when compared with 1 (42.8 mm) and 2 (43.6 mm) ($P < .0001$). Means for PREBarrel were significantly different among parities ($P < .0001$). Means for PRETip increased significantly with parity and were 19.3, 19.6, and 20.0 mm for parities 1, 2, and ≥ 3, respectively ($P < 0.001$). A positive association was found between PREBarrel and PeakFlow ($P < .0001$) for primiparous cows only. Teat dimensions were affected by milking. During milking, teat length increased by 1.3 mm, teat barrel decreased by 2.2 mm and teat tip decreased by 0.7 mm. Changes in teat dimensions on length, barrel, and tip were not influenced by parity. Out of the 1751 teats, 163 (9.3%) became congested at the barrel. Out of the 1751 teats, 163 (9.3%) teat barrels became congested. Congestion was defined as PREBarrel measurements that were smaller than PostTeatBarrel measurements, implying congestion of the tissue during milking. There was a strong association between pre-milking teat barrel dimension and peak milk flow for primiparous cows. Further research on teat dimensions changes and its influence on mastitis is required.

Key Words: dairy cow, induced changes, teat dimension

Table 1239. Descriptive statistics for the impact of machine milking on teat dimensions

Teat dimension (n = 1751 quarters from 445 cows)	Mean ± SD	Range
Pre-milking (mm)		
PRELength	44.3 ± 8.3	26.0–80.0
PREBarrel	23.9 ± 3.7	14.0–50.0
PRETip	19.6 ± 2.3	10.0–30.0
Post-milking (mm)		
PostLength	45.6 ± 8.5	24.0–100.0
PostTeatBarrel	21.7 ± 2.8	12.0–40.0
PostTeatTip	19.0 ± 2.2	10.0–30.0
Absolute change[1] (mm)		
DeltaLength	1.3 ± 5.5	-20.0–26.0
DeltaBarrel	-2.2 ± 3.0	-20.0–10.0
DeltaTip	-0.7 ± 2.3	-10.0–8.0
Relative change[2] (%)		
DeltaLengthREL	5.5 ± 23.4	−83.3–118.2
DeltaBarrelREL	−8.3 ± 11.2	−50.0–50.0

1240 (W149) Comparison of ecological indices of bacterial communities in bovine milk varying in somatic cell count. J. E. Williams*[1], S. M. Reynolds[1], K. M. Yahvah[1], S. L. Brooker[1], L. K. Fox[2], B. Shafii[1], and M. A. McGuire[1], [1]*University of Idaho, Moscow,* [2]*Washington State University, Pullman.*

Somatic cell count (SCC) of milk is often used to determine the health status of the mammary gland. However, little is known about the bacterial community structure within milk of varying SCC. Next generation sequencing technology has provided researchers the opportunity to characterize the bacterial diversity and community structure within bovine milk. We hypothesized that the bacterial diversity and community structure would be different among milk with low (< 200,000 cells/mL), medium (200,000 to 400,000 cells/mL), and high (> 400,000 cells/mL) SCC. Utilizing ecological indices that describe bacterial diversity, we analyzed 16S rRNA (V1-V3 region) sequencing data from quarter milk samples collected from 15 Holstein cows. Comparisons among quarter milk samples with different SCC were performed using analysis of variance and mixed model procedures of SAS (v9.3) and significance was declared at $p \leq 0.05$. Additionally effects of SCC status were compared using predetermined contrasts of milk with low versus medium and high, as well as medium versus high levels of SCC. Based on richness estimators (Chao1 and abundance-based coverage estimators [ACE]), milk with high SCC had a bacterial community less rich and diverse than milk with low or medium SCC. Also, according to Shannon's and Simpson's diversity indices when SCC is medium and high, there is a decrease in number of bacterial genera present as well as a decrease in the evenness of the bacterial community membership compared to milk with low SCC. While milk categorized as high SCC is different from milk with low and medium SCC, the bacterial diversity and community structure in low SCC milk is not different from milk with medium SCC. Future studies are needed to explore how bacterial community membership among milk samples differs with varying SCC. *This work was supported by the Idaho Agricultural Experiment Station, NIH grants P20 RR15587 and P20 RR016454 and the Institute for Bioinformatics and Evolutionary Studies (IBEST) at the University of Idaho.*

Key Words: milk, microbiome, diversity

1241 (W150) Effects of arginase inhibition on casein expression and proliferation of bovine mammary epithelial cells. *L. Ding[1], M. Wang*[1], L. Chen[1], H. Wang[1], and J. J. Loor[2], [1]Yangzhou University, China, [2]University of Illinois, Urbana-Champaign, Urbana.*

Reviews of the ruminant literature concluded that the uptake of Arg by the mammary gland greatly exceeds its output in milk. Furthermore, milk protein yield was increased by post-ruminal infusion of Arg compared with a control treatment that included infusion of water and a mixture of essential amino acids (AA) excluding Arg. Those results indicated that Arg might have an important role on casein synthesis regulation. Our previous research subsequently revealed that excess Arg has a regulatory function on the casein synthesis via effects on transcription of the casein gene. Whether Arg regulates the synthesis of casein by the metabolism of enzymes is not very clear. The specific objective of this work was to elucidate the effect of arginase on the regulation of casein expression using an arginase inhibitor in vitro. Primary bovine mammary epithelial cells (The mammary epithelial cell were isolated from three healthy multiparous dairy cow at lactation stage) were cultured with different concentrations (0, 0.5, 1, 2 μmol/L) of the arginase inhibitor nor-NOHA. The casein expression and the proliferation of mammary epithelial cells were determined after 24-h of in vitro culture triplicate/treatment). Statistical analysis was done using the OneWay Analysis of Variance (ANOVA) with multiple comparison test of Duncan using SPSS v16.0. And the P values less than 0.05 were declared to be significant ($P < 0.05$). The results showed that the concentration of arginase-1 in different groups dropped ($P < 0.05$) when the concentrations of nor-NOHA increased, and was quite small in the cells incubated with 1 and 2 μmol nor-NOHA/L. The different concentrations of nor-NOHA had no effect ($P > 0.05$) on the proliferation of mammary epithelial cells. Compared with the control group (0 μmol/L), the expression of casein was lower ($P < 0.05$) in other groups and was lowest in the group with the nor-NOHA concentration of 2 μmol/L. Additionally, in cells incubated with 0.5 μmol/L nor-NOHA the expression

level of OTC and ODC was significantly lower ($P < 0.05$) than other treatments. The expression of eNOS was lowest ($P < 0.05$) in the group with the nor-NOHA concentration of 1 μmol/L. In conclusion, the activity of arginase can be inhibited by nor-NOHA. Furthermore, nor-NOHA affected expression of casein and some arginine metabolism-related enzymes. With the increase of nor-NOHA concentration, the inhibitory effects on casein increased.

Key Words: arginine, casei expression

1242 (M154) Proximate composition and physic-chemical characteristics of broiler fed varying levels of honey in their diet. F. Patience Olusola[*1], A. Victor O.[2], O. Bayonle O.[2], and O. Olumuyiwa Jacob[2], *[1]Osun State University, Osogbo, Nigeria, [2]Osun State University, College of Agriculture, Osogbo, Nigeria.*

Heat stress is a major limiting factor in poultry production especially in hot–humid zones of the world. It could cause suffering, death, reduction in feed consumption, could reduces production and growth rate of broiler chicken. To combat this limitation, different anti-stress is used containing vitamins like honey, which is a natural energy booster, with antioxidant, antibacterial properties and act as anti-stress due to it mineral and vitamins composition, e.g, it has about 20.3 mg of calcium, 13.6 mg of phosphorus, 176 mg of potassium, etc. This study evaluate the effect varied level of honey at 0 mL of honey inclusion/kg of feed as treatment 1 (T1), 10 mL of honey/kg of feed as treatment 2 (T2), 20 mL of honey/kg as treatment 3 (T3) and 30 mL of honey/kg of feed as treatment 4 (T4), arranged in a completely randomized design. One hundred and fifty-six d old Gallus domesticus were used and fed with formulated broiler starter and finisher feed for 8 wk and mixed with honey at varied level, while water was given ad libitum. Results shows that for physicochemical parameters, T1 had significant higher ($P < 0.05$) values for Cold shortening, Thermal shortening, Cooking loss and Water-holding capacity than, T2, T3, and T4, respectively. For fresh broiler meat, T2 had the lowest protein content but highest significant values for moisture, ether extract and ash content than T1, T2, and T4, respectively. For boiled broiler meat, T2 (48.75 ± 0.56) had the lower protein content ($P < 0.05$) than T1 (50.60 ± 0.56), T3 (51.00 ± 0.56), and T4 (51.23 ± 0.56), with T4 having same significant value as T1. For grilled broiler meat, T3 had the highest protein content 57.15 ± 0.83 than T2 having the least value of 52.70 ± 0.83. Broiler fed with 20 mLs (T3) and 30 mLs (T4) of honey inclusion in their diet, performed better than T1 (0 mL) and T2 (10 mLs). While Ti proved to have the best physio-chemical parameter compared to other treatments.

Key Words: grilled, boiled, physicochemical, honey and broiler

1243 (M155) Carcass and organ characteristics of broilers fed varying levels of honey. A. Victor Olabisi*, F. Patience Olusola, O. Olumuyiwa Jacob, and O. Kehinde O., *Osun State University, Osogbo, Nigeria.*

The synergestic relationship between Broiler Production and Animal Protein cannot be over emphasised as the later does better by converting feed into the final product, meat. This study has looked in manuvering the kind of feed which is readily available to the birds so as to foster a good feed conversion ratio. The results obtained for carcass characteristics are as presented below. The results showed that there were variation in the figures recorded for the live weight, dead weight, de-feathered weight, full gizzard, flat weight, lungs weight, kidney weight, breast weight among all the treatments. From the study, it was observed that liver weight was highly significant ($P > 0.05$) but numerically birds fed with 20 mL of honey had the highest liver weight followed by birds fed 30 mL of honey and the least weight was in the birds fed 10 mL of honey. The heart weight was significantly ($P > 0.05$) affected by honey, though 20 mLs of honey fed birds had the largest heart weight, but it was not significantly different ($P < 0.05$) from birds fed 30 mLs of honey while birds fed 10 mL of honey had the least heart weight and testis weight has no significant difference ($P < 0.05$) among the treatments. However, birds fed with 20 mL of honey had the highest weight, live weight, dead weight, neck weight, back weight, liver weight, heart weight and trachea weight. The empty crop weight appeared same for all the inclusion at different meals of honey.

Key Words: meat, honey, weight gain

1244 (M156) Ractopamine and immunocastration: Effects on enhanced pork loin. A. F. S. I. de Freitas[*1,2], D. S. Lucas[3], D. A. Fausto[4], S. F. N. Pertile[4], E. F. Delgado[4], N. S. Janzantti[5], and E. T. F. Silveira[6], *[1]UNESP, São José do Rio Preto, São Paulo, Brazil, [2]IFMT, Campo Novo do Parecis, Mato Grosso, Brazil, [3]UFF, Rio de Janeiro, Brazil, [4]ESALQ/USP, Piracicaba, São Paulo, Brazil, [5]UNESP, São José do Rio Preto– São Paulo, Brazil, [6]ITAL, Campinas, São Paulo, Brazil.*

The consumer is increasingly demanding high quality meat produced under the criteria of respect for the environment and animal welfare. The aim of this study was to evaluate the influence of ractopamine (RAC) in pig diets as well as castration method, physical or immunocastration, on the quality of pork loin. Male pigs were commercial selected Agroceres, AGPIC 337 (initially with $n = 120$ males). In maternity phase (0 to 21 d old) half of the piglets were physically castrated at 5 d postpartum. The males underwent immunocastration (Vivax, Pfizer Animal Health) in two doses of 2 mL, 8 and 4 wk before slaughter. For half of the pigs physically- and immunocastrated, ractopamine was included (RAC, 7.5ppm, Ractosuin, Ourofino Agribusiness) in feed for 21 d (± 2 d) before slaughter. After the slaughter were randomly selected five carcasses of each treatment and removed the *Longissimus dorsi* (LM). The experiment was completely randomized designer ranged in a 2 × 2 factorial with five repetitions. There was no difference ($P > 0.75$) for the meat water content; however, RAC in the diet resulted in more protein ($P < 0.05$) and less ether extract fat ($P < 0.05$) in the muscle, even though there was

no effect on carcass yield. The addition of RAC also resulted in less tender meat ($P < 0.01$) at 24 h postmortem. The meat from the animals fed RAC had higher meat yield by the injection process (enhancement). However, there was no influence of RAC in weight loss by exudation (purge loss) ($P \geq 0.78$) indicating an improvement pork loin juiciness. Immunocastration and RAC had a negative impact while physically castrated males with RAC a positive impact on cooking loss, which favor higher income by providing greater juiciness.

Key Words: swine, castration method, meat quality

1245 (M157) Analysis of porcine myosin heavy chain isoforms by liquid chromatography and mass spectrometry.

G. D. Kim*[1], E. Y. Jung[2], H. W. Seo[2], J. Y. Jeong[3], S. T. Joo[4], and H. S. Yang[2], *[1]Dep. of Food Science and Biotechnology, Kyungnam University, Changwon, South Korea, [2]Division of Applied Life Science, Gyeongsang National University, Jinju, South Korea, [3]Institute of Agriculture and Life Science, Gyeongsang National University, Jinju, South Korea, [4]Dep. of Animal Science, Gyeongsang National University, Jinju, South Korea.*

Myosin, a myofibrillar protein in the skeletal muscle, consists of two heavy chains (MHC) and four light chains. Nine MHC isoforms have been observed in muscles of mammalian species, and four MHC isoforms (I/slow, 2a, 2x, and 2b) were recognized in porcine skeletal muscle. MHC is a critical component that determines the metabolic and contractile properties of muscle fibers, which in turn related to meat quality. Therefore, analysis of MHC isoforms expression is important in animal muscles such as porcine and bovine skeletal muscle. However, MHC isoforms from porcine skeletal muscle is complicated due to the similarity in molecular weights among the MHC isoforms (i.e., 223.743, 223.924, 223947, and 224.010 kDa for MHC I/slow, 2a, 2x, and 2b, respectively). We analyzed the porcine MHC isoforms by LC-MS/MS system following SDS-PAGE electrophoresis. The *longissimus dorsi* muscle was taken from each of three commercial pigs (Landrace×Yorkshire×Duroc) for SDS-PAGE electrophoresis and LC-MS/MS analysis (Tempo nano-LC system, Applied Biosystems, CA). A total of 525 unique peptides were identified and compared to each amino acid sequence of the porcine MHC isoforms. We selected four representative peptides that were identical to MHC I/slow, 2a, 2x, and 2b. The peptide identified as TLEDQLSEVKTKEEEHQR corresponds to residues 1253–1270 of MHC 2b, and differs from the other MHC isoforms (TLEDQLSELKSKEEEQQR, TLEDQLSELKTKEEEQQR, and TLEDQMNEHRSKAEETQR for MHC 2a, 2x, and I/slow). MHC 2x was confirmed by the peptide ELEGEVESEQKRNVETVK, which corresponds to residues 1925–1942. MHC I/slow and 2a were also confirmed by the unique peptides DIGTKGLNEE (residues 1926–1935) and TNAACAALDKK (residues 1539–1549), respectively. These types of unique peptides are useful for confirmation of MHC isoforms and could be used as MHC-specific markers for porcine skeletal muscle.

Key Words: myosin heavy chain, porcine skeletal muscle, LC-MS/MS

1246 (M158) Occurrence of dietary unsaturated fatty acids and their biohydrogenation products in muscles of non-ruminating foregut fermenters.

A. Schwarm*[1], M. Kreuzer[2], F. Leiber[3], S. Ortmann[4], and M. Clauss[5], *[1]ETH Zurich, Institute of Agricultural Sciences, Switzerland, [2]ETH Zurich, Switzerland, [3]Research Institute of Organic Agriculture (FiBL), Frick, Switzerland, [4]Leibniz Institute for Zoo and Wildlife Research, Berlin, Germany, [5]University of Zurich, Clinic for Zoo Animals, Exotic Pets and Wildlife, Switzerland.*

Muscles of ruminants contain higher proportions of saturated fatty acids (SFA) and monounsatured FA, but lower proportions of polyunsaturated FA (PUFA), than those of monogastric herbivores, which is considered unfavourable for human health. This is explained by an almost complete microbial biohydrogenation (saturation) of dietary PUFA in the rumen before reaching the site of FA absorption, the small intestine. The objective was to investigate whether the muscles of non-ruminating foregut fermenter contain more PUFA and more biohydrogenation products than those of ruminants, due to their shorter passage times and thus incomplete biohydrogenation of C18 PUFA in the forestomach. The studied intermediates formed during biohydrogenation were *cis*-9, *trans*-11 C18:2 conjugated linoleic acid (CLA) and *trans*-11 C18:1 vaccenic acid (TVA). The study species included Bennett wallabies (*Macropus rufogriseus*, $n = 12$) and collared peccaries (*Pecari tajacu*, $n = 10$). Wallabies were free-ranging on grass pastures. Peccaries were maintained on a zoo diet (75% apples, carrots; 25% hay, bread). *Biceps femoris* muscles were sampled from carcasses. Fatty acid methyl esters were separated on a Supelcowax–10 column and the isomers of C18:1 on a Varian column after split injection in a HP 6890 gas chromatograph. The ratio of SFA:PUFA in muscles of wallaby and peccary was with 0.6 and 1.6, respectively, lower than in domestic ruminants (> 4) and in domestic pigs (2.6). In wallaby muscles, the concentration of TVA plus CLA was with 8% of total fatty acids (tFA) higher than in ruminants (2.6% tFA), with a TVA:-CLA ratio of 3.7 (ruminants: 2.1). In peccary muscles, CLA and TVA were not detectable (< 0.1% tFA), which therefore resembled the domestic pig. In conclusion, the results indicate that muscles of non-ruminating foregut fermenters are less saturated than those of ruminants and pigs. However, occurrence of *trans*-fatty acids was not uniform for the studied non-ruminating foregut fermenters, which may be related to differences in diet, microbial population and endogenous desaturation.

Key Words: *trans*-fatty acids, wallaby, peccary

1247 (M159) Effects of amino acid supplementation of reduced crude protein (RCP) diets on fatty acid compositions of subcutaneous fat and muscle. A. N. Young*, J. K. Apple, J. W. Yancey, T. M. Johnson, T. C. Tsai, and C. V. Maxwell, *Dep. of Animal Science, University of Arkansas Division of Agriculture, Fayetteville.*

Barrows and gilts ($n = 210$/gender) were used to test the effects of crystalline AA supplementation of reduced CP diets on fatty acid composition of the LM and s.c. fat from the jowl from growing-finishing swine. Pigs were blocked by BW, and pens (6 pigs/pen) within each block and gender were assigned randomly to either corn-SBM diets (C) devoid of crystalline LYS and formulated to 95% SID AA requirements or 1 of 4 RCP diets (CP and crystalline LYS levels for the dietary treatments during each are presented in the accompanying table, 1247). During the last 3-wk feeding phase, 10 mg/kg of Paylean were included in all diets. Jowls and a subsample of whole pork loins (2 loins/pen) were captured during carcass fabrication, and the LM and s.c. fat from each jowl was freeze-dried for determination of fatty acid composition. The LM from barrows had greater ($P < 0.001$) proportions of SFA than the LM from gilts, whereas LM MUFA content increased in the LM of barrows but decreased in the LM of gilts with decreasing dietary CP (linear RCP × gender, $P = 0.037$). Conversely, LM PUFA composition increased in gilts and decreased in barrows with decreasing dietary CP (linear RCP × gender, $P = 0.056$). Jowl fat from barrows had more ($P = 0.008$) SFA and less ($P < 0.001$) PUFA than jowl fat from gilts, whereas the proportions of SFA– particularly palmitic and stearic acids– and PUFA– specifically linoleic acid– in jowl s.c. fat decreased (linear, $P \leq 0.019$) with decreasing dietary CP. Also, weight percentages of all MUFA, especially oleic acid, increased (linear, $P < 0.001$) as dietary CP was reduced in the diet. Results indicate that the fatty acid composition of pork lean and fat were altered by reducing dietary CP, and the pattern of increased MUFA composition of jowl s.c. fat may imply enhanced de novo synthesis in pigs fed RCP diets supplemented with crystalline AA.

Key Words: fatty acid composition, reduced CP, swine

Table 1247. CP (added LYS) of experimental diets for each feeding phase (% as fed)

Phase	C	RCP1	RCP2	RCP3	RCP4
1	23.70	21.61 (0.19)	19.58 (0.37)	17.61 (0.56)	15.72 (0.75)
2	21.53	19.46 (0.18)	17.44 (0.36)	15.49 (0.54)	13.61 (0.71)
3	18.97	17.34 (0.15)	15.75 (0.29)	14.16 (0.44)	12.68 (0.59)
4	17.66	16.30 (0.13)	14.96 (0.24)	13.64 (0.36)	12.37 (0.48)

1248 (M160) Postmortem pH evolution in four muscles and onset, state and resolution of rigor mortis of guinea pigs (*Cavia porcellus*) carcass. D. Núñez-Valle[1], L. P. Cevallos-Velastegui[1], A. Morales-delaNuez[2], N. Castro[3], A. Argüello[3], and D. Sánchez Macías[*1], *[1]Agroindustrial Engineering, Universidad Nacional de Chimborazo, Riobamba, Ecuador, [2]Facultad de Ciencia Pecuarias, Escuela Superior Politécnica de Chimborazo, Riobamba, Ecuador, [3]Dep. of Animal Science, Universidad de Las Palmas de Gran Canaria, Arucas, Las Palmas, Spain.*

The effect of pH on meat quality is a subject that has been deeply investigated extensively in meat science, and there is a wealth of qualitative knowledge. In the same way, rigor mortis is one of the most important physicochemical changes in skeletal muscles occurring at a relatively earlier postmortem period and then maintaining for a certain period, which results in an increasing toughness of meat. No information exists in the literature about the pH evolution or instauration and resolution of rigor mortis in guinea pig. The objective of this work was to determine the postmortem evolution of pH in four different muscles of guinea pig, as well as to establish the rigor mortis instauration, rigor state and its resolution. Forty-eight guinea pigs, randomly selected from the same production system were divided into four groups of 12 animals as follows: 3-mo-old female, 3-mo-old male, 12-mo-old female, and 12-mo-old male. Four muscles, *longissimus dorsii* (LD*), quadriceps femoris* (QF), *triceps braquii* (TB), and *psoas major* (PM), were used to measure pH at 15, 30, 45 min, each hour from 1 to 12, 15, 18, 21, and 24 h postmortem. These muscles were selected because of energy metabolism described in other species, which PM displays the lowest and LD the highest anaerobic capacity. Analysis of variance with repeated measures was conducted to test the significance of the two variables muscle and time postmortem. Splitting the data was used to check the effect of age or sex. Least squares means were calculated and considered significantly different if $P < 0.05$. pH started near 7 in LD and TB, followed by QF, and PM had the lower pH value at 15 min postmortem. pH decreased during the experimental time until 5 h in TB and QF, and 6 h in LD and PM. However, pH decline rate was slower for PM, being higher after 6 h than the other muscles. After 12 to 15 h postmortem, pH values increased slightly. Rigor mortis was onset after 5 to 6 h postmortem. After rigor onset, the muscle undergoes a longer period of rigor state, which was resolved after 13 to 15 h postmortem. No differences were found regardless sex or age. In conclusion, authors recommend at least 15 h of chilling for guinea pigs carcass, until the rigor mortis was resolved.

Key Words: guinea pig, pH, rigor mortis

1249 (M161) Water holding capacity and cooking losses of different muscles of guinea pigs (Cavia porcellus). L. P. Cevallos-Velastegui[1], D. Núñez Valle[1], A. Morales-delaNuez[2], N. Castro[3], A. Argüello[3], and D. Sánchez Macías[*1], *[1]Agroindustrial Engineering, Universidad Nacional de Chimborazo, Riobamba, Ecuador, [2]Facultad de Ciencia Pecuarias, Escuela Superior Politécnica de Chimborazo, Riobamba, Ecuador, [3]Dep. of Animal Science, Universidad de Las Palmas de Gran Canaria, Arucas, Las Palmas, Spain.*

It is well-known that aging produces changes in meat characteristics. Meat quality depends on organoleptic properties (color, texture, flavor and juiciness) which are related to zootechnical characteristics (breed, age, sex) or anatomical characteristics such as type of muscle. The main objetive of this study was to describe the water holding capacity and cooking losses of ten different muscles of guinea pig after chilling for 12 h at 4°C. Forty eight guinea pigs randomly selected from the same production system were divided into four groups of 12 animals as follows: 3-mo-old female, 3-mo-old male, 12-mo-old female, and 12-mo-old male. Ten muscles were excised after 12 h postmortem: *longissimus dorsii, quadriceps femoris, triceps braquii, psoas major, biceps femoris, semimembranosus, semitendinosus, gracilis, gluteal,* and *gastrocnemio*. Water-holding capacity (WHC) was measure using 0.3 g of muscle between two papers with 1 kg of weight during 10 min. Vacuum packaged muscle was introduced in a 70°C water bath for 30 min, and cooking losses (CL) were measured. A two-way analysis of variance was conducted to test the significance of the two fixed variables muscle and age or sex. Least squares means were calculated and considered significantly different if $P < 0.05$. With regard to WHC, *triceps braquii, psoas major,* and *gracilis* showed the lower values, while *gastrocnemio* had the higher values. *Quadriceps femoris* displayed similar values than *longissimus dorsii*. The 12-mo-old animals had lower WHC than 3-mo-old guinea pigs. However, when we compare data splitting male and female, it is possible to observe that female guinea pigs lost more water than males at 3 mo of age. With regard to CL, *longissimus dorsi*, *gastrocnemio, quadriceps femoris* and *biceps femoris* had similar CL values, while the higher values corresponded to *triceps braquii* and *gracilis*. It was also observed that male guinea pigs had higher values of CL than female animals; these differences were more clearly observed in 3-mo-old animals.

Key Words: guinea pig, water holding capacity, cooking losses

MEAT SCIENCE & MUSCLE BIOLOGY II

1250 (T153) Effect of the inclusion of plant extracts, vitamins and their association on biological efficiency, carcass length, total beef cuts, tissue composition and carcass muscularity of Nellore cattle.
M. B. Silva[*1], A. M. Jorge[2], F. D. Resende[3], G. R. Siqueira[4], G. F. Berti[5], J. M. B. Benatti[6], C. L. Francisco[1], and D. C. M. Silva[1], *[1]Universidade Estadual Paulista-FMVZ, Botucatu, Brazil, [2]Faculdade de Medicina Veterinária e Zootecnia, Universidade Estadual Paulista, Botucatu-SP, Brazil, [3]Agência Paulista de Tecnologia dos Agronegócios-APTA, Colina, Brazil, [4]APTA-Polo Regional Alta Mogiana, Colina, Brazil, [5]Centro Universitário da Fundação Educacional de Barretos, Barretos, Brazil, [6]Universidade Estadual Paulista-FCAV, Jaboticabal, Brazil*.

This study evaluated the effects of four treatments [(C) Control diet including A, D and E vitamin; (V) Control diet plus 50% A, D and E vitamin; (E) Diet including plant extracts; (A)Diet with an association of these two additives (50% A,D and E vitamin + plant extract)] on biological efficiency, carcass length, tissue composition, carcass muscularity and total beef cuts of 56 Nellore (*Bos indicus*) young bulls (+360 kg initial weight and +20 mo of age). The treatments provided the same diet for all animals (85 and 15%, for concentrate and forage, respectively), varying only the inclusion of the different additives. All treatments received monensin (30 mg/kg of concentrate). Animals were individually weighed, blocked by initial body weight, and maintained in individual pens for 105 d (finishing phase; 21 and 84 d, for adaptation and trial period, respectively). At the slaughterhouse, carcasses were identified, cooled for 24 h, and weighed to determine the biological efficiency. Right carcass half was used to calculate total beef cuts. Sample from ninth to 11th ribs (HH section; left carcass half) was obtained to determine tissue composition and carcass muscularity. There was no effect of treatments for carcass traits ($P > 0.10$), and total beef cuts ($P > 0.10$). In conclusion, the inclusion in the diet of plant extracts, vitamins and their associations not affected the carcass characteristics and total beef cuts of Nellore cattle. *Supported by CNPQ/NUTRON.*

Key Words: plant extracts, tissue composition, beef cattle, Nellore

1251 (T154) Pearson's correlation between fatty acid profile and gene expression of transcription factors and lipogenic enzymes in the muscle of young bulls fed soybean or cottonseed, with or without vitamin
E. M. M. Ladeira[*1], D. M. Oliveira[1], A. Chalfun Junior[1], M. L. Chizzotti[2], P. D. Teixeira[1], and T. C. Coelho[1], *[1]Universidade Federal de Lavras, Brazil, [2]Universidade Federal de Viçosa, Brazil.*

This study had the objective to evaluate the correlations between mRNA expression of peroxisome proliferator-activated receptor-α (PPAR-α), sterol regulatory element binding protein-1c (SREBP-1c); stearoyl-CoA desaturase-1 (SCD1), acetyl CoA carboxylase (ACC) and fatty acid profile in the muscle of young bulls fed diets containing soybean grain or cottonseed, with or without vitamin E supplementation. Twenty-eight Red North young bulls with an average age of 20 mo and initial average live weight of 339 +15 kg were allotted in a completely randomized design using a 2 × 2 factorial arrangement. The animals were slaughtered at an average weight of 456 ± 15.1 kg ($P > 0.05$), and two samples were then taken from the longissimus dorsi (LD) muscle of each animal between the 12th and 13th ribs. The first sample was stored at -20°C for subsequent lipid extraction and fatty acid analysis using gas chromatography; and the second sample was stored at −80°C for quantitative gene expression analysis by RT-qPCR. After analyzes of fatty acid content and relative gene expression according to the diets, data of all treatments were used to carry out the Pearson's correlation study using the PROC CORR tool of SAS 9.3. Linoleic acid content was negatively (-0.38; $P < 0.05$) and positively (0.38; $P < 0.05$) correlated with expression of PPAR-α and SREBP-1c, respectively. On the other hand, α-linolenic and oleic acids were positively (0.55; $P < 0.01$ and 0.46; $P < 0.05$, respectively) correlated with PPAR-α, showing an agonistic effect of these fatty acids on the nuclear receptor. In addition, correlations between linoleic acid content and expression of SCD1 (0.39; $P < 0.05$) and ACC (-0.38; $P < 0.05$) were observed in the LD muscle. No correlations ($P > 0.05$) between arachidonic acid and the expression of PPAR-α and SREBP-1c were observed. Oleic and palmitoleic acids had positive correlations with ACC mRNA (0.47; $P < 0.05$ and 0.41; $P < 0.05$, respectively), but a negative correlation between stearic acid content and ACC gene expression was observed (-0.38; $P < 0.05$). In conclusion, linoleic acid was the main fatty acid that influenced expressions of PPAR-α, SREBP-1c, SCD1 and ACC. Furthermore, unsaturated fatty acids affect in different ways gene expression of these genes. *Funded by Fapemig, CNPq, Capes, and INCT-CA.*

Key Words: PPAR, SCD, SREBP-1c

1252 (T155) Effect of functional oils and high levels of glycerine in the diet of Purunã bulls finished in a feedlot on fatty acid composition in the Longissimus muscle grilled. F. Zawadzki*[1], D. C. Rivaroli[2], A. Guerrero[1], J. A. Torrecilhas[1], C. A. Fugita[1], J. Torrent[3], and I. N. D. Prado[1], *[1]State University of Maringá, Maringá, Brazil, [2]Universidade Estadual Paulista-FMVZ, Botucatu, Brazil, [3]Oligo Basics USA LLC., Chanhassen, MN.*

Bulls were distributed in a complete randomized design by a factorial scheme 2 × 2 to evaluate the effects of the addition of a commercial mixture of functional oils– cashew and castor oil (Essential, Oligo Basics, Paraná, Brazil) and the effects of corn replace by glycerine (800 g of glycerol kg^{-1}) in the diet of Purunã bulls on fatty acids of the *Longissimus* muscle grilled. Thirty-three bulls (206.1 ± 20.0 kg BW, 8 mo old) were allocated in individual pens and distributed into 4 treatments: CON, without glycerine or functional oils); FOL, functional oil (3 g $animal^{-1}$ d^{-1}); GLY, 203 g kg^{-1} of glycerine of dry matter; and GFO, 203 g kg^{-1} of glycerine of dry matter and 3 g $animal^{-1}$ d^{-1} of functional oils. The bulls were fed during 252 d a diet with 420 g corn silage, 477 g ground corn, and 103 g soybean meal d^{-1}; or a diet with 420 g corn silage, 203 g glycerol and 150 g soybean meal. All diets were kept isonitrogenous and isoenergetic. The bulls were slaughtered at commercial slaughterhouse with BW of 468 kg (SD 31.53) ± 19 mo old. The carcasses were labeled and chilled for 24 h at 4°C. *Longissimus* muscle samples were taken by complete cross-section between the 12th and 13th ribs and taken to the laboratory and was frozen at -20°C. *Longissimus* muscle samples were sliced into 1-cm-thick steaks 2 h before grilling. Industrial grill was used to samples grilling at 200°C until reaching 75°C internal temperature. Total lipids were extracted using method with a chloroform/methanol mixture. Fatty acid methyl esters (FAME) were prepared by triacylglycerol methylation according ISO-R-5509 (1978). Then, the esters were extracted with 2 mL of n-heptane and stored at -18°C for later chromatographic analysis (Thermo 3300 gas chromatograph). Retention times and peak area percentages were automatically computed with Chronquest 5.0 software. The fatty acids composition in the *Longissimus* muscle grilled were similar ($P > 0.05$) for bulls fed with functional oils addition. On the other hand in the diet with high level of glycerine the fatty acids ($P < 0.05$) pentadecanoic, margaric, *cis*-10-heptadecaenoic, oleic, *cis*-vaccenic, and ∑-monounsaturated increase in the *Longissimus* muscle grilled. Whereas the fatty acids 15:1 *n*-9, stearic, docosapentaenoic, ∑-saturated fatty acid and ratio ∑-Omega-6:∑-Omega-3 had reduction in the *Longissimus* muscle grilled of bulls feed with glycerine.

Key Words: cashew nutshell liquid; castor oil; meat quality

1253 (T156) Effects of dietary rolled barley grain processed by lactic and citric acid on meat quality in feedlot cattle. M. Nematpoor*[1], K. Rezayazdi[2], and M. Dehghan-Banadaky[3], *[1]University of Tehran, Karaj, Iran, [2]Dep. of Animal Science, Faculty of Agriculture, University of Tehran, Karaj, Iran, [3]University of Tehran, Iran.*

The objectives of the present study were to evaluate the effects of feeding barley grain steeped in lactic acid and citric acid on meat quality in feedlot cattle. Thirty Holstein male calves (initial BW = 308 ± 22 Kg) were used in a completely randomized design. Data were analyzed by the GLM procedure of SAS and Tukey test used considering 5% probability. Feedlot cattle fed twice daily a total mixed ration containing rolled barley grain (51% in DM) steeped for 48 h in an equal quantity of top water, in 0.5% lactic acid or 1% citric acid. The experiment was conducted with 3 rations and 10 animals in each group. Rations were: 1) Control (with rolled barley), 2) rolled barley treated with citric acid, and 3) rolled barley treated with lactic acid. Calves were stunned and dressed at the abattoir. All samples were collected from the *M. longissimus lumborum* (LL) on the day after slaughter. Measurements were performed on fresh (24 h post mortem) and a steak was sampled from the right LL between the 12th and 13th vertebrae (Canadian grade side). The used of treatments had no effect on yellowness (6.85, 6.08 and 6.50, respectively), cook loss (36.79, 34.80 and 35.77, respectively), WB shear force (5.07, 5.29 and 5.12, respectively), water-holding capacity (2.10, 1.94 and 1.82, respectively) and pH (5.50, 5.41 and 5.33, respectively) in steaks from calves ($P > 0.05$). The lightness (34.79, 35.23 and 35.94, respectively) and the redness (14.13, 15.51 and 15.96 kg respectively) of LL muscle were significantly affected by treatments ($P < 0.05$). Moreover, feeding feedlot cattle barley grain steeped in 0.5% LA was improved meat quality, but was not observed any effect from CAB diets.

Key Words: meat quality, lactic acid, citric acid

1254 (T157) Natural additives in the diet of bulls (Angus vs. Nellore) finished in feedlot: Fatty acids composition. C. A. Fugita*, R. Prado, I. N. D. Prado, F. Zawadzki, C. Eiras, M. Valero, and R. Passetti, *State University of Maringá, Brazil.*

Natural extracts could be an alternative for the use of antibiotics as growth promoters in animal feed. The objective of this study was to evaluate the effects of the inclusion of natural additives in the diet of bulls finished in feedlots on *Longissimus* muscle fatty acids composition. Forty-eight bulls (Angus vs. Nellore) finished in feedlot during 94 d were used. The experiment was completely randomized and animals were distributed into four treatments: control (CON); essential oils (EOL– addition of 4 g/animal/day of a mix of essential oils from castor bean- *Ricinus communis*- and ca-

shew- *Anacardium occidentale*); Confimax (MAX– addition of 10 g/animal/day of mix of essential oils from oregano- *Origanum vulgare*, castor bean and cashew, and yeast); and yeast (YST– addition of 5 g/animal/day of yeast- *Saccharomyces cerevisiae*). Bulls were an average of 22 mo old and 318 ± 30 kg at the beginning of the trial and were slaughtered with an average of 468 ± 45kg. Roughage:concentrate ratio was 50:50. A variance analysis was performed and a comparison of means was performed using Tukey test at 10% of significance. Most fatty acids in the *Longissimus* muscle were not altered by the inclusion of additives. The myristic acid was higher ($P < 0.10$) in the CON (3.27%) treatment compared to the EOL (2.83%). Palmitic acid was lower ($P < 0.10$) for the YST. Oleic acid was higher ($P < 0.10$) for the YST (41.4%) and lower for MAX (39.0%) treatment. Natural additives had no effect on SFA, MUFA, PUFA, *n*-3, *n*-6, and the ratio between PUFA/SFA and *n*-6/*n*-3. When fatty acids were analysed individually, some differences were found for YST, indicating a healthier meat fatty acid composition profile for this treatment. The used natural additives had mild effects on fatty acid composition of bulls finished in feedlot.

Key Words: animal nutrition, essential oils, meat quality

1255 (T158) Effects of tannins extract addition in to the diet on physicochemical characteristics of meat from finishing bulls. B. O. Lopez[*1], M. A. Mariezcurrena[1], M. D. Mariezcurrena[1], and R. Barajas[2], *[1]Universidad Autónoma del Estado fde México, Toluca, México, [2]FMVZ-Universidad Autónoma de Sinaloa, Culiacan, México.*

Meat samples of *Longisimus dorsi* obtained from sixteen finishing bulls (*Bos Taurus x Bos indicus*) were used to determine the effects of effects of tannins extract addition in to the diet on physicochemical characteristics of meat from finishing bulls. Animals were fed during last 70 d in finishing period diets supplemented or not with 0.3% DM of a condensed and hydrolyzable tannins blend. After harvested and 24-h chilling period, loin of left carcass side was cross-sectioned at 12th rib level, and four 2.5-cm thickness steaks were removed from each carcass. Steaks sample were immediately placed in identified plastic bags and were vacuum-sealed and transported to laboratory. One subsample bag was open and used for water retention determinations. The remainder of the bag samples were frozen at -20°C and kept frozen until used for laboratory determination. Samples were slowly defrosted, then bags were opened, and aliquots were taken by duplicate and subjected to next measurements: dry matter (forced-air oven), crude protein (N x 6.25 Kjeldhal), ether extract content, ash (550°C; 3 h), and shear force. Results were analyzed by ANOVA for a completely randomly design, with eight replicates by treatment, carcass was consider as the experimental unit. Water retention capacity was similar ($P = 0.48$) between treatments (86.7 ± 114%); dry matter content was not affected ($P = 0.39$) by treatments (25.6 ± 308%), crude protein was not altered ($P = 0.48$) by TE addition (20.15 ± 304%), ether extract was similar ($P = 0.19$) across treatments (5.24 ± 1.22%), ash (2.0 ± 114%) was not altered by TE level ($P = 0.20$), shear force tended to increase ($P = 0.07$) in meat samples from TE supplemented cattle (8.88 and 10.21 kg/cm^2). Loss by cooking was not different ($P = 0.30$). It is concluded that tannin extract supplementation did not alter substantially physicochemical characteristics of frozen meat from finishing bulls.

Key Words: finishing-bulls, meat, tannin

1256 (T159) Effect of polymorphsims in the DECR1 and LDHB genes on beef color stability. J. D. Neal*, J. W. Buchanan, and R. G. Mateescu, *Oklahoma State University, Stillwater.*

The mitochondrial 2,4-dienoyl CoA reductatse gene (DECR1) encodes an enzyme that is associated with the β-oxidation of polyunsaturated fatty enoyl-CoA esters. The lactate dehydrogenase B gene (LDHB) encodes an enzyme that catalyzes the interconversion of muscle lactate to pyruvate. These enzymes affect the oxidative capacity of muscles and potentially influences meat color stability. Meat color plays a crucial role in customer preference of retail beef cuts, and losses of $1 billion annually can be attributed to discolored products. This experiment was created to evaluate the influence of polymorphisms in the DECR1 and LDHB genes on beef color stability. A population of 140 beef cattle finished on grain and grass based diets was harvested, and steaks from these animals were evaluated by panel and instrumental means. Measurements were taken every 12 h for 156 h to evaluate the overall appearance of the steaks. Steaks were separated into high, moderate, or low color stability groups. DNA was extracted from individual tissue samples and SNPs within the DECR1 and LDHB genes were identified. Real time polymerase chain reaction (RT-PCR) and High Resolution Melt curve analysis were run on the extracted DNA samples to determine the genotypes of the cattle. A regression analysis was used to test the association between the new SNPs in the DECR1 and LDHB genes and the beef color stability.

Key Words: beef, meat, quality

1257 (T160) Meat quality in yearling bulls fattened in three production systems from Mexican dry tropic. G. Corral-Flores[1], C. Rodríguez-Muela[1], A. Flores-Mariñelarena[1], J. A. Ramírez-Godínez[1], F. S. Solorio[2], and C. R. Duran[*2], *[1]Universidad Autónoma de Chihuahua, México, [2]Universidad Autónoma de Yucatán, Merida, México.*

The objective was to evaluate the effect of the production system and genetic group in carcass measurements in yearling bulls from mexican dry tropic. Forty-eight animals of

two genetic groups (Brahman*Charolais Bh*CH and Brahman*Brown Swiss Bh*BS) were randomly asigned to Intensive Silvopastoral (ISP, $n = 19$), Silvopastoral + Suplementation (ISP+S, $n = 15$) and Feedlot (F, $n = 14$). Animals were harvested in a commercial abattoir when they target 450 ± kg live weight, to evaluate hot carcass weight (HCW), yield (Y), rib eye area (REA), fat thickness (FT), and marblilng score. As well as bromatological (humidity, ash, crude protein, ether extract) and physicochemical characteristics (*P*H, meat and fat color for L, a*b*). PROC MIXED of SAS was used. Difference was found ($P < 0.05$) for systems, marbling score was higher in F (446.36 ± 31.77), followed by ISP+S (245.7 ± 26.2) and ISP (167.6 ± 26.9). Genetic group was different ($P < 0.05$), in yield better response was in Bh*CH (58.9 ± 0.7%) than Bh*BS (57.7 ± 0.6%), as well as REA (74.0 ± 2.7 cm^2 *vs* 66.2 ± 2.5 cm^2. Cattle fattened in F had DFD meat with highiest pH at 48 h postmortem (6.7 ± 0.06), while bulls in ISP+S and ISP were similar ($P > 0.05$) because they were near to normal pH value. In meat color F had lower L, higher a* and b* 36.9 ± 1.1, 15.9 ± 0.8 and 20.1 ± 0.9), respectively; while ISP+S and ISP had similar values ($P > 0.05$) for fat color as well as protein and humidity. In ash, ISP and ISP+S were similar ($P > 0.05$; 4.0 ± 0.07% y 4.0 ± 0.07), but they were higher than F (3.4 ± 0.08%). Ether extract was high in F (5.76 ± 0.5%) vs. 2.03 ± 0.4% in ISP+S *vs*1.5 ± 0.4% to ISP. It was concluded that cattle in ISP can produce the same carcass characteristics, nutritional facts than F; however, they have the advantage to produce lean meat. Also, carcass characteristics may be affected by genetic group. Supplementation can improve beef quality related with marbleing score.

Key Words: silvopastoral, feedlot, marbling, cattle

1258 (T161) Effect of diet without forage on beef quality in *Bos taurus* and *Bos indicus* young bulls.

M. L. Chizzotti*[1], P. D. Teixeira[2], M. M. Ladeira[2], J. R. R. Carvalho[2], K. C. Busato[2], R. A. Gomes[2], A. C. Rodrigues[2], and M. C. L. Alves[2], *[1]Universidade Federal de Viçosa, Brazil, [2]Universidade Federal de Lavras, Brazil.*

The objective was to evaluate beef quality of finishing young bulls Nellore or Aberdeen Angus fed a whole grain corn diet without roughage (WR, 85% of whole corn and 15% of commercial pellet) or a traditional diet containing 30% of corn silage and 70% of concentrate (30:70). Thirty-six animals with average initial body weight of 381.2 ± 11.87 kg were used in a 2 × 2 factorial design (2 breeds and 2 diets). Both diets had 12.5% crude protein and 2.88 Mcal/kg of ME. Animals were fed for 82 d after a 28-d adaptation period and slaughtered at the end. Samples were taken from the *Longissimus dorsi* muscle between the 12th and 13th ribs for centesimal composition analyses, color (L*, a*, b*), cooking weight loss (CWL) and shear force (SF). The model included the effects of breed, diet, and their interaction and was analyzed using PROC GLM in SAS 9.1. The moisture, ashes, protein, CWL, a*, and b* were not affected by breed and diet. However, Angus bulls showed higher muscle ether extract in WR than Nellore animals. Angus animals showed greater tenderness when compared to Nellore, and WR had a tendency to increase tenderness. Nellore presented a higher brightness (L*) when compared to Angus animals. Angus animals and diet with whole grain corn increased the levels of ether extract, and the use of Angus animals improved meat tenderness.

Key Words: color, shear force, beef

1259 (T162) Prediction of lamb carcass back fat thickness by skin-fold measurement.

H. A. Ricardo*[1], and R. O. Roça[2], [1]*Grande Dourados Federal University* (*UFGD), Dourados, Brazil,* [2]*São Paulo State University* (*FCA/UNESP), Botucatu, Brazil.*

Skinfold measurement is a common method for determining body fat composition and nutritional status in humans for athletic and health goals. Many subjective and objective methods are available for prediction of sheep carcass composition, with more accuracy for automated methods. The objective of this preliminary study was to start the assessment of the use of skin-fold measurement as predictor of lamb carcass composition. The first trial evaluated the use of skinfold measurement to predict carcass back-fat thickness (BF) and rib eye area (REA). Twenty market lambs (29.73 ± 3.15 kg of BW) were chosen randomly at the slaughterhouse floor. Skin-fold measurement (mm) was taken in vivo with a clinical plicometer with sensibility of 2 mm, reading range of 80 mm, and pressure of ± 10 g/mm^2, including: skin fold on sternal bone (SSF); skin fold on m. *Longissimus* between first and least lumbar vertebra (LSF); skin fold on rump back-fat thickness location (RSF), and average skin fold (ASF), with the three measurements. After slaughter, carcasses were chilled over 24 h at 4°C. Hot and cold carcass weights (HCW and CCW) were recorded. BF and REA were taken in the cold carcass on m. *Longissimus* between 12th and 13th ribs. A stepwise regression was performed with BW, skin-fold measurement, and carcass weights to predict BF and REA. A two-step model was obtained for BF prediction with SSF and HCW ($P < 0.01$). SSF and HCW were responsible for 39.97 and 48.72%, respectively, of BF variation, resulting in a model $R^2 = 0.89$ (RSD = 0.40). A stepwise model for REA used SSF and BF ($P = 0.0847$). SSF and BF had a partial R^2 of 0.34 and 0.29, respectively, which model representing 63% of REA variation. In conclusion, skin-fold measurement can be used to predict lamb carcass BF and REA, and shows potential to be used in the estimation of carcass composition.

Key Words: back-fat prediction, lamb, plicometer

1260 (T163) Carcass traits and meat quality of goat kids supplemented with chromium-methionine.

A. Emami[1], M. Ganjkhanlou[2], A. Zali[2], and M. Dehghan-Banadaky*[2], [1]*University of Birjand, Iran,* [2]*University of Tehran, Iran.*

The objective of this study was to evaluate the effects of supplementing chromium-methionine (Cr-Met) on carcass traits and meat quality in Mahanadi goat kids. Thirty-two male kids (BW = 22 ± 2 kg, 4 mo of age) were used in a completely randomized design in one of four treatments: 1) control (without Cr), 2) 0.5, 3) 1.0, and 4) 1.5 mg Cr as Cr-Met/animal/d. Diet was formulated to meet the requirements recommended by NRC with forage (alfalfa and corn silage): concentrate ratio of 30:70 in TMR form. Diets were the same, except for top-dress addition of Cr-Met fed in two equal meals (0700 and 1700 h). Animals were kept in individual pens for 84 d. Kids were slaughtered following the end of trial after 16-h fasting. The area of the ninth, 10th, 11th, 12th and 13th ribs together with the adjoined section of spinal column were used to estimate the amount of bone-free meat, fat and bone in the carcass. The meat, fat and bone were weighed after separation and the bone-free meat component stored at -20°C for the chemical analysis. Physical meat quality parameters (drip loss, DL, pH and Warner-Bratzler shear force, WBS) were investigated on longissimus thoracis (LT) at 24 h after slaughter. Data were analyzed by GLM procedure of SAS 9.1 and Tukey test ($P \leq 0.05$). The muscle, fat, and bone percentages were not affected by Cr-Met ($P > 0.05$). pH, moisture (%), intramuscular fat (%), crude protein content (%) and DL percentage were also not affected by Cr supplementation ($P > 0.05$). Supplemental Cr decreased WBS (6.89, 5.97, 5.60 and 5.83 in control to 4, respectively; $P = 0.07$). These results suggest that supplementation diet with Cr-Met did not influence the carcass traits and meat quality but improved tenderness of LT in Mahabadi goat kids.

Key Words: chromium-methionine, Mahabadi goat kid, tenderness

1261 (T164) Effect of high level of copper on meat quality in Iranian Mahabadi goat kids.

M. Ganjkhanlou[1], A. Zali[1], A. Hatefi[1], A. Emami[2], A. Akbari-Afjani[3], and M. Dehghan-Banadaky*[1], [1]*University of Tehran, Iran,* [2]*University of Birjand, Iran,* [3]*University of Zanjan, Iran.*

This study was performed to determine the effects of supplementing high level of copper (Cu) on meat quality in goat kids. Fourteen male kids (BW = 21 ± 2 kg, 4 mo of age) were used in a completely randomized design with two treatments: 1) control (without Cu), and 2) 100 mg Cu as copper sulfate/animal/d. Diet was formulated to meet the requirements recommended by NRC with forage (alfalfa and corn silage): concentrate ratio of 30:70 in TMR form. Diets were the same, except for top-dress addition of Cu-So_4 fed in two equal meals (0700 and 1700 h) and orts were collected before morning meal. Experimental period was 90 d. The end of trial following 16 h fasting kids were weighed and slaughtered. Meat samples were taken from the *Longissimus dorsi* muscle (LDM). Color [lightness (L*), redness (a*) and (b*) yellowness] and Warner-Bratzler shear force (WBS) were measured at 24 h after slaughter. Cooking loss (CL) was determined by weighing the samples before and directly after cooking in a water bath at 70°C for 1 h. Percentage of CL was calculated. Data were analyzed by GLM procedure of SAS 9.1 and adjust Tukey test ($P \leq 0.05$). Addition of Cu failed to significantly affect lightness (L*) and CL percentage ($P > 0.05$). However, Cu supplementation de-

creased WBS (41.31 and 38.00 in control to 2, respectively) but increased redness (a*: 14.90 and 16.43 for treatment 1 and 2 respectively) and yellowness (b*: 12.53 and 17.60 for treatment 1 and 2; $P < 0.05$). These results indicated that dietary supplementations of Cu did not influence CL and lightness. Although Cu supplement increased redness, yellowness, and improved tenderness of LDM in Mahabadi goat kids.

Key Words: Mahabadi goat kid, meat quality, lightness

1262 (T165) Effect of fish oil and thyme on meat quality and meat oxidative stability of Mahabadi kids.

A. Hozhabri[1], M. Ganjkhanlou[1], A. Zali[1], A. Emami[2], A. Akbari-Afjani[3], and M. Dehghan-Banadaky[*1], *[1]University of Tehran, Iran, [2]University of Birjand, Iran, [3]University of Zanjan, Iran.*

This study was performed to determine the effects of supplementing fish oil and thyme on meat quality and meat oxidative stability in Mahabadi goat kids. For this aim, 28 Mahabadi goat kids (BW = 17.8 ± 2.8 kg, 4 to 5 mo of age) were randomly assigned to four treatments: 1) basal diet (BD), 2) BD + 0.2% thyme essence, 3) BD +2% fish oil, and 4) BD + 2% fish oil and 0.2% thyme essence (DM basis of concentrate). Diets were formulated to meet the requirements recommended by NRC with forage (alfalfa and corn silage): concentrate ratio of 30:70 in TMR form. Animals were kept in individual pens with self-mangers for 94 d. Kids were weighed and slaughtered at the end of the trial. Meat samples were taken from the *Longissimus dorsi* muscle (LDM). Color [lightness (L*), redness (a*), chroma, hue angle, and yellowness (b*)], cooking loss and drip loss percentage, Warner-Bratzler shear force, and pH of LDM were measured at 24 h after slaughter. Some of the LDM were immediately stored at -20°C for assaying moisture, intermuscular fat and crude protein content. TBARS values were measured at 1 and 2 mo after slaughter. Data were analized by GLM procedure of SAS 9.1 and Tukey test ($P \leq 0.05$). Addition of fish oil and thyme failed to significantly effect on redness (a*), yellowness (b*), chroma, hue angle, lightness (L*), pH, moisture (%), intramuscular fat (%), crude protein content (%), Warner-Bratzler shear force, cooking loss, and drip loss percentage of LDM ($P > 0.05$). TBARS values of the LDM were significantly increased as the storage time increased from 1 to 2 mo ($P < 0.05$). It was also found that diets 2 and 4 significantly decreased and diet 3 significantly increased lipid oxidation and the TBARS value compared with diet 1 at during of storage ($P < 0.05$). The results of this experiment indicated that supplementation of diet with 0.2% thyme essence decreased oxidative stability and improved quality of LDM during refrigerated storage.

Key Words: fish oil, Mahabadi goat kid, thyme essence

1263 (T166) Effect of fish oil and thyme on performance, blood metabolites, meat sensory of Mahabadi kids.

A. Hozhabri[1], A. Zali[1], M. Ganjkhanlou[1], A. Emami[2], A. Akbari-Afjani[3], and M. Dehghan-Banadaky[*1], *[1]University of Tehran, Iran, [2]University of Birjand, Iran, [3]University of Zanjan, Iran.*

This study was performed to determine the effects of supplementing fish oil and thyme on performance, blood metabolites and meat sensory in Mahabadi goat kids. For this aim, 28 Mahabadi goat kids (BW = 17.8 ± 2.8 kg, 4 to 5 mo of age) were randomly assigned to four treatments: 1) control (basal diet), 2) 0.2% thyme essence, 3) 2% fish oil, and 4) 2% fish oil +0.2% thyme essence. Animals were kept in individual pens with self-mangers for 94 d. Diet was formulated to meet the requirements recommended by NRC with forage (alfalfa and corn silage):concentrate ratio of 30:70 in TMR form. For measuring blood metabolites (glucose, triglyceride, cholesterol, high and low density lipoprotein, albumin, total protein and blood urea nitrogen), blood samples were collected every 21 d before morning feeding. Kids were weighed after 14 d of adaptation and at 21-d intervals after feed restriction and slaughtered at the end of the trial. Meat samples were taken from the *Longissimus dorsi* muscle and frozen at -20°C until taste panel evaluation. Feed conversion ratio (FCR) was calculated according to FCR = DMI (kg)/average daily gain (kg). Data were analyzed using PROC MIXED of SAS 9.1. The Tukey test was used for comparison of treatment means. Dry matter intake, average daily gain and feed conversion ratio were not affected by fish oil and thyme essence ($P > 0.05$). Plasma glucose, triglyceride, cholesterol, high and low density lipoprotein, albumin, total protein and blood urea nitrogen were not affected by treatments ($P > 0.05$). Addition of fish oil and thyme failed to significantly affect sensory properties of meat ($P > 0.05$). The results of this experiment indicate that supplementation of goat kid diet with fish oil and thyme did not influence performance, blood metabolites and meat sensory.

Key Words: fish oil, thyme essence, performance

MEAT SCIENCE & MUSCLE BIOLOGY III

1264 (W151) Sun dried meat quality derived from young bulls fed licuri cake derived from biodiesel production. R. L. Oliveira*, A. A. L. Govêa, A. G. Leão, N. G. D. N. Júnior, W. F. D. Souza, S. T. Carvalho, T. M. Silva, A. D. S. Nunes, and R. R. D. Albuquerque, *Universidade Federal da Bahia, Salvador, Brazil.*

This study was conducted to determine the best level of licuri cake in the diets of young bulls based on physical-chemical evaluation and sensory sun dried meat. The experiment was conducted at the School of Veterinary Medicine and Animal Science of the Federal University of Bahia, located in São Gonçalo do Campos, Bahia, Brazil, for 99 d with 15 d for the adaptation of animals, management and diets. Thirty two Nellore bulls non castrated average age of 24 mo and initial body weight of 368 ± 32 kg. Before beginning, the animals were vaccinated against clostridia, and wormed against endo and ectoparasites. Later, they were housed in individual 8-m^2 pens, with slatted floors, and provided with food and water in a covered area. The animals were distributed into four treatment groups, constituting diets with 0, 7, 14, and 21% of licuri cake in the dry matter. The forage used was hay of Tifton with particle size of approximately 5 cm and forage:concentrate ratio of 40:60. Treatments consisted of isonitrogen diets and formulated for 1.2 kg/day for gain according to NRC (1996). For the preparation of sun dried meat, a sample of the soft round (*Semimenbranosus*) was then divided into sections 5 in thick each. We used salt in a proportion of 5% (± 150 g) in relation to the weight of natural matter (3 kg), which was manually rubbed surfaces of the pieces evenly. After this process, the pieces were kept in an ambient temperature of 25°C for better penetration of salt. At the end of 16 h curing was taken drainage of exudate and washing the pieces in water to remove excess salt. The licuri cake added to the diet quadratic effect on the shear force ($P < 0.05$). For sensory parameters was no effect on aroma where the inclusion of 7 to 14% of the licuri cake reduced of sun meat appreciation ($P < 0.05$). There was no effect for the other characteristics evaluated. Licuri cake can be added to the diet of crossbred cattle to the level of 7% without causing changes in the quality of sun dried meat.

Key Words: flavor, *semimembranosus*, shear force

1265 (W152) Processed burguer quality derived from young bulls fed licuri cake from biodiesel production. R. L. Oliveira*[1], A. A. L. Govêa[1], A. G. Leão[1], C. B. D. Pellegrini[1], N. G. D. N. Júnior[1], C. L. D. Abreu[1], T. M. Silva[1], V. B. D. Silva[1], and E. S. dos Santos[2], *[1]Universidade Federal da Bahia, Salvador, Brazil, [2]Federal University of Bahia, Salvador, Brazil.*

This study was conducted to determine the physicochemical and sensory parameters of burgers from young bulls fed diets containing licuri cake. The experiment was conducted at the School of Veterinary Medicine and Animal Science of the Federal University of Bahia, located in São Gonçalo dos Campos, Brazil, over a period from July to October 2012. Thirty-two Nellore bulls were used, with initial weight of 368 ± 32 kg. Before the beginning of the experiment, the animals were vaccinated against clostridia, wormed against endo and ectoparasites and then assigned to individual 8-m^2 pens with food and water in a covered area. The experimental period was 84 d, with 15 d added for animal adaptation, totaling 99 d. The experimental design was completely randomized. The animals were divided into four treatments consisting of diets with 0, 7, 14, and 21% of licuri cake inclusion, based on dry matter. The forage used was hay of Tifton with particle size of approximately 5 cm and forage:concentrate ratio of 40:60. Treatments consisted of isonitrogen diets and formulated for 1.2 kg/d for gain according to NRC (1996). At the end of the experiment, the animals were submitted to feed fasting and slaughtered. The portion of beef burger used in processing was *Semimenbranosus* muscle (81.3%) and pig fat (15%). Other ingredients added to the burger were salt (3%), black pepper (0.2%), garlic paste (0.3%), and sugar (0.2%). The centesimal composition of the burgers was not altered by levels of licuri cake ($P > 0.05$). However, the inclusion of licuri cake promoted increased linearly between physicochemical characteristics of brightness ($P < 0.05$) and color of meat hamburger, increasing consumer acceptability and appearance of the product. The licuri cake can be added in the diet of beef cattle to the level up to 21% without causing significant changes in the qualitative parameters of the burger.

Key Words: color, confinement, *semimenbranosus*

1266 (W153) Collagen, cooking losses and shear force of aged meat from Nellore steers fed protected or unprotected linseed oil. W. Henrique*[1], L. R. Simonetti[2], T. M. Pivaro[3], V. G. Carvalho[2], E. A. Oliveira[2], C. C. P. D. Paz[1], and A. A. M. Sampaio[2], *[1]Instituto de Zootecnia, Sertãozinho, Brazil, [2]Universidade Estadual Paulista "Júlio de Mesquita Filho", Jaboticabal, Brazil, [3]FCAV/UNESP JaboticabaL, Pradópolis, Brazil.*

This work assess the effects of aging times and the inclusion of protected or unprotected linseed oil of rumen degradation on the diet of 21 Nellore steers finished on feedlot on collagen (COL), cooking losses (CL) and shear farce (SF) of *Longissimus* muscle. At the beginning of the experiment, animals had 18 mo of age and 397.74 ± 14.07 kg of BW, and they were kept in individual pens and adapted during 21 d. The diets were composed by 40% corn silage and with no oil addition (73% TDN and 2.9% EE), with in natura linseed oil or with protected linseed oil (76% TDN and 6.1% EE). After 105 d at feedlot, the animals were slaughtered with 522.72 ± 27.99 kg of BW and carcasses were chilled for 24 h. After this period, a section of the *Longissimus* between sixth and 13th ribs was removed and separated in 2.54 cm steaks, which were individually vacuum packed and chilled to 2°C for 1, 7, or 14 d. The amino acid hydroxyproline was quantified to measure the collagen content by spectrophotometer reading at 500 nm; for CL, the steaks were roasted in an electric woven up to 71°C at its geometric center, and the weights before and after cooking were used for the calculation. After 24 h of cooling, six cylinders of 1.27 cm diameter were removed from the steaks to determine the force required to cut across each cylinder using a texturometer, and the average were used to represent the SF. The results were submitted to analysis of variance using mixed models, considering a random block one, and a 3 × 3 factorial scheme. For COL (0.70 mg/100 g muscle), no differences were found among treatments ($P = 0.5806$), and for the aging times, a quadratic effect ($P = 0.0168$) was observed. An interaction for CL was found ($P = 0.0433$), and its evaluation showed a quadratic effect ($P = 0.0134$) for unprotected linseed oil during aging periods, the remaining variables showed no differences ($P > 0.05$). SF was not influenced by the treatments ($P = 0.2718$) and aging times showed a quadratic effect ($P < 0.0001$) (5.38; 3.35 and 3.34 kgf, for 1, 7, and 14 d, respectively). Meat tenderness is not affected by the addition of linseed oil on the bovine diet, but it is improved by aging up to 14 d. On the other hand, collagen content is increased by aging.

Key Words: *Longissimus*, tenderness, Zebu

1267 (W154) Effect of aging times and inclusion of unprotected or protected linseed oil on the diet of Nellore steers over the color of *Longissimus*. W. Henrique*[1], L. R. Simonetti[2], T. M. Pivaro[3], V. G. Carvalho[2], E. A. Oliveira[2], C. C. P. D. Paz[1], and A. A. M. Sampaio[2], *[1]Instituto de Zootecnia, Sertãozinho, Brazil, [2]Universidade Estadual Paulista "Júlio de Mesquita Filho", Jaboticabal, Brazil, [3]FCAV/UNESP Jaboticabal, Pradópolis, Brazil.*

The objective was to evaluate the effects of aging time and the inclusion of unprotected or protected linseed oil from rumen degradation on the diet of 21 Nellore steers, finished at feedlot in individual pens, and their influence over the color aspects of *Longissimus* muscle. At the beginning of the experiment, animals had 18 mo of age and 397.74 ± 14.07 kg of BW and they were kept in adaptation during 21 d. The diets were composed by 40% corn silage and with no oil addition (73% TDN and 2.9% EE), with in natura linseed oil or with protected linseed oil (76% TDN and 6.1% EE). After 105 d at feedlot, the animals were slaughtered with 522.72 ± 27.99 kg of BW and carcasses were chilled for 24 h. After this period, a section of the *Longissimus* between sixth and 13th ribs was removed and separated in 2.54 cm steaks, which were individually vacuum packed and chilled to 2°C for 1, 7 or 14 d. After this processing, in different points of these steaks, we cut a cross-section of muscle for exposure of myoglobin to oxygen for 30 min. Then a colorimeter was used to determine the color of the meat by evaluating the lightness (L*), 0 = black and 100 = white; redness (a*); and yellowness (b*). The results were submitted to analysis of variance using mixed models, considering a random block one, and a 3 × 3 factorial scheme. No interactions were observed between diets and aging times ($P > 0.05$). For L* (40.84) and b* (14.85), no difference among treatments were found ($P = 0.4145$ and $P = 0.0703$, respectively), and the aging time showed a quadratic effect on both characteristics ($P = 0.0002$ and $P < 0.0001$). The values of a* (16.49) were not affected by diets ($P = 0.3116$) and aging times (linear regression- $P = 0.9565$; quadratic- $P = 0.5068$). Protected or unprotected linseed oil can be used on Nellore steers diet without changing aspects of meat color.

Key Words: cattle, luminosity, meat

1268 (W155) Aging times and inclusion of unprotected or protected linseed oil on Nellore steers diet and its influence on cholesterol and lipid oxidation of the meat.

L. R. Simonetti*[1], W. Henrique[2], T. M. Pivaro[3], V. G. Carvalho[2], E. A. Oliveira[2], C. C. P. D. Paz[2], and A. A. M. Sampaio[2], *[1]Universidade Estadual Paulista "Júlio de Mesquita Filho", Jaboticabal, Brazil, [2]Instituto de Zootecnia, Sertãozinho, Brazil, [3]FCAV/UNESP Jaboticabal, Pradópolis, Brazil.*

The objective was to assess the effects of aging time and the inclusion of unprotected or protected linseed oil from rumen degradation on the diet of 21 Nellore steers, finished at feedlot, over the cholesterol content and lipid oxidation of *Longissimus* muscle. At the beginning of the experiment, animals had 18 mo of age and 397.74 ± 14.07 kg of BW, and they were kept in individual pens and adapted during 21 d. The diets were composed by 40% corn silage and with no oil addition (73% TDN and 2.9% EE), with in natura linseed oil or with protected linseed oil (76% TDN and 6.1% EE). After 105 d of feedlot, the animals were slaughtered with 522.72 ± 27.99 kg of BW and carcasses were chilled for 24 h. After this period, a section of the *Longissimus* between sixth and 13th ribs were removed and sampled as 2.54 cm steaks, individually vacuum packed and chilled to 2°C for 1, 7 or 14 d. For cholesterol content, 10 g of fresh meat were used after each aging time, and the lipid oxidation was obtained by the method based on 2-thiobarbituric acid (TBARS), both using spectrophotometer with 538 nm. The results were submitted to analysis of variance using mixed models, considering a random block one, and a 3 × 3 factorial scheme. No interactions were observed, cholesterol content was not influenced by diet ($P = 0.5727$) or by aging times (linear regression- $P = 0.5008$, and quadratic- $P = 0.7493$), showing lower levels than those considered normal for the *Longissimus* muscle (36.5 and 33.16 mg/100 g of muscle to diets and times aging, respectively), which is important because of its influence in preventing cardiovascular disease. Lipid oxidation was also not influenced by factors evaluated ($P > 0.005$), and the average was 0.41 mg of malonaldehyde/kg of muscle. Add linseed oil on the diet of Nellore steers does not cause a loss in quality of meat for human consumption, using *in natura* or protected form.

Key Words: *Longissimus*, human health, TBARS

1269 (W156) Effect of aging times and inclusion of unprotected or protected linseed oil from ruminal degradation on the diet of Nellore steers over pH and water holding capacity of meat.

L. R. Simonetti*[1], W. Henrique[2], T. M. Pivaro[3], V. G. Carvalho[2], E. A. Oliveira[2], C. C. P. D. Paz[2], and A. A. M. Sampaio[2], *[1]Universidade Estadual Paulista Júlio de Mesquita Filho, Jaboticabal, Brazil, [2]Instituto de Zootecnia, Sertãozinho, Brazil, [3]FCAV/UNESP Jaboticabal, Pradópolis, Brazil.*

This work assess the effects of aging times and the inclusion of protected or unprotected linseed oil of rumen degradation on diet of 21 Nellore steers, finished at feedlot, over pH and water holding capacity (WHC) of *Longissimus* muscle. At the beginning of the experiment, the animals had 18 mo of age and 397.74 ± 14.07 kg of BW and they were kept in individual pens and adapted during 21 d. The diets were composed by 40% corn silage and with no oil addition (73% TDN and 2.9% EE), with in natura linseed oil or with protected linseed oil (76% TDN and 6.1% EE). After 105 d at feedlot, the animals were slaughtered with 522.72 ± 27.99 kg of BW and carcasses were chilled for 24 h. After this period, a section of the *Longissimus* between sixth and 13th ribs was removed and separated in 2.54-cm steaks, which were individually vacuum packed and chilled to 2°C for 1, 7, or 14 d. The pH was determined using a pHmeter with a penetration electrode and the WHC was obtained by the difference between the weights of the meat samples of approximately 2 g before and after being submitted to pressure of 10 kg for 5 min. The results were submitted to analysis of variance using mixed models, considering a random block one, and a 3 × 3 factorial scheme. No interactions were observed between diets and aging times ($P > 0.05$). No differences were observed for pH among treatments ($P = 0.9276$) and aging times (linear regression- $P = 0.3454$, and quadratic- $P = 0.3147$), with an average of 5.45 considered normal for beef. The diets did not influence ($P = 0.7500$) the WHC (74.61%), and for aging times, a quadratic effect ($P = 0.0286$) was observed (69.27, 75.88 and 78.68% for 1, 7, and 14 d, respectively). The addition of linseed oil in any form on Nellore steers diet does not alter pH and WHC, however, aged meat for up to 14 d is benefic because it increased the WHC, which influences many other aspects of meat quality, as juiciness.

Key Words: meat quality, *Longissimus*, Zebu

1270 (W157) Aged beef from Nellore young bulls fed crude glycerin in diets with different roughage sources. J. F. Lage*, A. F. Ribeiro, M. Machado, L. R. Simonetti, E. A. Oliveira, E. E. Dallantonia, and T. T. Berchielli, *Universidade Estadual Paulista Júlio de Mesquita Filho, Jaboticabal, Brazil.*

This trial aimed to evaluate the effects of feeding crude glycerin (CG)- 80% glycerol- included on 10% of DM diet, replacing corn with three roughage sources: corn silage (CS), sugarcane (SC) and sugarcane bagass (SCB) on pH, water holding capacity (WHC), Warner-Bratzler shear force (WBSF) and cooking losses (CKL) of aged beef from Nellore young bulls fed in feedlot. Thirty animals with 416 ± 24.68 kg initial BW were randomly assigned to three treatments, with ten replicates and fed during 90 d in feedlot. Animals were slaughtered at average BW of 550.50 kg BW and all carcasses were refrigerated at 0°C for 24 h. *Longissimus* muscle (LM) section 10 cm thick was removed from the posterior end of the wholesale rib, individually vacuum-packaged and aged for 7 and 14 d at 0 to 2°C. The WHC was measured for the difference between the weights of the sample before and after it was subjected to a pressure of 10 kg for 5 min. Steaks of 2.54 cm were removed and same samples were used to analysis of WBSF and CKL. The experiment was conducted according to a completely randomized design in a factorial arrangement 3 × 3 (three diets x three aging times). Data were analyzed by the PROC PROC MIXED of SAS, and the Tukey test used considering 5% probability. The WHC ($P = 0.68$), WBSF ($P = 0.15$) and CKL ($P = 0.88$) did not differ among diets, however, the beef from animals fed SC had a higher pH values than animals fed other diets ($P < 0.01$). The WHC was not different between beef aged in 7 or 14 d ($P = 0.72$). The pH was higher and CKL was lower ($P = 0.02$) in beef aged for 14 d. The WBSF was lower in d 14 than d 7($P < 0.01$). The use of corn silage, sugarcane or cane bagass in diets with crude glycerin replacing corn in 10% of DM did not affect the tenderness, WHC and CKL, but animals fed sugarcane had beef with higher pH values. The aging time until 14 d reduces the cooking losses and is an effective method to improve the tenderness of beef from Nellore young bulls.

Key Words: aging times, glycerol, meat quality

1271 (W158) Effect of aging times on tenderness of five muscles from carcass of Nellore young bulls. L. R. Simonetti*, J. F. Lage, E. E. Dalanttonia, E. A. Oliveira, M. B. Abra, G. M. Delamagna, L. Maneck Delevatti, and T. T. Berchielli, *Universidade Estadual Paulista Júlio de Mesquita Filho, Jaboticabal, Brazil*.

The objective of this study was to evaluate the aging effects on cooking losses (CKL) and Warner-Bratzler shear force (SF) of five muscles: *biceps femoris* (BF), *gluteus medius* (GM), *longissimus* (LD), *semitendinosus* (ST) and *trapezius thoracis* (TT) of Nellore young bulls fed in feedlot. Fourteen animals at 15 mo of age were confined in individual pens with feeders and drinkers. The diet was consisted of 40% corn silage and 60% concentrate. After 60 d of feedlot, the animals were slaughtered and the carcasses were chilled to 0°C for 24 h. The muscles were removed, cut into steaks of 2.54 cm and individually vacuum packed and chilled to 0 to 2°C for 1, 7, and 14 d postmortem. Steaks 2.54 cm thick were removed and same samples were used to analysis of WBSF and CKL. The experiment was conducted according to a completely randomized design in a 3 × 5 factorial arrangement (3 aging times × 5 muscles) with 14 replicates. The data were analyzed by PROC MIXED of the SAS and the Tukey test considering 5% probability. The interaction between muscles and aging times was significant ($P < 0.01$) to CKL and SF. The greater value for CKL was observed in muscle ST (36.73%) on d 7, being that muscles BF (33.82%) and TT (35.68%) at d 7 did not differ from the ST. Muscle LD (29.65%) on d 7, GM (28.64%, 29.60%) on d 1 and 7, BF (28.42%) on d 1 and TT (28.14%) at d 14 showed smallest values for CKL. The CKL at d 1 compared to d 14 was not different to muscles LD, ST and TT ($P > 0.05$). ST muscle (5.56 kgf) showed the highest values of SF in all aging times ($P < 0.01$). GM muscle (4.03 kgf) and BF (3.73 kgf) was not changed the SF at aging times. The LD muscle had the SH decreased with seven d of aged, not differing from d 14. The smallest SF was obtained for TT (2.96 kgf) in 14 d of aged. The ST muscle not changes the tenderness as an aging time up to 14 d. GM and BF muscles are considered tenderest on the d 1.

Key Words: beef cattle, meat quality, shear force.

1272 (W159) Color and pH of meat aged from Nellore young bulls fed crude glycerin associated with soybean grain in low or high starch diets. M. B. Abra, J. F. Lage*, L. G. Rossi, L. R. Simonetti, E. A. Oliveira, G. M. Delamagna, E. E. Dalanttonia, V. B. Carvalho, and T. T. Berchielli, *Universidade Estadual Paulista Júlio de Mesquita Filho, Jaboticabal, Brazil.*

This trial aimed to evaluate the meat quality aged in 7 or 14 d from Nellore young bulls fed crude glycerin (CG; 80% of glycerol) associated with soybean grain (SG) in low (LS) or high starch (HS) diets finished in feedlot. Twenty-eight animals that were 20 mo old and 428.57 ± 35.33 kg of initial BW were used in a randomly design in a factorial arrangement 2 × 2 x 2 (LS or HS diets, with or without oil and two aging times) with seven replicates. The diets (40:60) were: 10% of CG in DM diet replacing corn (HS); 10% of CG in DM diet replacing corn plus SG; 10% of CG in DM diet replacing soybean hulls (LS) and 10% of CG in DM diet replacing soybean hulls plus SG. After 140 d of feeding, all animals were slaughtered with a 590.21 ± 52.29 kg of BW. All carcasses were refrigerated at 0°C for approximately 24 h. A boneless *Longissimus* muscle

(LM) section 10 cm thick was removed from the posterior end of the wholesale rib. The LM was sliced into steaks of 2.54 cm, individually vacuum packaged and chilled at 0 to 2°C for 7 and 14 d. The color reading was conducted using the CIE L*a*b* system. The water holding capacity (WHC) was measured for the difference between the weights of the sample before and after it was subjected to a pressure of 10 kg for 5 min. Data were analyzed by the PROC MIXED of SAS, and the Tukey test used considering 5% probability. There was no interaction ($P > 0.05$) for any of the variables evaluated. Thus, effects were discussed independently. Similar values of lightness (L*), redness (a*), yellowness (b*), pH and WHC were observed for beef from animals fed LS or HS diets. Likewise, the inclusion of SG was not affected the meat quality traits. However, the lightness ($P < 0.01$) and yellowness ($P < 0.01$) was higher in beef aged for 14 d. The crude glycerin (10% of DM) associated with SG in LS or HS diets did not affect the meat quality traits as a pH, WHC and color of Nellore young bulls. The aging time for 14 d increases the lightness and yellowness of beef.

Key Words: glycerol, meat quality, oil

1273 (W160) Effects of excess dietary sulfur on beef carcass characteristics and quality after aging.

J. Hawley*, E. B. Kegley, J. W. Yancey, and J. K. Apple, *Dep. of Animal Science, University of Arkansas Division of Agriculture, Fayetteville.*

To test the effects of excess dietary S on beef carcass characteristics and quality (color shelf-life, oxidative stability, and sensory attributes), 20 steers (initial BW = 279 ± 60.4 kg) were blocked by BW and assigned randomly to 1) no additional S (~ 0.15% S) or 2) high S (0.40% S). Steers grazed fall pastures and were offered corn and soybean meal supplements for 114 d. Steers were moved to the feedlot, remained on prior dietary treatments, and received corn and soybean meal rations for 123 d. Steers were slaughtered at an average BW of 565 ± 38.4 kg. Boneless rib sections were obtained and aged 14 d at 4°C before fabrication into 2.54-cm-thick steaks. Steaks were overwrapped with oxygen permeable film and stored in open-topped, coffin-chest display cases (2.8°C) under continuous warm-white, fluorescent lighting (1600 lx) for 7 d of simulated retail display. Trained panelists ($n = 11$) evaluated raw LM color on d 0, 1, and 7. Instrumental (L*, a*, and b*) color was evaluated on d 0, 1, 4, and 7. Thiobarbituric acid reactive substances (TBARS) were measured on d 0 and 7 from LM cross-sections. Consumer sensory panel ($n = 151$) assessed cooked LM sensory attributes. Steer growth did not differ ($P = 0.58$) between dietary S levels. Dietary S did not affect HCW ($P = 0.50$), dressing percentage ($P = 0.44$), USDA yield grade ($P = 0.56$), LM area ($P = 0.36$), or 12th rib fat thickness ($P = 0.66$). Although TBARS were greater ($P < 0.0001$) on d 7 than 0 of simulated retail display, values did not ($P = 0.19$) differ between dietary S levels. No differences were observed in total color ($P = 0.27$) or percent discoloration ($P = 0.42$); however, LM from steers fed 0.40% S were perceived to display greater worst-point color ($P < 0.05$; treatment × day) on d 1 of simulated retail display. Dietary S did not effect a* ($P = 0.50$), b* ($P = 0.61$), or L* ($P = 0.64$). Furthermore, consumers failed to perceive a difference in tenderness ($P = 0.26$), juiciness ($P = 0.61$), overall impression ($P = 0.37$), beef flavor ($P = 0.40$), or off-flavor ($P = 0.79$) between the two dietary S levels. These results suggest that supplementing beef cattle diets with 0.40% S had no appreciable effects on steer performance or beef carcass characteristics, objective color, oxidative stability, and sensory attributes.

Key Words: beef, quality, sulfur

1274 (W161) Effect of β agonist and immunocastration on meat characteristics Nellore cattle.

M. Rezende Mazon[1], S. Luz e Silva[*2], D. Silva Antonelo[1], K. Nubiato[1], D. Juliana Brigida[1], B. Baptista[1], and P. R. Leme[2], *[1]University of Sao Paulo, Pirassununga, Brazil, [2]University of Sao Paulo/FZEA, Pirassununga, Brazil.*

Beta agonists (BAA) have been used to improve feedlot performance and carcass yielding, but some negative effects on meat quality. Immunocastration could be an alternative because increasing fat deposition. Therefore, this work was developed to evaluate the effect of BAA and immunocastration on meat quality traits of feedlot finished Nellore cattle. Ninety-six males (409 ± 50 kg LW; 20 mo old) were divided in two groups, and half of the animals received two doses of immunocastration vaccine (Bopriva) within 30-d interval. Animals were fed during 70 d a common diet containing 76% concentrate and 24% roughage (corn silage). Each of these groups were them splitted in three groups and fed during 30 d: control diet without BAA (CON); CON diet plus 80mg/day zilpaterol hydrochloride (Zilmax) (ZIL); CON diet plus 300mg/day of ractopamine hydrochloride (Optaflexx) (RAC). After 100 d of feeding, animals were slaughtered, and four samples of LM was collected between 12th and 13th ribs and aged for 0, 7, 14 or 21 d. Following aging samples were analyzed for L*, a*, b* color, cooking loss (CL), Warner-Bratzler shear force (WBSF). Data was analyzed as repeated measurements in a block (initial BW) complete randomized design with a 2 × 3 factorial arrangement, considering sex condition, treatment, ageing period and first and second order interactions as fixed effects. Immunocastrated males showed higher values ($P < 0.001$) of L* (36.4 vs. 33.3), a* (14.9 vs. 13.9) and b* (10.0 vs. 8.1) compared to non-castrated. Sex condition did not affect CL (22.2%) or WBSF (4.1 kg). There was a significant sex x aging period interaction ($P = 0.0053$) for WBSF that, different from expected, non-castrated males showed smaller WBSF than immunocastrated for non-aged (time 0) samples (5.2 vs. 6.3 kg; $P = 0.0131$). There was no sex difference for samples aged for 7, 14, or 21 d (4.4, 3.2 and 3.1 kg). Treatments had no effect on L* (34.9, but treatments

CON and RAC showed higher a* values (14.8 and 14.6) than ZIL (13.7; $P < 0.05$). CON had higher b* value than ZIL (9.5 vs. 8.6; $P = 0.0271$), but they did not differ from RAC (9.0). CL was not significantly affected by treatments. The WBSF was greater for ZIL (4.4 kg) than to RAC (4.0 kg) and CON (3.8) treatments. Sex condition affects meat color but has no impact on CL or WBSF. Use of BAA alter color attributes and WBSF of meat from Nellore cattle.

Key Words: feedlot, color, maturation

1275 (W162) The use of bioelectrical impedance analysis to predict carcass composition in calf-fed Holstein steers. N. D. May*[1], T. J. McEvers[1], L. A. J. Walter[1], J. A. Reed[1], J. P. Hutcheson[2], and T. E. Lawrence[1], *[1]West Texas A&M University, Canyon, [2]Merck Animal Health, DeSoto, KS.*

The beef industry relies heavily on subjective evaluation of beef carcasses to quantify carcass composition. Bioelectrical Impedance Analysis may offer the ability to objectively quantify carcass composition in a rapid, repeatable manner and more accurately determine composition of cattle fed growth promotants. Thus, bioelectrical impedance analysis was utilized to estimate the percentage of salable red meat yield (SRMY), fat trim (FT), and bone (BONE) within Holstein ($n = 110$) carcasses supplemented zilpaterol hydrochloride (ZH) or not supplemented (CON). Following a 36-h chilling period, bioelectrical impedance analysis was conducted by placing source and detector electrodes in the semimembranosus muscle posterior to the aitch bone and in the intercostal muscles between the first and third ribs to attain measures of electrical resistance (Rs) and electrical reactance (Xc). Additional measurements of hot carcass weight (HCW), carcass temperature (TEMP), electrode gap (EGAP) were collected to calculate measurements of impedance (I), resistive density (RsD), reactive density (XcD), resistive volume (RsVOL), and reactive volume (XcVOL). Upon completion of measurements, carcasses were subsequently fabricated into subprimal yield components reflective of industry standards (max. fat depth $\leq$ 6mm). Dependent variables of SRMY (52.26 to 67.72%), FAT (10.39 to 29.35%) and BONE (12.03 to 23.11%) were used in multiple linear regression equations. Estimates were calculated via STEPWISE regression methods in SAS (SAS 9.3, SAS Institute, Cary, NC). Predictive models for FT included variables of XcD, TEMP, RsD and EGAP accounted for 72 and 81% ($R^2 = 0.72$ and 0.81) of the variation in CON and ZH cattle, respectively. Moreover, predictive models for BONE included variables of Xc and HCW accounted for 43 and 58% ($R^2 = 0.43$ and 0.58) of the variation in CON and ZH cattle. Percentage of SRMY used variables RsD and XcD and accounted for 54 and 70% ($R^2 = 0.54$ and 0.70) of the variation in CON and ZH cattle, respectively. These results suggest that bioelectrical impedance analysis may serve as a reliable objective measure of carcass composition for concentrate fed Holstein steers.

Key Words: Holstein, impedance, composition

1276 (W163) Increasing levels of sodium benzoate affect myosin heavy chain type expression in cultured bovine satellite cells. J. O. Baggerman*, J. E. Hergenreder, and B. J. Johnson, *Texas Tech University, Lubbock.*

Sodium benzoate is used by commercial bakers to increase tolerance in yeast to calcium propionate, a mold inhibitor. Yeast cell wall is produced during the production of yeast extract from primary grown bakers yeast. While this primary grown yeast is washed before yeast cell wall is produced from the culture, some residual sodium benzoate may be retained. Due to increasing interest in feeding yeast cell wall to feedlot cattle, the present study was conducted to examine the effects of sodium benzoate on bovine muscle satellite cells (BSC). Cultured BSC were grown to confluence and treated with increasing levels of sodium benzoate added to the differentiation media, a negative control, 0.001 μ*M*, 0.01 μ*M*, 0.1 μ*M*, 1 μ*M*, 10 μ*M*, and 100 μ*M*, with four wells per dose. The cells were allowed to differentiate for 48 h and then harvested for RNA and protein analysis. The 1 μ*M* dose increased ($P < 0.05$) the gene expression of AMPKα compared with the 0.001 μ*M* dose and tended ($P < 0.10$) to be greater than the 0.01 μ*M* dose. The 0.1 μ*M* dose tended ($P < 0.10$) to have a greater expression of the AMPKα gene compared with the 0.001 μ*M* dose. Concentrations IGF-1 mRNA were greater in the 0.1 μ*M* dose compared with the control ($P < 0.05$). Among the cultures receiving sodium benzoate, there was a numerical increase of myosin heavy chain (MHC) type I gene expression as concentration of sodium benzoate increased, with the 10 μ*M* and 100 μ*M* doses having greater ($P < 0.05$) gene expression than the control, 0.001 μ*M*, and 0.01 μ*M* doses. The 0.001 μ*M* dose tended ($P < 0.10$) to have a lower abundance of MHC type I mRNA than the 0.1 μ*M* and 1 μ*M* doses. The 100 μ*M* dose had a greater expression of MHC type IIA than the control, 0.001 μ*M*, and 0.01 μ*M* doses ($P < 0.05$). The 10 μ*M* and 100 μ*M* doses had greater ($P < 0.05$) levels of MHC type IIX mRNA compared with the control, 0.001 μ*M*, and 0.01 μ*M* doses. The 0.01 μ*M* dose had a greater ($P < 0.05$) concentration of AMPKα protein than the 10 μ*M* and 100 μ*M* doses. These results indicated sodium benzoate could induce MHC type I expression in cultured BSC.

Key Words: benzoate, myosin, satellite cells

1277 (W164) Surgical castration and immunocastration improve cuts yield of high market value from animals crossbred Aberdeen Angus x Nellore. A. D. Moreira[1], F. D. Resende[2], G. R. Siqueira[3], J. M. B. Benatti[1], M. H. Moretti[4], J. A. Alves Neto[1], B. S. Lima[1], J. F. Lage[*1], G. Z. Miguel[5], P. H. Gonçalves[6], and F. D. Santos[6], *[1]Universidade Estadual Paulista, Jaboticabal, Brazil, [2]Agência Paulista de Tecnologia dos Agronegócios, Colina, Brazil, [3]APTA-Polo Regional Alta Mogiana, Colina, Brazil, [4]UNESP-FCAV, Jaboticabal, Brazil, [5]Universidade do Estado de Mato Grosso, Pontes e Lacerda, Brazil, [6]Centro Universitário da Fundação Educacional de Barretos, Brazil.*

This trial aimed to evaluate the effect of castration methods (surgical or immunological) on percentage of main cuts from hindquarter of beef cattle raised in pasture. Thirty animals 1/2 Angus × 1/2 Nellore with 233.0 ± 38.2 kg of initial BW and 8 mo of age were fed in pasture of *Brachiaria brizantha* cv. Marandu receiving 3 g/kg BW/day of proteic-energetic supplement (25% crude protein and 60% of total digestible nutrients). Animals were supplemented for 356 d (20 d for adaptation and 336 d of experimental period (July 21, 2011, to July 11, 2012). The treatments comprised 10 replicates: non-castrated animals (NC); surgical castrated (SC) and immuno-castrated (IC). The surgical castration was realized on last day of adaptation period and the immunocastration was realized with Bopriva (anti-GnRH) being applied on the first day, 84 and 237 d after beginning of the experiment. The animals were slaughtered and all carcasses were chilled at 0°C for 24 h. After slaughter were recorded the carcass weight (CW; hot and cold) and carcass shrink loss (CSL). Cuts from left carcass (Rib Eye, Striploin Back Chain, Rump Heart, RumpCap e Tenderloin Chain) were removed and weighed. These cuts are considered of high market value in Brazil. Data were analyzed (randomly design) by the PROC MIXED of SAS and the Fisher test used considering 10% probability. Animals NC had greater final hot CW (281.8 kg; $P < 0.001$) and cold CW (278.3 kg; $P < 0.001$) than those animals SC and IC. However, the castration methods did not affect the hot and cold DP ($P > 0.10$). Animals NC had higher CSL (1.26%; $P = 0.024$) than those animals SC (0.76%) and IC (0.87%). Animals castrated showed greater hindquarter yield (47.8%; $P = 0.003$) than animals NC (46.3%). The total weight (sum of all cuts evaluated) in relation the total weight of hindquarter was not affect by castration methods ($P > 0.10$). However, when these sum of all cuts were realized in relation to cold CW had greater percentage these cuts of hindquarter from both animals castrated than animals NC ($P = 0.049$). A greater commercial cuts yield from hindquarter in the carcass is profitable in a beef cattle market. The castration methods evaluated in the animals produces carcass with greater commercial cuts yield from hindquarter in relation to cold carcass weight.

Key Words: anti-GnRH, commercial cuts, yield carcass

MILK PROTEIN AND ENZYMES

1278 (T167) Separation and quantification of major milk proteins in different species by reversed phase high performance liquid chromatography. L. Ma, D. P. Bu*, J. Q. Wang, and J. T. Chen, *State Key Laboratory of Animal Nutrition, Institute of Animal Science, Chinese Academy of Agricultural Sciences, Beijing, China.*

To detect milk proteins, reversed phase high performance liquid chromatography (RP-HPLC) (Waters 2695 Series chromatograph, USA) was successfully performed to separate and quantify the major proteins from cow (n = 20), goat (n = 20), buffalo (n = 20) and yak (n = 20) milk which were collected around the fourth month of lactation for each species from February to April 2013 within 30 min. Descriptive statistics and Duncan's multiple comparison of protein contents were obtained by SAS 9.1 via GLM model (SAS Institute Inc., Cary, NC). Main protein data sets were analyzed by PCA using the Unscrambler 9.8 (CAMO software AS, Oslo, Norway). Results showed that the contents (g/L) of milk total protein were significantly different in milk from yak (62.87), buffalo (56.09), goat (42.83), and cow (37.35), respectively. Average content of major protein fractions obtained were all converted by purity of individual protein standard (Sigma-Aldrich, St. Louis, MO) to assess the real individual protein content. Composition (g/L) of yak milk contained the highest κ-CN content (9.80), and this was significantly higher than in buffalo, cow, and goat milk (7.35, 6.24 and 5.56). Content (g/L) of α-CN in yak milk (16.14) was significantly higher than those for buffalo, cow, and goat milk (11.53, 11.81, and 9.48). The β-CN content (g/L) was similar in yak and buffalo milk (23.34, 22.68), but higher than in goat and cow milk (20.53, 13.31). The β-LgB quantification (g/L) in goat and buffalo milk was similar (3.69, 3.88), significantly lower than in yak milk (9.46), but higher than in cow milk (1.19). The α-La content (g/L) was highest in buffalo milk (7.96), while significantly lower in cow, goat, and yak milk (1.45, 1.28 and 1.47). Cow milk contained highest content (g/L) of β-LgA (2.15), and this was significantly higher than that in buffalo, yak, and goat milk (0.13, 0.12 and 0.14). And different chromatographic profiles were obtained for them. The data of milk protein can be differentiated according to animal species by principal component analysis (PCA). It was concluded that major milk proteins from different animals had special profiles.

Key Words: milk protein, reversed phase high performance liquid chromatography, species

1279 (T168) Size distribution of casein micelles in milk from dairy cows with different crossbreding levels of Holstein-Zebu cattle. D. R. Freitas[1], M. M. Santoro[1], F. N. Souza[1], C. V. Ladeira[1], M. O. Leite[2], C. F. A. M. Penna[2], S. A. Diniz[1], M. X. Silva[1], J. P. Haddad[1], L. M. Fonseca[1], and M. P. Cerqueira[*2], *[1]Universidade Federal de Minas Gerais, Belo Horizonte, Brazil, [2]Universidade Federal de Minas Gerais (School of Veterinary Medicine), Belo Horizonte, Brazil.*

Over the years, there has been an increasing interest in milk casein, because of their industrial importance. Casein micelle structure is crucial for gel formation in cheese and yogurt, and it is correlated with milk stability after of heating, freezing or drying. The present study evaluated the casein micelles mean size distribution in raw milk from crossbred Holstein-Zebu dairy cows, as follows: 1/2 Holstein-Zebu (n = 41); 9/16 Holstein-Zebu (n = 21); 5/8 Holstein-Zebu (n = 31); 3/4 Holstein-Zebu (n = 29); 7/8 Holstein-Zebu (n = 51); and 15/16 Holstein-Zebu (n = 27). The milk composition (protein, lactose, fat, nonfat and total solid contents), somatic cell count score, age, d in milk, and milk production were also recorded. Size of casein micelles was determined by Photon Correlation Spectroscopy (PCS) after milk fat removal by centrifugation. The mean size of the casein micelles was 170.22 + 21.18 nm (121.8– 235.6 nm). The logistic regression analysis was adjusted ($P < 0.20$) for days in milk, crossbreeding levels of Holstein-Zebu cattle, age, milk production, somatic cell count score, urea levels, fat, protein, lactose, and nonfat milk solids. The final model of the logistic regression analysis ($P < 0.05$) showed that the mean size of the casein micelles was associated with the crossbreeding levels of Holstein-Zebu cattle (odds ratio: 0.27; $P = 0.001$), somatic cell count score (odds ratio: -1.40; $P = 0.001$) and nonfat contents (odds ratio: −6.55; $P = 0.033$). To the best of our knowledge, this is the first study that access the effect of the crossbreeding levels of Holstein-Zebu on the mean diameter of casein micelles. This fact has important implications to production of milk-based products, and thus economic output of the dairy industry.

Key Words: casein, milk quality, raw milk

1280 (T169) Comparative analysis of immunoglobulin and lactoferrin in bovine milk from different species. J. T. Chen[1,2], L. Ma[1], J. Q. Wang[1], Y. X. Yang[1], and D. P. Bu[*1], *[1]State Key Laboratory of Animal Nutrition, Institute of Animal Science, Chinese Academy of Agricultural Sciences, Beijing, China, [2]College of Animal Science and Technology, Gansu Agricultural University, Lanzhou, China.*

Immune active components in milk play an important role in the host defence. Bovine milk from different speices has its own character. The objective of the current study was to char-

acterize the concentrations of immunoglobulins (IgA, IgG, IgM) and lactoferrin in bovine milk samples of different species. Sandwich enzyme-linked immunosorbent assay (ELISA) was performed according to the manufacturers instructions to quantify the immunoglobulins and lactoferrin (Lf) contents in yak milk (n = 20), buffalo milk (n = 20) and Holstein cow milk (n = 20) samples, and correlation analysis was completed. The results showed that immunoglobulins and lactoferrin in yak milk, buffalo milk, and Holstein cow milk samples had linear relationsship between concentration and absorbance values, and the standard curve equation R was greater than 0.99. There were significant differences of IgA, IgG, IgM and Lf in different milk samples ($P < 0.05$). The contents of IgA, IgG, IgM and Lf in different species bovine milk samples showed remarkable individual differences. IgA and IgG concentrations in yak milk were significant higher than in the other two kinds of milk. While IgM and Lf in Holstein cow milk were higher than others. In addtion to negative correlation between IgA and IgM existed only in Holstein cow milk samples, the trends of IgA, IgG, IgM and Lf in the same kinds of bovine milk all showed a positive correlation. The results indicated that the content of immunoglobulins and lactoferrin in different species milk samples were influenced by genetic factors and had distinctive characteristics. According to the correlation of immunoglobulins and lactoferrin, forecasting the content of immunoglobulins and lactoferrin within species may be possible.

Key Words: bovine milk, immunoglobulin, lactoferrin

1281 (T170) Effect of thermal conditions on the concentration of biological active whey protein in cow milk.

J. T. Chen[1,2], L. Ma[1], D. P. Bu[1], Y. X. Yang[1], and J. Q. Wang[*1], *[1]State Key Laboratory of Animal Nutrition, Institute of Animal Science, Chinese Academy of Agricultural Sciences, Beijing, China, [2]College of Animal Science and Technology, Gansu Agricultural University, Lanzhou, China.*

Biological active whey protein in cow milk play an important role in the health of human, which is sensitive to thermal conditions during dairy processing. The objective of the present study was to investigate the variation of mainly immune active proteins concentration in cow milk, which was heated by reference commercial pasteurized milk processing technical specification of China dairy industry standards. The contents of the immunoglobulins (IgG, IgM, IgA), lactoferrin (Lf) and bovine serum albumin (BSA) were determined after different thermal processing by Sandwich enzyme-linked immunosorbent assay (ELISA), respectively. The results showed that pre-heat treatment and homogenizing had relatively mild effects on immune active protein concentration. From 75 to 115°C with holding times for 15 sec, immune active proteins contents were decreased significantly. The concentration of immune active proteins remained fairly constant and lightly decreased over time when heating temperature maintained at 85°C. Immune active proteins contents were extremely low and the diversity among different treatments was small at heating temperatures ranging from 125 to 145°C for 4s. When heated at 138°C for 4s, 6s and 8s, concentrations of immune active proteins had shown no significant difference. When milk heated at UHT and superheated conditions, treatment of raw milk at 140°C for 4s had a relatively higher content. These finding indicated that the appropriate condition of pasteurization heating at 75°C for 15s, and treatment at 140°C for 4s are fit for UHT processing. Moreover, there is no need for superheated which has no benefit for dairy nutritional properties.

Key Words: cow milk, biological active whey protein, heat-stability

---

1282 (T171) Effect of extraction methods on the 2-DE map of whey proteome in cow milk.

J. T. Chen[1,2], L. Ma[2], D. P. Bu[2], Y. X. Yang[2], and J. Q. Wang[*1,2], *[1]Heilongjiang Bayi Agricultural University, Daqing, China, [2]State Key Laboratory of Animal Nutrition, Institute of Animal Science, Chinese Academy of Agricultural Sciences, Beijing, China.*

For all proteomic approaches, protein extraction and sample preparation are the most critical steps for optimal results. However, protein isolation is often complicated. The objective of this study was to investigate the effect of extraction methods on two-dimensional electrophoresis (2-DE) maps of whey proteome in cow milk and explore an optimal eatraction method. Samples were extracted from cow milk by different isoelectric precipitations and ultracentrifugation methods. SDS-PAGE and 2-DE maps were analysised by QuantityOne v4.62 and PDQuest 8.0 software, respectively. The results of 2-DE maps showed that milk whey protein could be effectively extracted by the methods above with less background, no significant strips and good repeatability. However, there were still some residual caseins appearing in each map. 2-DE maps of whey protein refined by isoelectric precipitations were relatively informative compared with the gel maps obtained by ultracentrifugation. Moreover, the richness of different whey proteins in various maps extracted by the method adjusting pH to 4.6 as isoelectric point is slightly higher than adjusting pH to 4.8. The results indicated that adjusting pH to 4.6 as isoelectric point to extract whey protein has some advantages than the other two methods. However, all the methods used in this research could effectively remove high abundant casein to improve the detection sensitivity of low abundance proteins, which could provide some useful information for the futher research on whey protein proteomic of cow milk.

Key Words: whey protein, extraction methods, two-dimensional electrophoresis maps

1283 (T172) Effect of metabolic acidosis in lactating dairy cows on concentration of milk proteins.

C. M. de Magalhães Rodrigues Martins, K. C. Welter, M. A. Arcari, C. A. Fernandes de Oliveira, J. L. Golçalves, V. L. Schvartzaid, A. Saran Neto*, and M. Veiga dos Santos, *University of São Paulo, Pirassununga, Brazil.*

Milk casein subunits (α, β and κ-casein) play a role to avoid the formation of toxic amyloid fibrils and maintain the milk thermal stability. When milk is produced by healthy cows fibrils are not formed because an alternative aggregation pathway is followed that results in formation of the casein micelle. However, nutritional disorders of lactating cows may negatively influence on composition and quality of milk. Thus, the present study aimed to evaluate the effect of the dietary cation-anion difference on concentrations of milk subunits of casein and whey proteins. Sixteen Holstein cows were distributed in four contemporary 4 × 4 Latin square, consisting of four periods of 21 d. Cows were distributed to four treatments according to the dietary cation-anion difference (DCAD): 1) +290 mEq/kg of DM; 2) +192 mEq/kg of DM; 3) +98 mEq/kg of DM; 4) −71 mEq/kg of DM. The cows were fed total mixed ration and the DCAD was calculated according to the contents of Na, K, Cl, and S of the diets. Individual milk samples were collected for determination of the concentrations of α (α-CN), β (β-CN) and κ-casein (κ-CN), α-lactalbumin (α-La) and β-lactoglobulin (β-Lg), by high performance liquid chromatography. The results were analyzed using the PROC MIXED of SAS (2001) (α = 0.05). The DCAD reduced linearly the concentration of κ-CN [κ-CN = 5.02(0.30)–0.00098(0.0004)*DCAD] as well as increased the concentration of β-LG [β-LG = 1.41(0.16) + 0.00047(0.0002)*DCAD] (Table 1283). The κ-CN and β-LG have a potential tendency to assemble into toxic amyloid fibrils. Thus, as a consequence of metabolic acidosis due to reduction of DCAD, β-LG may be associated with the κ-CN in the micelle and the milk stability during the heat treatment may be reduced.

Key Words: casein, DCAD, milk stability

Table 1283. Effect of dietary cation-anion difference (DCAD) on the milk proteins concentration (mg/ml of milk)

Milk proteins	DCAD (mEq/Kg of DM)					*P*

1284 (T173) Process optimization for production of whey protein hydrolysate from cheese whey having antioxidant property.

S. Athira*, B. Mann, R. Sharma, and R. Bajaj, *National Dairy Research Institute, Karnal, India.*

Oxidative stress, the increased production of reactive oxygen species and reactive nitrogen species combined with overtaking endogenous antioxidant defense mechanisms, is a significant causative factor for the initiation or progression of several life style mediated diseases. Dietary consumption of antioxidants appears to benefit endogenous antioxidant defense strategies in the fight against oxidative stress. Cheese whey is a rich by-product in nutritional terms: possessing high biological value components, excellent functional properties, and an inert flavour profile. In particular, biological activities of whey proteins and their hydrolysates have received more attention in recent years. Peptides generated from whey protein hydrolysis have antioxidant properties and it depends on the protease specificity as well as hydrolysis conditions. Currently, data on the hydrolysis conditions for the direct production of hydrolysate from whey is lacking. So in the present study, mozzarella cheese whey was ultrafiltrated to concentrate the protein content and the retentate after preheat treatment was hydrolyzed using commercial food grade enzyme alcalase. Response Surface Methodology (RSM) was applied to optimize the hydrolysis conditions, including incubation time, hydrolysis temperature and pH with the purpose of obtaining the most powerful antioxidant hydrolyzate from whey proteins. A central composite circumscribed (CCC) design was employed to study the effect of the experimental variables on the antioxidant activity determined by 2, 2'-azinobis (3-ethylenebenzothiazoline-6-sulphonic acid) ($ABTS^{\cdot+}$) radical scavenging activity and the parameters of the model were estimated by multiple linear regression. The highest antioxidant activity (1.18 ± 0.015μM of trolox/mg of protein) was found in retentate hydrolyzed for 8 h at pH 9 and temperature 55°C. Seven β-lactoglobulin derived peptides were identified by RP-HPLC-MS/MS in this hydrolyzate. Amino acid composition of the peptides DTDYK f(96–100) and VLDTDYK f(94–100) indicating their important contribution on antioxidant property of whey protein hydrolysate (WPH) was evaluated. Hydrolysis of ultrafiltrated retentate of whey can be an energy and cost effective method for the direct production of WPH from whey compared to the industrial production of WPH from Whey protein concentrate. This study suggests that WPH with good nutritional and biological properties can be effectively used in health promoting foods as a biofunctional ingredient.

Key Words: whey protein hydrolysate, antioxidant property, bioactive peptides

1285 (T174) The effect of heat and extraction technique on β-lactoglobulin hydrolysis. C. Kembel[*1], and R. Jimenez-Flores[2], *[1]California Polytechnic State University, San Luis Obispo, [2]Dairy Products Technology Center, California Polytechnic State University, San Luis Obispo.*

Whey proteins are an abundant source of biologically active peptides that have a diverse set of properties. One limitation in the production of novel peptides is the native folding of the proteins secondary and tertiary structure. β-Lactoglobulin is a barreled protein with a hydrophobic core capable of binding other proteins and fatty acids. Due to its prevalence in whey, it represents an important source of bioactive peptides. Presenting a method for the production of novel peptides by native whey protein change in conformation will bring value added products to market. Previous studies have shown the resistance of isolated, native, β-lactoglobulin to trypsin hydrolysis in protein-lipid emulsions. However incorporation of washed cream (40% fat) into this system (natural emulsion from cream) significantly changes the hydrolysis patterns of β-lactoglobulin. The hydrolysis patterns of β-lactoglobulin was evaluated using electrospray ionization mass spectrometry (ESI-MS) after three heat treatments (none, 50°C– 20 min, and 70°C–20 minutes) and four extraction methods (none, supercritical carbon dioxide, hexane, and Folch). Although hydrolysis was improved compared to native β-lactoglobulin, the degree of hydrolysis did not exceed 42% in any of the treatments. Substitution of purified native β-lactoglobulin with whey protein isolate (WPI) in the 40% cream solution significantly increased the number and type of β-lactoglobulin peptides released when subjected to various heat treatments and fat extraction methods. The degree of hydrolysis reached a maximum 64% and there appeared to be sequential, predictable peptide release depending on the heat treatment and extraction technique used. The heat treatment and extraction method change the absorption and spreading process of β-lactoglobulin within and along the MFGM and thus, effecting which peptides are available and released by the enzymatic action.

Key Words: β-lactoglobulin, peptides, mass spectrometry

1286 (T175) Evaluation of the viscosity profile during simulated conditions of thermal processing. A. Souza[1], L. C. Junior[2], R. Stephani[1], M. Pinto[3], A. Carvalho[*3], Perrone[3], and R. Costa[2], *[1]Gemacom Tech, Juiz de Fora, Brazil, [2]EPAMIG, Juiz de Fora, Brazil, [3]Federal University of Viçosa, Brazil.*

The understanding about milk protein interactions provides better cost/benefit ratio to food industry by using each type of protein within the desired characteristics in final product. Denaturation and interaction of different proteins occur in different way and intensity when pH value varies accordingly to the medium in which they are located. This study aimed to verify the influence of whey protein/casein interaction in the evolution of viscosity at different pH (6.0, 6.5 and 7.0) values using the Rapid Viscosity Analyzer (RVA) (model 45000, Perten Instruments, Sweden) as thermal processing simulator. Samples of commercial whey protein concentrate (WPC) and milk protein concentrate (MPC) were analyzed. Thermal denaturation and level of protein interaction were measured by RVA. Further, fat, protein, ash, lactose, pH, protein concentration and moisture were performed according to procedures described by the Association of Analytical Communities (AOAC, 2005). The solid-liquid concentration of the dispersion measured in the RVA was 0.3 gg^{-1} dry weight in water. Viscosity was as low as possible in low pH and high MPC/WPC level. At pH 7.0 and 100% whey protein concentrate results in higher final viscosity. At pH 6.0 and 100% milk protein concentrate results in lower final viscosity. High viscosity can be related with favoured κ-CN-whey protein complex formation at high pGH (Anema, 2008). Further, increased viscosity in treatments with high proportion of WPC can be explained by the difference in size of aggregates formed between whey proteins and/or κ-CN-whey proteins and by the higher degree of denaturation at higher pH values. References: (1) Anema, S.G. On heating milk κ-casein from the casein micelles can precede interactions with the denatured whey proteins. Key Words: protein denaturation, pH, RVA

1287 (T176) Viscosity measurement of solutions composed by whey protein using a rapid viscosity analyser (RVA). M. Alves[1], M. Martins, P. H. Junior, R. Moreira, G. Mendes, M. Pinto, Perrone, and A. Carvalho[*], *Federal University of Viçosa, Brazil.*

The evaluation of the viscosity performance of protein solutions used as ingredients in food is essential for this application in the food production. The Rapid ViscoAnalyzer (RVA) is a rotational viscometer capable of continuously measuring the viscosity of a sample under controlled temperature conditions (Booth & Bason, 2007). Using a RVA, the current study aimed to evaluate the viscosity of solutions prepared from whey protein concentrates (WPCs) produced from milk whey samples initially subjected to thermal treatment 72°C for 15 s (*P*T72) or microfiltration (0.8 μm- MF0.8 or 1.4 μm- MF1.4). Each treatment was ultrafiltered and subjected to vacuum evaporation using a rotary evaporator and dried in a spray dryer. The resulting WPCs were evaluated for their content of fat, total solids, moisture, ashes, and total protein. Furthermore, water activity (Aw) of each WPC was measured. The solutions prepared from the WPCs were also evaluated for their viscosity. Data analysis was performed using Statistical Analysis System v9.2 software (SAS Institute Inc., 2006). The WPCs presented

composition compatible with the international standards, with a significant difference ($P < 0.05$) for fat concentration. Viscographic profiles indicated that WPCs produced from microfiltered whey had higher viscosities than those subjected to heat treatment. In addition, 10 min was determined to be the optimal length of time for heat treatment to maximise WPCs viscosity. The WPC solutions obtained from pasteurized whey showed lower viscosities than solutions obtained from microfiltration whey. This result demonstrates the importance of technological choices on the behavior of the WPC and further, WPC can be design for different food applications. Finally, a rapid viscosity analyzer was demonstrated to be an appropriate tool to study the application of whey proteins in food systems.

Key Words: milk protein, microfiltration, RVA

NONRUMINANT NUTRITION: AMINO ACID, MINERAL AND ENERGY NUTRITION IN MONOGASTRICS

1288 (M162) Calcium level and dEB affect the protein and mineral digestibility of lactating sows.
R. Davin[*1], S. A. Guzmán-Pino[1], D. Solà-Oriol[2], E. G. Manzanilla[1], and J. F. Pérez[1], [1]*Animal Nutrition and Welfare Service, Dep. of Animal and Food Sciences, Universitat Autònoma de Barcelona, Bellaterra, Spain,* [2]*Animal Nutrition and Welfare Service, Dep. of Animal and Food Sciences, Universitat Autònoma de Barcelona, Bellaterra, Spain.*

Limestone ($CaCO_3$) and sodium bicarbonate are included in pig diets to supply Ca and increase dietary electrolyte balance (dEB = Na + K– Cl, in mEq/kg diet), respectively. However, both ingredients increase the diet acid-binding capacity and may interfere with the phytate-protein and phytate-Zn complex in the digestive tract. The aim of this study was to assess if diets differing in Ca level and dEB may affect the whole-tract apparent digestibility in lactating sows fed on a typical European sow diet (25.0% corn, 20.0% barley, 20.0% wheat, 18.3% soy meal, 10.0% wheat bran, 2% rapeseed meal) containing a high phytic acid level (2.9 g phytic P/kg), and supplemented with an overdose of phytase (1260 FTU/kg). A total of 48 lactating sows (14 d of lactation) were distributed according to their parity number and number of piglets into six experimental diets (2 × 3 factorial) differing in the Ca level: 6 or 9 g/kg (lowCa or highCa, respectively), and dEB: 40, 176 or 235 mEq/kg (lEB, mEB or hEB, respectively). Calcium chloride (10 g/kg) was added to lEB diets. The rest of Ca was provided as $CaCO_3$. Sodium bicarbonate was added (5 g/kg) to hEB diets. Titanium dioxide (3 g/kg) was used as indigestible marker. Diets were offered ad libitum for 7 d. Two fecal samples were obtained in two different times on d 21 of lactation for each sow and then pooled. Blood samples from sows fed highCa diets were individually collected on Day 21 to measure acid-base status of the sows. Sows fed highCa diets showed higher ($P < 0.05$) digestibility of CP (87.4%), Ca (21.4%), P (45.2%), and Zn (20.9%) than sows fed lowCa diets (85.8, 14.3, 40.8 and 7.04%, respectively). The use of sodium bicarbonate in lowCa diets (hEB) decreased ($P < 0.05$) DM digestibility as compared to the lowCa-mEB and the three highCa diets. The lBE diet reduced blood pH, bicarbonate and base excess values as compared with mBE and hBE ($P < 0.05$). In conclusion, the results showed that low Ca diets and sodium bicarbonate may reduce nutrient whole-tract digestibility in lactating sows fed on high phytic acid diets, even when phytase was overdosed.

Key Words: calcium, dietary electrolyte balance, digestibility

1289 (M163) Early dietary amino acid restrictions and flaxseed oil supplementation on the leanness of pigs and quality of pork: growth performance, serum metabolites, and carcass traits.
C. K. Adhikari[*1], L. I. Chiba[1], S. D. Brotzge[1], M. D. S. Vieira[2], S. P. Rodning[1], W. G. Bergen[1], C. L. Bratcher[1], and E. G. Welles[1], [1]*Auburn University, Auburn, AL,* [2]*Federal University of Rio Grande do Sul, Porto Alegre, Brazil.*

A total of 64 pigs were used to assess the effect of early dietary AA restrictions [100 or 80% of the 2012 NRC standardized ileal digestible (SID) Lys requirements during the grower (G) and finisher (F)-1 phases] and lipids (0 or 3% flaxseed oil + 2% poultry fat) on G-F pig. Each phase was based on weight, and at 24.7 ± 0.5 kg, pigs were assigned to 4 G diets with 4 gilt pens and 4 barrow pens/diet, and switched to F-1 diets when they reached 51.2 ± 0.3 kg. Pigs were switched to common F-2 diets at 80.0 ± 0.4 kg, and pigs fed 0 or 5% lipids earlier were continued to receive 0 or 5% lipids until harvest at 110.5 ± 0.5 kg. There were no interactions between dietary AA restrictions and lipids. Pigs fed the AA restricted diets consumed less SID Lys and DE ($P < 0.015$) and had depressed ADG compared with unrestricted pigs during the G phase, but they grew faster ($P = 0.042$) and utilized feed ($P = 0.064$) and SID Lys ($P < 0.001$) more efficiently during the F-1 phase. Dietary AA restrictions had no effect on overall ADG or carcass traits. Overall efficiency of feed, SID Lys, and DE utilization for BW gain ($P < 0.004$) and SID Lys utilization for fat-free lean gain (FFLG; $P < 0.001$) was improved by dietary AA restrictions. Dietary AA restrictions reduced serum urea N ($P < 0.025$) at the end of the G and F-1 phases and increased glucose ($P = 0.027$) at the end of the G-phase, but had no clear effect on triglycerides (TG) and other metabolites. Dietary lipids reduced ADFI ($P < 0.064$) during the G and F-2 phases, improved G:F ($P < 0.047$) during all phases and overall, and improved ADG during the G ($P = 0.003$) and F-1 ($P = 0.066$) phases. Belly firmness was reduced ($P < 0.001$), but dietary lipids had no effect on other carcass traits. Dietary lipids increased TG ($P < 0.075$) at the end of the G and F-1 phases, but reduced urea-N ($P = 0.037$) at the end of the F-2 phase. In conclusion, pigs subjected to early dietary AA restrictions improved overall efficiency of AA and DE utilization for BW gain and FFLG. As expected, dietary lipids improved G:F but reduced belly firmness.

Key Words: early amino acid restrictions, flaxseed oil, pigs

1290 (M164) Effects of supplementation with a commercial source of selenium in a laying hens feeding system. L. Betancourt*, *Universidad de La Salle, Bogotá, Colombia.*

Selenium enriched eggs are included as functional food in the market, because the role of selenium in human health and diseases has been recognized. The objective of this study was to enrich eggs with selenium from an organic source of selenium (seleno-yeast) on production parameters, egg quality and Leukocyte differential counts. Six hundred thirty laying hens of the Babcock line were used, between 27 and 65 wk of age. Hens were kept in cage and randomly distributed into two treatments with five replicated. The control treatment (T0) based on commercial feed without addition of seleno-yeast, and T1 treatment, based on commercial feed plus 450 ppm of seleno-yeast (1000 ppm selenium Kg-1). The eggs were lyophilized and selenium was measured through a plasma spectrophotometer ICAP 6300. The egg production and classification was recorded weekly, laying percentage and the feed conversion ratio were calculated. Egg tasting and conceptual evaluations were done. The egg selenium content was higher ($P < 0.05$) for T1 group with 1.376 mg kg-1 of lyophilized egg compared with T0 with 0.173 mg kg-1of lyophilized egg. The addition of selenium did not significantly affect the egg production. The egg production percentage was 94.6 ± 3.88 and 95.2 ± 5.15; and the feed conversion ratios were 1.49 ± 0.061 and 1.48 ± 0.082 for T0 and T1, respectively. Therefore, leukocyte differential counts were not affected. The heterophile: lymphocyte ratios were 1.22 ± 0.31 and 1.58 ± 0.45 to T0 and T1 treatments, respectively. Egg organoleptic characteristics such as taste, color and texture, did not presented differences. This study confirmed that it is possible to enrich the content of selenium in eggs under an egg commercial production system without affecting the growth performance and the organoleptic characteristics. The cost of feed with selenio-yeast inclusion did not exceed the 1%, thus producing selenium enriched eggs is technically feasible to improve consumer health and competitiveness of the poultry industry.

Key Words: antioxidant, egg, glutathione

1291 (M165) Correlating molecular spectroscopy and chemometrics to explore carbohydrate utilization of co-products from bio-fuel and bio-brewing processing. L. Chen[1,2], X. Zhang[1], X. Huang[*2], and P. Yu[2], *[1]Dep. of Animal Science, Tianjin Agricultural University, China, [2]Dep. of Animal and Poultry Science, University of Saskatchewan, Saskatoon, Canada.*

Co-products from bioethanol and brewing industry are excellent resources of protein and energy. Conventional studies often focus on traditional "wet" nutritional profiles. To date, there is little research on the relationship between carbohydrate molecular structural and nutritional values of the co-products. In this study, five kinds of corn DDGS and two kinds of barley DDGS with different batches were collected from different manufacturers in the north of China. The objectives of this project were to investigate the correlation between carbohydrate molecular structure and nutritional values, in terms of the carbohydrate chemical profile, true digestible nutrient, energy values, and digestion. The result showed that acid detergent fiber content in corn DDGS and barley DDGS had negative correlation ($P < 0.05$) with structural carbohydrate peak area, cellulose compounds, and carbohydrate component peaks. The correlation between carbohydrate peak area and true digestible neutral detergent fiber (tdNDF) were negative ($P < 0.05$). Spectral peak area of cellulose compounds, carbohydrate peak area had negative correlations ($P < 0.05$) with the dry matter content. There were no correlation between carbohydrate spectral intensities and energy values, carbohydrate sub-fractions partitioned and digestion. The results indicate that carbohydrate spectral profiles are highly associated with carbohydrate utilization in co-products from bio-fuel and bio-brewing processing.

Key Words: carbohydrate nutritional values, molecular spectral features, carbohydrate molecular structure

1292 (M166) Phosphorus utilisation and sodium-dependent phosphate co-transporters gene expression in growing pigs fed low available phosphorus diets. B. B. Pokharel[*1], C. M. Nyachoti[2], and W. K. Kim[3], *[1]Dep. of Animal Science, University of Manitoba, Winnipeg, Canada, [2]University of Manitoba, Winnipeg, Canada, [3]University of Georgia, Athens.*

Type II sodium-dependent phosphate co-transporters (NaPi) encoded by the SLC34A gene family are involved in renal and intestinal phosphate (Pi) absorption to maintain plasma Pi content. However, the effects of reduced dietary phosphorus (P) content on the expression of these genes and P utilisation in growing pigs are poorly defined. Thus, an experiment was conducted with 54 growing pigs (19.5 ± 1.11 kg BW) to examine the effects of reduced dietary available phosphorus (aP) content on P utilisation and NaPi gene expression. Pigs housed in groups of three per pen were randomly allotted to three experimental diets containing 0.23 (control), 0.17, and 0.11% aP to give six observations per diet and had ad libitum access to feed and water. All diets contained 0.3% TiO_2 as an indigestible marker. After each wk, one pig per pen was housed in a metabolic crate for 24 h to collect fecal and urine sample and then sacrificed to obtain jejunal and kidney sample. Fecal and urine sample were subsampled and analysed for P content. Expression of NaPi co-transporter genes (NaPi-IIb in jejunum, NaPi-IIa and NaPi-IIc in kidney) was analysed using quantitative real-time polymerase chain reaction (qRT-PCR). The expression of the NaPi-IIb gene in the jejunum was enhanced up to 250% ($P < 0.01$) in first wk of

pigs fed diet with 0.11% level of aP compared to the other dietary treatments. During wk 1, 2, and 3, the digestibility of P was lower ($P < 0.05$) in pigs fed diet with 0.11% level of aP (28.23, 27.14 and 23.33%, respectively) compared to control (39.07, 37.71 and 41.51%, respectively). Expression of NaPi-IIa and NaPi-IIc gene in kidney was enhanced ($P < 0.05$) by up to 160 and 180%, respectively, in wk 2 in pigs fed 0.11% aP diet. Urinary P was lower ($P < 0.05$) in pigs fed 0.11% aP diet (26.03 mg/L) compared to control (85.3 mg/L) in wk 3. In conclusion, dietary P content affected NaPi gene expression and P utilisation. Enhanced expression of NaPi-IIb in jejunum was seen in earlier period of reduced aP diets followed by higher expression of NaPi-IIa and NaPi-IIc in kidney later on. NaPi-IIb was not directly associated with the jejunal P uptake suggesting either post-transcriptional regulation or very low amount of aP for intestine to be able to pick up.

Key Words: sodium-dependent phosphate co-tranporters, pigs, available phosphorus

---

1293 (M167) The impact of an inflammatory challenge and dietary omega-6 to omega-3 fatty acid ratios on protein deposition in nursery pigs. L. Eastwood* and D. Beaulieu, *Prairie Swine Centre, Inc., Saskatoon, SK, Canada.*

The objective of this experiment was to determine if decreasing the dietary omega (ω)-6 to ω-3 fatty acid ratio would affect protein deposition in nursery pigs during a prolonged *E. coli* lipopolysaccharide (LPS) inflammatory challenge. Twenty-four barrows were assigned to one of four treatment groups at 21 d of age (d 0). Treatments, arranged as a 2 × 2 factorial, were diets (10:1 and 5:1 ω-6:ω-3 plant based FA ratios) and challenge (LPS injection, *ad lib* intake; or saline injection, pair fed to match LPS injection intake levels). On d 15 and 18, pigs were injected with 15 µg/kg BW LPS in saline or saline alone. On d 21, 1.5 h post-feeding, pigs were given a flooding dose of ^2H_2O and at 2.5 h post-feeding received another LPS or saline injection. Following the final injection, pigs were slaughtered (5.5 h post-feeding). Liver, semi-tendinosus muscle and blood samples were collected, and the remaining carcass was ground and analyzed for N and DM. Whole carcass protein deposition was determined relative to an initial slaughter group of pigs. Liver, muscle and blood samples were analyzed for ^2H_2O enrichment to determine the fractional rate of protein synthesis (FSR) during final day of the LPS challenge. ADFI (d 0 to 15) was unaffected by diet ($P > 0.05$); however 5:1 fed pigs tended to have higher ADG relative to the 10:1 fed pigs (28.8 vs. 25.0 ± 1.4 g/d; $P = 0.06$). Pigs consuming the 5:1 diet, regardless of challenge group, had higher whole body protein deposition rates for the 3 wk period relative to pigs consuming the 10:1 diet (87.8 g/d vs. 61.3 g/d; $P = 0.04$). Similarly, 5:1 fed pigs tended to have increased FSR in the liver on the final day of the challenge relative to those consuming the 10:1 diet (8.55% synthesized/h vs. 6.16%/h; $P = 0.08$). There was no effect of LPS challenge on carcass composition, protein deposition rate or on liver or muscle FSR measured using ^2H_2O enrichment ($P > 0.05$). Protein deposition measured over time and on the final challenge day (FSR) provided similar results. This experiment shows that altering the FA ratio in nursery pig diets can alter the efficiency by which the animal utilizes nutrients for growth, as evidenced by similar feed intakes but improved ADG and protein deposition rates.

Key Words: Swine, omega-3, protein synthesis

1294 (M168) Phosphorus digestibility in high protein canola meals, conventional canola meal, and soybean meal fed to growing pigs. C. K. Parr*, Y. Liu, C. M. Parsons, and H. H. Stein, *University of Illinois at Urbana-Champaign, Urbana.*

An experiment was conducted to determine the digestibility of Ca and P in 2 high protein canola meals (CMA; 45.69% CP and CMB; 46.97% CP) fed to growing pigs, and to compare values obtained in high protein canola meal with digestibility of Ca and P in conventional canola meal (CM-CV; 35.10% CP) and soybean meal (SBM). The Ca and P contents of CMA, CMB, and CM-CV were 0.64 and 1.26%, 0.51 and 1.16%, and 1.25 and 1.16%, respectively. Four cornstarch-based diets were formulated using each source of canola meal or SBM as the sole source of P in the diet. Four additional diets that were similar to the initial four diets with the exception that 500 FTU/kg of microbial phytase were added to each diet were also formulated. Therefore, a total of eight diets were formulated. Forty-eight barrows were divided into two periods and randomly allotted via a randomized complete block design using a 2 × 4 factorial arrangement to the eight dietary treatments based on initial BW. There were six replicate pigs per dietary treatment. Experimental diets were provided for 12 d with the initial 5 d being the adaptation period. Indigo carmine was added as an indigestible marker to the morning meals on d 6 and 11, respectively. Fecal collections started when the first marker appeared in the feces and ceased when the second marker appeared. The endogenous loss of P was assumed to be 190 mg kg^{-1} DMI. At the conclusion of the experiment, feed intake, Ca and P intake, apparent total tract digestibility (ATTD) of Ca and P, and standardized total tract digestibility (STTD) of P were calculated. Results indicate that ATTD of Ca and P and STTD of P were not different among treatments. Apparent total tract digestibility of Ca was 62, 66, 69, and 73% for CMA, CMB, CM-CV, and SBM, respectively. Standardized total tract digestibility of P was 55, 60, 49, and 66% for CMA, CMB, CM-CV, and SBM, respectively. Inclusion of phytase to the diets reduced both Ca and P outputs ($P < 0.05$). Inclusion of phytase improved ($P < 0.05$) ATTD of Ca and P and STTD of P regardless of the ingredient in the diet and there was no interaction between diet and phytase supplementation.

Key Words: canola meal, phosphorus, pig

1295 (M169) Effect of dietary net energy concentrations on the growth performance of growing gilts housed individually. G. I. Lee[1], K. S. Kim[2], J. C. Park[2], and D. Y. Kil[*1], *[1]Chung-Ang University, Anseong-si, South Korea, [2]Rural Development Administration, Cheonan-si, South Korea.*

Dietary net energy (NE) concentrations influence pig performance, but the information for their effects on young gilts has been limited. Therefore, the objective of this experiment was to determine the effect of different NE concentrations in diets on the growth performance of growing gilts. A total of 60 growing gilts (Landrace × Yorkshire; initial BW = 15.9 ± 0.55 kg) were allotted to five dietary treatments of 9.6, 10.1, 10.6, 11.1, or 11.6 MJ NE/kg with 12 replicate pens and one pig per pen in an 28-d feeding experiment. Ratios between standardized ileal digestible AA and NE concentrations in all diets were similar. The NE and AA concentrations in diets were calculated based on the values from NRC (2012). Pigs were allowed ad libitum access to feed and water. The NE concentrations of five diets used in the growth trial were also determined based on digestible nutrients, DE, and ME measured in metabolism experiments with replicated 5 × 5 Latin square design using 10 growing pigs (initial BW = 15.9 ± 0.24 kg). Results indicated that calculated NE concentrations in diets were close to measured NE concentrations (9.5, 10.1, 10.4, 11.0, and 11.4 MJ NE/kg) in diets. The final BW, ADG, and ADFI were not affected by dietary treatments. However, there was a quadratic relationship ($P = 0.01$) between feed efficiency and dietary NE concentrations (0.51, 0.50, 0.49, 0.50, and 0.52 for 9.6, 10.1, 10.6, 11.1, and 11.6 MJ NE/kg of diets, respectively). The NE intake per BW gain (MJ NE/kg of BW gain) was increased (linear and quadratic, $P < 0.01$) with increasing NE concentrations in diets. In conclusion, dietary NE concentrations affect feed efficiency and NE intake per BW gain of growing gilts.

Key Words: growing gilts, growth performance, net energy,

1296 (M170) Gluconeogenesis and substrate utilization in chicken embryos during later development determined by *in ovo* continuous infusion of [$^{13}C_6$] glucose and [$^{13}C_3$]glycerol. Q. Hu*, U. Agarwal, and B. J. Bequette, *Dep. of Animal and Avian Sciences, University of Maryland, College Park.*

We aimed to quantify the rates of gluconeogenesis (GNG) and substrate partition to the Krebs cycle in embryonic (e) day e14 and e19 chicken embryos ($n = 5$ to 6 per group). An in ovo continuous tracer infusion approach was employed to test the hypotheses that GNG and non-essential amino acid (NEAA) synthesis increase from e14 to e19. [$^{13}C_6$]Glucose or [$^{13}C_3$] glycerol was continuously infused (8 h) into the chorio-allantoic compartment on e14 and e19. Based on [$^{13}C_6$]glucose infusion, glucose entry rate, Cori cycling and GNG were higher ($P < 0.05$) in e19 than in e14 embryos, presumably to support greater deposition of glycogen in the muscle and liver in preparation for pipping and hatching. In the liver, the contribution of glucose to alanine, aspartate, and glutamate synthesis was greater ($P < 0.05$) in e14 than in e19 embryos whereas the synthesis of NEAA from glycerol was higher ($P < 0.05$) in e19 than in e14 embryos. These patterns of glucose and glycerol utilisation by the liver suggest a metabolic shift to conserve glucose for glycogen synthesis and an increased utilisation of yolk glycerol (triacylglycerides) after e14. Although the contribution of glycerol to GNG in e19 embryos was greater ($P < 0.05$) than in e14 embryos, the contribution of glycerol to GNG (1.3−6.0%) was minor. Based on [$^{13}C_6$]glucose tracer kinetics, the activities of both pyruvate carboxylase (*P*C) and pyruvate dehydrogenase (*P*DH) in the liver were higher ($P < 0.05$) on e19; however, the higher ($P < 0.05$) relative activity of PC *vs* PDH on e14 suggests a greater anaplerotic flux into the Krebs cycle of the e14 liver. In conclusion, the in ovo continuous tracer infusion approach allowed for measurement of chicken embryo whole body and liver metabolism over a shorter window of development compared to our previous approach of dosing tracer in ovo for 3 to 4 d. Lastly, this study provided quantitative estimates of the developmental shifts in substrate utilisation, GNG and NEAA synthesis by chicken embryos, as well as qualitative estimates of the activity of enzymes central to the Krebs cycle, and glucose and fatty acid metabolism.

Key Words: chicken, embryo, metabolism

1297 (M171) Plasma vitamin concentrations are altered by fat-soluble vitamin administration in suckling pigs. Y. D. Jang[*1], J. Y. Ma[1], J. S. Monegue[1], H. J. Monegue[1], R. L. Stuart[2], and M. D. Lindemann[1], *[1]University of Kentucky, Lexington, [2]Stuart Products Inc, Bedford, TX.*

Plasma concentrations of some vitamins are purported to be low in nursing piglets raised in confinement. This experiment was conducted to investigate the effect of fat-soluble vitamin administration by different administration routes on plasma concentration of those vitamins in suckling pigs. A total of 45 pigs from five litters were allotted to three treatments at birth (three pigs/treatment within each litter). Treatments were oral and i.m. injection of 400 IU of α-tocopherol, 40,000 IU of retinyl palmitate, and 40,000 IU of vitamin D_3 at d 1 of age with the control treatment that had no vitamin administration. Blood samples were collected at d 0 (initial), 1, 2, 3, 4, 6, 9, 14, and 20 post-administration. Plasma 25-hydroxycholecalciferol (25OHD_3), α-tocopherol, retinyl palmitate, and retinol concentration were analyzed. Growth performance did not differ by vitamin administration. Effects of treatment, d, and d × treatment interaction ($P < 0.01$) were observed in which plasma concentration increased immediately regardless of administration routes to peak at d 2 (4.0, 155.4, and 235.4 ng/

mL) for $25OHD_3$ and at d 1 post-administration (3.9, 14.3, and 32.3 ug/mL) for α-tocopherol for control, oral, and injection, respectively. The injection treatment had greater plasma values than the oral treatment. Plasma retinyl palmitate concentration increased only with the injection treatment and peaked at d 1 post-administration (0.13, 0.44, and 3.10 ug/mL for control, oral, and injection, respectively). Plasma α-tocopherol and retinyl palmitate concentration in the oral and injection treatments decreased from the peak plasma values to be similar with the values in the control treatment at d 9 and 3 post-administration, respectively. Plasma $25OHD_3$ concentration in the oral and injection treatments was maintained greater than that in the control treatment until d 20 post-administration. These results demonstrate that plasma status of $25OHD_3$, α-tocopherol, and retinyl palmitate are changed after administration to newborn pigs, and that the change of plasma profiles of these vitamins is different between types of vitamins administered and between administration routes. The injection administration is more efficient to enhance plasma $25OHD_3$ level until weaning than the oral administration.

Key Words: fat-soluble vitamin administration, plasma vitamin concentration, suckling pigs

---

1298 (M172) Digestibility of amino acids in distillers dried grains with solubles produced in Europe from wheat, maize, or mixtures of wheat and maize and fed to growing pigs. S. M. Curry*[1], J. K. Htoo[2], H. V. Masey O'Neill[3], and H. H. Stein[1], *[1]University of Illinois at Urbana-Champaign, Urbana, [2]Evonik Industries AG, Hanau-Wolfgang, Germany, [3]AB Vista Feed Ingredients, Marlborough, UK.*

European ethanol plants may use wheat or maize or combinations of wheat and maize as feedstock. The distillers dried grains with solubles (DDGS) produced, therefore, may vary in composition and nutritional attributes according to the grain that was used in the production. There are, however, limited data on how these differences influence the digestibility of AA in DDGS. Therefore, an experiment was conducted to compare the standardized ileal digestibility (SID) of AA by growing pigs in European DDGS produced from wheat, maize, or wheat-maize mixtures. Twelve barrows (average initial BW: 23.0 ± 2.2 kg) were equipped with a T-cannula in the distal ileum and allotted to a replicated 6 × 6 Latin square design with 6 diets and 6 periods. The five sources of European DDGS that were used included wheat DDGS from 2011, wheat DDGS from 2012, wheat-maize DDGS (80% wheat and 20% maize), maize-wheat DDGS (70% maize and 30% wheat), and maize DDGS. A diet containing each source of DDGS as the sole source of AA was formulated and a N-free diet was used to determine basal endogenous losses of CP and AA. Results indicated that the SID of CP was greater ($P < 0.05$) in maize DDGS compared with wheat DDGS from 2011, wheat DDGS from 2012, and maize-wheat DDGS. The SID of all indispensable AA except Trp was also greater ($P < 0.05$) in maize DDGS compared with all other DDGS sources. For Trp, the SID in wheat-maize DDGS, wheat DDGS from 2011 and wheat DDGS from 2012 was not different from that of maize DDGS, but greater ($P < 0.05$) than in maize-wheat DDGS. The SID of all indispensable AA except Leu in maize-wheat DDGS did not differ from the values calculated for wheat DDGS from 2011 and wheat DDGS from 2012, and no differences between SID values for AA in wheat DDGS from 2011 and wheat DDGS from 2012 were observed. In conclusion, the SID of AA in maize DDGS produced in Europe is greater than in European wheat DDGS and DDGS produced from mixtures of wheat and maize.

Key Words: amino acid digestibility, distillers dried grains with solubles, pigs

1299 (M173) The determination of the amino acid requirements of pigs in the nursery phase. E. A. Vermillion*, C. R. Dove, and M. J. Azain, *University of Georgia, Athens.*

An experiment using 202 total pigs, assigned to one of four diets was conducted to determine the essential amino acid requirements of nursery pigs. Except for lysine, diets met or exceeded 1998 NRC. Treatment 1 was slightly deficient in lysine relative to the 1998 NRC (1.40, 1.23, and 1.10% of total dietary lysine in phases I, II, and III, respectively). Treatment 2 was equivalent to the 1998 NRC recommendations (1.50, 1.33, and 1.20% of total dietary lysine in phases I, II, and III, respectively). Treatment 3 was intermediate between the 1998 recommendations and the newly revised 2012 publication (1.60, 1.43, and 1.30% of total dietary lysine in phases I, II, and III, respectively). Treatment 4 was equivalent to the 2012 NRC publication (1.70, 1.53, and 1.40% of total dietary lysine in phases I, II, and III, respectively). Crystalline amino acids (LYS, THR, MET) were used to maintain an ideal amino acid pattern (1.00, 0.62, 0.57 respectively) across treatments. Treatments were fed over three phases: Phase I, D0–7; Phase II, D7–21; and Phase III, D21–35. There were no significant differences ($P > .10$) in growth rate or feed intake, but feed efficiency improved linearly ($P < .05$) as amino acid content increased (Gain:Feed of 0.66, 0.69, 0.70, and 0.72 in treatments 1, 2, 3, and 4, respectively). Blood samples were obtained from pigs at the end of each dietary phase (d 7, 21, and 35) for determination of plasma urea concentration. There was a significant linear response to diet on d 7, 21, and 35 ($P < 0.05$), with a significant quadratic response on d 21 and 35 ($P < 0.001$). This suggests that nitrogen excretion is reduced in pigs fed higher levels of crystalline amino acids, which could potentially reduce environmental impact. In contrast to the positive linear correlation between dietary lysine levels and feed efficiency, the blood urea response indicated that the requirement for amino acids was met at 1.33% total lysine diets in Phase II, and 1.20% lysine in Phase III; these results most closely corre-

spond to the 1998 NRC guidelines. These results suggest that the decision whether to feed the higher levels of amino acids in the nursery depends on the added cost associated with those diets. Based on growth rate and feed intake, there is no evidence that the higher dietary levels are needed. However, feed efficiency and plasma urea response indicate that the higher levels may be justified.

Key Words: lysine, nursery, pigs

1300 (M174) Effect of dietary energy level and weaning weight on growth performance and digestibility in weanling piglets.

M. D. S. Vieira[1], A. M. L. Ribeiro[1], A. D. M. Kessler[1], L. I. Chiba*[2], M. L. Somensi[1], L. Bockor[1], and L. G. Teixeira[1], *[1]Federal University of Rio Grande do Sul, Porto Alegre, Brazil, [2]Auburn University, Auburn, AL.*

The experiment was conducted to determine the capacity of piglets weaned at light weight to achieve similar growth performance with those weaned at heavy weight by increasing the ME content of the diet and keeping constant Lys:ME. Thirty-two male piglets were classified according to their weaning weight (WW) as light (4.5 ± 0.4 kg) or heavy (6.7 ± 0.5 kg) and housed individually in metabolic cages for 28 d. Six treatments, 2 WW and 3 ME levels (I: 3400; II: 3600; and III: 3800 kcal/kg) in a 2 × 3 factorial arrangement, were used in pre-starter (PS, d 0 to 14) and starter (ST, d 14 to 28) period. The control diet (I) was formulated with standard energy and nutrient recommendations (Brazilian Tables for Poultry and Swine), whereas indispensable and dispensable AA, Ca, P, and lactose levels in the diets II and III were adjusted for the increased ME (e.g.,4.14 and 3.91 g Lys/Mcal ME for the PS and ST periods, respectively). Fecal and urine samples were collected to determine apparent total tract digestibility (ATTD) of energy and nutrients. Age at weaning was used as covariate in the statistical model. There were no WW x ME interactions for any of the response criteria. Overall, light WW piglets had less ADG and AFDI ($P < 0.05$), but there was no difference in the G:F. Heavy WW piglets ingested more ME, Lys, and N than light WW piglets during the entire phase ($P < 0.05$). During the PS period there was a linear effect of ME on G:F; increasing ME improved G:F ($P < 0.05$). Also in this period, the increment in ME increased ATTD of GE, and DE and ME values ($P < 0.05$). During the ST and total period, there was no effect of increased ME levels on ME and Lys intake, but increasing ME levels increased ATTD of GE, CP, and DM, N retention, and DE and ME values ($P < 0.05$). In conclusion, light piglets did not improve growth performance when fed diets with increasing ME levels. Increased ME levels improved digestibility and utilization of nutrients, but did not improve growth performance.

Key Words: energy density, nursery piglets, weaning weight

1301 (M175) Effect of dietary energy level and weaning weight on body composition and efficiency of energy utilization in weanling piglets.

M. D. S. Vieira[1], A. M. L. Ribeiro[1], A. D. M. Kessler[1], M. L. Somensi[1], L. I. Chiba*[2], L. Bockor[1], and C. S. Marcolla[1], *[1]Federal University of Rio Grande do Sul, Porto Alegre, Brazil, [2]Auburn University, Auburn, AL.*

The experiment was conducted to evaluate the effects of dietary ME and weaning weight (WW) on body composition and energy utilization in weanling piglets. Thirty-two male piglets were classified according to their WW as light (4.5 ± 0.4 kg) or heavy (6.7 ± 0.5 kg), and housed individually in metabolic cages for 28 d. Six treatments, 2 WW and 3 ME (I: 3400; II: 3600; and III: 3800 kcal/kg) with constant Lys:ME were used. The control diet (I) was formulated with standard energy and nutrient recommendations (Brazilian Tables for Poultry and Swine), whereas AA, Ca, P, and lactose levels in the diet II and III were adjusted for the increased ME. Body composition, energy and nutrient deposition rates, and energy efficiency of gain were measured through comparative slaughter technique. There were no WW x ME interactions for any of the responses. BW, ADFI, and ADG were greater ($P < 0.05$) in piglets with heavier WW than lighter WW, but there was no difference in G:F. Also, heavy WW piglets had greater fasted BW, eviscerated carcass and empty BW (EBW), compared to light WW piglets ($P < 0.05$), but there was no difference in the organ + blood (OB) fraction. When those responses were equalized per kilogram of fasted BW, light WW piglets had greater OB than heavy WW piglets. Gastrointestinal tract and kidneys were greater in heavy WW piglets, while urinary tract and blood were greater in light WW piglets when equalized per kilogram of fasted BW ($P < 0.05$). There was no effect of ME on physical body composition, and ME and WW did not affect chemical body composition. The rates of water, ash, and protein deposition in the carcass and OB were greater in heavy WW piglets ($P < 0.05$). Water and protein deposition in EBW also were greater in heavy WW piglets ($P < 0.05$). Increasing ME did not affect energy and nutrient deposition rates in any of the body fractions. Heavy WW piglets had greater intakes of ME, with higher estimates of ME for maintenance and heat production ($P < 0.05$). Energy efficiency was not affected by the WW or ME content of the diets. In conclusion, heavy WW piglets had greater protein deposition and efficiency of gain than light WW piglets. The ME level did not improve the response criteria evaluated in the current study.

Key Words: energy deposition, metabolizable energy, weaning weight

1302 (M176) Egg quality of brown laying hens fed with different Met + Cys and chelate Cu levels.

J. E. D. Moraes[1], C. C. Pizzolante[1], A. P. O. Saccomani[2], E. A. D. Oliveira[3], S. K. Kakimoto[4], J. C. Dadalt*[5], and M. A. D. T. Neto[5], *[1]APTA-Unidade de Pesquisa de Brotas-SAA-SP, Brotas, Brazil, [2]Instituto de Zootecnia-APTA-SAA-SA, Nova Odessa, Brazil, [3]Secretaria de Agricultura de Brotas, Brazil, [4]Granja Kakimoto, Bastos, Brazil, [5]University of São Paulo, Pirassununga, Brazil.*

The objective of the current study was to evaluate effects from Met + Cys levels combined with chelated Cu concentrations for brown laying hens. Nine hundred sixty brown laying hens (6 replicates/treatment, 8 birds/replicate) from 22 to 26 wk of age were allotted in a randomized bloc design under factorial scheme 5 × 4 (Met+Cys x Chelated Copper). The diets were formulated according had similar composition (2800 kcal/kg ME, 15.5% CP) and were formulated according with the lineage of the birds, except for Met + Cys and copper levels. At the final day of period two eggs/experimental unit were evaluated for weight, specific gravity-change, % shell, shell thickness, % albumen, % yolk, Haugh unit, yolk index, and yolk color. Statistical analysis was performed using ANOVA and Tukey's test 5%. In conclusion, Met + Cys and Chelate Cu did not affect external and internal quality results of eggs from brown layer hens at 26 wk of age.

1303 (M177) Validation of net energy system of feed formulation in growing-finishing pigs fed barley based diets with alternative feed ingredients.

D. E Velayudhan*, and C. M. Nyachoti, *University of Manitoba, Winnipeg, Canada.*

The aim of this study was to determine the growth performance and carcass characteristics of growing-finishing pigs fed diets formulated on net energy (NE) basis thereby validating the NE system of feed formulation. Twenty-four pigs (12 barrows and 12 gilts) with an initial BW of 25 kg were blocked by sex and allotted one of the three treatments, resulting in 8 replicates, 4 barrows and 4 gilts per treatment. Dietary treatments were; a barley-based control diet with alternative feed ingredients (distillers dried grains with soluble, canola meal and peas) formulated on digestible energy (DE) basis (Diet A), control diet formulated on a NE basis (Diet B) and Diet B + Multi-carbohydrase enzyme (Diet C). Pigs were offered their respective diets in a three-phase feeding program for 25 to 50 kg (Phase 1), 50 to 75 kg (Phase 2), and 75 to 110 kg (Phase 3) BW. Diet A was formulated to contain 3402 kcal/kg of DE and Diet B and Diet C to contain 2475 kcal/kg of NE with 0.98, 0.85, and 0.73% SID Lys for phases 1, 2, and 3, respectively. Individual pig BW and feed disappearance were monitored biweekly during each phase to determine average daily gain (ADG), average daily feed intake (ADFI), and gain to feed ratio (G:F) ratio. Pigs were slaughtered once they reached 100 kg BW to determine carcass characteristics. During Phase 1, an improvement in ADFI ($P = 0.02$) was observed for diets formulated on NE basis with enzyme supplementation (1.78 kg/d) when compared to Diet B without enzymes (1.57 kg/d). In Phase 3, a significant difference was observed for ADG ($P = 0.01$), wherein Diet B showed a BW gain of 0.89 kg/d compared to 0.79 kg/d for the control diet. Also a trend for an increase in G:F ratio ($P = 0.072$) was observed between diets formulated on DE and NE basis. For overall performance, when compared to the control diet, pigs fed Diet B showed significant improvement in ADG (0.90 vs. 0.96 kg/d; $P = 0.02$) and G:F (0.43 vs. 0.47; $P = 0.05$). No significant differences ($P > 0.10$) were observed among dietary treatments for any of the carcass characteristics. In conclusion, the results indicate a better growth performance when diets were formulated on a NE basis when compared to the DE system. Though not significant, enzyme supplementation numerically enhanced the overall performance.

Key Words: enzyme, net energy, pig

1304 (M178) Effects of dietary tryptophan:lysine ratio and sanitary conditions on performance of weaned pigs fed antibiotic-free diets. B. Jayaraman[*1], J. K. Htoo[2], and C. M. Nyachoti[1], *[1]University of Manitoba, Winnipeg, Canada, [2]Evonik Industries AG, Hanau-Wolfgang, Germany.*

The aim of this study was to determine the optimum standardized ileal digestible (SID) Trp:Lys ratio for weaned pigs reared in clean or unclean sanitary conditions and fed antibiotic-free diets. Mixed-sex pigs (Duroc x [Yorkshire x Landrace]; average initial BW of 7.0 ± 0.5 kg) weaned at 21 ± 1 d were randomly assigned to 10 dietary treatments in a 2 × 5 factorial arrangement in a 28-d study giving 6 replicates (3 pigs per pen) per treatment. The main factors were sanitary conditions (clean, CL and unclean, UCL) and 5 dietary SID Trp:Lys (16, 18, 20, 22, and 24%) in a completely randomized design. Diets were corn-wheat-soybean meal based with a constant SID Lys of 1.18% that was set to be seconding limiting AA. For the first 14 d, CL group (n = 90) were kept in pens, followed immediately by the UCL group (n = 90) for the next 14 d in the same room. Piglets were provided ad libitum access to feed and water. Under the CL condition, the room was disinfected before arrival of piglets and the room was cleaned weekly. For the UCL pigs, the room was not disinfected and cleaned after CL group and manure from swine herd was added (5 kg per pen) to the pens on d 0 and d 7 of the experiment. Pigs BW and pen feed disappearance were recorded weekly to determine ADG, ADFI and G:F. The effect of sanitary conditions was observed (P < 0.05) for ADG and G:F throughout the study. During d 0 to 7 and d 8 to 14, the ADG for CL vs. UCL were 206 vs. 160 g and 420 vs. 364 g, respectively. During d 0 to 7 and d 8 to 14, the G:F for CL vs. UCL was 0.73 vs. 0.54 and 0.76 vs. 0.64, respectively. Increasing dietary SID Trp:Lys ratio did not affect ADG and ADFI during d 0 to 14. The highest ADG was achieved at SID Trp:Lys of 20% for CL and 24% for UCL pigs, respectively. Increasing dietary Trp:Lys had a linear trend (P < 0.10*)* towards improved G:F during d 0 to 7 in the UCL group showing that SID Trp:Lys of 24% improved G:F. In conclusion, pigs raised under unsanitary conditions had reduced ADG and G:F in piglets, and increasing the level of SID Trp:Lys 24% could improve G:F after weaning.

Key Words: tryptophan, sanitation, piglets

1305 (M179) Egg quality of brown layers fed with different levels of threonine and chelate zinc. J. E. D. Moraes[1], C. C. Pizzolante[1], A. P. O. Saccomani[2], E. A. D. Oliveira[3], S. K. Kakimoto[4], J. C. Dadalt[*5], and M. A. D. T. Neto[5], *[1]APTA-Unidade de Pesquisa de Brotas-SAA-SP, Brotas, Brazil, [2]Instituto de Zootecnia-APTA-SAA-SA, Nova Odessa, Brazil, [3]Secretaria de Agricultura de Brotas, Brazil, [4]Granja Kakimoto, Bastos, Brazil, [5]University of São Paulo, Pirassununga, Brazil.*

The objective of this study was to evaluate effects from Thr levels combined with chelated Zn concentrations for brown laying hens. Nine hundred sixty brown laying hens (6 replicates/treatment, 8 birds/replicate) from 22 to 26 wk of age were allotted in a randomized block design under factorial scheme 5 × 4 (Met+Cys x Chelated Copper). The diets were formulated according had similar composition (2800 kcal/kg ME, 15.5% CP) and were formulated according with the lineage of the birds, except for Thr and Zn levels. At the final day of period, two eggs per plot were evaluated for weight, specific gravity, Haugh unit, yolk index, and for percentages of yolk, albumen and shell. Statistical analysis was performed using ANOVA and contrast between mean for (P < 0.05) by Tukey's test. There was no interaction effect of Thr and Zn. Egg weight (56.36 ± …g), specific gravity (1.099 ±), Haugh units (126.00 ±) yolk index (27.72 ±) and shell thickness (39.61 ±) shell percentage (10.05 ±) had no significant effect under Thr and chelate Zn levels. Effects (P < 0.05) were observed for Thr on percentages of yolk and albumen (Table 1305). The lower percentages of egg yolk occurred under 1.1 and 0.80% Thr and albumen under 0.65% Thr levels.

Key Words: albumen, yolk, chelate minerals

Table 1305. Percentages of yolk and albumen of eggs from brown layers fed Thr

	Thr (%)						
	1.1	0.95	0.80	0.65	0.50	Mean	CV (%)
Yolk %	21.92^{b}	22.40^{ab}	21.79^{b}	23.08^{a}	22.36^{ab}	22.32	9.23
Albumen %	68.03^{a}	67.62^{ab}	68.14^{a}	66.77^{b}	67.66^{ab}	67.64	3.24

Means bearing different superscript letters within a row differ by Tukey (P < 0.05). In conclusion, Thr levels may affect the internal egg quality. Zn concentrations did not affect the external and internal qualities of egg.

1306 (M180) Tryptophan:lysine ratio for pigs from 15 to 30 kg of body weight. T. J. Pasquetti*[1], P. C. Pozza[2], I. Moreira[2], L. M. Diaz Huepa[2], L. D. Castilha[2], M. R. Fachinello[2], L. A. C. Esteves[2], V. R. C. Paula[2], and S. W. Kim[3], *[1]Universidade Estadual de Maringá, Bolsista CAPES, Maringá, PR, Brazil, [2]Universidade Estadual de Maringá, PR, Brazil, [3]North Carolina State University, Raleigh.*

The aim of this study was to determine the digestible Tryptophan:Lysine (Trp:Lys) ratio for starting pigs (15 to 30 kg). A previous study was performed to determine the true ileal amino acids digestibility of the diet with low Trp and Lys levels. In the growth performance study, a total of 64 individually housed barrows (15 ± 0,23 kg) were allotted in a completely randomized block design, with 16 treatments and four replicates. Treatments were arranged as a 4 × 4 factorial scheme (four levels of digestible Trp: 0.155, 0.185, 0.215, 0.245% and four levels of digestible Lys: 0.972, 1.112, 1.252 and 1.392%). Glutamic acid was used to keep the diets with the same nitrogen levels. At the end of the study, body weight (BW) and feed intake were recorded and feed:gain ratio (F:G) calculated. Ultrasonography was performed using an Aloka (SSD 500) and Sonograder (Renco) equipments, and measurements of backfat thickness and loin depth were performed using the ImageJ software. Considering the regression analysis, the BW (P = 0.03) and average daily gain (P = 0.005) increased linearly with increased levels of digestible Trp. By surface response method, the average daily feed intake (ADFI) increased linearly (P = 0.014) as the levels of digestible Trp increased in the diets, while Lys showed a quadratic effect (P = 0.004). For the ADFI the optimum Lys level was estimated at 1.195%. An interaction between digestible Trp and Lys (P = 0.056) was found on F:G. Considering the surface response method, there was a quadratic effect (P = 0.042) of digestible Trp and Lys levels on F:G, estimating on 0.210 and 1.198% the optimum levels of digestible Trp and Lys levels, respectively, which results in a Trp:Lys ratio of 0.175. No differences (P > 0.05) were observed on backfat thickness. A quadratic effect of digestible Trp (P = 0.021) and Lys (0.026) levels was observed on loin depth (measured through Aloka SSD 500), which by surface response method the optimum Trp and Lys levels were 0.208 and 1.136%, respectively, providing a Trp:Lys ratio of 0.183%. Using the regression analysis we observed a quadratic effect (P = 0.042) of digestible Trp on loin depth (Sonograder- Renco), which was estimated to be optimum at 0.210%. In conclusion, the optimum digestible Trp and Lys levels for growth performance are 0.210 and 1.198%, and for loin depth are 0.208 and 1.136%, which provide a Trp:Lys ratio of 0.175 and 0.183%, respectively.

Key Words: response surface; growth performance, requirements.

1307 (M181) Energy intake and nutrient digestibility in heavy finishing swine fed varying levels of soluble fiber. D. J. Rodrigues*[1], M. C. Thomaz[1], U. D. S. Ruiz[2], M. M. Lima[1], M. S. F. Oliveira[1], M. V. Marujo[1], F. F. Castro[1], and E. Daniel[3], *[1]Sao Paulo State University, Jaboticabal/SP, Brazil, [2]Univ. Estadual Paulista, Dracena, Brazil, [3]Dep. of Animal Science, FCAV/UNESP, Jaboticabal/SP, Brazil.*

Depending on its characteristics, dietary fiber may depress daily energy intake and utilization of dietary nutrients in growing pigs. These effects are likely lower in finishing pigs. This study was conducted to determine the effect of increasing dietary levels of soluble fiber on daily feed and energy intake, as well as apparent fecal nutrient and energy digestibility in finishing pigs. In total 36 individually housed barrows (commercial crossbred; initial BW 78.38 ± 0.32 kg), were assigned to four dietary treatments in a randomized block design: control (corn and soybean meal based; 3229 kcal/kg calculated ME, 13.9% CP, 1.5% soluble fiber) and three isonitrogenous diets with increasing levels of soluble fibers (4, 8, and 12%; from added pectin, containing 63% of soluble fiber), and consequently decreased levels of calculated ME (3095, 3017, and 2946 kcal/kg). Pigs were fed ad libitum. At a BW of 105 kg, feces were collected twice daily, during 3 d. Insoluble ash was used as marker for determining digestibility. Statistical analyses were performed using the PROC MIXED of SAS. The results showed a linear decrease for both daily feed intake (P = 0.0157) and daily DE intake (P = 0.0005) between 100.86 and 126.19 kg BW. Quadratic effects (P < 0.0001) were observed for the digestibility of DM, GE and CP; the maximum digestibility values were obtained at 0.74, 1.33 and 1.60% additional soluble fiber in diet, respectively. There was linear decrease (P < 0.0001) for the digestibility of ash. These results confirm that feedstuffs containing soluble fiber can be used to reduce daily energy intake in heavy finishing pigs through qualitative feed restriction, but its negative effect on the nutrient digestibility must be considered.

Key Words: daily energy intake, feed restriction, soluble fiber

Table 1307. Daily feed (kg/d) and DE intake (kcal/d), as well as apparent fecal digestibility (AFD, %) of energy and nutrients in finishing pigs fed diets containing different levels of soluble fiber (SF)

	Experimental diets (% SF)					
	1.5	4	8	12	SE	Effect of diet SF

1308 (M182) Amino acid digestibility in field peas, fish meal, corn, soybean meal, and soybean hulls.

J. K. Mathai*, and H. H. Stein, *University of Illinois at Urbana-Champaign, Urbana.*

An experiment was conducted to determine the standardized ileal digestibility (SID) of AA in field peas, fish meal, corn, soybean meal, and soybean hulls. Six ileal-cannulated gilts (initial BW: 26.5 ± 0.74 kg) were allotted to a 6 × 6 Latin square design with 6 diets and 6 periods. A N-free diet was formulated to determine basal endogenous losses of AA and CP and to enable the calculation of SID of AA. The remaining diets were formulated with each test ingredient as the sole source of AA, with the exception that the soybean hulls were included in a diet that also contained soybean meal to compensate for the low CP in soybean hulls. The AID and SID values were calculated in the soybean hulls diet using the difference procedure whereas AID and SID in the other ingredients were calculated using the direct procedure. The SID of Lys was greater ($P < 0.05$) in field peas, fish meal, and soybean meal than in corn and soybean hulls (Table 1308). The SID of Trp was greater ($P < 0.05$) in corn than in soybean meal, and greater ($P < 0.05$) in soybean meal than in field peas. The SID of His, Lys, and Trp was less ($P < 0.05$) in soybean hulls than in other ingredients. These data indicate that the SID of AA in most indispensable AA is not different between field peas, fish meal, and soybean meal, whereas the SID of some indispensable AA is less in soybean hulls than in other ingredients.

Key Words: amino acid digestibility, feed ingredients, pigs

Table 1308. Standardized ileal digestibility (SID; %) of AA in field peas, fish meal, corn, soybean meal (SBM), and soybean hulls fed to pigs

1309 (M183) Lysine and tryptophan levels in diets for gilts from 15 to 30 kg of body weight.

T. J. Pasquetti[*1], P. C. Pozza[2], I. Moreira[2], T. C. D. Santos[2], D. Perondi[3], C. D. L. Costa Filho[2], W. Tanamati[2], P. L. D. O. Carvalho[4], and C. F. Muniz[2], *[1]Universidade Estadual de Maringá, Bolsista CAPES, Maringá, PR, Brazil, [2]Universidade Estadual de Maringá, PR, Brazil, [3]Dep. of Animal Science-FCAV/UNESP, Jaboticabal/SP, Brazil, [4]Universidade Estadual do Oeste do Paraná, Marechal Cândido Rondon, PR, Brazil.*

The aim of this study was to determine the optimum levels of digestible lysine (Lys) and tryptophan (Trp) in diets for gilts from 15 to 30 kg of body weight. A previous study was performed to determine the true ileal digestibility of amino acids in the basal diet (low Lys and Trp levels), to verify if some deficiencies occurred with other essential amino acids. The growth performance study was performed using a total of 64 individually housed gilts (15,03 ± 0,19 kg), allotted in a completely randomized block design, with 16 treatments and four replicates. Treatments were arranged as a 4 × 4 factorial scheme (four levels of digestible Trp: 0.155, 0.185, 0.215, 0.245% and four levels of digestible Lys: 0.972, 1.112, 1.252 and 1.392%). Glutamic acid was used to keep nitrogen levels similar across diets. The body weight (BW) and feed intake were recorded and F:G was calculated. Ultrasonography was performed using an Aloka (SSD 500) and Sonograder (Renco) equipments, and backfat thickness and loin depth were measured using the ImageJ software. Considering the regression analysis, a quadratic effect of digestible levels of Trp was observed on ADG ($P = 0.038$), in which the optimum level was obtained 0.224%. The increased levels of digestible Trp improved linearly ($P = 0.005$) the ADFI. An interaction between Trp and Lys was observed for F:G ($P = 0.007$). No interaction was observed for ADG ($P = 0.247$), ADFI ($P = 0.233$), backfat measured with Sonograder ($P = 0.603$), and Aloka ($P = 0.462$) and for loin depth measured with Sonograder ($P = 0.632$) and Aloka ($P = 0.086$). By surface response method, a quadratic effect ($P = 0.034$) of digestible levels of Trp and a linear effect of Lys ($P = 0.005$) were observed on F:G, in which the optimum level of digestible Trp was obtained at 0.216%. Trough regression equation method, the backfat thickness (measured through Aloka or Sonograder) increased linearly ($P = 0.052$ and 0.021, respectively) and the loin depth (measure through Aloka) showed quadratic effect ($P = 0.034$) for Trp levels, in which the optimum level was estimated at 0.205%. The loin depth, measured through Sonograder, increased linearly ($P = 0.039$) with digestible levels of Lys. In conclusion, the optimum levels of digestible Trp, to improve average daily gain and loin depth, are 0.224 and 0.205%, respectively.

Key Words: amino acids, ileal digestibility, growth performance.

1310 (M184) Effects of mineral supplementation on the performance of nulliparous and multiparous does fed forage containing diets. L. Verjel-Trigos*[1], I. Rodriguez-Carrascal[1], and C. Ordoñez-Gomez[2], [1]*Universidad Francisco de Paula Santander-Ocaña, Colombia,* [2]*Universidad Nacional de Colombia, Bogotá.*

The effect of the mineral supplementation on the performance of nulliparous and multiparous rabbit does fed forage containing diets was evaluated in 18 rabbit does crossed New Zealand and Russian californian with an average live weight 3.65 ± 0.15 kg, placed in individual cages, distributed following a complete randomized design with factorial arrangement 2 × 3, with two levels of parity (PA), multiparous (M) and nulliparous (N), and three levels in salt supplementation (S), without salt (NS), with 6% P (S6), 11.4% Ca y 6% P, and 8% P (S8), 15.2% Ca y 8% P, with three replications. The diet consisted of 85% of commercial feed and 15% trichantera forage based in DMI (Mineral composition: 1.4% Ca and 0.56% P). Salts was formulated to keep a constant calcium:phosphorus ratio and levels of trace minerals. The salt was offered in plastic licks from 15 d before mating to weaning. Lactation period was 30 d. To rabbit does performance was evaluated farrowing weight, weaning weight and DMI. In the performance of kits the litter size at birth, at weaning and weight gain in lactation was evaluated. Data were analyzed in module GLM of SAS ver. 9.2. Analysis of covariance to the initial weight of the rabbit does and comparison of means by orthogonal contrasts was performed. The performance of kits was not affected ($P > 0.05$). In rabbit does performance no interaction between S and PA was observed ($P > 0.05$). There were no differences ($P > 0.05$) between groups for DMI, 101.1, 107.7, 109.9, 101.0, 107.8 and 103.0 g/d of DMI to N-NS, N-S6, N-S8, M-NS, M-S6 and M-S8, respectively and 0.42, 0.37, 0.38 and 0.34 g/d of salt to N-S6, N-S8, M-S6 and M-S8, respectively. The farrowing weight of rabbit does was higher ($P < 0.01$) in S8 compared to S6, 3841, and 3388 g to S8 and S6, respectively. S8 increase ($P < 0.05$) the weaning weight of the rabbit does relative to S6, 4055, and 3608 g to S8 and S6, respectively. In conclusion, supplementation with salt 8% P improves the performance of rabbit does fed forage containing diets, but not affect the performance of the litter.

Key Words: phosphorus, rabbit does, salt

1311 (M185) Amino acid digestibility in oilseed meals fed to growing pigs. C. S. Park*, A. R. Son, and B. G. Kim, *Konkuk University, Seoul, South Korea.*

An accurate determination of the standardized ileal digestibility (SID) of AA is important for swine diet formulation, especially in protein supplements. The objective of this experiment was to determine the SID of AA in 11 sources of oilseed meals fed to growing pigs. The oilseed meals used in this study were sesame meal (SM, 50.0% CP), two sources of soybean meal (SBM) produced in Korea (SBM-K1, 47.4% CP; SBM-K2, 47.1% CP), SBM produced in India (SBM-I, 39.6% CP), high-protein distillers dried grains (HPDDG, 38% CP), perilla meal (*P*M, 43.2% CP), canola meal (CNM, 37.5% CP), copra meal (CM, 21.7% CP), corn germ meal (CGM, 21.4% CP), palm kernel expeller (*P*KE, 15.3% CP), and tapioca distillers dried grains (TDDG, 18.4% CP). Experimental diets were prepared to contain each ingredient as a sole source of AA and an N-free diet was also prepared to estimate the basal endogenous losses of AA. Twelve barrows with an initial BW of 29.0 ± 3.0 kg were surgically fitted with a T-cannula at the distal ileum and were allotted to a 12 × 9 incomplete Latin square design with 12 diets and 9 periods. Following the 5-d adaptation period, ileal digesta were collected for 8 h on d 6 and 7. Values for the SID of Lys in SM, SBM-K1, SBM-K2, SBM-I, HPDDG, PM, CNM, CM, CGM, PKE, and TDDG were 16.6, 81.2, 86.9, 85.3, 66.1, 32.5, 61.6, 21.4, 51.8, 46.0, and 43.3, respectively (SEM = 4.8, $P < 0.01$). Values for the SID of Met in SM, SBM-K1, SBM-K2, SBM-I, HPDDG, PM, CNM, CM, CGM, PKE, and TDDG were 64.6, 91.5, 87.9, 85.8, 91.5, 38.3, 76.6, 55.2, 73.4, 67.4, and 20.8, respectively (SEM = 5.5, $P < 0.01$). In conclusion, values for the SID of most AA in SBM-K1, SBM-K2, SBM-I, HPDDG, and CNM were greater than those in SM, PM, CM, and TDDG.

Key Words: feedstuffs, protein supplements, swine

1312 (M186) Standardized total tract digestibility of phosphorus in oilseed meals fed to growing pigs. C. S. Park*[1], Y. D. Jeong[2], B. G. Kim[1], and S. K. Park[2], [1]*Konkuk University, Seoul, South Korea,* [2]*Rural Development Administration, Suwon, South Korea*.

We determined the standardized total tract digestibility (STTD) of P in 11 sources of oilseed meals fed to growing pigs. The test ingredients were sesame meal, two sources of soybean meal (SBM) produced in Korea (SBM-K1 and SBM-K2), SBM produced in India, high-protein distillers dried grains (HPDDG), perilla meal (PM), canola meal, copra meal (CM), corn germ meal (CGM), palm kernel expeller, and tapioca distillers dried grains. Experimental diets were formulated to contain each ingredient as a sole source of P and a P-free diet was also prepared to estimate the basal endogenous loss of P. Twelve barrows with an initial BW of 47.9 ± 2.6 kg were allotted to a 12 × 8 incomplete Latin square design with 12 diets and 8 periods. After 4 d of adaptation period, feces were collected for 4 d of collection period according to the marker-to-marker method. There was a difference ($P < 0.001$) in the STTD of P among oilseed meals (Table 1312). Values for the STTD of P in SBM-K1, HPDDG, CM, and CGM were greater ($P < 0.05$) than that in PM. In conclusion, the STTD of P in oilseed meals were in the range of 58.5 to 76.8% except HPDDG, PM, and CGM.

Key Words: feedstuffs, macromineral, swine

1313 (M187) Standardized total tract digestibility of phosphorus in cereal grains and coproducts fed to growing pigs.

Y. D. Jeong[1], C. S. Park[*2], B. G. Kim[2], and S. K. Park[1], *[1]Rural Development Administration, Suwon, South Korea, [2]Konkuk University, Seoul, South Korea.*

The objective of this experiment was to determine the standardized total tract digestibility (STTD) of P in 2 sources of cereal grain including barley and wheat and nine sources of byproduct ingredient including almond meal, two different sources of corn gluten feed, corn gluten meal (CGM), lupin hull (LH), lupin kernel (LK), rice bran (RB), soybean meal, and wheat bran. Each ingredient was included to an experimental diet as a sole source of P. A P-free diet was formulated to estimate the basal endogenous loss of P. A total of 12 diets were assigned to a 12 × 8 incomplete Latin square design with 12 barrows and 8 periods. Pigs with an initial BW of 46.7 ± 3.2 kg were individually housed in metabolism crates. Each period lasted 8 d consisted of 4-d adaptation and 4-d collection periods. Feces were collected based on the marker-to-marker method. Despite of the greatest concentration of P in RB, the STTD of P in RB was lower ($P < 0.05$) than CGM and LK (Table 1313). Value for the STTD of P in LH was also lower ($P < 0.05$) than those in CGM and LK. In conclusion, the STTD of P in barley and wheat were not significantly different and these values were similar to values in cereal coproducts used in this experiment.

NONRUMINANT NUTRITION: THE IMPACT OF FEED ADDITIVES ON THE HEALTH AND PERFORMANCE OF SWINE AND POULTRY

1314 (T177) Evaluating the toxicity of metabolites derived from the trichothecene biotransformation using Biomin BBSH 797 in vitro. S. Schaumberger*[1], and U. Hofstetter[2], [1]*BIOMIN Holding GmbH, Herzogenburg, Austria,* [2]*Biomin Holding GmbH, Herzogenburg, Austria.*

Biomin BBSH 797, a *Gen. nov. sp. nov*. of the family *Coriobateriaceae* isolated from bovine rumen fluid, is able to specifically detoxify trichothecenes in the intestinal tract of animals. The live strain is able to produce enzymes that reduce the epoxide group of these mycotoxins, which results in the formation of non-toxic metabolites. The objective of this trial was to prove that the metabolite de-epoxy-deoxynivalenol (DOM-1), formed during the degradation of deoxynivalenol (DON), has lower toxicity. The lymphocyte proliferation assay (LPA) was used to show the effects of DON and DOM-1 on the clonal proliferation on isolated chicken lymphocytes. Lymphocytes were cultured with DON (10–0.08 µg/mL) and DOM-1 (232–1.18 µg/mL). As a control, the mitogen Concanavaline A (ConA) was used. The number of proliferated cells was quantified with a colorimetric immunoassay after in vitro stimulation. 5-Bromo-2'-deoxyuridine (BrdU) was added and incorporated into the DNA of proliferating cells. Incorporated BrdU was measured with an ELISA-method. The absorbance values directly correlated with the amount of DNA synthesis and hence the number of proliferating cells. Results show that at a concentration of 15 µg DON/mL the proliferation of lymphocytes was lower in comparison to ConA. After adding 0.3 µg DON/mL to the cells only one-third of them could proliferate whereas at a concentration of 0.63 µg DON/mL the growth of the lymphocytes stopped. In comparison, the metabolite DOM-1 only stopped the proliferation of cells at a concentration of 113 µg DOM-1/mL. The results show that the metabolite DOM-1 is almost 500 times less toxic than DON.

Key Words: Biomin BBSH 797, trichothecene, biotransformation

1315 (T178) Effects of dietary supplementation of β-mannanase on ileal digestibility of fiber and viscosity of jejunal digesta in nursery pigs fed corn and soybean meal-based diets. I. Park*[1], T. J. Pasquetti[1,2], and S. W. Kim[1], [1]*North Carolina State University, Raleigh,* [2]*Bolsista do, CNPq, Brazil.*

This study is to determine the effects of β-mannanase (CTCZYME, CTCBIO Inc., Seoul, South Korea) on ileal digestibility of nutrients and viscosity of jejunal digesta in nursery pigs fed corn and soybean meal-based diets. Forty-eight barrows at 6 wk of age (initial BW: 15.7 ± 1.1 kg) were assigned to four dietary treatments with different levels of β-mannanase (0, 200, 400, and 600 Unit/kg feed). Experimental diets contained 56.4% corn, 30.0% soybean meal, 10.0% DDGS, and 3.7% others. Pigs were housed individually in metabolism crates and received experimental diets at a fixed amount based on BW of pigs (daily feed allowance = 0.09 x $BW^{0.75}$ kg) for 11 d. Chromium oxide (0.3%) in experimental diets as an indigestible marker was provided from d 8 to 11. Actual feed intake, any feed refusals, and BW were measured on d 7 and 12 to monitor growth. On d 12 after 8 h of last meal, pigs were euthanized to collect digesta from jejunum and ileum. Digesta from jejunum were used to measure viscosity with a viscometer (DV+, Brookfield Engineering Laboratories, Inc., MA). Digesta from ileum were used to measure apparent ileal digestibility of energy, NDF, and ADF. Tissues from jejunum were fixed for morphological evaluation. The data were analyzed using PROC MIXED of SAS based on randomized complete block design. Morphology of jejunum was not affected by dietary supplementation of β-mannanase. Viscosity of digesta in jejunum tended to decrease linearly (P = 0.076, 5.2 to 3.8 mPa·s) with increasing supplementation of β-mannanase. Dietary β-mannanase also tended to increase (P = 0.093, 53.4 to 64.7%) apparent ileal digestibility of energy in a quadratic manner at the highest digestibility at 600 Unit of β-mannanase per kg feed. There was no change in ileal digestibility of NDF and ADF by supplemental β-mannanase indicating that the increase in energy digestibility is not due to the release of monosaccharides from mannans by β-mannanase. Collectively, dietary supplementation of β-mannanase enhanced energy utilization in nursery pigs by reducing viscosity of digesta potentially enhancing digestibility of nutrients.

Key Words: ADF, β-mannanase, energy utilization, NDF, pigs, viscosity

1316 (T179) Effects of dietary supplementation of selenium-enriched probiotics on productive performance and intestinal microflora of weanling piglets raised under high ambient temperature. C. Lv[1], T. Wang*[2], S. F. Liao[2], and K. Huang[1], [1]*Nanjing Agricultural University, Nanjing, Jiangsu, China,* [2]*Mississippi State University, Starkville.*

Probiotics have been suggested as one of the most desirable alternatives to feed antibiotics for swine. The objective of this study is to evaluate the efficacy of a selenium-enriched probiotics (SeP) preparation on productive performance and intestinal microflora of piglets raised under high ambient temperature. Forty-eight crossbred weanling piglets (28 d old) randomly allotted into 12 pens (four piglets/pen) and four dietary treatments (three pens/treatment) were fed ad libitum for 42 d a basal diet (control; Con), or the basal diet supplemented with

probiotics (Pro), sodium selenite (ISe), or the SeP preparation. The basal diet contained 0.16 mg/kg-diet of total intrinsic Se, and the ISe and SeP preparations elevated the total Se level to 0.46 mg/kg-diet. The Pro and SeP preparations contained equivalent amounts of *Lactobacillus acidophilus* and *Saccharomyces cerevisiae* (approximately 10^{11} and 10^{9} CFU/mL, respectively). Blood and fecal samples were collected on d 0, 14, 28, and 42 post-initiation of the feeding trial. The SeP group had higher final BW ($P < 0.05$), greater ADG ($P < 0.05$), lower FCR ($P < 0.01$), and lower diarrhea incidence ($P < 0.01$) than the Pro, ISe or Con group. Blood Se concentration and GSH-Px activity were both higher ($P < 0.01$) in the SeP group than in the Pro, ISe or Con group. On d 28 and 42, the serum concentrations of T3 were higher ($P < 0.01$) and T4 lower ($P < 0.01$) in the SeP group than in the ISe, Pro or Con group. On d 28, the serum T3 in the ISe group was higher ($P < 0.01$) than in the Pro or Con group, and on d 28 and 42 the serum T4 were lower ($P < 0.01$) in the ISeP group than in the Pro or Con group. Also on d 28 and 42, the fecal counts of *Lactobacillus* bacteria was higher ($P < 0.01$) while *Escherichia coli* lower ($P < 0.01$) in the SeP or Pro group than in the ISe or Con group. The results of RFLP showed that the fecal microbial flora in the SeP group changed the most (numerically) as compared to the Pro or ISe group. In conclusion, the overall results of this study indicate that this SeP preparation may serve as a better alternative to antibiotics than pure probiotics for using as a growth promoter for piglets.

Key Words: probiotics, selenium, pig, productive performance, fecal microflora, glutathione peroxidase, thyroid hormone

1317 (T180) Growth performance and carcass characteristics of pigs fed high-fiber diets supplemented with *Bacillus* spp. expressing multi-enzyme activities.

A. Owusu-Asiedu[*1], R. Lizardo[2], J. Brufau[2], and A. Awati[1], [1]*DuPont Industrial Biosciences- Danisco Animal Nutrition, Marlborough, Wiltshire, United Kingdom,* [2]*IRTA-Mas de Bover, Constantí, Tarragona, Spain.*

Increasing the amount of cereal byproducts such as corn distillers-dried grain with solubles; CDDGS, and wheat bran; WB in swine diets decreases pig performance and negatively affects carcass characteristics. The current study evaluated the potential of specifically selected *Bacillus* spp. direct fed microbial product with multi-enzyme activities (BDFM) to counteract the negative effect in pigs fed diets containing 20% CDDGS and 20% WB. Ninety-six Pietrain X (Landrace X Duroc) pigs (initial BW 31.60 ± 1.30 kg) were used in a 14-wk study. Pigs were blocked by BW and sex and randomly assigned to two dietary treatments with three pigs/pen and 16 replicate pens/treatment. The basal diets were formulated to meet the nutritional requirements of the pigs and contained corn and SBM and cereal byproducts. The NE and digestible Lys in the basal starter, grower and finisher phases diets were; 9.77, 9.85, and 9.71 MJ/kg, and 1.01, 0.93, and 0.85%, respectively, and AA were adjusted on ideal protein basis. The *Bacillus* product containing 3×10^{8} CFU/g was added at 0 (Control) or 500 g/MT of feed in the test diet (BDFM). Pigs were allowed to consume the assigned experimental diet for the entire study period, and ADG, ADFI and G:F determined. Backfat and loin depth were measured at slaughter using a Fat-O-Meater device and carcass lean meat percentage determined. Data were analyzed using the Proc PROC MIXED in SAS. Overall, ADFI (1910 vs. 1887; SEM = 27.34) and ADWG (762 vs. 779 g/d; SEM = 11.20) were not affected ($P > 0.05$) by BDFM supplementation. However, compared with Control, pigs fed the BDFM supplemented diet had improved ($P < 0.05$) overall G:F ratio (0.400 vs. 0.413; SEM = 0.004). Carcass weight and killing-out percentage tended to improve ($P < 0.10$), whereas backfat depth was reduced (16.8 vs. 15.1 mm; $P = 0.01$) and lean meat percentage improved (58.9 to 61.5%; $P = 0.01$) with BDFM supplementation compared with control. In conclusion, dietary inclusion of specifically selected *Bacillus* spp. expressing multi-enzyme activities improved feed efficiency and carcass characteristics in pigs fed high fiber-based diets.

Key Words: *Bacillus* spp., dietary fiber, pigs

1318 (T181) Effects of star anise (*Illicium verum*) on growing performance and antioxidant status of sows and nursing piglets.

G. Y. Wang[1], C. Yang[2], Y. X. Guo[1], Z. Yang[*3], and Y. Wang[4], [1]*College of Animal Science, Shandong Agricultural University, Tai-an, China,* [2]*College of Life Science, Shandong Agricultural University, Taian, China,* [3]*College of Animal Science, Shandong Agricultural University, Taian, China,* [4]*Agriculture and Agri-Food Canada, Lethbridge, AB*.

To investigate the effects of star anise (*Illicium verum*) that was processed to particle sizes of 300 μm on performance and antioxidant status of sows and nursing piglet**s**. Thirty sows (Landrace × Large White) at 85 d of gestation were randomly allocated into 5 treatments with 6 replicates in a complete randomized design. Pregnant sows were fed corn-soybean meal

based diets and supplemented with 0, 2.5, 5.0, 7.5 and 10.0 g/kg diet of star anise (SA) powder, respectively. After farrowing, all sows were fed a lactation diet without star anise until weaning and litter size was standardized to 10 piglets by cross-fostering within 24 h postfarrowing. ADFI, body weight loss of lactating sows, body weight and eliminating ratio of piglets of each replicate were measured weekly. Blood samples from 6 sows and 12 piglets per treatment were obtained at weaning to determine the serum antioxidant enzymatic activities. All treatments had similar body weight loss of sows, birth weight, body weight at d 7 and mortality rates of piglets. However, pregnant sows supplemented with 5 g/kg SA had higher ($P < 0.05$) average daily gain and body weight of piglets at d 14 and d 21 as compared with that of control. With pregnant sows supplemented SA at the level of 2.5 to 10 g/kg, lactating sows had higher ($P < 0.05$) activities of superoxide dismutase (SOD) than the control. In lactation period, concentration of malondialdehyde (MDA) was lower ($P < 0.05$) with dietary supplementation star anise from late pregnancy to the end of breastfeeding at the level of 5.0 g/kg. The activities of glutathione peroxidase (GSHPx) and total antioxidant capacity (T-SOD) in serum of lactating sows were increased by the addition SA at levels of 5.0 and 7.5 g/kg. As compared with that of control, all additions of star anise had lower ($P < 0.05$) MDA, however, piglets had higher ($P < 0.05$) activities of SOD, T-SOD and GSHPx in serum with pregnant sows supplemented SA at the level of 2.5 to 10 g/kg. Dietary supplementation star anise from late pregnancy to the end of breastfeeding improved growing of piglets and serum antioxidant status of lactating sows and weaning piglets. The optimum supplementation rate of SA in the pregnant sow's diet appeared to be between 2.5 and 5 g/kg diet.

Key Words: star anise, sow, piglets, growing performance, antioxidant status

1319 (T182) The effects of Calibrin-Z or a Calibrin-Z-based blended product on post-weaning performance of nursery pigs. S. L. Johnston*[1], F. Chi[1], S. Ching[1], R. Cravens[1], and O. Adeola[2], *[1]Amlan International, Chicago, IL, [2]Purdue University, West Lafayette, IN.*

One hundred ninety-two pigs (BW = 5.8 kg, 21 d old) were used in an experiment to evaluate the effects of two clay-mineral products on the post weaning performance of nursery pigs. The two products were a clay-mineral product, Calibrin-Z (Z), and a Calibrin-Z-based blended with a fermentable fiber and an organic acid (CBZ). There were four treatments: 1) Control (C); 2) C+Z at 0.2%; 3) C+CBZ at 0.1%; and 4) C+CBZ at 0.3%. The experiment was conducted as a randomized complete block design with weight and sex as blocking factors. There were four pens of gilts and four pens of barrows per treatment, with six pigs per pen. Pigs had ad libitum access to feed and water. The trial lasted 35 d, diets were corn and soybean meal-based complex nursery diets, all ingredients were commercially available so mycotoxins concentration would be those comonly found in commercial diets. There were decreasing amounts of whey, plasma, soy protein concentrate, fishmeal and lactose as the trial progressed. No differences ($P > 0.1$) in ADG were seen during the experiment with values for ADG for d 0 to 35 of 302 g for the C fed pigs vs. an average of 324.4 g for the pigs fed the two products. There was a significant improvement ($P < 0.05$) in the G:F ratio from diet supplementation from the two products from d 21 to 28, but there was no difference ($P > 0.1$) between products indicating that either product would increase feed efficiency. Furthermore, there was a linear ($P < 0.05$) improvement in G:F from d 21 to 28 when pigs were fed increasing concentrations of CBZ. During the last 2 wk, there was a tendency ($P < 0.10$) for improved G:F with diet supplementation from the two products, again with no difference ($P > 0.1$) between products, and a tendency ($P < 0.10$) for linear improvement in G:F with addition of CBZ. For the overall period there was a tendency ($P < 0.10$) for linear improvement in G:F from increasing concentration of CBZ and an improvement in G:F ($P < 0.05$) from dietary supplementation from Z or CBZ, with overall G:F ratios of 653 g/kg for the C pigs vs. an average of 680 g/kg for the pigs fed the C or CBZ, with no difference ($P > 0.1$) between the two products. Thus, supplementing the diet of nursery pigs with Calibrin-Z based products improved feed efficiency.

Key Words: feed efficiency, nursery, pigs

1320 (T183) Nutrient digestibility of rice bran, with or without exogen enzymes, for weaned piglets. J. C. Dadalt*, G. D. V. Polycarpo, C. Gallardo, P. D. A. P. Ribeiro, B. Alves, and M. A. D. T. Neto, *University of São Paulo, Pirassununga, Brazil.*

The objective of the current study was to evaluate the digestibility of dry matter (DM), crude protein (CP), mineral matter, apparent digestible (DE) and metabolizable (ME) energy, and nitrogen retention of rice bran (RB), with or without exogen enzymes inclusion, in weaned piglets. Twenty-five crossbred barrows with initial weight 6.86 kg ± 1.3 kg, were alloted in a completely randomized design under five treatments and five replicates. The experimental unit was represented by one pig within its respective metabolic cage. The experimental period was 10 d, 5 d of adaptation and 5d of total feces and urine collection. The treatments were: Control diet (CD); CD + 30% rice bran (CD + RB); CD + 30% RB + 200 mg/kg of carbohydrase (CD+RB+Carb); CD + 30% RB + 50 mg/kg of phytase (CD+RB+Phy); CD + 30% RB+ Carb + Phy (CD+RB+Carb+Phy). The control diet was based on corn (61.33%), skim milk powder (10%) and dried whey (15%). The enzymes used were: commercial phytase with an activity of 10,000 FTU/g; carbohydrase providing 10% of Galactomananase, 10% of Xilanase, 10% of β-glucanase, 60% of malted barley and 10% of α-galactosidase. Isolated or combined with carbohydrase,

phytase did not influence ($P > 0.05$) the digestibility of rice bran nutrients. These results would be associated with adverse factors such as animal and nutritional profile of feedstuff. The DE– 3062 kcal/kg and ME– 3029 kcal/kg were similar to Brazilian tables for poultry and pigs (2011). The apparent digestibility coefficients of DM, CP, mineral matter and nitrogen retention were 65.47%; 72.58%; 36.59% and 62.21%, respectively. These results were similar some found in the literature using growing and finishing pigs, however, there are different results. The current study suggests that the used enzymes are not effective to improve nutritional value of gross energy, DM, CP and MM of rice bran for young pigs after weaning.

Key Words: carbohydrase, metabolism, phytase

Table 1320. Digestibility coefficients of rice bran for weaned piglets

	Ingredients					
Variables	RB	RB+ Carb	RB+ Phy	RB+ Carb+ Phy	*P*-values	SEM
DM %	65.47	68.76	68.38	67.38	05730	0.866

1321 (T184) The improvements in growth, bone mineral status and nutrient digestibility in pigs following the addition of phytase is accompanied by modifications in ileal nutrient transporters.

S. Vigors*[1], T. Sweeney[2], D. N. Doyle[1], C. J. O'Shea[1], and J. V. O'Doherty[1], *[1]School of Agriculture and Food Science, University of College Dublin, Ireland, [2]College of Agriculture, Food Science and Veterinary Medicine, University College Dublin, Belfield, Ireland.*

Phytase improves growth performance, nutrient digestibility and bone structure in pigs. However, little is known about its effect on ileal nutrient transporter gene expression. Before the start of the experiment all pigs were allowed an adaption period of 14 d and were fed a standard weaning diet. Forty-eight weaner pigs (11.75kg, sem 0.75) were randomly assigned to one of three experimental diets for a period of 44 d to measure growth performance. Following this six animals per treatment were randomly selected and slaughtered to measure the coefficient of apparent ileal nutrient digestibility (CAID), coefficient of apparent total tract nutrient digestibility (CATTD) and ileal nutrient transporter gene expression. The experimental treatments were as follows, 1) a high phosphorus (HP) diet containing 5.9 g/kg total P (tP), 3.2 g/kg available P (aP) and 6.8 g/kg calcium (Ca), 2) a low phosphorus (LP) diet containing 4.5 g/kg (tP), 1.8 g/kg aP and 5.2 g/kg Ca and 3) a phytase (*P*HY) diet containing the LP diet + 1000 FTU/kg of phytase. The addition of PHY increased ADG (700 g/day vs. 610 g/day sem 0.02; $P < 0.05$), final BW (43kg vs. 37kg sem 1.02; $P < 0.01$) and decreased FCR (1.74 vs. 2.05 sem 0.09; $P < 0.05$) compared with the LP diet. Pigs offered the PHY diet had higher CAID of gross energy (748 g/kg vs. 699 g/kg vs. 700 g/kg, sem 7.0; $P < 0.001$) compared to the HP and LP diets, respectively. Pigs offered the PHY diet had a higher CAID of nitrogen (716 g/kg vs. 669 g/kg sem 14.3; $P < 0.05$) compared to the HP diet. The addition of PHY improved the CATTD of Ca (766 g/kg vs. 487 g/kg vs. 451 g/kg sem 42.96; $P < 0.001$) and P (558 g/kg vs. 220 g/kg vs. 389 g/kg sem 43.12; $P < 0.001$) compared to both LP and HP, respectively. The PHY diet had increased gene expression of PEPT1 (1.40 vs. 0.47 sem 0.29, $P < 0.05$) and a tendency towards increased gene expression of FABP2 (1.67 vs. 0.73 sem 0.37 $P < 0.10$) compared to the LP diet. The LP diet had lower gene expression of SGLT1 (1.32 vs. 0.51 sem 0.31) and GLUT2 (0.26 vs. 1.26 sem 0.29) ($P < 0.05$) compared to the HP diet. In summary, offering a diet supplemented with PHY improves growth performance and ileal and nutrient digestibility. PHY addition increases the gene expression of the peptide transporter PEPT1 and tended to increase the fatty acid transporter FABP2.

Key Words: phytase, nutrient transporter gene expression, pigs

1322 (T185) Effects of bromelain supplementation on growth performance, nutrient digestibility, blood profiles, fecal microbial shedding, fecal score, and fecal noxious gas emission in weanling pigs.

M. M. Hossain*, H. L. Li, and I. H. Kim, *Dep. of Animal Science, Dankook University, Cheonan, South Korea.*

A total of 140 weanling pigs [(Yorkshire × Landrace) × Duroc] with an average BW of 6.75 ± 1.48 kg were used in a 6-wk trial. Pigs were randomly allotted to one of four experimental treatments according to their initial BW (7 pens per treatment with 5 pigs per pen). Dietary treatments were: CON, basal diet; T1, CON + 0.05% bromelain; T2, CON + 0.10% bromelain; T3, CON + 0.20% bromelain. The experiment was divided into two phases (d 1 to 14 and d 15 to 42). All diets, in mash form, were formulated to meet or exceed the nutrient requirements (NRC, 2012) for weanling pigs. Feed intake and BW were monitored at the end of each phase. T3 treatment had greater (342 vs. 305 g; 409 vs. 387 g; $P < 0.05$) ADG and ADFI than CON treatment in phase 1. In phase 2, the ADG was improved (from T1 to T3: 612, 616, 637 vs. 583 g; $P < 0.05$) in all bromelain treatments compared with CON treatment, ADFI and G:F ratio of T3 treatment was higher (833 vs. 803 g; 0.765 vs. 0.726; $P < 0.05$) compared with CON treatment. Overall, T3 treatment showed greater (539 vs. 490 g; 691 vs. 664 g; $P < 0.05$) ADG and ADFI than CON. Moreover, pigs fed bromelain diets increased (0.769, 0.770, 0.780 vs. 0.738; $P < 0.05$) G:F ratio compared with those fed CON diet. Pigs fed bromelain diets increased (2 wk: 79.06,

79.96, 79.42 vs. 77.98%; 78.51, 78.86, 78.43 vs. 75.69%; 6 wk: 74.49, 74.67, 75.02 vs. 72.70%; 69.43, 70.78, 71.32 vs. 73.39%; $P < 0.05$) the ATTD of dry matter and nitrogen compared with those fed CON diet at wk 2 and wk 6. On d 42, the blood creatinine in CON group was higher (1.30 vs. 1.04, 0.97, 0.88 mg/dL; $P < 0.05$) compared with those in bromelain treatments. The concentration of fecal *E. coli* counts were decreased (6.22 vs. 6.41 $\log_{10}$cfu/g; $P < 0.05$) in T2 treatment compared with CON treatment. The fecal NH_3 emission in T2 and T3 treatments decreased (17.72, 17.33 vs. 22.95 ppm; $P < 0.05$) compared with CON. In conclusion, dietary supplementation with 0.2% bromelain has been shown to improve the growth performance, ATTD of DM and N, and decreased *E. coli* and excreta NH_3emission in weaning pigs.

Key Words: bromelain, growth, performance, fecal microbial, weanling pigs

---

1323 (T186) Effect of nutrifen supplementation with different levels of metabolic energy on growth performance, nutrient digestibility, meat quality, blood profile, excreta microflora, and excreta gas emission of broiler chickens. H. Shin, A. Hosseindoust, and I. H. Kim*, *Dep. of Animal Science, Dankook University, Cheonan, South Korea.*

A total of 816 ROSS 308 both male, female 1-d old, body weight 45.2 ± 0.7 g broiler chicken were used in this 4-wk trial to evaluate the effect of nutrifen supplemented to broiler chicken diets containing different levels of metabolizable energy. Experimental diets consisted of two different levels; high energy diet (HE) and low energy diet (LE, 100kcal lower than HE diet, ME in HE diet: phase 1, 2950 kcal/kg; phase 2, 3100 kcal/kg) and the experimental treatments were: 1) LCON (low energy diet); 2) LNF (LCON + nutrifen 0.09%); 3) HCON (high energy diet); and 4) HNF (HCON + nutrifen 0.09%). There were 12 replications and 17 chickens per replication in each treatment. Results showed that HNF treatment enhanced body weight gain (431 vs. 398 g; 1523 vs. 1470 g; $P < 0.05$) compared with LCON treatment at d 14 and 28. There was no effect ($P > 0.05$) on carcass and meat quality among treatments. However, yellowness in high energy level diets was increased (HCON and HNF vs. LCON and LNF: 8.53, 8.55 vs. 7.95, 7.69; $P = 0.036$) compared with that in low energy level diets. Digestibility of dry matter in nutrifen treatments was higher (LNF and HNF vs. LCON and HCON: 77.43, 77.70 vs. 74.95, 75.47%; $P = 0.025$) than that in CON treatments. As to nitrogen digestibility, HNF treatment was higher (67.87 vs. 64.90%; $P < 0.05$) compared with that in LCON treatment. Total cholesterol in LNF treatment was decreased (106.8 vs. 117.8, 118.9mg/dL; $P < 0.05$) than that in LCON and HCON treatments. Also, total cholesterol of chickens fed with nutrifen diets was decreased (LNF and HNF vs. LCON and HCON: 106.8, 114.1 vs. 117.8, 118.9 mg/dL; $P < 0.05$) compared with those fed with CON diets. Ammonia gas emission in LNF treatment was decreased (34.8 vs. 42.9, 40.3 ppm; $P < 0.05$) than that in HCON and HNF treatments. Moreover, low energy level treatments were decreased (LCON and LNF vs. HCON and HNF: 38.8, 34.8 vs. 42.9, 40.3 ppm; $P = 0.003$) excreta ammonia gas emission compared with high energy level treatments. No interaction effect was observed in this trial. These results showed that adding nutrifen at a level of 0.09% in diet can improve the growth performance, nutrient digestibility, blood cholesterol contents of broiler chickens.

Key Words: broiler chickens, energy level, growth performance, nutrifen

---

1324 (T187) Effect of fermented organic rare earth (ORE) on growth performance, nutrient digestibility, blood profiles, meat quality, relative organ weight, excreta microflora, and noxious gas emission in broiler chickens. Y. Liu, S. D. Upadhaya, and I. H. Kim*, *Dep. of Animal Science, Dankook University, Cheonan, South Korea.*

This study was to evaluate the effect of fermented organic rare earth (ORE) in broiler chickens. A total of 765 ROSS 308 1-d-old broilers, BW of 48.97 ± 0.11 g, were used in this 4-wk feeding trial, 1 to 14 d for starter and 15 to 28 d for finisher. Dietary treatments included 1) NC (Basal diet, free antibiotics diet), 2) ORE1 (NC + fermented ORE 0.05%), 3) ORE2 (NC + fermented ORE 0.10%), 4) ORE3 (NC + fermented ORE 0.15%), and 5) PC (Antibiotics diet, NC + tiamulin 0.1%). All birds were allotted into one of five treatments with nine replications (17 birds per replication) in a completely randomized design. At the starter stage, feed intake (FI) was increased (1.250 vs. 1.284; $P < 0.05$) in ORE2 compared with NC. At the finisher stage, BW gain (BWG) tended to increase (NC, ORE1, ORE2, ORE3: 953, 973, 976, 992 g; linear, $P = 0.061$) as the level of fermented ORE increased in the diets. The FCR in PC was improved (1.699 vs. 1.764, $P < 0.05$) compared with the NC. At the end of the trial, DM (78.31 vs. 75.52%; $P < 0.05$; linear, $P = 0.050$) and GE (79.96 vs. 76.61%; $P < 0.05$; linear, $P = 0.010$) in treatment ORE3 increased compared with NC, and they also increased as the level of fermented ORE increased in the diets. The DM digestibility in PC was higher (78.49 vs. 75.52%; $P < 0.05$) than that in NC. The pH value of breast muscle in ORE2 increased (5.58 vs. 5.41; $P < 0.05$) compared with PC. Yellowness (NC, ORE1, ORE2, ORE3: 15.51, 15.34, 16.14, 17.17; linear, $P = 0.003$) increased with the increasing amount of fermented ORE in the diets. And the lower value of drip loss was observed in broiler chickens fed the diet with 0.15% fermented ORE (3.14 vs. 4.32%; $P < 0.05$) than PC treatment. There was a tendency to increase the weight of liver (NC, ORE1, ORE2, ORE3: 2.95, 2.86, 3.23, 3.23; $P < 0.01$) as the amount of fermented ORE increased in the diet. However, there was no influence on the relative organ weight, excreta microflora, and noxious gas emission. In conclusion, the results from this study demonstrate that feeding

0.10 or 0.15% fermented ORE improved growth performance, nutrient digestibility, and meat quality in broiler chickens.

Key Words: broiler chicken, excreta microflora, fermented organic rare earth, growth performance, meat quality, nutrient digestibility

1325 (T188) Apparent total tract digestibility and Ileal digestibility of dry matter, nitrogen, energy and amino acids in conventional, *Bacillus subtilis* fermented and enzyme treated soybean meal fed to weanling pigs. H. Yun, E. Balolong Jr., and I. H. Kim*, *Dep. of Animal Science, Dankook University, Cheonan, South Korea.*

This experiment was conducted to determine the apparent total tract digestibility (ATTD), apparent ileal digestibility (AID) and standardized ileal digestibility (SID) dry matter, nitrogen, energy and amino acids of six soybean products. The products were soybean meal (SBM), fermented soybean meal A (FSMA), fermented soybean meal B (FSMB), fermented soybean meal C (FSMC), enzyme treated soybean meal (ETSM) and speciality soya protein (HP300). There are six treatments: SBM, FSMA, FSMB, FSMC, HP300 and N-free dietary treatments. In the experiment, six [(Landrace × Yorkshire) × Duroc] weanling barrows with average BW 8.99 ± 0.40 kg were surgically equipped with simple T-cannulas approximately 15 cm before the ileo-cecal junction and allowed to a 6-wk feeding trial. Results of the experiment showed that FSMC and HP300 had the greatest (90.03, 89.35%; $P < 0.05$) ATTD for most AA, but the ATTD for Arg, Ile, Lys, Met and Phe in FSMB similar to FSMC. Piglet fed FSMC and HP300 had higher (89.02, 88.86 vs. 85.84%; 88.19, 87.69 vs. 84.42%; $P < 0.05$) DM and energy digestibility compared to SBM. AID of DM, N and energy and total AA in FSMB, FSMC and HP300 were higher (82.40, 82.71, 82.59 vs. 78.45%; 82.54, 83.24, 82.95 vs. 79.33%; 81.26, 82.27, 81.68 vs. 76.77%; 80.90, 81.45, 80.78 vs. 77.83%; $P < 0.05$) than SBM in which the value was highest in the FSMC diet. The AID of Isoleucine was greater in pigs fed FSMB and HP300 than in FSMA. The AID of Arg, Leu, Phy and Val in FSMC was greatest of all the other soybean meals. The AID of Lys (74.73%) and total AA (77.90%) in FSMA was the least ($P < 0.05$) among the entire soybean products, but the AID for most other AA in FSMA was not different from the value of AID of AA in SBM. The SID of His (82.28%), Lys (78.65%) and total AA (82.34%) in FSMA was the least ($P < 0.05$) among all the protein sources but SID for most other AA in FSMA was not different from the SID of AA in SBM. In conclusion, dietary supplementation of FSMC and/or HP300 can improve the ATTD, AID and SID of DM, N, energy, total AA and most of the essential amino acids in weanling pigs.

Key Words: amino acids, apparent ileal digestibility, apparent total tract digestibility, fermented soybean meal, hamlet protein, weanling pigs

1326 (T189) Effect of bromelain supplementation on growth performance, nutrient digestibility, blood profiles, fecal score, fecal microflora and noxious gas emission in sows and piglets. M. Jung, Y. Lei, and I. H. Kim*, *Dep. of Animal Science, Dankook University, Cheonan, South Korea.*

This study was conducted to investigate the effect of dietary bromelain on growth performance, nutrient digestibility, blood profiles, and fecal microflora of sows and piglets. Twenty sows (Landrace × Yorkshire) were randomly assigned to three dietary treatments. Dietary treatments included: 1) CON (basal diet), 2) T1 (basal diet + 0.05% Bromelain), 3) T2 (basal diet + 0.10% Bromelain), 4) T3 (basal diet + 0.20% Bromelain). Individual piglet BW was assessed on d 0, 7, 14, and 21 (weaning), and 7 d after weaning to calculate ADG. Fecal *Lactobacillus* and *E. coli* shedding were measured by using MacConkey agar plates and lactobacilli medium III agar plates. No difference ($P > 0.05$) was observed on body weight loss, parity, litter number, weanling pig number, backfat, estrus interval and ADFI in sows. The birth weight of litter from CON treatment was lower (1.343 vs. 1.510, 1.491 kg; $P < 0.05$) compared with T2 and T3 treatments and the piglets of T3 group also had higher (6.953 vs. 6.073 kg; $P < 0.05$) weanling weight compared with CON group. Moreover, T3 treatment had a higher (212 vs. 182 g; $P < 0.05$) ADG than CON treatment. However, there is no difference ($P > 0.05$) in piglet survival rate and stillbirth rate among treatments. After weaning of piglets, the ATTD of N in sows fed with T3 diet was higher (68.95 vs. 63.96, 64.55%; $P < 0.05$) compared with sows fed with CON and T1diets. The ATTD of E and DM showed no difference ($P > 0.05$) among treatments. The blood BUN of sows in T3 group was lower (12.0 vs. 15.7 mg/dL; $P < 0.05$) compared with CON group. Moreover, the BUN of piglets in T3 group was lower (12.6 vs. 15.9 mg/dL; $P < 0.05$) compared with T1 group. There was no difference ($P > 0.05$) in WBC, RBC, lymphocyte, IgG and ceatinine observed among treatments in sows and piglets. The fecal *Lactobacillus* of sows fed with T2 and T3 diets were higher (7.39, 7.40 vs. 7.28 $\log_{10}$cfu/g; $P < 0.05$) compared with sows fed with CON diet. Moreover, the fecal *E. coli* concentration of sows fed with T2 and T3 diets were lower (6.26, 6.28 vs. 6.57 $\log_{10}$cfu/g; $P < 0.05$) compared with sows fed with CON diet. In conclusion, the addition of 0.2% Bromelain in the diet can improve weaning BW in piglets and increase nutrient digestibility of sows during lactating period.

Key Words: Bromelain, performance, piglet, sow

1327 (T190) Effect of Calsporin on growth performance, nutrients digestibility, organ weight, meat quality and excreta and intestinal microflora and slurry noxious gas emission in broiler chickens. H. Beak, H. L. Li, and I. H. Kim*, *Dep. of Animal Science, Dankook University, Cheonan, South Korea.*

This study was conducted to determine the effect of dietary Calsporin supplementation on growth performance, nutrient digestibility, relative organ weight, meat quality, intestinal microbial flora, and slurry noxious gas emissions in broilers. A total of 816 1-d-old male ROSS 308 broilers (BW of 46.06 g ± 0.67 g; 16 pens/treatment and 17 broilers/pen) were used in a 5-wk study. Broilers were randomly allotted to 1 of 3 dietary treatments and Calsporin BBS, which contains 1×10^9 CFU/g *Bacillus subtilis* C-3102.: T1) CON, basal diet, T2) CON + 300 ppm Calsporin (3×10^5 CFU/g), and T3) CON + 600 ppm Calsporin (6×10^5 CFU/g). The T3 enhanced BW gain (BWG) (700 vs. 658 g; $P < 0.05$) compared with the CON treatment during the d 8 to 21. During d 22 to 35, T3 showed greater BWG (843 vs. 801 g; Linear, $P < 0.05$) and better feed conversion ratio (FCR) (1.665 vs. 1.792; Linear, $P < 0.05$) than those in CON. The FCR (1.686 vs. 1.792; Linear, $P < 0.05$) in T2 was linearly improved compared with CON. In the overall period, the BWG (1630, 1662 vs. 1573 g; $P < 0.05$) and the FCR (1.544, 1.534 vs. 1.624; $P < 0.05$) in T2 and T3 were higher than the control. The apparent total tract digestibility (ATTD) of dry matter (DM) (73.43 vs. 76.54, 77.20%; $P < 0.05$) and energy was linearly increased (75.34 vs. 78.83, 79.87%; $P < 0.05$) by Calsporin inclusion in the diet. Slurry NH3 emissions were linearly reduced (9.9 vs. 8.2, 7.8 ppm; $P < 0.05$) by dietary supplementation of Calsporin. The *Lactobacillus* counts in cecum and ileal were linearly (6.25, 6.59, 7.16 $\log_{10}$cfu/g; $P < 0.05$) increased by Calsporin inclusion in the diet. Dietary supplementation of Calsporin linearly reduced *E. coli* counts in cecum (6.12, 5.74, 5.43 $\log_{10}$cfu/g; $P < 0.05$) *Cl. Perfringens* counts in large intestine (3.14, 2.97, 2.86 $\log_{10}$cfu/g; $P < 0.05$) and excreta (3.31, 3.17, 3.03 $\log_{10}$cfu/g; $P < 0.05$), and *Salmonella* counts in cecum (2.66, 2.23, 2.13 $\log_{10}$cfu/g; $P < 0.05$), ileal (2.87, 2.58, 2.42 $\log_{10}$cfu/g; $P < 0.05$), large intestine (3.04, 2.59, 2.44 $\log_{10}$cfu/g; $P < 0.05$) and excreta (2.88, 2.76, 2.61 $\log_{10}$cfu/g; $P < 0.05$). In conclusion, results indicate that Calsporin inclusion can improve BWG and FCR, increase cecum *Lactobacillus* counts and reduce intestinal *E. coli, Cl. Perfringens* and *Salmonella* counts, especially at 6×10^5CFU/g.

Key Words: growth performance, probiotics, fecal microbial, broilers

1328 (T191) Evaluation of Korean aged garlic extract (AGE) by *Leukonostoc citreum* SK2556 on production achievement, meat quality, relative organ weight, targeted *Escherichia coli* colony, slurry gas emission and hematological profiles in broilers. *J. W. Park, S. D. Upadhaya, and I. H. Kim*, Dep. of Animal Science, Dankook University, Cheonan, South Korea.*

The aim of this study was to investigate the effects of dietary supplementation of Korean aged garlic extract (AGE) fermented by *Leukonostoc citreum* SK2556 on growth performance, meat quality, excreta microbiota, slurry gas emission and blood profiles in broilers. A total of 765 broilers were randomly allotted to 5 treatments with 9 replications per treatment and 17 chicks per pen in this 5-wk trial. The experiment lasted for 5 wk and dietary treatments were as follows: 1) NC (basal diet, no antibiotics); 2) PC (NC + 5ppm enramycin); 3) AGE1(NC + 0.05% aged garlic extract); 4) AGE2 (NC + 0.1% aged garlic extract); 5) AGE3 (NC + 0.2% aged garlic extract). The broilers were weighed and feed intake were recorded on d 1, 14, 28, and 35 for calculating BW gain (BWG), feed intake (FI), and feed conversion ratio (FCR). All data were subjected to GLM procedures of SAS (1996) as a randomized complete block design, with pen as the experimental unit. Differences among treatments were separated by Duncan's multiple range test; $P < 0.05$ was considered statistically significant. Broiler fed with AGE2 treatment showed significantly higher ($P < 0.05$) disparity in BWG compared to NC treatment (910 g vs. 842 g) at the d 15 to d 28. In the same time, FCR was higher ($P = 0.0454$) in NC (1.95) treatment compared with AGE3 (1.83) and AGE2 (1.81). Growth performance was increased in AGE3 (1756 g) and AGE2 (1735 g) than NC (1638 g) diet ($P < 0.05$) though FCR value was decreased ($P = 0.012$). Liver weight was decreased in AGE3 (28.27%) and AGE2 (28.27%) compared to NC (40.60%) treatment ($P = 0.0478$). On analyzing of different profiles of breast meat, only redness (a*) was improved in NC treatment than AGE2 (15.94 vs. 12.23; $P < 0.05$). With regards to *E. coli* load ($\log_{10}$cfu/g), broiler fed NC (6.70) showed distinctly higher count than AGE2 (6.54; $P < 0.05$). The percentage of lymphocyte in blood presented higher in numeric value in AGE1 treatment which was followed by PC, AGE2, NC and AGE3 respectively ($P > 0.05$). In conclusion, our findings demonstrated that the administration of AGE at a level of 0.1 and/or 0.2% can improve body weight gain but reduce the FCR, liver weight as percentage, and *E. coli* load without significant change in other criteria in broiler.

Key Words: aged garlic extract, broilers, *Leukonostoc citreum* SK2556, enramycin, growth performance, microflora

1329 (T192) The effect of vitality mineral liquid complex on production performance, nutrient digestibility, blood characteristics, egg quality and excreta microflora in laying hens. M. Mohammadi Gheisar, J. P. Lee, and I. H. Kim*, *Dep. of Animal Science, Dankook University, Cheonan, South Korea.*

A total of 360 Hy-line brown laying hens (40-wk-old), were used in this 5-wk experiment to evaluate the effect of vitality mineral liquid complex on production performance, nutrient digestibility, blood characteristics, egg quality, and excreta microflora in laying hens. Laying hens were randomly allocated into 5 dietary treatment groups which consisted of: 1) CON (normal water), 2) I2 (pH 2.2, Ion water), 3) P2 (pH 2.2, polymerization water), 4) I3 (pH 3.0, Ion water), and 5) P3 (pH 3.0, polymerization water). In this study, feed intake and egg broken rate was unaffected ($P > 0.10$), but egg production was increased in I3 and P3, respectively, when compared to CON treatment (96.63, 96.45 vs. 94.55; $P < 0.05$) at wk 3, egg production in P3 was higher (96.85 vs. 94.74; $P < 0.05$) than CON treatment at wk 5. Nutrient digestibility of the Ca in P2, I3, and P3 treatment, respectively, was higher (56.50, 57.58, 55.27 vs. 51.15%; $P < 0.05$) than CON treatment. The blood profile of calcium counts was increased (26.05, 27.23, 27.70 vs. 22.45; $P < 0.05$) in P2, I3, and P3 treatments compared with CON treatment and phosphorus counts was improved (5.28 vs. 4.58; $P < 0.05$) in I3 treatments compared with CON treatment. Moreover, effect of vitality mineral liquid complex improved the eggshell thickness (40.44 vs. 39.72 mm^{-2}; 40.59 vs. 39.68 mm^{-2}; $P < 0.05$) with P3 treatment at 4 and 5 wk of trial. The inclusion of I3 and P3 diets showed a lower (2.24, 2.19 vs. 2.40 log_{10}cfu/g; 6.24, 6.20 vs. 6.50 log_{10}cfu/g; $P < 0.05$) amount of excreta *Salmonella* and *E.coli* counts compared with CON diets. Our results indicated the vitality mineral liquid complex improve the egg production, calcium, phosphorus counts in blood, and decrease the *Salmonella* and *E.coli* counts in laying hens.

Key Words: Egg production, egg quality, laying hens, mineral, nutrient digestibility

1330 (T193) Effects of nutrifen on growth performance, nutrient digestibility, blood profiles, fecal microflora, fecal gas emission, and fecal score in weanling pigs. D. Jung*, H. L. Li, and I. H. Kim, *Dep. of Animal Science, Dankook University, Cheonan, South Korea.*

A total of 135 weanling pigs (7.96 ± 1.03kg; 28 d of age) were used in a 42-d feeding trial to evaluate the effect of nutrifen on growth performance, apparent total tract digestibility (ATTD), blood profiles, fecal microflora, fecal gas emission and fecal score. Pigs were randomly distributed into 1 of 3 treatments on the basis of BW (9 replicate pens per treatment with 5 pigs per pen). Dietary treatments were: CON, basal diet; NF1, basal diet + 0.1% nutrifen; NF2, basal diet + 0.2% nutrifen. The diets were fed during the experiment in 2 phases: d 0 to 14, and 15 to 42. All diets, in mash form, were formulated to meet or exceed the nutrient requirements (NRC, 2012) for weanling pigs. Feed intake, BW and incidences of diarrhea were monitored at d 14 and 42. Incidences of diarrhea were monitored using a fecal scoring system. At the end of each phase two pigs per pen were bled for serum and fresh fecal samples were collected to determine nutrient digestibility and noxious gas emission. Average daily gain (ADG) was greater (337, 338 vs. 316 g; $P < 0.05$) in nutrifen supplemented pigs during d 0 to 14. During d 14 to 42, ADG and Gain:Feed ratio (G:F) was higher in NF2 treatment compared with that of CON. ADG and G:F was greater (500, 509 vs. 481 g, $P < 0.05$; 0.699, 0.714 vs. 0.676, $P < 0.05$) in nutrifen supplemented pigs during d 0 to 42. Energy digestibility was higher (82.56, 83.13 vs. 79.05%; $P < 0.05$) in nutrifen supplemented pigs compared to CON at d 42. At d 42, pigs fed with NF2 diet had lower (4.83 vs. 6.45 $10^6/\mu\lambda$; $P < 0.05$) blood RBC concentration compared with those fed CON. IgG concentration was greater (525, 532 vs. 499 mg/dL; $P < 0.05$) in nutrifen treatments compared with that of CON. HDL-cholesterol concentration in NF2 treatment higher (40 vs. 33, 34 mg/dL; $P < 0.05$) compared with that in other treatments. The fecal *Lactobacillus* and *E. coli* counts, and fecal score showed no difference ($P > 0.05$) among treatments. The ammonia emission concentration in NF2 treatment decreased (9.7 vs. 13.6 ppm; $P < 0.05$) compared with that in CON treatment. In conclusion, nutrifen could increase growth performance, energy digestibility, IgG and HDL-cholesterol, decrease fecal gas emission without impact on fecal microflora and fecal score in weanling pigs.

Key Words: blood profiles, growth performance, nutrient digestibility, nutrifen, weanling pigs

1331 (T194) Effect of rare earth element-yeast on egg production, nutrient digestibility, egg quality, blood profiles, excreta gas emission, and excreta microbiota in laying hens. J. H. Cho*, L. Cai, and I. H. Kim, *Dep. of Animal Science, Dankook University, Cheonan, South Korea.*

Rare earth elements (REE) are considered as an alternative to antibiotic because they have the similar action to antibiotic. Rare earth elements–yeast, an improved form of organic REE, may be more effective when fed to livestock because of the lower REE concentration. The objective of this study was to determine the effects of REE–yeast on egg production, nutrient digestibility, egg quality, blood profiles, excreta gas emission, and excreta microbiota in laying hens. A total of 216 ISA brown laying hens at 52 wk of age were used in this 5-wk feeding trial. Treatments consisted of soybean meal based diets supplemented with 0, 0.05, and 0.1% REE–yeast. All birds were allotted to one of three treatments with six replicates (12 hens per replication). All diets were formulated according to

recommendations of the manual of the breeder for ISA brown and to meet NRC (1994). During wk 1 and 2, laying hens fed 0.05% and 0.1% REE-yeast had a higher egg production (90.33, 92.67 vs. 87.00%; 90.33, 92.50 vs. 86.67%; $P < 0.01$) than those fed diets without REE-yeast and egg production improved (linear, $P < 0.01$) as dietary REE-yeast increased in the diet. During wk 3, 4, and 5, laying hens fed 0.1% REE–yeast had a higher egg production (92.50 vs. 86.83%; 92.33 vs. 86.33%; 92.17 vs. 85.67%; $P < 0.05$) than those fed without REE–yeast. Nitrogen digestibility (65.22, 66.31, 69.22%; linear, $P = 0.03$) increased with increasing REE–yeast levels in the diet, and the greatest value was observed in laying hens fed 0.1% REE yeast. In wk 4, laying hens fed REE–yeast had higher yolk height (9.25, 9.58, 9.72 mm; linear, $P < 0.01$) and Haugh unit (92.79, 96.63, 97.11; linear, $P = 0.01$) increased with increasing REE-yeast in diets. In wk 5, Haugh unit (94.53, 97.17, 95.60; $P < 0.05$) increased quadratically with increasing REE–yeast levels in the diet. At the end of experiment, ammonia tended to decrease linearly (15.25, 13.25, 12.75 ppm; $P < 0.1$) with increasing REE–yeast in the diet. However, effects were not observed in blood profiles and excreta microbiota. In conclusion, dietary supplementation with REE–yeast improved egg production, nutrient digestibility, and egg quality in laying hens.

Key Words: egg production, egg quality, laying hen, nutrient digestibility, rare earth elements–yeast

1332 (T195) Effects of *Bacillus subtilis* on growth performance, relative organ weight, meat quality, salmonella population, and blood profiles in broilers.

J. H. Cho*, M. Begum, and I. H. Kim, *Dep. of Animal Science, Dankook University, Cheonan, South Korea.*

A total of 720 male and female ROSS308 broiler chicken (1 d old, initial BW 46.12 ± 0.51 g) were used in this 4-wk trial (5 treatments with 9 replications/treatment and 16 chicks/pen). Dietary treatments were: 1) CON (basal diet), 2) A (CON + 0.1% *Bacillus subtilis B2A* 1.0×10^9 cfu), 3) B (CON + 0.1% *Bacillus subtilis B2A* 1.0×10^7 cfu), 4) C (CON + 0.1% *Bacillus subtilis B2A* 1.0×10^8 cfu), and 5) D (CON + 0.1% *Bacillus subtilis B2A* 1.0×10^9 cfu). The broilers were weighed and feed intake were recorded on d 1, 8, 18, and 28 for calculating body weight gain (BWG), feed intake (FI), and feed conversion ratio (FCR). All data were subjected to GLM procedures of SAS (1996), with pen as the experimental unit. Differences among treatments were separated by Duncan's multiple range tests; $P < 0.05$ was considered statistically significant. During 1 to 8 d, BWG was higher (163 vs.149 g; $P < 0.05$) in treatments D compared with treatment A. During 19 to 28 d, FI (1359 vs. 1242 g) and FCR were higher (1.776 vs. 1.613; $P < 0.05$) in CON compared with treatment D. Overall (1 to 28 d), birds from CON treatment had higher ($P < 0.05$) FI (2286 vs. 2126 g) and FCR (1.658 vs. 1.538) than D treatment. The drip loss of birds from treatment A was lower (3.14 vs. 6.18%; $P < 0.05$) than that of treatment C on d 1. No difference ($P > 0.05$) was observed in relative organ weight and blood profiles among treatments. However, the salmonella populations in chicken fed with CON diet was higher (3.88 vs. 2.73, 2.83, 2.64, 2.75 $\log_{10}$ cfu/g; $P < 0.05$) compared with those fed with other four diets in large intestine. Moreover, the salmonella populations in CON treatment was higher (2.67 vs. 2.18 $\log_{10}$cfu/g; $P < 0.05$) than that in treatment B in small intestine. In conclusion, *Bacillus subtilis B2A* partially improved FCR, while decreasing salmonella populations in big or small intestine without any adverse effect on relative organ weight and blood profiles in broilers.

Key Words: *Bacillus subtilis*, blood profiles, broilers, growth performance, meat quality, salmonella populations

1333 (T196) The effect of *Salicornia herbacea* and *Dendropanax morbifera* on the growth performance, meat quality, fecal microbial population and fecal noxious gas emission in broilers.

J. P. Lee, M. M. Hossain, and I. H. Kim*, *Dep. of Animal Science, Dankook University, Cheonan, South Korea.*

This experiment was conducted to examine the effect of *Salicornia herbacea* and *Dendropanax morbifera* as a phytogenic additive on performance, carcass traits, fecal microbial population and fecal noxious gas emission of broiler chicks. In this study, 680 1-d-old chicks (Ross 308) were allocated to five treatments with eight replicates (17 birds/replication) based on a completely randomized design. Diet was same for all treatments, but two different liquid phytogenic additives used as these treatments: CON, basal diet; SAL1, 1cc/l *S. herbacea*; SAL2, 5cc/l *S. herbacea*; SAL3, 10cc/l *S. herbacea*; DPM, 5cc/l *D. morbifera*.All broilers were fed maize-soybean meal-based diets that were formulated to meet or exceed the National Research Council (1994)nutrient recommendations. The broilers were weighed and feed intake were recorded on d 1, 7, 21, and 35 for calculating BW gain (BWG), feed intake (FI), and feed conversion ratio (FCR). At d 35, two birds were randomly selected from each replication (16 broilers/treatment) and slaughtered by cervical dislocation for meat quality. During d 8 to 21, broilers fed with SAL2, SAL3 and DPM diets increased (968.3, 987.5, 994.2 vs. 963.4 g; $P < 0.05$) BWG with those used CON treatment. During d 22 to 35, broilers fed with SAL1, SAL2 and SAL3 diets increased (729.0, 728.2, 729.3 vs. 684.4 g; $P < 0.05$) BWG compared with those used CON treatment. Overall, birds in CON treatment had the lowest BWG and highest feed conversion ratio at d 35, compared with SAL1, SAL2, SAL3 and DPM treatments (1820.4 vs. 1887.3, 1885.1, 1892.1, 1873.8 g; 1.468 vs. 1.388, 1.394, 1.383, 1.406; $P < 0.05$). The application of *S. Herbacea* and *D. Morbifera* had no significant effect on the

organ weights of chicken liver, breast muscle, gizzard, kidneys, or spleen, and was similar among all treatments. The relative weight of abdominal fat, however, was reduced (22.09, 21.30 vs. 29.55%; $P < 0.05$) in the treatments which were supplemented with *S. Herbacea* (SAL2 and SAL3) compared with that of the control. The result of excreta microbial analysis and fecal noxious gas emission did not show any significant effects. In conclusion, the result of this study showed that addition of *S. herbacea, D. morbifera* have a positive influence on growth performance and they can be considered as a growth promoter substitution for broiler chicks.

Key Words: broilers, *Salicornia herbacea, Dendropanax morbifera,* growth performance, meat quality

1334 (T197) The effect of salmonella inhibitors supplementation on egg production, egg quality, blood profiles, and excreta salmonella in laying hens.

J. H. Cho*, H. Shin, and I. H. Kim, *Dep. of Animal Science, Dankook University, Cheonan, South Korea.*

This study was conducted to investigate the effect of salmonella inhibitors supplementation on egg production, egg quality, blood profiles and excreta salmonella in laying hens. A total of 288 ISA-brown laying hens (40-wk-old) were selected for a 5-wk feeding trial. Hens were randomly allocated into 6 treatments with 4 replications per treatment, and 12 hens per replication, according to a completely randomized design. The experimental treatments included: 1) NC (basal diet), 2) PC (basal diet + 0.1% virginiamycin, antibiotics), 3) A (NC + 0.1% *Bacillus subtilis* 1.0×10^{10}cfu/kg), 4) B (NC + 0.1% *Bacillus subtilis* RX71.0 $\times 10^{10}$cfu/kg) and 5) C (NC + 0.1% *Bacillus subtilis* B2A 1.0×10^{10}cfu/kg), 6) D (NC+0.1% *Bacillus subtilis* RX7 1.0×10^{9}cfu/kg). Daily records of egg production and feed consumption were kept throughout the experimental period. Egg production was expressed as an average production of hen per day, which was calculated from the total number of eggs divided by the number of experimental time (week as a unit) and summarized on an average basis. All data were arranged to evaluate by analysis of variance following the GLM procedure in a completely randomized design using the SAS software program (SAS Institute, 1996). Laying hens were blocked with identical age. The difference among treatment was compared using the Duncan's multiple range tests. The treatment effect was observed significant with the probability value below 0.05. Egg production was higher (96 vs. 90, 91%; $P < 0.05$) in treatment B than in NC and PC treatments at 3 wk. Eggshell thickness was higher (40.87 vs. 40.24, 40.32 mm^{-2}; $P < 0.05$) in treatment D than in NC and PC treatments at 1 wk. B and D treatments had higher (41.17, 41.17 vs. 40.48, 40.51, 40.64, 40.53 mm^{-2}; $P < 0.0.5$) eggshell thickness than those in other treatments at 3 wk. But no differences ($P > 0.05$) on eggshell color, egg weight, yolk height, yolk color, haugh unit and eggshell strength were observed during the whole experiment.There was no difference ($P > 0.05$) in WBC, RBC, lymphocyte and haptoglobin among dietary treatments. Excreta salmonella was higher (2.59 vs. 2.23, 2.28, 2.28, 2.28, 2.29 $\log_{10}$cfu/g; $P < 0.05$) in NC treatment compared with those other treatments. In conclusion, dietary salmonella inhibitors have no effects on eggshell color, egg weight, yolk height, yolk color, haugh unit and eggshell strength and blood profiles in laying hens. However, *Bacillus subtilis* supplementation improved egg production, eggshell thickness and excreta salmonella in laying hens.

Key Words: egg production, eggshell thickness, excreta salmonella, laying hens, salmonella inhibitors

1335 (T198) Feed additives affects RNA expression in the brush border membrane in broilers.

M. F. Fernandez Alarcon*[1], J. P. Steibel[2,3], L. S. Antonio[4], R. Lunedo[1], G. Baldissera[1], R. L. Furlan[1], and L. R. Furlan[5], *[1]Dep. of Animal Morphology and Physiology, Sao Paulo State University, Jaboticabal, SP, Brazil, [2]Michigan State University, East Lansing, [3]Dep. of Fisheries and Wildlife, Michigan State University, East Lansing, [4]Dep. of Biological Sciences–Biochemistry, University of São Paulo, Bauru, Brazil, [5]Aquaculture Center, Sao Paulo State University, Jaboticabal, Brazil.*

Probiotics and essential oils have been investigated as replacements for antibiotic growth promoters (AGP) by improving the performance and gut health of chickens. However, studies reported contrasting responses from these additives in intestinal digestion and absorption. We investigated the effects of addition of *Bacillus subtilis* (probiotic), an essential oil blend (carvacrol, cinnamaldehyde, cineol and pepper extract) and their combination in the performance and expression of genes related to digestion and absorption in Coob broilers, by RT-qPCR. Basal diet was used as negative control and the avilamycin AGP as positive control. One thousand, three hundred twenty male broiler chicks from Coob strain were divided among five treatments, in six pens of 44 chicks each. Birds were raised following breeder's recommendations. Performance was assessed in terms of feed intake (FI), weight gain (WG) and feed conversion ratio (FCR) recorded at 7, 21, and 42 d of age. At these same ages, one bird per pen ($N = 6$), was slaughtered to collect the mucosa of the ileum for RT-qPCR analysis. The investigated genes were: aminopeptidase N (APN), sucrase isomaltase (SI), maltase-glucoamylase (MGA), intestinal transporter peptide-1 (*P*EPT1), transporter of glucose and galactose Na^+ dependent-1 (SGLT-1), glucose transporter, galactose and fructose independent Na^+-2 (GLUT -2) and ATP ase Na^+/K^+ (ATP1A-1). Except for an increased feed intake presented in birds fed probiotics in relation to fed AGP at 21 d, no differences were found in broiler performance during the experiment. Regarding gene expression, at 7 d, birds treated with AGP presented lower ($P < 0.05$) expres-

sion of ATP1A-1 mRNA than the negative control. At 21 d, birds fed with the combination of probiotics and essential oil showed lower mRNA concentration of MGAM than those fed with AGP. In addition, no difference was observed in gut gene expression at 42 d. The lack of difference in growth performance between treatments could be due to the environment in which the birds were raised, more hygienic than that normally found in poultry farms. Moreover the changes in ATP1A-1 and MGAM RNA expression observed herein highlight the role of feed additives in host gut enzymes and transporter gene expression. These results encourage analysis of brush border enzymes activity, jejunum morphometry and indirect absorption trials of glucose in the jejunum, which are underway.

Key Words: broiler, feed additives, gene expression, intestine, RT-qPCR

1336 (T199) Apparent digestibility of wheat bran nutrients with or without exogen enzymes addition in weaned piglets. J. C. Dadalt*, P. D. A. P. Ribeiro, G. D. V. Polycarpo, C. Gallardo, G. D. Ricci and M. A. D. T. Neto, *University of São Paulo, Pirassununga, Brazil.*

Non-ruminant animals have a limited capacity for food digestion with low digestibility as those with high fiber or phytic acid contents. Some researches indicated that enzyme additions may decrease the effects of antinutritional factors present in vegetable feedstuffs, improving its digestion and nutrient utilization. Using weaned piglets, this study evaluated the apparent digestibility of dry matter (DM), crude protein (CP), mineral matter, energy (DE) and, metabolizable energy (ME) and N retention of the wheat bran (WB) supplied or not with exogen enzymes. Twenty-five crossbred barrows with initial weight 9.35 kg ± 1.61 kg, were allotted in a completely randomized design under five treatments and five replicates. The experimental unit was represented by one pig within its respective metabolic cage. The experimental period was 10 d, in which 5 d for cage adaptation and 5 d for feces and urine collection. The treatments were: Control diet (CD); CD + 30% wheat bran (WB); CD + 30% WB + 200 mg/kg of carbohydrase (WB+Carb); CD + 30% WB + 50 mg/kg of phytase (WB+Phy); CD + 30% WB+ Carb + Phy (WB+Carb+Phy). The control diet was based on corn (61.33%), skim milk powder (10%) and dried whey (15%). The enzymes were commercial phytase (10,000 FTU/g), carbohydrase providing 10% of Galactomananase, 10% of Xilanase, 10% of β-glucanase, 60% of malted barley and 10% of α-galactosidase. Data were analyzed by ANOVA and LS Means using the GLM procedure (SAS Inst. Inc., Cary, NC). Significance was defined as $P < 0.05$. Carbohydrase and phytase combination improved the digestibility coefficients ($P < 0.05$) in most of the variables, excepting nitrogen retention which did not show statistical difference among treatments. Wheat bran without enzyme addition had lower values for DE and ME (2862 and 2804 kcal/kg), respectively. The higher values observed for DE and ME were: WB+Carb+Phy (3164 and 3082 kcal/kg) without statistical difference with WB+Carb (3098 and 3056 kcal/kg) ($P = 0.4785$ and $P = 0.9766$) and WB+Phy (3051 and 2996 kcal/kg) ($P = 0.0970$ and $P = 0.5421$) (values expressed on dry matter). Lower digestibility of CP was observed for WB and WB+Phy (72.52 and 73.98%) respectively, which statistical results were similar to WB+Carb diet (75.69%) ($P = 0.9324$). The enzymes showed an effective improvement on digestibility of wheat bran for young pigs after weaning.

Key Words: carbohydrase, metabolism, phytase

1337 (T200) Evaluating the effects of *Salicornia* extract on performance, egg quality and blood profile of laying hens. I. H. Kim*, H. L. Li, and M. M. Hossain, *Dep. of Animal Science, Dankook University, Cheonan, South Korea.*

An experiment was conducted to evaluate the effects of adding *Salicornia* extract to the drinking water of laying hens on their performance, egg quality, and blood profile. A total of 216 Hy-line Brown at the age of 40 wk were used in a 10-wk experiment. The birds were allotted into 3 experimental treatments and there were 24 replications per treatment with three birds per pen. Treatments consisted of CON (basal diet), T1 (1 cc *Salicornia* extract water per liter drinking water), and T2 (5 cc *Salicornia* extract water per liter drinking water). Daily records of egg production and feed consumption were kept throughout the experimental period. Egg production was expressed as an average production of hen per d, which was calculated from the total number of eggs divided by the number of experimental time (wk as a unit) and summarized on an average basis. A total of 42 salable eggs (no shell defects or cracks) were randomly collected biweekly from each treatment at 1700 h (three eggs per replication). The egg quality of the collected eggs was then determined at 2000 h on the day of collection. Laying hens were blocked with identical age. The difference among treatment was compared using the Duncan's multiple range test. The treatment effect was observed significant with the P value < 0.05. Addition of *Salicornia* extract to the drinking water of laying hens didn't show any negative effects on performance, egg quality, and blood profile. Treatments T1 and T2 increased egg production remarkably (86.3 vs. 89.0, 91.0%; $P < 0.05$) at the first wk compared with CON. Moreover, at last week, the egg production in T1 was significantly higher (91.3 vs. 86.0%; $P < 0.05$) than CON treatment. Birds in T2 treatment showed improved (111.2 vs. 110.6 g; $P < 0.05$) feed intake compared with CON at first week. The ratio of broken shell was decreased (7.6 vs. 11.3%; 8.3 vs. 12.1%; 7.8 vs. 10.6%; 9.2 vs. 11.1%; 8.6 vs. 13.6%; $P < 0.05$) in T2 treatment than that in CON treatment in 1, 4, 6, 8, and 10 wk. The results of this study showed that addition of *Salicornia* extract can improve the egg shell quality, thereby

decreasing the rate of breaking eggs and increasing the benefit of production in commercial farms.

Key Words: blood profile, breaking eggs rate, egg production, laying hens, *Salicornia*

1338 (T201) Effect of material bioconversion natural complex on the growth performance, nutrient digestibility, fecal microbiota, fecal score, fecal moisture and pH in weanling pigs. M. Jung, Y. Lei, and I. H. Kim*, *Dep. of Animal Science, Dankook University, Cheonan, South Korea.*

A total of 150 pigs [(Yorkshire × Landrace) × Duroc], BW of 6.57 ± 0.49 kg, were used in a 6-wk trial to investigate the effects of material bioconversion natural complex (STR) on growth performance, nutrient digestibility, fecal microflora, fecal score, fecal moisture, and pH in weanling pigs. STR is a propolis feed additive contained more than 60% propolis and 6% of total flavonoid in powder form and produced from fermentation of mulberry leaves and turmeric with bacterial of mulberry yellow mushroom. Pigs were randomly allocated into 1 of 5 dietary treatments on the basis of BW and sex [6 replicate pens per treatment with 5 pigs (2 gilts and 3 barrows) per pen]. Dietary treatments were: 1) NC (basal diet, free of antibioitics), 2) PC (NC + 3 ppm Tiamulin), 3) STR-1 (NC + 0.1% STR1), 4) STR-2 (NC + 0.1% STR2), 5) STR-3 (NC + 0.1% STR3). STR1, STR2, and STR3 contain 1.5, 3, and 6% of active complex powder, respectively. Apparent nutrient digestibility was measured following the procedures by the AOAC (2000). Throughout the experimental period, pigs fed with STR-2 and STR-3 diets had higher (487, 492 vs. 474 g; $P < 0.05$) ADG compared with pigs fed with NC diet and the G/F ratio of STR-3 treatment was higher (0.720 vs. 0.692; $P < 0.05$) than that of NC treatment. The apparent total tract digestibility (ATTD) of dry matter was higher (1 wk: 83.96 vs. 82.22%; 3 wk: 85.92 vs. 82.47%; 6 wk: 81.05 vs. 77.23%; $P < 0.05$) in STR-3 treatment than in NC treatment. The ATTD of nitrogen was higher (79.98, 78.69, 78.87 vs. 76.54%; $P < 0.05$) in STR-1, STR-2, and STR-3 treatments than in NC treatment at wk 3. The ATTD of energy was higher (83.75 vs. 82.23% and 82.70 vs. 79.23%; $P < 0.05$) in STR-3 treatment than in NC treatment at wk 1 and 6, respectively. The fecal score of pigs fed with STR-3 diet was lower (3.00 vs. 3.18; $P < 0.05$) compared with pigs fed with STR-2 diet during wk 4. Moreover, fecal *Escherichia coli* concentration of pigs fed with STR was lower (5.75, 5.75, 5.76 vs. 5.90 $\log_{10}$cfu/g; $P < 0.05$) compared with pigs fed with NC diet. In conclusion, inclusion of STR3 (an antibiotic free diet) at a level of 0.1% could increase growth performance, nutrient digestibility, and decrease fecal score and fecal microbiota in weanling pigs.

Key Words: growth performance, fecal score, nutrient digestibility, STR, weanling pig

1339 (T202) Effects of microencapsulated *Enterococcus faecalis* and enzyme supplementation on piglet response to an *Escherichia coli* (K88) challenge. H. S Chen[1,2], D. E Velayudhan*[1], A. K Li[3], Y. Z Feng[2], D. Liu[2], Y. L Yin[4], and C. M. Nyachoti[1], *[1]University of Manitoba, Winnipeg, Canada, [2]Institute of Animal Husbandry, Harbin, China, [3]Academy of State Administration of Grain, Beijing, China, [4]Institute of Subtropical Agriculture, Chinese Academy of Sciences, Changsha, China.*

The objective of this study was to determine the effect of dietary probiotic microencapsulated *Enterococcus faecalis* and multi-enzyme complex (MC) in enterotoxigenic *Escherichia coli* K88 (ETEC)-challenged piglets fed wheat-barley soybean based diets. Thirty-six, 21-d-old weanling pigs with an initial BW of 6.7 ± 0.6 kg were allotted in a completely randomized design to 4 dietary treatments; a wheat-barley soybean based negative control (NC) with no antimicrobial growth promoters (Diet A), NC + MC (Diet B), NC + probiotic (Diet C) and NC + MC + probiotic (Diet D). Piglets were housed individually in cages. Diets were formulated to meet or exceed NRC 2012 specifications for weaned pigs. MC supplied 500, 50, 400, 1200, 450, and 45 units of pectinase, cellulase, mannanase, xylanase, glucanase, and galactanase, respectively, per kg of diet. The probiotic was added at the rate of 10 mg (1.0×10^{11} cfu/g) per kilogram of diet. Pigs were acclimated to treatments for a 7-d period. On d 8, pigs were weighed, blood sampled for determining baseline immunological parameters (IL6 and TNF α) and then orally challenged with 6 mL (5×10^{10} cfu/mL) of the freshly grown ETEC K88 inoculum. At 6, 12, 24, 48, and 150 h post-challenge, blood samples were taken, performance measures and fecal consistency scores were recorded, and on d 14 all pigs were killed to obtain intestinal tissue and digesta samples to evaluate GIT morphology, microbial ecology, and immunological parameters. Data were analyzed using the PROC MIXED of SAS. No significant enzyme x probiotic interaction was observed for any of the parameters evaluated. During pre-challenge, pigs receiving enzyme, probiotic and combination of both improved the ADG ($P = 0.03$) by 49, 62, and 51% and G:F ($P = 0.04$) by 25, 32, and 32%, respectively. However, during the post-challenge period only a numerical improvement in G:F was observed for Diet C when compared with Diet A (0.70 vs. 0.59). Also, pigs fed Diet C had greater ($P = 0.05$) ileal villus height than those receiving the NC. Moreover, Diet C significantly reduced the severity of diarrhea ($P = 0.04$) by 12% during the challenge phase compared to pigs fed NC. In summary, the results indicate that dietary supplementation of microencapsulated *Enterococcus faecalis* in weaned pigs challenged with ETEC was effective in maintaining gut health and thereby controlling post-weaning diarrhea.

Key Words: *Escherichia coli,* probiotic, piglets

1340 (T203) Sodium alginate addition improves water stability and utilization of extrudated feed for farmed saltwater crocodiles (*C. porosus*).

M. Francis[1], T. J. Wester[*1], P. C. H. Morel[1], and B. H. P. Wilkinson[2], [1]*Institute of Veterinary, Animal and Biomedical Sciences, Massey University, Palmerston North, New Zealand,* [2]*Institute of Food, Nutrition and Human Health, Massey University, Palmerston North, New Zealand.*

Saltwater crocodile (*C. porosus*) farming in Papua New Guinea is an emerging industry that supplies high quality raw skins for fashion industries worldwide. Extrudated animal by-product feed (non-heat treated feed forced through a die at low pressure) is used to get a consistent high quality feed; however, this feed disintegrates quickly in water which leads to loss of nutrients, inefficient feed conversion ratio, and water contamination. We evaluated Na alginate as a binding agent to improve feed stability in water and determined its effect on nutrient availability in a digestibility trial. A 24-h in vitro water solubility test of exudated chicken by-product-based diets (35% minced chicken carcasses, 15% chicken blood, 5% poultry offal meal, 5% pulped eggs, 15% wheat millrun, and 25% supplement, as-fed basis) with and without 1.5% Na alginate and 1.9% $CaCO_3$ added showed the inclusion of Na alginate improved the dry matter retention in feed by 12.6-times ($P < 0.05$). These diets were then compared in vivo in a digestibility trial. Ten juvenile crocodiles (2.2 to 2.4 yr of age, 1.2 to 1.9 kg BW) were chosen from farm raised stocks and fed exudated chicken by-product-based diets with and without 1.5% sodium alginate and 1.9% $CaCO_3$ added. Animals were fed 2% BW for 12 d, with feces collected the last 5 d. Animals were then slaughtered and digesta sampled from the ileum. Acid insoluble ash was used as an internal marker. There were no differences in any amino acid, N (65.0 vs. 55.8%, SE = 12.2%), and organic matter (46.8 vs. 39.6%, SE = 12.8%) digestibility at the ileum between diets with and without alginate, respectively. However, fecal digestibility of organic matter (69.8 vs. 39.2% SE = 9.1%) and energy (72.2 vs. 44.4%, SE = 8.3%) were greater in alginate containing diets ($P < 0.05$). This shows that alginate addition does not have deleterious effects on digestion in crocodiles, and because it improves feed stability in water, should greatly enhance nutrient uptake and feed efficiency. Results will be used to formulate diets with increased feed utilisation and decreased feed wastage, with the ultimate goal of increasing economic return to Papua New Guinea while decreasing effluent discharge and pollution of the ecosystem.

Key Words: saltwater crocodile, ileal digestibility, sodium alginate

1341 (T204) Impact of allicin on enzyme activity, cytokine secretion, and gene expression dynamics in oxidative- and endotoxin-stressed porcine intestinal epithelial cells.

N. L. Horn[*1], G. Miller[2], K. M. Ajuwon[1], and O. Adeola[1], [1]*Dep. of Animal Sciences, Purdue University, West Lafayette, IN,* [2]*Biomatrix, Princeton, MN.*

Environmental stress and endotoxins can negatively affect gastrointestinal function by influencing cellular antioxidant systems, tight junctions, and inflammatory mediators. Allicin is a botanical derived from garlic that has anti-inflammatory and antioxidant properties. The objective of the current study was to determine if allicin could mitigate oxidative and endotoxin stress using an IPEC cell model. The experiment was arranged as a 2 × 2 x 2 factorial of allicin (0 or 40 μM), oxidative stressor, hydrogen peroxide (0 or 100 μM), and endotoxin stressor, lipopolysaccharide (0 or 10 μg/ml). Cells were incubated with allicin or lipopolysaccharide (LPS) for 18 h or with hydrogen peroxide for 3 h approximately 1 wk following confluency. Trans-epithelial resistance (TER), reactive oxygen species (ROS), antioxidant enzymes, interleukin 8 and 1 β (IL-8 and IL-1β), and tumor necrosis factor α (TNF-α) secretion were measured. Gene expression was measured by RT-PCR for cytokines IL-8, IL-1β, and TNF-α and tight junction proteins claudin 1 (CL-1), occludin (OC), and zonula occludens 1 (ZO-1). Treatment did not affect TER although addition of allicin to hydrogen peroxide- and LPS-treated cells reduced ($P < 0.05$) ROS. Allicin decreased superoxide dismutase (SOD) activity ($P < 0.001$), whereas hydrogen peroxide increased SOD activity ($P = 0.02$). Furthermore, addition of allicin to hydrogen peroxide-treated cells restored SOD activity similar to untreated cells ($P < 0.05$). Addition of allicin to hydrogen peroxide- and LPS-treated cells decreased catalase activity ($P < 0.05$). There was an increase in TNF-α and IL-8 gene expression due to LPS ($P < 0.001$) although there was no effect of hydrogen peroxide or allicin ($P > 0.05$). Experimental treatment had no effect on tight junction gene expression ($P > 0.05$). There was an increase ($P < 0.001$) in IL-8 secretion due to LPS which was further increased ($P < 0.05$) by addition of allicin to LPS-treated cells and hydrogen peroxide incubation increased ($P = 0.01$) TNF-α secretion. Based on the results from the current study, allicin can ameliorate oxidant effects of hydrogen peroxide and LPS as well as alter cytokine secretion in IPEC cells.

Key Words: allicin, hydrogen peroxide, lipopolysaccharide

1342 (T205) Evaluation of a new probiotic strain of *Bifidobacterium longum* subsp. *infantis* CECT 7210 to improve health status of weaning piglets orally inoculated with *Salmonella* typhimurium.
E. Barba-Vidal[*1], L. Castillejos[2], V. F. Buttow Roll[3], M. Rivero[4], J. A. Moreno Muñoz[4], and S. Martín-Orúe[1], *[1]Animal Nutrition and Welfare Service Dep. of Animal and Food Sciences Universitat Autònoma de Barcelona, Bellaterra, Spain, [2]Animal Nutrition and Welfare Service, Dep. of Animal and Food Sciences, Universitat Autònoma de Barcelona, Bellaterra, Spain, [3]Dep. of Animal Science, Faculty of Agronomy Eliseu Maciel, Federal University of Pelotas, Pelotas, Brazil, [4]Laboratorios Ordesa S. L., Parc Científic de Barcelona, Spain.*

A new probiotic strain of *Bifidobacterium longum* subsp *infantis* CECT 7210 (Laboratorios Ordesa, S.L.) was evaluated on an oral challenge against *Salmonella* typhimurium. Seventy-two animals (28 d old, 7.7 ± 1.27kg) were distributed during an experimental period of 16 d in 24 pens and 4 experimental groups in a 2 × 2 factorial design: with or without probiotic (10^9 CFU/day in 2-mL water suspension) and inoculated with *Salmonella* (5×10^8 CFU) or placebo. Animals were fed ad libitum a multicereal diet with selected protein sources (soybean meal 44, fishmeal and bovine sweet whey), without antibiotics and that met NRC 2012 requirements. The probiotic was administered orally and individually on a daily basis. Feed consumption and body weights were monitored during the whole experimental period. After an adaptation week the animals were challenged. From this moment onward fecal shedding of *Salmonella* [d 0, 1, 3, and 7 post-inoculation (PI)], fecal consistency (d 1, 2, 3, 5, and 7 PI) and rectal temperature (24 and 48 h PI) were assessed. On d 4 and 8 PI, one animal from each pen was euthanized and blood, intestinal content and tissue samples were collected. Blood was obtained to assess the inflammatory response (TNF-α and plasma Pig-Map); intestinal content to assess the presence of *Salmonella* in colon as well as fermentation products (lactic acid and volatile fatty acids) and tissue samples to evaluate microscopic ileal morphology. All parameters responded significantly to infection ($P < 0.05$). The administration of the probiotic tended to increase average daily gain (ADG) of the animals during the postinoculation period (d 0 to 7 PI; 145 vs. 226 g/d, $P = 0.067$) and increased the overall ADG (d 0–16; 90 vs.150 g/d, $P = 0.042$). Moreover, it significantly reduced febrile response of infected animals at 48h PI (39.48 vs. 39.06°C, Probiotic*Day, $P = 0.003$) and improved fecal consistency (1.62 vs. 1.95, $P = 0.014$). A reduction of *Salmonella* counts at 48 h ($P = 0.028$) and d 4 PI ($P = 0.056$) were also observed. In addition, the probiotic promoted an increase of ileal intraepithelial lymphocytes on d 8 PI (0.86 vs. 1.32, $P = 0.015$) and also a numerical reduction in TNF-α (87.70 vs. 72.11 pg/dL, $P = 0.12$). No significant changes in fermentation products were registered related to the probiotic ($P > 0.05$). Results demonstrate that oral administration of the probiotic *Bifidobacterium longum* subsp. *infantis* CECT 7210 improves growth, reduce clinical response and improve some immunitary parameters of pigs orally challenged with *Salmonella* typhimurium.

Key Words: probiotic, *Salmonella,* weaning, *Bifidobacterium*

1343 (T206) A standardized blend of capsicum oleoresin, cinnamaldehyde and carvacrol improves performance of lactating sows.
C. Oguey[1] and C. Bruneau[*2], *[1]Pancosma, Geneva, Switzerland, [2]Pancosma, St.-Hyacinthe, QC, Canada.*

The main concern in sow farming is to optimize progeny performance during suckling and minimize fertility concerns. In monogastric animals, a standardized blend of capsicum oleoresin, cinnamaldehyde and carvacrol (XT, XTRACT 6930, Pancosma) was shown to positively affect fat digestibility and immune modulation. Therefore, given these modes of action, XT should be beneficial to the performance of lactating sows. As scarce information is available on this matter, a study was designed to evaluate the effect of XT supplementation on performance of sows raised under commercial conditions. A total of 428 sows were randomly allocated from 15 d before farrowing until piglets' weaning to one of the two treatments: CT: basal diet and XT: basal diet supplemented with 100 g/t XT. Animals had ad libitum access to feed and water. Sows' ADFI during gestation and lactation, backfat loss during lactation and weaning to estrus interval were individually recorded. Piglet birth weight, number of piglets born alive, mummies and weaned, and piglets weights at birth and weaning were evaluated per sow. Results were statistically analyzed by ANOVA, using the treatment, the parity and their interaction as fixed effects. Results showed that XT did not affect sow ADFI during gestation and lactation, backfat loss, the numbers of piglets born alive and mummies, and piglets' weight gain during suckling ($P > 0.28$). However, the interaction treatment*parity had a significant impact on lactation ADFI ($P < 0.05$). More specifically, XT increased ADFI during lactation of primiparous sows compared to CT (+4.1%, $P < 0.05$). XT supplementation tended to increase the number of piglets weaned per sow (+0.2 piglets/sow, $P = 0.09$) and to reduce pre-weaning mortality (-15.8%, $P = 0.09$). Finally, XT significantly decreased the weaning to estrus interval by 2.2 d ($P = 0.04$). There results suggest that XT has the potential to improve sow performance during lactation under commercial conditions, through more piglets weaned per litter and improved fertility.

Key Words: phytonutrients, sow performance

1344 (T207) Zilpaterol hydrochloride improves growth performance of meat producer Japanese quails. H. Dávila-Ramos and J. C. Robles-Estrada*, *Universidad Autonoma de Sinaloa, Culiacan, México.*

Zilpaterol hydrochloride (ZH) is a β-adrenergic agonist that was approved in México (2002) and the United States (2006) to promote growth and carcass dressing in beef cattle. However has been tested in other species such as lambs and poultry. The objective of this experiment was determinate the effect of zilpaterol hydrochloride supplementation during 21 d on growth performance of meat producer Japanese quail (*Coturnix coturnix japonica*). Two hundred twenty Japanese quails (both sexes; 90.3 ± 1.19 g) were distributed in 20 birdcages with four treatments (five birdcages per treatment). Treatments consisted in different doses (0, 0.20, 0.25, and 0.30 mg/kg of live weight/d) of zilpaterol hydrochloride supplementation, the basal diet contained 55% ground corn grain and 35% soybean meal (24%CP and 2.9 Mcal/kg of ME). Quails were weighted weekly and adjusted zilpaterol dose. The results were analyzed with completely randomized design and comparing means of treatments with orthogonal contrasts and orthogonal polynomials. Zilpaterol supplementation increased final live weight (5.6%; $P \leq 0.01$), total weight gain (9.7%; $P \leq 0.01$), feed conversion (6.1%; $P \leq 0.01$) and feed intake (2.8%; $P = 0.02$). Similarly, supplementation with 0.30 mg/kg of live weight increases the final live weight, total weight gain and feed conversion ($P \leq 0.01$) when compared with control treatment, however this dose showed no changes in feed intake ($P = 0.24$). No significance difference ($P \geq 0.21$) were showed in all variables when compare minimum and maxim dose (0.20 vs. 0.30 mg/kg of live weight), neither differences were detected for linear ($P \geq 0.25$) and quadratic ($P \geq 0.14$) analysis. These results indicated that zilpaterol supplementation in meat producer Japanese quail improve the growth performance without changes between doses. Levels below 0.20 mg/kg live weight need to be tested to determine the max inclusion rate needed.

Key Words: zilpaterol hydrochloride, *Coturnix coturnix japonica*, growth performance

1345 (T208) Effects of increasing levels of curcumin on growth performance and immune response of nursery pigs. M. R. Bible*, S. D. Carter, H. Kim, and K. F. Coble, *Oklahoma State University, Stillwater.*

Curcumin (CUR), a curcuminoid in turmeric, has antimicrobial and anti-inflammatory properties that may be beneficial to pigs. Two experiments (Exp.) were conducted to determine the effect of increasing levels of CUR on growth performance and immune response. Pigs were weaned at 21 d, blocked by BW, and allotted randomly to dietary treatments (trts) in a randomized complete block design (RCBD). Each experiment utilized corn-soybean meal based diets with a 4-phase feeding program. Growth performance was calculated for d 0 to 21 and 0 to 42. Exp. 1 (6 reps/trt) used 168 pigs (6.2 kg) with the following trts: carbadox (55 mg/kg; AB), 12, 23, and 46 mg/kg of CUR. Exp. 2 (7 reps/trt) used 112 pigs (6.0 kg) with the following trts: carbadox (55 mg/kg; AB), 46, 93, and 186 mg/kg of CUR. On d 20, selected pigs were challenged with an *E. coli* lipopolysaccharide (LPS). Rectal temperatures (RT) were measured and blood collected for analysis of tumor necrosis factor-α (TNF-α) and C-reactive protein (CRP) at h 0 and 3, 6, 12, and 24 h post-injection (PI). Data were analyzed as a RCBD using a GLM/PROC MIXED. In Exp. 1, there were no differences ($P > 0.10$) in growth performance for d 0–21. Curcumin did not affect ($P > 0.10$) ADG, but decreased ADFI and improved G:F ($P < 0.08$) for d 0–42 compared to the AB. As CUR increased, ADFI decreased and G:F increased ($P < 0.08$; quad). In Exp. 2, ADG ($P = 0.09$; quad) and ADFI decreased ($P = 0.009$; linear) as CUR increased for d 0 to 21. Compared to the AB, CUR decreased ($P = 0.03$) ADFI. For d 0 to 42, CUR decreased ($P < 0.06$; linear) ADG and G:F; and decreased ($P < 0.04$) ADG and G:F compared to AB. For the LPS challenge in Exp. 1, there was a numerical decrease in TNF- α at h 3 PI followed by a decrease ($P = 0.05$; quad) in CRP at h 6 PI as CUR increased. For Exp. 2, increasing CUR decreased ($P < 0.07$; linear) RT at h 0 and 3 PI. As CUR increased, TNF-α tended ($P = 0.09$; linear) to increase at h 6 PI. However, CUR decreased ($P < 0.10$; linear) CRP at h 0, 3, 6, and 24 PI. Compared to the AB, CUR decreased ($P < 0.03$) CRP at h 0, 3, and 6 PI. When data were combined for both experiments, the optimum response in growth performance and immune response was between 46 and 93 mg/kg of CUR.

Key Words: curcumin, growth performance, immune response

1346 (T209) Mannan oligosaccharides and β-glucan in diets for weaned piglets. U. V. Luna*, J. G. Caramori Junior, G. S. S. Corrêa, S. D. Assis, E. Brusamarelo, J. C. R. Ribas, M. A. Souza, A. B. Corrêa, B. S. Vieira, E. Rovaris, and S. A. P. V. Barbosa, *Federal University of Mato Grosso, Cuiabá, Brazil.*

The objective of this study was to evaluate the effect of supplementation with mannan oligosaccharides, β-glucan and antibiotic in diets for castrated male piglets during the nursery phase (21 to 54 d of age) on performance, morpho-histological characteristics of the intestinal mucosa and occurrence of diarrhea. A total of 368 piglets of the same strain, weaned to 21 d of age, with average weight of 6.9 kg were distributed in a completely randomized design with four treatments: 1) control [basal diet without supplementation: 36.05% corn, 18.4% Soybean meal (45%), 2.9% Soybean oil, 2.5% Crystal sugar, 40% de Pig Mix e 0.15% kaolinite); 2) basal diet + 1500 g mannan oligosaccharides/t of diet; 3) basal diet + 500 g β-glucan/t of diet; and 4) basal diet + 250 g colistin/t of diet. These were used with four replications with 23 animals per experimental unit. The man-

nan oligosaccharides and β-glucan were extracted cell wall of yeas *Saccharomyces cerevisiae*. The piglets were weaned to 21 d of age, heavy and distributed in experimental unit. Performance was assessed through weight gain, feed intake and feed conversion. The morpho-histological characteristics of the intestinal mucosa studied were villus height, intestinal crypt depth, villus circumference and villus height:crypt depth of duodenum, jejunum and ileum ratio. The occurrence of diarrhea was observed daily by the evaluation of fecal score. Not there was a difference for weight gain (P = 0.0750; averages: 14.000, 13.635, 14.018, 12.605 kg), feed intake (P = 0.1574; averages: 28.053, 28.577, 29.202, 26.920 kg) and feed conversion (P = 0.2239; averages: 2.005, 2.098, 2.084, 2.134 kg) the piglets the diets receiving control, mannan oligosaccharides, β-glucan and antibiotic, respectively. Thus, it is concluded, that the use of mannan oligosaccharides, β-glucan and antibiotic in the diet of castrated male piglets in the nursery phase did not affect performance and occurrence of diarrhea. The use β-glucan increases villus height and crypt depth in the duodenum and ileum and the villus circumference the jejunum.

Key Words: additives, diarrhea, intestinal morphology

NONRUMINANT NUTRITION: EVALUATION OF FEED INGREDIENTS FOR MONOGASTRIC DIETS

1347 (W165) Nutritional value of macauba pulp presscake (*Acrocomia aculeata*) for growing pigs. *J*. H. B. Pereira[1], S. L. S. Cabral Filho[1], C. G. D. Q. Roriz[1], C. B. Bernardes[1], T. M. Barbosa[1], L. R. Roos[1], A. P. Santana[1], J. B. Lopes[2], and L. S. Murata[*1], *[1]University of Brasilia, Brazil, [2]Federal University of Teresina, Brazil.*

The aim of this study was to determine the apparent digestibility coefficients of the dry matter (DCDM), crude protein (DCCP) and fiber (DCFB). Also, we aimed at determining the apparent digestible (DE) and metabolizable energy (ME) in macauba pulp presscake (*Acrocomia aculeata*) for pig feeding. The apparent digestibility of dry matter (DM), crude protein (CP), fiber (NDF), DE and ME of treatments was also assessed for growing pigs. The study was conducted using a randomized block design with three treatments distributed in two blocks of four replications/block. Twenty-four commercial barrows with an initial weight of 28+0.13 kg were used with an adaptation period of 10 d followed by a 5-d total collection of feces and urine. The diets were formulated by replacing the reference diet (corn and soybean meal) with 0, 10 or 20% macauba pulp presscake. The treatments were: T1 = Reference diet (RD), T2 = 90% RD+10% macauba pulp presscake, and T3 = 80% RD+20% macauba pulp presscake. The DCDM, DCCP, and DCFB for a 20% dietary inclusion level of macauba presscake were 16.5%, -2.25%, and 30.80%, respectively, which were not significantly different from the values observed with a 10% dietary inclusion level. The DE value for macauba pulp presscake in T2 (10%) was 2888.3 and T3 (20%) was 2900.6 kcal/kg. The ME for the same treatments was 2690.0 and 2680.5 kcal/kg, respectively. Diet DM digestibility values were 79.1% in T2 and 72.0% T3, while CP digestibility in T2 and T3 were 77.9% and 71.2%, respectively. Diet NDF digestibility for T2 was 64.3% and T3 was 55.7%. Significant difference ($P < 0.05$) for diet nitrogen balance (NB) was found only in fecal nitrogen (FN), showing that diet fiber increased the excretion of endogenous nitrogen. The inclusion level of macauba pulp presscake in the diet had an effect on the digestibility of DM, CP, and NDF, where the apparent digestibility coefficient decreased with the increase of macauba pulp inclusion, without influencing the DE, ME and NB values. This diet is considered to have a low nutritional value and its use is not recommended for growing pigs with 28 to 40 kg of body weight. The possible usage as alternative foods to feed pigs will depend on the understanding of their possibilities and limitations as well as reduction of production costs. Inclusion rates of this ingredient in pork diet must be considered, especially the fiber content values.

Key Words: alternative feed, biodiesel, by-products

1348 (W166) Different corn hybrids fed to growing pigs. I. Chemical composition, energy concentration, and digestibility of nutrients. Y. Liu[*1], R. C. Sulabo[1], T. E. Sauber[2], and H. H. Stein[1], *[1]University of Illinois at Urbana-Champaign, Urbana, [2]Pioneer Hi-Bred International Inc., Johnston, IA.*

Fifty-two barrows (26.8 ± 3.42 kg) were used in five experiments to determine the variability in the chemical composition, energy concentration, and digestibility of nutrients in 48 different corn hybrids sourced from DuPont Pioneer (Johnston, IA) and fed to growing pigs. In Exp. 1, 12 ileal cannulated barrows were allotted to a 12 × 12 Latin square design with 12 diets and 12 7-d periods. In Exp. 2 to 5, 10 ileal cannulated barrows were allotted to a 10 × 10 Latin square design with 10 diets and 10 7-d periods. In all experiments, corn was 97.0% (as-fed basis) of the diet and the only ingredient contributing energy, starch, ADF, NDF, lipids, and AA to the diets. The only difference in diet composition among diets was that different corn hybrids were used. Descriptive statistics for chemical component, energy concentration, and digestibility of nutrients in corn hybrids were determined using PROC MEANS. Correlation coefficients among chemical components, energy concentration, and digestibility of nutrients in all corn hybrids were determined using PROC CORR. On an as-fed basis, the GE concentration of the corn hybrids ranged from 3736 to 3989 kcal/kg, with an average of 3884 ± 63.6 kcal/kg. The average concentration of acid-hydrolyzed ether extract (AEE), starch, NDF, ADF, and ash was 3.86 ± 0.59%, 62.91 ± 1.79%, 8.13 ± 1.40%, 2.43 ± 0.53%, and 1.02 ± 0.28%, respectively. The average apparent ileal digestibility of GE, CP, AEE, NDF, ADF, and starch of the corn hybrids was 75.44 ± 4.38%, 62.63 ± 7.62%, 57.64 ± 7.62%, 19.02 ± 21.52%, −7.56 ± 19.53%, and 95.35 ± 2.48%, respectively, whereas the average apparent total tract digestibility of GE, CP, AEE, NDF, ADF, and starch was 87.78 ± 1.70%, 77.62 ± 4.36%, 53.53 ± 7.85%, 54.20 ± 13.03%, 38.46 ± 16.36%, and 99.90 ± 0.09%. On a DM basis, DE of the corn hybrids ranged from 3803 and 4217 kcal/kg DM with an average of 4058 ± 93 kcal/kg. The DE of corn hybrids may be predicted using the model: DE, kcal/kg DM = 1.719 × CP– 11.600 × AEE + 2.188 × NDF + 5.198 × ADF + 0.378 × Starch + 2.480 × GE– 7320.52 ($R^2 = 0.77$, RMSE = 54.3; $P < 0.001$). In summary, the chemical composition, energy concentration, and digestibility of nutrients varied among corn hybrids.

Key Words: chemical compositions, corn, pigs

1349 (W167) Different corn hybrids fed to growing pigs. II. Concentrations and digestibility of amino acids.

Y. Liu*[1], R. C. Sulabo[1], T. E. Sauber[2], and H. H. Stein[1], [1]*University of Illinois at Urbana-Champaign, Urbana,* [2]*Pioneer Hi-Bred International Inc., Johnston, IA.*

A total of 42 barrows (initial BW: 28.2 ± 2.91 kg) were used in four experiments to determine the variability in concentration and digestibility of AA in corn hybrids sourced from DuPont Pioneer (Johnston, IA) and to develop prediction equations to estimate the concentration of digestible AA in corn hybrids fed to growing pigs. In Exp. 1, 12 ileal cannulated barrows were allotted to a 12 × 12 Latin square design with 12 diets and 12 7-d periods. In Exp. 2, 3, and 4, 10 ileal cannulated barrows were allotted to a 10 × 10 Latin square design with 10 diets and 10 7-d periods. All diets had the same composition with the only difference being that different corn hybrids were used in each diet. Corn was included as 97.0% (as-fed basis) of the diet and was the only AA-contributing ingredient. Descriptive statistics for each chemical component of corn hybrids were determined using PROC MEANS. Simple linear regression analyses were performed using PROC REG of SAS. On an as-fed basis, the average concentration of CP, Arg, His, Ile, Leu, Lys, Met, Phe, Thr, Trp, and Val in the corn hybrids was 7.95 ± 0.79%, 0.36 ± 0.03%, 0.22 ± 0.02%, 0.30 ± 0.03%, 1.00 ± 0.14%, 0.21 ± 0.04%, 0.16 ± 0.02%, 0.41 ± 0.04%, 0.28 ± 0.03%, 0.05 ± 0.01%, and 0.40 ± 0.03%, respectively. The average standardized ileal digestibility (SID, %) of CP in the corn hybrids was 84.59 ± 4.92%. The average SID of indispensable AA was 92.63 ± 3.34% for Arg, 87.75 ± 3.99% for His, 86.96 ± 3.30% for Ile, 89.87 ± 2.58% for Leu, 85.25 ± 14.34% for Lys, 91.93 ± 2.49% for Met, 89.29 ± 2.74% for Phe, 80.75 ± 4.81% for Thr, 79.46 ± 6.74% for Trp, and 86.02 ± 3.89% for Val, respectively. The concentrations of standardized ileal digestible AA is not accurately estimated from the concentration of CP ($0.11 \leq R^2 \leq 0.78$). However, the concentration of each AA can be used to predict the concentration of digestible AA in corn ($R^2 \geq 0.80$). In summary, the variability in AA composition and digestibility of corn hybrids differed between individual AA. The concentration of digestible AA cannot be predicted from CP, but the concentration of each AA can be used to predict the concentration of digestible AA in corn.

Key Words: amino acid digestibility, corn, pigs

1350 (W168) A high dietary electrolyte balance reduces growth performance and CP and Zn total tract apparent digestibility in weanling piglets.

S. A. Guzmán-Pino[1], D. Solà-Oriol[1], R. Davin*[1], E. G. Manzanilla[1], C. Torrente[2], and J. F. Pérez[1], [1]*Animal Nutrition and Welfare Service, Dep. of Animal and Food Sciences, Universitat Autònoma de Barcelona, Bellaterra, Spain,* [2]*Servei d'Emergències i Cures Intensives de la Fundació Hospital Clínic Veterinari-UAB, Departament de Medicina i Cirurgia Animals, Universitat Autònoma de Barcelona, Bellaterra, Spain.*

It is generally accepted that dietary electrolyte balance (dEB, Na + K– Cl, in mEq/kg diet) influences feed intake and growth performance of pigs. However, there is a not clear optimal recommendation for piglets. The objective of this study was to assess the effect of diets differing in the mineral source and dEB on feed intake, total tract apparent digestibility and growth of weanling pigs. A total of 240 piglets (21 d after weaning, initial BW 13.4 ± 1.17 kg) were blocked by BW into three blocks (heavy, middle and light), and then distributed into eight pens per block (10 pigs/pen) and randomly assigned to one of four experimental diets differing in the dEB level: 16 and 133 mEq/kg diets (VL, L), based on the incorporation of CaCl (3.6 g/kg); and 152 and 269 mEq/kg diets (H, VH), based on the addition of calcium carbonate (10.6 g/kg), without or with sodium bicarbonate (10 g/kg), respectively. Titanium dioxide (3 g/kg) was used as indigestible marker. The diets were offered for 16 d when performance was evaluated. One fecal sample was collected per pen on d 7 to measure whole-tract digestibility, and five venous blood samples per treatment were collected on d 12 to measure acid-base status of animals. Piglets fed VL and L diets reached higher BW on d 16 (19.01 kg and 19.46 kg, respectively) than did piglets fed VH diet (17.05 kg, $P < 0.05$). Diet L also promoted a lower ($P < 0.05$) feed:gain ratio (2.10) and a higher ($P < 0.05$) digestibility of the CP (74.6%) and Zn (13.0%) than did diet VH (3.23, 68.2 and 1.1%, respectively). The VL diet reduced blood TCO2, bicarbonate and base excess values, as compared with L, H and VH diets ($P < 0.01$), reflecting the acidogenic nature of that diet. In conclusion, the results show that a high dEB diet (269 mEq/kg) may reduce piglets' performance and the total tract digestibility of nutrients, possibly associated to its higher acid-binding capacity (427 mEq/kg).

Key Words: dietary electrolyte balance, digestibility, growth performance

1351 (W169) Acceptance and palatability of different inclusion levels of protein solutions by feed restricted and non-restricted nursery pigs.

J. E. Figueroa[1,2], D. Solà-Oriol[3], R. Davin[*4], J. F. Pérez[4], and D. Dwyer[5,6], *[1]SNiBA, Departament de Ciència Animal i dels Aliments, Universitat Autònoma de Barcelona, Bellaterra, Spain, [2]Universidad de Chile, Santiago, [3]Animal Nutrition and Welfare Service, Dep. of Animal and Food Sciences, Universitat Autònoma de Barcelona, Bellaterra, Spain, [4]Animal Nutrition and Welfare Service, Dep. of Animal and Food Sciences, Universitat Autònoma de Barcelona, Bellaterra, Spain, [5]Cardiff University, Wales, [6]School of Psychology, University of New South Wales, Australia.*

The aim of the present work was to study the productive performance of nursery pigs when sweet milk whey (SMW) is replaced by porcine digestive peptides (PDP; 620 g/kg of CP, Bioibérica SA, Palafolls, Barcelona, Spain). A total of 240 pigs were randomly distributed after weaning into two groups (12 pens/group) depending on the presence of SMW or PDP on their diets. The SMW group was fed a pre-starter (0 to 14 d) and starter (15 to 33 d) diet with 142 g/kg and 49 g/kg SMW respectively; the PDP group was offered an iso-caloric and iso-proteic diet with 20 g/kg of PDP and 300 g/kg of wheat replacing dairy products. Feed intake and body weight were measured weekly to calculate average daily feed intake (ADFI), average daily gain (ADG) and gain: feed ratio (GFR). A choice test and one-feeder test of 30 min each were performed in another group of animals 3 wk wk weaning (36 pen pairs) to evaluate the preference and acceptance for both diets, respectively. Feed intake was recorded by measuring the initial and final weight of the feeders. SMW and PDP diet positions were balance across pig's pairs. Data were analyzed with ANOVA using the GLM procedure (performance values) or the PROC MIXED (preference and acceptance values) of the statistical package SAS. Despite clear differences on feed preference (211 vs. 77 g; $P = 0.039$) and acceptance (287 vs. 192 g; $P = 0.001$) between diets with or without whey respectively, no effects were observed on performance at the end of the nursery period (20.92 vs. 21.13 kg for BW, 0.62 vs. 0.63 kg/d for ADFI and 0.52 vs. 0.53 kg/d for ADG). Despite the reduced preferences and acceptance observed, the use of dairy products appears to be unnecessary if a high valuable protein source is offered during nursery.

Key Words: familiarity, feed preferences, lactose

1352 (W170) Nutritional value of whey permeate and egg products fed to growing pigs.

T. A. Woyengo[*1], E. Sánchez[1,2], J. Yanez[3], M. Cervantes[4], and R. T. Zijlstra[1], *[1]University of Alberta, Edmonton, Canada, [2]Universidad Autónoma de Baja California, Mexicali, México, [3]Universidad Autnonoma de Tlaxcala, México, [4]ICA, Universidad Autónoma de Baja California, Mexicali, México.*

Inedible eggs from egg-breaking plants have high AA and fat content. Instead whey permeate (WP), co-product from dairy industry, has high lactose content. Thus, blends of eggs and WP can be good sources of protein and energy in swine diets; however, their nutritional value is unknown. A study was conducted to determine standardized ileal digestibility (SID) of AA and calculated NE value for dried whole egg (egg), and two blends of WP and egg (70% WP and 30% egg, 7030PE; and 60% WP and 40% egg, 6040PE). Eight ileal-cannulated barrows (35.1 kg BW) were fed four diets in a replicated 4 × 4 Latin square design. The diets were a pre-grower-corn-starch-based basal diet, and this basal diet with energy- and AA-yielding ingredients replaced with 30% of egg, or 40% of 7030PE or 6040PE. Energy and nutrient digestibility in the test products was determined by difference method. The SID of AA were calculated using published values for basal ileal endogenous AA losses. On DM basis, egg, 7030PE, and 6040PE contained 48.9, 18.6, and 21.4% CP; 3.60, 0.98, and 1.17% Lys; and 39.3, 8.89, and 12.4% ether extract, respectively. The SID of Lys was greater ($P < 0.05$) for egg (86.9%) than for 7030PE (73.6%) or 6040PE (70.8%). However, egg had lower ($P < 0.05$) SID of Arg, Ile, and Phe than 7030PE or 6040PE. The 7030PE and 6040PE were similar in apparent total tract GE digestibility and SID of all AA except His. The NE (on DM basis) for egg (4.67 Mcal/kg) was greater ($P < 0.05$) than that for 7030PE (3.34 Mcal/kg), which was lower ($P < 0.05$) than that of 6040PE (3.61 Mcal/kg). In conclusion, the proportion of egg (30 vs. 40%) in the egg-WP blend did not affect the digestibility of GE and of most AA; however, the NE value was greater for the blend with 40% egg due to the high fat content in egg. Egg-WP blends had lower Lys digestibility than egg, implying that Lys was partly damaged by the blending and drying process. Nonetheless, the egg-WP blends had high AA digestibility and NE values, and hence they can be good sources of AA and energy in swine diets.

Key Words: egg, whey permeate, pig

1353 (W171) Inclusion of recycled wastes from the food industry in phase I diets for piglets: Effects on nutrient digestibility and growth performance.
B. Saldaña[1], P. Guzmán[1], G. Fondevila[1], J. F. Diaz Berrocoso[1], L. Cámara[1], X. Roca[2], and G. G. Mateos*[1], *[1]Universidad Politecnica de Madrid, Spain, [2]Promic, S. A., Barcelona, Spain.*

We studied the effects of inclusion of food by-products in the phase I diet on growth performance and total tract apparent digestibility (TTAD) of nutrients in 288 weaned pigs (7.9 ± 0.15 kg BW). On DM bases, the ingredients tested were a) lactal, a combination of yogurt (52%), milk (26%), and 22% of a wheat flour + broken rice meal mixture, b) lactal-cheese, a combination of yogurt (39%), milk (20%), cheese (19%), and 22% of the cereal mixture, and c) Infant, a mixture of out of date infant formulas based on cereals. In phase I (d 0 to 21 of experiment) there were eight dietary treatments arranged as a 2 × 4 factorial with two levels of lactose (7% and 10%) and four feed formulation: 1) a control commercial diet, 2) a diet with 15% lactal (LACTAL), 3) a diet with 15% lactal-cheese (LACTAL-cheese), and 4) a diet with 15% lactal-cheese and 20% Infant formula (INFANT). All diets were formulated to be isonutritives. On d 13 to 15 of the experiment, 300 g of feces per pen were collected by rectal massage for the TTAD analysis. From d 21 to 35 (phase II) all pigs received a common diet. Each treatment was replicated six times and the experimental unit was the individual pen with six pigs. Data were analyzed as a completely randomized design, with level of lactose and feed formulation as main effects. In phase I, an increase in dietary lactose increased ($P < 0.05$) ADFI and ADG but did not affect G:F. Pigs fed the INFANT diets (with 7 or 10% lactose) had higher ADFI ($P < 0.05$) than pigs fed the LACTAL diets, with pigs fed the other diets being intermediate. In phase II, pig growth was not affected by previous dietary treatment. Cumulatively, ADFI was higher ($P < 0.05$) for pigs fed the INFANT diet than for pigs fed the LACTAL diets. TTAD of DM, OM, GE, and CP was higher ($P < 0.05$) for pigs fed the high lactose level diets. Similar results were obtained for pigs fed the INFANT diets ($P < 0.05$). It is concluded that an increase in lactose content of the diet improved piglet performance and that the food by-products tested can substitute successfully high quality ingredients, such as dried whey and heat processed cereals, in phase I diets for weanling pigs.

Key Words: cheese, food by-products, infant formulas, lactose, yogurt

1354 (W172) Effect of wheat and wheat with corn distillers grain on growth performance in nursery pigs.
D. J. Bloxham*, R. Dove, and M. J. Azain, *University of Georgia, Athens.*

An experiment was conducted to evaluate the effect of substituting wheat or wheat and corn distiller's grains with solubles (DDGS) for corn in the phase 2 and 3 starter diets. The objective of this study was to determine if wheat is a viable alternative to corn in starter diets. A total of 126 pigs (4 to 6 pigs per pen and 8 pens per treatment) were blocked by weight and randomly assigned treatments within block. Pigs were weaned at 20 ± 2 d and fed a common diet (ME 3.4 kcal/kg; 1.5% SID lysine) 0 to 7 d post weaning, initial weight of 6.3 kg, NS. The three experimental diets [1, control, corn diet (C); 2, 30% wheat (W); and 3, 30% wheat and 30% DDGS (WCD)] were fed in two phases: phase 2 (ME:3.3 kcal/g, 1.4% SID lysine) from d 7 to 21 post-weaning, and phase 3 diets (ME: 3.3 kcal/g, 1.2% SID lysine) from d 21 to 35. All diets were formulated to meet the dietary requirements according to the 2012 Swine NRC. Body weight gain and feed disappearance were determined weekly. Data were analyzed using PROC GLM of SAS. Overall, pigs fed 30% W (21.6 kg) had body weights that were similar to those fed the C diet (21.0 kg, $P = 0.17$). Pigs fed the WCD diet were significantly heavier (22.6 kg, $P < 0.01$) than those fed C (21.0 kg). The ADFI was similar among treatments in phase 2 (569 g/d, NS), but was greater in those fed WCD in phase 3 (C, 888; W, 870; WCD 1006 g/d; $P < 0.02$) and overall (C, 728; W, 718; WCD 791 g/d; $P < 0.02$). The G: F was improved in pigs fed WCD in phase 2 (C, 0.62; W, 0.62; WCD 0.67; $P < 0.02$), but not in phase 3 or overall. In conclusion, these results indicate that wheat can be substituted for corn in nursery diets and that wheat in combination with DDGS may be superior to corn based diets.

Key Words: wheat, DDGS, nursery pig performance

1355 (W173) Effects of dietary protein and rapidly fermentable carbohydrate contents on microbial fermentation profile in the hindgut of weanling pigs.
V. V. Almeida[1], M. C. Thomaz[1], A. J. C. Nuñez[2], P. V. A. Alvarenga[1], F. R. Castelini[1], D. Perondi[1], R. G. Isola[1], A. Remus[1], Y. V. Silva-Guillen[1], E. Daniel[1], and S. L. Silva*[2], *[1]Dep. of Animal Science, FCAV/UNESP, Jaboticabal/SP, Brazil, [2]Dep. of Animal Science, FZEA/USP, Pirassununga/SP, Brazil.*

Protein fermentation in the hindgut of piglets leads to the production of potentially toxic metabolites such as ammonia, which may increase the risk of postweaning diarrhea. In this way, the objectives in this study were to determine the effects of dietary CP and dried citrus pulp (DCP, rapidly fermentable carbohydrate source) contents on short-chain fatty acids (SCFA), branched-chain fatty acids (BCFA), and ammonia concentrations in the colon digesta of weanling pigs. One hundred eight barrows weaned at 21 d of age were blocked by initial BW (5.82 ± 0.16 kg) and randomly assigned to one of four treatments with nine replicate pens per treatment and three pigs per pen. Treatments were arranged in a 2 × 2 factorial, with 2 CP contents (HCP and LCP, high- and low-CP diets, respectively) and 2 DCP contents (0 and 7.5%, as-fed basis). The HCP treatments consisted of feeding a 20 and 21%

CP diet (as-fed basis) during the pre-starter I (1 to 14 d) and pre-starter II (15 to 28 d) phases, respectively. For the LCP treatments, diets were reduced by 4% units compared with the HCP diets in both phases. The AA contents in the diets were balanced by supplementation with crystalline AA, such as L-Lys, DL-Met, L-Thr, L-Trp, L-Val, and L-Ile to maintain constant ratios in relation to standardized ileal digestible Lys. Colon digesta samples were collected from one randomly selected pig per pen on d 7 and 28 postweaning for determinations of SCFA and BCFA by gas chromatography, and ammonia concentrations by colorimetry. Statistical analyses were conducted using the PROC MIXED of SAS. Feeding pigs diets containing 7.5% DCP increased ($P < 0.01$) acetic acid concentrations, and decreased propionic ($P < 0.05$) and valeric ($P < 0.01$) acids concentrations, whereas butyric acid production was not affected ($P > 0.05$) by treatments. Dietary DCP inclusion increased ($P < 0.05$) isobutyric acid concentrations in the colon only at 28 d postweaning. Adding 7.5% DCP to the diet resulted in lower isovaleric acid ($P < 0.01$) and ammonia ($P < 0.01$) concentrations in the colon only for pigs fed the LCP diet. In conclusion, low-protein AA-supplemented diets with 7.5% DCP inclusion depresses harmful protein fermentation in the hindgut, and therefore may be contributing to enhance intestinal health of weanling pigs.

Key Words: intestinal health, piglets, protein fermentation

1356 (W174) Effects of dietary supplementation rice bran extracton production performance, feed intake, egg quality and excreta microbiota in laying hens.

H. L. Li, Y. Lei, and I. H. Kim*, *Dep. of Animal Science, Dankook University, Cheonan, South Korea.*

This experiment was conducted to evaluate the effects of dietary supplementation of rice bran extract on production performance, feed intake, egg quality and excreta microbiota in laying hens. A total of 288 Hy-line Brown (46-wk old) laying hens were randomly assigned to 1 of 3 treatments. The trial lasted for 20 wk. The dietary treatments were as follows: 1) CON, free antibiotics diet; 2) RB01, CON +0.01% rice bran extract; 3) RB02, CON + 0.02% rice bran extract. There were 8 replicates per treatment with 12 birds per replicate. Daily records of egg production and feed consumption were kept throughout the experimental period. Egg production was expressed as an average production of hen per day, which was calculated from the total number of eggs divided by the number of experimental time (week as a unit) and summarized on an average basis. A total of 42 salable eggs (no shell defects or cracks) were randomly collected biweekly from each treatment at 1700 h (3 eggs per replication). The egg quality of the collected eggs was then determined at 2000 h on the day of collection. All data were arranged to evaluate by analysis of variance following the GLM procedure in a completely randomized design using the SAS software program (SAS Institute, 1996). Laying hens were blocked with identical age. The difference among treatment was compared using the Duncan's multiple range test. The treatment effect was observed significant with the probability value below 0.05. The egg production of RB02 was higher (92.3 vs. 88.1%; 93.3 vs. 90.3%; $P < 0.05$) than CON at wk 5 and 6. Moreover, the *E. coli* content of excreta microflora of CON was higher (6.62 vs. 6.37 $\log_{10}$cfu/g; $P < 0.05$) than RB02. The Lactobacillus content of CON was lower (7.44 vs. 7.72 $\log_{10}$cfu/g; $P < 0.05$) compared with RB02. In conclusion, dietary supplementation of 0.02% rice bran extract can increase egg production performance and *Lactobacillus content*, and decrease *E. coli* content in laying hens.

Key Words: egg quality, excreta microbiata, feed intake, laying hens, production performance, rice bran extract

1357 (W175) Injection of glycosaminoglycans and vitamin C in incubation on the weight loss and shell conductance of the eggs.

E. T. T. Santos*[1], D. M. C. C. Castiblanco[1], L. L. Borges[1], C. H. D. F. Domingues[2], T. C. O. D. Quadros[1], S. Sgavioli[1], G. M. D. A. R. Garcia[1], R. D. G. Isola[2], and S. M. B. Artoni[1], *[1]Dep. of Morphology and Animal Physiology, São Paulo State University, Jaboticabal, Brazil, [2]Dep. of Animal Science, São Paulo State University, Jaboticabal, Brazil.*

Injection of nutrients into eggs can improve the incubation process. This study injected different percentages of a supplement consisting of glycosaminoglycans and vitamin C into eggs and evaluated the effect during incubation on weight loss and shell conductance of the eggs. Two hundred forty fertile broiler (Cobb) eggs from breeder hens at 43 wk of age were used. The eggs were 64 ± 4 g each. The experimental design was completely randomized with five treatments (non-injected eggs, eggs injected with milli-Q water, eggs injected with glycosaminoglycans and vitamin C at 2, 4, and 6% diluted with 100 µL of milli-Q water), distributed in three horizontal Ecological Premium, model IP 120, incubators, with three repetitions and 16 eggs per treatment. Each 100 g of the supplement were composed of: 30,000 mg of chondroitin sulfate, 30,000 mg of glucosamine and 5000 mg of vitamin C and vehicle q.s 100 g. The supplement was injected into the albumen, approximately 6 mm below the eggshell on d 4 of incubation. The injection site was then covered with a label identifying the treatment and repetition. Statistical analsyses were performed using the Statistical Analysis System SAS (2002) program with the averages compared by Tukey test at 5% probability. The weight loss was calculated as a percent from the difference between the weight of the egg at the start of the incubation and at d 18 of incubation. Shell conductance was calculated by weight loss in grams until the transfer/saturation vapor pressure (23.86 mm/Hg at 25°C). Shell conductance is the ability to exchange gases between the egg and the environment, and

is related to the weight loss. The higher the conductance and loss of mass, the greater the evaporative heat loss from the egg will be. In this study, the weight loss was approximately 7.6% and conductance was 0.320 and both were not significantly affected ($P > 0.05$) by the treatments. Therefore, the intra-egg injection of the glycosaminoglycans and vitamin C supplement did not alter the heat loss from evaporation.

Key Words: ascorbic acid, chondroitin, nutrition in ovo

1358 (W176) Effect of material bioconversion natural complex on growth performance, nutrient digestibility, blood characteristics, and fecal microbiota in weanling pigs. J. H. Cho*, M. Begum, and I. H. Kim, *Dep. of Animal Science, Dankook University, Cheonan, South Korea.*

A total of 150 weanling pigs [(Yorkshire × Landrace) × Duroc] with an average initial body weight (BW) of 5.76 ± 1.36 kg were used in a 6-wk trial to investigate the effect of material bioconversion natural complex on growth performance, nutrient digestibility, blood characteristics, fecal characteristics in weanling pigs. All these weanling pigs were randomly allotted into one of the five experimental diets according to their initial BW and sex (6 replicate pens/treatment, 5 pigs/pen, 2 barrows and 3 gilts/pen). Dietary treatments consisted of 1) NC, free antibiotics diet; 2) PC, NC + 0.1% tiamulin; 3) STR1, NC + 0.1% fermented material 1; 4) STR2, NC + 0.1% fermented material 2; and 5) STR3, NC + 0.1% fermented material 3. STR is material bioconversion natural complex powder produced from fermentation of mulberry leaves and turmeric with bacterial of mulberry yellow mushroom. STR1, STR2, STR3 contains 1.5, 3, and 6% of active complex powder, respectively. All diets, in mash form, were formulated to meet or exceed the nutrient requirements (NRC, 2012) for weanling pigs. During wk 3 to 6, pigs fed with PC, STR2 and STR3diets had higher (457, 463, 453 vs. 393 g; $P < 0.05$) ADG than NC treatments. During the overall period, pigs fed NC diet had lower (342 vs. 385, 388 g; $P < 0.05$) ADG than PC and STR2 treatments and the G:F in PC, STR2 and STR3 treatments was significantly higher (0.745, 0.740, 0.715 vs. 0.638; $P < 0.05$) compared with NC treatment. The ATTD of dry matterin STR2 treatment was higher (83.35 vs. 81.36%; 81.27 vs. 79.06%; $P < 0.05$) than NC treatment atthe end of wk 3 and 6. Moreover, the ATTD of nitrogen in PC and STR2 treatments was higher (81.81, 81.35 vs. 78.54%; $P < 0.05$) than NC treatment at the end of 3 wk. Pigs fed with PC diet had higher (8.21 vs. 7.43 $\log_{10}$cfu/g; $P < 0.05$) *Lactobacillus* population than those fed with NC diet. But there was no difference ($P > 0.05$) detected on *E. coli*, and *Salmonella* content at 6 wk. Through the experimental period, there was no difference ($P > 0.05$) observed on fecal score among dietary treatments. During the whole experimental period, no significant difference ($P > 0.05$) was observed on fecal moisture or fecal pH among dietary treatments. In conclusion, supplementation of material bioconversion natural complex may be helpful to improve the growth performance and nutrient digestibility, increase *Lactobacillus* concentrations of weanling pigs.

Key Words: nutrient digestibility, growth performance, *Lactobacillus* population, material bioconversion natural complex, weanling pigs

---

1359 (W177) The effects of fermented cotton seed meal on growth performance and egg quality in laying hens. Y. Wang*[1], A. Li[1], Y. Hou[1], Y. Li[2], X. Zhang[1], and H. Wei[1], *[1]Academy of State Administration of Grain, Beijing, China, [2]Animal Diseases Control and Prevention Centre of Miyun City, Beijing, China.*

Cottonseed meal (CSM) is very rich in China, but its nutrient bioavailability is low. Microbial solid-state fermentation is an effective way to improve the nutrient bioavailability of CSM. Therefore, deeply evaluating the nutritional value of fermented cottonseed meal (FCSM) in poultry, pig and ruminants can provide important data support for its reasonable application in animal feed and alleviate the shortage of high quality protein feedstuff. The objective of this study was to evaluate the effects of FCSM on growth performance and egg quality in laying-hens. A total of 660 47-wk-old laying hens were randomly divided into two groups with 110 birds/replicate. A corn-soybean meal (SBM) based control diet was formulated and the experimental diets included FCSM to replace 15% SBM on a kg basis. The trial period was 2 mo. Laying rate, feed to egg ratio, and egg quality were measured. The statistical analysis was performed with SPSS 18.0 software for Windows. Independent sample *t* test was used and a probability level of $P \leq 0.05$ was considered statistically significant. The results indicated that, compared to non-fermented CSM, free gossypol (FG) content of FCSM declined from 706 mg/kg to 257mg/kg, apparent metabolism energy (AME) increased from 8.93 MJ/kg to 9.37 MJ/kg. The number of *Saccharomyces cerevisiae* and *Bacillus subtilis* in FCSM was 1.86×10^8 and 3.1×10^8, besides, the content of small peptides (molecular weight < 600 Da) in FCSM was higher than CSM. No difference was found between treatments regarding the laying rate ($P = 0.383$), feed to egg ratio ($P = 0.318$). Compared to control diet, the FCSM had no adverse effects on yolk relative weight ($P = 0.201$), Haugh unit ($P = 0.499$), yolk color ($P = 0.817$), egg shell strength ($P = 0.923$). In conclusion, FCSM can be used in laying hen diets at up to 15% of the total diet as a promising alternative protein source.

Key Words: laying hen, fermented cotton seed meal, growth performance

1360 (W178) Soybean meals and soy protein concentrates as main source of protein in phase 1 diets for piglets: Growth performance data.

P. Guzmán, B. Saldaña, L. Cámara, and G. G. Mateos*, *Universidad Politecnica de Madrid, Spain.*

In total, 192 weanling pigs were used to study the growth performance and incidence of post-weaning diarrhea (PWD) in piglets fed diets based on soybean meals (SBM) of different origins or soy protein concentrates (SPC) from 21 to 58 d of age. In phase 1 (21 to 49 d of age) piglets received one of eight diets that differed in the source of soy protein used. Six of the diets were based ($n = 2$) on SBM from three different origins [USA, Argentina (ARG), and Brazil (BRA)] and the other two diets were based on 2 SPC with 60 or 65% CP, respectively. All diets were isonutritive and contained the same amount of dietary CP from soy origin. In phase 2 (49 to 58 d of age) all pigs received a common commercial diet. In phase 1, growth performance was not affected by diet but PWD was higher in pigs fed the ARG SBM than in pigs fed the other diets ($P < 0.05$). From 28 to 35 d of age, piglets fed the SPC tended to grow faster ($P = 0.056$) than piglets fed the SBM. From 35 to 42 d of age piglets fed USA SBM showed higher ADG ($P < 0.05$) and better G:F ratio ($P < 0.05$) than the average of piglets fed the other diets. However, no differences among diets were observed in phase 2. Cumulatively (21 to 58 d of age), the only difference observed among treatments was for G:F ratio that tended to be better for pigs fed the USA SBM as compared with the average of pigs from all the other treatments ($P = 0.064$). Also, PWD was higher in piglets fed ARG SBM than in piglets fed the other diets ($P < 0.01$). In conclusion, soy source had little effect on performance of pigs but G:F ratio tended to be better in pigs fed SBM of USA origin and PWD was higher in pigs fed the ARG SBM. Therefore, the choice of soy source (SPC and SBM) and SBM origin (USA, ARG, and BRA) might depend at high extent on the objectives and the relative cost of available sources.

Key Words: piglet growth, soybean meal origin, soy protein concentrate

1361 (W179) Standardized total tract digestibility of phosphorus in camelina (*Camelina sativa*) meal fed to growing pigs without or with phytase supplementation.

P. A Adhikari, and C. M. Nyachoti*, *University of Manitoba, Winnipeg, Canada.*

A study was conducted to determine the apparent (ATTD) and standardized (STTD) total tract digestibility of phosphorus (P) in camelina meal fed to growing pigs and the effect of phytase supplementation on STTD of P in camelina meal. Eighteen growing pigs (average initial BW of 18.1 ± 0.70 kg) were placed individually in metabolism crates which allowed for the total but separate collection of feces and urine. Pigs were allotted to one of three experimental diets, containing either 1) 20% camelina meal without phytase, 2) 20% camelina meal with 500 FTU/kg phytase or 3) a constarch-gelatin based P-free diet, in a completely randomised design to give six replicates per diet. The P-free diet formulated to contain 18.0% CP was used to determine endogenous P losses (EPL) to estimate STTD of P in camelina meal. Pigs were fed their respective diets in two equal portions at 0830 and 1630 h. Daily feed allowance was based on the body weight at the beginning of experiment and was calculated to supply 2.6 times the estimated maintenance energy requirements. The experiment lasted for 14 d, and pigs were adapted to their respective diets for the initial 9 d followed by a 5-d period of total collection of feces and urine. The ATTD of P and EPL were 55.4% and 108 ± 48.9 mg/kg DMI, respectively, whereas the STTD of P was 57.4%. Phytase supplementation increased ($P < 0.05$) the ATTD and STTD of P in camelina meal to 68.3 and 70.0%, respectively. Phytase supplementation increased ($P < 0.05$) P retention (66.8 vs. 54.6%) and reduced ($P < 0.05$) P output in the feces (0.50 vs. 0.71 g/d). The standardized total tract digestible P content in camelina meal was estimated at 5.45 g/kg.

Key Words: camelina meal, endogenous losses, phosphorus, pig

1362 (W180) Effects of adding a dried food waste product to the diets of finishing pigs on growth, feed intake, and nutrient digestibility.

H. L. Acuff* and L. A. Pettey, *California State Polytechnic University, Pomona.*

A study was conducted to measure the effects of adding a dried food waste product (DFWP) to the diets of late finishing pigs. The product was derived from bakery and vegetable food waste being aerobically digested (BioGreen 360) and heated to over 150°C during drying. Before mixing the diets, the DFWP used in the study was analyzed for nutrient content and found to have 84.0% DM, 10.95% CP, 15.42% EE, 0.42% Lys, 0.17% Ca, and 0.22% P. Nine finishing pigs (132 kg BW) were allotted randomly to one of three dietary treatments: 1) corn-SBM-based control diet; 2) control with 5% DFWP added; and 3) control with 10% DFWP added. All diets were balanced for lysine, Ca, and P (NRC, 2012). The study was conducted in three 1-wk periods, with each pig being fed a different diet each week with a 5-d adjustment period followed by a 2-d collection of feces. Pigs were weighed weekly and feed disappearance was measured daily. Fecal grab samples were dried and analyzed for DM, CP, EE, and ADF. Acid-insoluble ash was used as an indigestible marker for digestibility calculations. During the experiment, average daily gain (ADG) increased linearly ($P < 0.05$) with increasing DFWP addition to the diet. Average daily feed intake (ADFI) decreased numerically in pigs fed diets with 10% DFWP, as expected due to the high fat content of DFWP. Digestibility

estimates for DM, CP, fat, and ADF were not influenced by collection period and were pooled across period to estimate the effect of dietary DFWP addition. DM digestibility averaged 94.6% for all diets and was not influenced ($P > 0.10$) by DFWP addition. CP digestibility was also not affected ($P > 0.10$) by DFWP addition to the diet and were 81.1%, 81.2%, and 80.9% for Diets 1, 2, and 3, respectively. Fat digestibility (51.9%, 55.3%, and 62.8% for Diets 1, 2, and 3, respectively) increased linearly ($P < 0.01$) with increasing DFWP addition to the diet and was higher ($P < 0.10$) than the control diet when 5 or 10% DFWP was added. ADF digestibility was not affected ($P > 0.10$) by DFWP addition to the diet. Based on this experiment, the DFWP produced by the Biogreen 360 food waste digester is palatable for growing pigs, increases the fat digestibility of a corn-SBM based diet, and does not negatively influence protein or ADF digestibility when added up to 10% of the diet.

Key Words: pigs, food waste, digestibility

1363 (W181) Determination of the effect of the level of corn starch in the diet on the energy value of crude glycerin in swine. C. Ordoñez-Gomez*[1,2], C. Ariza-Nieto[3], and G. Afanador-Tellez[2], *[1]Universidad Francisco de Paula Santander-Ocaña, Colombia, [2]Universidad Nacional de Colombia, Bogotá, [3]CORPOICA, Mosquera, Colombia.*

Crude glycerin (CG), a byproduct of biodiesel, generates interest in animal feed because of its energy value. To determine the effect of the level of starch in the diet on the digestible energy (DE) of crude glycerin in swine this study was developed. The DE was determined for crude glycerin with 10 barrows placed in metabolic cages using 0.5% chromium oxide as an indigestible dietary indicator. The treatments consisted in two starch levels (SL) 10 and 12%, and five levels of CG substitution 0, 2.5, 5, 7.5 and 10%. Each period consisted of 5-d adjustment period, a 2-d collection period. During the collection period, feces and urine were collected separately and stored at 0°C until analysis to calculate metabolized energy (ME). The data were subjected to multiple linear regression analysis determining the value of the DE and ME of CG, as the slope of the line and N metabolism data as a Latin square design using the GLM and REG modules of SAS ver. 9.2. DE value of diet corrected by dietary starch content was described as, DE of diet corrected by starch (Kcal/kg) = 2952.1 +30.9(period) +4427.3(CG) + 31.5(SL)- 691.5(CG: SL). According to the slope, DE value of CG depended of SL ($P < 0.001$) estimated in 4427 and 3769 Kcal/kg DM for 10 and 12% of SL, respectively. ME of CG was determined as 3436 Kcal/kg DM, no effect ($P > 0.05$) of SL on the value of the ME of the CG was observed, although no quadratic effect of level of CG was observed ($P > 0.05$). An increase ($P < 0.001$) in urinary energy (UE) was observed as CG increased in the diet; UE (Kcal/kg DMI) = 159.6 +7.99(CG). There was an interaction between CG and SL ($P < 0.001$) which caused an increased in the amount of nitrogen digestible (AND) when CG increased by the 10% SL. However, the AND decreased when CG was increased by the 12% SL. According to these results, it was established that SL affects DE value of CG and the nitrogen metabolism in pigs.

Key Words: energy, crude glycerin, starch

1364 (W182) Effect of the substitution of soybean meal and sorghum for cull chickpeas on the apparent digestibility of nutrients in diets for growing pigs. J. M. Uriarte*, R. Barajas Cruz, J. A. Romo Rubio, H. R. Guemez Gaxiola, J. M. Romo Valdez, J. F. Nuñez, and N. A. López, *Universidad Autónoma de Sinaloa, Culiacán, México.*

The objective of this experiment was to determine the effect of the substitution of soybean meal and sorghum for cull chickpeas (CP average value of 24%, and 3.0 Mcal ME/kg, crude fat 5%) on apparent digestibility of nutrients in diets for growing pigs. Six pigs (BW = 36.15 ± 1.5 kg; Large White × Landrace × Large White × Pietrain) were used in a replicated Latin square design. Pigs were assigned to consume one of three diets: 1) Diet with 18.2% CP and 3.2 Mcal ME/kg, containing sorghum 68.6%, soybean meal 27.4%, and premix 4.0% (CONT); 2) Diet with 17% CP and 3.2 Mcal ME/kg with sorghum 48.5%, cull chickpeas 35%, soybean meal 10.0%, vegetable oil 2.5%, and premix 4.0% (CHP35), and 3) Diet with 20.5% CP and 3.1 Mcal ME/kg with sorghum 17.0%, cull chickpeas 70%, soybean meal 5.0%, vegetable oil 4.0%, and premix 4.0% (CHP70). Pigs were individually placed in metabolic crates (0.6 × 1.2 m). The adaptation period was 6 d and sample collection period was 4 d. From each diet and period, one kg of diet was taken as a sample and the total fecal production was collected. Feed Intake (1.88, 1.86 and 1.68 kg/day) was not affected by treatments ($P = 0.10$) for CONT, CHP35 and CHP70, respectively. Apparent digestibility of DM (82.9, 83.7 and 82.9%) was equal ($P = 0.81$) across treatments. Apparent digestibility of crude protein was not altered ($P = 0.35$) by CHP inclusion (78.4, 77.5 and 76.0%). These results suggest that cull chickpeas can be used up to 70% in growing pig diets without affecting nutrient digestibility.

Key Words: chickpeas, digestibility, pigs

NONRUMINANT NUTRITION: FACTORS IMPACTING FEED INTAKE

1365 (W183) Antioxidant activity of intestinal mucosa in piglets fed deoxynivalenol naturally contaminated diet. F. Guay[1], M. Lessard[2], Y. Chorfi[3], and B. V. Le Thanh[*4], *[1]Universite Laval, Quebec City, Canada, [2]Agriculture and Agri-Food Canada, Sherbrooke, QC, [3]Université de Montréal, Faculté de Médecine Vétérinaire, St-Hyacinthe, QC, Canada, [4]Universite Laval, Quebec City, Canada.*

Deoxynivalenol (DON) is a mycotoxin commonly detected in cereals and grains, and is the most prevalent contaminating trichothecene in North American crops. In young piglets, the main effects of DON are reduced feed intake and weight gain, impaired immune response and enhanced oxidative stress. The influence of DON-contaminated feed on the antioxidant status of the intestinal mucosa in weaned piglets is not well known. Therefore, the aim of this study was to evaluate the activity of antioxidant enzymes and markers associated with oxidative stress in jejunal and ileal mucosa of piglets fed DON naturally contaminated diet. A total of 24 castrated weanling piglets with an initial weight of 6.0 ± 0.5 kg were used for a 14-d experimental period. After 1 wk post-weaning on a commercial diet, piglets were randomly assigned to either control diet or 4 ppm DON diet and housed individually. Samples of jejunum and ileum mucosa were collected at the end of the experiment to determine the total activity of glutathione peroxidase (GPx), catalase (CAT), superoxide dismutase (SOD) and xanthine oxidase (XO) as well as malondialdehyde (MDA) concentration and total antioxidant capacity (TAC). Data were analyzed using the SAS PROC MIXED in a randomized complete block design (initial body weight) with DON contamination as main independent factor. DON-contaminated diet decreased catalase activity (3.69 vs. 3.03 μmol/min/g, $P = 0.045$) and tended to increase MDA concentration in jejunal mucosa (7.09 vs. 9.86 nmol/g, $P = 0.087$). Also it decreased total SOD activity (48.1 vs. 35.9 μU/g, $P = 0.021$), but increased the total GPx activity (2.49 vs. 2.95 μmol/min/g, $P = 0.035$) in ileal mucosa. Activity of XO and TAC were not affected by DON-contaminated diet neither in jejunal nor in ileal mucosa. These results showed that DON affect intestinal enzyme activities involved in the oxidative stress reaction, which can affect the function and the integrity of the intestinal mucosa.

Key Words: piglet, deoxynivalenol, antioxidants

1366 (W184) Effects of different feed processing procedures with expander on broiler performance. M. Gierus[*1], C. Elwert[2], and S. Sternowsky[3], *[1]University of Natural Resources and Life Sciences–Institute of Animal Nutrition, Products, and Nutrition Physiology, Vienna, Austria, [2]Feedtest, Wettin-Löbejün, Germany, [3]Amandus Kahl GmbH & Co KG, Reinbek, Germany.*

For particle agglomeration after grinding, pelleting is successfully used, but it does not increase considerably starch gelatinization, which would be maximized after hydrothermic treatment (HT). Among feed processing methods with HT, expanding may achieve the most efficient feed conversion rate (FCR). The objective was to compare different feed processing methods of broiler ration on animal performance. Ration was mixed with the same ingredients, differing in composition between phase I and II only. Rations were processed to obtain mash (negative control), pelleted only (positive control), or four expander processes [crumble I (2.7 kWh/t) and II (12 kWh/t), shaped crumble (30 kWh/t), and pelleting after expander processing (exp. + pel., 15 kWh/t)]. Broilers were kept in boxes of 10 animals each and were fed in two phases [age 1 to 21 d (phase I), and 22 to 36 d (phase II)]. Body weight gain and feed intake were measured. Treatments were arranged in a completely randomized design ($r = 8$); means separated by Tukey ($P < 0.05$). Among feed processing methods, feed intake was highest for pellets, crumbles I and II. Expanding could preserve coarse structure inside the expandat, in contrast to the pelleted ration. The most efficient FCR among expander treatments was achieved with the shaped crumble, next to pelleted feeds. Whereas crumble I (low energy input as kWh/t) contributed to particle agglomeration, this expander treatment was not able to increase substantially starch gelatinization or avoid selective feed intake. The shaped crumble had higher energy input (as kWh/t) than crumble II, which may explain the comparable FCR to pelleted rations. The reduced bulk density however may explain the lower feed intake for the shaped crumble treatment. The FCR of broilers fed on shaped crumbles compared to the pelleted treatments is attributed to the coarse particles inside the expandate after processing and the HT on improved starch gelatinization.

Key Words: broiler, feed processing, feed conversion

1367 (W185) Influence of pre-pelleting inclusion of whole corn on performance, nutrient utilization and digestive tract measurements of young broilers. Y. Singh[1], V. Ravindran[*1], and T. J. Wester[2], *[1]Massey University, Palmerston North, New Zealand, [2]Institute of Veterinary, Animal and Biomedical Sciences, Massey University, Palmerston North, New Zealand.*

The objective of the present study was to examine the effects of pre-pelleting inclusion of whole corn on performance, digestive tract measurements and nutrient utilization in broiler starters. Five diets, containing 60% ground corn or 15, 30, 45, and 60% whole corn replacing (w/w) ground corn, were formulated and cold-pelleted at 65°C. Each diet was offered ad libitum to six replicates (eight birds per replicate cage) from d 1 to 21 post-hatch. Weight gain (1005, 990, 919, 933, and 857 g/bird, respectively) and feed intake (1303, 1312, 1214, 1226, and 1136 g/bird, respectively) decreased linearly ($P < 0.001$) with increasing pre-pelleting inclusion of whole corn. Feed per gain (quadratic effect, $P < 0.05$) increased as the inclusion level of whole corn increased to 30% and then plateaued with further inclusions. Relative gizzard weight (12, 14, 15, 16, and 16 g/kg body weight, respectively; quadratic effect, $P < 0.05$) and apparent metabolizable energy (3400, 3450, 3466, 3424, and 3435 kcal/kg, respectively; quadratic effect, $P < 0.05$) increased with increasing inclusion of whole corn up to 30% and then leveled off. Ileal digestibility of starch (linear effect, $P < 0.001$) and nitrogen (linear effect, $P = 0.07$) increased with increasing inclusion levels of whole corn. Pellet quality, measured as pellet durability index (64, 78, 78, 82, and 84, respectively; quadratic effect, $P < 0.001$), increased sharply with the inclusion of whole corn to 15%, then plateaued and a further increase was observed at the inclusion level of 45%. The present data showed that, despite improvements in gizzard development, nutrient utilization and pellet quality, weight gain of broilers were poorer with pre-pelleting inclusion of whole corn due largely to the reduced feed intake.

Key Words: broilers, pre-pelleting, whole corn

Table 1367.

	Feed intake, g/day		Body weight gain, g/day		FCR
Treatment	Phase I	Phase II	Phase I	Phase II	0–36 d

1368 (W186) Divergent selection for residual feed intake may be impacted by differences in feeding behavior. S. Vigors[*1], T. Sweeney[2], A. G. Fahey[1], C. J. O'Shea[1], and J. V. O'Doherty[1], *[1]School of Agriculture and Food Science, University of College Dublin, Ireland, [2]College of Agriculture, Food Science and Veterinary Medicine, University College Dublin, Belfield, Ireland.*

Reduced activity related to feeding behaviour traits may explain the reduced feed intake and improved feed efficiency in low residual feed intake (LRFI) pigs, as less active animals will have a lower maintenance requirement. The objective of this study was to examine the effect of divergent selection for RFI on selected feeding behavior traits. Male pigs [$n = 75$; initial BW 22.42 kg (SD = 2.03)] were fed a standard finishing diet (12.5 g/kg lysine and 14.5 MJ/kg Digestible Energy) for 43 d to evaluate feed intake and growth for the purpose of calculating RFI. Feeding behavior was measured using electronic feeders that recorded consumption per visit and feeding time. Phenotypic RFI was calculated as the residuals from a regression model regressing DMI on ADG and midtest $BW^{0.75}$ (MWT). Fifteen high RFI (HRFI) and 15 LRFI pigs were chosen for the purpose of examining feeding behavior parameters. RFI was strongly correlated with both ADFI ($r = 0.67$) and FCR ($r = 0.73$). LRFI pigs had lower ADFI (2.44kg vs. 1.87kg) and improved feed conversion ratio (1.96 vs. 2.48) relative to HRFI pigs ($P < 0.001$) with no difference in ADG or MWT. Behavioral analysis indicated that LRFI pigs ate less ($P < 0.0001$), spent less time eating per d ($P < 0.05$), had smaller meals ($P = 0.05$) and spent less time eating each meal than HRFI pigs ($P = 0.09$). LRFI pigs had less variation in there time spent eating ($P = 0.09$) than HRFI pigs, indicating that LRFI pigs had a more consistent feeding pattern. There was interactions between residual feed intake and the number of visits per d ($P < 0.05$) with LRFI pigs having fewer visits to the feeder than HRFI pigs across the experimental period. The results from this study suggest that LRFI pigs have lower activity related to feeding actions. This may partly explain the reduced feed intake in LRFI pigs.

Key Words: residual feed intake, feeding behavior, pigs

1369 (W187) Effect of dietary aflatoxin from contaminated corn on performance of turkey poults. A. S. Oyegunwa, E. O. Ewuola, A. F. Agboola, and E. A. Iyayi*, *University of Ibadan, Nigeria.*

Eighty 21-d-old Nicholas turkey poults were fed diets containing different levels of aflatoxin from naturally contaminated corn using *Aspergillus flavus*. The aim of the study was to investigate growth and feed intake responses in the birds to the dietary aflatoxin levels to determine the safe level of the toxin in the diets of turkey poults. The birds were weighed and assigned to 4 treatments of 4 replicates each and 5 poults per replicate in a randomized complete block design with an aver-

age initial body weight of 341 g. The diets were T1 = control; T2 = 400ppb aflatoxin; T3 = 800ppb aflatoxin; T4 = 1200ppb aflatoxin/diet. The poults were fed the experimental diets for 2 wk, at the end of which feed intake and body weight records were taken and statistically analyzed using linear regression. At d 14 there was a significant ($P < 0.05$) reduction in feed intake (1316, 710, 519, and 306 g) and body weight (1055, 554, 383, and 306 g) for diets T1, T2, T3 and T4, respectively. Mortality was significantly higher ($P < 0.05$) in the 400, 800, and 1200 ppb aflatoxin diets compared to the control diet. Results of the study showed that dietary aflatoxin concentration of 400 ppb and above from contaminated corn is deleterious to turkey poults reared from d 21 to 35.

Key Words: dietary aflatoxin, turkey poults, performance

1370 (W188) Worldwide occurrence of mycotoxins in feeds and feed components in the year 2013.

S. Schaumberger*, K. Nährer and U. Hofstetter,
Biomin Holding GmbH, Herzogenburg, Austria.

In 2013, a follow-up on the worldwide Biomin mycotoxin survey (started in 2004) covering the most important mycotoxins in feedstuffs was conducted. Information was collected concerning the presence of mycotoxins in commodities most commonly used for feed production. A total of 4218 samples (mainly corn/corn silage, soybean meal, wheat, finished feed and other grains) sourced in America, Europe and Asia were analyzed for the presence of mycotoxins including aflatoxins (Afla), zearalenone (ZEN), deoxynivalenol (DON), fumonisins (FUM) and ochratoxin A (OTA). Samples were analyzed by high performance liquid chromatography (HPLC) and Enzyme-Linked Immunosorbent Assay (ELISA). Only single commodities were analyzed by ELISA. More complex matrices which could interfere with the ELISA method such as DDGS and finished feed were tested by HPLC. For the purpose of data analysis, the quantification limits (LOQ) of the test method for each toxin were implemented. In the more than 4000 samples analyzed worldwide, Afla were present in 30%, ZEN in 37%, DON in 59%, FUM in 55% and OTA in 23%. Average contamination levels of all positive samples were 10 ppb for Afla, 49 ppb for ZEN, 458 ppb for DON, 778 ppb for FUM and 2 ppb for OTA. In total, only 19% of the samples were tested negative for the presence of the five investigated mycotoxins. Thirty-six percent of all samples contained one mycotoxin and 45% of the samples showed a co-contamination with two or more mycotoxins. Results of this survey highlight the necessity of mycotoxin testing before the feeding of animals. More than 80% of the samples were positive for at least one mycotoxin. The presence of more than one mycotoxin in almost half of the samples draws attention to the multi-mycotoxin contamination. The results underline the necessity of constant monitoring of mycotoxins in feedstuffs and a proper mycotoxin risk management.

Key Words: mycotoxins, worldwide survey

PHYSIOLOGY AND ENDOCRINOLOGY I

1371 (M188) Comparison of endocrine changes, timing of ovulations, ovarian follicular growth, and efficacy associated with Estradoublesynch and Heatsynch protocols in Murrah buffaloes (*Bubalus bubalis*). R. Mirmahmoudi[*1] and B. S. Prakash[2], *[1]Dep. of Animal Science, Faculty of Agriculture, University of Jiroft, Iran, [2]National Dairy Research Institute, Karnal, India.*

Experiments were conducted on 135 cycling and 31 anestrus buffalos to compare a) the endocrine changes, timing of ovulations, ovarian follicular growth and efficacy of Estradoublesynch (*P*$GF_{2\alpha}$ 0, GnRH 2, $PGF_{2\alpha}$ 9, Estradiol Benzoate; EB 10) and Heatsynch (GnRH 0, $PGF_{2\alpha}$ 7, EB 8) protocols in cycling buffaloes, and b) the efficacy of Estradoublesynch and Heatsynch protocols for fertility improvement in cycling and anestrus buffaloes. Ovulation was confirmed following all GnRH and EB treatments by ultrasonographic examination at 2-h intervals. Plasma progesterone and total estrogen concentrations were determined in blood samples collected at daily intervals, beginning 2 d before onset of protocols until the day of second ovulation detection. Ovulatory follicle size was measured at the time of a) first $PGF_{2\alpha}$ administration/2 d before onset of protocol, b) GnRH administration, c) 2 h before ovulation detection post GnRH administration, d) second $PGF_{2\alpha}$/$PGF_{2\alpha}$ injection, e) EB injection and, f) 2 h before ovulation detection post EB injection. Plasma LH, total estrogen and progesterone concentrations were determined in blood samples collected at 30-min intervals for 8 h, beginning GnRH and EB injections, and thereafter at 2-h intervals until 2 h after detection of ovulation. The first ovulatory rate was significantly ($P < 0.05$) higher in Estradoublesynch (84.6%) protocol than that in Heatsynch protocol (36.4%). The first LH Peak concentration in Estradoublesynch (74.6 ± 10.4 ng/ml) protocol was significantly ($P < 0.05$) higher than that of Heatsynch (55.3 ± 7.4 ng/ml) protocol. In Estradoublesynch protocol, the total estrogen concentration gradually increased from the day of GnRH administration coinciding with LH peak, and then gradually declined to the basal level until the time of ovulation detection. However, in Heatsynch protocol, the gradual increase in total estrogen concentration after GnRH was observed only in those buffaloes which responded to treatment with ovulation. In both Estradoublesynch and Heatsynch protocols, ovulatory follicles size increased from GnRH/EB injections until ovulation. The pregnancy rate after Estradoublesynch (60.0%) protocol was significantly ($P < 0.05$) higher than that achieved after Heatsynch protocol (32.5%). Satisfactory success rate using Estradoublesynch protocols was attributed to the higher release of LH following GnRH injection, leading to most of the animals ovulating post GnRH injection and hence creating the optimum follicular size at EB injection for ovulation and pregnancy to occur.

Key Words: estradoublesynch, heatsynch, endocrine changes

1372 (M189) Development of a novel strategy for synchronization of ovulation and fertility augmentation in cycling buffalo cows. R. Mirmahmoudi[*1] and B. S. Prakash[2], *[1]Dep. of Animal Science, Faculty of Agriculture, University of Jiroft, Iran, [2]National Dairy Research Institute, Karnal, India.*

The aim of present study was to investigate the endocrine changes (progesterone, total estrogens, and LH), ovarian follicular growth, timing of ovulation and efficacy in terms of pregnancy rate in cycling Murrah buffaloes subjected to a novel protocol named Estradoublesynch ($PGF_{2\alpha}$ 0, GnRH 2, $PGF_{2\alpha}$ 9, Estradiol Benzoate; EB 10, timed artificial insemination (TAI) 48 and 60 h later). Twelve cycling buffaloes were subjected to the Estradoublesynch protocol. Ovarian follicle size and the rate of induction of ovulation were examined using transrectal ultrasonography at two hourly intervals post EB injection. Plasma progesterone and total estrogens concentrations were measured in blood samples collected at daily intervals. In addition, plasma LH and total estrogens concentrations were determined in intensive blood samples collected post EB administration. Ovulation occurred in all buffaloes 48.5 ± 1.6 h post EB treatment. Follicle size was gradually increased from second $PGF_{2\alpha}$ injection (9.7 ± 0.3 mm) until ovulation (12.9 ± 0.4 mm). Peak LH concentration of 34.2 ± 7.7 ng/ml occurred 18.3 ± 0.8 h after EB treatment. Peak total estrogen of 50.8 ± 6.9 pg/ml occurred 5.7 ± 1.0 h after EB treatment. Fourteen cycling buffaloes were subjected to the Estradoublesynch protocol, with TAI 48 and 60 h following EB injection, and 58 cycling buffaloes were inseminated after spontaneous estrus (control group). Pregnancy rates were 62% for TAI of cycling buffaloes and 34.5% for control group. These results demonstrated that the Estradoublesynch protocols can be potentially used to obtained satisfactory fertility after TAI in cycling buffaloes. This is a practical application of endocrine study toward fertility augmentation at farm level.

Key Words: Estradoublesynch, ovulation, ovarian follicle

1373 (M190) Maternal dietary effects on embryonic ovarian development in cattle. S. E. Echternkamp[*], D. R. Eborn, and R. A. Cushman, *USDA, Agricultural Research Service, Clay Center, NE.*

Ovarian gametogenesis and folliculogenesis begins early in fetal development with peak numbers of follicles present in bovine fetal ovaries in the second trimester of gestation and may be altered by maternal nutrition. The objective was to

determine whether maternal dietary energy intake by replacement beef heifers before breeding affects ovarian development in female progeny. Over three breeding seasons, puberal heifers were fed either a high (HE) or low (LE) energy diet for 6 mo before breeding plus the first 22 d of a 47-d breeding period to achieve 55 vs. 65% of mature BW; heifers were subsequently managed together on pasture. Female progeny (n = 68 LE and 67 HE) were developed on a standard management protocol for replacement beef heifers. Numbers of antral follicles (AFC), corpora lutea (CL), and ovarian length and height were measured in progeny ovaries by transrectal ultrasonography at 14 mo of age before a 29-d breeding period with fertile bulls; pregnancy was diagnosed at about 75 d of gestation. Data were analyzed by ANOVA with diet, year and diet x year as fixed effects. Progeny of LE vs. HE dams did not differ in birth (33.8 vs. 34.4 ± 0.6 kg, respectively) or prebreeding BW (381.2 vs. 385.0 ± 3.6 kg, respectively). Ovaries of LE progeny contained fewer small (2 to 5 mm) (18.0 vs. 21.9 ± 1.0, LE vs. HE; P = 0.02) and total antral follicles (AFC, 19.9 vs. 24.0 ± 1.0, LE vs. HE; P = 0.01). Overall, 96.5% of progeny had a CL at examination. Although AFC was correlated positively (r = 0.36; P < 0.01) with ovarian size (length x height), size did not differ between diets (357.4 vs. 348.4 mm^2 ± 12.6, LE vs. HE, P > 0.10). The AFC was similar between left and right ovary (r = 0.77; P < 0.01), but not between progeny and dam AFC (r = 0.05). Proportion of daughters pregnant to the 29-d breeding period did not differ between maternal diets (72.4 vs. 70.7 ± 0.5%, LE vs. HE) and was not influenced by prebreeding AFC. Results indicate that nutrient intake by first-parity heifers during early embryonic development may affect fetal ovarian development. USDA is an equal opportunity provider and employer.

Key Words: beef heifers, diets, developmental programming

1374 (M191) Effects of excessive energy intake and supplementation with chromium propionate on insulin resistance parameters in lactating dairy cows: I. Performance and weekly physiological measurements. T. Leiva[1], R. F. Cooke[2], F. G. Dantas[1], F. P. Santos[1], A. P. Brandao[1], J. Ranches[1], A. C. Aboin[1], and J. L. M. Vasconcelos[*1], *[1]UNESP–FMVZ, Botucatu, Brazil, [2]Oregon State University–EOARC Burns, Burns.*

The objective of this experiment was to compare performance and insulin resistance parameters in lactating dairy cows with adequate or excessive energy intake, as well as in lactating dairy cows with excessive energy intake receiving Cr-propionate supplementation. Seventeen primiparous and multiparous, lactating Holstein cows were ranked by parity, BW, and BCS, and assigned to 1 of 3 dietary treatments on d 0: 1) diet to meet their NE_l requirements without Cr supplementation (MAN; n = 5), 2) diet to exceed their NE_l requirements without Cr supplementation (HIGH; n = 6), and 3) HIGH with 2.5 g/d of Cr-propionate (HIGHCR; n = 8, with 10 mg of Cr/cow daily). Cows were maintained in a single group and offered corn silage for ad libitum consumption, but received a corn-based concentrate twice daily via individual self-locking head gates from d 0 to 210. Concentrate intake was formulated to provide 100% of daily NE_l requirements of MAN and 160% of daily NE_l requirements of HIGH and HIGHCR cows. Cow BW, BCS, and milk production were recorded weekly. Blood samples were also collected weekly, before and at 2 and 4 h after the morning concentrate feeding, and analyzed for serum glucose, insulin, and NEFA. Pre-prandial revised quantitative insulin sensitivity check index (RQUICKI) was determined using serum glucose, insulin, and NEFA concentrations obtained before concentrate feeding. No treatment effect was detected for BW change (P = 0.74), although BCS change from d 0 to 210 was greater (P = 0.02) in HIGH and HIGHCR compared with MAN. Milk production was similar between treatments (P = 0.92). Serum glucose concentrations and RQUICKI were also similar ($P \geq 0.68$) across treatments, whereas mean serum NEFA concentrations (pre-prandial samples only) were greater (P = 0.04) for MAN compared with HIGH and HIGHCR. Treatment × parity × day interactions were detected (P < 0.01) for serum insulin and insulin:glucose ratio. These parameters were generally greater ($P \leq 0.05$) for HIGH, intermediate for HIGHCR cows, and lesser for MAN beginning on d 70 of the experiment for multiparous cow, and beginning on d 168 for primiparous cows. In conclusion, lactating dairy cows consuming excessive energy experienced reduced insulin sensitivity compared to cows consuming adequate amounts of energy, characterizing a state of insulin resistance, whereas Cr-propionate supplementation alleviated this outcome. However, milk production was not impacted by excessive energy intake or Cr-propionate supplementation.

Key Words: chromium, dairy cows, energy intake, insulin resistance

---

1375 (M192) Association of monocyte chemoattractant protein-1 and vascular endothelial growth factor in subcutaneous and visceral adipose tissue of early lactating dairy cows. S. Häussler[*1], C. Sacré[1], P. Friedrichs[2], S. Dänicke[3], and H. Sauerwein[1], *[1]University of Bonn, Institute of Animal Science, Germany, [2]Institute of Animal Science, Physiology and Hygiene Unit, University of Bonn, Germany, [3]Institute of Animal Nutrition, Friedrich Loeffler Institute (FLI), Braunschweig, Germany.*

Adipose tissue (AT) is an endocrine organ, producing and secreting a wide range of adipokines, which are known to regulate metabolism and immune function. Metabolic adaptations during early lactation in dairy cows may be accompanied by changes in vascularization within AT to ensure nutrient supply for the adipocytes and/or to support the release of NEFA and

glycerol through increased blood flow. Small concentrations of monocyte chemoattractant protein-1 (MCP-1) can stimulate AT vascularization through the vascular endothelial growth factor (VEGF). Based on the virtual absence of macrophages in bovine AT, we hypothesized that MCP-1 in bovine AT is rather related to vascularization than to recruiting monocytes. Therefore, we aimed to investigate MCP-1 together with VEGF in different bovine AT. Primiparous German Holstein cows (n = 25) from a feeding trial were allocated to 3 groups that were slaughtered on Day 1 (n = 5), 42 and 105 (each n = 10) postpartum (P.p.). Subcutaneous (sc) AT (tailhead, withers, sternum) and visceral (vc) AT (omental, mesenteric, retroperitoneal) were sampled. Quantification of MCP-1 and VEGF was done by qPCR; mRNA abundance was summarized for sc and vc AT (means ± SEM). Differences throughout lactation were analyzed using the Kruskal–Wallis test, comparison between the sc and vc AT was done by Mann–Whitney-U test, and Spearman correlation was used to investigate the relation between the two variables (SPSS 21, $P \leq 0.05$). From d 1 to d 105 p.p. the mRNA abundance of MCP-1 and VEGF decreased 1.6-fold (P = 0.008) and twofold (P = 0.002), respectively, irrespective of AT depot. Comparing different AT across all days, MCP-1 mRNA abundance was 2.5-times ($P < 0.001$) and VEGFA mRNA abundance was 1.4-times ($P < 0.001$) higher in vc than in sc AT. Together with the previous finding that hardly no macrophages were observed in bovine AT, the positive correlation between MCP-1 and VEGF (r = 0.297; $P < 0.001$) indicates that MCP-1 may play a role in vascularization of bovine AT. High levels of MCP-1 and VEGF at the onset of lactation might increase vascularization to improve the essential blood flow in bovine AT right after calving. The higher expression of both MCP-1 and VEGF in vc than in sc AT might be due to the higher metabolic activity of vc AT.

Key Words: VEGF, MCP-1, adipose tissue

1376 (M193) Reactive oxygen metabolites (ROM) and advanced oxidation protein products (AOPP) as influenced by energy intake and niacin supplementation in the periparturient dairy cow.

H. Sadri*[1], D. Nakov[2], S. Dänicke[3], U. Meyer[3], R. Tienken[3], and H. Sauerwein[4], *[1]Institute of Animal Science, Physiology and Hygiene Unit, University of Bonn, Germany, [2]Institute for Animal Biotechnology, University St. Cyril and Methodius, Skopje, Macedonia, [3]Institute of Animal Nutrition, Friedrich Loeffler Institute (FLI), Braunschweig, Germany, [4]University of Bonn, Institute of Animal Science, Germany.*

Increasing metabolic requirements related to late pregnancy, calving, and initiation of lactation may result in augmented production of ROM and, if not compensated by endogenous antioxidants, in oxidative stress. Niacin, as a precursor for NAD+ synthesis, upregulates the expression of glucose-6-phosphate dehydrogenase, the rate-limiting enzyme in the pentose phosphate pathway and the principal source of cellular NADPH. Increased levels of NADPH decrease cellular ROM through regulating ROM-generating oxidases or by maintaining anti-oxidant enzymes in active form. We hypothesized that niacin by increasing NAD(p)H levels ameliorates oxidative stress in dairy cows and that this effect will differ depending on the portion of concentrate in the diet fed during late pregnancy and the first 100 d of lactation. Fifty-six Holstein cows were studied from d 42 ante partum (a.p.) through d 100 post partum (p.p.), and were assigned to 1 of 4 treatment groups (n = 14 each) in a 2 × 2 factorial arrangement of the level of concentrate feeding (high or low concentrate portion in the diet), with or without 24 g/d of niacin from d −42 to d 24. Blood was collected in weekly intervals (3-d intervals around calving). Derivatives of ROM (dROM; indirect photometric assessment of free radicals) were measured in all serum samples, and AOPP (marker of oxidative protein damage) in sera from d −42, -21, 14, 21, 28, and 35. Data were analyzed by the PROC MIXED of SAS using repeated measure analysis ($P < 0.05$). The model included the effects of diet, niacin, time, and two- and three-way interactions of main effects with time. Serum concentrations of dROM were not affected by concentrate level or niacin supplementation, and no interactions between concentrate and niacin, as well as no three-way interactions between treatments and time on dROM concentrations were observed. Serum concentrations of dROM were affected by time reaching a nadir around calving, and increasing immediately thereafter to relatively constant concentrations slightly higher than a.p. Serum AOPP was not different between treatment groups, but changed over time. Decreasing dROM values around calving might result from increased antioxidant protection. The two serum markers of oxidative stress selected herein yielded no effects of diet or niacin, however, markers of antioxidant status should additionally be considered.

Key Words: niacin, energy intake, oxidative status, dairy cow

---

1377 (M194) The effect of aspirin on prostaglandin $F_{2\alpha}$ secretion in lactating dairy cows during the luteal phase of the estrous cycle.

J. A. Spencer*, K. Steinkamp, B. Shafii, and A. Ahmadzadeh, *University of Idaho, Moscow.*

Approximately, 70 to 80% of total embryonic loss in dairy cattle occurs between Days 8 and 16 after artificial insemination (AI). Early embryonic loss may be due to the premature secretion of prostaglandin $F_{2\alpha}$ ($PGF_{2\alpha}$) during Days 14–16 after fertilization. The objective of this study was to examine the effect of Aspirin, a non-steroid anti-inflammatory drug (NSAID), on $PGF_{2\alpha}$ secretion in lactating dairy cows by characterizing blood plasma prostaglandin metabolites (PGFM) and progesterone (P_4) during the luteal phase of the estrous cycle. Twenty-four lactating Holstein cows were synchronized

to ovulation. The ovulation was confirmed by ultrasonography (d 1). On d 14 and after detection of corpora lutea, cows were assigned randomly to receive Aspirin (total of 140 g) or no Aspirin (control) and the blood sample was obtained from each cow. Aapirin was given orally on d 14 (2×) and d 15 (1×), 12 h apart. On d 15, 6 h after the last dose of aspirin, hourly blood samples were taken for 6 h for PGFM concentrations. Daily blood samples were also collected (d 15 to 23) to examine P_4concentrations. One cow was eliminated from the study for having < 1 ng/mL P_4 on d 15. Analyses of repeated measures, using the mixed model procedure of SAS were utilized. The model included treatment, the repeated factor time, and treatment × time interaction. Cow was the random effect. On d 14, mean P_4 was > 1 ng/mL for all cows and it was similar between groups. Before treatment, there was no difference in mean PGFM concentrations between the groups, (203 vs. 224 ng/mL; SE ± 39 for aspirin and control, respectively). There was an effect of treatment and treatment × time on mean PGFM ($P < 0.05$). Mean PGFM concentrations were decreased ($P < 0.05$) 30 h after initiation of treatment and remained low for 5 h after last treatment, whereas they remained unchanged in the control. Overall, mean PGFM concentrations were 106 and 190 ng/mL (SE ± 33) for aspirin and control, respectively. Blood P_4 concentrations post-treatment were similar between the two groups (3.6 vs. 3.2 ng/mL; SE ± 0.6), but declined from d 15 to d 23 ($P < 0.01$). The study indicated that oral administration of aspirin treatment may suppress $PGF_{2\alpha}$ during d 14 to 15 after estrus and prevent early luteal tissue regression; however, no effect on P_4 was observed.

Key Words: dairy cows, NSAID, prostaglandin $F_{2\alpha}$

1378 (M195) Association between oxidative stress through excessive fat accumulation and the number of mitochondrial DNA copies in adipose tissue of dairy cows.

L. Laubenthal[*1], L. Locher[2], J. Winkler[3], U. Meyer[3], J. Rehage[2], S. Dänicke[3], H. Sauerwein[1], and S. Häussler[1], *[1]University of Bonn, Institute of Animal Science, Germany, [2]University for Veterinary Medicine Foundation, Hannover, Germany, [3]Institute of Animal Nutrition, Friedrich Loeffler Institute (FLI), Braunschweig, Germany.*

In the transition period, overconditioned cows usually have more problems to adapt to the needs of lactation than leaner cows and are thus more prone to health problems. The mitochondrial DNA (mtDNA) copy number reflects the abundance of mitochondria in a cell and may change under different energy requirements and physiological conditions. Increased metabolic demands as well as increased mtDNA copies per cell are associated with elevated oxidative stress. However, the association between oxidative stress through excessive fat accumulation and mtDNA copy numbers in bovine adipose tissue (AT), being considered as a major contributor to systemic oxidative stress, has not been investigated so far. We hypothesized that the mtDNA copy number in AT will increase concomitant with oxidative stress [assessed by quantifying the derivates of reactive oxygen species (dROM)] during fat accretion in cows. Eight non-lactating, non-pregnant pluriparous German Holstein cows (age: 4 to 6 yr) were fed diets with increasing portions of concentrate feed during the first 6 wk of the experiment until 60% were reached, which was maintained for 9 wk. Within this period cows had an average body weight (BW) gain of 243 ± 33.3 kg. Blood samples were collected monthly and dROM were photometrically quantified in serum using N,N,diethyl-1,4-phenylendiamine as chromogen. Biopsies from the subcutaneous tailhead AT were taken every 8 wk and immediately snap frozen for genomic DNA isolation. The number of mtDNA copies/cell was measured by a multiplex quantitative PCR using β-globin as reference gene. Data (mean ± SEM) for mtDNA copies and dROM as well as for BW were analyzed using non-parametric tests or repeated measurement ANOVA, respectively. Correlations were calculated using the Spearman (r) correlation coefficient. Throughout the fat accumulation period mtDNA copies/cell and dROM increased fourfold (329 ± 57.5 to 1385 ± 160; $P = 0.002$) and 2.5-fold (49.9 ± 9.24 to 125 ± 16.0 µg H_2O_2equivalents/mL; $P = 0.003$), respectively. We observed a positive correlation between mtDNA copy numbers and BW ($r = 0.596$, $P = 0.003$) and dROM ($r = 0.550$, $P = 0.005$). Increased mtDNA copies in AT might be an adaptation in response to oxidative stress that evolves from excessive fat accumulation in overconditioned cows. It is known, that mtDNA copy numbers increase as a compensatory response mechanism to mtDNA damage. Therefore, increased numbers of mitochondria and thus increased numbers of mtDNA copies per cell might then amplify the production of ROM leading to further mtDNA damage.

Key Words: mtDNA, oxidative stress, fat accumulation

1379 (M196) Telomere length shortening in response to an excessive fat accumulation in subcutaneous adipose tissue of dairy cows.

L. Laubenthal[*1], L. Locher[2], J. Winkler[3], U. Meyer[3], J. Rehage[2], S. Dänicke[3], H. Sauerwein[1], and S. Häussler[1], *[1]University of Bonn, Institute of Animal Science, Germany, [2]University for Veterinary Medicine Foundation, Hannover, Germany, [3]Institute of Animal Nutrition, Friedrich Loeffler Institute (FLI), Braunschweig, Germany.*

With the onset of lactation, overconditioned cows mobilize more body tissue than thin cows and are prone to develop metabolic disorders. The metabolic stress in cows with higher body condition score (BCS) before calving and greater loss of BCS after calving comprises oxidative stress. Increased production of reactive oxygen metabolites may damage cells and accelerate telomere shortening which serves as biological marker for age and stress-related conditions. Herein we aimed to investigate the telomere length (TL) in subcutaneous

adipose tissue (AT) during exemplarily induced excessive fat accumulation in cows. We hypothesized that TL is associated with the production of derivates of reactive oxygen metabolites (dROM), as indicator for oxidative stress, in overconditioned cows. Eight non-lactating, non-pregnant German Holstein cows (4 to 6 yr) received diets with increasing concentrate feed proportions (0 to 60% of the total daily dry matter intake) during the first 6 wk of the experiment which was maintained for 9 wk. The BCS (5-point scale) increased from 2.3 ± 0.12 to 4.57 ± 0.14 and the average body weight (BW) gain was 243 ± 33.3 kg. Blood samples were taken monthly for photometric quantification of dROM in serum using N,N,diethyl-1,4-phenylendiamine as chromogen. Subcutaneous AT from tailhead was collected at the beginning and of the experiment and after 15 wk. Samples were snap frozen for isolation of genomic DNA. A multiplex quantitative PCR was used to analyze the relative quantity of telomere (qT) products compared with β-globin products which served as reference gene to estimate TL in AT. Data (mean ± SEM) for TL, BCS and BW as well as for dROM were evaluated using repeated measurement ANOVA or non-parametric tests, respectively. Correlations were calculated using the Spearman (*r*) and Pearson (*r*) correlation coefficient. Relative qT decreased throughout the experiment (51.8 ± 3.26 to 43.6 ± 1.76; $P = 0.01$) whereas dROM increased more than two-fold ($P = 0.003$). Shorter TL were correlated with BCS ($r = -0.586$, $P = 0.017$), BW ($r = -0.653$, $P = 0.008$) and dROM ($r = -0.596$, $P = 0.015$). Increasing dROM indicating oxidative stress were observed in overconditioned cows. Fat accumulation was accompanied by reduced TL in bovine AT. Shortening of telomeres might indicate fibrosis and would thus result in AT dysfunction which might compromise the adaptive capability of AT to the needs of lactation in overconditioned cows.

Key Words: telomere length, adipose tissue, oxidative stress

1380 (M197) Pregnancy per AI of high producing Holstein cows treated with norgestomet ear implant or progesterone intravaginal device.

H. Ayres[*1,2], C. M. Azevedo[3], J. B. Solak[4], O. Corso[4], S. Soriano[5], M. C. Wiltbank[6], and R. M. Ferreira[2], *[1]MSD Animal Healtg, São Paulo, Brazil, [2]Departamento de Reprodução Animal, USP, São Paulo, Brazil, [3]Qualy Calf Consultoria Ltda, Venceslau Braz, Brazil, [4]Castrovet Consultoria Veterinária, Castro, Brazil, [5]Fazenda Colorado, Araras, Brazil, [6]University of Wisconsin, Madison.*

The aim of present study was to compare pregnancy per AI (p/AI) of high producing Holstein cows subjected to timed artificial insemination (TAI) using a new or previously used progesterone intravaginal device or a Norgestomet ear implant. In Experiment 1, 359 cows (173 primiparous and 186 multiparous) received 2 mg estradiol benzoate i.m. (Gonadiol, MSD Animal Health, Brazil) at random days of the estrous cycle (d 0) and were homogenously distributed in two groups. Cows on group NEW-PROGESTERONE received a new progesterone releasing intravaginal device (CIDR, Zoetis, Brazil), while cows on group NEW-NORGESTOMET received a new Norgestomet ear implant (Crestar, MSD Animal Health, Brazil). On d 8, 500 mg Cloprotenol (Ciosin, MSD Animal Health, Brazil) and 1 mg estradiol cypionate (E.C.P., Zoetis, Brazil) were administered and the ear implants or intravaginal devices were removed. On d 10, 100 μg gonadorelin (Fertagyl, MSD Animal Health, Brazil) was administered and TAI was performed 10 h later. In Experiment 2, 293cows (146 primiparous and 147 multiparous) were subjected to the same experimental design described above except for using implants and devices previously used for 8 d (USED-PROGESTERONE = 146 cows vs. USED-NORGESTOMET = 147 cows). The experimental period began in May and ended in September 2012. Statistical analyses were performed using logistic regression (*P*ROC GLIMMIX of SAS). There were no interactions for treatment and parity, farm, and times in bred. The P/AI 30 d after TAI was similar ($P > 0.10$) between groups NEW-PROGESTERONE [31.6% (50/158)] and NEW-NORGESTOMET [35.3% (71/201)], and between groups USED-PROGESTERONE [35.6% (52/146)] and USED-NORGESTOMET [36.7% (54/147)]. These results indicate that both CIDR and Crestar, either new or previously used for 8 d, can be used for TAI treatments producing similar P/AI.

Key Words: norgestomet, pregnancy per AI, Holstein

1381 (M198) Telomere length in different visceral and subcutaneous adipose tissue depots of overconditioned cows.

L. Laubenthal[*1], L. Locher[2], J. Winkler[3], U. Meyer[3], J. Rehage[2], S. Dänicke[3], H. Sauerwein[1], and S. Häussler[1], *[1]University of Bonn, Institute of Animal Science, Germany, [2]University for Veterinary Medicine Foundation, Hannover, Germany, [3]Institute of Animal Nutrition, Friedrich Loeffler Institute (FLI), Braunschweig, Germany.*

Telomeres are short and repetitive sequences of the chromosomes which shorten with every cell-division. Therefore telomere length (TL) is considered as a biological marker for aging and cell proliferation depending on the tissue type. Increasing oxidative stress in response to nutrient surplus, e.g., in overconditioned dairy cows at the onset of lactation, accelerates telomere attrition. Adipose tissue (AT) is mobilized in early lactating cows to cope with the nutrient demands for milk synthesis. The different AT depots are divided into visceral (vc) and subcutaneous (sc) depots which exhibit different metabolic functions and cellular composition. We hypothesized that TL shortening within AT is depot specific in overconditioned cows due to different metabolic activities of sc and vcAT. Herein, we aimed to characterize the TL in seven different fat depots after rapid, diet-induced fat accumulation in cows. Eight German Holstein

cows (non-lactating, non-pregnant, age: 4 to 6 yr) were gradually adapted to a high-energy ration by increasing the portion of concentrate in the ration from 0 to 60% of daily dry matter intake within 6 wk. Animals were fed the 60% diets for further 10 wk and were then slaughtered; tissue samples from scAT (sternum, withers and tailhead) and vcAT (*P*ericardial, mesenteric, omental and retroperitoneal) were collected and snap frozen for further analyses. After isolation of genomic DNA, a multiplex quantitative PCR was used to analyze the relative quantity of telomere (qT) products compared with β-globin products which served as reference gene to estimate TL in AT. Differences between qT in the single AT depots were analyzed using the Student's *t* test (SPSS; mean ± SEM). Mesenteric AT exhibited 1.3-fold lower qT compared to omental (59.1 ± 7.4; $P = 0.01$) and pericardial (57.7 ± 7.9; $P = 0.004$) depots and 1.2-fold lower qT than retroperitoneal (53.5 ± 4.9; $P = 0.01$) AT. In scAT depots, fat from withers displayed 1.3-fold higher qT values than sternum (47.3 ± 3.5; $P = 0.005$) AT and 1.1-fold higher qT compared to tailhead (54.1 ± 8.2; $P = 0.05$) fat. Although vcAT is known to have a higher metabolic activity than scAT in dairy cows, we did not observe any differences in TL when comparing all sc versus all vcAT. Depot specific differences of TL might nevertheless be a hint to depot specific roles

Key Words: telomere length, adipose tissue, dairy cow

1382 (M199) Liveability of buck spermatozoa after cold storage using egg yolk citrate extender.

A. O. Ladokun*, J. A. Abiona, J. O. Daramola, E. O. Oke, and A. M. Onifade, *Federal University of Agriculture, Abeokuta, Nigeria.*

Preservation and extension of West African Dwarf (WAD) buck semen has been a challenge, because AI centres are far from farms where they are needed. This study was performed to investigate the liveability of buck spermatozoa extended with egg yolk citrate of West African dwarf goat buck spermatozoa. Twenty matured bucks were used for this experiment. Semen from these bucks was collected by means of artificial vagina after which evaluation was done. Buffer and extender were prepared using egg Yolk Citrate to preserve the semen and it was stored at 5°C in a refrigerator. Data were collected for 5 d at 0, 24, 48, 72, and 96 h on sperm concentration, percentage liveability, percentage dead, intact, damage, missing acrosome and sperm morphology. Data were analyzed using Statistical Package for Social Sciences (SPSS). Results show that the percentage sperm liveability at 0, 24, 48, 72, and 96 h were 57.50, 56.30, 54.03, 51.27, 47.00 respectively indicating a decrease with time. However, the percentage sperm dead increased with time: 42.50, 43.68, 45.97, 48.73, and 50.92% for 0, 24, 48, 72, and 96 h, respectively. The sperm motility (percentage) also reduced as the length of storage increased. The morphological characteristics of the spermatozoa also decreased with increase in the length of storage. It was concluded that liveability of sperm reduced as the storage time increased in West African Dwarf buck even with egg yolk citrate extender.

Key Words: egg yolk citrate, liveability, goat buck

1383 (M200) Bedding surface does not alter circulating patterns of cortisol, corticosteroid-binding globulin, or free cortisol index in preweaned Jersey calves.

H. G. Kattesh*, C. A. Kurman, B. E. Gillespie, P. D. Krawczel, and A. M. Saxton*, University of Tennessee, Knoxville.*

Previous research found no significant treatment differences in behavior or performance of Jersey calves residing at one farm when housed individually in hutches bedded with gravel ($n = 11$), sand ($n = 12$), or rubber mat ($n = 11$) from birth to 10 wk of age. The aim of the present study was to further examine the effects of these bedding surfaces on plasma total cortisol (CORT) and corticosteroid binding globulin (CBG) concentrations, and free cortisol index (FCI) analyzed from blood samples (10 mL) collected weekly from each of the calves during this earlier study beginning within 24 h of birth. Calves were provided 4 L of waste milk 1x/d from birth to 6 wk of age, and 2 L of waste milk 1x/d with calf starter and water ad libitum during the remaining 4 wk. Serum CORT was analyzed using a commercial RIA kit procedure and bovine CBG by an indirect ELISA developed and validated in our laboratory. The FCI was calculated using the ratio of serum CORT (nmol/L) to CBG (mg/L) concentrations. Data were analyzed by PROC MIXEDs in SAS 9.3 for repeated measures. No differences were found ($P > 0.10$) in CORT, CBG or FCI among treatment groups at any time point measured. Age-related changes ($P < 0.01$) among the three variables were found such that CORT was greatest (132.7 ± 32.0 nmol/L) at birth, reached a nadir (2.1 ± 0.5 nmol/L) at 6 wk of age, and increased ($P < 0.05$) to 8.0 ± 2.0 nmol/L by 9 wk of age. Serum CBG increased ($P < 0.01$) between birth and 1 wk of age (1.1 vs. 1.4 mg/L; SE = 0.1) and remained unchanged until the calves reached 6 wk of age at which time CBG was at its lowest (0.8 ± 0.1 mg/L; $P < 0.05$). Subsequently, CBG increased (1.4 ± 0.1 mg/L; $P < 0.05$) at 7 wk of age where it persisted thereafter. The FCI reflected the changes observed in CORT. The data are consistent with our previous results indicating that any of these bedding types may be used without compromising the welfare of preweaned Jersey calves. Whether the changes in CORT, CBG and calculated FCI noted here are age and/or diet related await further study.

Key Words: dairy calf, free cortisol index, bedding

1384 (M201) Niacin increases chemerin mRNA abundance in differentiated bovine preadipocytes in vitro. C. Kopp[1], H. Khalilvandi-Behroozyar[1,2], H. Sauerwein[*3], and M. Mielenz[1,4], *[1]Institute of Animal Science, Physiology & Hygiene Unit, University of Bonn, Germany, [2]Dep. of Animal Science, Urmia University, Iran, [3]University of Bonn, Institute of Animal Science, Germany, [4]Leibniz Institute for Farm Animal Biology (FBN), Institute of Nutritional Physiology, Dummerstorf, Germany.*

Chemerin is thought to be involved in controlling immune responses as a chemoattractant for antigen-presenting cells and has anti-inflammatory as well as pro-inflammatory functions; the latter are linked with obesity and insulin resistance. It is highly expressed as prochemerin in liver and adipose tissue and was recently identified as adipokine that regulates adipogenesis and adipocyte metabolism. The role of chemerin on glucose metabolism is controversially discussed. However, chemerin enhances insulin-stimulated glucose uptake, insulin signaling and increases insulin sensitivity in murine adipocytes. Niacin (NA) is an antilipolytic and lipid-lowering compound which is used since decades to treat dyslipidemia in humans. Furthermore, NA affects the secretion of several adipokines (e.g., adiponectin) and improves insulin sensitivity in humans. These effects are mediated through binding the G protein coupled receptor 109A (GPR109A). Our objective was thus to examine both, the effect of NA on chemerin mRNA expression in bovine adipocytes and the involvement of GPR109A in NA sensing. A primary cell culture system using differentiated bovine preadipocytes was established. Subcutaneous adipose tissue was collected from five Holstein-Friesian cows. Stromal-vascular cells were isolated, pooled and seeded at 2500 cells/cm^2. Preadipocytes after 12 d of differentiation were used. After serum starvation (4 h), cells were incubated either with 100 ng/mL pertussis toxin (*P*TX), a non-selective G protein uncoupling agent, or PBS for 16 h to characterize the NA mediating pathway. Cells were then treated with NA (10 or 15 μM) for 12 or 24 h or with PBS as controls, respectively. Chemerin mRNA abundance was quantified by qPCR. Data normalization was based on five stable reference genes. Statistical analyses were performed using ANOVA with Bonferroni post hoc tests ($P < 0.05$). The mRNA abundance of chemerin was increased 3.3-fold compared to controls after treatment with 10 μM NA for 24 h ($P = 0.006$). Treatment for 12 h or with 15 μM NA showed no difference in the mRNA abundance of chemerin. Pre-incubation with PTX abolished the observed NA-induced increase of chemerin mRNA abundance. Our results showed a NA-stimulated increase of chemerin mRNA expression in differentiated bovine adipocytes, which may point to improved insulin sensitivity by NA. Due to the annihilated increase after PTX treatment, we suggest that GPR109A mediates the effect of NA.

Key Words: chemerin, niacin, bovine adipocytes

1385 (M202) Macrophage infiltration into subcutaneous adipose tissue in overconditioned cows after excessive fat accumulation. S. Häussler[*1], L. Laubenthal[1], L. Locher[2], J. Winkler[3], U. Meyer[3], J. Rehage[2], S. Dänicke[3], and H. Sauerwein[1], *[1]University of Bonn, Institute of Animal Science, Germany, [2]University for Veterinary Medicine Foundation, Hannover, Germany, [3]Institute of Animal Nutrition, Friedrich Loeffler Institute (FLI), Braunschweig, Germany.*

Adipose tissue (AT) secretes adipokines regulating both metabolism and immune function. In monogastrics, diet-induced obesity is associated with changing adipokine profiles and increased macrophage (Ms) infiltration. However, in early lactating dairy cows we found virtually no Ms infiltration in different AT depots; non-lactating overconditioned heifers had increased accumulation of Ms in AT related with larger adipocytes, albeit in low total numbers. We hypothesized that the portion of Ms in bovine AT will remain small, even if fat is excessively accumulated in short time. Therefore we aimed to investigate the Ms infiltration in subcutaneous (sc)AT after rapid, diet-induced fat accumulation in cows. Eight non-pregnant, non-lactating pluriparous German Holstein cows, were adapted to diets with increasing concentrate feed proportions (from 0 to 60% of total dry matter intake) during the first 6 wk of the experiment which was maintained for 9 wk at 60% concentrate feeding. The body condition score (5-point scale) increased from 2.31 ± 0.12 to 4.53 ± 0.14, and the body weight increased from 540 ± 20 kg to 792 ± 29 kg. Three biopsies were taken every 8 wk of the entire experimental period from scAT of the tailhead region. Immunohistochemistry was performed on cryosections (12 μm) using the Ms-specific marker CD68. Bovine lymph nodes were used for positive and negative controls. The number of Ms and adipocytes per mm^2 were counted (100-fold magnification; 10 fields per sample). The portion of Ms was calculated from the mean number of positive stained cells/mean number of total adipocytes × 100. In total, 12 out of 23 samples yielded CD68-positive stainings. Considering the different time points, 5 out of 7, 5 out of 8 and 2 out of 8 samples were Ms-positive at the beginning, the middle and the end of the experiment, respectively. However, the average portion of Ms was only marginal: 3.7 ± 3.0% (n = 7) at the beginning, 0.9 ± 0.3% (n = 8) at the middle and 0.5 ± 0.3% (n = 8) at the end of the experiment. Thus even a rapid and pronounced increase of fat mass was not accompanied by Ms infiltration into subcutaneous AT. In consideration of the virtual absence of Ms in AT in earlier studies about cows during the first weeks of lactation, and the low portion of Ms in overconditioned heifers and in the present study, we assume that Ms infiltration is of no importance for bovine AT.

Key Words: macrophages, adipose tissue, cow

1386 (M203) Rumen-protected methionine, histidine, and slow-release urea: Effects on plasma 3-methylhistidine and ubiquitin proteasome-related gene expression in skeletal muscle of dairy cows receiving a diet deficient in metabolizable protein. H. Sadri*[1], F. Giallongo[2], A. N. Hristov[2], C. Lang[3], J. Werner[2], C. Parys[4], B. Saremi[5], and H. Sauerwein[1], *[1]Institute of Animal Science, Physiology and Hygiene Unit, University of Bonn, Germany, [2]Dep. of Animal Science, Pennsylvania State University, University Park, State College, [3]Dep. of Cellular and Molecular Physiology, Hershey Medical Center, Penn State College of Medicine, [4]Evonik Industries AG, Hanau, Germany, [5]Evonik Industries AG, Hanau, Germany.*

Skeletal muscle, the largest organ in vertebrates, plays a major role in homeostasis. The ubiquitin-proteasome system (UPS) is regarded as the main proteolytic pathway in muscle. It requires the coordinated reactions of three enzymes including ubiquitin-activating enzyme (E1), ubiquitin-conjugating enzyme (E2), and ubiquitin_ligases (E3). We hypothesized that supplementation of diets deficient in metabolizable protein (MP) with slow-release urea or rumen-protected (RP) Met and His will affect the gene expression of UPS-related factors in skeletal muscle of dairy cows in support of decreased proteolysis. Sixty Holstein cows were blocked based on DIM and milk yield and randomly assigned to one of five diets: MP-adequate diet (AMP); MP-deficient diet [DMP; 5% below the requirements (NRC, 2001)]; DMP supplemented with slow-release urea as Optigen (Alltech Inc., Nicholasville, KY; DMPO); DMPO supplemented with RPMet (Mepron; Evonik Industries AG, Hanau, Germany; DMPOM); and DMPOM supplemented with RPHis (Balchem Corp., New Hampton, NY; DMPOMH). The experimental period was 10 wk, with first 2 wk as covariate period. Muscle biopsies were collected from *M. longissimus dorsi* during the last week of the experiment. The mRNA abundance of the following UPS-related target genes was quantified by qPCR: F-box protein 32 (FBXO32), muscle ring-finger protein 1 (MuRF-1), both being muscle-specific E3 ubiquitin ligases, ubiquitin-like modifier activating enzyme 1 (UBA1), and ubiquitin-conjugating enzymes (UBE2G1 and UBE2G2). Data were normalized based on the geometric mean of the 4 most stable reference genes: lipoprotein receptor-related protein 10, marvel domain containing 1, RNA polymerase II, and emerin. The concentration of 3-methylhistidine (3-MH) as marker of muscle catabolism was measured in plasma samples collected at the end of the experiment. Data were analyzed by the PROC MIXED of SAS. With the exception of MuRF-1, the mRNA abundance of the target genes was not affected by treatment. In DMP cows, about twofold more (P = 0.05) MuRF-1 mRNA than in DMPO was observed. Plasma 3-MH did not differ among treatments. In conclusion, the UPS seemed to be upregulated at the level of the mRNA during protein deficiency but this effect was apparently not sustained to increased 3-MH plasma concentrations.

Key Words: rumen-protected amino acid, ubiquitin-proteasome system, dairy cow

1387 (M204) Antioxidant supplementation during in vitro maturation increased oocyte mitochondrial membrane potential and bovine embryo development. B. C. D. S. Leão*, N. A. D. S. Rocha Frigoni, P. C. Dall'Acqua, and G. Z. Mingoti, *University of Sao Paulo State (UNESP), Araçatuba, Brazil.*

This study evaluated the effects of bovine oocytes IVM medium supplementation with intracellular (cysteine and cysteamine) and extracellular (catalase) antioxidant on the oocyte competence, based on evaluation of nuclear maturation rates, occurrence of apoptosis, mitochondrial membrane potential and the subsequent embryonic development. Oocytes were matured during 22h in TCM-199 medium with bicarbonate, hormones and 10% FCS, without supplementation (Control group) or supplemented with: 0.6 mM cysteine associated with 100 µM cysteamine (C+C group); 100 UI catalase (CAT group); or 0.6 mM cysteine associated with 100 µM cysteamine and 100 UI catalase (C+C+CAT group), at 38.5°C and 5% CO_2 in air. A sample of matured and immatured oocytes were stained with 500 nM of the fluorescent probe MitoTracker Red (CMXROs, Molecular Probes, Invitrogen, Oregon, USA) or TUNEL (In Situ Cell Death Detection Kit, Fluorescein, Roche Applied Science, IN, USA), to evaluate mitochondrial membrane potential (n = 344) and apoptotic index (n = 565), respectively. Stained oocytes were evaluated under an epifluorescence inverted microscope (excitation 579/510–550nm and emission 599/590nm, respectively for MitoTracker and TUNEL) and the mitochondrial membrane potential (quantified in arbitrary fluorescence units- AFU) were measured by Q-Capture Pro image software. The intensity values of the fluorescence signal obtained from oocytes were subtracted from mean values of "background" in the images. The rest of oocytes were submited to IVF and presumptive zygotes were IVC in SOFaa, at 38.5°C and 5% CO_2 in air, for 7 d. Cleavage and blastocyst rates were evaluated at 72 and 168 hpi, respectively. Were made 10 replicates with 50 oocytes per dish, and it was considered the experimental unit. The mitochondrial membrane potential was analyzed by ANOVA followed by Tukey's test and percentage of apoptosis, cleavage and blastocyst rates by Chi-square test ($P < 0.05$). Data are presented as mean ± SEM. The AFU for membrane mitochondrial potential were 1.00 ± 0.05^{a} (immature oocytes), 1.60 ± 0.05^{b} (Control), 0.94 ± 0.03^{a} (C+C), 1.41 ± 0.05^{c} (CAT) and 1.81 ± 0.07^{d} (C+C+CAT). The oocyte maturation rates were 0.0% (immature) 76.7% ± 1.7 (Control), 80.3% ± 4.1 (C+C), 80.5% ± 5.2 (CAT) and 78.2% ± 1.1 (C+C+CAT), and the percentage of apoptotic oocytes were $1.55\%^{a}$ (immature), $5.83\%^{ab}$ (Control), $5.45\%^{ab}$ (C+C),

1.92%[a] (CAT) and 10.78%[b] (C+C+CAT). Cleavage and embryo development were 72.5%[a] and 28.2%[a] (Control), 75.7%[a] and 31.1%[a] (C+C), 75.4%[a] and 33.3%[a] (CAT) and 73.1%[a] and 46.2%[b](C+C+CAT). In conclusion, supplementation with association of cysteine, cysteamine and catalase improved blastocyst development that can be associated with the increase mitochondrial membrane potential and oocyte competence.

Key Words: mitochondrial membrane potential, antioxidant, in vitro maturation, blastocyst development

---

1388 (M205) Hepatic and adipose mRNA expression of genes related to FGF21 in response to conjugated linoleic acid (CLA) supplementation in dairy cows during early lactation. H. Sadri[*1], S. Dänicke[2], J. Rehage[3], and H. Sauerwein[1], *[1]Institute of Animal Science, Physiology and Hygiene Unit, University of Bonn, Germany, [2]Institute of Animal Nutrition, Friedrich Loeffler Institute (FLI), Braunschweig, Germany, [3]University for Veterinary Medicine Foundation, Hannover, Germany.*

The hepatokine fibroblast growth factor 21 (FGF21), a member of the FGF super-family, is emerging as an important regulator of metabolism. It is induced by fasting, ketogenic diets, and by peroxisome proliferator-activated receptor (PPAR) agonists. The glycemic and insulin sensitizing effects of FGF21 are mediated through the adipokine adiponectin that is induced by FGF21. We recently reported that the postpartal increase of adiponectin is attenuated in dairy cows receiving the PPAR-agonistic CLA and thus hypothesized that supplementation of cows with CLA in early lactation will affect the expression of FGF21, of the FGF receptor (FGFR) isotopes FGFR1c and FGFR2c, and of the essential co-receptor b-Klotho in liver and adipose tissue. German Holstein cows receiving 100 g/d CLA (n = 11; Lutrell pure, BASF, Germany; each 12% of *trans*-10, *cis*-12 and *cis*-9, *trans*-11 CLA) or a control fat supplement (Silafat, BASF; CTR; n = 10) from DIM 1 to 182 were biopsied (liver and subcutaneous fat) on d -21, 1, 21, 70, and 105 relative to calving. The target mRNAs were quantified by real-time RT-PCR. Data were analyzed by the PROC MIXED of SAS 9.2. Hepatic FGF21 and FGFFR2c mRNA abundance were affected by time ($P < 0.05$) and by treatment (FGF21: $P = 0.08$; FGFR2c: $P < 0.01$). In CTR cows, a 4.5-fold increase in FGF21 mRNA was observed from d -21 to d 21, followed by a decline to nearly prepartum values by d 105. The CLA cows had less FGF21 mRNA than the CTR cows. The mRNA abundance of FGFR2c increased during lactation in CTR but not in CLA; the greatest difference (1.5-fold) between the CLA and the CTR group was observed on d 70. The mRNA abundance of b-Klotho in the liver and adipose tissue changed over time ($P < 0.05$), while CLA had no effect. Expression of FGFR1c mRNAin adipose tissue was neither affected by time nor by treatment. The observed upregulation of hepatic FGF21 expression during the first 3 wk in liver supports a role of FGF21 in metabolic regulation and nutrient partitioning during early lactation. The inhibiting effects of CLA supplementation on hepatic mRNA expression of FGF21 and its receptor might promote glucose availability for the mammary gland by reducing peripheral insulin sensitivity.

Key Words: FGF21, CLA, liver and fat tissues, dairy cow

1389 (M206) Effect of melatonin (MEL) or maternal nutrient restriction on vascularity of the ovine placenta. K. A. Vonnahme[*1], M. E. Wilson[2], S. Romero[1], S. T. Dorsam[1], J. Haring[1], P. P. Borowicz[1], D. A. Redmer[1], and C. O. Lemley[3], *[1]North Dakota State University, Fargo, ND, [2]West Virginia University, Morgantown, WV, [3]Mississippi State University, Starkville.*

Objectives were to determine placental vascularity following dietary MEL treatment in a maternal nutrient restriction model. A second experiment was performed to assess MEL receptor dependent modulation in placental vascularity. For Exp. 1, 31 ewes were supplemented with 0 (CON) or 5 mg of MEL per d and allocated to receive 100% (adequate fed; ADQ) of daily nutrient requirements or a 40% restriction in total feed intake (RES) from d 50 to 130 of gestation. Placentomes were collected on d 130 of gestation. For Exp. 2, 14 ewes were fitted with Alzet mini osmotic pumps and infused with vehicle, MEL, or MEL receptor 1 and 2 antagonist (luzindole, LUZ) from d 62 to 90 of gestation. Placentomes were collected on d 90. Placentomes from both Exp. 1 and 2 were fixed, paraffin embedded, and examined for capillary area density (CAD, total capillary area as a proportion of tissue area), capillary number density (CND, total number of capillaries per unit of tissue area), capillary surface density (CSD, total capillary circumference per unit of tissue area), and average cross-sectional area per capillary (APC) for both maternal (caruncular) and fetal (cotyledonary) compartments. For Exp. 1, a MEL x nutritional plane interaction ($P = 0.02$) was observed for caruncle CAD, which was decreased in MEL-RES vs. CON-RES (0.145 vs. 0.269 ± 0.031). A MEL x nutritional plane interaction ($P = 0.01$) was observed for caruncle APC, which was decreased in MEL-RES vs. all other groups (95.8 vs. 171.7, 195.2, 165.6 ± 18.2 μm^2). Cotyledon CND tended to be higher in MEL versus CON, while a tendency ($P = 0.06$) for a MEL x nutritional plane interaction was observed for cotyledon APC, which was decreased in MEL-RES vs. all other groups (85.9 vs. 122.3, 122.2, 124.9 ± 10.2 μm^2). For Exp. 2, LUZ infusion tended ($P = 0.08$) to increase caruncle CAD (0.171 vs. 0.083 ± 0.026) and APC (129.2 vs. 48.1 ± 23.4 μm^2) compared to vehicle infusion. Measurements of cotyledon vascularity were not different ($P > 0.10$) across infusion treatments. *Supported in part by USDA-NIFA-AFRI grant 2011–67012–30683.*

Key Words: placenta, sheep, vascularity

1390 (M207) Follicle-stimulating hormone stimulates β-catenin via protein kinase B in granulosa cells.
B. I. Gomez*[1], C. A. Gifford[1], D. M. Hallford[2], and J. Hernandez Gifford[1], *[1]Oklahoma State University, Stillwater, [2]New Mexico State University, Las Cruces.*

Follicle-stimulating hormone regulation of ovarian estradiol production requires involvement of β-catenin (CTNNB1), a transcriptional co-factor. In cultured bovine granulosa cells, FSH treatment increases protein abundance of CTNNB1 as well as protein kinase B (AKT), a molecule known to regulate components of the CTNNB1 degradation complex. However, whether FSH induction of CTNNB1 is through direct modulation of AKT remains to be determined. To elucidate the effects of AKT signaling on CTNNB1 induction and subsequent estradiol production, bovine granulosa cells were cultured in the presence or absence of known AKT activators and inhibitors. Total protein was collected for analysis by Western blot and culture medium for estradiol quantification by RIA. Values were analyzed using one-way ANOVA procedure of SAS. To investigate specific contributions of AKT to CTNNB1 accumulation, granulosa cells were treated with IGF-1, a well-established AKT activator, in the presence or absence of FSH. Granulosa cells treated with FSH, IGF-1, and FSH+IGF-1 increased (0.68-fold) CTNNB1 accumulation compared to controls ($P = 0.09$; $n = 6$). Estradiol medium concentrations increased ($P = 0.001$; $n = 4$) in cells treated with FSH, IGF-1, and FSH+IGF-1 (166, 379, and 397%, respectively) compared to non-treated controls. A subsequent study utilizing lithium chloride (LiCl), another activator of the AKT pathway, demonstrated similar results. Granulosa cells were cultured in the presence or absence of LiCl with and without FSH. Consistent with data from IGF-1 treated cells, LiCl, FSH, and FSH+LiCl increased CTNNB1 accumulation (0.79-fold) compared to non-treated controls ($P = 0.03$; $n = 3$). In contrast, inhibition of AKT signaling with LY294002 suppressed ($P = 0.02$; $n = 3$) CTNNB1 by 1.93-fold compared to controls. Co-treatment of FSH and LY294002 reduced the ability of FSH to increase CTNNB1 ($P = 0.03$). LY294002 treatment reduced estradiol medium concentrations 1.14-fold when compared to control levels, while co-incubation of FSH+LY294002 and FSH treatment induced estradiol to similar levels above controls ($P = 0.0001$; $n = 4$). Results demonstrate activation of AKT is required for CTNNB1 accumulation and estradiol production in bovine granulosa cells. These data suggest that induced CTNNB1 accumulation by FSH and IGF1 activation of AKT may be the lynch pin molecule responsible for FSH and IGF1 synergistic steroidogenic activity.

Key Words: protein kinase B, β-catenin, granulosa cells

1391 (M208) Ileal tight junction gene expression in glucagon-like peptide 2-treated dairy bull calves with and without coccidiosis.
M. P. Walker*[1], E. E. Connor[2], R. L. Baldwin[3], and S. Kahl[1], *[1]USDA-ARS, BFGL, Beltsville, MD, [2]USDA-ARS, Bovine Functional Genomics Laboratory, Beltsville, MD, [3]USDA-ARS, Beltsville, MD.*

Intestinal gut permeability is partially regulated by the intestinotrophic hormone glucagon-like peptide 2 (GLP-2). Specifically, disease models in mice and human cell lines have implicated GLP-2 in the regulation of the tight junction milieu within the intestinal tract. Therapeutic administration of GLP-2 ameliorates gastrointestinal lesions and mechanical damage in rodent models of ileitis, porcine models of bowel resection, and humans with small bowel disease. These damages can reduce nutritional absorption and increase bacteria in the blood stream, both of which are in part attributed to tight junction protein disregulation. The purpose of the present study was to determine whether GLP2 therapy alters tight junction gene expression in ileum of neonatal dairy calves with scours induced by *Eimeria bovis* infection. Neonatal Holstein bull calves ($n = 18$) were separated into 4 treatment groups; uninfected-buffer ($n = 5$), uninfected-GLP-2 ($n = 4$), *E. bovis*-buffer ($n = 5$), and *E. bovis*-GLP-2 ($n = 4$). On d 0, calves in the *E. bovis*-buffer and *E. bovis*-GLP-2 groups were orally dosed with 200,000 sporulated oocysts of *E. bovis*. For 10 d (d 18 to d 27 of the study), uninfected-GLP-2 and *E. bovis*-GLP-2 calves were injected every 12 h with 50 µg of GLP-2/kg BW and at d 28 calves were sacrificed for collection of intestinal tissues for RNA extraction. Tight junction genes including CAR, CLDN1, CLDN2, CLDN4, F11R/JAMA, JAM2/JAMB, and TJP1/ZO-1 were evaluated in ileal epithelium by realtime quantitative PCR. Relative mRNA expression normalized to ATP5B and HMBS revealed greater expression of TJP1/ZO-1 in *E. bovis*-infected calves compared to uninfected calves ($P \leq 0.03$) and an *E. bovis* infection vs. GLP2 treatment interaction ($P \leq 0.004$). Expression of all other genes did not differ ($P > 0.05$) with GLP-2 treatment or *E. bovis*infection status. The lack of significant findings among the majority of genes investigated may be explained by large variation among individuals or the timing of sample collection relative to infection status and GLP-2 treatment. Alternatively, tight junctions may not be regulated at the RNA level, whereby analysis at the protein level may be more appropriate. Finally, the cellular localization of tight junction proteins may become altered during infection and with GLP2 treatment due to post-translational modifications or other regulating molecules. A more in-depth histological study could reveal significant findings that analysis of RNA levels alone cannot detect.

Key Words: dairy cattle, ileum, tight junction

1392 (M209) Effects of heat stress on the metabolic transcriptional profile of peripheral tissues in growing pigs. M. Sanz Fernandez[*1], J. S. Johnson[1], J. T. Seibert[1], R. L. Boddicker[1], S. C. Isom[2], L. Cox[2], J. W. Ross[1], R. P. Rhoads[3], and L. H. Baumgard[1], *[1]Iowa State University, Ames, [2]Utah State University, Logan, [3]Virginia Tech, Blacksburg.*

Heat stress (HS) alters postabsorptive metabolism and nutrient partitioning, independently of reduced nutrient intake. Surprisingly, despite marked hypophagia, heat-stressed animals have reduced plasma non-esterified fatty acids (NEFA), and decreased sensitivity to lipolytic signals. In addition, HS increases plasma insulin parameters in a variety of animal models. Further, HS seems to alter systemic fuel utilization, favoring aerobic glycolysis rather than oxidative phosphorylation. Study objective was to determine if these metabolic changes have their origin at the transcriptional level. Seventeen crossbred gilts (57 ± 5 kg BW) were subjected to one of two environmental treatments: 1) constant HS conditions (32°C, 23% RH) and ad libitum feeding (n = 7), or 2) pair-feeding in thermoneutral conditions (20°C, 36% RH; PFTN; n = 10) to eliminate the confounding effects of dissimilar intake. Feed intake decreased 38% on average and was not different between treatments (P = 0.75). After 8d of environmental exposure, pigs were sacrificed and liver, subcutaneous adipose tissue (AT) and muscle (longissimus dorsi, LD) immediately collected. Gene expression was determined using qPCR (BioMark System, Fluidigm Corporation) on an average of 42 genes per tissue. Genes were selected based on the RNA-Seq output of a similar experiment. Gene expression was normalized to housekeeper genes and statistical analysis was performed in delta delta Ct values (*P*ROC GLM, SAS 9.2). Data is reported as fold change. As expected, heat shock protein-related genes (e.g., HSF2, HSPA4, HSPB8, HSPCB, HSPE1, HSP90AA1) were up-regulated (41–156%, $P \leq 0.10$) across all tissues in HS compared to PFTN conditions. Supporting the phenotypic observation, adipose triglyceride lipase was downregulated (36%, P = 0.07), hepatic fatty acid synthase was up-regulated (1.5-fold, $P < 0.01$), and TCA cycle and electron transport chain proteins (i.e., IDH2, NDUFB7, NDUFS7) were downregulated (43%, P = 0.06; 22%, P = 0.05; 23%, P = 0.10; respectively) in liver and LD of HS pigs. Unexpectedly, AT insulin receptor and LD pyruvate dehydrogenase kinase 4 were downregulated (32%, P = 0.07; 61%, P = 0.05; respectively) in HS compared to PFTN pigs. Abundance of most of the genes involved in bioenergetic pathways did not differ between treatments. These data suggest that changes in metabolism and fuel selection after chronic HS (8d) may partially arise from differences in post-transcriptional regulation. Whether gene expression control at the transcriptional level has a role on metabolic adaptation to acute HS remains unknown.

Key Words: heat stress, pig, postabsorptive metabolism

1393 (M210) Effect of feeding high or low portions of concentrate during the transition period on serum adiponectin concentrations and mRNA expression of adiponectin and its receptors in subcutaneous and retroperitoneal fat of dairy cows. P. Friedrichs[1], M. Weber[1], L. Locher[2], S. Dänicke[3], U. Meyer[3], R. Tienken[3], H. Sauerwein[*1], and M. Mielenz[4], *[1]Institute of Animal Science, Physiology and Hygiene Unit, University of Bonn, Germany, [2]University for Veterinary Medicine Foundation, Hannover, Germany, [3]Institute of Animal Nutrition, Friedrich Loeffler Institute (FLI), Braunschweig, Germany, [4]Leibniz Institute for Farm Animal Biology (FBN), Institute of Nutritional Physiology, Dummerstorf, Germany.*

The mRNA expression of adiponectin (ADIPOQ) and its receptors ADIPOR1/2 in adipose tissue (AT) decreases with the onset of lactation in dairy cows; the serum concentrations of ADIPOQ have also been demonstrated to drop during the lactation-induced negative energy balance (NEB) but not during feed-restriction induced NEB at later stages of lactation (Singh et al. (2014), doi:10.3168/jds.2013–7598). As to whether the extent of NEB during the lactation-induced NEB may affect ADIPOQ system was not known and we thus hypothesized that the ADIPOQ system will be affected by feeding different portions of concentrate in the diet throughout the transition period, and that visceral (VC) and subcutaneous (SCAT) respond concordantly. Twenty pluriparous German Holstein cows were fed with rations containing either 60% (HC) or 30% (LC) concentrate (DM basis, n = 10 per group) from d 1 to 21 postpartum. The SCAT (tail head) and RPAT were biopsied at d -21, 1, and 21 relative to parturition. Blood samples were collected weekly. ADIPOQ and AdipoR1/2 mRNA abundances were quantified by qPCR, and serum ADIPOQ by ELISA. The statistical analyses were performed using SPSS 21.0 ($P < 0.05$). The NEB was more negative in LC than in HC animals (Δ = 18.5 MJ/d, third week of lactation). Effects of diet were limited to ADIPOQ in SCAT, with 4.1-fold lower mRNA abundance in LC than in HC at d 21 ($P < 0.02$). With the exception of AdipoR2 mRNA in RPAT, we detected time-related changes in SC and RPAT with higher abundances ante partum ($P < 0.05$) for all target mRNAs, and for ADIPOQ in serum. AdipoR2 mRNA abundance in RPAT was highest at d 1. Irrespective of time, ADIPOQ and AdipoR2 expression was higher in RPAT than in SCAT ($P < 0.05$), whereas AdipoR1 mRNA abundance was not different between both tissues. ADIPOQ and AdipoR1 mRNA abundance were positively correlated in SCAT (r = 0.461, $P < 0.01$) and RPAT (r = 0.745, $P < 0.01$). AdipoR1 and AdipoR2 were correlated in SCAT (r = 0.422, $P < 0.01$). The lower ADIPOQ mRNA abundance in SCAT of the LC group points to greater responsiveness towards dietary effects in this depot; however, this was apparently not reflected in serum ADIPOQ indicating that other fat depots might compensate the decrease. The observed time-related changes in SCAT and of

serum ADIPOQ confirm earlier reports, whereas the likewise regulation in RPAT for ADIPOQ and AdipoR1 has not been previously investigated in cows. The correlation between ADIPOQ and AdipoR1 mRNA abundances points to a co-regulation of both genes in AT.

Key Words: adiponectin

1394 (M211) Heat stress affects insulin sensitivity in primary bovine adipocytes.

P. P. Faylon[*1], L. H. Baumgard[1], R. P. Rhoads[2], and D. M. Spurlock[1], *[1]Iowa State University, Ames, [2]Virginia Tech, Blacksburg.*

Animals experiencing heat stress (HS) have diminished lipolytic response. Current research on lipid metabolism in lactating cows shows a clear disconnect between in vivo and in vitro data, wherein bovine cells cultured under HS conditions were found to be more sensitive to lipolytic stimuli. The objective of this study was to determine if HS affects insulin sensitivity in subcutaneous adipose tissue (AT) of dairy cattle. Bovine primary adipocytes, isolated from 7 multiparous Holstein cows in late lactation, were cultured at either 42°C (HS) or 37°C (thermal neutral, TN) and incubated with varying concentrations of insulin (0 to 2.5 mU) in combination with isoproterenol (ISOP, 10^{-6} M). Glycerol release was measured as an indicator of lipolytic response. The effects of temperature and insulin concentration, as well as their interaction on AT lipolysis were evaluated. Likewise, the abundance of several lipolytic proteins in relation to HS was analyzed. A significant insulin concentration by temperature interaction was observed in HS ($P < 0.001$) but not TN ($P = 0.34$) cells. Insulin significantly reduced the amount of glycerol released ($P < 0.001$), indicating a decline in response to lipolytic stimuli. Meanwhile, in the absence of insulin, adipocytes cultured under HS exhibited an elevated response to ISOP ($P < 0.001$) relative to their TN counterparts. Basal lipolytic (-ISOP/-insulin) response was not different between HS and TN cells ($P > 0.05$). Furthermore, a significant decrease in the phosphorylation of hormone sensitive lipase (HSL) at Serine 563 ($P = 0.03$) and perilipin ($P = 0.04$) with respect to increasing insulin concentrations was observed for cells cultured under HS but not TN conditions. These data support the view that HS affects insulin sensitivity of bovine adipocytes, suggesting that HS may indirectly prevent in vivoadipose tissue mobilization as a result of heat-induced increase in circulating insulin concentrations, combined with higher AT sensitivity to insulin.

Key Words: heat stress, adipose tissue, insulin, lipolysis

1395 (M212) mRNA expression of chemerin and its receptor in a subcutaneous and a visceral fat depot of dairy cows fed with high or low portions of concentrate during the transition period.

P. Friedrichs[1], H. Khalilvandi-Behroozyar[2], L. Locher[3], S. Dänicke[4], U. Meyer[4], R. Tienken[4], H. Sauerwein[*1], and M. Mielenz[5], *[1]Institute of Animal Science, Physiology and Hygiene Unit, University of Bonn, Germany, [2]Dep. of Animal Science, Urmia University, Iran, [3]University for Veterinary Medicine Foundation, Hannover, Germany, [4]Institute of Animal Nutrition, Friedrich Loeffler Institute (FLI), Braunschweig, Germany, [5]Leibniz Institute for Farm Animal Biology (FBN), Institute of Nutritional Physiology, Dummerstorf, Germany.*

Chemerin (RARRES2) is involved in adipogenesis and in mediating fat mobilization in mature adipocytes, exerting its effects via its receptor ChemR23. In humans, circulating chemerin levels are regulated by the energy intake. We hypothesized that the expression of RARRES2 or ChemR23 in subcutaneous (SC) and retroperitoneal (RP) adipose tissue (AT) of dairy cattle will change throughout the transition period and will be affected by different portions of concentrate in the diet. Twenty pluriparous German Holstein cows were divided into a high-concentrate group (HC, $n = 10$) receiving a diet with 60% and a low-concentrate group (LC, $n = 10$) receiving a diet with 30% concentrate on DM basis from d 1 until d 21 post partum. The SCAT from tail head and RPAT were biopsied at d -21, 1, and 21 relative to calving. RARRES2 and ChemR23 mRNA abundance were quantified by qPCR. The statistical analyses were performed with SPSS 21.0 ($P < 0.05$). The mRNA abundances of both genes were not different between the HC versus the LC group neither in SCAT nor in RPAT, thus, groups were pooled for further analyses. In both tissues RARRES2 and ChemR23 mRNA expression were time-dependent, i.e., less RARRES2 and ChemR23 mRNA was observed ante partum than post partum in both AT ($P < 0.05$). When comparing both AT depots within the individual sampling times, RPAT had 1.33-fold higher RARRES2 mRNA abundance than SCAT on d 1 ($P = 0.004$), whereas no differences between both depots were seen on d -21 and 21. For ChemR23, RPAT and SCAT did not differ at any time point. In conclusion, the different concentrate portion and the difference in energy balance ($\Delta = 18.5$ MJ/d in the third week of lactation) between HC vs. LC group were apparently not relevant for the expression of RARRES2 or ChemR23. Considering time-related differences we observed that RARRES2 and its receptor are regulated in a likewise manner in bovine AT. Due to their functions, the higher mRNA abundances of RARRES2 and its receptor in both AT after parturition may reflect the paracrine/autocrine involvement of RARRES2 in stimulation of lipolysis to provide non-esterified fatty acids as energy source to other peripheral tissues.

Key Words: chemerin, adipose tissue, transition period

1396 (M213) Individual *trans* monounsaturated fatty acids have distinct effects on lipogenesis in 3T3-L1 adipocytes. P. Vahmani*[1], T. D. Turner[1], P. D. Duff[1], D. C. Rolland[1], C. Mapiye[2], W. J. Meadus[1], and M. E. R. Dugan[1], *[1]Agriculture and Agri-Food Canada, Lacombe, AB, Canada, [2]Stellenbosch University, Western Cape, South Africa.*

The objective of this research was to determine the isomer specific effects of *trans* 18:1 isomers on lipogenic gene expression and fatty acid composition in adipocytes. Differentiated 3T3-L1 adipocytes were treated with 200 μM of either *trans*-9 18:1, *trans*-11 18:1, *trans*-13 18:1, or *cis*-9 18:1 (control) for 120 h. Cells were then analyzed for changes in gene expression and fatty acid composition using real-time PCR and gas liquid chromatography, respectively. The experiment was repeated three times and data were analyzed using the PROC MIXED of SAS. The *trans*-9 18:1 treatment increased the expression of acetyl-CoA carboxylase (1.6-fold, $P = 0.08$), fatty acid synthase (1.5-fold, $P = 0.03$) and stearoyl-CoA desaturase-1 (1.7-fold, $P = 0.03$) compared to the control, whereas *trans*-11 18:1 and *trans*-13 18:1 did not affect ($P > 0.10$) the expression of these genes. Consistent with the gene expression results, the content of *cis*-9 16:1 ($P = 0.01$; SEM = 8.63), total monounsaturated fatty acids ($P = 0.002$; SEM = 31.5) and total fatty acids ($P = 0.04$; SEM = 41.7) were higher in *trans*-9 18:1 (191, 986, and 1502 μg/well respectively) compared with *cis*-9 18:1 (144, 783, and 1272 μg/well respectively), *trans*-11 18:1 (141, 716, and 1370 μg/well respectively) or *trans*-13 18:1 (128, 659, and 1349 μg/well respectively). The *trans*-9 18:1 treatment also increased the *cis*-9 16:1/16:0 ratio ($P < 0.01$; SEM = 0.016) compared to the *cis*-9 18:1, *trans*-11 18:1 or *trans*-13 18:1 treatments (0.61, 0.52, 0.41 and 0.42 respectively). The amount of treatment fatty acid deposited in cells was highest ($P = 0.01$; SEM = 31.5) for *trans*-9 18:1 (585 μg/well) followed by *cis*-9 18:1 (493 μg/well), *trans*-11 18:1 (382 μg/well) and *trans*-13 18:1 (339 μg/well). About 32% of *trans*-13 18:1 was desaturated to *cis*-9, *trans*-13 18:2, whereas 19% of *trans*-11 18:1 was desaturated to *cis*-9, *trans*-11 18:2. Our results suggest that *trans*-9 18:1, the most abundant industrial *trans* fatty acid, is more lipogenic than *trans*-11 18:1 or *trans*-13 18:1. We also found that *trans*-13 18:1 is used as a preferred substrate for delta-9 desaturation. Our results demonstrate that *trans*-13 18:1, the second most abundant *trans*-18:1 isomer in beef when feeding forage based diets, is metabolized differently and may have differing bioactivity than major industrially produced *trans* fatty acids. Consequently, potential bioactivities of *trans*-13 18:1 and its delta-9 desaturation product deserve further investigation.

Key Words: adipocytes, mouse, *trans* monounsaturated fatty acids

1397 (M214) Modeling diurnal variation in ruminal temperature of beef cows. B. H. Boehmer*, and R. P. Wettemann, *Oklahoma Agricultural Experiment Station, Stillwater.*

Ruminal temperature (RuT) of beef cows is an effective measure of core body temperature. Monitoring RuT may be useful for the prediction of physiological events in cattle including estrus, parturition, and health status. Daily variation in core body temperature of cattle is well documented and may influence prediction models using temperature. The objective of this experiment was to develop a method to reduce the impact of diurnal variation in RuT of beef cows. Hourly reporting temperature boluses (SmartStock, LLC) were administered to postpartum, lactating, Angus cows. The data set used for modeling contained 12,358 RuT values (58 cows; 14 d), with a daily mean of 19.3 ± 0.3 RuT readings per cow. Models were developed to generate hourly correction factors for RuT, which reduce the impact of diurnal variation. Briefly, the RuT for a cow at an hour was subtracted from the mean RuT of all cows at all hours in the experimental group (Ac), or mean RuT of an individual cow for all hours (Cc), or all RuT during a 72 h running average for an individual cow (Ra). Correction factors for each daily hour (0000 to 2300 h) were calculated as the hourly least squares mean for the hourly deviations from the means (Ac, Cc, Ra). Hourly least square means of the deviations for an hour were calculated for all cows (AM) or for individual cows (CM). Unadjusted RuT and RuT excluding drinking events (W; less than 2 x SD of mean RuT) were used for model evaluation. Ruminal temperature for each model was analyzed using PROC UNIVARIARTE, PROC REG, and PROC MIXED (SAS Inst. Inc.). All six correction models reduced the variation (> 54%) and skewdness (> 30%) of RuT. Hourly variation in RuT occurred for unadjusted RuT, W, and RaAM ($P < 0.05$), but was eliminated in AcAM, AcCM, CcAM, CcCM, and RaCM models. Bayesian information criterion values (goodness of fit), were least when AcCM was used to model RuT. When the AcCM model was used, variation in RuT was greatly diminished. Daily hour did not influence RuT when AcCM, CcCM, and RaCM models ($P = 0.87$, 0.83, 0.91, respectively) were used to adjust RuT. These results indicate models can be developed to greatly reduce diurnal variation in RuT. The usefulness of RuT can be enhanced through the use of models to reduce diurnal variation in body temperature of cows.

Key Words: beef cow, diurnal variation, ruminal temperature

1398 (M215) β-Hydroxybutyrate profile of high-yielding dairy cows of a Brazilian intensive system.

C. Bespalhok Jacometo*[1], J. Oliveira Feijó[1], P. Mattei[1], A. Marangon Oliveira[1], E. Schmitt[2], V. Coitinho Tabeleão[1], C. Cassal Brauner[1], F. B. Del Pino[1], S. Soriano[3], and M. Nunes Corrêa[1], *[1]Federal University of Pelotas, Brazil, [2]Embrapa, Porto Velho–RO, Brazil, [3]Fazenda Colorado, Araras, Brazil.*

This study aimed to investigate the β-hydroxybutyrate (BHB) profile of high-yielding primiparous and multiparous cows according to milk yield level. A total of 174 Holstein cows was evaluated and divided as: 1) primiparous with mean milk yield equal to or higher than 35 kg/d (42.92 ± 0.78 kg/d) (HP group, n = 37); 2) primiparous with mean milk yield lower than 35 kg/d (26.44 ± 0.91 kg/d) (LP group, n = 50); 3) multiparous with mean milk yield equal to or higher than 35 kg/d (44.28 ± 0.87 kg/d) (HM group, n = 37), and 4) multiparous with mean milk yield lower than 35 kg/d (24.87 ± 0.91 kg/d) (LM group, n = 50). The animals belonged to a commercial herd located in São Paulo State, Brazil, and were kept in free stall barns, according to their production level, and were given high-concentrate diet based on NRC recommendations (NE_L: H groups: 1.74 MCal/kg DM and L groups: 1.56 MCal/kg DM). Blood samples were collected from the coccygeal vein to evaluate BHB by an enzymatic method using a commercially available kit (Randox-Ranbut Laboratories, Oceanside, CA). The mean lactation period of all evaluated cows was 216 ± 12. Statistical analysis was performed using SAS software by One-way ANOVA and Pearson Correlation Test. The mean dry matter intake of each free stall barn during the period in which blood samples were collected was similar between groups (HP: 24 kg/d; LP: 22.7 kg/d; HM: 26.9 kg/d and LM: 22.7 kg/d). There were no statistical differences between groups ($P > 0.05$). The BHB concentrations for primiparous groups were: HP 0.45 ± 0.05 mmol/L, and LP 0.48 ± 0.08 mmol/L; for the multiparous ones, HM 0.42 ± 0.04 mmol/L, and LM 0.42 ± 0.09 mmol/L. When the same production level was compared, HP and HM tended to have a negative correlation, and so did LP and LM (Pearson´s correlation coefficients: -0.26 and -0.22, respectively); when the same category was compared, both HP– LP and HM– LM combinations tented to have a positive correlation (0.21 and 0.40, respectively). The results suggest that the cows with the mean lactation period in this study did not show a negative energy balance (NEB), probably due to the fact that milk production requirements were provided by their diet, which did not alter BHB concentration levels, an NEB marker.

Key Words: β-hydroxybutyrate, dairy cows, negative energy balance

1399 (M216) Analysis of transcription regulator gene networks in peripartal bovine liver during summer and spring seasons.

K. Shahzad*[1], H. Akbar[1], L. Basiricò[2], P. Morera[2], U. Bernabucci[2], and J. J. Loor[1], *[1]University of Illinois, Urbana-Champaign, Urbana, [2]Università degli Studi della Tuscia, Viterbo, Italy.*

Gene network analysis was used on hepatic transcriptome data from cows calving during spring (SP) or summer (SU) to uncover transcription regulators (TR) and their target genes. Liver tissue was harvested from multiparous Holstein cows at -30, 3, and 35 d relative to parturition during SP. (March–April, n = 6) and SU (June–July, n = 6). Mean temperature-humidity indeces for SP. (day/night, below 72) and SU (day, 79.5 ± 2.9; night, 70.1 ± 4.7) were recorded. Transcriptomics was conducted using the 45K-Agilent bovine microarray. Statistical analysis with FDR $\leq$ 0.10 resulted in 618, 1030 and 894 differentially expressed genes during SU vs. SP. at -30, 3, and 35 d, respectively. Ingenuity pathway analysis (IPA) was used for gene network reconstructions. Among molecular and cellular functions, the IPA analysis identified cell death and survival and cellular growth and development as the most-enriched functions. Carbohydrate metabolism was the most enriched at -30 and 3 d, while nucleic acid metabolism and cellular development were the most enriched at 3 and 35 d. A total of 50, 78, and 74 TR were identified at -30, 3, and 35 d. The IPA analysis uncovered HNF4A, MYC, and NCOA1 (-30, 3, and 35 d), STAT3, and RELA (-30 and 35 d), BCL6 (3 and 35 d), KAT2B (-30 d), and GATA2 (3 d) as key TR. Comparing SU vs. SP. at -30d uncovered HNF4A and MYC (both triggered by RELA) as key TR. Both are linked with several downstream up-regulated target genes involved in oxidation of xenobiotic compounds (CYP3A4), tryptophan catabolism (ACMSD1), arginine catabolism (ARG1), apoptosis regulation, and ER Calcium homeostasis (CFLAR, TMBIM6). In contrast, among the downregulated targets there were several involved in cellular proliferation, anti-apoptotic activities, immune related disorders (CDKN1, LGALS1, TSPO), and liver disease (SERPINA1, FTH1). At 3 d, both HNF4A and MYC were downregulated. Up-regulation of BCL6 was directly linked with the IL-6-dependent immune-response and cell growth. In contrast, BCL6 was associated with downregulation of IL7R, IL13R1 and CXCL10-dependent immune responses. At 35 d, the up-regulation of RELA was associated with target genes involved in activation of anti-inflammatory responses (CCL3, B2M), extracellular matrix breakdown (MMP1), regulation of cell cycle (MYC, PTEN, CASP8) and gluconeogenesis (*P*CK1). These results suggests that the molecular phenotype of the liver differs when calving during the summer compared with spring.

Key Words: temperature-humidity index, transcription regulator network analysis, transition cows

PHYSIOLOGY AND ENDOCRINOLOGY II

1400 (T210) Fertility of lactating dairy cows treated with gonadotropin-releasing hormone at estrus, 5 d after AI, or both, during summer heat stress. L. G. D. Mendonça*[1], F. M. Mantelo[1], and J. S. Stevenson[2], [1]*Dep. of Animal Sciences and Industry, Kansas State University, Manhattan,* [2]*Kansas State University, Manhattan.*

Objective was to evaluate fertility of lactating dairy cows after treatment with GnRH on the day of estrus, 5 d after AI, or both, under heat stress conditions in two Kansas dairies. Cows (n = 2855) detected in estrus based on tail paint removal were assigned to four treatments in a 2 × 2 factorial arrangement: 1) control (CON = 722); 2) GnRH treatment at AI (G0 = 739); 3) GnRH treatment 5 d post-AI (G5 = 697); or 4) GnRH treatment at AI and 5 d post-AI (G0G5 = 697). Daily temperature and humidity data were collected during study enrollment and temperature humidity index (THI) was calculated. Blood samples were collected from a subgroup of cows at AI (d 0), d 5 and d 12 to determine progesterone concentrations (CON = 58, G0 = 57, G5 = 58, G0G5 = 65). Pregnancy diagnosis was conducted by transrectal ultrasonography on d 36 and 94. Treatment with GnRH at AI did not affect pregnancy per AI (P/AI) on d 36 (P = 0.89) or d 94 (P = 0.53). Treatment with GnRH 5 d after AI did not affect P/AI on d 36 (P = 0.49) or d 94 (P = 0.36). Furthermore, the interaction between GnRH treatments on d 0 and 5 did not affect P/AI on d 36 (P = 0.90) or d 94 (P = 0.75). In contrast, the interaction between lactation number and treatment with GnRH on d 5 affected P/AI on d 36 (P = 0.01) and d 94 (P = 0.03) because GnRH treatment increased P/AI of ≥ 3-lactation cows (27.0 vs. 19.3%, 23.1 vs. 16.1%, respectively). Average THI at AI was 83.8 ± 0.1 and tended (P = 0.08) to be associated with P/AI at d 36, but was not (P = 0.34) associated with P/AI on d 94. Overall, treatment with GnRH on d 0 (P = 0.82), d 5 (P = 0.61), and the interaction between treatments on d 0 and 5 (P = 0.28) did not affect progesterone concentration on d 5 and 12 (1.8 ± 0.1 and 6.7 ± 0.2 ng/mL, respectively). Treating cows under heat stress conditions with GnRH at AI did not increase P/AI, but treatment with GnRH 5 d post-insemination increased fertility of ≥ 3-lactation cows.

Key Words: fertility, summer heat stress, dairy cow

1401 (T211) Luteolysis and pregnancy outcome in 5-d Resynch dairy cows after 1 or 2 injections of prostaglandin $F_{2\alpha}$. J. S. Stevenson*, S. L. Pulley, and S. L. Hill, *Kansas State University, Manhattan.*

Our objective was to determine pregnancy outcome after 50 mg PG administered on d 6 or 25 mg PG delivered on d 5 and 6, respectively, in a 5-d Ovsynch-Resynch (GnRH 5 d before [d 0] and 56 [p.m. on d 7] or 72 h [d 8] after 25-mg doses of PG [d 5 and 6 after GnRH]; timed artificial insemination [AI] on d 8). Lactating Holsteins in herd 1 diagnosed not pregnant between 30 and 36 d since last AI were enrolled randomly to receive either 50 mg PG on d 6 (1 × 50; n = 134) or 25 mg PG on d 5 and 6 (2 × 25; n = 139) after GnRH-1 (d 0), with GnRH-2 at 56 h after PG (d 5) and timed AI 16 h after GnRH-2. In herd 2, even-tagged cows received the 2 × 25 (n = 422) treatment and odd-tagged cows received the 1 × 50 (n = 450) treatment after a not pregnant diagnosis between 34 and 40 d since last AI. Blood collected from all cows in herd 1 at d 0, 5, 6, and 8 was assayed for progesterone. Defined luteolysis occurred when progesterone was ≥ 1 ng/mL on d 5 and 72 h later was < 0.5 ng/mL or < 1 ng/mL on d 8. Progesterone was similar between treatments on pretreatment d 0 and 5, but was greater (P < 0.01) in 1 × 50 than 2 × 25 cows on d 6 (4.7 ± 0.2 vs. 1.1 ± 0.2 ng/mL) and d 8 (0.43 ± 0.04 vs. 0.19 ± 0.04 ng/mL), respectively. Luteolysis was greater (P < 0.01; 93.3 vs. 78.5%) in the 2 × 25 vs. 1 × 50 treatment when the cutpoint was 0.5 ng/mL on d 8, whereas no difference was detected when the cutpoint was < 1 ng/mL (100 vs. 96.3%), respectively. Luteolytic failure was greater in cows classified as early cycle on d 0 or having a new corpus luteum after d 0 than for cows classified as late cycle on d 0 or having low progesterone on d 0 and 5. Luteolytic failure also was greater (P < 0.01) in 1 × 50 than 2 × 25 cows with a cutpoint of 0.5 ng/mL at AI and pregnancy per AI in combined herds was slightly reduced (30.4 vs. 25.1%), respectively.

Key Words: luteolysis, pregnancy per AI, progesterone

1402 (T212) Physiological characteristics of cows with divergent genetic merit for fertility traits during the transition period. S. Moore*[1,2], P. Lonergan[2], T. Fair[2], and S. Butler[3], [1]*Teagasc Moorepark, Fermoy, Ireland,* [2]*University College Dublin, Ireland,* [3]*Animal & Grassland Research and Innovation Centre, Teagasc, Moorepark, Fermoy, County Cork, Ireland.*

Cows with similar genetic merit for milk production, but with extremes of good (Fert+; n = 15) or poor (Fert-; n = 10) genetic merit for fertility traits were monitored. DMI was recorded daily from wk -2 to 5 relative to calving. Blood metabolites and metabolic hormones were measured from wk -2 to 8 relative to calving. Vaginal mucus (VM) was scored weekly on a scale 0 (no pus) to 3 (≥ 50% pus) from parturition to wk 6. Uterine polymorphonuclear neutrophil count was measured at

wk 3 and 6. Continuous data were analyzed using mixed model procedures. PROC NPAR1WAY was used to analyse VM score data. Logistic regression was performed to analyse the proportion of animals classified as having endometritis or to have resumed cyclicity by wk 6 postpartum. Prepartum DMI was similar between genotypes, but during the postpartum period, Fert+ cows had greater DMI than Fert- cows (19.7 vs. 16.8 kg DM/d, $P = 0.02$). Energy balance at wk 1 was greater in Fert+ cows than Fert- cows (2.3 vs. -1.12 UFL/d, $P = 0.02$). Fert+ cows had greater milk solids production (1.89 vs. 1.74 kg/d, $P = 0.05$). Fert+ cows had greater mean circulating insulin-like growth factor-I (102.62 vs. 56.85 ng/mL, $P = 0.001$) and tended to have greater mean circulating insulin (3.25 vs. 2.62 µIU/mL, $P = 0.08$) compared with Fert- cows from wk -2 to 8 relative to parturition. Mean circulating glucose (3.40 vs. 3.01 mmol/L, $P = 0.04$) concentrations were greater in Fert+ cows compared with Fert- cows from wk -2 to 3 relative to parturition. Fert+ cows maintained greater mean BCS throughout lactation compared with Fert- cows (2.98 vs. 2.74 units, $P < 0.0001$). Fert+ cows had better uterine health compared with Fert- cows as evidenced by lower weekly VM scores during wk 2 to 6 postpartum, and based on uterine cytology a smaller proportion were classified as having endometritis at wk 3 (0.42 vs. 0.78, $P = 0.09$) and 6 (0.25 vs. 0.75, $P = 0.04$). A greater proportion of Fert+ cows had resumed cyclicity by wk 6 postpartum (0.86 vs. 0.20, $P = 0.009$) compared with Fert- cows. These results indicate that good genetic merit for fertility traits is associated with a more favourable bioenergetic and uterine health status, earlier resumption of cyclicity and greater BCS, without antagonizing milk production.

Key Words: genetic merit for fertility, transition period, endometritis

---

1403 (T213) Characterization of luteal dynamics in lactating dairy cows for 32 d after synchronization of ovulation and timed artificial insemination.

A. Ricci*[1], P. D. Carvalho[2], M. C. Amundson[1], and P. M. Fricke[1], *[1]Dep. of Dairy Science, University of Wisconsin–Madison, Madison, [2]University of Wisconsin, Madison.*

Approximately 20% of cows diagnosed not pregnant 32 d after TAI do not have a CL, and cows that begin a resynchronization protocol in the absence of a CL have about 10% fewer pregnancies per AI compared to cows with a CL. An understanding of luteal dynamics after synchronization of ovulation and timed AI (TAI) may help to refine strategies for resynchronizing cows failing to conceive. Lactating Holstein cows ($n = 141$) were synchronized for first TAI (80 to 86 DIM) using a Double Ovsynch protocol. Thrice weekly (MWF) from 4 to 32 d after TAI, luteal diameter was measured using ultrasonography and blood samples were collected for evaluation of progesterone (P4) concentrations. Pregnancy status was determined using ultrasound 32 d after TAI. Cows ($n = 13$) were removed if they had twins ($n = 2$), if they did not synchronize ($n = 4$), or if they had pregnancy loss ($n = 7$). For cows diagnosed pregnant ($n = 48$), luteal volume increased from 4 to 13 d after TAI then remained constant until 32 d, whereas P4 increased from 4 to 15 d after TAI then remained constant until 32 d. For cows diagnosed not pregnant 32 d after TAI ($n = 80$), P4 profiles were evaluated using statistical cluster analysis (PROC CLUSTER of SAS) based on the day after TAI that P4 decreased to < 1 ng/mL. Cows diagnosed not pregnant were segregated into 5 clusters: 1) luteal regression 15 d after TAI (1.3%, 1/80); 2) luteal regression 18 to 22 d after TAI (55.0%, 44/80); 3) luteal regression 25 to 27 d after TAI (18.8%, 15/80); 4) luteal regression 29 to 32 d after TAI (3.8%, 3/80); and 5) original CL present 32 d after TAI (21.3%, 17/80). Pregnancy-associated glycoproteins (PAG) were measured in serum samples collected 25 and 32 d after TAI using a commercial assay (IDEXX Laboratories, Inc., Westbrook, ME). Relative serum PAG levels (mean ± SEM S-N values) differed among clusters at both 25 ($P = 0.03$) and 32 ($P < 0.01$) d after TAI and were similar for cows in clusters 2, 3, and 4 but were greater for cows in cluster 5. We conclude that cows maintaining their original CL for 32 d after TAI were initially pregnant but underwent pregnancy loss based on residual serum PAG levels at 24 and 32 d after TAI. *Supported by Hatch project WIS01171.*

Key Words: progesterone, luteal dynamics, pregnancy loss

1404 (T214) Influence of fat supplementation on LH pulses and FSH concentration in Nellore heifers.

R. S. Cipriano*[1], M. C. V. Miguel[2], H. F. Costa[2], J. S. Souza[2], L. M. Pavanello[2], M. A. Maioli[2], D. Giraldo-Arana[2], D. M. Pinheiro[2], F. M. Abreu[3], L. H. Cruppe[3], M. L. Day[3], and G. Nogueira[2], *[1]UniSalesiano, Araçatuba, Brazil, [2]Unesp, Araçatuba, Brazil, [3]Ohio State University, Columbus.*

The aim of this study was to verify whether protected fat supplementation, after weaning increases LH pulses and FSH concentration in Nellore heifers (*Bos taurus indicus*). Contemporary heifers ($n = 30$; 167 ± 13 kg; 9 mo) were sorted into three experimental groups: Control Group (CG, $n = 10$), sugarcane bagasse plus 4.2 kg concentrate and 500 g of ground corn; Fat Group (FG, $n = 10$), sugarcane bagasse, plus 4.2 kg of concentrate and plus 200 g of rumen protected fat (Ca salts of soybean oil); and Excess Group (EG, $n = 10$), sugarcane bagasse plus 4.2 kg of concentrate, 500 g of ground corn plus 200 g of rumen protected fat per animal per day (13.85% of palmitic acid, 17.92% of oleic acid and 49.09% of linoleic acid). After an adaptation period, animals remained under nutritional treatments for 92 d (13 to 16 mo of age). Blood samples were collected every 24 h during 17 d, in 10, 12, 14, and 16 mo of age, and every 20 min per 12 h on 11, 13, 14, and 16 mo of age for FSH and LH quantification. The

results were evaluated by repeated measures ANOVA and the Duncan´s test was the post-test of SAS. During the treatment, the FG presented a higher number LH pulses (3.12 ± 1.64; P = 0.05) in comparison with EG (1.86 ± 0.90) and CG (2.63 ± 0.74), from samples collected every 20 min per 12 h. The CG showed higher FSH concentration area (15.71 ± 3.72 ng/ml/day), P = 0.06) than GG (11.23 ± 2.51 ng/ml/day) and EG (14.17 ± 4.22 ng/ml/day) at the 14 mo of age. There was no difference on FSH concentration area between groups in 10 (P = 0.80), 12 (P = 0.55) and 16 (P = 0.35) mo of age. The CG showed higher FSH amplitude (1.86 ± 0.72 ng/ml, P = 0.08) than GG (1.12 ± 0.51 ng/ml) and EG (1.54 ± 0.22 ng/ml) also at the 14 mo of age. There was no difference on FSH amplitude between groups at the 10 (P = 0.89), 12 (P = 0.78) and 16 (P = 0.36) mo of age. We concluded that fat treatment increased frequency LH pulses, decreased FSH amplitude and FSH concentration area during supplement period.

Key Words: *Bos indicus*, LH, pulses, FSH, fat, supplementation

1405 (T215) Pregnancy outcomes based on pregnancy-associated glycoproteins in milk and serum during the first trimester of gestation in Holstein dairy cows.

A. Ricci[*1,2], P. D. Carvalho[3], M. C. Amundson[1], S. Koller[4], R. H. Fourdraine[5], L. Vincenti[2], and P. M. Fricke[1], *[1]Dep. of Dairy Science, University of Wisconsin-Madison, Madison, [2]University of Turino, Italy, [3]University of Wisconsin, Madison, [4]IDEXX Laboratories, Inc, Westbrook, ME, [5]AgSource Laboratories, Verona, WI.*

Our objective was to compare pregnancy outcomes based on pregnancy-associated glycoproteins (PAGs) in milk and serum samples from cows of known pregnancy status during the first trimester of gestation. Lactating Holstein cows (n = 141) were synchronized using a Double-Ovsynch protocol for first timed AI (TAI). Blood and milk samples were collected from all cows 25 and 32 d after TAI, and pregnancy status was determined 32 d after TAI using ultrasound. Pregnant cows with singletons (n = 48) continued the experiment in which blood and milk samples were collected and pregnancy status was assessed weekly from 39 to 102 d after TAI. Milk samples were assayed for PAGs by AgSource Laboratories (Menomonie, WI) and serum samples were assayed for PAGs by IDEXX Laboratories (Westbrook, ME). Milk and serum assay outcomes included relative PAG levels (S-N values), and cows were classified as pregnant (PG), nonpregnant (NP), or recheck (RC) based on threshold S-N values. Sensitivity, specificity, negative predictive value, positive predictive value, accuracy for milk PAG outcomes were 88, 87, 92, 83, and 88%, respectively 25 d after TAI, and 98, 83, 98, 79, and 88%, respectively 32 d after TAI. These values for serum PAG outcomes were 94, 92, 96, 88, and 93%, respectively, 25 d after TAI, and 100, 88, 100, 83, and 92%, respectively, 32 d after TAI. Overall, 87% (48/57) of cows maintained their pregnancy until 102 d after TAI. For the milk assay, NP and RC outcomes occurred for pregnant cows 25 (11 and 36%), 46 (4 and 17%), 53 (4 and 20%), 60 (5 and 18%), and 67 (7 and 20%) d after TAI when relative PAG levels were low. For the serum assay, NP and RC outcomes occurred for pregnant cows 25 d after TAI (6 and 35%), whereas RC outcomes occurred for pregnant cows 39 (30%), 46 (46%), 53 (59%), 60 (70%), 67 (52%), 74 (28%), 81 (20%) and 88 (11%) d after TAI. Relative PAG levels in both milk and serum were negatively correlated (P < 0.01) with milk production in multiparous but not primiparous cows at 53 and 60 d after TAI when relative PAG levels were at their nadir. We conclude that low relative PAG levels in both milk and serum resulted in NP and RC outcomes in pregnant cows using these assays and that both parity and milk production affected relative PAG levels in milk and serum. *Supported by Hatch project WIS01171.*

Key Words: pregnancy diagnosis, pregnancy associated glycoprotein, milk

1406 (T216) Comparison of two gonadorelin formulations and two luteolytic agents on pregnancy rates in beef cattle synchronized with a 5-d CO-Synch + CIDR program.

S. Bas[*1], T. A. Brick[1], G. Starkey[1], G. Messerschmidt[1], A. A. Barragan[1], G. M. Schuenemann[1], and M. L. Day[2], *[1]Dep. of Veterinary Preventive Medicine, Ohio State University, Columbus, [2]Ohio State University, Columbus.*

The objective of the present study was to compare the effect of two gonadorelin formulations and two luteolytic agents (PGF) injected as part of a 5 d CO-Synch + CIDR program on fixed timed AI (FTAI) pregnancy rates (PR) in beef cattle. Postpartum beef cows (n = 473) and heifers (n = 78) from two herds received GnRH and a CIDR insert on d 0; 5 d later, at CIDR removal, animals received two doses of PGF. On d 8, cows and heifers received a second dose of GnRH and were FTAI. At the initiation of the breeding program, cows were blocked by age and d postpartum (DPP) and randomly assigned into one of two treatment groups. For animals in the control group (CON = 280), the hormones used for the synchronization program were gonadorelin diacetate tetrahydrate (100 μg; Cystorelin) and dinoprost tromethamine [50 mg (two 25 mg doses); Lutalyse]; while animals in the Parnell group (PAR = 271) received gonadorelin acetate (100 μg; GONAbreed) and Cloprostenol sodium [1000 μg (two 500 μg doses); estroPLAN]. Determination of pregnancy status was performed by transrectal ultrasonography at 35 to 45 d after FTAI and after the conclusion of the breeding season. Age (CON = 4.8 ± 0.2; PAR = 4.6 ± 0.2), DPP (CON = 73.8 ± 1.6; PAR = 75.9 ± 1.5), and body condition score (CON = 6.6 ± 0.9; PAR = 6.6 ± 0.1) were not different (P > 0.05) between treatments. No difference (P > 0.05) in PR at FTAI was observed for the

CON (54.9%) and PAR (55.9%) treatment groups. Similarly, no difference ($P > 0.05$) in PR was observed between treatments for cows [CON ($n = 236$) = 55.1%; PAR ($n = 243$) = 56.9%] and heifers [CON ($n = 37$) = 54%; PAR ($n = 35$) = 51.4%]. Breeding season PR (89.8%) did not differ ($P > 0.05$) between treatments. In conclusion, the use of gonadorelin diacetate tetrahydrate plus dinoprost tromethamine (CON) resulted in similar FTAI PR when compared to gonadorelin acetate plus cloprostenol sodium (PAR).

Key Words: beef, GnRH, prostaglandin

1407 (T217) Rams treated with testosterone induce sexual activity in anovulatory dorper adult sheep.

L. M. Tejada*, *Universidad Autónoma Agraria Antonio Narro, Torreón, México.*

The aim of this study was to determine whether rams treated with testosterone induce estrus in multiparous anovulatory ewes in northern México. On April 15, Dorper multiparous ewes ($n = 60$) were randomly distributed to two experimental groups; all females received daily 30 mg i.m. of progesterone from d −8 and d −4 before contact with males. On April 20, while one group (GMT, $n = 31$) was exposed to three males treated with testosterone (25 mg i.m., every 3 d × 2 wk before mating), the other group (GMC, $n = 29$) was exposed to three non-testosterone treated males. Estrous response was evaluated in two periods. The first period from d 0 to 14 while the second period from 15 to 25 d after male introduction (twice daily, during 1 h). On d 10 and 25 of the experimental period, ovulation rate was assessed throughout ultrasonographic scanning. Estrus activity was compared using chi2 (SYSTAT program 12). During the first 14 d after male introduction, 87% of the GMT-ewes (27/31) ovulated but only 9.6% (3/31) showed estrus activity, whereas 68% of the GMC-females (20/29) ovulated and 3.4% (1/29) showed estrous activity. After 15 d post-male introduction, 83% of the GMT-females(26/31) ovulated, with 80% of the ewes showing signs of estrus (25/31). Regarding the GMC-females, 51% (15/29) ovulated, and 68% (13/29) showed signs of estrus activity. Results of this study confirm that males treated with testosterone are more effective to induce ovulation and estrus activity during the second phase of the experimental period (15 to 25 d after male introduction) in Dorper adult ewes, regarding the untreated-males.

Key Words: testosterone, sheep, anestrus, estrus activity

Table 1407. Sexual response in sheep exposed to male control group (GC) or treated with testosterone (GT)

	Response 0 to 14 d after introduction of males		Response 15 to 25 d after introduction of males	
	Ovulation	Estrous	Ovulation	Estrous
GT	87% (27/31)a	9.6% (3/31)a	83%(26/31)a	80%(25/31)a
GC	68%(20/29)a	3.4%(1/29)a	51%(15/29)b	68%(13/29)b

Different letters in columns indicate different statistical differences $P > 0.05$.

1408 (T218) Regulation in vivo and in vitro of G protein-coupled receptor 34 (GPR34) mRNA in ovarian granulosa cells of cattle and its role in steroidogenesis.

L. J. Spicer*[1], J. A. Williams[1], L. F. Schutz[1], M. L. Totty[1], N. B. Schreiber[1], and J. Gilliam[2], *[1]Oklahoma State University, Stillwater, [2]Oklahoma State University Center for Veterinary Health Sciences, Stillwater.*

Abundance of *G* protein-coupled receptor 34 (GPR34) mRNA is greater in granulosa cells (GC) of cystic follicles *vs*. normal dominant follicles of cattle. The present experiments were designed to determine if: 1) GPR34 expression in GC changes during normal follicular development in estrogen-active (EA) and estrogen-inactive (EI) follicles of cattle, 2) hormones that have been shown to influence steroidogenesis such as IGF-I and FSH regulate expression of GPR34 mRNA, and 3) GPR34 ligands function to regulate GC function. In Exp 1, estrous cycles of non-lactating Holstein cows were synchronized and ovariectomized on either Day 3 or 6 after ovulation; a 2 × 2 factorial ANOVA (Day 3 vs. 6; EA vs. EI) indicated that GPR34 mRNA abundance in GC increased ($P < 0.05$) from 6.1 to 14.1 ± 4.3 relative mRNA units between Day 3 ($n = 5$ cows) and 6 ($n = 5$ cows) post-ovulation but did not differ ($P > 0.10$) between EA ($n = 15$) and EI ($n = 23$) follicles. In Exp 2, ovaries were collected at a local slaughterhouse and GC were isolated and treatments applied in vitro for 24 h; a 2 × 2 factorial ANOVA (± IGF-I with ± tumor necrosis factor (TNF)-α) indicated that IGF-I increased ($P < 0.05$) GPR34 expression from 3.5 to 7.8 ± 0.3 relative mRNA units and TNFα decreased ($P < 0.05$) the IGF-I-induced GPR34 mRNA abundance to 6.0 ± 0.4 relative mRNA units in small-follicle (1–5 mm) GC ($n = 3$ replicates and GC pools/treatment). Also in Exp 2, IGF-I and TNFα decreased ($P < 0.05$) GPR34 expression from 17.1 to 9.4 and 2.2 relative mRNA units, respectively, in large-follicle (8–22 mm) GC, indicating a change in GPR34 responsiveness occurs during follicle development. Other in vitro experiments (Exp 3–7; $n = 3$ replicates) revealed that treatment with IL-2, prostaglandin E2 and angiogenin decreased ($P < 0.05$) GPR34 expression by 62, 19, and 21%, respectively, whereas FSH, IL-6 and cortisol did not affect ($P > 0.10$) *GPR34* expression in small-follicle GC. In Exp 8, the presumed ligand of GPR34, L-a-lysophosphatidyserine (LPPS), increased GC numbers by 1.74-fold and estradiol production by 5.4-fold (0.19 vs. 1.03 ng/10^5 cells/24 h) in small-follicle GC ($n = 3$ replicates). For the first time, we have identified the lysophosphatidylserine receptor GPR34 as a developmentally and hormonally regulated gene in GC, the ligand of which enhances GC proliferation and estradiol production.

Key Words: G protein coupled receptor, granulosa cell, cattle

1409 (T219) Interaction between a mammary immune response to lipopolysaccharide and luteal function in lactating dairy cows. J. Luettgenau[1], O. Wellnitz*[1,2], R. M. Bruckmaier[2], and H. Bollwein[1], *[1]Clinic of Reproductive Medicine, Vetsuisse Faculty University of Zurich, Switzerland, [2]Veterinary Physiology, Vetsuisse Faculty, University of Bern, Switzerland.*

In a previous study we observed negative effects of an intravenous injection of *Escherichia coli* lipopolysaccharide (LPS) on luteal size and blood flow (LBF) as well as on plasma P4 concentrations. Because there are several reports about negative effects of mastitis on fertility of dairy cows, the objective of the present study was to investigate if LPS applied into the mammary gland could also suppress luteal function. Each of 8 lactating dairy cows received once 200µg LPS into one quarter of the mammary gland on d 9 of the estrous cycle (d 1 = ovulation). Plasma cortisol (stress hormone) and haptoglobin (acute phase protein), both indicating a systemic immune response, as well as P4 were determined immediately before (0h), hourly until 9, 12, and 24 h after administration of LPS. Luteal size and LBF were measured 0, 3, 6, 9, 12, and 24 h after LPS-injection. Cows showed local and systemic symptoms (swelling of the udder, pyrexia, increased cardiac and respiratory frequencies), increased ($P \leq 0.02$) cortisol concentrations between 2 and 8 h, and a fivefold increase ($P = 0.02$) of haptoglobin between 0 and 24 h after treatment. Plasma P4 increased between h 2 and 4, and decreased between h 4 and 6 after LPS exposure. There was no effect ($P > 0.05$) of treatment on luteal size, but LBF increased ($P = 0.05$) during the first 3 h after LPS-injection, remained constant ($P > 0.05$) between h 3 and 6, and decreased ($P < 0.0001$) between h 6 and 12. Results indicate that in contrast to an intravenous injection the application of LPS into the mammary gland does not show an obvious suppression of luteal function, although inducing systemic effects.

Key Words: mastitis, corpus luteum

1410 (T220) Influence of maternal nutrient restriction and realimentation on vascularity of bovine placentomes. B. R. Mordhorst*[1], L. E. Camacho[2], C. O. Lemley[3], P. P. Borowicz[1], D. A. Redmer[1], K. C. Swanson[1], and K. A. Vonnahme[1], *[1]North Dakota State University, Fargo, [2]University of Arizona, Tucson, [3]Mississippi State University, Starkville.*

To investigate maternal global nutrient restriction and realimentation impacts on placentome vascularity and mRNA expression for angiogenic and vasoactive factors in cotyledonary (COT) and caruncular (CAR) tissues, multiparous beef cows were randomly assigned to either 100% (CON; $n = 18$) or 60% NRC requirements for all nutrients (RES; $n = 28$) on d 30 of gestation. On d 85, tissues were collected, or cows remained on CON or RES diets, or were realimented to CON. On d 140, tissues were collected and all remaining cows were placed on CON diets until d 254 where all remaining cows were slaughtered to collect tissues. At tissue collection, placentomes were separated and portions snap frozen until qPCR analyses for mRNA expression of platelet endothelial cell adhesion molecule-1 (PECAM-1), soluble guanylate cyclase-β, endothelial nitric oxide synthase, vascular endothelial growth factor, fms-like tyrosine kinase, and kinase insert domain containing receptor were performed with all normalized to 18S. Vascularity measurements in CAR and COT were stained for PECAM-1, Rhodamine labeled lectin, and DAPI, and micrographs analyzed with Image-Pro Premiere. Treatment did not affect ($P \geq 0.06$) mRNA expression in any tissue on any day. Data from d 85 was presented previously where COT capillary size was smaller in RES vs. CON (465 vs. 764 ± 91 μm^2). Treatment did not affect any CAR or COT measurements d 140 or 254. In CON cows, CAR tissue area decreased ($P = 0.02$) and capillary number density increased ($P < 0.01$) from d 85 to 254 (0.76 vs. 0.59 ± 0.05 mm^2; 114 vs. 301 ± 26 number/μm^2). In COT, tissue area increased ($P = 0.02$) from d 85 to 254 (2.66 vs. 2.84 ± 0.05 mm^2). Capillary area and surface densities were similar ($P \geq 0.19$) on d 85 and 140 and increased ($P \leq 0.04$) by d 254. Capillary size decreased ($P < 0.01$) from d 85 to 140 and were similar ($P = 0.14$) from d 140 to 254. Capillary number density increased ($P < 0.03$) throughout gestation (45.6, 66.6, vs. 162.6 ± 6.5 number/μm^2). Capillary changes throughout gestation are more prevalent in COT vs. CAR. While we have previously reported that realimentation can augment uterine blood flow and placental arteriole vasoreactivity, the histologic and mRNA expression for angiogenic/vasoactive factors do not appear to be altered by maternal dietary intake. *Supported partly by AFRI Competitive Grant no. 2009–65203–05812 from the USDA-NIFA.*

Key Words: cow, placenta, vascularity

1411 (T221) Lysophosphatidic acid (LPA) activates ERK1/2-P90RSK signaling in porcine trophoblast cells. J. Kim*, J. Lee, S. Jung, H. Bang, Y. Sung, Y. Choi, and J. Kim, *Dankook University, Cheonan, South Korea.*

LPA (lysophosphatidic acid) is a phospholipid having diverse biological effects on various types of tissues. Recently, we indicated that LPA and their specific G protein-coupled receptors appear to play a lipid regulator during implantation and establishment of pregnancy in a human, mice and pig. In pig, LPA with various fatty acyl groups and receptors (LPA_{1-3}) were expressed in the uterine endometrium and conceptus during pregnancy. The extracellular-signal-regulated kinase (ERK1/2) pathway has emerged as one of the critical components in LPA signaling cascades. However, little is known of the biological role of LPA in the porcine conceptus during implantation. Therefore, this study examined LPA and the ERK1/2 signal transduction pathway in porcine conceptuses

during early pregnancy. The effects of LPA on the ERK1/2 signaling pathway were studied using established porcine trophectoderm cells (PTr) isolated from Day 12 pig conceptuses. The pTr cells were serum starved for 24 h and then treated with LPA (0–20 uM) for 30 min. LPA dose dependently increased ERK1/2 phosphorylation. Western blot analyses of whole cell extracts with antibodies to target proteins also found that LPA increased levels of pERK1/2 and pP90RSK (ribosomal protein S6 kinase, 90 kDa) by 2.3- and 1.6-fold, respectively, within 15 min which was maintained for up to 90 min. MEK inhibitor U0126 and LPA_3 receptor blocker significantly decreased LPA-induced ERK and P90RSK activity. Collectively, these results indicate that LPA coordinately activates ERK1/2, P90RSK in pTr cells and supports the hypothesis that LPA is a critical regulator of trophoblast survival, growth and differentiation during early pregnancy.

Key Words: LPA, pig trophoblast, ERK1/2

1412 (T222) Relationship between dry-matter intake and subclinical endometritis in healthy postpartum dairy cows.

A. H. Souza*[1], P. D. Carvalho[2], A. R. Dresch[3], L. M. Vieira[4], K. S. Hackbart[3], R. D. Shaver[2], and M. C. Wiltbank[2], *[1]University of California Cooperative Extension, Tulare, [2]University of Wisconsin, Madison, [3]Dep. of Dairy Science, University of Wisconsin—Madison, Madison, [4]University of Sao Paulo-VRA, Brazil.*

The main objective was to study the relationship between dry matter intake (DMI) and subclinical endometritis of postpartum dairy cows. A secondary objective was to evaluate whether colostrum quality at calving was associated with subclinical endometritis. Postpartum Holstein cows (n = 70 total; primiparous = 28; multiparous = 42), were milked twice daily and housed and fed individually in tie-stalls. Dry matter intake was measured daily from individual cows from calving to 10 wk postpartum. Four cows that were evidently sick in the first wk after calving with depressed DMI for over 3 d and/or detected with fever were removed from further analysis. Colostrum was collected from the first milking and frozen for later quality analysis (digital Brix refractometer, 0 to 53% scale). To measure level of subclinical endometritis, uterine swabs were performed at 40 ± 3 d postpartum and a single treatment-blind technician evaluated all the slides by counting a minimum of 100 cells at 400x magnification and determined the number and percentage of polymorphonuclear cells (PMN) in the endometrial smear. The statistical analyses were performed with PROC CORR and PROC GLIMMIX of SAS. Dry matter intake averaged 18.5 ± 0.3 kg/d and 23.6 ± 0.4 kg/d, for primiparous and multiparous, respectively. There was no significant association between proportion of uterine PMN cells and average DMI (r = 0.16; P = 0.20), with no significant interactions with parity. In a further retrospective analysis, cows were divided in three classes of subclinical endometritis [0% PMN (n = 22); 1 to 20% PMN (n = 32); or > 20% PMN (n = 16)]. Similarly, the repeated measures comparison indicated no effects (P = 0.42) of subclinical endometritis on DMI. Interestingly, greater colostrum quality at calving was associated with greater DMI in multiparous (r = 0.40; P = 0.01), but not in primiparous cows (r = -0.08; P = 0.69). Further, colostrum quality was not associated with subclinical endometritis in older cows (r = 0.19; P = 0.25); but surprisingly, greater colostrum quality was associated with lower subclinical endometritis in primiparous cows (r = -0.37; P = 0.05). In conclusion, healthy postpartum cows with lower DMI had similar incidence of subclinical endometritis as compared to cows with greater intake levels. Associations between colostrum quality at calving and DMI and/or proportion of subclinical endometritis need further examination, but could represent an interesting tool to predict postpartum performance. *Support: USDA Grant 2010–85122–20612.*

Key Words: dairy cows, postpartum, dry matter intake, subclinical endometritis

1413 (T223) The effect of the initial GnRH and dose of PGF2α on pregnancy rate to TAI in beef heifers submitted to the 5-d CO-Synch + CIDR program.

L. H. Cruppe*[1], S. L. Lake[2], F. M. Abreu[1], S. G. Kruse[3], S. L. Bird[3], K. Heaton[4], B. R. Harstine[1], M. L. Day[1], and G. A. Bridges[3], *[1]Ohio State University, Columbus, [2]University of Wyoming, Laramie, [3]University of Minnesota, Grand Rapids, [4]Utah State University, Logan.*

The objective was to determine the effects of GnRH (Factrel) at CIDR insertion and number of doses of $PGF_{2\alpha}$ (PGF; Lutalyse) at CIDR removal in a 2 × 2 factorial on pregnancy rates to timed AI (TAI) in beef heifers enrolled in a 5-d CO-Synch + CIDR program. Yearling beef heifers (n = 1105) in seven locations (Ohio [2 locations; n = 149 and n = 116; Angus x Simmental], Utah [n = 274; Angus x Hereford], Wyoming [n = 156; Angus] and Minnesota [3 locations; n = 150, n = 150 and n = 110; Crossbred]) were enrolled in the 5-d CO-Synch + CIDR protocol and randomly assigned to either receive 100 µg GnRH (G+, n = 547) or not to receive GnRH (G-, n = 558) at CIDR insertion (d 0 of the experiment). At CIDR removal (d 5), heifers within G+ and G- groups were randomly assigned to receive either a single 25 mg PGF (PGF1) or two 25 mg PGF 6 ± 2 h apart (PGF2), resulting in four distinct treatments (G+PGF1, n = 272; G+PGF2, n = 275; G-PGF1, n = 277; G-PGF2, n = 281). All heifers received either tail paint or Estrotectpatches at CIDR removal to determine estrus response and were inseminated by TAI concomitant with 100 µg GnRH at 60 h after CIDR removal. Pregnancy diagnosis was performed between 32 and 36 d after TAI. Estrus response, as determined by estrous detection aids, did not differ among treatments. Pregnancy rate to TAI averaged 55.5% and was similar among treatments (G+PGF1, 53.3%; G+PGF2,

57.4%; G-PGF1, 55.2%; G-PGF2, 55.9%). Heifers classified as having been in estrus before TAI had a greater ($P < 0.05$) pregnancy rate to TAI (64.6%; 277/429) than either heifers with minimal (49.8%; 150/301) or no (48.7%; 172/353) evidence of estrus before TAI. In conclusion, omission of the initial GnRH treatment in the 5-d CO-synch + CIDR program did not influence TAI pregnancy rate in yearling beef heifers. Moreover, an additional dose of PGF at CIDR removal did not improved fertility in these yearling beef heifers, regardless of whether or not the initial GnRH treatment was given.

Key Words: GnRH, PGF, yearling beef heifers

1414 (T224) Use of a CIDR in the 5-d CO-synch estrous synchronization protocol improves pregnancy rates to timed artificial insemination. G. A. Bridges[1], R. P. Lemenager[2], E. Taylor[3], and P. J. Gunn[*4], *[1]University of Minnesota, Grand Rapids, [2]Purdue University, West Lafayette, IN, [3]Purdue University, Lafayette, IN, [4]Iowa State University, Ames.*

The objective of this experiment was to compare timed-AI (TAI) pregnancy rates in suckled beef cows synchronized with the 5-d CO-Synch protocol with (5CIDR) or without (5NoCIDR) the inclusion of an EAZI-BREED CIDR insert (CIDR). The experiment was conducted in 879 cows over 2 yr, and at three locations with a total of five replications. Cows were assigned to either the 5CIDR ($n = 438$) or 5NoCIDR ($n = 436$) protocol by breed, age, and days postpartum. Blood samples were collected to determine estrous cyclicity status for four of five replications. On d 0 all cows received GnRH (100 μg) and cows in the 5CIDR treatment received a CIDR. On d 5 CIDR were removed (5CIDR) and all cows received two separate doses of $PGF_{2\alpha}$ (25 mg/dose) between 2 and 10 h apart. Cows were TAI 72 h after CIDR removal (d 8), concurrent with GnRH (100 μg). Timed-AI and breeding season pregnancy rates were determined via ultrasonography 32 to 38 d after TAI and end of the breeding season, respectively. Data were analyzed with the GLMIIX procedure of SAS. There were no significant treatment-based interactions with year, age, or cyclic status; therefore data were pooled across year and cyclic status. In reps that had cyclicity determined, the proportion of cyclic cows was 89.3% (583/653). Timed-AI pregnancy rates were greater ($P = 0.0002$) in 5CIDR (62.3%, $n = 438$) than 5NoCIDR (50.7%, $n = 436$) treatment. Age classification, year, and cyclicity did not affect TAI pregnancy rates ($P \geq 0.33$). In conclusion, to optimize TAI pregnancy rates in beef cows synchronized with the 5 d CO-Synch protocol, the inclusion of a CIDR is recommended.

Key Words: 5-d CO-synch, beef cow, CIDR

1415 (T225) Incidence of ovulation to GnRH at onset of 5-d CO-synch + CIDR and impact on reproductive responses. H. P. Dias[*1], S. G. Kruse[2], S. L. Bird[2], B. J. Funnell[2], T. C. Geppert[3], E. L. Lundy[3], P. J. Gunn[3], and G. A. Bridges[2], *[1]Aluno do Programa de Pós Graduação em Zootecnia, FMVZ-UNESP-Botucatu, Brazil, [2]University of Minnesota, Grand Rapids, [3]Iowa State University, Ames.*

The objective of this study was to determine how response to GnRH at the onset of the 5-d CO-Synch + CIDR protocol (5dCO) affected estrous response, follicular dynamics, and pregnancy success to timed-AI (TAI) in beef cows. Suckled primiparous ($n = 95$) and multiparous ($n = 264$) beef cows at four locations (1; $n = 126$, 2; $n = 121$, 3; $n = 73$, 4; $n = 39$) were enrolled in the 5dCO that consisted of GnRH (GnRH-1) and CIDR insertion on d −8, CIDR removal and two 25-mg doses of $PGF_{2\alpha}$ given concurrently on d -3, and TAI on d 0 concurrent with GnRH (GnRH-2). Estrus was detected twice daily from d -3 to 0. Estrous cyclicity (70.6%) was determined at locations 1 and 2 via assessment of circulating progesterone concentrations. Ovarian ultrasound was conducted on d −8, -3, 0, and 2. Ovulation to GnRH-1 was defined by the disappearance of a dominant follicle observed on d −8 and development of a new corpus luteum on d -3. Follicle diameter at GnRH-2 (d 0) was assessed and ovulation confirmed on d 2 via ultrasonography. Pregnancy to TAI was determined approximately 30 d after TAI via ultrasonography. Cows were classified as having ovulated (OV; $n = 196$) or not ovulated (NoOV; $n = 163$) to GnRH-1. Statistical analyses were conducted using the MIXED and GLIMMIX procedures of SAS with location included as a random variable. Response to GnRH-1 (54.6%) was not influenced by parity (multiparous versus primiparous) or estrous cyclicity status. Estrus before TAI was greater ($P < 0.05$) in NoOV (47.6%) than OV (40.8%) cows. In cows that displayed estrus, interval from CIDR removal to estrus tended to be greater ($P = 0.07$) in OV (64.4 ± 0.9 h) than NoOV (60.6 ± 1.0 h), and was greater ($P < 0.01$) in multiparous (64.4 ± 0.8 h) than primiparous (58.3 ± 1.4 h) cows. Ovulation to GnRH-1 did not impact follicle diameter at GnRH-2. Pregnancy rate to TAI was greater ($P < 0.05$) in NoOV (65.0%) than OV (51.5%), primiparous (68.4%) than multiparous (53.8%) cows, and those cows that did (63.9%) than did not (52.7%) exhibit estrous. In summary, ovulation in response to GnRH-1 at the onset of the 5dCO protocol reduced estrous response and TAI pregnancy rates in suckled beef cows.

Key Words: timed-AI, beef cow, 5-d CO-synch + CIDR, GnRH

1416 (T226) The use of 5-d CO-synch+CIDR and 7-d EB+CIDR synchronization programs in Nellore females. M. V. C. Ferraz Jr.[*1], A. V. Pires[2], M. V. Biehl[2], R. Sartori[2], J. R. S. Gonçalves[3], E. M. Moreira[1], M. H. Dos Santos[1], L. H. Cruppe[4], and M. L. Day[4], *[1]University of São Paulo– FMVZ/USP, Pirassununga, Brazil, [2]University of São Paulo–ESALQ/USP, Piracicaba, Brazil, [3]Experimental Station Hildegard Georgina Von Pritzelwitz, Londrina, Brazil, [4] Ohio State University, Columbus.*

Reproductive performance of heifers and cows submitted to either the 5-d CO-Synch+CIDR or 7-d EB+CIDR program was evaluated. Nellore females (n = 411) were used (nulliparous, n = 198; primiparous, n = 80; multiparous, n = 133). The 5-d CO-Synch+CIDR program consisted of insertion of a CIDR and 100 μg of GnRH (Fertagyl) on d 0. On d 5, CIDR was removed and two doses of 25 mg $PGF_{2\alpha}$ (PGF; Lutalyse) were administered 6 h apart. Timed-AI was performed on d 8 (72 h after CIDR removal). The 7-d EB+CIDR program consisted of insertion of a CIDR and 2 mg estradiol benzoate (EB) on d 0. On d 7, CIDR was removed and 25 mg of PGF, 0.6 mg of estradiol cypionate (ECP) and 150 IU of eCG (Novormon) administered. Timed-AI was performed 55 h after CIDR removal. Estrotect patches were applied at CIDR removal and visual estrus detection performed on a 12 h interval for the following 96 h. Blood samples for progesterone (P4) analysis were collected 10 d after AI to confirm ovulation. Concentration of P4 was assessed by chemiluminescent immunoassay. Data were analyzed using the GLIMMIX and PROC MIXEDs of SAS. Estrus response was greater (P < 0.05) in 7-d EB+CIDR than the 5-d CO- Synch+CIDR program (nulliparous, 95.8 vs. 66.0%; primiparous, 48.7 vs. 0.0%; and multiparous, 76.9 vs. 13.4%, respectively). In contrast, ovulation rate (89.8%) was similar between programs. Concentration of P4 10 d post AI was greater (P < 0.05) in primiparous and multiparous cows in the 7-d EB+CIDR than 5-d CO-Synch+CIDR program (6.8 vs. 4.9 ng/mL; and 6.9 vs.5.8 ng/mL, respectively); but did not differ between treatments in nulliparous females (4.4 ± 0.14 ng/mL). Timed-AI pregnancy rate was greater (P < 0.05) in multiparous cows (58.4 vs. 32.8%), but did not differ for nulliparous (51.0 vs. 41.0%) and primiparous, (25.6 vs. 31.7%) for the 7-d and 5-d program, respectively). The 7-d EB+CIDR program resulted in a greater number of females in estrus, and either greater or similar P4 on the subsequent estrous cycle and timed-AI pregnancy rates. In conclusion, reproductive performance seems to be enhanced with the 7-d EB + CIDR in comparison to the 5-d CO-Synch+CIDR program in Nellore females.

Key Words: Nellore, 7-d EB-P4, 5-d CO-synch

1417 (T227) The efficacy of different PGF2α treatments to promote luteolysis on D 7 or D 9 of the estrous cycle in nonlactating Nellore cows. M. V. Biehl[*1], A. V. Pires[1], L. H. Cruppe[2], M. V. C. Ferraz Jr.[3], R. Sartori[1], A. D. B. Ribeiro[3], J. A. Faleiro Neto[3], J. R. S. Gonçalves[4], and M. L. Day[2], *[1]University of São Paulo– ESALQ/USP, Piracicaba, Brazil, [2]Ohio State University, Columbus, [3]University of São Paulo–FMVZ/USP, Pirassununga, Brazil, [4]Experimental Station Hildegard Georgina Von Pritzelwitz, Londrina, Brazil.*

The objective was to evaluate the luteolytic competence of different PGF2α (PGF, Lutalyse) treatments on d 7 and 9 of the estrous cycle. Nonlactating Nellore cows (n = 270) were synchronized with the 7-d EB + CIDR program. Cows received Estrotect patches at CIDR removal to determine estrus response. Presence of an ovulatory follicle and its disappearance were confirmed 48 and 72 h after CIDR removal, respectively. Cows detected in estrus within 48 h and with confirmed ovulation 72 h after CIDR removal remained in the study (n = 225). Cows were assigned to treatments according to BW (389 ± 3.1) and BCS (2.7 ± 0.01, scale 1 to 5). One of four PGF treatments were administered either 7 or 9 d after confirmed ovulation (a single 12.5-, 25- or 50-mg dose or two 25-mg doses 8 h apart), in a 2 × 4 factorial. Presence of a corpus luteum was determined by ultrasound and progesterone (P4) analyses (P4 ≥ 1 ng/ml) on either d 7 (h 0) or d 9 (h 0) of the estrous cycle. Blood samples were collected at h 24, 48, and 72 after PGF treatment to assess the incidence of luteal regression (defined as concentrations of P4 < 1 ng/ml at 48 and 72 h after PGF). Serum P4 concentrations were quantified using a chemiluminescent immunoassay. Cows received a new Estrotect patch at PGF and were observed for estrus twice daily for 5 d. The incidence of luteal regression was greater (P < 0.05) in cows receiving either a single 50-mg (89.3%; 50/56), or two 25-mg doses of PGF (89.5%; 51/57) compared to cows receiving 12.5-mg (67.9%; 38/56) or one 25-mg PGF dose (66.1%; 37/56). Moreover, estrus response was greater (P < 0.05) for cows receiving the single 50-mg or two 25-mg doses of PGF (80.4 and 78.9%, respectively) compared to cows receiving 12 mg (55.4%); cows that received a single 25-mg dose were intermediate (66.1%) and did not differ from other treatments. Neither day of estrous cycle (7 or 9) nor its interaction with PGF treatment influenced luteal regression and estrus response. In conclusion, luteal regression and estrus response were greater in nonlactating cycling Nellore cows treated with 50 mg of PGF either in a single or split dose injection on d 7 or 9 of a synchronized estrous cycle.

Key Words: beef cows, luteolysis, PGF

1418 (T228) Effect of timing of artificial insemination and estrus expression using sexed semen on pregnancy rates in Holstein dairy cows.
S. E. Crego*, E. L. Larimore, and G. A. Perry, *South Dakota State University, Brookings.*

The use of sexed semen has become important in dairy herds across the United States, but reported lower conception rates have limited the adaptation in some herds. The objective of this study was to determine if timing of AI and expression of estrus impacted fixed-time AI pregnancy success with sexed semen. Primiparous and multiparous lactating Holstein cows (n = 130) were synchronized with a Presynch-Ovsynch protocol (PGF d -29; PGF d -19; GnRH and CIDR insertion d −9; PGF and CIDR removal d -2; GnRH d 0) starting at 35 DIM. The cows were allotted into a 2x2 factorial randomized block (lactation) design with 1) sexed (n = 68) versus conventional (n = 62) semen, and 2) insemination at second GnRH (n = 54) versus 16 h later (n = 76). Follicle size was determined in all cows by transrectal ultrasonography at GnRH and ovulation was confirmed on d −5 and 4. Only those cows that ovulated after AI were utilized in the analysis (n = 130). Estrus detection was determined by visual observation with the aid of tail chalk. Blood samples were collected on d -16, −9, -2, 0, and 4 to determine circulating concentrations of progesterone and estradiol by RIA. Data were analyzed using the GLIMMIX procedures of SAS. There was a significant effect of time of insemination (P = 0.04) and estrus expression (P = 0.02) on pregnancy success. Cows inseminated 16 h after GnRH had greater pregnancy success compared to cows bred at time of second GnRH (53 vs. 35%, respectively), and cows expressing estrus had greater pregnancy success compared to cows not expressing estrus (54 vs. 34%, respectively). However, there was no effect of semen (P = 0.20; 50 vs. 38% for conventional and sexed, respectively) or any interaction of semen by estrus (P = 0.55); semen by time (P = 0.47); or time by estrus (P = 0.23) on pregnancy success. There was no difference between treatments (P = 0.62) or between cows that became pregnant and cows that did not (P = 0.45) for follicle size at the second GnRH injection, but cows that expressed estrus had larger (P < 0.01) follicles than cows that did not express estrus. In conclusion, pregnancy success was significantly influenced by time of insemination and estrus expression, but was not influenced by semen, or any interactions.

Key Words: fixed-time AI, sexed semen, estrus

1419 (T229) Evaluation of the hypothalamic kisspeptin system throughout the estrous cycle in gilts.
E. S. Jolitz*, and J. A. Clapper, *South Dakota State University, Brookings.*

Kisspeptin has been demonstrated to increase peripheral concentrations of LH in pigs, presumably by its actions on GnRH, as has been demonstrated in other species. To determine if hypothalamic expression of kisspeptin (Kiss1), kisspeptin receptor (Kiss1R), estrogen receptor α (ER-α), and estrogen receptor β (ER-β) varies throughout the estrous cycle, the following experiment was performed. Forty crossbred prepubertal gilts of similar age (191 d) and weight (121 kg) were administered an intramuscular injection of PG600 (200 IU human chorionic gonadotropin and 400 IU equine chorionic gonadotropin). Twelve days after the administration of PG600, gilts were fed 15 mg of altrenogest (Matrix) daily for 15 d to synchronize estrus. Estrus detection was performed by exposing gilts to a mature boar beginning 4 d after the cessation of altrenogest and continuing for 4 d. The first day gilts stood immobile was denoted d 1 of the estrous cycle. Blood samples were collected via jugular venipuncture on d 1, 4, 7, 10, 13, 16, 19, and 21 of the estrous cycle. Ten animals were slaughtered on d 1, 9, 14, and 21 of the estrous cycle, when hypothalami, anterior pituitary glands, and blood were collected. Relative expression of hypothalamic Kiss1, Kiss1R, ER-α, ER-β, and β-actin was determined using real-time reverse transcriptase PCR. Fold changes in relative expression were determined using the Relative Expression Software Tool. Relative expression is based on the expression ratio of a target gene versus a reference gene. The expression ratio results of the investigated transcripts were tested for significance by a Pair Wise Fixed Reallocation Randomized Test with day compared as independent time effects. Relative expression of Kiss1 was increased (P < 0.05) 3.2-fold on d 1 vs. d 21 and 2.3-fold on d 9 versus d 21 of the estrous cycle. Relative expression of Kiss1 was not different (P > 0.05) among the remaining days. Relative expression of ER-β was decreased (P < 0.05) 0.8-fold on d 9 versus d 21 and 0.7-fold on d 14 vs. d 21. Relative expression of ER-β was not different (P > 0.05) when comparing the remaining slaughter days. Relative expression of Kiss1R and ER-α were each not different (P > 0.05) among days. These data provide preliminary evidence that hypothalamic expression of kisspeptin varies throughout the porcine estrous cycle, which may modulate the subsequent release of GnRH.

Key Words: kisspeptin; hypothalamus; pig

1420 (T230) Levels of IGF-1, thyroxine, triiodothyronine and cortisol in yearling bulls in feedlot or silvopastoral system.
M. E. Romero*[1], J. A. Ramírez-Godínez[1], G. Corral-Flores[1], A. Flores-Mariñelarena[1], C. Rodríguez-Muela[1], P. F. Mancillas[1], J. A. Gutierrez[1], and A. Ayala[2], *[1]Universidad Autónoma de Chihuahua, México, [2]Universidad Autónoma de Yucatán, Mérida, México.*

The aim of this research was to compare serum levels of Insulin-like growth factor (IGF-1), triiodothyronine (T3), thyroxine (T4) and Cortisol (C) in 80 yearling bulls from two genetic groups, Brahman x Charolais (40 BhXCH) and Brahman x Brown Swiss (40 BhXBS), which were randomly assigned to the feeding system in the dry tropic region in Michoacan,

México; feedlot (F) or intensive silvopastoral (ISPS). Animals were bled from the jugular vein at 0, 71, 132, and 195 d to quantify serum hormones by radioimmunoassay. Effects of feeding system and genetic group across time were analyzed using mixed models from SAS with time repeated measures. Differences were found for IGF-1, T3 and C by feeding system ($P < 0.05$). Means were higher in IGF-1 (201.36 ± 8.25; 117.74 ± 7.74 ng mL^{-1}).T3 of F was higher ($P < 0.05$) than ISPS (1.15 ± 0.03; 0.99 ± 0.03 ng mL^{-1}). C of F was lower ($P < 0.05$) than ISPS (19.13 ± 1.80; 25.30 ± 1.71 ng mL^{-1}), respectively. Genetic group had no effect ($P > 0.05$) on T3, T4 and C concentration; however, effect on IGF-1 was found ($P < 0.05$). T4 was similar ($P > 0.05$) between systems. It was conclude that IGF-1 and T3 were higher in F than in ISPS. Genetic group only had effect on IGF-1. Handling of ISPS animals were more susceptible to stress than F, since the values for C were higher but decreased with time.

Key Words: silvopastoral, IGF-1, thyroid hormones, bovine.

1421 (T231) Meta-analysis of the effect of estrus expression before fixed-time AI on conception rates in beef cattle. B. N. Richardson*[1], S. L. Hill[2], J. S. Stevenson[2], G. D. Djira[1], and G. A. Perry[1], *[1]South Dakota State University, Brookings, [2]Kansas State University, Manhattan.*

Expression of estrus after PGF and before fixed-time AI has been reported to change the uterine environment, increase fertilization rates, accessory sperm numbers, and overall embryo survival. Thus, expression of estrus can strongly impact overall pregnancy success. Because of variation in percentage of beef animals exhibiting estrus and number of animals per study, it can be difficult to detect a significant effect of estrus on pregnancy success. Thus, a meta-analysis was conducted using data from 6981 animals in 20 studies that utilized variations of the 5 most common fixed-time AI protocols (CO-Synch, CO-Synch+CIDR, 5-d CIDR, PG 6-d CIDR, and the 14-d CIDR protocols) to examine the effect estrus had on conception rates. A random-effects model was used to combine the studies. The overall model indicated a positive effect of estrus on conception rates with cows expressing estrus before fixed-time AI having a 27% greater conception rate compared with those not exhibiting estrus ($P < 0.05$; 95% CI = 22% to 32%). Next we determined factors that influenced expression of estrus. Data were available on 547 cows synchronized with one of the CIDR based fixed-time AI protocols and observed for estrus for 2 to 4 yr. Analysis of these cows indicated that days postpartum ($P = 0.22$) did not impact estrus expression. In contrast, BCS influenced estrus expression ($P = 0.04$) with cows in a BCS of ≤ 4 (51 ± 5%) having decreased expression of estrus compared to those with a BCS > 4 ($\geq$ 70 ± 4%). Initiation of estrous cycles before the breeding season also influenced estrus expression ($P = 0.03$), with anestrous cows having greater expression of estrus compared with estrus-cycling cows (78 ± 5% versus 70 ± 5%, respectively). In conclusion, among all currently recommended fixed-time AI protocols, cows expressing estrus before fixed-time AI improved conception rates, and BCS and estrus-cycling status had the greatest influence on expression of estrus.

Key Words: fixed-time AI, estrus, pregnancy success

1422 (T232) Comparison of estrus parameters in nulliparous heifers by two automated activity monitoring systems. B. F. Silper*, A. M. L. Madureira, T. A. Burnett, M. Kaur, E. L. Drago Filho, A. M. de Passillé, J. Rushen, and R. L. A. Cerri, *Faculty of Land and Food Systems, University of British Columbia, Vancouver, Canada.*

The aim of this study was to compare a commercial (Heatime, SCR Engineers, Israel) and a research based (IceTag, IceRobotics, Scotland) activity monitoring system on their ability to measure estrus episodes in nulliparous heifers (n = 57; 119 estrus episodes) starting at 12 mo old. Only heifers detected by Heatime system were evaluated, therefore only the sensitivity of the systems could be measured for accuracy. Ultrasound scanning to describe ovarian structures and blood sampling for estradiol were performed at each estrus episode and later used to determine heat detection precision. Secondary signs of estrus (mucus, uterine tonus, and visual mounting and standing) were also recorded. Heifers were housed in dynamic groups of 24 animals in a free stall barn from May 2012 to August 2013. Data was analyzed using ANOVA and Pearson correlations using proc GLM, CORR and REG of SAS. Sensitivity of Heatime system was 84.7% (94/111), whereas IceTag had 98.7% (74/75) sensitivity. Estrus episodes lasted 12.7 ± 5.6 h on Heatime and 15.0 ± 3.9 h on IceTag and were highly correlated between them ($r = 0.60$; $P < 0.01$). Mean time difference of estrus initiation and end was 3.5 ± 4.3 h and 2.9 ± 4.9 h (IceTag as reference). Peak activity was also positively correlated ($r = 0.62$; $P < 0.01$) between systems and was 76.6 ± 19.9 index value and 4.6 ± 1.7 times increase related to baseline on Heatime and IceTag, respectively. Duration and peak activity were highly correlated for Heatime ($r = 0.63$; $P < 0.01$), but not significant when using the IceTags ($r = 0.13$; $P = 0.26$). Diameter of preovulatory follicle (15.7 ± 2.6 mm; mean ± SD) had no correlation with duration or peak activity as measured by both sensors. However, concentrations of estradiol in plasma were correlated with both duration ($r = 0.47$) and peak activity ($r = 0.36$; $P < 0.01$) measured only by the Heatime system. Number of baseline steps/h measured by the IceTag system had a strong negative correlation ($P < 0.01$) with peak activity in both sensors (r = -0.37 and -0.70). Heifers with more than one secondary sign of estrus had great peak activity and duration ($P < 0.05$) on the Heatime system, but not on the IceTag sensor. Secondary signs were not affected by follicle diameter and concentration of estradiol. Re-

sults indicate that both activity monitoring systems identified estrus with high sensitivity and that major measurements (i.e., episodes, duration, peak/intensity, initiation of estrus) were mostly correlated. However, some variables such as concentration of estradiol and secondary signs of estrus should be analyzed independently for research purposes.

Key Words: automated monitoring system, dairy cows, estrus detection

1423 (T233) Cryopreserved sperm quality in young Brangus bulls raised on pasture and supplemented with vitamin E.

P. P. Tsuneda*, L. K. Hatamoto-Zervoudakis, R. D. Almeida, W. A. D. S. Marinho, J. T. Zervoudakis, B. H. Tsuneda, F. A. D. P. D. B. Arguello, M. F. Duarte, Jr., and T. B. Castaldeli, *Federal University of Mato Grosso, Cuiaba, Brazil.*

Vitamin E (or tochopherol) is a fat-soluble antioxidant that inhibits propagation of chain reactions induced by reactive oxygen (ROS) species in biological membranes, being an important defense mechanism against oxidative damage caused to sperm membrane, and reducing lipid peroxidation of membranes. The objective of this study was to evaluate semen characteristics and semen quality after freezing of young bulls raised on pasture and supplemented with vitamin E (α-tochopherol acetate). Sixteen Brangus bulls with 24 mo of average age and 462.2 kg of body weight mean, were randomly assigned to two treatments. Treatments were control group (CG, without supplementation) and group supplemented with vitamin E (GE- 400 IU of vitamin E/day added into concentrate). Each group was kept in separate paddocks formed by Panicum maximum cv. Mombaça and received 4.5 kg concentrate/animal/day. Animals received vitamin E supplementation for 60 d. Semen was collected by electroejaculation and diluted in TRIS–egg-yolk citrate extender with 4% of glycerol and were manually frozen. Cryopreserved semen was thawed in a water bath at 360°C for 30 sec. Immediately after thawing were evaluated sperm motility (percentage of mobile sperm), sperm vigor (intensity of motility, 1–5), sperm viability (percentage of live sperm), acrosome integrity (percentage of acrosome membrane integrity), sperm integrity (percentage of sperm with membrane integrity), and occurrence of acrosome reaction (percentage). The experiment was a completely randomized design with repeated measures and data were analyzed by ANOVA with a significance level of 5%. Supplementation with vitamin E improved the sperm viability ($P = 0.0225$) post-thaw (76.83 ± 2.07 vs. 81.91 ± 2.56). None effects of supplementation ($P > 0.05$) was observed in other traits. Based on parameters evaluated and results obtained from supplemented animals, it is concluded that this level of supplementation was beneficial for semen subjected to cryopreservation process indicating a better protection of the sperm membrane to membrane damage caused by freezing semen, justified by increased percentage of viable cells found in the supplemented group compared with control group.

Key Words: cryopreservation, oxidative stress, sperm viability

1424 (T234) Addition of vitamin C extender and post-cryopreservation semen quality in bulls.

A. L. Cândida de Resende Fraga, L. K. Hatamoto-Zervoudakis, T. B. Castaldeli*, R. A. Minozzo, J. T. Zervoudakis, P. P. Tsuneda, F. M. Wingert, and R. D. Almeida, *Federal University of Mato Grosso, Cuiaba, Brazil.*

The process of spermatozoa freezing provides a resting state of cell while preserving cellular structure and fertilizing capacity of sperm. However, after thawing, semen quality is reduced compared to fresh semen. Sperm cell is able to generate and degrade reactive oxygen species (ROS) necessary for cell functioning, and oxidative stress is a cellular damage caused by imbalance between increased ROS and decreased antioxidant mechanisms. During cryopreservation can occur an increase in oxidative stress due deficiency of intra and extra cellular antioxidant defense system. Vitamin C is considered a great antioxidant of extracellular fluid, working mainly preventing formation of lipid hydroperoxide in plasma lipoproteins and protecting phospholipids in cell membranes. Thus, this study aimed to evaluate the use of vitamin C in cryopreservation extender medium of bull semen to reduce damage caused by cryopreservation process. Sixteen Brangus bulls in reproductive age were used. Ejaculate was collected by electrostimulation. After analyzed, samples were diluted in a extender (TRIS-citrate-egg-yolk with 4% of glycerol), divided into two treatments: the control group (without additive, CG) and other group supplemented with vitamin C (0.45 mg/mL, GS). Thawing was performed in water bath at 37°C for 30 sec. After that aliquots were evaluated to: sperm motility, sperm vigor, sperm viability and sperm membrane integrity. Data were analyzed by analysis of variance with a significance level of 5%. Vitamin C did not improved sperm motility after cryopreservation ($P > 0.005$, CG 45.06 ± 5.51 vs. SG 43.18 ± 4.04). Sperm vigor on GC (0.93 ± 0.85) not differ ($P > 0.05$) of SG (1.00 ± 0.89). Sperm viability in GC (51.71 ± 9.70) was not different ($P > 0.05$) to SG (49.99 ± 6.46). Sperm membrane integrity was not affected by supplementation ($P > 0.05$). Medium supplementation with vitamin C did not affect seminal parameters evaluated, demonstrating that supplementation was not effective in reducing damage caused by cryopreservation in bovine semen.

Key Words: antioxidant, sperm viability, oxidative stress

1425 (T235) Concentrations of progesterone during early follicular development and pregnancy rate to AI in beef cows. F. M. Abreu*[1], M. L. Day[1], M. A. Coutinho da Silva[1], C. A. Madsen[2], T. Martins[2], L. H. Cruppe[1], B. R. Harstine[1], G. A. Bridges[3], and T. W. Geary[2], *[1]Ohio State University, Columbus, [2]USDA ARS Fort Keogh, Miles City, MT, [3]University of Minnesota, Grand Rapids.*

The objective was to investigate if decreased progesterone (P4) concentrations earlier during follicular growth would impact fertility in beef cows. Crossbred (Angus x Hereford) cows (n = 261) received estradiol benzoate (EB; 1 mg, i.m.) and a previously used CIDR on d −7, to induce emergence of a new follicular wave approximately 3 d later (d −4). On d 0, all cows received 100 µg GnRH and were randomly assigned to one of the two treatments. In the high P4 (H; n = 131) treatment, the previously inserted CIDR was replaced with a new CIDR on d 0. In the low P4 (L; n = 130) treatment, 25 mg PGF was administered on d 0, and the CIDR previously inserted on d −7 remained. On d 5, blood samples to determine P4 concentrations were collected, all cows received two 25 mg PGF doses and CIDRs were removed. Estrous detection coupled with artificial insemination (AI) 12 h later (Estrus-AI) was performed for 60 h after PGF. Cows not detected in estrus within this period were bred by timed-AI (TAI) and received 100µg GnRH at 72 h. Pregnancy diagnosis was performed approximately 40 d after AI. P4 concentrations at CIDR withdrawal (d 5) were greater ($P < 0.01$) in the H (2.81 ± 0.10 ng/ml) than in the L (1.73 ± 0.05 ng/ml) treatment. Within the first 60 h after PGF, estrus response (82% vs. 85%) and estrus distribution (56.1 ± 0.7 h vs. 54.0 ± 0.7 h) did not differ between H and L treatments, respectively. Synchronized pregnancy rate was similar between H (77.1%) and L (82.3%) treatments. Across treatments, pregnancy rates were greater ($P < 0.01$) with Estrus-AI (82.9%) than TAI (63.6%). Concentrations of P4 on d 5 were negatively related ($P < 0.01$) with estrus response and time to estrus; across treatments. In conclusion, P4 concentrations during early follicular development did not influence synchronized pregnancy rate in beef cows.

Key Words: beef cattle, progesterone, pregnancy rate

1426 (T236) Tocopherol in bovine semen cryopreservation extender: Fertility and oxidative stress. L. K. Hatamoto-Zervoudakis*, L. Soares, J. T. Zervoudakis, F. M. Wingert, P. P. Tsuneda, M. F. Duarte Junior, and L. E. S. Silva*, Federal University of Mato Grosso, Cuiaba, Brazil.*

The study was conducted to evaluate effects of supplementation with tocoferol (α-tocopherol acetate) in bovine semen extender for cryopreservation on sperm quality and oxidative stress. Thirty-eight Nellore bulls with average age of 36 mo and average body weight of 490 kg were used. Ejaculate was obtained by electroejaculation and semen was diluted in lactose–egg yolk extender with 4% of glycerol. After semen + extender were divided in four fractions and subjected to four concentrations of vitamin E: TC, Control treatment, without supplementation medium; T10, 10 mmol mL of tocopherol supplementation/mL; T30, 30 mmol of tocopherol supplementation/mL; T50, 50 mmol of tocopherol/mL. Semen were frozen with a concentration of 45 million sperm per straw. Straws were thawed at 36°C for 30 sec, and evaluated for sperm motility, sperm viability, and oxidative stress. The experiment was a completely randomized design and data were analyzed using ANOVA and SNK test (Student- Newman-Keuls) with a significance level of 5%. Treatment control afforded less decrease in progressive motility rectilinear (P = 0.0135) after thawing (13.31 ± 2.34%) compared to the other experimental groups (T10: 5.36 ± 0.92%; T30: 8.15 ± 1.80%; and T50: 27.90 ± 3.89%). Oxidative stress on sperm in T10, T30 and T50 treatments (50.91 ± 7.22, 65.88 ± 2.58, 84.22 ± 11.68 ng/mL respectively) were higher (P = 0.0001) shown in the TC control treatment (13.07 ± 1.87 ng/ml). However, the treatment T10 provided a higher sperm viability (P = 0.0001, 73.91% ± 3.72) compared to supplementation levels (54.29% ± 4.20 T30, T50 46.41% ± 5.49), but was not superior to CT (68.95% ± 3.88). It can be concluded that use of antioxidants in bovine semen extender for cryopreservation did not protect sperm plasma membrane of lipid peroxidation, or against damage caused by cryopreservation, and the levels used in this work were detrimental to sperm fertility.

Key Words: TBARS, fertility, antioxidant

1427 (T237) Embryonic growth between d 33 and 45 of pregnancy in lactating dairy cows differing in hormone and metabolite concentrations. T. J. Stratman*[1], S. E. Poock[2], S. L. Murphy[1], A. Thomas[1], D. Bouhan[1], D. H. Keisler[1], and M. C. Lucy[1], *[1]University of Missouri, Division of Animal Sciences, Columbia, [2]University of Missouri, College of Veterinary Medicine, Columbia.*

Embryonic loss in dairy cows continues to occur into the 5 and 6 wk of pregnancy, and there is an association between slower embryonic growth and pregnancy loss during this period. Individual differences in hormone and metabolite concentrations may affect the growth of the embryo via endocrine mechanisms or by affecting nutrient flux across the placenta. The objective was to examine the relationship between postpartum hormones/metabolites and embryonic growth from d 33 to 45 of pregnancy. Holstein cows (n = 56; 86 ± 17 d postpartum at AI) were examined by transrectal ultrasonography on d 33, 35, 38, 40, 42, and 45 of pregnancy. Length (l) and width (w) of the embryo and amnionic vesicle were measured and the volumes for the embryo (e_vol) and amnionic vesicle (a_vol) were calculated [volume = 4/3*π*(0.5*l)*(0.5*w)*(0.5*w)]. There was an effect of day of pregnancy ($P < 0.001$) because

e_vol and a_vol increased from d 33 to d 45 (0.14 ± 0.01 cm^3 vs. 0.60 ± 0.06 cm^3; and 1.52 ± 0.05 cm^3 vs. 10.57 ± 0.59 cm^3, respectively). Across all days, the a_vol of male embryos was larger than female (4.25 ± 0.20 vs. 3.70 ± 0.20 cm^3) but e_vol was similar for male vs. female. Blood was collected on the d of ultrasound and plasma analyzed for glucose, progesterone (*P*4), growth hormone (GH), IGF1, and insulin (INS). Plasma hormone and metabolite concentrations were not affected by day of pregnancy ($P > 0.1$) but differed for individual cows ($P < 0.001$; range = 51 to 82 mg/dL for glucose, 4.7 to 13.5 ng/mL for P4, 2.3 to 13.4 ng/mL for GH, 50 to 131 ng/mL for IGF1, and 0.2 to 0.7 ng/mL for INS). Individual cows were categorized as being above or below the median for each blood hormone/metabolite concentration. Cows that were above or below the median for glucose, P4, GH, or INS were similar for e_vol and a_vol ($P > 0.1$). There was a category by day interaction ($P < 0.05$) for IGF1, however, because cows with IGF1 above the median (mean = 102.4 ± 16.4 ng/ml) had greater e_vol on d 42 compared with low IGF1 cows (mean = 69.9 ± 13.0 ng/mL) (1.11 ± 0.04 vs. 0.98 ± 0.04 cm^3; above vs. below). A_vol was not affected by IGF1 category. Conclusions were that male embryos have greater amnion vesicle volume from d 33 to 45 of pregnancy. Plasma concentrations of IGF1 were positively associated with a larger embryo on d 42. Chronically low IGF1 concentrations in lactating cows may lead to embryonic loss via slower embryo growth.

Key Words: bovine, embryo, metabolites

1428 (T238) Altered ovarian dynamics in lactating dairy cows undergoing embryonic mortality. *R*. Wijma*[1], M. L. Stangaferro[1], J. R. Branen[2], J. M. Howard[2], and J. O. Giordano[1], *[1]Dep. of Animal Science, Cornell University, Ithaca, NY, [2]Biotracking LLC, Moscow, GA.*

Our objective was to characterize ovarian dynamics in lactating dairy cows undergoing embryonic mortality. Cows ($n = 62$) received timed AI at 60 to 79 DIM after Presynch-Ovsynch. At AI, cows were blocked by parity (primiparous vs. multiparous) and randomly assigned to AI with regular semen ($n = 52$) or extender only ($n = 10$; Cycling; CY). Blood was collected every 48 h from 14 to 42 d after AI to determine concentrations of progesterone (P4) and pregnancy specific protein B (PSPB). Transrectal ultrasound was performed daily to assess ovarian dynamics. Cows were considered: 1) pregnant (PG; $n = 18$) if a viable embryo with a heartbeat was observed, 2) embryonic mortality (EM; $n = 6$) when a viable embryo or its heartbeat was no longer observed, and/or PSPB concentrations were initially above and then below 0.8 ng/mL, and 3) Non-pregnant (NP; $n = 28$) when no viable embryo was observed and PSPB concentrations remained below 0.8 ng/mL. Pregnant and EM cows had greater ($P < 0.01$) PSPB concentrations than NP and CY cows beginning 24 d after AI. Percentage of cows with complete luteal regression (CLR) was affected ($P = 0.02$) by group (CY and NP = 100 vs. 66.7% for EM) and occurred later ($P < 0.01$) in EM (39.5 ± 2.1) than in CY and NP cows (20.2 ± 1.3 and 22.9 ± 0.8). At 18 d after AI, NP cows had greater ($P < 0.05$) P4 than CY cows, whereas EM and PG cows had greater ($P < 0.05$) P4 concentrations than CY and NP cows. Among cows with CLR, the percentage ovulating was similar ($P = 0.21$) for CY, NP, and EM (90.0, 85.7, and 50.0%) cows. The interovulatory interval (IOI) was affected by group ($P < 0.01$). Cycling cows had the fewest days to ovulation (22.9 ± 0.96) followed by NP cows (25.8 ± 0.6) whereas EM cows had the longest interval to ovulation (40.0 ± 2.0 d). Days from CLR to ovulation was similar ($P = 0.52$) for CY (5.0 ± 0.9), NP (6.0 ± 0.6), and EM (7.0 ± 1.9) cows. Ovulatory follicle growth rate for the 5 d preceding ovulation was similar ($P = 0.28$) for all groups (CY = 1.6 ± 0.2, NP = 1.5 ± 0.1 and EM = 0.8 ± 0.5 mm/day). Likewise, diameter at ovulation was similar ($P = 0.77$) for all groups (CY = 22.7 ± 1.1, NP = 23.9 ± 1.8 and EM = 24.8 ± 3.8 mm). Thus, cows with EM were less likely to undergo complete luteal regression, and had extended IOI. The observed differences in IOI were due to delayed luteal regression rather than alterations in follicular wave dynamics. The longer IOI for NP than CY cows may have been caused by undetected EM. *Supported by Hatch project NYC127813.*

Key Words: ovarian dynamics, embryonic mortality, dairy cow

PHYSIOLOGY AND ENDOCRINOLOGY III

1429 (W189) Estimated energy balance of periparturient ewes grazing in rangelands. E. González-García[*1], D. Tagliatella[2], M. Jouven[3], and F. Bocquier[3], *[1]INRA UMR868 Systèmes d'Elevage Méditerranées et Tropicaux (SELMET), Montpellier, France, [2]Universidade Estadual de Londrina (UEL), Rodovia Celso Garcia Cid, Campus Universitário, Londrina, Brazil, [3]Montpellier Supagro, Sciences Animales, UMR868 Systèmes d'Elevage Méditerranées et Tropicaux (SELMET), Montpellier, France.*

In a previous work we demonstrated that efficiency in body reserves (BR) mobilization/accretion was affected by parity [multiparous (MULT) ewes being more flexible than primiparous], litter size and physiological stage (peaks of BR mobilization attained around lambing and 1 mo after mating). The objective of this study was to estimate the dynamic individual energy balance of periparturient MULT Romane grazing ewes, from 15 d before until 15 d after lambing. A group of MULT ewes (n = 20), allocated according to litter size (lambing and suckling singletons, SING-n = 10-, or twins, TWIN-n = 10) was used. Details on management and feeding were reported by González-García et al. (2014). At late pregnancy, ewes were in rotational grazing of native rangeland and supplemented with 0.7, 2.0 and 0.8 kg/d of hay (*Dactylus glomerata* and alfalfa), silage (*Lolium perenne* and alfalfa) and barley, respectively. After lambing, ewes were fed on fertilized paddocks without supplementation. Individual progression of BW, BCS, plasma NEFA as well as ADG of lambs was considered for energy balance interpretation. Some estimation is established based on NRC (2007) recommendations. Data were analyzed using the PROC MIXED of SAS (2007) with repeated measures. During the last 4 wk of gestation, one 50 kg ewe from this flock is estimated to display a daily consumption of around 1.6 kg of DM (3.2% BW) to support around 180 g of BW gain, requiring 3.4 mcal of ME. During the first 6–8 wk lactation, feed intake is affected by litter size (NRC, 2007; 2.1 or 2.4 kg of DM/d for ewes suckling SING or TWIN; 4.2 or 4.8% BW, respectively) with an increase in energy requirement of 4.9 or 5.6 mcal of ME for SING or TWIN, respectively. At late pregnancy, a positive energy balance of > 1.1 mcal/d was observed (4.7 mcal of ME vs. 3.6 of ME requirements) due to the advantageous supplementation regime established in the farm. Paradoxically, at this stage (late pregnancy) NEFA values showed a peak in BR mobilization. After lambing, ewes suckling SING and TWIN were both required to mobilize their BR to meet energy requirement despite the high quality of the fertilized paddocks and the BW increase. More precise and targeted studies are required to better address the combined anabolic and catabolic phases experimented under the conditions of this experiment in periparturient ewes. Reference: González-García E. et al. (2014). Domestic Animal Endocrinology 46:37–48.

Key Words: periparturient ewes, rangelands, energy balance, body reserves

1430 (W190) Effects of adsorbent on milk aflatoxin M1 and lactation performance of dairy cows exposed to long-term challenge of aflatoxin B1. J. L. Xiong[1], Y. M. Wang[*2], W. M. Huang[1], Y. Zhang[1], H. M. Guo[1], and J. X. Liu[3], *[1]Institute of Dairy Science, Zhejiang University, Hangzhou, China, [2]Novus International Trading Co., Ltd, Shanghai, China, [3]Zhejiang University, Hangzhou, China.*

The objective of the study was to evaluate the effects of adsorbent on milk aflatoxin (AF) M1 and lactation performance of dairy cows exposed to long-term challenge of AFB1. Forty dairy cows were blocked based on days in milk (33 ± 7; mean ± SD) and milk production (33.9 ± 3.1 kg; mean ± SD), and were randomly assigned to one of four treatments in a 2 × 2 factorial arrangements with AFB1 (0 or 20 μg/kgDM) and Solis Mos (Novus International Inc., 0 or 0.25% of DM). The experiment lasted 9 wk, with the first week for adaptation. Milk yield and milk composition were recorded weekly, and serum concentrations of biochemical and antioxidant variables were analyzed in the first and the last week of the experiment. Milk AFM1 was analyzed by HPLC-MS/MS. Variables of data were analyzed using the PROC MIXED of SAS. Dry matter intake, milk yield, contents of milk protein and milk fat, and linear somatic cell count averaged 23.9 kg/d, 35.5 kg/d, 2.9%, 3.6%, and 5.1, respectively and were not affected (P > 0.05) by either AFB1 or Solis Mos supplement. Addition of Solis Mos in AFB1-contaminated diet significantly reduced (P < 0.01) milk AFM1 concentration (0.19 vs. 0.13 μg/kg) and transfer rates (1.38 vs. 0.89%). Dairy cows fed AFB1-contaminated diet had lower level of superoxide dismutase activity, total antioxidant capacity, glutathione peroxidase, IgG and IgA (P < 0.05), and higher level of malondialdehyde in plasma (P < 0.05). Inclusion of Solis Mos into diets increased the plasma superoxide dismutase activity, total antioxidant capacity, and IgG, while deceased malondialdehyde (P < 0.05). Neither AFB1 nor Solis Mos affected (P > 0.05) the plasma levels of alanine transaminase, aspartate aminotransferase, and alkaline phosphatase and IgM. It is concluded that inclusion of Solis Mos did not affect lactation performance, but reduced milk AFM1 concentration and transfer rate, and increased antioxidant capacity and immunity in early-lactating dairy cows exposed to long-term challenge of AFB1.

Key Words: adsorbent, aflatoxin, transfer

1431 (W191) Effects of excessive energy intake and supplementation with chromium propionate on insulin resistance parameters in lactating dairy cows: II. Glucose tolerance tests and follicular flushing. T. Leiva[1], R. F. Cooke[2], F. N. Correa[1], A. C. Aboin[1], A. P. Brandao[1], H. F. Soares[1], M. B. Piccolo[1], and J. L. M. Vasconcelos[*1], *[1]UNESP-FMVZ, Botucatu, Brazil, [2]Oregon State University-EOARC Burns, Burns.*

The objective of this experiment was to compare insulin resistance parameters and reproductive outcomes in lactating dairy cows with adequate or excessive energy intake, as well as in lactating dairy cows with excessive energy intake receiving Cr-propionate supplementation. Seventeen primiparous and multiparous, lactating Holstein cows were ranked by parity, BW, and BCS, and assigned to 1 of 3 dietary treatments on d 0: 1) diet to meet their NE_l requirements without Cr supplementation (MAN; $n = 5$), 2) diet to exceed their NE_l requirements without Cr supplementation (HIGH; $n = 6$), and 3) HIGH with 2.5 g/d of Cr-propionate (HIGHCR; $n = 8$, with 10 mg of Cr/cow daily). Cows were maintained in a single group and offered corn silage for ad libitum consumption, but received a corn-based concentrate twice daily via individual self-locking head gates from d 0 to 210. Concentrate intake was formulated to provide 100% of daily NE_l requirements of MAN and 160% of daily NE_l requirements of HIGH and HIGHCR cows. Glucose tolerance tests (GTT) were performed on d 40, 82, 124, 166, and 208 by infusing cows with 0.5 g of glucose/kg of BW, whereas blood samples were collected at -15, 0, 10, 20, 30, 45, 60, 90, and 120 min relative to infusion for determination of serum insulin and glucose. Follicle aspiration for in vitro embryo production was performed 2 d after each GTT. No treatment effects were detected ($P = 0.53$) for serum glucose concentrations. Treatment x min interactions ($P < 0.01$) were detected for serum insulin and insulin:glucose ratio, given that these parameters were greater ($P \leq 0.05$) for HIGH compared with HIGHCR and MAN from 10 to 60 min relative to glucose infusion, but always similar between HIGHCR and MAN ($P \geq 0.25$). A treatment x parity interaction was detected for oocyte collection ($P = 0.05$). Within multiparous cows, HIGHCR had greater ($P \leq 0.03$) number of viable oocytes collected compared with HIGH and MAN, whereas the same outcome was not detected ($P \geq 0.36$) within primiparous cows. No treatment effects were detected ($P \geq 0.33$) for number of embryos produced, or oocyte collected:embryo produced ratio. In conclusion, Cr-propionate supplementation prevented the increase in insulin resistance caused by excessive energy intake in lactating dairy cows during a GTT, and increased the number of viable oocytes collected during follicle aspiration for in vitro embryo production.

Key Words: chromium, dairy cows, energy, insulin resistance

1432 (W192) Deuterium enrichment in plasma, rumen fluid and urine of growing sheep dosed with D_2O intravenously and intraruminally does not differ. C. C. Metges[*1], S. Görs[1], H. M. Hammon[1], U. Agarwal[2], and B. J. Bequette[2], *[1]Leibniz Institute for Farm Animal Biology (FBN), Dummerstorf, Germany, [2]Dep. of Animal and Avian Sciences, University of Maryland, College Park.*

The D_2O method has been used in humans to measure fractional gluconeogenesis. The advantage of this method is that all contributions of gluconeogenic substrates are considered. In ruminants, we aimed to determine whether the route of D_2O administration affects equilibration of deuterium with protons from water in various body water pools. Four sheep (23.5 ± 1 kg BW), equipped with a rumen fistula and a jugular vein catheter, were fed a pelleted ration (35 g/kg BW and d; 9 MJ ME/d) at 2-h intervals. Water was offered ad lib. To label body water, sheep were given two boli of 7 g D_2O/kg BW (99.2 atom% D) at 800 and 1200 h either into the rumen (IR) or into the jugular vein (IV) in a balanced crossover design. Two weeks separated each site of administration. Plasma was sampled before and hourly for 11 h following the first bolus whereas rumen fluid and urine were collected before and at 3, 6, 9, and 11 h. Samples were diluted and D_2O enrichments were measured by isotope ratio mass spectrometry. Paired *t* test was used to evaluate route effect. D_2O enrichments did not differ with route of tracer administration. A quasi-plateau in D2O enrichment was reached 2 h after the first bolus (IR: 0.76; IV: 0.78 atom% excess (APE)) with a further increase to a second plateau 2 h after the second bolus (IR: 1.48; IV: 1.47 APE; $P > 0.1$). Urine D_2O enrichment 3 h after the initial IR dose tended ($P = 0.09$) to be lower than with the IV route (IR: 0.47; IV: 0.78 APE), however, both routes of dosing lead to a similar maximum enrichment 9 to 11 h after the initial bolus (IR: 1.51; IV: 1.52 APE; $P > 0.1$). Rumen fluid D_2O enrichment attained a plateau 6 h after the initial bolus (IR: 1.51; IV: 1.43 APE; $P > 0.1$). This study verified that for measurement of fractional gluconeogenesis using the D_2O method, the kinetics of D_2O labelling are similar with the IR and IV routes of administration, and that either approach can be employed in ruminants.

Key Words: gluconeogenesis, deuterium oxide, rumen

1433 (W193) Manipulated plasma insulin, glucose, and BHBA affect immune factors in somatic cells in milk with and without intramammary LPS challenge in dairy cows. M. Zarrin[*1,2,3], R. M. Bruckmaier[1], and O. Wellnitz[1], *[1]Veterinary Physiology, Vetsuisse Faculty, University of Bern, Switzerland, [2]Dep. of Animal Science, Yasouj University, Iran, [3]Graduate School for Cellular and Biomedical Sciences, University of Bern, Switzerland.*

Changes of plasma hormones and metabolites affect mammary immunity during onset of lactation. Somatic cells are important for the initial udder defense and they are additionally recruited into milk during the immune response. This study aimed to investigate effects of long term (56 h) elevated insulin at simultaneous hypoglycemia or euglycemia, and elevated β-hydroxybutyrate (BHBA) concentrations, and additional intramammary LPS challenge on mRNA abundance of immune factors in somatic cells in milk. Animals were subjected to four intravenous treatment groups: an insulin infusion (HypoG, $n = 5$) to decrease plasma glucose concentration to 2.5 ± 0.1 mmol/L, a hyperinsulinemic euglycemic clamp to maintain plasma glucose concentration at pre-infusion level (EuG, $n = 6$), a BHBA infusion (HyperB, $n = 5$), and a 0.9% NaCl infusion (Control, $n = 8$). Two udder quarters were challenged with 200 µg *E.coli* LPS at 48 h of infusions. Cells were extracted from milk of control and treated quarters obtained before, after 48 h, and at the end of infusion with a quarter milking device. The mRNA abundances of immune factors were measured by RT-qPCR. Changes of mRNA abundance between before and after 48 h of infusions, and before and after LPS challenge were evaluated by analysis of variance with treatments as fixed effect. In HypoG mRNA abundance of interleukin (IL)-1β and RANTES (regulated on activation, normal T cell expressed and secreted) decreased ($P < 0.05$) during 48 h. In HyperB the mRNA abundance of IL-1β, IL-8, and RANTES tended to increase ($P < 0.1$) during 48 h. Intramammary LPS challenge up-regulated mRNA abundance of IL-1b, IL-8, and nuclear factor kappa-light-chain-enhancer of activated B cells after 8 h in all treatment groups ($P < 0.05$), and tumor necrosis factor-α in HypoG ($P < 0.05$). The mRNA abundance of IL-1β and IL-8 was up-regulated in HypoG ($P < 0.05$), and IL-1β, IL-8, and RANTES was downregulated in control quarters of HyperB ($P < 0.05$) 8 h after LPS challenge. Results demonstrate that intravenous insulin infusion downregulates the expression of immune factors in somatic cells in milk during hypoglycemia, whereas induced hyperketonemia seems to up-regulate some of these factors during 48 h. It can be speculated that the downregulation of immune factors in HypoG is related to a lack of energy (glucose) for the immune system, while BHBA is an alternative energy source for the immune system during immune response. Up-regulation of immune factors after LPS challenge was predictable, whereas mechanisms of downregulation in control quarters after LPS challenge are unclear.

Key Words: immunity, metabolite, LPS

1434 (W194) Effects of road transportation on metabolic and immunological responses in dairy heifers. M. Baik[*1], H. J. Kang[1], I. K. Lee[1], M. Y. Piao[1], C. W. Kwak[1], M. J. Gu[1], C. H. Yun[1], H. J. Kim[1], G. H. Kim[2], S. K. Kim[2], and J. K. Ha[1], *[1]Dep. of Agricultural Biotechnology, College of Agriculture and Life Sciences, Seoul National University, Seoul, South Korea, [2]Dep. of Animal Science and Technology, Konkuk University, Seoul, South Korea.*

This study was performed to determine the effects of road transportation on metabolic responses in dairy heifers. Twenty-two Holstein heifers (average 17.6 mo of age, 440 kg of average body weight) were divided into non-transported (NT; $n = 8$) and transported (T; $n = 14$) groups. Feed and water in the NT heifers were restricted the same amount as the T heifers. The heifers were acclimated in stanchion barn. All heifers were restrained with a halter in a stanchion, and blood was collected using vaccutainer by jugular venipuncture. The NT heifers In the T group, blood was collected before transportation (BT), after 100 km (T1) and 200 km transportation (T2), and at 24 h after transportation (AT). In the NT group, blood was collected at same time as the T group. The T heifers showed higher ($P < 0.001$) blood cortisol concentrations after T1 and T2 than the NT heifers. The T heifers showed higher ($P < 0.01$) serum non-esterified fatty acid (NEFA) concentrations after T1 and T2 than the NT heifers. In contrast, the T heifers showed lower serum triglyceride (TG) concentrations after T1 ($P = 0.01$) and T2 ($P < 0.001$) than the NT heifers. Serum concentrations of cortisol, NEFA, and TG at 24 h AT were returned ($P > 0.05$) to those of the BT in the T heifers. Other serum lipid concentrations, including phospholipid ($P = 0.02$), high density lipoprotein ($P = 0.03$), low density lipoprotein ($P = 0.01$), and cholesterol ($P = 0.04$) were lower in the T heifers after T2 than the NT heifers. Serum glucose concentrations were not changed by T1 and T2. The ratio of granulocytes to lymphocytes ($P < 0.001$) and the percentage of monocytes ($P < 0.05$) were shown higher after T2 in the T heifers when compared to those of the NT heifers, suggesting increased number of innate immune cells on transportation stress. In conclusion, short transportation increases cortisol secretion, which was coincident with induction of metabolic responses and up-regulation of peripheral innate immune cells in dairy heifers.

Key Words: transportation, stress, metabolic responses, dairy heifers

1435 (W195) Differences in mitochondrial DNA copy numbers in various subcutaneous and visceral fat depots of overconditioned cows. L. Laubenthal[*1], L. Locher[2], J. Winkler[3], U. Meyer[3], J. Rehage[2], S. Dänicke[3], H. Sauerwein[1] and S. Häussler[1], *[1]University of Bonn, Institute of Animal Science, Germany, [2]University for Veterinary Medicine Foundation, Hannover, Germany, [3]Institute of Animal Nutrition, Friedrich Loeffler Institute (FLI), Braunschweig, Germany.*

In dairy cows, adipose tissue (AT) is mobilized during early lactation to meet the increased energy demands through lactation. Overconditioned cows are more prone to metabolic disorders during this period than lean cows. Just like in other tissues, mitochondria are the main site of energy production within AT. Different energy demands may lead to changes of mitochondrial DNA (mtDNA), which reflects the abundance of mitochondria in a cell. Different bovine AT depots differentiated into visceral (vc) and subcutaneous (sc) regions, might present different mtDNA contents, due to diverse metabolic functions. Therefore, we aimed to compare the number of mtDNA copies per cell between various sc and vcAT depots from overconditioned cows. Eight non-lactating, non-pregnant German Holstein cows (age 4 to 6 yr) received diets with increasing proportions of concentrate feed during the first 6 wk of the trial until 60% were reached. This diet was maintained for 10 wk and cows had an average body weight (BW) gain of 243 ± 33.3 kg within this period. Animals were slaughtered at the end of the experiment and tissue samples from sc (sternum, withers and tailhead) and vc (mesenterial, omental and retroperitoneal) AT were collected and snap frozen for genomic DNA isolation. The number of mtDNA copies/cell was quantified by multiplex quantitative PCR using β-globin as reference gene. Data (mean ± SEM) were analyzed using Mann–Whitney-U-test and the Spearman (r) correlation coefficient (SPSS). The number of mtDNA copies/cell was 2.6-fold higher in all vc compared to all sc ($P < 0.001$) AT. Retroperitoneal AT exhibits greatest mtDNA copies/cell (3488 ± 190) compared to all other AT depots. The mtDNA copy number/cell in mesenterial and omental AT were 3058 ± 405 and 2921 ± 235, respectively. In tailhead and sternum AT mtDNA copy number/cell was three-fold and in withers AT two-fold lower compared to retroperitoneal. Different amounts of mtDNA copies/cell might reflect individual energy demands and metabolic functions in different sc and vcAT depots. In this study, mtDNA was isolated from whole AT including both adipocytes and the cells belonging to the stromal vascular cell fraction (SVF). Therefore, lower values of mtDNA copies in scAT might be due to an increased SVF, which contains significantly less mtDNA copy numbers. Higher amounts of mtDNA copies per cell in vcAT compared to scAT are in accordance to the higher metabolic activity of vcAT, particularly the retroperitoneal AT depot.

Key Words: adipose tissue, mtDNA copy number, cows

1436 (W196) In vitro insulin sensitivity of subcutaneous and omental adipocytes of precalving dairy cows across a range of BCS. J. De Koster[*1], L. Hulpio[1], V. Fievez[2], W. Van den Broeck[3], and G. Opsomer[1], *[1]Dep. of Reproduction, Obstetrics and Herd Health, Faculty of Veterinary Medicine, Ghent University, Belgium, [2]Dep. of Animal Production, Faculty of Bioscience Engineering, Ghent University, Belgium, [3]Dep. of Morphology, Faculty of Veterinary Medicine, Ghent University, Belgium.*

The adipose tissue of dairy cows plays an important role during the transition period. Recent research indicates a selective mobilization of adipose depots during negative energy balance. In the present study, we investigated the effect of the size of the adipocytes and type of adipose depot (omental versus subcutaneous) on insulin sensitivity of the lipolytic activity of adipocytes from precalving dairy cows. Ten pregnant dairy cows (BCS 2.75–5) were euthanized and samples of subcutaneous (at the tail base) and omental adipose tissue were transferred to sterile falcon tubes containing medium (Krebs ringer bicarbonate hepes + 3% BSA). Adipose tissue fragments were minced and approximately 100 mg adipose tissue explants were incubated in 3 mL medium at 38°C on a shaker. Five different culture conditions were tested in duplicate: lipolytic activity in all the plates was stimulated with 10^{-6} mol/l isoproterenol and five different insulin concentrations (0; 1; 10; 200; 1000 μU/ml) were added. After 3 h of incubation, media were sampled for glycerol analysis. Results are expressed as nmol glycerol release per 3 h per million adipocytes. The number and volume of adipocytes were determined as described by DiGirolamo et al. (1971). Insulin decreased glycerol release and insulin sensitivity was expressed as percentage decrease of the maximal glycerol release (10^{-6} mol/l isoproterenol; 0 μU/ml insulin). Dose response curves were created using PROC NLIN in SAS to determine maximal effect and insulin dose needed to elicit halfmaximal effect (logED50). Effects on both parameters were analyzed using PROC MIXED in SAS with cow as random factor, adipose depot and volume of adipocytes as fixed factors. One cow was excluded because insulin failed to inhibit lipolytic activity. The maximal effect and logED50 for the insulin sensitivity were 0.32 ± 0.1279% and -0.22 ± 0.415 μU/ml, respectively in subcutaneous adipocytes and 0.23 ± 0.148% and 0.15 ± 0.849 μU/ml in omental adipocytes (mean ± stdev), respectively. Statistical analysis revealed negative effects of volume of the adipocytes (β = -0.2569; $P < 0.05$) and adipose depot (β = -0.2145; $0.1 < P < 0.05$, subcutaneous depot as reference) on the maximal effect while no significant effects were found on the logED50. Insulin sensitivity of the lipolytic activity of adipocytes in precalving dairy cows is influenced by the size of the adipocytes and the adipose depot with a lower maxi-

mal effect in omental adipocytes and lower maximal effect in larger adipocytes. The dose to elicit halfmaximal effect is not influenced by adipocyte size or adipose depot.

Key Words: in vitro insulin sensitivity, adipose depot, dairy cow

1437 (W197) Dietary melatonin supplementation during late gestation alters concentrations of progesterone and milk yield in Holstein heifers. C. O. Lemley*, K. E. Brockus, C. G. Hart, and S. H. Ward*, Mississippi State University, Starkville.*

The objective was to examine the effects of supplementing dietary melatonin during late gestation Holstein heifers on maternal concentrations of progesterone and estradiol-17β as well as subsequent milk yield during the first 30 d of lactation. On d 190 of gestation, heifers (n = 20) were blocked by body weight and then randomly assigned to one of two dietary treatments: 1) 20 mg of dietary melatonin per day (MEL) or 2) no melatonin supplementation (CON). At 0800 h, MEL heifers received 0.7 kg of grain top dressed with 2 mL of 10 mg/mL melatonin in ethanol while CON heifers received 0.7 kg of grain top dressed with 2 mL of ethanol alone. A TMR was provided after grain consumption. Supplementation ceased on d 262 of gestation for both treatment groups. Blood samples were collected on d 180 (baseline), 210, 240, and 262 of gestation. Serum concentrations of progesterone and estradiol-17β were determined via radioimmunoassay. Milk yield was recorded for the first 30 d of lactation. Dependent variables were analyzed using repeated-measures ANOVA of the PROC MIXED of SAS with the model statement containing dietary treatment, day, and their respective interaction. Main effects of dietary treatment or day are discussed in the absence of significant ($P < 0.05$) treatment by day interactions. Serum progesterone was decreased ($P < 0.05$) by 12% in MEL vs. CON heifers. Moreover, concentrations of progesterone were decreased ($P < 0.0001$) on d 262 of gestation vs. d 180, 210, and 240. Serum estradiol-17β tended to be decreased ($P = 0.06$) by 19% in MEL vs. CON heifers. Concentrations of estradiol-17β increased ($P < 0.0001$) as gestation proceeded. Gestation length was not different ($P > 0.50$) between treatments and averaged 275 ± 2 d. Daily milk yield showed a treatment by day interaction ($P < 0.01$), whereby milk yield was increased by 41% and 33% on d 2 and 3 of lactation in MEL vs. CON heifers, respectively. Dietary melatonin supplementation during late pregnancy altered steroid synthesis and/or clearance. In addition, the decreased concentrations of steroids during late gestation in MEL heifers had no adverse effects on subsequent milk yield during early lactation.

Key Words: melatonin, pregnancy, progesterone

1438 (W198) Dry-matter intake level and its effects on follicle growth and circulating progesterone in Nellore (*Bos indicus*) and Holstein (*Bos taurus*) heifers. E. O. S. Batista*[1], R. V. Sala[1], M. D. D. V. Ortolan[1], E. F. Jesus[2], T. A. D. Vale[3], G. G. Macedo[1], F. P. Rennó[3], A. H. Souza[4], and P. S. Baruselli[5], *[1]USP, São Paulo, Brazil, [2]School of Agricultural and Veterinary Sciences of UNESP, Jaboticabal, Brazil, [3]USP, Pirassununga, Brazil, [4]University of California–Davis, Davis, [5]University of Sao Paulo-VRA, Brazil.*

The aim of this study was to evaluate circulating progesterone concentration (P4) and ovarian follicular dynamics in *Bos indicus* and *Bos taurus* heifers under high (HDM; weight gain of 900 g per d) and low (LDM; maintenance, NRC 2001) consumption of dry matter. Cycling Holstein (n = 16) and Nellore (n = 16) heifers were used in a 2 × 2 factorial arrangement (crossover). The experimental diet was given during 32 d (15 d before and 17 d during the hormonal protocol). The animals were pre-synchronized with two applications of cloprostenol (0.53mg, i.m. $PGF_{2\alpha}$, Sincrocio, Ourofino Agronegócio) 12 d apart and 18 and 12 h before device insertion. At onset of synchronization protocol (d 0), heifers received a new intravaginal P4 device (CIDR, Zoetis Brasil), 2 mg of estradiol benzoate i.m. (BE, Sincrodiol, Ourofino Agronegócio) and a dose of $PGF_{2\alpha}$. After 8 d, the P4 device was removed and 1 mg of BE was administered 24 h later. Ultrasonographic exams were performed every 24 h during P4 device treatment (d 0 to 8), and at every 12 h from P4 device removal to ovulation. Blood samples were collected daily from d 0 to 10. The results were analyzed using PROC MIXED of SAS 9.2 and presented as mean ± standard error. An interaction (genetic group*d, $P < 0.0001$; diet*d, $P = 0.03$) was observed between genetic group, diet and d of the hormonal protocol on the diameter of the dominant follicle (DDF). The effect of diet on the DDF during hormonal protocol was observed as soon as two d after follicular wave emergence (d 5 to 10 of the hormonal protocol, $P < 0.05$). However, the effect of genetic group was observed only towards the end of the protocol (d 8 to 10, $P < 0.05$). Regardless of the diet, the DDF on d 8 ($P = 0.04$) and d 10 ($P = 0.01$) of the hormonal protocol were larger in Holstein (11.6 ± 0.4 and 14.4 ± 0.4) than Nellore (10.3 ± 0.4 and 12.2 ± 0.4) heifers. Independently from genetic group, the DDF on d 8 ($P < 0.0001$) and d 10 ($P = 0.01$) of the hormonal protocol was larger in heifers receiving to HDM (12.2 ± 0.4 and 14.3 ± 0.4) than LDM (9.6 ± 0.4 and 12.2 ± 0.4). Curiously, lowering DM intake caused a greater increase in circulating P4 in Nellore than in Holsteins (genetic group*diet*d, $P = 0.05$). In conclusion, heifer breed had a market effect in hormonal profile and follicle growth during synchronization programs, but increasing DM intake greatly influenced ovarian dynamics and circulating P4. *Acknowledgements: FAPESP, CNPq.*

1439 (W199) Association between insulin signaling and oxidative stress in serum and subcutaneous adipose tissue of overconditioned cows. S. Häussler[*1], L. Locher[2], L. Laubenthal[1], S. P. Singh[1], U. Meyer[3], J. Rehage[2], S. Dänicke[3], and H. Sauerwein[1], *[1]University of Bonn, Institute of Animal Science, Germany, [2]University for Veterinary Medicine Foundation, Hannover, Germany, [3]Institute of Animal Nutrition, Friedrich Loeffler Institute, Braunschweig, Germany.*

Cows with higher BCS or greater BCS loss in early lactation have more problems to adapt to the needs of lactation and are more sensitive to oxidative stress. Mitochondrial (mt)DNA copy numbers, reflecting the abundance of mitochondria in a cell, can increase to compensate mtDNA damage. Moreover, reactive oxygen species produced through lipid-induced mitochondrial dysfunction impair insulin signaling. We hypothesized that decreasing insulin sensitivity in overconditioned cows will be associated with oxidative stress concomitant with increased numbers of mitochondria. Therefore, we aimed to investigate the association between oxidative stress (assessed by quantifying derivates of reactive oxygen species (dROM)) and mtDNA copies/cell in subcutaneous (sc) adipose tissue (AT) with variables describing insulin sensitivity (IS) in overconditioned cows independently from homeorhetic processes. Non-pregnant, non-lactating German Holstein cows (n = 8) were gradually adapted to a high-energy ration (corn-grass-silage with increasing portion of corn-silage and increasing concentrate feed from 0% up to 60% of total dry matter intake). Over a period of 15 wk, the average weight gain of the animals was 243 ± 33.3 kg. Blood samples were collected once per month and were analyzed for insulin, glucose and NEFA to calculate a surrogate marker for IS (RQUICKI). Adiponectin was measured in serum using an in-house developed ELISA. Derivates of reactive oxygen metabolites (dROM) were indirectly measured in serum using a photometric method with N,N,diethyl-1,4-phenylendiamine as chromogen. Every 8 wk, scAT from tailhead was biopsied and snap frozen for genomic DNA isolation. The number of mtDNA copies/cell was measured by multiplex qPCR. Data (mean ± SEM) were analyzed using repeated measures ANOVA and Spearman correlations (SPSS). Decreasing insulin sensitivity throughout the experiment, indicated by decreasing RQUICKI values (P = 0.001), were negatively correlated with dROM (r = -0.543, P = 0.007) and mtDNA copies (r = -0.568, P = 0.005). Moreover, adiponectin concentrations were decreased throughout the experiment (P < 0.05) and tended to be negatively correlated (r = -0.381, P = 0.067) with mtDNA copies. Increased oxidative stress seems to enhance insulin resistance. However, dROM was not associated with serum adiponectin which is known for its insulin sensitizing and lipolysis inhibiting effects. In contrast to reports about insulin resistance being related to reduced mitochondrial content in humans, increasing mtDNA copies in the present study seem to compensate mitochondrial damage caused by enhanced dROM.

Key Words: insulin resistance, oxidative stress, mtDNA

1440 (W200) Serum apelin concentrations in dairy cows receiving different amounts of concentrate and a nicotinic acid supplement. M. Weber[1], L. Locher[2], K. Huber[3], J. Rehage[2], R. Tienken[4], U. Meyer[4], S. Dänicke[4], U. Müller[5], H. Sauerwein[*5], and M. Mielenz[6], *[1]Institute of Animal Science, Physiology and Hygiene Unit, University of Bonn, Germany, [2]University for Veterinary Medicine Foundation, Hannover, Germany, [3]University of Hannover, Germany, [4]Institute of Animal Nutrition, Friedrich Loeffler Institute, Braunschweig, Germany, [5]University of Bonn, Institute of Animal Science, Germany, [6]Leibniz Institute for Farm Animal Biology, Institute of Nutritional Physiology, Dummerstorf, Germany.*

Apelin, a 77 amino acid preproprotein, which is also known as an adipokine, is suggested to play a physiological role in glucose metabolism. It stimulates glucose uptake by adipose tissue in humans and mice, whereas lipolysis in humans is not affected. This might lead to a decreasing lipolysis during the transition period in cattle and may prevent lipid-related disorders. Nicotinic acid (NA), a known antilipolytic agent, might decrease plasma NEFA concentrations and enhances the response to insulin. As plasma apelin concentrations are decreased by a hypochaloric diet, we hypothesized, that different levels of concentrate in the diet combined with NA supplementation would affect the serum apelin concentrations in dairy cows. Thus the objectives of the present study were to quantify apelin in bovine serum samples and to examine the impact of different levels of concentrate in combination with a NA supplementation on apelin serum concentrations. Serum samples were obtained from 20 pluriparous Holstein-Friesian cows at d −42, −14, 1, 7, 14, 21, 42 and d 100 relative to calving. Until d −42 all cows were fed the same silage-based diet. Between d −42 and d −1 10 animals each were assigned to either a high-concentrate (HC, 60:40 concentrate:roughage) or a low concentrate group (LC, 30:70 concentrate:roughage). Both groups were further subdivided into a control and a niacin group (n = 5), the latter receiving 24 g/d NA (Lonza, Basel, Switzerland) until d 24. Serum apelin concentrations were measured using a commercially available ELISA kit (*P*hoenix Pharmaceuticals, Burlingame, CA) validated for bovine samples. Statistical analysis was done using Mixed-Model procedure followed by Bonferroni correction (SPSS 22); d −42 values were considered as covariate. The serum apelin concentrations were not affected by treatment and time (P > 0.05) and remained on a constant concentration (mean 1.21 ± 0.08 ng/ml). The results of this study indicate that serum apelin concentrations are independent of the prepartum feeding regimen as well as of the stage of lactation.

Key Words: apelin, nicotinic acid, dairy cow

1441 (W201) Nuclear related factor-E2 is downregulated by hyperinsulinemic euglycemia in dairy cows.

M. Zarrin[*1,2,3], O. Wellnitz[1], and R. M. Bruckmaier[1], *[1]Veterinary Physiology, Vetsuisse Faculty, University of Bern, Switzerland, [2]Dep. of Animal Science, Yasouj University, Iran, [3]Graduate School for Cellular and Biomedical Sciences, University of Bern, Switzerland*.

At the onset of lactation the liver undergoes a high load to provide metabolites for milk synthesis in dairy cows. The endocrine and metabolic changes induce inflammation that impairs liver function. The liver is protected by nuclear factor E2-related factor 2 (Nrf2), which is activated by inflammatory signals such as reactive oxygen species (ROS), and has anti-oxidative effects, diminishes inflammatory damage, neutralizes ROS, and suppresses pro-inflammatory signaling. We have studied hepatic mRNA abundance of Nrf2 as a response to long-term (48 h) insulin and β-hydroxybutyrate (BHBA) infusion in mid-lactation dairy cows. Twenty four Holstein dairy cows were randomly assigned to four intravenous treatment groups including an hyperinsulinemic clamp infusion to decrease plasma glucose concentration to 2.5 ± 0.1 mmol/L (HypoG, n = 5), a hyperinsulinemic euglycemic clamp to maintain plasma glucose concentration at pre-infusion level (EUG, n = 6), a BHBA infusion (HyperB, n = 5), and a 0.9% NaCl infusion (Control, n = 8). Liver tissue samples were taken 1 wk before and 48 h after the start of infusion. Changes of hepatic mRNA abundance (RT-qPCR) of several acute-phase proteins and of Nrf2 between before and after 48 h infusions were evaluated by analysis of variance with treatment as fixed effect. SAA and Hp mRNA was up-regulated in all treatment groups ($P < 0.05$) during 48 h infusions. The mRNA of glutathione peroxidase 3 (GPX3), metallothionein (MT) 1A, MT1E, and MT2A was up-regulated after 48 h of infusions in Control ($P < 0.05$). Insulin infusion downregulated mRNA abundance of microsomal glutathione S-transferase 3 (MGST3), MT1E, MT2A, NAD (P) H dehydrogenase, quinone 1 (NQO1), and superoxide dismutase 1 (SOD1) ($P < 0.05$). Changes of GPX3, MGST3, MT1A, MT1E, MT2A, and SOD1 mRNA abundance during 48 h of infusion differed significantly between EUG and Control ($P < 0.05$). Change of mRNA abundance of NQO1 after 48 h of infusions differed significantly between EUG and HyperB ($P < 0.05$). Results show that infusions and experimental condition up-regulated mRNA abundance of APP in all treatments, and up-regulated some of Nrf2 in control, whereas induced hyperinsulinemic euglycemic clamp downregulated most of Nrf2 factors in EUG. It seems that the up-regulation of these factors in Control occurs despite unchanged metabolites during the infusion. Although insulin has an anti-inflammatory role different results observed in both HypoG and EUG. It can be assumed that downregulation of Nrf2 mRNA factors in EUG is related to a decrease of hepatic gluconeogenesis through the decline in glucagon secretion.

1442 (W202) Bovine oocytes in vitro matured in the presence of antioxidants: Implications for intracellular levels of glutathione and reactive oxygen species and blastocyst development.

N. A. D. S. Rocha Frigoni[*1], B. C. D. S. Leão[1], P. C. Dall'Acqua[1], L. Rigon[1], Nogueira[2], and G. Z. Mingoti[1], *[1]University of Sao Paulo State (UNESP), Araçatuba, Brazil, [2]EMBRAPA Pantanal, Corumbá, Brazil.*

Production of reactive oxygen species (ROS) is a physiological process that occurs mainly on mitochondrial metabolism. Some, in vitro culture conditions can lead an increase in ROS production, making the oocytes more susceptible to oxidative stress damage. This study was conducted with the main objective to assess the effects of supplementation of in vitro maturation (IVM) medium with intracellular (cysteine and cysteamine) and extracellular (catalase) antioxidants on the intracellular levels of glutathione (GSH) and ROS in bovine oocytes and its implications on the subsequently embryonic development. *Cumulus*-oocyte complexes were matured in TCM-199 with bicarbonate, hormones and 10% FCS without supplementation (Control group) or supplemented with 0.6 mM cysteine associated with 100 µM cysteamine (C+C group), 100 UI catalase (CAT group) or 0.6 mM cysteine associated with 100 µM cysteamine and 100 UI catalase (C+C+CAT group) for 22 h at 38.5°C in 5% CO_2 in air. A sample of matured and immature oocytes (0 h) were stained (n = 192) with 5 µM of the fluorescent probe 6-carboxy-2'7'-dichlorodihydrofluorescein diacetate (H_2DCFDA; Molecular Probes, Invitrogen, Oakville, Canadá) or stained (n = 246) with ThiolTracker Violet (Glutathione Detection Reagent; Molecular probes, Invitrogen, Oregon) to evaluate ROS and GSH, respectively. Stained oocytes were evaluated immediately under an epifluorescence inverted microscope (excitation 495/510–550 nm and emission 404/526 nm, respectively for H_2DCFDA and ThiolTracker™) and the images were analyzed by Q-Capture Pro image software for determining the fluorescent intensity. Other oocytes were submitted to IVF and the presumptive zygotes were IVC in SOF medium, at 38.5°C in 5% CO_2 in air, for 7 d. The cleavage rates and embryonic development were evaluated, respectively, at 72 and 168 hpi. The differences of fluorescent intensity among groups was compared by ANOVA followed by Tukey's test and embryonic development was analyzed by Chi-square test ($P < 0.05$). The fluorescent intensity for ROS quantification was 1.00 ± 0.12^{a} (0 h), 1.91 ± 0.10^{c} (Control), 1.11 ± 0.04^{a} (C+C), 1.45 ± 0.08^{b} (CAT) and 1.07 ± 0.04^{a} (C+C+CAT). The fluorescent intensity for GSH quantification was 1.00 ± 0.4^{a} (0 h), 0.21 ± 0.01^{bd} (Control), 0.47 ± 0.02^{c} (C+C), 0.32 ± 0.01^{b}

(C+C+CAT) and 0.15 ± 0.01[d] (CAT). The cleavage rates were 73.5[a] (Control), 75.7[a] (C+C), 75.4[a] (CAT) and 73.1[a] (C+C+-CAT). The blastocyst rates were 28.2%[a] (Control), 31.1%[a] (C+C), 33.3%[a] (CAT) and 46.2%[b] (C+C+CAT). In conclusion, supplementation with cysteine, cysteamine and catalase during IVM reduced intracellular ROS levels and improved the embryonic development; however, such improvement was not due to an increase on intracellular amounts of GSH.

Key Words: antioxidants, in vitro maturation, ROS, GSH, blastocyst

1443 (W203) Heat stress alters adipose adrenergic signaling in lactating dairy cows. G. Xie*[1], L. W. Hall[2], M. Nearing[2], L. C. Cole[2], D. M. Spurlock[3], L. H. Baumgard[3], and R. P. Rhoads[1], *[1]Virginia Tech, Blacksburg, [2]University of Arizona, Tucson, [3]Iowa State University, Ames.*

Malnourished animals mobilize adipose tissue to alleviate the impact of energy deficiency on galactopoiesis, but heat-stressed (HS) lactating cows lessen their dependence on this strategy. One possibility is that lipolytic response becomes refractory to adrenergic signaling. To test this hypothesis, multiparous dairy cows (n = 6; parity = 4 ± 0.9; 436 ± 93 DIM; 721 ± 39 kg BW) housed in climate chambers were fed a TMR consisting primarily of alfalfa hay and steam-flaked corn and subjected to 2 experimental periods: 1) thermoneutral conditions (TN; 18°C, 20% humidity) with ad libitum intake for 9 d and 2) HS conditions (cyclical temperature 31 to 40°C, 20% humidity: min THI = 73, max THI = 86) with ad libitum intake for 9 d. Rectal temperature (Tre) was measured thrice daily at 0600, 1400, and 1800 h. During each period, cows were administered epinephrine intramuscularly (0.02 mg/kg) twice daily from d 6 to 9. Before and after epinephrine treatment, adipose biopsies were obtained from contralateral tailhead areas. Adipose lipolysis and lipogenic-related proteins were measured by western immunoblotting. During period 2, HS caused a 1.3°C increase in Tre compared with TN (P < 0.001). Heat stress reduced DMI by 18% (P < 0.001) and milk yield by 10% (P < 0.01). Epinephrine increased 5' adenosine monophosphate (AMP)-activated protein kinase (AMPK) (P < 0.1), cyclic-AMP response element-binding protein (CREB) (P < 0.05) and hormone sensitive lipase (HSL) (P < 0.05) phosphorylation abundance during TN but not in HS. Beta2 adrenergic receptor (BAR2) abundance was stable in all periods and treatments. Adipose triglyceride lipase (ATGL) protein expression was blunted (P < 0.05) by epinephrine in TN and HS. Fatty acid synthase (FAS), acetyl-CoA carboxylase (ACC) and phosphorylated ACC protein abundance were decreased (P < 0.05) by HS but did not respond to epinephrine challenge. In contrast, insulin receptor (IR) increased (P < 0.05) in HS regardless of epinephrine administration. Protein kinase B (AKT) phosphorylation tended to increase (P < 0.1) in response to epinephrine during HS. These observations indicate HS may alter adrenergic signaling by blunting lipolytic response in lactating cows. Potential cross talk between epinephrine and insulin may underlie HS adaptation.

Key Words: heat stress, lactation, catecholamine

1444 (W204) Effect of vitamin C supplementation on biochemical parameters and haemagglutination potential of Giant African Land Snail (*Archachatina marginata*) haemolymph. J. A. Abiona*, A. O. Ladokun, J. O. Daramola, D. M. Abioja, E. O. Oke, and O. M. Onagbesan, *Federal University of Agriculture, Abeokuta, Nigeria.*

A study was conducted on the effect of vitamin C on biochemical parameters and haemagglutination potential of Giant African Land Snail's haemolymph (*Archachatina marginata)*. Thirty-two snails with weight range of 100 to 180 g were used for this study. Eight snails were subjected to each of the four treatments which included: concentrate only, concentrate + 50 mg vitamin C, concentrate + 100 mg vitamin C and concentrate + 150 mg vitamin C. After 9 wk, haemolymph was collected from the mantle cavity from all the snails. Parameters monitored were: haemolymph total protein, albumin, globulin, cholesterol, glucose and haemagglutination titre. The result showed that haemolymph albumin, total protein, glucose, and cholesterol were not significantly affected (P > 0.05) by the treatment. However, the different levels of vitamin C with concentrate had significant effect (P < 0.05) on globulin. Snails fed concentrate + 150 mg of vitamin C had the highest least square mean (29.46 ± 1.47). For the haemagglutination test, 100 mg and 150 mg of vitamin C with concentrate for 120 min and 150 min had better haemagglutination titre (strength). It was however recommended that Inclusion of vitamin C in concentrate feed of snails should be encouraged with levels not less than 200 mg/kg of feed.

Key Words: vitamin C, biochemical parameters, haemagglutination potential

1445 (W205) Effects of grape seed supplementation on blood metabolic profile, immunity and milk production traits of dairy ewes. F. Correddu[1], A. Marzano[1], P. Bonelli[2], P. Nicolussi[2], and A. Nudda*[1], *[1]Dipartimento di Agraria, University of Sassari, Italy, [2]Istituto Zooprofilattico della Sardegna, Sassari, Italy.*

Grapes (*Vitis vinifera*) are rich in polyphenols with approximately 60 to 70% of these being in the seeds. The grape seeds (GS) are rich in proanthocyanidins that exert anti-oxidant and anti-inflammatory activities. The aim of this work was to study the effect of GS by-products in lactating sheep diet on milk production, blood metabolic profile and immune function. Twelve Sarda ewes in the first part of lactation, were divided in two isoproductive groups (1.7 kg/head/d): a control group (CON) and a treated group supplemented with 300 g/d

of grape seed (GS). Milk yield was measured weekly. Blood samples were collected every 2 wk and analyzed for total bilirubin, creatinine, aspartate transaminase (AST), alanine transaminase (ALT), γ glutamyl transpeptidase (GGT), alkaline phosphatase (ALP), total protein and urea nitrogen (BUN). Plasma samples were used to perform ELISA to evaluate the anti-OVA IgG titers, CD4 and CD8 cells. Lymphocyte proliferation was determined in vivo in each ewe by the measurement of changes in skin-fold thickness. Milk yield not affected by GS supplementation. All kidney and liver function biomarkers in serum did not differ between dietary groups. A slight suppressing effect of GS on immune activities was evidenced by the reduction of skin-fold thickness, IgG titers, Cd4/Cd8 ratio compared to CON. Grape seed by-product can be supplemented to lactating ewes for 2 mo without altering the immunity and the hepatic and renal metabolism status. *Acknowledgements: Research supported by Cargill–Animal Nutrition Division, Milan, Italy.*

1446 (W206) Determination of glucose metabolism and TCA cycle activity of early antral and late antral feline cat follicles employing [$^{13}C_6$]glucose and mass spectrometry. J. L. Colvin[1], N. Songsasen[2], C. L. Keefer[1], and B. J. Bequette[*1], *[1]Dep. of Animal and Avian Sciences, University of Maryland, College Park, [2]Center for Species Survival, Smithsonian Conservation Biology Institute, Front Royal, VA.*

Improving in vitro culture systems for follicles and oocytes requires knowledge of their metabolism. Thus, our objectives were to establish glycolytic and TCA cycle activity in feline follicles at two developmental stages, and after 13 d of in vitro culture. Paired feline ovaries from sexually mature cats ($\geq$ 1 yr) were acquired from a clinic. Morphologically healthy early (< 0.5 mm o.d.) and late (> 2 mm o.d.) antral follicles with a visible antrum were isolated. Early (n = 10 per cat, n = 9 cats) and late (n = 1 per cat, n = 9 cats) antral follicles were placed into individual wells with culture media (0.5 mL, DMEM containing glutamine and pyruvate plus a 50:50 mix of unlabeled and [$^{13}C_6$]glucose) and incubated for 24 h (5% CO_2) at 38.5°C. To determine whether in vitro culture of early antral follicles leads to acquisition of a late antral metabolism, a group of early antral follicles (n = 10 per cat, n = 9 cats) were encapsulated in 0.5% alginate hydrogel and cultured individually for 13 d with media containing [$^{13}C_6$]glucose the last 24 h. Following incubation, in vivo derived and in vitro cultured early antral follicles were pooled separately by cat for analysis, while late antral follicles were analyzed individually. Metabolites from follicles were extracted, and ^{13}C-isotopomer enrichments of metabolites determined by gas chromatography-mass spectrometry. The TCA cycle intermediate equilibrium partners alanine (pyruvate) and glutamate (α-ketoglutarate) were monitored for calculation of glycolytic and TCA cycle fluxes. Data were analyzed as a mixed model ANOVA with cat and cat age as blocking factors. A greater proportion of pyruvate flux derived from glucose metabolism in late (56%) compared to early (33%) antral follicles, indicating higher rates of glycolysis by late antral follicles. For both early and late antral follicles, only 2% of acetyl-CoA flux derived from glucose, indicating that TCA cycle oxidative metabolism relies on other substrates. Early antral follicles cultured in vitro for 13 d metabolized glucose and had TCA cycle flux activity similar to that of the early antral follicles cultured for 1 d. Thus, in vitro culture of early antral follicles for 13 d did not result in these follicles acquiring a similar metabolism as late antral follicles. The current research demonstrates a metabolic shift between early and late antral follicles derived in vivo, as well as a limited ability of early antral follicles to acquire a late antral metabolism after in vitro culture for 13 d.

Key Words: feline, follicle, metabolism

1447 (W207) Interrelationships between methods of blood mineral measurement in early postpartum dairy cows. B. M. Sweeney[*1], E. M. Martens[1], K. P. Zanzalari[2], J. C. Lawrence[3], and T. R. Overton[1], *[1]Cornell University, Dep. of Animal Science, Ithaca, NY, [2]Prince Agri Products, Inc., Franklin, IN, [3]IDEXX Laboratories, Inc., Westbrook, ME.*

The objective of this study was to determine the relationship between blood minerals measured by different methods and to determine the relationship between blood total (tCa) and ionized calcium (iCa) measured on samples taken from early postpartum dairy cows, as well as the agreement of tCa and iCa for diagnosis of subclinical hypocalcemia (SCH). Seventeen multiparous Holstein dairy cows were sampled 2× in the 24 h period postpartum and 1×/d for the following 4 d. Whole blood was analyzed immediately after collection for iCa by an iSTAT Portable Clinical Analyzer (*P*CA), and serum was analyzed for tCa, Mg and P using both the IDEXX VetTest (VT) and colorimetric methods at a veterinary diagnostic laboratory (DL). Serum total minerals measured by VT vs. DL were highly correlated (tCa $r = 0.95$,$P < 0.0001$;Mg $r = 0.91$,$P < 0.0001$;P $r = 0.97$,$P < 0.0001$). A VT tCa cutpoint with the highest combined sensitivity (96%) and specificity (85%) for diagnosing SCH (defined as DL tCa $\leq$ 8.0 mg/dL) was found to be 8.9 mg/dL as determined by receiver operator characteristic (ROC) analysis. The correlation between tCa measured by DL and iCa measured by PCA was high ($r = 0.89$,$P < 0.0001$). Generally when iCa is used to diagnose SCH, a cutpoint of 4.0 mg/dL iCa is used based on the assumption that iCa constitutes 50% of tCa. Using this assumption, agreement (as determined by McNemar's Test) for diagnosis of SCH ($\leq$ 8.0 mg/dL tCa, $\leq$ 4.0 mg/dL iCa) was poor (Exact $P = 0.06$; Kappa = 0.45, $P < 0.05$). Based on the two samples taken postpartum [7(± 4) h and 20(± 4) h postpartum], this data showed that iCa constituted 58% of tCa in the 24 h postpartum. The iCa cutpoint

with the greatest combined sensitivity (91%) and specificity (87%) for diagnosing SCH was determined by ROC analysis and found to be 4.68 mg/dL. Overall, serum minerals (tCa, Mg and P) measured by standard laboratory techniques are highly correlated with minerals measured by the VT and different cut-points can be used to accurately diagnose SCH with tCa measured by the VT. The relationship between iCa and tCa in the period immediately postpartum must be better characterized before iCa can be used for diagnosis of SCH.

Key Words: ionized calcium, subclinical hypocalcemia, serum minerals

1448 (W208) Development of a multiplex assay for simultaneous quantification of endocrine analytes.

E. A. Benavides*[1], K. D. Wells[1], and D. H. Keisler[2], *[1]University of Missouri–Division of Animal Sciences, Columbia, [2]University of Missouri–Division of Animal Sciences, Columbia.*

Since the advent of the radioimmunoassay in the 1950s, numerous immunologically-based methods have evolved for sample analysis. Although each immunological method possesses unique assets and liabilities, all share limited abilities in range of detection and the number of analytes resolvable simultaneously; most procedures are limited to one analyte determined per replicate per sample. The objective of this study was to adapt technology evolving from the genomics revolution for multiplexed hormonal analysis in livestock. We sought to complete this objective using sequencing technologies and tools: Illumina BeadXpress, Luminex xMAP, and quantitative immuno-PCR. The Illumina BeadXpress and Luminex xMAP both share similar characteristics; each platform consists of a laser spectrum analyzer and a bead-set. Each bead-set contains microscopic beads; each set with unique identifying signatures. As a test of proof of concept, the surface of a bead set was conjugated to an LH antibody. Using these technologies, we were able to establish an assay for LH on the Luminex platform, but not on the Illumina platform. The proprietary nature of both the Luminex and Illumina platforms however, greatly limited assay flexibility. Therefore, we chose to establish an assay for LH using quantitative immuno-PCR. Quantitative immuno-PCR exploits PCR amplification with antibody detection. Briefly, a sandwich immunoassay is performed with capture antibody immobilized to a PCR plate. A second detection antibody is conjugated to an oligonucleotide and after a series of washes, the plate is subjected to quantitative PCR (qPCR). Detection of LH was achieved, but background binding was a problem. Subsequently, to simplify the design and demonstrate proof of concept, a biotinylated oligonucleotide was incubated with streptavidin coated PCR plates and subjected to qPCR. The results of this latter experiment suggested that the assay performed well with over six orders of magnitude linearity. In conclusion, background binding was found to be a major problem with quantitative immuno-PCR but one that is believed to be resolvable. Moreover, our observations suggest that immuno-PCR has the potential to improve detection capabilities of hormonal assays with six orders of magnitude sensitivity, reproducibility, and ultimately in a multiplex capacity with the oligonucleotide serving as both a label and as a barcode for identifying the analyte. The technological leap in capabilities provided by successful multiplexing can be used for understanding the complex interaction of endocrine and metabolic signals in the dynamically changing animal.

Key Words: multiplexing, endocrine profiling, immuno-PCR

1449 (W209) Effect of periconceptual growth hormone injection on feed intake and early fetal development in ewes.

C. H. Pereira*[1,2,3], K. C. Swanson[3], H. O. Patino[4], F. E. Doscher[3], V. C. Kennedy[3], B. R. Mordhorst[3], J. D. Kirsch[3], and K. A. Vonnahme[3], *[1]Universidade Federal do Rio Grande do Sul, Porto Alegre, Brazil, [2]North Dakota State University, Fargo, [3]North Dakota State University, Fargo, [4]Universidade Federal do Rio Grande Do Sul, Porto Alegre, Brazil.*

Researchers have reported improved birth weight and numbers of lambs from ewes treated with growth hormone (GH) at the time of breeding. Therefore, our hypothesis was that the administration of GH at time of breeding could increase DMI which consequently could result in greater early development of the fetus. Thirteen individually-penned ewes (mean BW = 69.8 ± 3.14 kg and BCS = 3.2 ± 0.13 [1-to-5 scale]) were fed a pelleted diet (CP 12.88%, ash 6.48%, fat 1.69%, NDF 37.86%, ADF 23.83% of DM) for ad libitum intake. Estrus was synchronized by administering 2 doses of prostaglandin $F_{2\alpha}$(*P*GF) 11 d apart. At the second dose of PGF, six ewes were injected IM with GH (500 mg) and seven ewes with saline solution (control). The ewes in both treatments were exposed to the same ram at 0700 and 1900 h and allowed to breed. Doppler ultrasound measurements were taken on d 25, 30, 40, and 50 of gestation for fetal length, fetal width, kidney length, kidney width, placentome size, biparietal distance and umbilical blood flow (BF; at d 50 of gestation). Data were analyzed in PROC MIXED (SAS; 2011) to test for the effects of treatment, day and treatment × day. No differences between treatments were observed for BW ($P = 0.16$), BCS ($P = 0.54$) and DMI ($P = 0.84$) after injection of GH. There was a day effect ($P < 0.05$) for fetal length, fetal width, kidney length, placentome size, and biparietal distance with all increasing as gestation advanced. No difference ($P > 0.05$) was observed between treatments for any ultrasound measurements. Growth hormone administration did not influence DMI or conceptus development as measured using ultrasonography. It is still unknown how periconceptual GH treatment could enhance growth and

development of the conceptus, or umbilical BF, after d 50 of gestation when exponential growth of the fetus occurs.

Key Words: ewe, growth hormone, ultrasound

1450 (W210) Relationship between plasma concentrations of thyroid hormones and physiological state of beef cow/calf pairs.

B. H. Boehmer*, M. R. Davis, and R. P. Wettemann, *Oklahoma Agricultural Experiment Station, Stillwater.*

Triiodothyronine (T_3) and thyroxine (T_4) are important mediators of energy expenditure, growth, and thermogenesis. The prohormone T_4 is converted to the biologically active form, T_3. Relationships between concentrations of T_3 and T_4 in cows and their offspring have not been defined. Spring calving, Angus cow/calf pairs (n = 27) were used to evaluate the relationship between plasma concentrations of T_3, T_4, and T_4:T_3 in cattle of different physiological ages. Calves were weighed at birth and bulls were castrated by banding. Weights of cows and calves were recorded at 48 and 97 d post partum and blood samples were collected at 97 d postpartum. Plasma concentrations of T_3 and T_4 were quantified by RIA. Triiodothyronine, T_4, and the ratio of T_4 to T_3 (T_4: T_3) were analyzed with PROC CORR and PROC MIXED (SAS Inst. Inc.). Plasma concentrations of T_4 did not differ between cows (P = 0.17, 40.5 ± 7.4 ng/ml) and calves (59.2 ± 7.4 ng/ml). Concentrations of T_4 in cows and their calves were not correlated (P = 0.40). Concentrations of T_3 tended to be greater in calves (P = 0.06; 1.99 ± 0.17 ng/ml) compared with cows (0.88 ± 0.17 ng/ml). Concentrations of T_3 in plasma were correlated (r = -0.43, P = 0.03) between cows and their calves. Plasma concentrations of T_4:T_3 in cows were greater (P < 0.001; 49.0 ± 9.3) compared with calves (31.3 ± 9.3) and T_4:T_3 was not correlated between cows and their calves (P = 0.83). The T_4: T_3 in calves was correlated with T_3 (r = 0.45, P = 0.02) in their dams and tended to be positively correlated with T_4 (r = 0.38, P = 0.06) in their dams. Concentrations of T_4 in calves and T_3 in cows were not correlated (P = 0.87). Average daily gain of calves was not correlated with T_4, T_3, or T_4: T_3 in cows or calves ($P \geq 0.12$). Concentrations of T_3 tended to be greater in calves compared with their dams; however, concentrations of T_4 were similar. These results indicate thyroid function in cows and their calves was related as plasma concentrations of T_3 were negatively correlated. Production efficiency of beef cows and calves may be enhanced by identifying individuals with greater metabolic efficiency.

Key Words: thyriod hormone, beef cattle, metabolism

1451 (W211) Follicle-stimulating hormone converges with canonical WNT signaling to enhance Cyp19a1 promoter activity in granulosa cells.

B. I. Gomez*[1], J. O. E.[1], C. A. Gifford[1], D. M. Hallford[2], and J. Hernandez Gifford[1], *[1]Oklahoma State University, Stillwater, [2]New Mexico State University, Las Cruces.*

Biosynthesis of estradiol in the adult ovary requires activation of the tissue specific cytochrome P450 aromatase (*Cyp19a1*) type II promoter (*PII*) by FSH. Canonical wingless-type mammary tumor virus integration-site (WNT) signaling has been recognized to contribute to ovarian regulation of steroidogenesis by increasing the transcriptional co-factor, β-catenin. Recent data suggest WNT3A is inhibitory on FSH mediated mRNA induction of key steroidogenic enzymes and steroid biosynthesis; however, the mechanism by which WNT3A negatively regulates FSH remains to be determined. Therefore, the objective of this study was to investigate the inhibitory effects of WNT3A on FSH-mediated *Cyp19a1* activity. Immunofluorescence was performed on primary rat granulosa cells treated with WNT3A (500 ng/mL) in the presence or absence of FSH (100 ng/mL) for 24 h (n = 4) to determine if FSH prevents WNT3A translocation of β-catenin. Treatment with WNT3A and WNT3A+FSH resulted in nuclear accumulation of β-catenin, while FSH treated cells resembled control groups with the majority of β-catenin remaining at cell membrane. To identify if WNT3A+FSH prevents β-catenin ability to bind the *Cyp19a1 PII*, a 516 bp fragment of the *Cyp19a1 PII* (516-*Cyp19a1 PII*) was transfected into primary cultures of rat granulosa cells, treated with vehicle or WNT3A (500 ng/mL) for 24 h, then co-cultured with or without FSH (100 ng/mL) for an additional 24 h (n = 4). Promoter activity was measured by the luciferase reporter assay and statistical differences for treatment interaction were quantified using one-way ANOVA procedure of SAS. Activity of *Cyp19a1 PII* with WNT3A alone was similar to controls, while FSH treatment increased (P = 0.01) *Cyp19a1 PII* activity 6.65-fold when compared to controls. Co-incubation of FSH and WNT3A was synergistic resulting in a 16.09-fold increase in *Cyp19a1 PII* activity (P = 0.01; n = 4). To evaluate if regions upstream of the 516 bp *Cyp19a1 PII* fragment are responsible for the inhibition of estradiol biosynthesis, the full length *Cyp19a1 PII* (full-*Cyp19a1 PII*) and 2000 bp (2000-*Cyp19a1 Promoter*) upstream of the ATG site on *Cyp19a1* was cloned into a luciferase reporter. Preliminary data suggest *full-Cyp19a1 PII* and *2,000-Cyp19a1 promoter*activity is not synergistic (n = 2) with co-incubation of WNT3A+FSH. Future studies are needed to determine the regions on the promoter responsible for WNT3A inhibition on FSH signaling.

Key Words: Cyp19a1, granulosa cells, WNT

1452 (W212) Effects of various doses of gonadotropin stimulation on reproductive performance of seasonally anestrous ewes. S. L. Rastle-Simpson*, K. N. D'Souza, A. K. Redhead, C. D. Paul, E. N. Keller, and M. Knights, *West Virginia Univeristy, Morgantown.*

The use of exogenous gonadotropins as part of an estrous induction protocol can have beneficial effects on fertility in ewes bred out-of-season. Few studies have evaluated the ability of a mixture of eCG (FSH-like) and hCG (LH-like) (*P*.G. 600, Intervet, Millsboro, DE) to increase fertility in ewes bred out-of-season, specifically following the pre-treatment with progesterone delivered via CIDR devices. Previously, our lab found that administering 3 mL of the gonadotropin mixture 1 d before CIDR removal increased conception rate, pregnancy to first service, lambing rate and the overall percentage of ewes that lambed. The objective of this study was to evaluate the dose effects of a gonadotropin mixture on reproductive performance of seasonally anestrous ewes. Crossbred ewes (n = 200) from three farms in West Virginia and Pennsylvania received CIDR inserts (between the months of May and July) 5 d before introduction of rams. At insert removal, all ewes were assigned randomly to receive a 5-mL injection (i.m., 400 IU eCG, 200 IU hCG) of P.G. 600, a 3-mL injection (i.m., 240 IU eCG, 120 IU hCG) of P.G. 600, or receive no further treatment. The reproductive performance parameters that were measured include pregnancy rate, prolificacy, pregnancy retention, and lambing rate. Analysis of variance was conducted using the GLM procedures of SAS, and least squares means were computed. None of measured reproductive performance parameters was significantly affected by the different doses of gonadotropin stimulation ($P > 0.05$). It is possible that no effect of the gonadotropin stimulation may be due to the high reproductive performance observed in the control ewes. In conclusion, administration of various doses of a gonadotropin mixture at progesterone withdrawal had no effect on reproductive performance of ewes bred outside their normal breeding season.

Key Words: gonadotropin stimulation, anestrus, ewe

1453 (W213) Effect of methionine supplementation on methylation and lipid accumulation of the preimplantation embryo in dairy cows. D. A. Velasco Acosta*[1,2], A. C. Denicol[3], C. S. Skenandore[1], Z. Zhou[1], M. Nunes Corrêa[2], D. N. Luchini[4], P. J. Hansen[3], J. J. Loor[1], and F. C. Cardoso[1], *[1]University of Illinois, Urbana, [2]Federal University of Pelotas, Brazil, [3]Dep. of Animal Sciences, University of Florida, Gainesville, [4]Adisseo S.A.S., Alpharetta, GA.*

The lipid profile of oocytes and early embryo can be influenced by the environment of the cow. Our objective was to determine effect of supplementing rumen-protected methionine on DNA methylation and lipid accumulation in preimplantation embryos of dairy cows. Lactating Holsteins entering their second or greater lactation were randomly assigned to two treatments from 30 ± 2 DIM to 72 ± 2 DIM; Control (CON; n = 5, fed a basal diet with a 3.4:1 Lys:Met) and Methionine (MET; n = 5, fed the basal diet plus Smartamine M to a 2.9:1 Lys:Met). On d 60, dominant follicles greater than 5 mm were aspirated using an ultrasound-guided transvaginal approach. A CIDR device was inserted in all cows after follicular aspiration (d 60) and superovulation began at d 61.5 using FSH treatment equivalent to 400 mg of NIHFSH-P1 (Folltropin) in 8 decreasing doses at 12-h intervals over a 4-d period. During the superovulatory period, all cows received two PGF2α injections at d 63 and 64 (concomitant with the fifth and seventh FSH injections), and CIDR was withdrawn at d 65. Twenty-four h after CIDR withdrawal, ovulation was induced with GnRH. Cows were artificially inseminated at 12 and 24 h after GnRH using a high-fertility sire. Embryos were flushed 6.5 d after artificial insemination. Embryos with stage of development 4 or greater were used for analysis. Methylation was assessed by immunofluorescent labeling with anti-5-methylcytosine while lipid accumulation was assessed by staining with Nile Red. ImageJ software was used for image analysis to determine intensity of labeling. For methylation, fluorescence intensity of nuclear 5-methylcytosine labeling was expressed as a ratio of labeling for DNA using propidium iodide. For lipids, fluorescence intensity of Nile Red staining was compared against a negative control embryo (subtraction of background). Nuclear staining (propidium iodide or Hoescht 33342) was used to count the total number of cells/embryo. A total of 37 embryos were harvested from cows (MET = 16; CON = 21). Statistical analysis was performed using the PROC MIXED of SAS. Cows receiving MET (1661) had greater ($P = 0.021$) lipid accumulation when compared with cows receiving CON (1033). There were no treatment effects ($P > 0.511$) on number of cells or stage of development. In conclusion, cows supplemented with methionine produced embryos with higher lipid concentration when compared to CON which could potentially serve as an important source of energy for the early embryo.

Key Words: methionine, embryo, methylation, lipid

1454 (W214) Expression of Foxp3 in peripheral blood mononuclear cells of pregnant cows. M. A. Paibomesai*[1], R. Machado Ferreira Saran[2], R. da Silva Nunes Barreto[2], F. V. Meirelles[2], and L. J. Oliveira[3], *[1]University of Guelph, ON, Canada, [2]Universidade de São Paulo, Pirassununga, Brazil, [3]Michigan State University, East Lansing.*

Pregnancy has been shown to have great influence over the immune system through the modulation of immune cell types, dampening of the immune response, and display of overall immunodysfunction. It is a period through which the maternal immune response must tolerate long periods of exposure to

foreign antigens produced by the growing fetus throughout gestation. To prevent loss of the fetus the maternal immune system will downregulate specific receptors, such as MHC, and push the system towards to tolerogenic state, as shown in mouse and woman studies. One of these strategies includes the increase in T-regulatory cells, which express the transcription factor FoxP3 and downregulate the immune response after activation. It has been previously shown in mice and woman that as gestation time lengthens the presence of T-regulatory cells increases both locally and systemically. However, this increase in T-regulatory cells has not been well defined in bovine pregnancy. The objective of this study is to determine the expression of FoxP3 transcription factor in $CD4^+$ T cells isolated from pregnant cows (n = 5) and non-pregnant (n = 5) at Day 30 after AI; periparturient (n = 5; 2 to 4 d before parturition) and nonpregnant (n = 5) n lactating cows. $CD4^+$ T cells were isolated by magnetic sorting from selected cows and snap-frozen for RNA extraction and reserve transcription. Gene expression of FoxP3 and PXT-3 were determined by quantitative RT-PCR. Preliminary results show that there is a tendency (P = 0.12) for decreased expression of FoxP3 on pregnant cows at d 30 compared to cow close to parturition. The absence of difference in expression of FoxP3 between pregnant and non-pregnant cows could be due to sample time as well as small group sizes. Additionally, PTX-3 expression is downregulated (P = 0.34) in the periparturient cows, although this was not significant. The decreased expression of PTX3 confirms that peripartum period represents a period of overall immunodysfunction as compared to early gestation. Overall, this study has the potential to identify cows that have higher conception rates due to an immunological system geared towards fetus tolerance.

Key Words: pregnancy, regulatory immune responses, dairy cows

1455 (W215) Luteinizing hormone (LH) profiles after either porcine LH or GnRH treatment in Holstein cows with or without FSH-stimulation.

A. Behrouzi*[1], M. Fakheri[1], R. Salehi[1], M. G. Colazo[2], and D. J. Ambrose[1,2], *[1]Dep. of Agricultural, Food and Nutritional Science, University of Alberta, EdmontonCanada, [2]Alberta Agriculture and Rural Development, Livestock Research Branch, Edmonton, AB, Canada.*

Using porcine LH (*P*LH) in lieu of GnRH for synchronizing ovulation in non-stimulated dairy cows resulted in a prolonged and elevated LH profile which favourably altered the expression of intrafollicular proteins associated with improved oocyte competence, and increased pregnancy rates. The wide variability in superovulatory responses and embryo yield in FSH-stimulated cows could potentially be reduced using pLH if the altered (i.e., prolonged and elevated) LH profile attained in non-stimulated cows could be established in superovulated cows. As a first step, our objective was to characterize LH profiles after giving pLH or GnRH in non-lactating Holstein cows subjected to different levels of ovarian stimulation. Cows (n = 13) assigned to no ovarian stimulation (NS; 0 mg FSH) received 100 μg GnRH followed by 500 μg cloprostenol (*P*GF) 7 d later. In ovarian-stimulated groups, cows received decreasing doses of FSH, twice daily over 4-d, with PGF treatments given with the sixth and seventh FSH, to attain either partial stimulation (PS; n = 8, 200 mg FSH) or full stimulation (FS; n = 12, 400 mg FSH). Cows received either 100 μg GnRH or 25 mg pLH 2 d after PGF in NS and 1 d after last FSH in PS and FS groups. Blood samples were collected to determine LH concentrations from 30 min before GnRH- or pLH- treatment, up to 20 h post-treatment and plasma LH concentrations were measured by radioimmunoassay using an anti-bovine LH monoclonal antibody. In GnRH-treated cows, mean (± SE) plasma LH (ng/mL) increased from 0.3 ± 0.1 to a peak of 14.3 ± 1.3 (NS), 6.3 ± 0.8 (PS) and 17.0 ± 2.6 (FS) by 1.5 h, remained elevated for up to 4 h after GnRH treatment ($P \leq 0.01$) returning to baseline by 8 h after treatment in all three groups. In pLH-treated NS and FS cows, plasma LH increased from 0.2 ± 0.2 to a mean peak of 2.1 ± 0.2 and 1.1 ± 0.1 by 1.5 h, and maintained above-basal concentrations ($P < 0.0001$) up to 20 h after treatment, respectively. In pLH-treated PS cows, however, LH concentrations increased from 0.1 ± 0.2 to a mean peak of 1.3 ± 0.2 ng/ml by 3 h, and remained above basal concentrations for up to 10 h post-treatment (0.5 ± 0.2; $P < 0.01$). In summary, LH concentrations in non- and FSH-stimulated cows given pLH remained elevated for a longer period than in cows given GnRH. Whether giving pLH to superovulated cows will reduce variability in ovarian response and improve embryo quality remains to be seen.

Key Words: LH, porcine LH, GnRH, dairy cow

PRODUCTION, MANAGEMENT, AND THE ENVIRONMENT: **INFLUENCE OF DIET AND MANAGEMENT ON HEALTH AND PERFORMANCE**

1456 (M217) A 6-yr study evaluating health, milk and milk quality in 427 dairy herds fed OmniGen-AF to dry and lactating cows. O. Bewley[1], T. Boyle[1], M. Brady[1], K. Brubaker[1], J. D. Chapman[*1], T. Elliott[1], L. O. Ely[2], S. Fitzner[1], A. E. Holland[1], D. Larson[1], R. Shaw[1], and J. Ydstie[1], *[1]Prince Agri Products, Inc., Quincy, IL, [2]University of Georgia, Athens.*

From 2007 through 2012, 427 U.S. dairy herds totaling 273,796 cows were enrolled in a study to evaluate health and production records collected from 90-dperiods before and during the feeding of OmniGen-AF (Prince Agri Products, Inc., Quincy, IL). Herd sizes ranged from 68 to 6700 cows with dairies starting the studies throughout the year (Januaury to March, $n = 158$, April to June, $n = 98$, July to September, $n = 84$, October to December, $n = 87$). All dry and lactating cows were fed OmniGen-AF (OG) at 56 g/hd/d for 90 d. Health events, milk quality and milk yields were collected from DC305, DRMS and PCDART systems. Data were analyzed using paired *t* test (SAS, Statistical Analysis System) comparing number of health events and production recorded during the 90 d OG was fed (post-OG) to those occurring in the 90 d before feeding OG (*P*re-OG). The resulting data were sorted and analyzed by all herds ($n = 427$), herd size (< 100 hd, $n = 68$: 101–500 hd, $n = 198$: 501–999 hd, $n = 76$: > 1000 hd, $n = 85$), and pre-OG somatic cell count (SCC) cells/ml (< 200k, $n = 103$: 201k-300k, $n = 127$: 301k-400k, $n = 72$: > 401k, $n = 62$). Significance was declared at $P < 0.05$. Reductions in mastitis cases/mo. (-24.3%), late term abortions/mo. (-28.6%), hospital pen cows/d (-16.7%) and dead cows/mo. (-33%) expressed as a % of total herd cows differed ($P < 0.001$) between the pre-OG to post-OG 90-d periods. Although incidence rates of health events varied across herd sizes and among herds grouped by SCC, common to all were significant differences detected in metritis and dead cows between pre-OG and post-OG. The average pre-OG SCC for all herds was 288,953 with an average of > 70% of herds reporting a reduction in SCC. Changes in SCC from pre-OG to post-OG were proportional to the pre-OG SCC. Herds with a pre-OG SCC of between 201k to 300k and 301k to 400k or > 400k were observed to have post-OG SCC reductions of 23,102; 56,463 and 127,911 cells/ml, respectively ($P < 0.001$). Milk production was reported in 208 herds with an average change from pre-OG to post-OG of 0.45kg/hd/d ($P < 0.05$); however, only herds of < 100 hd ($P < 0.05$) and herds with a SCC of 201k to 300k ($P < 0.001$) showed significant milk improvements. Results from this study suggest a nutritional strategy that includes feeding OG as part of a best-management practice program for dry and lactating cows can influence health, milk yield and milk quality in commercial dairies.

Key Words: health, milk quality, OmniGen-AF

1457 (M218) Crude glycerin as a replacement for dry ground corn in finishing diets for beef cattle: Economic analysis. P. Del Bianco Benedeti[*1,2], P. V. R. Paulino[3], M. I. Marcondes[1], A. Faciola[2], I. França *S*mith Maciel[1], and M. Custódio da Silva[1], *[1]Federal University of Viçosa, Brazil, [2]University of Nevada, Reno, [3]Nutron Alimentos Ltda., Campinas, Brazil.*

The objective of this study was to evaluate the effects of replacing dry ground corn (DGC) with crude glycerin (CG) on production costs of finishing beef bulls. A complete randomized design experiment with 25 d for adaptation and 95 d for sampling collection was conducted, in which 3640 Nellore bulls (367 ± 37 kg) were blocked by BW and assigned to 20 pens. Animals were randomly assigned to one of four treatments: 0, 5, 10, and 15% (DM basis) CG in diet. All diets contained 15% roughage and 85% concentrate and were formulated to meet NRC (2000) recommendations. Diets were isoenergetic, isonitrogenous, and allowed 1.4 kg/d BWG. Initially, twenty animals were slaughtered to serve as reference to estimate initial empty BW, which allowed carcass gain calculation. Sensitivity analysis was performed according to Diniz et al., 2010 (Asian-Aust. J. Anim. Sci. 23:1308–1318) to determine which diet was more economical according to current CG prices as a function of DGC prices. Data presented in Table 1457 shows the cost of each diet tested in this work during the period of August to November 2012. Treatment without CG had the lowest diet cost, followed by treatments with 5, 15, and 10% of CG inclusion, respectively. Sensitive analysis indicated that the treatment that provided the lowest cost per kg of carcass produced changes depending on the CG:DGC price relationship. When CG price was up to 110% of DGC price, the treatment that provided the lowest price per kg of carcass produced was 15% CG inclusion. When CG price was 120% or more of DGC price, the diet without CG was the most economical treatment. Data from this sensitive analysis indicates that CG may be an economical alternative to DGC for beef cattle feedlots in Brazil.

Key Words: economic analysis, feedlot, glycerin

1458 (M219) Inhibition of rumen methanogenesis induced by Bioflavex and its pure flavonoid components under in vitro fermentation using rumen fluid from steers fed high concentrate diets. A. R. Seradj[1], J. Crespo[*2], D. Villalba[1], and J. Balcells[1], *[1]University of Lleida, Spain, [2]Interquim |S. A.* (*Ferrer Health Tech), Barcelona, Spain.*

Four separated incubation series were performed in a complete randomized blocks design to determine the effect of a citrus extract rich in flavonoids (Bioflavex) and its main components on methane mitigation under in vitro condition. Rumen liquor from four rumen cannulated growing steers fed a high concentrate diet (90:10 commercial concentrate:barley straw) was used as inoculum. Bottles of 120 mL were prepared under the CO_2 stream and filled with incubation solution and a mixture of concentrate:barley straw (600:60 mg/bottle) was used as substrate. Bioflavex (BF) was added to the incubation media and its effect compared against its pure flavonoid components (Hesperidine [HS]; Isonaringine [IN]; Naringine [NG]; Neoeriocitrine [NE]; Neohesperidine [NH] and Poncirine [PC]) at 200µg/g dry matter (DM), and the substrate without flavonoids was also included as a control (CTR). Bottles were sealed and incubated at 39 ± 1°C for 72 h. The head space pressure was measured at intervals of 2 h, started from 2 to 12 h then 24, 48, and 72 h. Values (mbar) converted to volume (ml) by a linear regression. Since 12 h post incubation, a sample (0.1 mL) from head space gas was analyzed for methane concentration using GC. The pattern of cumulative gas production (y) was fitted to the model: $y = a(1\text{-}e^{-b(t-c)})$, being a the potential cumulative gas production (ml); b the production rate (ml/h) and c is the lag time (h). The addition of BF or any of its components reduced the cumulative gas ($P < 0.01$) and methane production (mmol/g DM) ($P < 0.01$) except for NE and PC, that did not differ from the CTR values. However, reduction in CH_4 production was more pronounced than it was in gas production ($P < 0.01$). No changes were observed in the gas (ml/h) and methane production rate (mmol/h) in relation to CTR. The addition of flavonoids in the in vitro culture media reduced gas production and it would reflect the activity of bioflavex and its main components against the fermentative activity of the rumen liquor although our result also showed specific activity against methanogenic archaea.

Key Words: in vitro incubation, methanogenesis, pure flavonoids

1459 (M220) Effects of trace mineral-fortified, limit-fed creep supplements on performance of beef calves (pre-weaning). A. Saran Neto[1], L. S. Caramalac[2], P. G. M. D. A. Martins[2], P. Moriel[2], H. J. Fernandes[3], and J. D. Arthington[*2], *[1]University of São Paulo, Pirassununga, Brazil, [2]UF/IFAS Range Cattle Research and Education Center, Ona, FL, [3]State University of Mato Grosso do Sul, Aquidauana, Brazil.*

To assess the effects of limit-fed creep supplements, with or without trace mineral (TM) fortification, 30 cow/calf pairs were stratified by birth date and randomly allocated to 1 of 15 bahiagrass pastures (1 heifer and 1 steer cow-calf pair/pasture). Calves were approximately 5 mo of age at the start of the study. Four treatments were randomly assigned to pastures, including, (1) limit-fed creep fortified with hydroxy-Cu, Zn, and Mn, (2) limit-fed creep fortified with Cu- and Zn-sulfate and Mn-oxide (sulfate/oxide), (3) limit-fed creep without TM fortification, and (4) no limit-fed creep (n = 3, 3, 4, and 5 pastures, respectively). Creep supplements for treatments 1 and 2 were also fortified with Co carbonate, Na selenite, and I (via EDDI). All pastures were provided free-choice access to salt with no mineral fortification. Supplements were offered 3 times weekly for 89 d (265 g/calf on Monday, Wednesday, and Friday) which targeted a maximum intake of 114 g/d. Calf BW was measured on d 0, 45 and 89 (weaning). Calf TM status was assessed in liver biopsy samples collected at weaning. Limit-creep intake increased over time ($P < 0.001$) and total limit-creep intake tended to be greater ($P = 0.10$) for hydroxy- vs. sulfate/oxide-formulated supplements (7.6 and 5.1 kg; SEM = 0.97). Limit-creep had no effect ($P = 0.22$) on pre-weaning BW gain (80.0 and 73.5 kg for limit-creep and no limit-creep, respectively; SEM = 5.44); however, BW gain tended ($P = 0.09$) to be greater for calves consuming hydroxy- vs. sulfate/oxide-formulated supplements (87.1 and 74.4 kg, respectively; SEM = 5.44). Efficiency of added BW gain did not differ ($P \geq 0.13$) among treatments (G:F = 1.94, 0.64, and 1.60 kg/kg for hydroxy, sulfate/oxide, and no TM fortification limit-creep feed, respectively; SEM = 0.850). The cost of added calf gain was $0.27, $1.98, and $0.60/kg for hydroxy-, sulfate/oxide-, and no-TM fortification limit-creep, respectively. Calves consuming TM-fortified, limit-creep, irrespective of source, had greater ($P \leq 0.02$) liver concentrations of Co, Cu, and Se compared to calves consuming no limit-creep or limit-creep without TM fortification. These results imply that the consumption of TM-fortified limit-creep increases the mineral status of calves and the use of hydroxy sources of Cu, Zn, and Mn may result in greater intake acceptability with a favorable cost of gain compared to sulfate/oxide alternatives.

Key Words: calves, creep feeding, trace minerals

1460 (M221) The effect of a maternal dietary yeast cell wall supplement during gestation on cow performance and calf growth and immunity.

M. C. Roberts*[1], S. E. Schmidt[2], D. A. Neuendorff[3], R. C. Vann[4], N. C. Burdick Sanchez[5], J. R. Corley[6], J. A. Carroll[7], T. H. Welsh, Jr.[8], and R. D. Randel[1], *[1]Texas A&M AgriLife Research, Overton, [2]Texas A&M University, College Station, [3]Texas A&M Agrilife Research, Overton, [4]MAFES– Brown Loam Experiment Station, Mississippi State University, Raymond, [5]USDA-ARS, Lubbock, TX, [6]Lesaffre Feed Additives, Milwaukee, WI, [7]USDA-ARS, Livestock Issues Research Unit, Lubbock, TX, [8]Texas A&M University Dep. of Animal Science, College Station.*

The objective of this study was to determine if feeding of yeast cell wall (YCW) to pregnant cows influences cow performance as well as postnatal calf growth and immunity. Multiparous cows were assigned by predicted calving date into either the control (C; n = 24) or supplemented (Y; n = 24) groups. The Y cows were fed 4 g of YCW in 230 g of ground corn top-dressed on 1.81 kg of corn gluten and soybean meal (4:1) from approximately 90 d prepartum through 28 d postpartum. Weight and body condition score (BCS) were taken at 28-d intervals prepartum and postpartum. Within 24 hof parturition, the BW and BCS of cows and BW of calves were recorded, and blood samples from calves were obtained to determine white blood cell numbers. These procedures were repeated on d 14 and 28 postpartum, and continued at 28-d intervals through weaning. Weaning weights were adjusted to 180 d of age. Cows were observed for estrus twice daily starting d 28 postpartum through first estrus. Data were analyzed using the PROC MIXED in SAS. Yeast supplementation did not affect cow prepartum BW (P = 0.39) or BCS (P = 0.14), postpartum BW (P = 0.97) or BCS (P = 0.89), or the postpartum interval (P = 0.98; C = 56.2 ± 3.3, Y = 56.3 ± 3.2 d). Calf weight was not different at birth; however, on d 14 and at weaning, C males tended to be heavier than Y group males as well as females from the C and Y groups (P = 0.08, 0.07, respectively). At d 28 C males were heavier than Y males or females (P = 0.02). There was a tendency for 180-d adjusted weaning weight to be heavier for C males than either Y males or C and Y females (P = 0.0563). There was also a treatment by day interaction in which C calves were heavier than Y calves (P = 0.01) and a calf sex by day interaction with males being heavier than females preweaning (P = 0.01). Treatment did not affect the white blood cell profile of calves on d 0 or 28 as C and Y calves had similar percentages (P > 0.2) of lymphocytes, monocytes, segmented neutrophils, banded neutrophils and eosinophils. The C males demonstrated a greater growth rate than prenatally supplemented calves in the neonatal and preweaning periods. These data suggest that prenatal YCW supplementation to healthy mature cows in a low stress environment does not benefit cow or calf performance.

Key Words: yeast cell wall, calf performance, cow performance

1461 (M222) Effect of restricted feeding on body weight, some hematological and biochemical parameters in sheep and goats raised under semiarid conditions.

E. B. Abdalla*, *Faculty of Agriculture, Ain Shams University, Cairo, Egypt.*

A total of 10 Barki sheep and 10 Baladi goats were used in 4-mo experiment to investigate to what degree local sheep and goats can tolerate feed shortage under semiarid conditions and to compare sheep and goats for their ability to withstand these harsh conditions. Animals were divided into two groups according to feeding level (50 and 100% of maintenance energy requirements). Changes in live body weight and some biweekly hematological and blood biochemical parameters were examined. Restricted feeding level did not affect (P > 0.05) live body weight. In both sheep and goats, restricted diets showed a significant (P < 0.05) decrease in hemoglobin (Hb) and packed cell volume (PCV %). Reduction was shown in erythrocytes cell counts (RBCs) especially in goats (P < 0.05). Restricted feeding showed a significant decrease in white blood cells (WBCs) in both species, but the reduction was much greater in goats than in sheep (17.15 and 7.75%). Animals fed restricted diets show a significant decrease (P < 0.05) in total protein, globulin, and triglyceride, and a nonsignificant increase in albumin, albumin/globulin ratio, and total lipids in both species. While glucose and cholesterol increased in sheep, both parameters decreased in goats. Alanine transferase (ALT), aspartate transferase (AST), and γ glutamyl transferase (GGT) were increased in both species that received restricted diet. The increase in the three enzymes was significant only in sheep, and the GGT was only significant in goats. While alkaline phosphatase was significantly decreased in sheep, it was significantly increased in goats. Restricted feeding resulted in a significant increase in blood urea and a significant decrease in creatinine concentration in both species. In conclusion, results revealed that both sheep and goats are adapted to feed shortage with higher tolerance in sheep than in goats under semiarid conditions.

Key Words: sheep, goats, restricted feeding

1462 (M223) Effects of trace mineral-fortified, limit-fed creep supplements on performance of beef calves (post-weaning).

A. Saran Neto[1], L. S. Caramalac[2], P. G. M. D. A. Martins[2], P. Moriel[2], H. J. Fernandes[3], and J. D. Arthington*[2], *[1]University of São Paulo, Pirassununga, Brazil, [2]UF/IFAS Range Cattle Research and Education Center, Ona, FL, [3]State University of Mato Grosso do Sul, Aquidauana, Brazil.*

The effects of limit-fed creep supplements, with or without trace mineral (TM) fortification, on measures of performance

and stress in heifers following weaning were evaluated. Heifers were derived from an experiment involving 30 cow/calf pairs, stratified by birth date and randomly allocated to 1 of 15 pastures (2/pasture). Calves were approximately 5 mo of age at the start of the study. Four treatments were randomly assigned to pastures, including, (1) limit-fed creep fortified with hydroxy-Cu, Zn, and Mn, (2) limit-fed creep fortified with Cu- and Zn-sulfate and Mn-oxide, (3) limit-fed creep without TM fortification, and (4) no limit-fed creep (n = 3, 3, 4, and 5 pastures, respectively). Creep supplements for treatments 1 and 2 were also fortified with Co carbonate, Na selenite, and I (via EDDI). All cattle were provided access to salt with no TM fortification. Supplements were offered Monday, Wednesday, and Friday (265 g/calf) for 89 d prior to weaning, targeting a maximum intake of 114 g/d. At weaning, heifers consuming TM-fortified creep, irrespective of source, had greater ($P \leq 0.02$) liver Cu concentrations compared to heifers consuming no limit-creep or limit-creep without TM fortification. Following weaning, 15 heifers were individually provided free-choice access to a soybean hull-based feed and ground grass hay for 16 d. The acute phase protein response (APR) was assessed via plasma concentrations of the Cu-dependent protein, ceruloplasmin, on d 0, 2, 5, 9, and 16. Shrunk BW was measured on d 0 and d 17. Total DMI of calves provided TM-fortified, limit-creep supplements, irrespective of TM source, was less ($P = 0.03$) than calves not provided limit-creep or calves provided limit-creep without TM fortification (1.21 vs. 1.80% BW; SEM = 0.262). This response was mostly the result of less ($P = 0.056$) grain DMI among heifers provided TM-fortified, limit-creep vs. no limit-creep or limit-creep without TM-fortification (0.45 vs. 0.86% BW, respectively; SEM = 0.320). Heifers provided TM-fortified limit-creep had a greater ($P = 0.05$) increase in post-weaning plasma ceruloplasmin (8.02 and 5.04 mg/dL, respectively; SEM; 2.354) and less ($P = 0.03$) BW gain (7.9 vs. 17.6 kg; SEM = 9.26) compared to calves provided no limit-creep or limit-creep without TM-fortification. These results imply that TM-fortified limit-fed creep feed results in increased Cu status of weaned calves which corresponded to a heightened Cu-dependent APR and less post-weaning DMI and BW gain.

Key Words: calves, creep feeding, trace minerals

1463 (M224) Young beef calves preferentially consume supplements fortified with hydroxy vs. organic and sulfate sources of Cu, Zn, and Mn.

L. S. Caramalac*[1], H. J. Fernandes[2], and J. D. Arthington[1], [1]*UF/IFAS Range Cattle Research and Education Center, Ona, FL,* [2]*State University of Mato Grosso do Sul, Aquidauana, Brazil.*

Our objective was to evaluate the preferential intake of supplements fortified with Cu, Zn, and Mn from; (1) hydroxy, (2) organic, and (3) sulfate-sources. This was achieved in 4 individual feeding studies involving 8 pens of early-weaned calves (2 calves/pen; average age = 120 d; average BW = 115 kg). Each pen was provided free-choice access to a mixed concentrate ration and ground grass hay. On each study day at 10:00, all feed was withdrawn and calves were offered 3 different mineral fortified supplements, for a 4 h period, provided in three separate feeding containers. Supplements were created using a base mixture containing 52, 46, and 2% cottonseed meal, ground corn, and salt. Supplements were fortified with 2,000 mg/kg Zn (Exp. 1), 750 mg/kg Cu (Exp. 2), 3,000 mg/kg Mn (Exp. 3), and all 3 elements (Exp. 4). Preferential intake was measured over 7- (Exp. 1, 2, and 3) and 14-d (Exp. 4) evaluation periods. In Exp. 1 and 2, calves consumed more ($P < 0.001$) of the supplement offer containing hydroxy Cu (Exp. 1) and hydroxy Zn (Exp. 2) then sulfate and organic sources, while consumption of sulfate sources was greater ($P \leq 0.04$) than organic sources (81.9, 72.2, and 45.5%, and 48.1, 35.1, and 9.5% consumption of supplement offer for hydroxy, sulfate, and organic sources of Cu and Zn, respectively; SEM = 3.94 and 7.93). In Exp. 3, calves consumed more ($P < 0.001$) of the supplement offer containing hydroxy Mn than sulfate and organic sources, while there were no differences ($P = 0.97$) in preferential intake of supplements containing Mn sulfate or organic Mn. In Exp. 4, when all 3 elements were combined within a single supplement, calves almost exclusively selected ($P < 0.001$) the supplements containing hydroxy-source elements vs. supplements containing sulfate or organic sources (70.0, 12.5, and 8.0% consumption of supplement offer for hydroxy, sulfate, and organic sources, respectively; SEM = 3.16. When offered to young calves, these results reveal a lesser preferential intake of trace mineral concentrated supplements fortified with organic and sulfate sources of Cu, Zn, and Mn compared to the same supplements fortified with hydroxy sources of these elements.

Key Words: trace minerals, supplementation, calves

1464 (M225) Predicting dry matter intake of steers and heifers in the feedlot by using categorical and continuous variables.

O. Koskan*[1], H. Koknaroglu[1], D. D. Loy[2], and M. P. Hoffman[2], [1]*Suleyman Demirel University, Isparta, Turkey,* [2]*Iowa State University, Ames.*

Close-out information, submitted by Iowa cattle producers to the Iowa State University Feedlot Performance and Cost Monitoring Program, was used to develop dry matter intake prediction model for steers and heifers by considering categorical and continuous variables. Close-out information consisting of 1651 pens of steers and 601 pens of heifers included information on start and end dates, cattle per pen, sex, housing type, days on feed, initial and sale weight, feed conversion (FC), proportion of concentrate, average daily gain (ADG), percent death loss, feed cost and total cost per 45.35 kg gain, breakeven sale price, non-feed variable cost, non-feed fixed cost and corn price. Dry matter intake (DMI) was not provided but

was calculated as DMI = ADG x FC. In predicting DMI, categorical regression analysis (optimal scaling) was applied for steers and heifers separately. Independent variables used were starting date on feed (season) (1 = winter: December through February; 2 = spring: March through May; 3 = summer: June through August, and 4 = fall: September through November), number of cattle per pen (head), housing type (housing) (1 = confinement, 2 = partially open lot, 3 = open lot), days on feed (dof), initial weight (iw), proportion of concentrate (concentrate). When the model was applied separately for steers and heifers, DMI prediction for steers was found as DMI = 0.540*iw + 0.017*season +0.143*housing -0.062*head– 0.096*concentrate– 0.186*dof (R^2 = 0.433), whereas DMI prediction for heifers was found as DMI = 0.706*iw + 0.086*season + 0.085*housing + 0.186*dof -0.099*head– 0.084*concentrate (R^2 = 0.468). With this model, categorical variables such as housing type and season are included in the regression model and this may help professionals predict the DMI of their steers and heifers in the feedlot.

Key Words: dry matter intake prediction, categorical regression, feedlot

---

1465 (M226) Comparison of high-performance dairy cows fed concentrates vs. those fed no concentrates over a period of 10 yr. P. L. Kunz*[1], M. Buergisser[1], and M. Furger[2], *[1]Bern University of Applied Sciences, Zollikofen, Switzerland, [2]Agricultural Education and Advisory Centre Plantahof, Landquart, Switzerland.*

Milk prices in Switzerland have been falling for years. As a result, farmers seek to reduce production costs by feeding lower amounts of the most expensive feed component, i.e., concentrates, or cease feeding concentrates altogether. To clarify how high-performance dairy cows respond to a lack of concentrates in their rations, the high-performance herd (75 Brown Swiss cows) at the experimental farm of the Plantahof Agricultural Centre was divided into two groups: one herd (forage herd = FH, 37 cows) has not received concentrates since 2003, while the other herd (concentrate herd = CH, 38 cows) received the same roughage feed components as the FH and an additional 1500 kg concentrates per cow and lactation. The ration was composed of hay, dried grass and maize silage in winter, and hay, grass and maize silage in summer. Both herds were of equal genetic value, as the same bulls were used to sire progeny. Cows which left the herds were replaced by daughters originate from the same herd. Because not all results have been analysed up to now, the results shown are based on different times. The two feeding regimes resulted in differences between the two trial herds: Over the past 6 yr, feed intake in CH cows was higher (25.6 ± 3.3 kg DM/day) than in FH cows (21.5 ± 2.3 kg DM/day). Similarly, over the past 9 yr, milk yields of CH cows (10,323 ± 731 kg/Lactation) exceeded that of FH cows (8279 ± 341 kg/Lactation). There was no difference in milk fat and milk protein content. The CH cows suffered higher incidences of milk fever, acetonemia and ovarian cysts over a 4-yr period than the FH cows. None of these results were statistically significant. A total of 48 of the CH cows and only 27 of the FH cows had to be sent to slaughter due to infertility or illness over a 4-yr period. The economic analysis shows that in the Swiss cost environment the forage herd (FH) yielded a higher agricultural income than the concentrate herd (CH). This was primarily due to the higher feed costs for and inferior health of the CH.

Key Words: dairy cows, concentrates, costs of production

1466 (M227) Effect of *Leukonostoc citreum* SK2556 fermented korean aged garlic extract (KAGE) on feed intake, production performance, egg quality, odor gas emission from feces, excreta microbiota and hematological profiles in laying hens. D. Jung*, J. H. Cho, and I. H. Kim*, Dep. of Animal Science, Dankook University, Cheonan, South Korea.*

The goal of this study was to investigate the impacts of dietary supplementation with Dorean aged garlic extract (KAGE) fermented by *Leukonostoc citreum* SK2556 on feed intake, production performance, egg quality, odor gas emission from feces, excreta microbiota and hematological profiles in laying hen. A total of 384, 54-wk (ISA- brown) laying hens were randomly assigned to 1 of 4 treatments with 8 replications per treatment and 12 adjacent cages as a replication (hens were caged individually). The experimental treatments were: 1) CON (Basal diet), 2) KAGE1 (CON + 0.05% Fermented Aged Garlic Feed Additive), 3) KAGE2 (CON + 0.1% Fermented Aged Garlic Feed Additive), and 4) KAGE3 (CON + 0.2% Fermented Aged Garlic Feed Additive). KAGE compounds were analysed by HPLC methods, IgG in the serum were then analysed using an automatic biochemistry blood analyser (HITACHI747, Tokyo, Japan), WBC, RBC and lymphocyte concentrations using an automatic blood analyser (ADVIA120, Bayer, Tarrytown, NY, USA) and fecal *Lactobacillus* and *E. coli* shedding were measured by using MacConkey agar plates and *lactobacilli* medium III agar plates. At 3 wk, laying hen fed with KAGE showed higher yolk height than CON (9.38, 9.47, 9.48 vs. 9.17 mm; $P < 0.05$). In the next week, KAGE3 proved better yolk height along with egg shell thickness compared to CON (9.47mm, 41.75mm^{-2} vs. 9.18mm, 40.26 mm^{-2}; $P < 0.05$). Likewise, 0.1 and 0.2% KAGE had meaningful higher value (96.23, 96.08 vs. 93.99; $P < 0.05$) on haugh unit than CON diets. In the last week of experiment, results showed that KAGE2 and KAGE3 treatment improved yolk height and egg shell thickness compared with basal diet (9.52, 9.52 vs. 9.25 mm; 41.89, 41.93 vs. 40.26 mm^{-2}; $P < 0.05$). Haugh unit was influenced by the 0.2% KAGE over CON (96.42 vs. 94.49; $P < 0.05$). However, laying hen feed with KAGE showed no significant result on feed intake, production performance, excreta gas production and microbiota

and blood composes in any level of experiment. In a nut shell, our findings demonstrated that the administration of KAGE at a level of 0.1% and/or 0.2% can improve yolk height, haugh unit and egg shell thickness in laying hen.

Key Words: aged garlic extract, laying hens, *Leukonostoc citreum* SK2556, haugh unit, gas emission

1467 (M228) Effects of probiotics supplementation on growth performance, nutrient digestibiliry, carcass characteristics, meat quality, intestinal microflora and fecal noxious gas emission in broilers. I. H. Kim*, Y. Lei, and S. Kim, *Dep. of Animal Science, Dankook University, Cheonan, South Korea.*

A total of 765 broilers (BW 36.77 ± 0.33 g; 1 d old) were used in a 35-d feeding trial to evaluate the effect of fermented plants on performance, carcass traits, blood profiles, nutrient digestibility, intestine microbial population and fecal noxious gas emission of broiler chicks. Broilers were randomly distributed into 1 of 5 treatments on the basis of BW (9 replicate pens per treatment with 17 broilers per pen). Dietary treatments were: 1) NC (basal diet); 2) PC (NC + 5ppm enramycin); 3) P1 (NC with 0.5% of CP reduced + 150ppm phytogenics; 4) P2 (NC + 0.1% probiotics); 5) P3 (NC + 0.2% probiotics). All nutrients in diets were formulated to meet or exceed the recommendation of NRC (1994) for broilers. The broilers were weighed and feed intake were recorded on d 1, 14, 28, and 35 for calculating BW gain (BWG), feed intake (FI), and feed conversion ratio (FCR). At d 35, fresh excreta samples were collected from each pen for the measurement of nutrient digestibility according to the procedures of AOAC (2003). All data were subjected to GLM procedures of SAS (1996) as a randomized complete block design, with pen as the experimental unit. Differences among treatments were separated by Duncan's multiple range test; $P < 0.05$ was considered statistically significant. Overall, broilers fed P3 diet had greater (1770 vs. 1681 g; $P < 0.05$) body weight gain (BWG), and lower (1.555 vs. 1.625; $P < 0.05$) feed conversion ratio (FCR) than those fed NC diet. The nutrient digestibility of dry matter (DM) and nitrogen (N) was increased (76.30 vs. 73.26%; 65.32 vs. 62.71%; $P < 0.05$) in P3 compared with NC. There was no difference ($P > 0.05$) in meat quality, relative organ weight and blood profiles. Addition of 0.2% probiotic enhanced the growth of *Lactobacillus*, but inhibited *Escherichia coli* in the small intestinal and large intestinal. Also, addition of 0.1% probiotic showed same result with P3 on the large intestinal microflora but no change in the number of *Lactobacillus* and *Escherichia coli* in small intestine. A significant increase in the rate of ammonia was observed in 1.0 g/kg and 2.0 g/kg probiotic-treated birds versus controls.

Key Words: broilers, growth performance, gas emission, nutrient digestibility, probiotic

1468 (M229) Effects of a synbiotic feed additive on milk quality and calving interval in Brazilian dairy herds. R. D. Sainz*[1], E. A. Filgueiras[2,3,4], C. U. Magnabosco[5], P. H. Medes[3], and K. S. Mendanha[2], *[1]University of California- Davis, Davis, CA, [2]Universidade Federal de Goiás, Goiânia-GO, Brazil, [3]Biofórmula Ltda, Goiânia-GO, Brazil, [4]CAPES, Brasília-DF, Brazil, [5]Embrapa Cerrados, Brasília, Brazil.*

Data on milk quality and reproduction were collected from 22 dairy herds in the Brazilian states of Paraná, Rio Grande do Sul, Minas Gerais and Goiás. These herds were selected because each one had used the synbiotic Biofórmula Leite (Biofórmula, Goiânia-GO, Brazil) at the minimum dose of 2 g·animal^{-1}·d^{-1}for a minimum of 1 yr and had records of milk yield and quality and herd reproduction for at least 1 yr before and 1 yr after the start of treatment. The synbiotic contained a mixture or probiotic microorganisms, prebiotics and fibrolytic enzymes. After data tabulation and verification, seven herds (total 189 cows) had sufficient information to study treatment effects on milk quality and three (total 115 cows) had enough for reproductive performance, all primarily Holsteins. The data for the 12 mo preceding treatment were considered as the control, and those for 12 mo following initiation of treatment as treated. Somatic cell count (SCC) data were log-transformed before analysis. These data were subjected to a meta-analysis using a mixed model considering herd as a random variable and treatment as a fixed effect nested within herd. There were no significant differences between treatments in milk yields and the concentrations of fat, protein and total milk solids in milk, but there were reductions in SCC (−41%, 654,963 vs. 386,473 SC/mL, $P < 0.001$) and in calving interval (−73 d, 446.3 vs. 373.4 d, $P < 0.01$) following initiation of treatment with the synbiotic. The synbiotic feed additive used in this study proved to be an effective tool in the reduction of somatic cells in milk as well as in improving the fertility of cows in commercial dairy herds, confirming results obtained under research conditions.

Key Words: dairy, somatic cells, reproduction

1469 (M230) Effects of injectable trace minerals at the start of the breeding season on attainment of pregnancy in commercial beef cows. J. D. Arthington[1], P. G. M. D. A. Martins[1], P. Moriel*[1], and L. Havenga[2], *[1]UF/IFAS Range Cattle Research and Education Center, Ona, FL, [2]MultiMin USA, Ft. Collins, CO.*

Our objective was to evaluate the effects of a single application of injectable trace minerals (ITM; MultiMin 90, MultiMin USA, Inc., Fort Collins, CO) on pregnancy attainment of lactating beef cows. Mature Brahman x British crossbred beef cows (n = 3750) were enrolled from 14 separate commercial cow/calf operations in central and southern Florida. Ranch breeding season ranged from 90 to 120 d with study

enrollment < 30 d after the start of the breeding season. During enrollment, cows were administered 5 mL of ITM or sterile saline subcutaneously in alternating order. The ITM contained 60, 10, 15, and 5 mg/mL of Zn, Mn, Cu, and Se, respectively. At the time of treatment administration, cow body condition score (BCS) was recorded and assigned a BCS category group (1 = low; 2 = moderate; 3 = high). In addition, samples of pasture forage and trace mineral supplement were collected. To estimate ranch trace mineral status, liver biopsy samples were collected from 10% (maximum of 16) of the enrolled cows. Treatment assignment was identified by an individual number and color coded ear tag. Tags were removed during pregnancy diagnosis. Overall tag loss was low and equally distributed between treatments (96.3 and 95.5% tag recovery for ITM and Saline, respectively) resulting in a total of 3597 collected tags for pregnancy analysis. Average Se and Cu were highly variable among ranches (Se, range = 0.39 to 4.36 and average = 1.14 ± 1.04 mg/kg DM; Cu, range = 65 to 307 and average = 158 ± 78 mg/kg DM). There were 5 and 3 ranches classified as Se and Cu deficient (liver concentrations < 0.60 and 100 mg/kg DM, respectively). There was no ranch x treatment interaction ($P = 0.50$) or overall treatment effect ($P = 0.19$) for pregnancy attainment (88.8 and 87.2% pregnant for ITM and Saline, respectively; SEM = 0.88). Attainment of pregnancy increased ($P < 0.001$) with increasing BCS category (83.9, 86.7, and 91.0 for low, medium and high BCS categories, respectively). Interestingly, although not statistically significant ($P = 0.62$), the numeric difference between the percentage pregnancy attainment due to ITM increased as cow BCS decreased (3.1, 1.8, and 0.1% for low, medium, and high BCS categories, respectively). Provided at the start of the breeding season, ITM injection did not significantly improve pregnancy outcome in the commercial cow/calf ranches enrolled in this study.

Key Words: injectable trace minerals, cow, pregnancy

1470 [Withdrawn]

1471 (M232) Cost analysis of feeding bermudagrass (*Cynodon dactylon*) or ryegrass (*Lolium multiflorum*) plus rye (*Secale cereale*) baleage based on nutrient composition and forage refusal of weaned crossbred beef calves. R. M. Martin*[1], R. J. Pruitt[2], B. Buttrey[3], and R. Walker[3], *[1]louisiana State University AgCenter, School of Animal Sciences, Baton Rouge, [2]Louisiana State University AgCenter, Agricultural Economics and Agribusiness, Baton Rouge, [3]Louisiana State University AgCenter, Hill Farm Research Station, Homer.*

In the Gulf Coast region, supplementation can be costly for weaned beef calves during the fall backgrounding period due to limited forage production and quality. A study was conducted evaluating performance of weaned Angus crossbred calves fed bermudagrass (*Cynodon dactylon*) or ryegrass (*Lolium multiflorum*) and rye (*Secale cereale*) baleage in hay rings during a 60-d fall backgrounding period. Four forage treatment comparisons included: early boot stage bermudagrass harvested for hay (BERH), early boot stage bermudagrass harvested for baleage (BERB), early boot stage ryegrass and rye harvested for baleage (ERRG), and bloom stage ryegrass and rye harvested for baleage (LRRG). Both BERH and BERB were harvested from the same hay field at the same time. Nutrient composition of forage treatments included 8.2% CP, 59.9% TDN, and 88.8% DM (BERH); 9.2% CP, 57.4% TDN, and 49.1% DM (BERB); 12.8% CP, 64.5% TDN, and 37.2% DM (ERRG); and 9.2% CP, 62.7% TDN, and 55.7% DM (LRRG). Forage refusal on a DM basis was estimated as amount of (kg) and percent of bale weight fed based on forage remaining outside of the hay ring. Cost estimates for each treatment were performed based on nutrient composition and forage refusal and were derived using standard performance assumptions associated with the tractor and implements used during harvesting of the forage and adjusted for the time needed to harvest forages for this study. Total costs of production were $293.92/ton DM (ERRG), $209.18/ton DM (LRRG), $128.33/ton DM (BERB), and $117.87/ton DM (BERH). On a cost per nutrient basis, ERRG had the greatest cost/lb of CP and TDN ($1.15 and $0.23) followed by LRRG ($1.14 and $0.17), BERB ($0.70 and $0.11), and BERH ($0.72 and $0.10), respectively. Forage refusal was greater ($P = 0.01$) for the BERH (115 kg and 10.0%) compared with BERB (27 kg and 3.4%), ERRG (26 kg and 5.0%), and LRRG (29kg and 3.7%) treatments, but similar among BERB, ERRG, and LRRG, respectively. Value associated with hay refusal measured outside the hay ring was $14.73/ton DM (ERRG), $7.66/ton DM (LRRG), $4.39/ton DM (BERB), and $11.74/ton DM (BERH). Production costs were lower for bermudagrass harvested as dry hay or baleage. While hay refusal was less outside the hay ring for all baleage treatments, the high value of hay refusal and production cost of the ERRB treatment was greatly associated with the high moisture content of the bales.

Key Words: baleage, economics, weaned beef calves

1472 (M233) Evaluation of three copper sources on measures of forage utilization and copper status in beef cattle. P. G. M. D. A. Martins[1], O. F. R. Cunha[1], G. P. Caputti[1], A. Saran Neto[2], J. M. B. Vendramini*[1], and J. D. Arthington[1], *[1]UF/IFAS Range Cattle Research and Education Center, Ona, FL, [2]University of São Paulo, Pirassununga, Brazil.*

We investigated the effect of Cu source on measures of subtropical forage utilization and Cu status in beef cattle. In Exp. 1, 24, 2-year old heifers (371 ± 48.1 kg) were individually fed limpograss hay and 2.1 kg/d of a molasses-based supplement (8.3 and 3.0 mg Cu/kg DM, respectively). Treatments were assigned to heifers consisting of, (1) no Cu, and 100 mg Cu/d

from (2) hydroxy Cu, (3) organic Cu, or (4) Cu sulfate. Forage DMI and liver Cu change was assessed over 33 d. In Exp. 2, forage DMI and DM, N, and NDF in situ ruminal disappearance was evaluated in 4 ruminally-fistulated steers using a 4 x 4 Latin square design with 4, 20-d periods with the same treatments as Exp. 1. Periods consisted of 10 d of no Cu, 7 d adaptation, and 5 d in situ bag incubation. Dried and ground bermudagrass (4 g) was placed into polyester bags and duplicate samples were incubated for 0, 3, 6, 9, 12, 24, 48, and 72 h. The non-linear model used was P=A+B [1-exp(-c x t)]. In Exp. 1, supplemental Cu had no effect ($P = 0.40$) on voluntary forage DMI; however, heifers provided hydroxy Cu tended ($P = 0.07$) to consume less hay than heifers consuming organic Cu (1.31 vs. 1.46% BW). All heifers experienced a decrease ($P < 0.001$) in liver Cu; however, heifers consuming no Cu tended ($P = 0.12$) to have a greater decrease vs. all other treatments, and heifers provided hydroxy Cu tended ($P = 0.14$) to have a lesser decrease than heifers consuming organic Cu (-94, -80, -64, and -44 mg/kg DM for no Cu, organic Cu, Cu sulfate, and hydroxy Cu, respectively). In Exp. 2, the DM, N, and NDF fractions were described as A, rapidly degradable; B, potentially degradable; and C, undegradable. There was no effect ($P \geq 0.15$) of treatment on forage DMI and in situ DM disappearance. Fraction A NDF and N did not differ among treatments; however, NDF fraction B tended ($P < 0.06$) to be greater for steers provided organic Cu vs. all other treatments (48.7 vs. 41.2%). Similarly, N fraction B was greater ($P = 0.03$) for steers receiving organic Cu vs. hydroxy Cu and No Cu (29.2 vs. 19.0%). These results imply that the organic Cu source utilized in these studies may positively influence the digestibility of subtropical forages.

Key Words: copper, digestibility, cattle

1473 (M234) Comparison of camelina meal and DDGS in the diet of replacement beef heifers. E. E. Grings, A. Sackey*, and G. A. Perry, *South Dakota State University, Brookings.*

The objective of this study was to evaluate the effect of supplementing beef heifers with either cold-pressed camelina meal or dried distillers grains with solubles (DDGS) for 75-d before breeding on weight gain and pregnancy rates. Heifers ($n = 110$) were blocked by weight (BW = 300 ± 1.1 kg) into five pens per treatment and assigned to one of two dietary treatments. Heifers fed camelina meal consumed an average of 5.3 kg/d millet hay, 0.7 kg/d camelina meal and 1.3 kg/d corn, whereas heifers fed DDGS consumed an average of 5.3 kg/d millet hay, 1.1 kg/d DDGS and 0.9 kg/d corn. Average nutrient composition of diets was 9.3% CP, 52.6% NDF and 29.5% ADF for the camelina diet and 9.6% CP, 54.7% NDF and 29.3% ADF for the DDGS diet. Supplements were placed in bunks each morning and millet hay fed after supplements had been consumed. Heifers were bred following a 5-d CO-synch + CIDR fixed time AI protocol and transported to pasture the next day. Fourteen d later, three clean-up bulls were placed in the pasture for 46 d. Pregnancy was determined by transrectal ultrasonography 96 d after AI. Weight and pregnancy data were analyzed using the GLM and GLIMMIX procedures of SAS, respectively. ADG (0.45 ± 0.08 kg/d; $P = 0.2$) and final BW (339 ± 1.26 kg; $P = 0.97$) did not differ between treatments during the 75-d treatment period. Similarly, no difference ($P = 0.35$) was detected for BCS (5.2 ± 0.04) at breeding between treatments. We noted no differences between treatments in conception to timed AI ($P = 0.57$) or in total pregnancy rate ($P = 0.35$). Our data suggests that camelina meal has the potential to serve as a feed resource for replacement heifers with no adverse effect on weight gain or pregnancy rates.

Key Words: beef heifers, protein supplement, reproduction

1474 (M235) Effects of prepartum evaporative cooling and vitamin E supplementation on immune function of Holstein cows during summer in Florida. G. C. Gomes*[1], J. E. Zuniga[1], E. Karakaya[1], L. F. Greco[1], L. D. P. Sinedino[1], N. Martinez[1], R. S. Bisinotto[1], E. S. Ribeiro[1], P. M. Leopoldo Junior[1], M. A. Engstrom[2], J. P. Driver[1], J. E. P. Santos[1], and C. R. Staples[1], *[1]Dep. of Animal Sciences, University of Florida, Gainesville, [2]DSM, Eden Prairie, MN.*

Objective was to evaluate the relationship of vitamin E (VitE) supplementation and prepartum environment on immunity of Holstein cows. Animals ($n = 70$) were blocked at 30 d prepartum by parity, milk yield, and body weight, and randomly assigned to treatments arranged in a 2 × 2 factorial. Cows were housed until parturition in either a free-stall barn equipped with fans and sprinklers (Cooling- C) or in an open lot providing only shade (No cooling- NC). After parturition, all cows were housed in a free-stall barn equipped with fans and sprinklers. All-rac-α-tocopherol (DSM, Parsippany, NJ) was top dressed daily at 1000 IU prepartum and 500 IU postpartum per cow for moderate VitE (M) or 3000 IU prepartum and 2000 IU postpartum per cow for high VitE (H). Blood samples were collected in the prepartum at d -30, and -14 relative to parturition. After calving, blood samples were obtained at d 3, 7, 14, 21, 28, 35, and 42. Analyses included phagocytosis and oxidative burst by neutrophils, percentage of lymphocytes positive for IL-10 and IFN-γ production after PMA/ionomycin stimulation, percentage of total, CD4(+), CD8(+), and γδ subtypes of T lymphocytes, concentrations of serum IgG against ovalbumin challenge at d -30, -14, and 3, and acute phase proteins. Data were analyzed by ANOVA for repeated measures with PROC GLIMMIX of SAS. Non -normally distributed data was appropriately transformed. Results from cytokines and neutrophil function analyses are presented as fold increase in percentage of positive cells or mean fluorescence intensity (MFI) relative to unstimulated

controls. Feeding more VitE increased ($P < 0.05$) the percentage of lymphocytes producing IFN-γ (10.0 vs. 5.4). Prepartum cooling tended ($P < 0.10$) to increase the percentage of T lymphocytes (31.0 vs. 23.4%) relative to total lymphocytes, CD4(+) subtype (12.4 vs. 7.4%), and IgG against ovalbumin (0.552 vs. 0.480 O.D.). Providing H vitE to NC cows tended to increase phagocytic activity (MFI) by neutrophils (4.83 vs. 4.25) whereas the reverse occurred when cows were cooled prepartum (4.52 vs. 5.20). Oxidative burst activity (MFI) of neutrophils from multiparous cows was enhanced when cows were cooled (8.72 vs. 6.59) whereas the opposite occurred for primiparous cows (4.84 vs. 5.84). VitE supplementation and prepartum cooling caused changes in adaptive immunity patterns. Additionally, prepartum cooling provided a conditional improvement of innate immunity depending on amount of vitE supplemented and parity, which might reflect differences in metabolic and oxidative stress status.

Key Words: cow, heat stress, vitamin E

1475 (M236) Forages used in high producing cow rations in CA. Y. Trillo[*1], A. Lago[2], and N. Silva-del-Rio[1], *[1]VMTRC, University of California, Tulare, [2]DairyExperts, Tulare, CA*

The objective of this study was to describe the forages included in the high cow ration of 16 California dairies ranging in size from 1000 to 6000 lactating cows. Records from a consecutive 12-mo period, starting from January to June 2012, were extracted from the feeding management software FeedWatch 7.0 (FW). Records from 16 high cow (HC) recipe and 13 high cow premix (HCP) recipe were used. Two dairies did not prepare premix and one dairy had sporadic premix records and records were not included in the final data set. Descriptive statistics were conducted with SAS 9.3. Across dairies, three to seven forage types were available to fed high producing cows. Most forages were directly included into the HC recipe. But some dairies included straw in the HCP recipe ($n = 5$). The median number of forages included daily in the HC recipe was two ($n = 7$), three ($n = 4$), four ($n = 4$), or five ($n = 1$). Throughout the 12-mo study period, the number of forages in the HC recipe varied within dairy in zero ($n = 1$), one ($n = 10$) or two ($n = 5$) forages. All dairies fed alfalfa hay, either for a twelve ($n = 14$) or seven ($n = 2$) month period. When alfalfa hay was not fed ($n = 2$), cows were fed green chop alfalfa. All dairies included corn silage in the HC recipe, but in some dairies it was only fed for 11 ($n = 3$), 9 ($n = 2$), 8 ($n = 1$), or 5 ($n = 1$) mo. BMR corn silage was fed ($n = 3$) in combination with conventional corn silage for 3 to 9 mo. High moisture earlage ($n = 5$) was fed for 2 to 6 mo in combination ($n = 4$) or not ($n = 1$) with corn silage. Other silages, such as wheat ($n = 5$), alfalfa ($n = 3$) or both ($n = 4$) were also included for 3 to 12 mo or 1 to 10 mo, respectively. Other crops were fed occasionally [sorghum silage ($n = 2$) and oat silage ($n = 1$)]. Some dairies fed straw for 6 to 12 mo ($n = 6$) while others for less than 2 mo ($n = 3$). Only 10 dairies had records of DM adjustments on FW. For corn silage, DM adjustments were made zero ($n = 4$), six ($n = 2$), eight ($n = 1$), nine ($n = 2$) or ten ($n = 1$) times in a year. Although corn silage and alfalfa hay are the most common forages used in California dairies, wheat silage, alfalfa silage and straw are other common roughage sources for high producing cows.

Key Words: dairy cow, forages, feeding management software

1476 (M237) Evaluating on-farm methods for measuring dry matter content of potatoes. R. J. Norell[*1], J. B. Glaze, Jr.[2], M. Chahine[2], and N. L. Olsen[3], *[1]University of Idaho, Idaho Falls, [2]University of Idaho, Twin Falls, [3]University of Idaho, Kimberly.*

Measuring dry matter content is critical for pricing cull potatoes and for effectively managing potato feeding rates on livestock operations. In this study, dry matter determinations from three on-farm methods (microwave, dehydrator, and Koster Moisture tester) were compared with a laboratory oven. Twenty lots of potatoes were obtained for the study (1 blue, 3 red, 3 yellow, and 14 burbank varieties). Ten potatoes from each lot were cleaned then sliced horizontally into 7mm thick slices. Duplicate 100-g subsamples were run with each drying method. Lab (L) samples were dried for 24 h at 55 C. Equipment for the on-farm methods included two 1000-W microwaves (M), four 500-W Nesco FD60 food dehydrators (D) set at 68 C, and two Koster Moisture Testers (K). Samples were weighed at specified time intervals during the drying process with the on-farm methods and a run was deemed complete when two identical weights were obtained. Drying time and dry matter (DM) data were analyzed as a completely randomized block design. Drying time differed significantly between on-farm methods ($P < 0.001$) and averaged 8.6, 248.5, and 428.6 min for M, K, and D, respectively. Mean DM was significantly higher ($P < 0.05$) for M (23.4%) and D (23.5%) than K (22.6%) or L (22.7%). A Bland-Altman assessment for agreement was used to compare difference in DM between each on-farm method and L. A range of agreement was defined as mean bias + or– 2 SD. The 95% limits of agreement between the lab oven and M, K, and D were: -0.7% to 1.5%; -1.6% to 1.4%; -1.0% to 1.6%, respectively. Overall, the three on-farm methods provided closely corresponding DM to L. The trend lines between Bland-Altman differences and oven DM were not statistically significant ($P > 0.75$) for D and K but was significant ($P < 0.05$) for M with a negative slope across the range of DM in the study. Drying potatoes with all three on-farm methods did not create objectionable odors and can therefore be conducted indoors if desired. This study indicates that the three on-farm methods are effective tools for measuring DM content of potatoes.

Key Words: potatoes, dry matter, on-farm testing

1477 (M238) Optimizing drying time of potatoes by food dehydrator and Koster Moisture Tester.

R. J. Norell*[1], J. B. Glaze Jr.[2], M. Chahine[2], and N. L. Olsen[3], *[1]University of Idaho, Idaho Falls, [2]University of Idaho, Twin Falls, [3]University of Idaho, Kimberly.*

Cull potatoes lose moisture over time when stacked outdoors in a pile. Measuring dry matter content on a frequent basis is therefore important for effectively managing potato feeding rates for cattle. In this study, different sample processing methods were compared for drying potatoes. In trial 1, drying time (DT) and dry matter content (DM) were evaluated for four potato sample sizes in food dehydrators and a lab oven 7-mm-thick horizontal slices (THICK), 3.5-mm-thick horizontal slices (THIN), 7-mm-square fries (LFF), and 3.5-mm-square fries (SFF). The dehydrators were 500-W, Nesco brand FD-60 with four trays, and each tray had a plastic insert to prevent sample movement between trays. Operating temperature was set at 68°C for the dehydrator and the lab oven was set at 55°C. Four lots of potatoes were used with a single lot analyzed each test day. Forty potatoes per lot were cleaned, and 10 were randomly selected for each processing method. A 100-g subsample from each processing method was then randomly assigned to an individual tray within dehydrator. Drying time was significantly different between potato processing methods ($P < 0.001$) with THICK requiring the longest time (459 min), LFF (264 min), SFF (225 min) and THIN (205 min). DM differed between processing methods with THICK slices having higher DM ($P < 0.053$) than the other three processing methods. DM was 0.8% lower ($P < 0.05$) in the lab oven than in dehydrator. In trial 2, DT and DM were evaluated for potatoes processed into THICK and LFF with two Koster Moisture Testers, lab oven, and eight potato lots. Twenty potatoes were cleaned from each lot, with 10 randomly assigned to each processing method. Three 100-g subsamples from each processed lot were randomly assigned to a Koster tester or lab oven. LFF reduced DT ($P < 0.001$) by 101 min compared to THICK. DM did not differ between the two processing methods ($P < 0.13$) nor between lab oven and Koster ($P < 0.16$). This study indicates that drying time is optimized by reducing potato particle size for both the food dehydrator and Koster Moisture Tester without reducing accuracy in estimating potato dry matter.

Key Words: potatoes, drying methods, sample processing

1478 [Withdrawn]

1479 (M240) Validating a refractometer to evaluate Immunoglobulin G concentration in Jersey colostrum and the impact of multiple freeze–thaw cycles on evaluating colostrum quality.

K. M. Morrill*[1], K. Hard[2], M. M. Spring[2], A. L. Robinson[2], and H. D. Tyler[2], *[1]Cornell University, Ithaca, NY, [2]Iowa State University, Ames.*

The objectives were: 1) validate an on farm method utilizing refractometry to rapidly and accurately determine immunoglobulin (IgG) concentration in Jersey colostrum and 2) evaluate the impact of freeze thaw (FT) cycles on radial immunodiffusion (RID) and refractometry to determine IgG concentration in bovine colostrum. Samples ($n = 58$; 3 L) of first-milking colostrum were collected from a single dairy in northwestern Iowa. Samples were analyzed within 2 h of collection for IgG concentration by RID, %Brix and refractive index (nD) by refractometer and an estimate of IgG concentration by colostrometer. Samples were then frozen, placed on dry ice and transported to the laboratory at Iowa State University (Ames). All samples arrived frozen and were placed in a -20°C manual defrost freezer until further analysis. On d 7 (1FT), 14 (2FT) and 1 yr (3FT), all samples were thawed, re-analyzed by RID, % Brix, nD and colostrometer and re-frozen. Fresh colostrum, had a mean IgG concentration, as determined by RID, of 72.91 mg/mL (SD = 3.30), mean % Brix of 21.21 (SD = 0.34) and mean nD of 1.3669 (SD = 0.0074). Immunoglobulin G concentration as determined by RID and IgG as estimated by colostrometer were impacted by the number of FT cycles. The estimates for IgG concentration by RID were greater in fresh and 1FT samples as compared to 2FT and 3FT samples (72.91, 75.38, 67.20 and 67.31 mg IgG/mL, respectively). The colostrometer reading was lower in 1FT samples compared to fresh and 2FT samples. There was no impact of multiple FT cycles on nD, or %Brix reading. In fresh samples, IgG concentration was moderately correlated with nD ($r = 0.79$), % Brix ($r = 0.79$) and colostrometer reading ($r = 0.79$). Diagnostic test characteristics utilizing the recommended cut-point of 1.34966 nD resulted in similar sensitivities for 1FT and 2FT samples (94.87 and 94.74%, respectively). Cut-points of 18, 19, 20, and 21% Brix were evaluated on Fresh samples. 18 and 19% Brix cut-points resulted in the greatest sensitivities (92.31 and 84.62%) and specificity (94.74 and 94.74%, respectively). Using the 18% cut-point resulted in 94.83% of the samples being correctly classified. This data supports the use of refractometry (nD and % Brix) to accurately and rapidly determine IgG concentration in fresh Jersey colostrum. Additionally the data suggests that IgG concentration as determined by RID is impacted by multiple FT cycles, whereas estimates obtained via refractometry are not impacted by multiple FT cycles.

Key Words: colostrum Jersey refractometer

PRODUCTION, MANAGEMENT, AND THE ENVIRONMENT: **MANAGEMENT AND HEAT STRESS**

1480 (T239) Concentrations of heavy metals in the whole raw milk of dairy cows under different management systems and country of origin: a meta-analytical study. G. Zwierzchowski and B. N. Ametaj*, *Dep. of Agricultural, Food and Nutritional Science, University of Alberta, Edmonton, Canada.*

The objective of this meta-analytical study was to investigate concentrations of toxic heavy metals including aluminium (Al), arsenic (As), cadmium (Cd), chromium (Cr), lead (Pb), nickel (Ni), and vanadium (Va) in whole raw bovine milk from different production systems (conventional vs. organic) and countries of origin. Data from 44 studies and 19 countries were used to create a dataset, which was used for statistical analyses. The average concentrations of Al, As, Cr, Va in the raw milk from the conventional system were greater (32.49, 0.27, 2.19, and 0.82, respectively) than those coming from ($P < 0.05$) organic farms (2.13, 0.14, 0.28, and 0.32 μmol/L, respectively). In addition, there were greater concentrations of Cd (0.25 μmol/L) and Pb (0.31 μmol/L) in the raw milk from conventional system vs. organic system (0.02 μmol/L and μmol/L 0.08, respectively) ($P < 0.05$). Lower amounts of Ni were reported for milk from conventional system (0.57 vs. 0.67 μmol/L; $P < 0.05$). Country of origin had significant effect on concentrations of toxic elements ($P < 0.05$). Turkey had greatest Al levels (283 μmol/L), whereas USA had the smallest means for this element (0.89 μmol/L) ($P < 0.05$). The lowermost concentrations of As were reported in Spain (0.01 μmol/L), whereas the greatest concentrations were found in Croatia (13.60 μmol/L) ($P < 0.05$). Average Cd level was 0.11 μmol/L; however, the greatest concentrations of Cd were reported in milk samples from Slovakia (6.49 μmol/L) ($P < 0.05$). In Nigeria concentrations of Cr in the milk were greater compared with other countries (38.04 μmol/L) ($P < 0.05$). Moreover, the greatest levels of lead (Pb) contamination were reported in milk samples from Egypt (4.63 μmol/L), whereas, the lowest means were observed in Poland (0.01 μmol/L) ($P < 0.05$). Regarding Ni, the lowest amounts were found in Brazil (0.03 μmol/L), whereas the greatest levels (50.25 μmol/L) were found in milk samples from Nigeria. Concentrations of Va varied from below 0.01 μmol/L (Spain) to 0.72 μmol/L (*P*oland). In conclusion, data from this meta-analytical study indicated that organic farms were characterized by lower concentrations of toxic heavy metals compared to the conventional system of management. This study also showed high variability in concentrations of heavy metals in raw milk with regards to the country of origin.

Key Words: whole raw milk, heavy metals, meta-analysis

1481 (T240) Macro- and microminerals in the whole raw milk of dairy cows from conventional and organic farms: A meta-analytical study. G. Zwierzchowski and B. N. Ametaj*, *Dep. of Agricultural, Food and Nutritional Science, University of Alberta, Edmonton, Canada.*

The objective of this meta-analytical study was to investigate selected macrominerals calcium (Ca), magnesium (Mg), phosphorous (P), potassium (K), and sodium (Na) and microminerals (copper (Cu), iodine (I), iron (Fe), manganese (Mn), selenium (Se), and zinc (Zn) in the bovine whole raw milk samples from two different management systems and 19 countries. An analytical dataset was constructed from 44 different studies and 19 countries with two types of production systems: conventional and organic. No differences in concentrations of Ca, Mg, and Na in the raw milk were observed when production systems were compared, whereas, concentrations of P and K were greater in the conventional production system ($P < 0.05$). The average concentrations of Cu, I, Fe, Mn, Se, and Zn in organic whole raw milk samples were 1.12, 1.77, 8.25, 0.47, 0.30, and 42.20 μmol/L respectively; and were lower ($P < 0.05$) compared with conventional milk (2.09, 2.37, 13.62, 1.97, 0.76, and 60.95 μmol/L respectively). The lowest concentrations of Cu (0.03 μmol/L), Se (0.17 μmol/L), and Zn (31.76 μmol/L) were reported in bovine raw milk samples from Italy, whereas Germany (Cu, 12.89 μmol/L) and Turkey (Se and zinc, 194.31, and 125.40 μmol/L respectively) had greater concentrations of those elements ($P < 0.05$). Raw milk samples from Polish and Czech dairy farms had greater concentrations of I (2.76 and 3.31 μmol/L respectively) compared to samples collected in Niger (0.17 μmol/L) and Germany (0.88 μmol/L). Iron levels varied from 3.47 μmol/L (USA) to 89.53 μmol/L (Pakistan) ($P < 0.05$). The lowest concentrations of Mn were observed in the milk samples from USA and Poland (0.38, and 0.48 μmol/L respectively), whereas the highest concentrations were reported in milk samples from China (5.89 μmol/L) and Republic of South Africa (3.62 μmol/L). In conclusion, data from this study indicate that concentrations of microelements in the samples of whole raw milk were lower in organic farms compared with the conventional production system. Moreover, milk samples originating from developed countries were characterized by normal concentrations of these minerals compared with other countries.

Key Words: whole raw milk, macro- and micro-minerals, production system

1482 (T241) Evaluating the accuracy of using reinforcing bar and an infrared thermometer versus long-stemmed thermometers in monitoring mortality compost pile temperature. E. Pacheco[1,2], A. Reyes[1,2], M. Negron[1,2], T. A. Gipson[2], and R. Merkel[*2], *[1]University of Puerto Rico, Mayaguez, [2]American Institute for Goat Research, Langston University, Langston, OK.*

Two mortality compost piles were constructed using a mixture of goat mortality and butcher waste with ground hay as the carbon source to compare core temperature recorded by long-stemmed thermometers (LST) vs. an infra-red thermometer (IR) to read temperature of a reinforcing bar (RB) thrust into the pile. One LST was inserted into the core of each pile along with a 3-m length of 0.95-cm-thick RB so that tips of both the RB and LST were in close proximity. For 30 d following pile construction, LST temperature was recorded daily between 1500 and 1600 h. Each RB was then withdrawn from the pile and the tip's temperature determined using an IR. Data were analyzed using repeated measures in a mixed model containing treatment (T = LST and RB), date as a covariate (D), and the interaction to test for heterogeneity of slope. Compost pile was a random effect. Date ($P < 0.001$) and T×D ($P < 0.001$) showed differences, whereas T was not significant ($P = 0.48$; 57.8 and 54.5°C for LST and RB, respectively, SE = 3.04). Date was used as a covariate as temperature in working mortality compost piles will spike soon after pile formation and slowly decline. As an example, LST recorded a temperature of 64.6°C on d 3 of data collection but only 50.4°C on d 30. The T×D test recorded a slope estimate of -0.320 for LST and -0.018 for RB (probability of slope > 0 of $P < 0.001$ and $P = 0.75$ for LST and RB, respectively). These results suggest that RB can be used to monitor mortality compost pile temperature but is not accurate enough to model the normal decline in temperature over time. Temperature of RB may have differed from LST due to location on reinsertion into the pile (cooler or hotter spot than LST tip) and alignment of IR on RB to record accurate RB temperature and not temperature of surrounding material. Using an IR with RB may be an acceptable method for monitoring mortality compost pile temperature and would be a cheaper alternative for producers composting multiple mortalities than to purchase LST for each pile. However, RB is not appropriate for use when precise temperature measurement is needed.

Key Words: goats, mortality compost, temperature

1483 (T242) Milk production, dry matter intake and body condition score evaluated in cross-bred commercial cows supplemented with OmniGen-AF during and following heat stress. A. E. Holland[1], J. D. Chapman[*1], and L. O. Ely[2], *[1]Prince Agri Products, Inc., Quincy, IL, [2]UGA, Athens, GA.*

Dairy cows in the United States are affected by heat stress for a significant part of the year, resulting in reduced dry matter intakes (DMI), milk yields (MY) and profits. In 2012, a 15-wk study (July 9 to October 16) was conducted in Texas to evaluate MY, DMI, and body condition score (BCS) in multiparous cross-bred (H x J) cows fed *OmniGen-AF* (OG) and subjected to heat stress. Two-hundred sixty-six early- to mid-lactation cows were enrolled based on parity, days in milk (DIM) and current MY and assigned to either the basal diet without OG (Controls, $n = 123$h) or basal diet plus OG ($n = 143$h). OG was fed at 56 g/h/d. The average parity and DIM for Controls and OG cows were 3.25, 134 d and 3.25, 130 d, respectively. Diets were fed as a TMR and orts collected daily to calculate DMI. Cows were housed in free-stalls with heat abatement and milked 3x/d. BCS was assessed at weeks 4, 10, and 15. Daily temperature (°C) was measured and weekly highs and lows calculated. Individual milk weights were retrieved from Westfalia Surge Dairy Plan System. Only cows with wk 1 and 15 milk weights and at least 12 total weekly weights were used. Data were analyzed using PROC GLM (SAS) and significance tested to $P < 0.05$. High and low average weekly temperatures (°C) for weeks 1 to 7 and 8 to 15 were 35.9, 21.8 and 25.9, 12.8, respectively. DMI did not differ between Controls or OG cows during wk 1 to 7 (26kg/d) or wk 8 to 15 (29.7kg/d). No differences in BCS were detected between Controls or OG cows at wk 4 (3.01), 10 (2.94) or 15 (2.75). Wk 1 to 7 MY's were not different between Controls (36.3kg/d) and OG cows (37.1kg/d); however, they differed ($P < 0.004$) in wk 8 to 15 (33.2kg/d; 35.5kg/d, respectively). OG cows MY averaged 1.3kg/d more ($P < 0.048$) than Controls from wk 1 to 15. MY's of Controls ($n = 43$h) and OG ($n = 51$h) cows that were 120 DIM or less at the start were not different in wk 1 to 7 (40.4kg/d; 42kg/d), however differed in wk 8 to 15 (36.5kg/d; 39.4kg/d, $P < 0.005$). Controls ($n = 80$h) and OG ($n = 79$h) cows 121 DIM or greater at the start were not different in MY, until wk 15 (28.8kg/d; 31.2kg/d, $P < 0.032$). All cows showed the typical MY and DMI response to heat stress; however, cows fed OmniGen-AF were observed to recover sooner as measured by milk production.

Key Words: heat stress, lactation, OmniGen-AF

1484 (T243) Factors affecting transition success in tie stall herds. D. E. Santschi[*1], M. S. Perreault[1,2], S. Adam[1], R. Lacroix[1], and D. M. Lefebvre[1], [1]*Valacta, Ste-Anne-de-Bellevue, QC, Canada,* [2]*Université Laval, QC, Canada.*

The transition period is the most critical time in the lactation cycle of a cow. It is generally accepted that a successful transition will have a positive impact on performances in the following lactation. Several years ago, Nordlund and collaborators have developped the Transition Cow Index (TCI): a tool to objectively evaluate transition. These authors have previously identified feedbunk space, number of group changes and size and comfort of rest area as the main factors affecting transition success in freestall herds. The aim of the present study was to identify factors that have an impact on transition success specifically in tie stall herds. Tie stall dairy herds (n = 48) from Québec, Canada, were selected based on their average TCI to have high and low TCI herds. Each herd was visited and producers were asked to complete a survey on their management decisions and practices (examples: number of place changes, number of daily feed push ups, boluses). In addition, several observations and measures (examples: stall dimensions, type and amount of bedding, lighting) were taken on each farm. Results suggest that nervousness of cows was the most important factor affecting transition success (calm vs. nervous cows, observed on the day of the visit; $P = 0.04$). Use of straw and woodshavings as bedding at any stage of the transition period significantly increased TCI ($P \leq 0.03$) whereas type of flooring (any type of mat vs. concrete) had no impact ($P \geq 0.15$). Providing a Rumensin bolus to dry cows tended to improve TCI ($P = 0.09$). Number of place changes during the transition period ($P = 0.09$) and number of times feed is pushed back ($P = 0.07$) tended to positively impact TCI. Stall dimension factors significantly correlated with TCI are reported in Table 1484.

Key Words: transition success, TCI, tie stall

Table 1484.

Factor	Corr. Coeff.	*P* value
Stall length far-off cows	0.35	0.02
Stall length precalving cows	0.40	< 0.01
Stall width precalving cows	0.32	0.03
Stall width fresh cows	0.32	0.02

1485 (T244) Effect of spatial orientation and shade on internal environment of a wooden 3-calf hutch. J. D. Allen[*1], and L. W. Hall[2], [1]*Northwest Missouri State, Maryville,* [2]*University of Arizona, Tucson.*

The objective of this study was to determine internal environments of California-style 3-calf hutches according to a combination of spatial orientation and shade. During mid-autumn at the University of Arizona's Campus Agricultural Center, Tucson, 8 California-style (3 cubicles/hutch) were designated to 1 of 2 treatments: exposure to direct sunlight (DS) or placement underneath a drylot shade structure (NDS). Hutches within each group were oriented to 1 of 4 directions: north, south, east, and west. Hutches were equipped with 6 temperature/relative humidity data loggers (two loggers/cubicle) evenly placed at 41 cm above the slatted wood flooring and 41 cm from the sides of the cubicle. For 4 d, each hutch was rotated clockwise once every 24-h period and before daylight hours so that each hutch was exposed to all 4 directions at least once. Ambient condition data were analyzed as a complete randomized block design with hutch as the experimental unit. Overall, DS hutches had a greater average temperature-humidity index (THI) (62.7 vs. 61.5 ± 0.17; $P < 0.01$) compared to NDS hutches. However, DS hutches had greater 24-h range ($P < 0.01$) for THI (56.1–69.2 vs. 57.4–65.7 ± 0.19), ambient temperature (26.3–13.4 vs. 22.5–14.6 ± 0.18°C), and relative humidity (24.8–42.3 vs. 27.5–39.9 ± 0.37%) compared to NDS hutches. A 24-h THI range of 60.5 (north-facing NDS) to 63.6 (east-facing DS) with a temperature range of 17.7 (north-facing DS) to 20.6°C (east-facing DS) was observed. Highest THI ($P < 0.01$) was recorded for all treatments except west-facing NDS during 1200 to 1800 h (THI > 70) compared to other 6-h periods (0000 to 0600, 0600 to 1200, 1800 to 0000 h). South-facing DS hutches recorded the greatest THI range (51.5 to 75.7; $P < 0.01$), while west-facing NDS hutches had the least THI range (57.3 to 64.5; $P < 0.01$). Grid mapping of daytime and nighttime THI for each treatment showed THI uniformity within each hutch was dependent on both orientation and shade. Results indicate shaded wooden three-calf hutches are kept at a cooler and less variable environment compared to unshaded hutches during a mid-autumn, southwestern climate. Also, a 13-point THI difference during a 24-h period can be observed within a hutch exposed to direct sunlight.

Key Words: calf hutch, internal environment, spatial orientation

1486 (T245) Effect of deterred and undeterred bird depredation on nutrient composition of a cattle diet and growth performance in cattle at a Southwestern feedlot facility. J. D. Allen[*1], L. W. Hall[2], S. Garcia[2], and J. Marchello[2], [1]*Northwest Missouri State, Maryville,* [2]*University of Arizona, Tucson.*

A summer study was performed to determine the effect of bird depredation on nutrient composition of a diet fed to and performance parameters of feedlot cattle with open or limited exposure to depredating birds at the University of Arizona West Agriculture Campus (Tucson). This study also investigated feeding preference of individual feedstuffs used at the feedlot. Feeder cattle (n = 50; 170 ± 15 kg) were sorted by gender then randomly assigned to 1 of 8 pens assigned to 1 of 2 treatments: open feed trough exposure to the existing bird

population (OP) or limited feed trough exposure to the bird population utilizing self-closing wire gates (LM). Cattle were fed until backfat ultrasound measurement reached 1cm (476.5 ± 2.8 kg). Diets were sampled at 0, 7, and 24 h post-feeding and analyzed for DM, NDF, ADF, CP, ash, and starch. Cattle performance parameters included G:F ratio, ADG, cost per kg of gain, and final BW. On separate days, DM disappearance was recorded for either individual feedstuffs included in cattle diet or grains varying in processing level placed in troughs not exposed to cattle. Cattle and feed data were analyzed as a complete randomized design with pen as the experimental unit. Both CP and ADF were greater ($P < 0.02$) in OP versus LM troughs at 7 and 24 h, although starch was greater ($P < 0.02$) in LM versus OP troughs after 24 h. Although LM and OP cattle had equivalent ADG, LM cattle had greater G:F ratio ($P < 0.02$), lower cost per kg gain ($P < 0.05$), and tended ($P < 0.10$) to have lower final BW when compared to OP cattle. Dry matter disappearance for diet feedstuffs was greatest ($P < 0.01$) for steam-flaked corn, followed by SBM, mineral mix, alfalfa, and urea, respectively. DM disappearance for grain type was greatest ($P < 0.01$) for whole milo, followed by rolled corn, steam-flaked corn, ground milo, ground barley, ground corn, and whole corn and whole barley, respectively. Birds feeding in the trough included pigeon (*Columbia livia*), mourning dove (*Zenaidura macroura*), and Eurasian dove (*Streptopelia decaocto*). Results indicate that bird populations present at Southwestern cattle feeding operations are capable of altering production parameters in cattle as well as altering nutrient composition in feed through feedstuff preference.

Key Words: bird depredation, cattle, nutrient loss

1487 (T246) Predicting Holstein heifer growth by genomic traits.

D. E. Cook*[1], D. K. Combs[1], R. W. Bender[1], P. M. Krump[1], and K. A. Weigel[2], *[1]Dep. of Dairy Science University of Wisconsin, Madison, [2]University of Wisconsin, Madison.*

Assessment of heifer weights and ADG is a recommended practice for managing dairy heifers, however the genetic variance of mature animal size obfuscates the meaning of a limited number of measured weights and ADG on a commercial dairy. The objective of this study was to use type traits and PTA milk from the heifer's first genomic test to predict the 24-mo body weight. This would allow an adjusted growth curve to be applied to heifers individually and management decisions made on the animal's current body weight status or deviation or both from its genetic potential. A database of heifers ($n = 802$, genotyped $n = 561$) and their body weights ($n = 2373$, ranging from 4 mo of age to 26 mo) was used in this study. An exponential model for heifer growth by age was made for all body weights, to fix the shape of the growth curve. A nonlinear regression was then fitted using the exponential model and the individual animal's measurements to solve for the model coefficient, setting the amplitude of the growth curve by animal. This resultant coefficient was regressed against the animal's PTA milk and type traits, using a criteria of $P > 0.20$ for removal of variables. The resultant regression equation ($R^2 = 0.12$) consisted of terms: PTA milk, final score, stature, body depth, rear leg side and rear view, udder height, udder depth, front and rear teat placement, and teat length. Using the genomic model by animal the mean square error for the growth model was reduced from 4937 to 4451. The present model, based on genomic body traits, did not yield the desired level of body size prediction to be utilized as an on-farm heifer assessment tool.

Key Words: heifer, growth, management

1488 (T247) Blood parameters in transition dairy cattle and their effects on milk production.

C. H. Ramires[1], R. B. Navarro[2], R. M. Silva[3], G. T. Santos[4], R. Locatelli-Dittrich[1], and R. D. Almeida*[1], *[1]Universidade Federal do Paraná, Curitiba–Paraná, Brazil, [2]Capal Cooperativa Agroindustrial, Arapoti- Paraná, Brazil, [3]Kemin do Brasil, Indaiatuba–São Paulo, Brazil, [4]Universidade Estadual de Maringá, Maringá–Paraná, Brazil.*

Circulating metabolites nonesterified fatty acids (NEFA), β-hydroxybutyrate (BHBA) and cholesterol are commonly used as parameters of negative energy balance (NEB) or ketosis in dairy cows, whereas concentrations of aspartate aminotransferase (AST) indicate the occurrence of hepatic lipidosis. The objective of this study was to evaluate the effects of blood parameters on milk production in pre and postpartum Holstein cows. Blood samples were collected from 197 animals in the prepartum (-14 to -1 d) and 285 animals postpartum (+1 to +14 d) from 30 herds of Parana State, Southern Brazil. At each visit, a sample of 10 mL of blood was collected from the coccygeal vessels into sterile tubes without anticoagulant and kept refrigerated until analysis. After collection, blood samples were centrifuged and the serum was analyzed in an automatic biochemical analyzer using commercial kits for NEFA, BHBA, AST and cholesterol parameters. Milk production was assessed using mature-equivalent 305-d (ME305) milk yield estimated at 100 d in milk. While controlling for body condition score (BCS) and parity, the effects of elevated NEFA, BHBA, and cholesterol concentrations on ME305 milk yield were estimated, with herd as a random effect. The mean values for the prepartum were 0.23 ± 0.21 mmol/L NEFA; 0.46 ± 0.27 mmol/L BHBA; 57.48 ± 16.34 U/L AST; and 84.00 ± 19.14 mg/dL cholesterol. In cows and heifers, ME305 milk yield was decreased ($P < 0.05$) by 760 kg when prepartum NEFA concentrations were ≥ 0.33 mEq/L. The mean values in the postpartum group were 0.53 ± 0.40 mmol/L NEFA; 0.64 ± 0.44 mmol/L BHBA; 85.17 ± 31.50 U/L AST; and 84.35 ± 23.45 mg/dL cholesterol. In this postpartum group, NEFA and BHBA were ($r = 0.49$; $P < 0.01$) correlated among themselves and with AST ($r = 0.31$ and $r = 0.27$, respectively; $P < 0.01$). In all animals sampled postpartum, ME305 milk yield

was increased ($P < 0.05$) by 852 kg when BHBA concentrations were $\geq$ 0.97 mmol/L. In primiparous and multiparous sampled postpartum, ME305 milk yield was increased by 492 and 1376 kg on hypercholesterolemic animals (> 120 mg/dL), compared with normocholesterolemic (between 80 and 120 mg/dL) and hypocholesterolemic animals (< 80 mg/dL), respectively. In cows sampled postpartum, ME305 milk yield was decreased ($P < 0.05$) by 793 kg when NEFA concentrations were $\geq$ 0.72 mEq/L. This study suggests that increased concentrations of NEFA and lower concentrations of cholesterol and BHBA had detrimental effects on milk production.

Key Words: β-hydroxybutyrate, cholesterol, nonesterified fatty acids

---

1489 (T248) A comparison of two implant protocols: Synovex-Choice and Synovex-Plus vs. Synovex-S and Revalor-S on steer feedlot performance and carcass characteristics. H. R. Nielson*[1], A. F. Summers[2], and R. N. Funston[1], [1]*University of Nebraska, West Central Research and Extension Center, North Platte,* [2]*University of Nebraska, Lincoln.*

An experiment was conducted to determine the impact of two implant protocols on steer feedlot performance and carcass characteristics. Over a 2-yr period, 109 crossbred (5/8 Red Angus, 3/8 Continental) steers were randomly assigned to 1 of 2 implant protocols; 1) Synovex-Choice [100 mg of trenbolone acetate (TBA) and 14 mg of estradiol benzoate (EB)] implanted at the beginning of the feeding period (CHPL); or 2) Synovex-S (200 mg of progesterone and 20 mg of EB; SS) as initial implant. Steers were fed for approximately 100 d, and the CHPL treatment was re-implanted with Synovex-Plus (200 mg of TBA and 28 mg of EB) while the SS treatment received Revalor-S (120 mg of TBA and 24 mg of estradiol). At 205 d on feed, steers were shipped to a commercial abattoir for slaughter. Carcass characteristics were evaluated 24 h following slaughter; HCW was determined on d of harvest. Average daily gain was similar ($P = 0.39$) for CHPL (1.75 ± 0.08 kg/d) and SS (1.70 ± 0.08 kg/d) steers. There was no difference ($P = 0.37$) in HCW for CHPL compared with SS steers (380 ± 7 vs. 374 ± 7 kg, respectively). Yield grade was also not affected ($P = 0.16$) by treatment, 2.5 and 2.7 ± 0.3 for CHPL and SS, respectively. There was no difference in LM area ($P = 0.98$) between CHPL and SS (90.52 vs. 90.52 ± 2.26 cm^2), and back fat was also similar ($P = 0.13$) between the treatments (1.37 vs. 1.50 ± 0.15 cm, CHPL vs. SS, respectively). Marbling score was similar ($P = 0.19$) between treatments (501 vs. 525 ± 13, CHPL and SS, respectively) resulting in a similar percentage of steers grading USDA Choice [CHPL vs. SS, 93 ± 3% vs. 96 ± 3% ($P = 0.42$)] and upper 2/3 USDA Choice [CHPL vs. SS; 47 ± 7% vs. 54 ± 7% ($P = 0.51$)]. Net revenue was similar ($P = 0.36$) between CHPL ($1083.11 ± 37.83) and SS ($1103.43 ± 37.83) steers. Both implant regimens utilized in the current study resulted in similar feedlot and carcass characteristics.

Key Words: carcass characteristics, feedlot performance, implants

1490 (T249) Mitigating heat stress in dairy cattle via conductive cooling. K. M. Perano*, K. G. Gebremedhim, J. G. Usack, T. J. Shelford, C. A. Gooch, and L. T. Angenent, *Cornell University, Ithaca, NY.*

The U.S. dairy industry, a $37 billion-per-year industry (2012), loses more than $1.5 billion in a typical year to the effects of heat stress on lactating dairy cattle. High ambient temperature or humidity leads to cows having trouble disposing of metabolic heat, causing an increase in respiration rates and body temperature along with a decrease in milk production. Our objective was to design, build, and test a conductive cooling system for relieving heat stress in lactating dairy cattle. Our study used eight first-lactation Holstein cows producing 34.4 ± 3.7 kg/d of milk at 166 ± 28 d in milk. Cows were milked twice per d at 0600 and 1800 h. Cows were exposed to heat stress in a climate-controlled room from 0930 until 1730 h daily but moved to well-ventilated pens at night. During the time the heat stress occurred, each of the four experimental cows was conductively cooled by pumping chilled water through a waterbed in her stall, but the four control cows were given no heat stress relief. The cooling system was tested at two different heat stress levels (THI = 81.3 ± 0.7 and THI = 79.7 ± 0.8) as well as two different chilled water temperatures (4.5°C and 10°C) for a total of four treatments. Each treatment lasted for 7 d. Milk production, feed consumption, and rectal temperature were recorded twice daily. Respiration rates and skin temperatures were measured five times per day. Data loggers recorded the cooling water temperature, the ambient temperature and humidity, and the vaginal temperature as well as standing and lying behavior of each cow. Results from the higher heat stress/lower water temperature treatment show that conductive cooling removed ~850 Watts (about 60% of the total metabolic heat from a lactating Holstein cow) whenever the cow was lying down. This significantly reduced the effects of the heat stress, with cooled cows producing 35.5 ± 2.0 kg/d of milk while control cows produced 26.2 ± 4.7 kg/d of milk ($P = 0.024$). Rectal temperatures for cooled cows were 39.2 ± 0.6°C while control cows were 40.3 ± 0.6°C ($P = 0.039$). Respiration rates were 64 ± 10 breaths/min for cooled cows compared to 84 ± 10 for control cows ($P = 0.033$). Such results indicate that conductive cooling shows promise for mitigating heat stress in lactating dairy cattle.

Key Words: conductive cooling, heat stress, milk production

1491 (T250) Changes in behavioral and physiological parameters around estrus in partially synchronized cows. K. A. Dolecheck*, W. J. Silvia, G. Heersche Jr., A. E. Sterrett, B. A. Wadsworth, and J. M. Bewley, *University of Kentucky, Lexington.*

The objective of this study was to compare estrus detection potential of cow behavioral and physiological parameters collected by multiple precision dairy farming technologies. Technologies included the SensOor (Agis Automatisering, Harmelen, Netherlands), DVM bolus (DVM Systems, LLC, Greeley, CO), HR Tag (SCR Engineers Ltd., Netanya, Israel), IceQube (IceRobotics Ltd., Edinburgh, Scotland), and Track a Cow (Animart Inc., Beaver Dam, WI, and ENGS, Rosh Pina, Israel). Ovulation was synchronized for 35 cows in three groups between January and June 2013 at the University of Kentucky Coldstream Dairy using a modified G7G/Ovsynch ending after the last $PGF_{2\alpha}$ injection (Day 0) to allow estrus expression. Visual observation of cows for four 30-min periods at 0330, 1000, 0230, and 2200 h on d 2, 3, 4, and 5 confirmed estrus by recording when cows stood to be mounted. Eighteen of the 35 cows stood to be mounted at least once during the observation period and were used for analysis. The GLM procedure of SAS (SAS Institute, Inc., Cary, NC) was used to compare differences between the 24-h period surrounding the standing event (estrus) and the week preceding that period (non-estrus) for all technology parameters. Significant differences ($P < 0.05$) between estrus and non-estrus were observed for the following parameters (reported as estrus vs. non-estrus ± SE): SensOor minutes ruminating/h (16.02 vs. 22.68 ± 0.84), SensOor minutes feeding/h (14.48 vs. 8.86 ± 0.94), SensOor minutes of high activity/h (13.66 vs. 4.18 ± 0.79), HR Tag minutes ruminating/2 h (22.30 vs. 28.67 ± 1.40), HR Tag activity units/2 h (49.10 vs. 26.74 ± 2.19), IceQube lying bouts/h (0.47 vs. 0.70 ± 0.06), IceQube total motion units/h (912.38 vs. 316.82 ± 59.82), IceQube steps/h (224.41 vs. 84.53 ± 14.09), IceQube minutes lying/h (16.35 vs. 24.12 ± 1.19), and Track a Cow activity units/h (197.07 vs. 78.19 ± 26.29). No significant differences between estrus and non-estrus were observed for SensOor mean temperature/h, DVM bolus twice-daily temperature, and Track a Cow lying percent/h. This data demonstrates that multiple measureable parameters may be useful for detecting estrus events.

Key Words: precision dairy farming technologies, estrus detection

1492 (T251) Effect of maternal heat stress during the dry period on development of immune system of offspring. B. M. Ahmed[*1], A. P. A. Monteiro[1], S. Tao[1], K. E. Merriman[2], J. P. Driver[2], B. L. Artiaga[1], J. Hayen[1], I. M. Thompson[1], C. D. Nelson[2], and G. E. Dahl[1], *[1]University of Florida, Gainesville, [2]Dep. of Animal Sciences, University of Florida, Gainesville.*

Maternal heat stress during the dry period affects calf immune response during postnatal life, but it is still unknown how in utero heat stress affects calf's immune system development. The objective was to evaluate the effects of in utero heat stress on distribution of different immune cell types in blood and primary and secondary lymphoid tissues of the calf. Cows were dried off 60 d before expected calving and randomly assigned to one of two treatments: heat stress (HT) or cooling (CL). During the dry period, all cows were housed in a freestall barn with fans over the feed line and stalls, but only the feeding area for CL cows was equipped with soakers. Heat stress was moderate compared with other studies, as HT cows had only 0.1°C increase in rectal temperature and 8 breath/min increase in respiration rate compared with CL cows. Immediately after birth, singleton calves (HT: $n = 200$; CL: $n = 188$) were weighted and then fed 3.8 L of colostrum (score: bull < 80; heifer > 80) within 1 h after birth. Blood samples were collected from a subset of heifers (HT: $n = 12$; CL: $n = 10$) at birth before colostrum feeding, d 3, 28, and 56 of age to evaluate the proportion of blood T and B lymphocytes, granulocytes, monocytes, and γδ-T cells by flow cytometry. Additionally, a subset of bull calves (5/treatment/day) were randomly selected and slaughtered at birth (without colostrum feeding), 1 and 2 d after birth. Thymus and spleen were weighed and then a sample was excised, homogenized and assayed using flow cytometry to determine the proportion of different immune cell types. No difference was observed between treatments for calf birth weight (CL: 41.0; HT: 40.6 kg; $P = 0.32$). However, the thymus of CL bull was proportionally heavier (0.18 vs. 0.14% of body weight, respectively; $P < 0.05$) compared with HT calves. Preliminary analyses indicate that treatments had no impact on the proportion of different immune cells of calf blood during the preweaning period. Thus, we conclude that the slight difference in heat strain on HT and CL cow during the dry period has no significant impact on general fetal growth during the dry period and blood immune cell profile during the preweaning period in current study; however, it seems that late gestation maternal heat stress influences fetal primary lymphoid tissue development.

Key Words: heat stress, dry period, dairy calf

1493 (T252) Impact of dry period heat stress on milk yield, reproductive performance and health of dairy cows. I. M. Thompson*, A. P. A. Monteiro, G. E. Dahl, S. Tao, and B. M. Ahmed, *University of Florida, Gainesville.*

Two studies were performed to determine the effects of heat stress during the dry period on subsequent lactation yield, occurrence of health disorders, and reproductive performance. In experiment 1, cows were dried off 60 d before calving and assigned to cooling (CL, n = 250) or heat stress (HT, n = 250). CL cows were housed with sprinklers, fans and shade, whereas the HT group had fans and shade. All cows were cooled postpartum. Rectal temperature (RT) and respiration rate (RR) were recorded during the dry period. BCS was recorded weekly during the dry period and at d 7 and 33 postpartum. Milk yield was recorded monthly. Occurrence of postpartum disorders was evaluated during the first 60 DIM. Reproductive performance included metritis check (MC), days to first breeding (DTAI) and pregnancy rates. In experiment 2, records of 147 multiparous cows over 5 yr that were under cooling (n = 73) or heat stress (n = 74) during the dry period were analyzed. In those studies, HT cows did not have fans or soakers. Traits analyzed were 305 d milk production, number of breedings, and occurrence of postpartum health disorders. In experiment 1, relative to HT, CL cows had lower RT (39.0 vs. 39.1°C; P = 0.03) and RR (51 vs. 59 breath/min; P < 0.01) when dry. BCS during the dry period and postpartum, DTAI and MC33 did not differ between treatments. CL cows tended to have a greater incidence of metritis at d 7, but no other differences in postpartum health disorders were observed. Milk yield for the first 2 mo of lactation did not differ. In experiment 2, HT cows had higher RT (39.0 vs. 39.4°C; P < 0.001) and RR (48 vs. 76 breath/min; P = 0.02) than CL cows. Additionally, CL cows produced 5.3 kg/d more milk (P = 0.01) than HT cows. BW and BCS after calving did not differ between treatments, but CL cows gained more BW and increased BCS during the dry period versus HT cows. Reproductive performance did not differ between treatments. CL cows had a higher incidence of ketosis, and tended to have a higher incidence of metritis and retained placenta versus HT cows. Cooling dry cows during the dry period improves subsequent lactation performance, but the severity of heat stress is a significant influence on the response.

Key Words: heat stress, dry period, lactation

1494 (T253) Extending the interval from Presynch to initiation of Ovsynch in a Presynch-Ovsynch protocol did not reduce fertility of lactating dairy cows not detected in estrus that received timed artificial insemination. J. O. Giordano[*1], M. J. Thomas[2], G. K. Catucuamba[2], and M. D. Curler[2], [1]*Dep. of Animal Science, Cornell University, Ithaca, NY,* [2]*Dairy Health and Management Services, LLC, Lowville, NY.*

Our objective was to determine if extending the interval from Presynch to initiation of Ovsynch by 2 d (from 12 to 14) in a Presynch-Ovsynch protocol would reduce pregnancies per AI (P/AI) for cows not detected in estrus that receive timed AI (TAI). Lactating dairy cows (n = 1817) from four commercial farms in New York (Farm A = 218, B = 1031, C = 258, and D = 310) were enrolled in the Presynch-Ovsynch protocol to receive TAI at 73 ± 3 DIM. Cows were blocked by parity and randomly assigned to two groups: PS12 (n = 909; PGF-14d-PGF-12d-Ovsynch-56) or PS14 (n = 908; PGF-14d-PGF-14d-Ovsynch-56). Timed AI was performed approximately 16 h after GnRH. Cows detected in estrus at any time from the second PGF injection of Presynch until the day before TAI were inseminated. Pregnancy was assessed at 39 ± 3 d after AI using transrectal ultrasound. The percentage of cows receiving TAI was greater (P < 0.001) for PS14 than PS12 (55.2 vs. 48.5% respectively), was greater (P < 0.001) for farm D (70.7%) than A (60.1%) and C (57.8%) whereas farm B (43.0%) had the lowest percentage of cows receiving TAI. More (P < 0.001) multiparous (58.4%; 661/1131) than primiparous (41.0%; 281/686) cows received TAI. There was no treatment by farm interaction (P = 0.74) or treatment by parity interaction (P = 0.96) for the percentage of cows receiving TAI. Pregnancies per AI for cows receiving AI after detection of estrus was similar (P = 0.41) for PS12 and PS14 (34.6 vs. 37.4% respectively), was not affected (P = 0.44) by farm, and was similar (P = 0.36) for primiparous and multiparous cows (37.5 vs. 34.5% respectively). Pregnancies per AI for cows receiving TAI after completing the Presynch-Ovsynch protocol were similar (P = 0.98) for PS12 and PS14 [35.4 (156/441) vs. 35.5% (178/501), respectively], tended to differ by farm (P = 0.10), and were similar (P = 0.50) for primiparous and multiparous cows (37.1 vs. 34.8% respectively). Also, there was no treatment by farm (P = 0.91) or treatment by parity interaction (P = 0.34) for P/AI after TAI. Thus, extending the interval from the second PGF injection of Presynch to the initiation of the Ovsynch protocol by 2 d (from 12 to 14 d) did not reduce fertility of lactating dairy cows that were not detected in estrus and completed Presynch-Ovsynch to receive TAI.

Key Words: Presynch-Ovsynch, timed AI, dairy cow

1495 (T254) Mortality and herd turnover rates in large dairy herds in the upper Midwest United States. T. Evink*, and M. I. Endres, *University of Minnesota, St. Paul.*

The objectives of this study were to describe mortality and herd turnover rates in large Upper Midwest dairy herds, and evaluate the association between breed and mortality rates. The study included 15 dairy farms in Minnesota, Wisconsin, Iowa, and South Dakota. All farms had over 2500 lactating cows housed in a freestall system. Twelve of the farms had Holstein cows, two farms had Jersey cows, and one farm had Jersey and Holstein crosses. Herd size (mean ± SD) was 4972 ± 2652 cows with a range of 2600 to 13,250 cows. On farm records were obtained for 2 yr on each farm from July 2011 to July 2013. Sold and died events were examined from the on farm record keeping system to determine mortality and herd turnover rates. Herd turnover rate was calculated as the number of animals that were sold or died during a 1-yr period, divided by the average herd size during that 1-yr period. Mortality rate was calculated as the number of animals that died during a 1-yr period, divided by the average herd size during that period. Overall mortality rate was 7.4 ± 2.1%. Deaths on farm were categorized as injury, mastitis, lameness, sickness, down cow, transition diseases, dystocia, euthanasia, miscellaneous, or unknown reasons. Main causes of death were sickness (33.5 ± 17.3), unknown reasons (15.3 ± 24.6), and injury (11.1 ± 10.6). Overall herd turnover rate was 41.6 ± 5.9%. Reasons for turnover were categorized as low production, lameness or injury, mastitis, reproduction, transition problems, abortion, udder conformation, sickness, miscellaneous, or unknown reasons. Main reasons for turnover were low production (30.0 ± 22.0), mastitis (16.4 ± 11.9), and sickness (12.7 ± 5.2). Turnover rate during the first 60 DIM was 8.3 ± 2.3%. The PROC MIXED in SAS was used to evaluate the association between mortality rate and breed (Jersey vs. Holstein). Breed was associated with yearly mortality rate (P = 0.038); mortality rates (LSMeans ± SE) were 5.3 ± 0.01 and 7.6 ± 0.003 for Jersey and Holstein herds, respectively. Mortality rate in the first 60 DIM was 3.1 ± 0.003 for Holstein and 2.2 ± 0.01 for Jersey herds and there was no association with breed. Based on these results, Jersey cows appear to have lower overall mortality rates but similar early lactation mortality rates compared to Holstein cows in large freestall herds.

Key Words: mortality rate, turnover rate, large dairy herd

1496 (T255) Biased milk production programmed by fetal sex affects sexed semen economics. A. De Vries*[1], K. Hinde[2], A. J. Carpenter[3], J. Clay[4], and B. Bradford[3], [1]*University of Florida, Gainesville,* [2]*Harvard University, Cambridge, MA,* [3]*Kansas State University, Manhattan,* [4]*Dairy Records Management Systems, Raleigh, NC.*

Recent research has shown that Holstein dairy cows produce more milk per lactation after giving birth to female calves and when gestating female calves compared to male calves. The objective of this study was to evaluate how the economics of the use of sexed semen are affected by these differences in milk production. A herd budget simulation program was used that included separate daily cash flow projections for heifers and at least 4 parities of cows. Cash flows were based on lactation curves, feed intakes, reproductive parameters, culling and prices for milk, feed, calves, cull cows, semen, among other inputs. Based on the recent research, a first parity cow produced 185 kg per lactation more milk when she had given birth to a female calf and was gestating a female calf compared to giving birth to and gestating a male calf. A second parity cow produced 269 kg per lactation more milk when she had given birth to female calves in the current and first parity. Third and greater parity cows produced 100 kg more milk when giving birth to a female compared to a male. Other combinations of males and females resulted in smaller effects. Compared to conventional semen, sexed semen reduced the probability of conception by 20% and was $15 more expensive. Female calves were $100 more valuable than male calves. Cow pregnancy rates were 21% without sexed semen. Five sexed semen scenarios were evaluated, ranging from 1x sexed semen in heifers to 3x in heifers and 2x in first parity cows. Sexed semen break-even prices ranged from $3 to-$2 without the effects of fetal sex on milk production, compared to no use of sexed semen. Including the effects of fetal sex on milk production, sexed semen break-even prices ranged from $15 to $4. Break-even female calf prices, compared to male calf prices, were up to $29 lower when including the effects of fetal sex on milk production than when ignoring these effects. In conclusion, the effects of fetal sex on milk production make the use of sexed semen more economically feasible and should be included in economic calculations.

Key Words: fetal sex, milk production, sexed semen, economics

1497 (T256) Study the temperature-humidity index and its effect on performance of dairy cows in Isfahan. G. Ghorbani*, and A. Ahangaran, *Isfahan University of Technology, Iran.*

A temperature-humidity index (THI) is a single value representing the combined effects of air temperature and humidity associated with the level of heat stress. The objective of

this study was to evaluate the effects of THI on milk yield and milk composition of dairy cows in climatic conditions of seven Isfahan dairy farms. The experiment performed during in July 2012 to October 2013. In this study, eight THI with different weightings of dry bulb temperature and humidity were compared. Ambient temperature and relative humidity were measured every 15 min with data loggers located throughout the farm. According to THI values, from mid-October to early May the heat stress was lower than the threshold, with lowest values in January. Then THI was higher than threshold until mid-October, which was the highest level in July. Indices with higher weightings of humidity are more appropriate for humid climates, and indices with the most emphasis on ambient temperature are more suitable for semiarid climates. Since that Isfahan is located in the dry climate, THI 5 is the best indicator of its eight temperature–humidity indicators. The threshold for heat stress was 65 by THI 5. When THI increased one unit upper than treshold, average milk production decreased 0.5 Kg. Disintegration of estimated THI thresholds of heat stress into corresponding temperature and relative humidity revealed that heat stress occurred in Isfahan at temperatures $\geq$ 21°C and relative humidity of 25%. Results clearly showed a negative relationship between milk production and THI. Indeed, as THI increases from 49.1 in the winter season to 70.8 in the summer season, heat stress reduced total milk production by 38.5 to 36.1 kg, respectively. This decrease can be largely explained by the effect of summer heat stress, particularly in July, August and September when THI values are well above the critical threshold of 65. The reason for the drop in milk yield during the early fall could be explained by the carry over effect of the unfavorable conditions during the summer particularly in the absence of environmental control systems.

Key Words: temperature-humidity index, heat stress, milk loss

---

1498 (T257) The influence of body weight on the efficiency of dairy cows. P. L. Kunz*, and A. Reinhard, *Bern University of Applied Sciences, Zollikofen, Switzerland.*

Questions about the efficiency of dairy cows are a consequence of the increasing pressure on milk prices. Efficiency is defined as the relationship between energy output (milk energy) and energy input (feed energy). For methodological reasons, it is often only the energy output (milk) which is assessed, ignoring the energy input (feed energy). As a result, research into the efficiency of dairy cows has so far shown uneven results. The aim of this study was to calculate efficiency by measuring the effective daily energy intake and energy expenditure in milk, and to investigate whether the body weight of cows had an influence on their efficiency. Efficiency was defined as: efficiency = (milk energy (MJ)/net energy intake (MJ NEL). Data were collected from the Holstein Frisian and Brown Swiss dairy cows at the research centre of the Swiss Federal Institute of Technology (Zurich). Throughout lactation and the subsequent dry period, the cows were weighed daily. The quantity of milk produced was recorded twice daily and the milk ingredients measured monthly. Feed samples of all ration components were taken every month and analysed. Using scales installed under each feed trough, the feed intake of individual cows was measured continuously during the whole lactation. In this way, the daily energy intake and the daily energy output in milk could be quantified. Data from 450 lactations of 158 cows were collected. After eliminating incomplete datasets, 105 lactations of 65 cows (40 Holstein Frisian and 25 Brown Swiss cows) were submitted to statistical analysis. The results show that the body weight of cows with two or more lactations positively correlated with both daily feed intake ($P = 0.018$) and milk yield ($P = 0.022$). This means that an additional 100 kg body weight required 2.0 kg DM/day more feed intake and yielded 630 kg more milk per lactation. However, there was no significant correlation between body weight and efficiency ($P = 0.39$), not even after dividing the samples by breed and lactation numbers. In this sample, heavy cows were equally efficient as light cows, compensating for their increased maintenance requirement by higher feed intake and higher milk yield. The differences in efficiency between individual cows must therefore be explained by other factors.

Key Words: dairy cow efficiency

1499 (T258) Effects of supplementation with propylene glycol in heat-stressed dairy goats. S. Hamzaoui[1], A. Salama[*1,2], G. Caja[1], E. Albanell[1], and X. Such[1], *[1]Group of Ruminant Research (G2R), Universitat Autonoma de Barcelona, Bellaterra, Spain, [2]Animal Production Research Institute, Dokki, Giza, Egypt.*

We hypothesized that supplementation with propylene glycol would increase blood glucose and spare amino acids for milk protein synthesis rather than glucose production. To test this hypothesis, we used eight multiparous Murciano-Granadina dairy goats (40.8 ± 1.1 kg BW; 84 ± 1 DIM) individually kept in metabolic cages. The design was a replicated 4 × 4 Latin square of 4 periods, 21 d each (14 d adaptation, 5 d for measurements). Goats were allocated to one of 4 treatments in a 2 × 2 factorial arrangement. Factors were no propylene glycol (C) or 5% of Propylene glycol (PG), and thermal neutral (TN; 15 to 20°C) or heat stress (HS; 12 h/d at 37°C and 12 h/d at 30°C) conditions. This resulted in 4 treatment combinations: TN-C, TN-PG, HS-C, and HS-PG. Feed intake, milk yield, milk composition, and blood parameters were measured. No significant interaction was detected between ambient temperature and PG effects. Compared to TN, HS goats had lower feed intake, FCM, and milk contents of fat, protein and lactose. The PG increased blood glucose and insulin, but decreased DMI, blood NEFA and β-hydroxybutyrate, resulting in lower milk fat with no change in milk protein content. In

conclusion, supplementation of heat-stressed dairy goats with propylene glycol did not affect milk yield or milk protein content, and caused milk fat depression syndrome.

1500 (T259) The effects of technology use in feedlot production systems on the heat stress and blood metabolites of finishing steers. B. C. Bernhard*[1], C. L. Maxwell[1], C. F. O'Neill[1], B. K. Wilson[1], C. G. Hixon[1], C. Haviland[1], A. Grimes[1], M. S. Calvo-Lorenzo[1], C. J. Richards[1], D. L. Step[1], B. P. Holland[2], and C. R. Krehbiel[1], *[1]Oklahoma State University, Stillwater, [2]Merck, Volga, SD.*

Crossbred, black-hided steers (n = 336; initial BW = 379 ± 8 kg) were utilized in a RCBD (8 pens/treatment; 14 steers/pen) to determine the effects of technology use in feedlot production systems during the summer on heat stress. Treatments consisted of an all-natural treatment (receiving no growth promoting technologies; NAT), a conventional treatment (implanted with 40 mg of estradiol and 200 mg of trenbolone acetate on d 0, and fed 33 and 9 mg/kg of monensin and tylosin daily, respectively; CONV), and a CONV treatment plus the addition of a β-adrenergic agonist (zilpaterol hydrochloride at 6.76 g/ton for the last 20 DOF with a 3–4 d withdrawal; CON-V-Z). Blood was collected every 10 d during the β-agonist period (d 112 to 132) on seven steers/pen to determine blood gases, pH, and metabolites. The same subset of steers was evaluated for respiration rates and panting scores during the final 23 DOF, and rumen temperatures were continuously measured. All blood metabolites measured were within clinically normal concentrations throughout the experiment. Blood pH was greater for the CONV-Z cattle compared to the NAT cattle (7.41 vs. 7.37; $P < 0.01$) and CONV cattle intermediary (7.39) at d 122. The CONV-Z cattle had reduced lactate concentrations compared to NAT and CONV cattle at d 122 (13.5 vs. 28.9 and 27.3 mg/dL, respectively) and 132 (12.5 vs. 25.1 and 27.2 mg/dL, respectively; $P < 0.01$). Conventional cattle exhibited greater glucose concentrations than NAT and CONV-Z (88.9 vs. 83.9 and 82.5 mg/dL, respectively; $P < 0.01$). The CONV-Z cattle exhibited greater potassium concentrations than NAT and CONV cattle at d 122 (4.40 vs. 4.16 and 4.23 mmol/L, respectively; $P < 0.01$). The CONV-Z cattle showed increased severity in the morning panting score compared to CONV and NAT cattle (1.23 vs. 1.00 and 1.08, respectively; $P < 0.03$), and the afternoon panting score compared to CONV cattle (1.84 vs. 1.67; $P < 0.01$), with NAT cattle intermediary (1.76). Respiration rates were lowest for CONV cattle, intermediate for NAT cattle, and highest for CONV-Z cattle in the morning (99.5 vs. 105.0 vs. 112.8 breaths/min, respectively) and afternoon (120.1 vs. 125.8 vs. 133.8 breaths/min, respectively; $P < 0.01$). The NAT cattle had lower mean rumen temperatures compared to CONV cattle in the morning (39.56 vs. 39.71°C; $P < 0.01$) and afternoon (40.70 vs. 40.95°C; $P < 0.01$), with CONV-Z cattle intermediary (39.62 and 40.88°C). Based on these results, zilpaterol increased respiration score and rate, as noted on the product label.

Key Words: β-adrenergic agonist, heat stress, respiration rate

1501 (T260) The effects of technology use in feedlot production systems on feedlot performance, carcass characteristics, and feeding behaviors of crossbred beef steers. C. L. Maxwell[1], B. C. Bernhard*[1], C. F. O'Neill[1], B. K. Wilson[1], C. Hixon[1], C. Haviland[1], A. Grimes[1], M. S. Calvo-Lorenzo[1], D. L. VanOverbeke[1], G. G. Mafi[1], C. J. Richards[1], D. L. Step[1], B. P. Holland[2], and C. R. Krehbiel[1], *[1]Oklahoma State University, Stillwater, [2]Merck Animal Health, DeSoto, KS.*

The objectives of this study were to examine the effects of a technology enhanced system compared to an all-natural production program on feedlot performance, feeding behaviors and carcass characteristics. Crossbred beef steers (n = 54; initial BW = 391 ± 2.6 kg) were randomized to one of two treatments in a RCBD (13 to 14 steers/pen; 27 steers/treatment). Treatments consisted of an all-natural treatment (NAT), and a conventional treatment (CONV-Z). The NAT cattle received no growth promoting technologies. The CONV-Z cattle were implanted with 40 mg of estradiol and 200 mg of trenbolone acetate on d 0, and were fed 33 and 9 mg/kg of monensin and tylosin daily, respectively as well as zilpaterol hydrochloride at 6.76 mg/kg (90% DM basis) for the last 20 DOF. Gain was improved by 45.1% (1.77 vs. 1.22 kg/d; $P < 0.01$) and feed efficiency by 45.5% (0.163 vs. 0.112; $P < 0.01$) for CONV-Z steers compared to NAT steers. Daily water intake was numerically greater for NAT steers compared to CONV-Z steers consistently throughout the study (56.26 vs. 53.59 L/d; $P = 0.43$).

Thus, total water and feed efficiency was improved by 50% for CONV-Z steers compared to NAT steers (0.027 vs. 0.018; $P < 0.01$). NAT steers consumed more (8.22 vs. 7.59 meals/d; $P = 0.03$), smaller feed meals (1.34 vs. 1.46 kg/meal; $P = 0.02$), resulting in more time spent at the feed bunk (85.36 vs. 73.19 min/d; $P < 0.01$) throughout the day compared to CONV-Z steers. Water meal length was greater for NAT steers compared to CONV-Z steers (3.23 vs. 2.58 min/meal; $P < 0.01$), resulting in more time spent at the water trough throughout the day (23.71 vs. 17.80 min/d; $P < 0.01$). Dressing percentage was increased by 2.17% units (65.31 vs. 63.14; $P < 0.01$) for CONV-Z steers compared to NAT steers, resulting in a 48 kg heavier carcass (388 vs. 340, kg; $P < 0.01$). *Longissimus* muscle area was increased by 11.09 cm^2 (87.25 vs. 76.15, cm^2; $P < 0.01$) for CONV-Z steers compared to NAT steers, and marbling score was greater for NAT steers compared to CONV-Z steers (504 vs. 410; $P < 0.01$). The results of this experiment show that CONV-Z production improves feedlot performance and resource-use efficiency compared to NAT with differences in feed and water intake behavior.

Key Words: beef cattle, conventional, natural

1502 (T261) Survey of fatty acid profile of milk fat in Italian Water buffalo. M. G. Manca[1], G. Cosenza[2], E. Apicella[2], A. Pauciullo[3], A. Coletta[4], A. Nudda[*1], N. P. P. Macciotta[5], L. Zicarelli[6], and L. Ramunno[7], *[1]Dipartimento di Agraria, University of Sassari, Italy, [2]Dep. of Agriculture, University of Naples Federico II, Italy, [3]ISPAAM, Laboratory of Animal Cytogenetics and Gene Mapping, National Research Council, Naples, Italy, [4]ANASB, Italian National Association of Buffalo Breeders, Caserta, Italy, [5]Università di Sassari, Italy, [6]Dep. of Veterinary Medicine and Animal Production, University of Naples Federico II, Italy, [7]Dep. of Agriculture, University of Naples, Italy.*

Dairy buffalo farming has a relevant economic importance in Italy, mainly due to the high value of the most important dairy product, the mozzarella. Fat is a major component of buffalo dairy products. Its consumption can provide great opportunities for increasing the intake of fatty acids (FA) with potential health properties, especially as far as CLA isomers and omega-3 FA are concerned. Therefore the purpose of this survey was to investigate the variation in FA profile of milk fat of Mediterranean water buffalo fed a total mixed ratio composed mainly by corn silage and pelleted concentrate. Milk samples from 398 Italian Water buffaloes farmed in 18 herds located in Campania were collected at different months of production. FA composition of milk samples was determined by GC. Data were analyzed using a linear model, that includes age, days in milk (DIM) and month of calving as fixed effects and herd as a random effect. Saturated FA (SFA) represented 71.6% of total FA (ranging from 57.9% to 85.9%) and C16:0 and C18:0 were the most represented (34.8% and 11.1%, respectively). Monounsaturated FA (MUFA) were 25.17% of total milk FA (ranging from 12.6% to 37.4%) and C18:1c9 represent the majority (76% of total MUFA). The concentration of polyunsaturated FA (PUFA) was 3.21% of total FA ranging from 1.39% to 5.11%. with C18:2 n6 predominating (49% of total PUFA) while C18:3 n3 was present in a lower amount 0.32% of total FA. Trans FA (TFA) represented 1.70% of total FA with C18:1 t11 the most abundant (59% of total TFA). CLA isomers amounted to 0.76% of total milk FA and the isomer c9, t11 CLA represent the majority (55% of total CLA). Statistical analysis showed that milk FA were not significantly influenced by the age of animal, except for TFA content ($P < 0.05$) that was higher in younger animals (1.94%). Month of calving significantly influenced FA composition of buffalo milk only for total CLA and TFA ($P < 0.05$), evidencing a seasonality effect of these traits. DIM affected significantly all the group of FA analyzed ($P < 0.01$) denoting a marked lactation curve effects. The FA profile obtained in this study is typical of animals farmed in intensive systems, with a reduced occurrence of unsaturated fatty acids, compared to graze-based systems.

Key Words: buffalo milk, fatty acid profile

1503 (T262) Comparative study between 5% copper sulfate and a β-ionone and limonene solution in a split footbath. A. C. Thompson*, and J. M. Bewley, *University of Kentucky, Lexington.*

Digital dermatitis (DD) is a major cause of lameness in dairy herds (NAHMS, 2002) often controlled with a copper sulfate footbath. Alternative solutions are being explored as copper retards crop growth and yield when waste footbath solution is applied to fields. An alternative to copper sulfate is a β-ionone and limonene solution (RotNot, Neogen Corporation, Lexington, KY). The objective of this study was to compare the frequency and severity of DD using a β-ionone and limonene solution versus copper sulfate. The study was performed on a commercial farm in Kentucky from March 2, 2013,through May 25, 2013, with 91 lactating Holstein cows. Footbath solutions were delivered through the use of a split footbath with a β-ionone and limonene solution, at a concentration of 1:1000 on the right hooves and 5% copper sulfate on the left hooves. The DD lesions were scored every 3 wk using the Döpfer scoring system (Döpfer et al., 1997): M0 indicates no lesion; M1 represents an early growth less than 2 cm in size and generally not painful; M2 indicates a growth greater than 2 cm and painful to the touch; M3 represents a growth in the healing stage covered with a scab; and M4 designates a chronic non painful growth. The FREQUENCY procedure of SAS (SAS Institute Inc., Cary, NC) was used to run a chi-square test. The results indicated a significant change in DD frequency from the beginning (29.1%) to the end (52.7%) of the study across treatments ($P < 0.01$). McNemar's test statistic indicated that no significant difference existed in the proportions of M1 and M2 lesions between the beginning (21.9%) and end of the

study (27.5%) for 5% copper sulfate ($P = 0.42$). McNemar's test indicated a significant increase in M1 and M2 lesions with a β-ionone and limonene solution from the beginning (13.2%) to the end (52.7%) of the study ($P < 0.01$). These results suggest that copper sulfate was more effective at preventing DD lesions than a β-ionone and limonene solution. A β-ionone and limonene solution footbath may not be a viable alternative to 5% copper sulfate footbath for DD lesion prevention.

Key Words: digital dermatitis, copper sulfate, split footbath, hoof care

1504 (T263) Comparison of milk components before and after passing through a novel inline milk filter.

D. T. Nolan*[1], M. J. Bakke[2], and J. M. Bewley[1], *[1]University of Kentucky, Lexington, [2]Custom Dairy Performance, Clovis, CA.*

The UV Milk Filter (GERA Ltd., Voronezh, Russia) is a new inline filter designed to help remove foreign matter and abnormalities in milk. UV Milk Filters are different from standard single-ply polyester fabric because they are spindle woven, making them thicker than the industry standard. The objective of this study was to determine if passing milk through the UV Milk Filter changed milk fat, protein, lactose, solids, or SCC. Samples were collected at the University of Kentucky Coldstream Dairy between Nov. 30 and Dec. 10, 2013. Before each milking, a new UV Milk Filter was placed in the filter holder within the pipeline. When milking was completed, three 90-mL samples were collected from two different points: 1) at the receiver jar, before the milk had gone through the filter, and 2) at the point the milk enters the bulk tank, after the milk from the receiver jar had passed through the filter. Therefore, a total of six samples were collected at each milking for 20 milkings ($n = 120$). Mean fat, protein, lactose, solids, and SCC were calculated for each milking ($n = 20$). The GLM procedure of SAS (Cary, NC) was used to determine the effects of the UV Milk Filter on milk component averages taken before and after milk had passed through the filter. Results are depicted in Table 1504. The results show that the UV Milk Filter can successfully filter milk without changing its composition.

Key Words: UV milk filter, milk composition

Table 1504. Milk component averages and corresponding *P*-values for the differences in milk before and after it had passed through the UV Milk Filter

	Treatment		
Component	Before Filter	After Filter	*P*-value
Fat	4.48%	4.43%	0.84
Protein	3.09%	3.12%	0.64
Lactose	4.90%	4.91%	0.91
Solids	8.93%	8.96%	0.53
SCS	3.30	3.43	0.75

PRODUCTION, MANAGEMENT, AND THE ENVIRONMENT: **REDUCING THE ENVIRONMENTAL FOOTPRINT THROUGH NUTRITION AND MANAGEMENT**

1505 (W216) Methane and carbon dioxide emissions from manure of dairy cows fed red clover- or corn silage-based diets supplemented with linseed oil.
F. Hassanat*, D. I. Massé, and C. Benchaar, *Agriculture and Agri-Food Canada, Dairy and Swine Research and Development Centre, Sherbrooke, QC, Canada.*

The objective of this study was to examine the effects of forage source (red clover: RC vs. corn silage: CS) and linseed oil (LO) supplementation of dairy cow diets on CH_4 and CO_2 emissions from manure storage. The diets contained 57% of RC or CS, on dry matter (DM) basis while LO was supplemented at 4% of dietary DM. For this purpose, twelve lactating cows were used in a block design with a 2 × 2 factorial arrangement of treatments. Manure (feces and urine) was collected from each cow on 2 consecutive days, mixed (1:1) with an inoculum from a bioreactor, and stored (at 20°C) under anaerobic conditions in glass bottles (6 replicates/cow) for 17 wk. Quantity of gas produced was measured daily and sampled to determine gas composition. The PROC MIXED of SAS was used to determine the effects of forage source, LO supplementation and their interaction, and statistical significance was declared at $P \leq 0.05$. Interactions between forage source and LO supplementation were not significant ($P \geq 0.16$) for the measured variables. Compared to manure from cows fed RC-based diets, manure of cows fed CS-based diets emitted more ($P < 0.01$) CH_4 (182 vs. 118 L/kg of organic matter, respectively) and CO_2 (134 vs. 91 L/kg of organic matter, respectively). Emissions of CH_4 and CO_2 from manure also increased ($P \leq 0.05$) by 15% and 11% for CH_4 and CO_2, respectively, when cows were fed LO-supplemented diets compared to those fed non-supplemented diets. Organic matter losses were higher ($P < 0.01$) from manure of cows fed CS-based diets compared to manure of cows fed RC-based diets (30.6 vs. 22.5%, respectively). Organic matter losses of manure increased (+ 12%) with the addition of LO to the diets. Thus, it can be concluded that CH_4 and CO_2 emissions and organic matter losses from manure storage are higher if cow are fed CS-based diets compared to RC-based diets, and increase if LO is supplemented to the diet at 4% of dietary DM.

Key Words: manure, CH_4 emissions, forage source, linseed oil

1506 (W217) Life cycle assessment of heavy pig production in a sample of Italian farms.
G. Pirlo[*1], S. Carè[2], G. Della Casa[2], R. Marchetti[2], G. Ponzoni[2], V. Faeti[2], V. Fantin[3], P. Msoni[3], P. Buttol[3], and F. Falconi[4], *[1]Consiglio per la Ricerca e Sperimentazione in Agricoltura, Cremona, Italy, [2]Consiglio per la Ricerca e Sperimentazione in Agricoltura, San Cesario S/P, Italy, [3]ENEA, Bologna, Italy, [4]LCA-Lab, Bologna, Italy.*

The purpose of this study was to estimate the environmental impact of breeding and fattening of heavy pig used for Italian cured ham production. For this purpose, a life cycle assessment (LCA) was applied to two samples of four breeding farms and of eight fattening farms. The functional unit was 1 kg of body weight of fattened pig. The system was subdivided into breeding and fattening phases. The following impact categories were analyzed: global warming (GW), abiotic resource depletion (AD), photochemical ozone formation (*P*O), acidification (AC), and eutrophication (EU). Reference units were kg of CO_2eq for GW, kg of Sbeq for AD, kg of C_2H_4eq for PO, kg of SO_2eq for AC, and kg of PO_4^{3-}eq for EU. System boundaries included the following farm activities: 1) on-farm energy consumption (EC); 2) manure management (MM); 3) manure application (MA); 4) on-farm feed production (ONFP); 5) off-farm feed production (OFFP); 6) enteric fermentation (ENF); and 7) transports (TR). Average final body weight was 167 ± 5.2. LCA was performed with the support of SimaPro 7.3.3 software. The average environmental impacts associated with 1 kg of fattened pig body weight were: GW 3.43 kgCO_2eq, AD 3.13 E-3 kg Sbeq, PO 1.78 E-3 kg C_2H_4eq, AC 5.37 E-2 kg SO_2eq, EU 3.20 E-2 kg PO_4^{3-}eq. Percentage contribution of breeding and fattening phases to GW, AC, PO, AC, and EU were: 30 and 70; 23 and 77; 31 and 69; 37and 63; 30 and 70, respectively. Normalization analysis showed that the major contributions to the environmental impact of 1 kg of fattened pig body weight come from GW, AC and EU, whereas AD and PO are negligible.

Key Words: heavy pig, life cycle assessment, sustainability

1507 (W218) Control of water consumption in swine barns: One step-closer to real time management.
C. Pineiro*, P. Castro, J. Morales, and G. Montalvo, *PigCHAMP Pro Europa, Segovia, Spain.*

Providing enough quality water is essential for good livestock husbandry. Given that drinking water needs are farm- and management-specific, water-metering equipment to obtain accurate measurements of water use should be applied in each location. The aim of this study was to use new technologies to monitor and predict daily water consumption of fattening pigs. To monitor water consumption, a real-time sensor monitoring system was installed and set in the fattening unit of

one Spanish commercial swine farm. The fattening unit consisted of two buildings, both including about 1000 pigs. Each building was filled with one-only batch of pigs, 60 d of life at the entrance. Pigs were allotted in pens of 10 pigs, with a stock density of 0.70 m^2/pig, natural ventilation, partly slatted concrete flooring and one hopper and one cup drinker per pen. Feed and water were available ad libitum. The metering system consisted in one flow and one temperature sensors, connected to a processing unit which polled the data from these devices and uploaded it to the database. Four batches of pigs were followed up in each building, registering water intake, room temperature and daily control of mortality and health. Water consumption was daily calculated per pig from 60 to 150 d of life. Simple linear regression was conducted to predict water intake in L per animal and day from age in days using the REG procedure of SAS. As expected, water consumption was highly correlated to age (r square = 0.72). In the experimental farm where this measurement was conducted, the most statistically valid equation to predict water consumption was y = 0.0324x– 0.2081, where y is individual daily water intake (L) and x is age in days. Therefore, an average water consumption range of 1.73 to 4.65 (at 60 to 150 d of age) L per animal and day was obtained. Values found in bibliography differ significantly among different authors and are higher than the mean values obtained in the present study, being the average difference 22.4% with the lower interval reviewed in the bibliography and 48.9% with the upper one. This system allows monitoring water consumption in a particular facility and then detecting in an early stage any significant deviation of water intake from the expected range. In addition, knowing water consumption in detail also allows ensuring proper dosing rate of medication provided through the watering system.

Key Words: water consumption, monitoring, pigs

1508 (W219) Increasing milk yield affects sustainability of dairy cattle production in terms of cultural energy use efficiency. H. Koknaroglu*, H. Saglam, and O. Koskan, *Suleyman Demirel University, Isparta, Turkey*.

Purpose of this study was to conduct cultural energy analyses of dairy cows having different levels of milk yield. Cultural energy (CE) is the energy other than solar energy needed to produce food and fiber and energy output/input ratios is one of the most useful methods to examine the potential long-term sustainability of various agricultural practices and this analysis is performed to quantify the energy return from products produced relative to the CE invested to produce the product. Study was conducted at a commercial dairy farm, which specialized only in dairying and had 175 heads lactating cow during a production year which covered Dec. 15, 2010, through Dec. 15, 2011. At the farm lactating cows were grouped into four levels according to their milk yield and were fed accordingly. Groups were classified as low (LO), low-intermediate (LI), intermediate (IM) and high (HI). At the first visit to the farm a file that recorded milk production of each cow and number of lactating cows per group was formed and these records were recorded for every day. Feed intake of cows was also recorded every day. Cultural energy used for feed and other production inputs was derived from their corresponding feed consumption and resource expenditure and their corresponding values from literature. Energy value of the milk comprised the output. Total cultural energy expenditure increased as milk yield increased ($P < 0.05$). Cultural energy expended for feed constituted more than half of the total cultural energy expenditure and increased as milk yield increased ($P < 0.05$). Cultural energy expended per kg milk and per Mcal protein energy decreased as milk yield increased and was lowest for HI group ($P < 0.05$). Energy use efficiency defined as the Mcal input/Mcal output was better for HI and worse for LO and as milk yield increased energy use efficiency became better ($P < 0.05$). Results show that higher yielding lactating cows convert cultural energy into food energy better than lower yielding cows. Thus optimum milk yield not interfering cows' health should be sought for sustainable dairy production.

Key Words: dairy cattle, milk yield, sustainability, cultural energy

1509 (W220) Effect of astaxanthin production by the yeast *Phaffia rhodozyma* on growth performance, blood profiles, meat quality, and slurry noxious gas emission in broilers. S. Kim, S. D. Upadhaya, and I. H. Kim*, *Dep. of Animal Science, Dankook University, Cheonan, South Korea*.

A ban on specific antibiotic growth promoters in animal diets was introduced in the world from 1980s, on the basis of the Precautionary Principle. A prospective alternative to antibiotics that is currently being evaluated is yeast and its derivative products. *Phaffia rhodozyma* is discovered from the yeast that is strikingly different from the other pigmented yeasts in producing the carotenoid pigment astaxanthin. Astaxanthin exhibits a wide variety of biological activities, including antioxidative, anti-*Helicobacter pylori*, anticancer and anti-inflammatory effects in animals. A total of 432 1-d-old male broilers (Arbor Acres) were used in a 29-d experiment and each dietary treatment consisted of nine replicate cages, with 16 broilers per replicate. Birds were randomly allotted to 1 of 3 corn-soybean meal based diets supplemented with 0 mg (CON, basal diet), 1000mg (TRT 1, CON + astaxanthin production 0.1%) or 2000mg (TRT 2, CON + astaxanthin production 0.2%) per kg feed, giving an intake of approximately 0 mg, 2.3 mg, and 4.6 mg astaxanthin/kg feed, respectively. All broilers were fed maize-soybean meal-based diets that were formulated to meet or exceed the National Research Council (1994), nutrient recommendations. The broilers were weighed and feed intake were recorded on d 14 and 29 for calculating BW gain (BWG), feed intake (FI), and feed conversion ratio

(FCR). At d 29, 2 birds were randomly selected from each replication (18 broilers per treatment) and slaughtered by cervical dislocation for meat quality. All data were subjected to GLM procedures of SAS (1996) as a randomized complete block design, with pen as the experimental unit. Differences among treatments were separated by Duncan's multiple range tests; $P < 0.05$ was considered statistically significant. The inclusion of astaxanthin linearly improved ($P < 0.05$) body weight gain in the phase 2 (969, 989, 1024 g; 15~29 d) and during the overall experimental period (1377, 1401, 1439 g; 1~29 d).No significant linear effects were observed in the red blood cells, white blood cells, and lymphocytes in response to TRT1 and TRT2 ($P > 0.05$). The ammonia emission from slurry obtained from broilers in the CON group was significantly higher than that of slurry obtained from broilers in the TRT1 and TRT2 (17.98 vs. 14.42, 14.32 ppm; $P < 0.05$). Taken together, these results indicated that supplementation with astaxanthin could improve body weight gain and reduced slurry ammonia emission in broilers.

Key Words: blood profiles, broiler, noxious gas emission, *Phaffia rhodozyma*

1510 (W221) Assessing variability in whole-farm environmental impact estimates using a partially-stochastic beef production model. K. A. Johnson, and R. R. White*, *Washington State University, Pullman.*

Environmental impact (EI) studies often aim to identify resource use and greenhouse gas (GHG) emissions from an average production system without accounting for biological variability. These models are frequently used as means to compare EI between systems but they do not account for the variability expected in EI calculations. Our objectives were to develop a partially-stochastic model of beef EI and to use that model to examine implications of increased efficiency through improved calving rate. A whole-system model of beef production EI was adapted to account for the variability in land use, water use and GHG estimates. Variability in animal production parameters was not assessed. Three scenarios were tested: LOW (80% conception), CON (89% conception) or HIGH (100% conception). Projected changes in calving rate were compared with and without accounting for EI ranges. Reported state average crop yield and irrigation values were collected over a 20-yr period and used to represent variability in yield and irrigation estimates. Equations for CH_4 and N_2O were varied by their reported confidence bounds. Land use was expressed in m^2/kg hot carcass weight beef (HCWb), water use was in L/kg HCWb and GHG were calculated as CO_2–equivalents (CO_2e)/kg HCWb. The LOW scenario (Table 1510) had the greatest EI while the HIGH scenario had the lowest. This is in agreement with current literature relating efficiency to EI. When the variability around each environmental estimate was accounted for (Table 1510), the ranges described by the model overlapped considerably for all levels of operation efficiency. As a percentage of the mean, crop yield variability resulted in land use estimates with an error bound of about 200% while GHG and water use varied by about 100%. Variability associated with EI estimates was typically greater than the projected differences between treatments simulated. The variability may be consistent with true biological variability thus before accurate assessments of on-farm management to improve EI can be conducted, better methods to understand and account for the causes of this variability must be developed.

Key Words: environmental impact, variability, beef production

Table 1510. Means and ranges of EI metrics across efficiency scenarios

Scenario	Land Use (m^2/kg HCWb)	Water Use (L/kg HCWb)	GHG (CO_2e/kg HCWb)
LOW	82 (50.1– 246.9)	258.1 (226.9– 328.1)	21.5 (10.4– 34.3)
CON	75 (45.9– 224.5)	265.8 (217.7– 315.0)	19.9 (9.8– 31.7)
HIGH	68 (42.0– 203.3)	258.1 (211.1– 306.0)	18.5 (9.1– 29.3)

1511 (W222) Environmental assessment of a representative grass-finished beef operation in southern Pennsylvania. J. A. Dillon*[1] and C. A. Rotz[2], [1]*Dep. of Animal Science, Pennsylvania State University, University Park,* [2]*USDA-ARS Pasture Systems and Watershed Management Research Unit, University Park.*

The objective of this study was to quantify environmental impacts of a representative grass-finished beef operation in southeastern Pennsylvania. A farm-gate life cycle assessment was conducted using the Integrated Farm System Model to estimate greenhouse gas emissions, reactive nitrogen loss, and water and energy use. Parameters describing the operation were obtained from published survey results of pasture finishing beef producers in the northeastern United States. Cattle were rotationally grazed on 101 ha of perennial cool season grass-legume mixed pasture. Supplementation included silage and dry hay produced on the farm. Alfalfa silage was purchased for winter feeding and the final finishing phase. Net forage production was 652 t DM. The Angus herd consisted of 80 cows, 12 replacement heifers, 60 stockers, and 59 finishing cattle on a spring calving cycle. Calf weaning weight and average mature cow weight were 182 kg and 454 kg, respectively. Cattle were finished at 21 mo of age on high quality pasture and silage, with an ADG of 0.9 kg/d and shrunk body weight (SBW = 96% of live weight) of 477 kg. Simulation results over 25-years of historical weather for Lancaster, PA were sensitive to pasture management. When pastures were limed, average annual carbon footprint was 14.4 ± 0.5 kg CO_2e/kg SBW sold, requiring 27.3 ± 1.9 MJ of energy/kg SBW sold. When lime was not applied to pastures, the average annual carbon footprint was 12.6 ± 0.4 kg CO_2e/kg SBW, requiring 12.6 ± 0.7 MJ of energy/kg SBW. Total water use

(water footprint) for both scenarios was 13,900 ± 1350 L H_2O/kg SBW, and the water footprint excluding rainfall was 41 ± 2 L H_2O/kg SBW. The reactive nitrogen footprint was 91.0 ± 29.5 g reactive N loss/kg SBW. Generating data related to the environmental impacts of grass finished beef production provides a baseline for management decisions intended to improve the sustainability of production systems.

Key Words: grassfed beef, environment, carbon footprint

1512 (W223) A modeling assessment of cow management decisions, sustainability and durability of beef production systems.

R. R. White* and K. A. Johnson, *Washington State University, Pullman.*

Sophisticated calculations of system durability should be incorporated into sustainability assessments. The objective of this study was to assess how cow herd management affected the environmental impact (EI), economic viability and stability of a simulated beef herd. A modeling approach was used incorporating dynamic simulation of cattle genetic improvement with cradle-to-farmgate EI and income over feed costs (IOFC). Two 15-yr systems were simulated, one looking at culling rates of 1, 5, 10, 15, or 20% (CULL) and one assessing culling rate differences with a trauma (random removal of 30% of the breeding herd) occurring in the fifth year (CULL+T). Yearly changes in genetic merit were simulated using Markov Chain Monte Carlo sampling, expected progeny differences and the Key equation. Changes in conception/birth rate, mature weight, offspring daily gain, birth weight, weaning weight and yearling weight were tracked. Land use, water use and greenhouse gas emissions (GHG) and IOFC per kg hot carcass weight beef (HCWb) produced were calculated annually and yearly change was compared across culling levels. Trauma effects were calculated by interpolating across the points where the trauma occurred and calculating the cumulative difference between the CULL+T and interpolated lines. In the CULL scenario, the 15% cull rate resulted in the largest average annual improvement in EI and IOFC. Average yearly reductions in land, water and GHG were 2.4 ± 5.7 m^2/kg HCWb, 29 ± 77 L/kg HCWb and 0.26 ± 0.53 kg CO_2–equivalents (CO_2e)/kg HCWb. Annual change in IOFC was $0.03 ± $0.09/kg HCWb. In the CULL+T scenario, a 2-yr system depression occurred, and IOFC and EI were compromised. Culling at 10% was the least stable option; beef produced during the 2-yr trauma period had greater land use, water use and GHG (4.0 m^2/kg HCWb, 420 L/kg HCWb and 3.74 kg CO_2e/kg HCWb) compared with the no trauma line. Culling at 5% was the most stable treatment; environmental changes were only 3.4 m^2/kg HCWb, 374 L/kg HCWb and 3.26 kg CO_2e/kg HCWb. Culling at 1% was the most economically stable treatment; IOFC decreased $0.27/kg HCWb, substantially lower than losses seen with 10 or 15% culling (-$0.32/kg HCWb). Management that best optimized EI and IOFC did not always result in the most durable system. This model presents one framework for assessing durability that is applicable to multiple cow management decisions.

Key Words: cow-calf, sustainability, durability

1513 (W224) Nitrogen excretion from beef cattle for 6 cover crop mixes as estimated by a nutritional model.

E. E. Grings*, A. Sackey, M. J. Hansen, V. Owens, D. Beck, and P. Sexton, *South Dakota State University, Brookings.*

The objective of this study was to predict fecal and urinary N excretion for different maturities of beef cattle using model simulations based on compositional analysis of cover crop mixes. Two replicates of six forage mixes containing differing legumes with and without rape were grown under dryland conditions at Dakota Lakes Research Farm near Pierre, SD, in 2010 and 2011. Samples were analyzed for DM, CP, soluble CP, ADF, NDF, acid detergent insoluble CP, neutral detergent insoluble CP, lignin, starch, simple sugars and crude fat. Data was entered into the Large Ruminant Nutrition System model (LRNS) for estimation of N excretion. Two animal scenarios were analyzed: a non-lactating, pregnant beef cow and replacement beef heifer. Dry matter intake was set to 2.33% of BW for all simulations. The experiment was a split-plot arrangement of a randomized complete block with animal type and cover crop mixture as the whole plot and harvest date as the sub-plot. Forage mix and harvest date were treated as fixed factors and replications were considered random. Student's *t* test was used to separate mean effects when an *F* test was significant ($P = 0.05$). Crude protein concentrations of forage mixes were always at least 14% but CP content was affected by month within year ($P < 0.01$). Predictions of N utilization, except kg/d of fecal N excreted, were affected by forage mix. Fecal N excretion ranged from 33.6 to 43.7% and urinary excretion from 52.5 to 58.8% of N intake. Predicted N intake varied by month within year due to varied CP concentration of the mixes. Differences in N intake resulted in difference in the amount of predicted N excreted (kg/d) for cows, but not heifers. The predicted percentage of N intake excreted in feces did not differ by animal maturity. There was an animal maturity by month within year interaction for urinary excretion both when expressed as total kg/d excreted and percentage of N intake. Urinary N excretion varied from a low of 43.8% of intake for heifers to a high of 66.4% for cows. These types of estimates may be useful to make assessments about N flows in crop-livestock systems.

Key Words: forage, nitrogen, beef cattle

1514 (W225) Effect of crude glycerin associated with energy sources on enteric methane emission from finishing Nellore bulls on pasture in the dry season. A. José Neto*[1], L. G. Rossi[2], A. F. Ribeiro[1], B. R. Vieira[1], E. E. Dalanttonia[5], J. Duarte Messana[2], E. Garbin Sgobi[2], and T. T. Berchielli[1], *[1]Universidade Estadual Paulista "Julio de Mesquita Filho", Jaboticabal, Brazil, [2]Universidade Estadual Paulista, Jaboticabal, Brazil.*

The objective of this study was to evaluate the enteric methane emission, average daily gain (ADG) and daily carcass gain (GC) of finishing Nellore young bulls maintained on tropical pasture during the dry season and supplemented with 28% crude glycerin (CG) in the supplement (DM basis) and replacing corn or soybean hulls, with or without a source of oil. Thirty six Nellore young bulls with 510.02 ± 40.66 kg average initial BW were distributed in a completely randomized design (three animals per paddock and three paddocks per treatment) with four experimental treatments and nine replicates in a 2 × 2 factorial arrangement (high or low starch, with or without a source of oil). Paddock was the experimental unit, and the model effects included each treatment. The animals were raised (finishing phase) *Brachiaria brizantha* cv. Xaraés in the dry season (June to October 2013) with the treatments supplemented at the rate of 1000 g/100 kg BW. The supplements were: T1, CG with high starch (corn), T2, CG with low starch (soybean hulls), T3, CG with high starch and a source of oil (corn and soybeans) and T4, CG with low starch and a source of oil (soybean hulls in soybean grain). The sulfur hexafluoride SF_6 tracer method was used to measure eructated CH_4. Average daily gain (ADG) was obtained by weighing animals at the beginning and end of methane measurement period (28 d). The animals were slaughtered at d 133 of the trial with determined carcass weight. Data were analyzed using the PROC GLM procedure of SAS with significance level at $P < 0.05$ including daily carcass gain (GC, kg d^{-1}) and average daily gain (ADG, kg d^{-1}) of the animals. Methane emission was expressed per year (kg CH_4 yr^{-1}), per day (g CH_4 d^{-1}), per kilogram of carcass produced (kg CH_4 kg CAR^{-1}) and per kilogram of average daily gain (kg CH_4 kg ADG^{-1}). Differences were not detected ($P > 0.05$) between treatments with average values of 0.65 kg d^{-1}, 0.68 kg d^{-1}, 47.22 kg yr^{-1}, 129.37 g d^{-1}, 0.20 kg CH_4 kg CAR^{-1} and 0.25 kg CH_4 kg ADG^{-1}, respectively. The average daily weight and enteric methane emission of Nellore bulls on pasture was not affected by supplementation of crude glycerin.

Key Words: beef cattle, glycerol, greenhouse gas

1515 (W226) Enteric methane emission from beef cattle fed diets containing crude glycerin associated with energy sources. L. G. Rossi[1], A. José Neto*[2], B. R. Vieira[2], E. E. Dalanttonia[2], A. S. Gómez I[2], and T. T. Berchielli[2], *[1]Universidade Estadual Paulista, Jaboticabal, Brazil, [2]Universidade Estadual Paulista "Julio de Mesquita Filho", Jaboticabal, Brazil.*

The objective of this study was to evaluate the enteric methane emission of Nellore young bulls finished in feedlot fed diets containing 10% crude glycerin (CG; DM basis) replacing corn or soybean hulls, with or without a source of oil. Twenty eight Nellore young bulls with 395 ± 32 kg of average initial body weight and 20 ± 2 mo were distributed in a completely randomized design with four experimental treatments and seven replications in a 2 × 2 factorial arrangement (high or low starch, with or without a source of oil). The treatments were: T1, CG with high starch (corn), T2, CG with low starch (soybean hulls), T3, CG with high starch and a source of oil (corn and soybeans), and T4, CG with low starch and a source of oil (soybean hulls in soybean grain). All treatments contained 60% corn silage and 40% concentrate. The sulfur hexafluoride SF_6 tracer method was used to measure eructated CH_4. Data were analyzed using the PROC GLM procedure of SAS with significance level at $P < 0.05$. Methane emission was expressed per day (g CH_4 d^{-1}), per kilogram of carcass produced (g CH_4 kg CAR^{-1}) and per kilogram of average daily gain (g CH_4 kg ADG^{-1}). Differences were not detected between treatments for all variables ($P > 0.05$). However, when compared the effects between factors, differences were detected, with average values of 118.74 and 164.40 g CH_4 d^{-1} ($P < 0.001$), 101.93 and 140.78 g CH_4 kg ADG^{-1} ($P < 0.01$), 141.14 and 180.46 g CH_4 kg CAR^{-1} ($P < 0.02$) to the factors with or without a source of oil, respectively. The starch in the diet did not affect enteric methane emission for all variables ($P > 0.05$). However, may be affected when an oil source with crude glycerin is added in diet Nellore young bulls finished in feedlot.

Key Words: environment, glycerol, ruminant

1516 (W227) Using fecal phosphorus, calcium and ash excretion to predict total and inorganic phosphorus intake of beef cattle consuming a forage-based ration. D. D. Harmon*, J. K. Smith, and M. A. McCann, *Virginia Polytechnic Institute and State University, Blacksburg.*

To mitigate the environmental and economic impact of phosphorus (P) supplementation in excess of beef cattle requirements, producers are currently being encouraged to re-evaluate P supplementation strategies. One of the major limiting factors in doing so is that P intake of grazing cattle is generally unknown. The objective of this evaluation was to determine the ability of fecal total P (P_t) and fecal inorganic P (P_i), calcium (Ca) and ash fractions to explain variation in P_t and P_i

intake. Results of dietary and fecal P_t, P_i, Ca and ash analyses were obtained from two previous experiments that quantified P excretion of beef cattle supplemented with P from different dietary sources. Steers included in each of the two experiments were fed a basal ration of low P chopped grass hay (0.10 and 0.13%) and supplemented with increasing levels of dicalcium phosphate (0, 33, 65, 95 g/d) or increasing levels of corn gluten feed (0, 0.5, 1.0, 1.5 kg/d) to provide increasing levels of dietary P that were below, met or exceeded NRC recommended P requirements. Steers in the dicalcium phosphate trial were 304 ± 22 kg BW and steers in the corn gluten trial were 427 ± 79 kg BW. Daily feed intake measurements and total fecal collections were used to quantify P_t, P_i, Ca and ash content (expressed as a percentage of DM) of feed offerings, orts and feces. Values were then used to determine respective nutrient intake and excretion. All statistical analyses were conducted using JMP Pro. Interpretation of the results of an initial factor screening indicated that fecal percentage of P_t, P_i, Ca and ash explained a significant ($P < 0.05$) portion of the variation in P_t and P_i intake. Full four-way factorial regression models were generated to predict P_t ($R^2 = 0.79$; $P < 0.0001$) and P_i ($R^2 = 0.83$; $P < 0.0001$) intake expressed in g per d using the Fit Model procedure. Refinement of the full factorial model using the reverse stepwise personality supports the use of the full factorial design, as removal of higher-order interactions resulted in a reduction of the R^2 value. These results indicate the ability of fecal P_t, P_i, Ca and ash percentages and their interactions to explain the majority of the variation in P_t and P_i intake. These and additional measurements could be utilized to develop a fractional P intake prediction model for beef cattle.

Key Words: beef, phosphorus, prediction

1517 (W228) Influence of low doses tannins extract addition on the presence of *Escherichia coli* in feces of beef cattle. T. D. J. Heras*[1], I. Enriquez[1], B. J. Cervantes[2], S. M. Gaxiola[1], J. A. Romo[1], and R. Barajas[1], *[1]FMVZ-Universidad Autónoma de Sinaloa, Culiacan, México, [2]Ganadera los Migueles, S.A. de C.V., Culiacan, México.*

Feces of twenty bulls 430 ± 4.5 kg (75% Brahman breed with remainder of Brown Swiss or Charolais) fed finishing diets were used to determine the influence of Influence of low doses tannin extract addition on the presence of *Escherichia coli* in feces of beef cattle. From each of four commercial feedlot pens containing 70 bulls, five bulls were randomly selected and moved to squeeze and fecal samples were taken. Feces of five bulls from a common pen were pooled and constitute the experimental unit. Pooled fecal sample were divides in four portions of proximately 60 g (wet basis), one portion was used for DM determination, and remainder three fecal samples by pen were randomly assigned for addition or not tannins extract (TE) as follows: 1) Feces without extra addition (Control); 2) Control plus 0.1008 g of condensed tannins extract (CTE); and 3) Control plus 0.1008 g of hydrolyzable tannins extract (HTE). TE was fed as SilvaTeam (Argentina). Feces was thoroughly mixed and placed on piece of Kraft paper underground 0.70 m outside of pen and covered with a 0.4 × 0.4 × 0.25 cm metal mesh cage, and exposed to feedlot environment during 0, 24, 48 or 72 h. Aliquots from each TE schedule, exposed time and pen were taken, and by triplicate placed in a *E. coli* selective medium and incubated during 24 h at 45°C, after incubation Colonies Former Units (CFU) were counted and transformed to $\log_{10}$CFU. Results were analyzed by ANOVA for a completely randomized design with a 3 × 4 factorial arrangement. Feces DM were 27.27%, and then TE dose was 0.6% of fecal DM. At 0 h, *E. coli* presence was 4.19, 4.08, and 4.28 $\log_{10}$CFU for Control, CTE and CTH, respectively. At 48 h CTE tended ($P = 0.07$) to decrease *E. coli* presence compared with 0 h (4.08 vs. 1.13 $\log_{10}$CFU). At 72 h CTE tended to diminished ($P = 0.07$) *E. coli* in bovine feces with means values of 4.07, 3.22 and 1.76 $\log_{10}$CFU for Control, CTE and HTE, respectively. It is concluded; that the addition of condensed tannin extract at very low concentration could contributes to reduce the *Escherichia coli* population in the feces of feedlot cattle.

Key Words: *Escherichia coli*, bovines, tannins extract

1518 (W229) Phosphorus excretion in beef steers as impacted by increasing levels of dicalcium phosphate supplementation. E. A. Riley, D. D. Harmon*, J. K. Smith, A. L. Zezeski, S. P. Greiner, K. F. Knowlton, and M. A. McCann, *Virginia Polytechnic Institute and State University, Blacksburg.*

Feeding phosphorus (P) to grazing cattle in excess of requirements can lead to increased P in surface water. The objective of this study was to determine the impact of increasing levels of dicalcium phosphate as a supplemental inorganic source of P. Eight Hereford steers, 304 ± 22 kg of BW, were randomly assigned to one of four dietary P treatments in a 4 × 4 replicated Latin square. Steers were fed a ration containing 80 ± 1% chopped grass hay (0.10%P) and 0, 33, 65 or 95 g/d of dicalcium phosphate. All steers were supplemented with 0.79 kg/d beet pulp, 0.23 kg/d rumen-protected fat supplement and 20 g/d trace mineral salt. Diets were formulated to approximate 50, 100, 150, and 200% of dietary P requirement for a growing beef steer. Steers were housed in individual pens and fitted with total fecal collection bags. Each period consisted of a 9-d adjustment period followed by a 5-d collection period. Following the final collection of each period, a 10-mL blood sample was collected via jugular venipuncture and analyzed to determine plasma inorganic P (P_i) concentration. Samples were analyzed for P_i and total P (P_t) using the molybdovanadate yellow and blue methods, respectively. Data were analyzed using the PROC GLIMMIX procedure of SAS with a model that included diet and period. Linear,

quadratic and cubic treatment effects were evaluated using preplanned contrasts. Dietary P increased linearly ($P < 0.05$) across diets at levels of 3.88, 10.45, 16.47 and 22.28 g/d, respectively. Total P excretion increased linearly with increasing dietary P content (7.73, 11.41, 15.50, and 21.51 g/d; $P < 0.05$) as did P_i excretion (3.19, 6.51, 10.50, 14.67 g/d, $P < 0.05$) and thus P_t excretion was highly correlated ($P < 0.05$; $r = 0.94$) with P_i excretion. Apparent P digestibility increased quadratically with increasing dietary P (−110.67, −9.32, 5.83, and 3.75%, $P < 0.05$), with negative digestibility's suggesting dietary P levels below requirement. P solubility ([P_i/P_t] x 100) increased quadratically with increasing dietary P (39.71, 56.64, 66.60, and 67.85%, $P < 0.05$), indicating that the percentage of water soluble P increases when feeding P levels above requirements. Similar to fecal P trends, blood plasma P_i increased linearly with increasing levels of dietary P (6.40, 8.35, 8.72, and 9.19 mg/dL, $P < 0.05$). Beef cattle operations can reduce environmental impacts by closely matching P supplementation to P requirements.

Key Words: beef, phosphorus, excretion

1519 (W230) Estimation of heat production and energy conversion efficiency using real time measurements of methane and carbon dioxide fluxes in mid-lactation holstein cows. A. B. D. Pereira*[1], A. F. Brito[1], and S. A. Utsumi[2], *[1]University of New Hampshire, Durham, [2]Dep. of Animal Science, Michigan State University, Hickory Corners.*

Real time measurements of CH_4 (Q_{CH4}) and CO_2 (Q_{CO2}) fluxes were used in a pilot study to estimate heat production[1] (HP) and energy conversion efficiency in lactating dairy cows. Oxygen utilization (Q_{O2}) was estimated according to the respiration quotient[2]. Eleven multiparous and four primiparous lactating Holstein cows averaging 176 ± 34 DIM, 42.9 ± 6.8 kg of milk yield and 681 ± 48 kg of BW were blocked by DIM, parity, and DMI (as % of BW) and, within each block, randomly assigned to 1 of 2 treatments: restricted intake (RI) (90% DMI) or ad libitum intake (AI) according to a crossover design. Each experimental period lasted 22 d with 14 d for treatments adaptation and 8 d for data and sample collection. Diets contained (DM basis): 40% corn silage, 12% grass-legume haylage, and 48% concentrate. Spot gas measurements were taken in 5-min sampling periods from all cows using a portable automated head chamber system [GreenFeed (GF); C-Lock Inc., Rapid City, SD] with intervals of 12 h between the two daily samplings. Sampling points were advanced 2 h from a day to the next to yield 14 gas samplings/cow over 7 d to account for diurnal variation in Q_{CH4} and Q_{CO2}. Data were analyzed using the Fit Model procedure in JMP, and least square means are reported. Cows on RI converted more feed gross energy[3] into milk energy[4] (28.3 vs. 27.0%, SEM = 0.63; $P = 0.04$) and more DMI into metabolizable energy[5] than AI cows (11.8 vs. 11.3 MJ/kg of DMI; SEM = 0.22 $P = 0.02$). Conversely, RI cows yielded more HP/kg of DMI (6.65 vs. 6.36 MJ/kg; SEM = 0.18; $P = 0.04$). Our results suggest that the proposed methodology has potential to identify more efficient dairy cows according to real time measurements of Q_{CH4} and Q_{CO2} using the GF.

Equations used for estimations:

[1]Estimated
$$HP_{MJ/cow/d} = [(3.86 \times Q_{O2}) + (1.2 \times Q_{CO2}) - (0.518 \times Q_{CH4})] \times 4.184/1000 \text{ (Brouwer, 1965)}$$

[2]$Q_{O2}/Q_{CO2} = 0.95$ (Madsen et al., 2010)

[3]Gross energy
$$\text{intake}_{MJ/cow/d} = [\text{dietary } CP_{\%} \times DMI_{kg} \times 17 \times 0.6] \times 4.184 \text{ (IPCC, 2006)}$$

[4]Milk
$$\text{energy}_{MJ/cow/d} = [(0.384 \times fat_{\%}) + (0.223 \times protein_{\%}) + (0.199 \times lactose_{\%}) - 0.108] \times \text{milk yield}_{kg/cow/d} \text{ (AFRC, 1993)}$$

[5]Metabolizable
$$\text{energy}_{MJ/cow/d} = HP + \text{Milk energy} \pm (19.99 \times \text{kg of mobilized weight}) \text{ (AFRC, 1990)}$$

Key Words: energy conversion efficiency, heat production, GreenFeed

1520 (W231) Effect of dietary nitrate and organic copper supplementation on dairy enteric methane and nitrous oxide emissions. S. J. Werth*[1], Q. Wang[1], C. J. Neumeier[1], G. Getachew[1], D. H. Putnam[1], A. R. Castillo[2], and F. M. Mitloehner[1], *[1]University of California–Davis, Davis, [2]University of California Cooperative Extension, Merced.*

Previous research on nitrate (NO_3^-) supplementation in dairy cattle diets demonstrated that NO_3^- is effective in decreasing methane (CH_4) production; however, it also induced nitrous oxide (N_2O) production under the rumen simulated conditions. One possible strategy to mitigate concomitant N_2O emission is by enhancing the activity of nitrous oxide reductase (N_2OR) to increase the reduction of N_2O to nitrogen gas (N_2). Nitrous oxide reductase is a metalloenzyme with one enzyme that contains 12 copper (Cu) atoms to be fully active. Copper availability under rumen condition is typically low, which could impede N_2OR activity and therefore the reduction of N_2O to N_2. Organic (OG), compared to inorganic (IN) Cu, might have a higher availability to microbes under rumen conditions. Organic Cu forms strong chelation complexes with small organic compounds, which renders the Cu complex high stability under the rumen environment (Stevenson, 1994), this may result in higher availability of OG Cu. The present study investigated the effect of OG vs. IN Cu on

decreasing NO_3^- induced N_2O production in the simulated rumen using in vitro gas production systems. Gas and liquid samples were obtained from the system every two-hours and were analyzed for carbon dioxide, CH_4, N_2O, NO_3^-, nitrite, and ammonium (NH_4^+) concentrations. Nitrate was totally consumed after 8h. Nitrate decreased ($P < 0.01$) ruminal CH_4 by 30.1% but increased ($P < 0.001$) N_2O production from 0 to 7.1 uL/g DM. Organic Cu was effective in decreasing ($P < 0.05$) NO_3^- induced N_2O production by 24.7% during enteric fermentation. Ammonium concentration in the rumen fluid was lower ($P < 0.01$) with the supplementation of NO_3^- compared to urea especially during the early incubation period. In summary, NO_3^- and OG Cu feeding decreased ruminal CH_4 and N_2O production concomitantly although total greenhouse gas gasses were not affected by OG Cu supplement.

Key Words: cattle, greenhouse gas, nitrous oxide reductase

1521 (W232) Influence of tannins extract addition on in vitro gas production of feces from beef cattle. R. Barajas*, E. X. Murillo, N. Castro, and E. A. Velazquez, *FMVZ-Universidad Autónoma de Sinaloa, Culiacan, México.*

Feces of 15 bulls 392 ± 5.1 kg (75% Brahman breed with remainder of Brown Swiss or Charolais) fed finishing diets were used an experiment to determine the influence of tannins extract addition on in vitro gas production of feces from beef cattle. From each of three commercial feedlot pens containing 72 bulls, five bulls were randomly selected and moved to squeeze and fecal samples were taken. Feces of five bulls from a common pen were pooled and constitute the experimental unit. Pooled fecal sample were divides in three portions of proximately 200 g (wet basis), one portion was used for DM determination, and two remainder fecal samples by pen were randomly assigned to one of two treatments: 1) Feces without extra addition (Control); 2) Control plus addition of 2 g of a tannins extract/100 g of wet feces (TE). Tannins extract were proportioned as SilvaFeed Bypro (SilvaTeam, Argentina), a premix integrated mainly for condensed tannin from quebracho tree blended with a minor proportion of hydrolyzable tannins from chestnut. Aliquots of 50 g (wet basis) were placed in 600 mL flask (three by treatment), closed and connected with a plastic pipe to a 250 mL glass graduate probet inverted in a water bath. Flask were incubated at 37°C during 24, and gas production was accounted as the amount of water displaced by gas inside of each probet, and was expressed as mL of gas by g of feces DM basis. This procedure was repeated during four consecutive days. Results were analyzed by ANOVA for a complete randomized block design where day run constitutes the block. Fecal dry mater content was 26.9% and dose of tannin extract was equivalent to 7.45% DM basis. The addition tannins extract diminished ($P < 0.001$) in 45% the in vitro gas production respect to Control treatment (8.92 vs. 16.24 mL/g of feces DM). It is concluded, that tannin extract addition could contributes to decreases gas production of feces from finishing beef cattle.

Key Words: feces, gas production, tannins

1522 (W233) Quantification of cephapirin in dairy cow feces and urine using solid phase extraction (SPE) coupled with ultra performance liquid chromatography-tandem mass spectrometry (UPLC/MS/MS). P. P. Ray*[1], K. F. Knowlton[2], C. Shang[3], and K. Xia[3], *[1]Dep. of Dairy Science, Virginia Polytechnic Institute and State University, Blacksburg, [2]Virginia Tech, Blacksburg, [3]Dep. of Crop and Soil Environmental Sciences, Virginia Polytechnic Institute and State University, Blacksburg.*

Antibiotic use in animal agriculture has been under scrutiny for two decades because of the persistency of excreted antibiotics in the environment and their potential contribution to bacterial antibiotic resistance. Cephapirin, a cephalosporin antibiotic, is commonly used for dry cow therapy and other therapeutic treatments in dairy cows. Fecal and urinary excretion of cephapirin could introduce this compound into the environment with land application of manure or runoff from the feedlot or barnyard. To date, however, the environmental loading of cephapirin by the livestock industry remains un-assessed, largely due to a lack of appropriate analytical methods. Therefore, an analytical method was developed and validated to qualify and quantify cephapirin in dairy cow feces and urine. The method includes extraction with phosphate buffer (0.05 M) and methanol at 50:50 (v/v) followed by solid-phase extraction (SPE) clean-up via elution through hydrophilic-lipophilic-balanced cartridges and filtering through 0.2-µm filters. Cephapirin in clarified sample extracts was qualified and quantified using ultra performance liquid chromatography-tandem mass spectrometry (UPLC/MS/MS). The limit of quantification (LOQ) of the developed method was 4.02 ng/g and 0.96 ng/mL for feces and urine, respectively. Recovery of cephapirin from spiked blank feces and urine was 64 to 73% and 81 to 84%, respectively. Intra- and inter-day variation [residual standard deviation (RSD), %] were used to estimate repeatability and reproducibility of the method, and ranged from 7.9 to 8.2% for feces and 3.07 to 9.59% for urine. This method was applied to feces and urine collected from dairy cows within 8 h of cephapirin administration. Trace amounts (ng/g) of the compound were detected in feces and very high concentrations (133 to 480 ng/mL) in urine. The described method is sensitive, accurate, and robust and will advance understanding of the fate and environmental impact of antibiotics used on farms.

Key Words: cephapirin, dairy cow feces and urine, ultra performance liquid chromatography-tandem mass spectrometry

1523 (W234) Method development and application: Solid phase extraction (SPE) clean-up and ultra performance liquid chromatography-tandem mass spectrometry (UPLC/MS/MS) quantification of pirlimycin in dairy cow feces and urine. P. P. Ray*[1], K. F. Knowlton[2], C. Shang[3], and K. Xia[3], *[1]Dep. of Dairy Science, Virginia Polytechnic Institute and State University, Blacksburg, [2]Virginia Tech, Blacksburg, [3]Dep. of Crop and Soil Environmental Sciences, Virginia Polytechnic Institute and State University, Blacksburg.*

In the last two decades antibiotic excretion by livestock has received significant attention because of the contribution of excreted antibiotics to bacterial antibiotic resistance. Reliable and accurate quantification of antibiotics in feces and urine is critical to assess environmental loading of antibiotics by the livestock industry in the effort to maintain or improving the sustainability of animal agriculture. Pirlimycin, a lincosamide antibiotic, is one of the most commonly used antibiotics for the treatment of mastitis in dairy cows. There is no published data on pirlimycin loading to the environment via fecal and urinary excretion, probably due to inadequate methodology to quantify pirlimycin in fecal and urine matrices. Therefore, the objective of this study was to develop and validate an analytical method to qualify and quantify pirlimycin in dairy cow feces and urine. Samples were extracted with methanol+0.05 M phosphate buffer (70:30, v/v). Sample extracts were cleaned using solid phase extraction (SPE) via elution through hydrophilic-lipophilic-balanced (HLB) cartridges and filtering through 0.2-μm filters. Clarified extracts were analyzed for pirlimycin using ultra performance liquid chromatography-tandem mass spectrometry (UPLC/MS/MS). This method was sensitive with a limit of quantification (LOQ) of 1.47 ng/g wet feces and 0.90 ng/mL urine. The developed method recovered 80 to 108% of pirlimycin spiked in feces and recovery was 89 to 98% in urine. Repeatability and reproducibility of the method was estimated by intra- and inter-day variations [residual standard deviation (RSD) %], and ranged from 2.3 to 13% and 2.3 to 14% for feces and urine, respectively. With the application of this method to samples collected in the 10 h following intramammary dosing, pirlimycin was detected at 61.2 to 71.8 ng/g and 153 to 254 ng/mL in feces and urine, respectively. This sensitive, accurate, and robust method can be used to quantify trace amounts of antibiotics in dairy cow feces and urine, and may help in the assessment of fate and environmental impact of antibiotics used on farms.

Key Words: pirlimycin, dairy cow feces and urine, ultra performance liquid chromatography-tandem mass spectrometry

1524 (W235) A larger proportion of grass feed components in the ration was associated with higher methane production rates of dairy cows. C. C. Metges*[1], M. Derno[1], J. Ziessler[1], N. Krattenmacher[2], G. Thaller[3], and B. Kuhla[1], *[1]Leibniz Institute for Farm Animal Biology (FBN), Dummerstorf, Germany, [2]Institute of Animal Breeding and Husbandry, Kiel University, Germany, [3]Christian-Albrechts-Universität, Kiel, Germany.*

Ruminants can utilize feedstuffs which are not in competition with human food. In 10 German Holstein cows, 4 in first (L1; BW 562 kg) and 6 in second (L2; BW 615 kg) lactation, 2 TMR rations fed ad lib were compared in regard to methane production. Ration 1 (R1) contained a mixture of grass silage, grass hay + straw (total of 22% DM), and corn silage (32% DM), and was fed to all cows from 20 to 103 DIM. Subsequently, from 104 to 140 DIM, cows received ration 2 (R2), comprising 41% DM of the grass silage, grass hay + straw mixture, and 18% DM of corn silage. Starch, fat and energy contents of R1 and R2 were 18, 4.5% DM, and 7.2 MJ NEL/kg, and 10, 2.7% DM, and 6.7 MJ NEL/kg, respectively. Water was offered ad lib. Appropriately acclimatized cows were measured in respiration chambers (see citation below) on 99 and 135 DIM for 36 h. The respective rations and water were provided ad lib. DMI, ECM yield, and methane production per d were determined. Data was analysed by PROC MIXED of SAS. DMI did not differ among rations and lactation number ($P > 0.1$). However, ECM was lower with R2 (L1: 23.3. vs. L2: 29.2 kg/d) than with R1 (L1: 30.9 vs. L2: 36.3 kg/d) as well as in L1 than in L2 cows ($P < 0.05$). Methane production was affected by ration but not by BW or lactation number with higher values in cows fed TMR with higher contents of grass components and lower proportions of corn silage (R2 vs. R1: 513 vs.455 L/d; 18 vs. 12 L/(kg ECM * d); 39 vs. 34 L/(kg DM * d); $P < 0.05$). In conclusion, using larger amounts of feedstuffs less in competition with human food, i.e., grass and straw, contributes relatively more to greenhouse gas emissions. The lower ECM yield with R2 was partly due to progressing stage of lactation. Citation: Derno et al. J. Dairy Sci. 92:2804–2808, 2009.

Key Words: dairy cow, starch content, methane emission

1525 (W236) Effect of eco-saline system on some hematological and biochemical parameters in damascus goats raised under semiarid conditions. E. B. Abdalla*, *Faculty of Agriculture, Ain Shams University, Cairo, Egypt.*

The effect of eco-saline system, composed of saline water and salt-tolerant plants, on hematological and biochemical responses of Damascus goats was investigated from August 2009 to June 2010. Forty-eight adult female Damascus goats were

equally assigned randomly into four groups. The first group (G1) fed berseem (*Trifolium alexandrnum*) hay (BH) and drank fresh water (247 ppm total dissolved solids), the second group (G2) fed BH hay and drank saline water (5980 ppm total dissolved solids), the third group (G3) fed salt-tolerant alfalfa (*Medicago sativa*) and drank fresh water and the fourth group (G4) fed alfalfa and drank saline water. Body weight changes, hematological and biochemical parameters were measured. Does of G1, G2, G3 and G4 gained 6.64, 8.2, 4.11 and 5.14 kg, respectively during gestation period. Feeding salt-tolerant plants and drinking saline water was negatively affected ($P < 0.05$) hemoglobin (Hb), mean corpuscular hemoglobin (MCH) and mean corpuscular hemoglobin concentration (MCHC) during different stages of pregnancy. However, packed cell volume (*P*CV %) and erythrocytes cell counts (RBCs) were not affected. Animals on saline water had significantly lower white blood cell counts than goats given fresh water. Values of WBCs increased with advancing pregnancy. Total protein (TP), albumin (A), globulin (G) and albumin/globulin ratio (A/G %) as well as alanine transferase (ALT) concentration of different groups were within the normal ranges reported for goats during different eco-saline systems. However, aspartate transferase was higher in salt tolerant groups. Except for phosphorus, serum minerals were higher in alfalfa groups. Concentrations of aldosterone of does fed salt-tolerant alfalfa were higher significantly than does fed berseem hay. It could be concluded that utilization of salt-tolerant plants as animal feeds in salt affected lands could be an appropriate option for alleviating the desertification problems and providing alternative feed resources, particularly in summer and autumn seasons when the other conventional forage resources are in short supply. Also, these results suggest that saline water can be used as a source of drinking water without any adverse effects on hematological and performance of Damascus goats.

Key Words: salt-tolerant plants, saline water, Damascus goats

1526 (W237) Fibrolytic bacteria isolated from the rumen of North American moose (*Alces alces*).

S. L. Ishaq* and A. D. G. Wright, *University of Vermont, Burlington.*

Fibrolytic bacteria were isolated from the rumen of North American moose (*Alces alces*), which eat a high-fiber diet of browse. It was hypothesized that fibrolytic bacteria isolated from the moose rumen could be candidates to improve fiber degradation and animal production. In vivo, an increase in cellulose degradation can increase weight gain, milk, and wool production. In industrial systems, digestion by microorganisms or enzymes can increase forage digestibility for livestock, improve ensiling, or provide glucose from biomass for bioethanol-production. Thirty-eight isolates were cultured from rumen digesta samples collected in October 2010 in Vermont. Using Sanger sequencing of the 16S rRNA gene, culturing techniques, and optical density, isolates were identified and screened for biochemical properties important to plant carbohydrate degradation. Isolates had the following percent identity to known sequences in NCBI: *Bacillus licheniformis*, 98- 100% ($n = 22$); *Enterococcus fecalis*, 95– 99% ($n = 6$); *Staphylococcus saprophyticus*, 99- 100% ($n = 4$), *B. chandrigarhensis*, 98% ($n = 1$); *B. firmus*, 98% ($n = 1$); *B. flexus*, 100% ($n = 1$); *B. niabensis*, 95% ($n = 1$); *Enterobacter ludwigii*, 99% ($n = 1$), and *Paenibacillus woosongensis*, 98% ($n = 1$). Using a 97% identity cutoff for near full-length 16S rRNA gene sequences, there are 22 novel strains of *B. licheniformis*; one novel strain each of *B. chandrigarhensis*, *B. firmus*, and *B. flexus*; one novel species of *Bacillus*; three novel strains of *Enterococcus fecalis*, two novel *Enterococcus sp*., one novel strain of *Enterobacter ludwigii*; one novel strain of *P. woosongensis;* and four novel strains of *S. saprophyticu.* Isolates were able to digest cellulose ($n = 38$), cellobiose ($n = 34$), xylan ($n = 31$), starch ($n = 25$), carboxymethylcellulose ($n = 24$), and lignin ($n = 20$) under minimal nutritional conditions. Fifteen isolates were able to digest all six carbohydrates tested. Isolates were able to tolerate up to 10% ($n = 17$) salinity, between pH 4.0 ($n = 34$) and pH 10.0 ($n = 33$), and between 20°C ($n = 35$) and 55°C ($n = 36$). Isolates were tolerant to sodium azide ($n = 37$), could reduce potassium tellurite ($n = 3$), metabolize mannitol ($n = 31$), produce indole from tryptophan ($n = 7$), and all isolates could use citrate or proprionate as a sole carbon source, as well as ammonium ions for nitrogen. New, highly efficient species or strains of fibrolytic bacteria could be utilized to improve fiber degradation in ruminants or in industrial applications. The isolates tested showed a wide range of carbohydrate digestion and were able to tolerate adverse growth conditions, making them good candidates for improved fiber digestion in vivo and suitable for high temperature industrial fiber digestion.

Key Words: fibrolytic, bacteria

RUMINANT NUTRITION I

1527 (M241) Metagenomic analysis of the rumen microbiome of dairy cows during the transition period. D. W. Pitta*[1], S. Kumar[1], N. Indugu[1], R. Sinha[2], B. Veiccharelli[1], B. Bhukya[1], and J. Ferguson[1], [1]*University of Pennsylvania, Kennett Square,* [2]*University of Pennsylvania, Philadelphia.*

In the current study we characterized the rumen microbiome of dairy cows belonging to different lactations which were grouped as first lactation (L1; $n = 5$), second lactation (L2; $n = 2$) and third lactation (L3; $n = 2$). The rumen samples were collected using stomach tube method at four time points i.e., 3 wk before the anticipated freshening date (S1), soon after the animal freshened (S2), 4 wk (S3) and 8 wk (S4) into lactation. We pooled the genomic DNA by lactation number (3 lactation groups × 4 sampling times) to yield 12 samples. All animals received the same dry cow ration (CP-14.65%; NDF-43.66%; Starch-21.9%) before calving and the same lactating cow rations (CP-17.21%; NDF-33.14%; Starch-27.19%) post calving. The pooled genomic DNA was subjected to shotgun sequencing on Ion-torrent platform, aligned for contigs using Nextgene and uploaded to MG-Rast server for further analysis. On average 17,000 contigs per sample were obtained and subsequently used for phylogenetic and functional assignments in MG-Rast. Based on the phylogenetic data, both study group and study day tended to have an effect on the community compositions ($P < 0.12$; Permanova test) while study groups differed in their functional profiles ($P < 0.05$; Permanova test). The most abundant bacterial phyla observed were *Bacteroidetes* (60%), *Firmicutes* (20%) and *Proteobacteria* (*7%)* across all communities. As the cows transitioned into lactation, the abundance of *Bacteroidetes* decreased while that of *Firmicutes* increased. The phylum *Proteobacteria* increased in abundance with the onset of lactation and also with increased parity. The abundance of archaeal communities were found to be higher in the dry period but reduced at the onset of lactation. Both carbohydrate and protein metabolism were the most predominant functional activities with a progressive increase ($P < 0.1$) in protein utilization from L1 to L3 dairy cows. Differences also occurred in the carbohydrate and protein metabolism before and after the onset of lactation ($P < 0.05$). This study is the first report to demonstrate distinct shifts in both phylogenetic and the associated metabolic activity in both primiparous and multiparous dairy cows in their transition period.

Key Words: dairy cows, transition period, rumen microbiome, Ion-torrent, metabolic potential

1528 (M242) Peripartal supplementation of Smartamine M has positive effects on blood neutrophil activation in dairy cows. J. S. Osorio[1], P. Ji[2], J. K. Drackley[3], D. N. Luchini[4], and J. J. Loor*[5], [1]*University of Illinois, Champaign,* [2]*William H. Miner Agricultural Research Institute, Chazy, NY,* [3]*University of Illinois, Urbana,* [4]*Adisseo S.A.S., Alpharetta, GA,* [5]*University of Illinois, Urbana-Champaign, Urbana.*

An effective immune response relies on efficient activation of polymorphonuclear neutrophils (*P*MN). We evaluated mRNA expression of genes associated with metabolism of Met, glutathione, and glucose as well as inflammation, cellular receptors, and oxidative stress in PMN during the peripartal period. Twenty-eight multiparous Holstein cows in a randomized complete block design were fed a controlled-energy diet (CE, $n = 9$; 1.24 Mcal/kg DM; high-straw) during the dry period (approximately 50 d), switched to a moderate-energy (ME, $n = 9$; 1.54 Mcal/kg DM) during the last 21 d before calving, or ME plus Smartamine M (SM, $n = 10$; Adisseo France S.A.S.). After calving all cows received the same lactation diet (1.75 Mcal/kg DM). The SM (0.07% of DM) was top-dressed over the ME diet from -21 through 30 DIM. Daily dry matter intake (DMI) and milk yield were recorded. Whole blood leukocyte phagocytosis (Phagotest) was assessed and RNA from PMN was extracted from samples collected at -10, 3, and 21 DIM. Data were analyzed using the PROC MIXED of SAS. Although prepartal DMI was not affected ($P = 0.21$) by diet, postpartal DMI was lower ($P < 0.005$) in ME than CE and SM. Milk yield was also lower ($P < 0.05$) in ME than CE and SM. There was a greater ($P < 0.001$) phagocytosis in CE cows than ME and SM. Although phagocytosis decreased ($P = 0.02$) from -10 to 21 DIM regardless of treatment, there was a trend ($P = 0.10$) for an increase in phagocytosis in SM. The selectin L (*SELL*) mRNA expression was greater in SM cows at 21 DIM than CE ($P < 0.001$) and to a lesser extent ($P = 0.11$) than ME. In fact, *SELL* increased ($P < 0.001$) in SM cows from -10 to 21 DIM, while it decreased ($P = 0.006$) in CE and was unchanged ($P = 0.87$) in ME. The diet×time effect ($P = 0.005$) for superoxide dismutase 2 (*SOD2*) expression was associated with greater ($P < 0.06$) expression at 21 DIM in SM than CE and ME cows. This was reflected in a linear decrease of *SOD2* expression in CE ($P < 0.001$) and ME ($P = 0.001$), while it remained unchanged in SM ($P = 0.65$). The lower performance in cows fed ME might be related to impaired neutrophil activation, which appears to have been corrected by SM supplementation.

Key Words: immune function, transition cows, methionine

1529 (M243) Effect of a limited supply of phenylalanine, threonine, and tryptophan on mammary metabolism of dairy cows. I. H. Iroshan[1], H. Lapierre[*2], and L. Doepel[1], [1]*University of Calgary, AB, Canada,* [2]*Agriculture and Agri-Food Canada, Sherbrooke, QC, Canada.*

Mammary metabolism is altered by deletion of essential AA (EAA) from an abomasal infusion of a total AA mixture. The objective of this study was to examine the effect of a limited supply of Phe, Thr and Trp on mammary uptake of AA and energy substrates. Five Holstein cows (63 ± 1.6 d in milk) in second lactation were used in a 5 × 5 Latin square with 10-d periods. The diet supplied 100% of net energy and 70% of metabolizable protein requirements based on NRC recommendations. Treatments were abomasal infusions of water (CTL), all AA with casein profile (TAA), TAA without Phe (No-Phe), TAA without Thr (No-Thr), and TAA without Trp (No-Trp). Mammary AA and energy substrate uptake was determined from arterio-venous differences (AV-diff) of 6 blood samples collected every 2 h on d 10, with mammary plasma flow (MPF) estimated using the Fick principle (*P*he+Tyr). Treatment differences were determined using contrasts, comparing each treatment to TAA. Arterial concentrations of Phe, Thr, and Trp decreased ($P < 0.01$) with their respective deletions. The mammary gland responded to a deficiency of Phe and Thr by reducing milk protein secretion through different mechanisms. With No-Phe, Phe uptake decreased mainly through a reduction ($P < 0.01$) of AV-diff as MPF only numerically increased. When Thr was deficient, MPF increased by 32%, and despite a large decreased ($P < 0.01$) AV-diff, Thr uptake only numerically (13%) decreased. Mammary uptakes of acetate, β-hydroxybutyrate, glucose and lactate were not affected by treatments. A limited supply of Trp had minimal impacts on mammary metabolism.

Key Words: amino acids, mammary metabolism, dairy

1530 (M244) Effects of supplementing rumen-protected met and lys on diets containing soybean meal or canola meal in lactating dairy cows. G. A. Broderick[*1], and A. Faciola[3], [1]*U.S. Dairy Forage Research Center, Madison, WI,* [2]*University of Wisconsin–Madison, Madison,* [3]*University of Nevada, Reno.*

Previously, replacing solvent soybean meal (SBM) with equal CP from canola meal (CM) was found to increase milk yield in lactating dairy cows by about 1 kg/d. We tested whether supplementing rumen-protected Met and Lys (RPML) would improve milk and protein yield in cows fed either CM or SBM. Sixteen lactating Holstein cows were blocked by DIM and parity into 4 squares of 4 cows each in a replicated 4 × 4 Latin square. There was a 2 × 2 arrangement of treatments: equal CP supplemented as either SBM or CM, with or without added RPML to provide 10 g absorbed Met/d (Mepron) plus 22 g absorbed Lys/d (AminoShureL). Cows within squares were randomly assigned to treatment sequences and fed experimental diets for 3-wk periods before switching diets. All diets contained (DM basis) 41% alfalfa silage, 25% corn silage, 2.3% mineral-vitamin premix, 1.4% ground shelled corn and 17% CP. Soybean meal diets contained 22% high moisture corn, 8.7% SBM and 28% NDF; CM diets contained 19% high moisture corn, 11.7% CM and 30% NDF. Data from the last week of each period were analyzed using the PROC MIXEDs of SAS; LS-means are reported in the table. Replacing SBM with CM increased DMI ($P = 0.04$) and tended to increase yields of energy-corrected milk and fat ($P \leq 0.09$), but there were no other affects on production ($P \geq 0.15$). Supplementing with RPML did not influence intake or yield ($P \geq 0.15$) and no significant of protein x RPML interactions were detected ($P \geq 0.15$). These results tended to support previous findings of improved milk yield on CM versus SBM. However, under the conditions of this trial, there were no effects of supplementing with rumen-protected Met plus Lys on either protein source.

1531 (M245) Determination of the comparative bioavailability of lysine in two rumen-protected lysine products using the in vivo plasma lysine response method. H. A. Tucker*[1], M. Miura[2], I. Shinzato[3], C. S. Ballard[1], and H. M. Dann[1], *[1]William H. Miner Agricultural Research Institute, Chazy, NY, [2]Ajinomoto Co., Inc., Kawasaki, Japan, [3]Ajinomoto Heartland Inc., Chicago, IL.*

The objective of this study was to use the commercially available rumen-protected lysine (RPL) AjiPro-L (AJI; Ajinomoto Heartland, Inc.) to estimate relative bioavailability of a second generation RPL product (A2G; Ajinomoto Heartland, Inc.). Ten multiparous lactating Holstein cows (109 ± 8 d in milk (DIM)) housed in a tie-stall facility were used in a replicated 5 × 5 Latin square design with 7-d periods. Cows, blocked by DIM and milk production, were assigned to treatment sequence. A common basal diet formulated to meet lysine (Lys) requirement, prepared once daily, was fed proportionately at three time points (33.4% at 0500 h, 33.3% at 1300 h, and 33.3% at 2100 h). Treatments included 0 g/d Lys, 75 g/d AJI, 75 g/d A2G, 150 g/d AJI, or 150 g/d A2G and were administered 3x/d 1 h before each feeding time on d 2 through 7 of each period in amounts proportional to feed offered to simulate inclusion in the diet. Blood samples were obtained from each cow on d 6 and 7 of each period from the tail vein at 2-h intervals starting at 0600 h resulting in four samples/cow/d. Resultant plasma was pooled by day and analyzed for amino acid (AA) concentrations. Data were reduced to a period mean and analyzed using the PROC MIXED (SAS, v. 9.2). The REG procedure was used to generate linear regression models for each RPL product using Lys (μmol) and Lys (% total AA (μmol basis)) to determine the slope of plasma Lys in response to treatment. Using the calculated slope for each product, relative estimated bioavailability of A2G was determined using the slope-ratio assay technique. Dry matter intake and milk yield did not differ ($P > 0.10$) among treatments. Plasma Lys was greater ($P < 0.05$) for 150 g/d AJI (93.8 ± 2.9 μmol) and 150 g/d A2G (95.0 ± 2.8 μmol) when compared to 0 g/d Lys (83.6 ± 2.9 μmol). The slope for A2G treatment was numerically greater (0.007; $r^2 = 0.91$) when compared to the slope for AJI treatment (0.005; $r^2 = 0.99$) when expressing the concentration of plasma Lys relative to that of total AA. This resulted in the calculated bioavailability of A2G being 132.1% of the bioavailability of AJI. Both first and second generation AjiPro-L products increased plasma LYS in lactating dairy cows with some comparative advantage for the second generation product.

Key Words: bioavailability, rumen-protected lysine, dairy cow

1532 (M246) Impacts of feeding ruminally protected phenylalanine and/or methionine to early lactation cows fed diets containing high levels of canola meal. N. Swanepoel*[1,2], P. H. Robinson[1], and L. J. Erasmus[2], *[1]University of California–Davis, Davis, [2]University of Pretoria, Pretoria, South Africa*.

The objective of this study was to determine if either Met or Phe was limiting performance of dairy cows fed a ration containing 200 g/kg of diet DM as canola meal (CM). The design used four pens of 320 early lactation (DIM < 125) cows/pen in a 4x4 Latin square with 28 d periods. Treatments were designed to deliver 8.0 and 7.5 g/cow/d of intestinally absorbable Met and Phe, respectively with treatment pens fed ruminally protected (RP) Phe (RPP) and RP Met (RPM), separately or in combination, mixed into the same control TMR based on alfalfa hay, winter wheat and corn silage, almond hulls, corn grain, fuzzy and cracked pima cottonseed and mineral premix. There were no difference in the chemical profiles of the TMR fed to the four treatments with CP, NDF, Fat and Starch amounting to 170, 310, 53, and 193 g/kg DM in the base TMR. There were no changes in plasma AA levels except plasma Met, which increased with both Met treatments, and plasma Trp that decreased with both Phe treatments. DM intake was not affected (avg: 27.6 ± 0.40 kg/d) by feeding either RP AA or the combination. Compared to control, supplemental Met increased milk protein (30.71 vs. 30.18 g/kg; $P < 0.01$) and fat (34.74 vs. 34.16 g/kg; $P = 0.01$) content, while decreasing milk lactose (47.47 vs. 47.80 g/kg; $P < 0.01$) content, thereby shifting milk energy amongst milk components without affecting milk energy output. Even though Phe alone had no effect at all on animal performance, adding it in combination with Met diverted energy away from milk components towards body condition score (BCS) gain, which increased (0.08 vs. 0.04 BCS unit change/28d; $P < 0.01$). Even though the supplemented Phe did not increase plasma Phe levels, or animal performance, it was clearly delivered and biologically active based on the finding that it changed the way that Met was utilized. While results suggest that neither Met nor Phe was a limiting AA in this study, results do suggest that both were bioactive. It may be time to reconsider the limiting AA

concept in lactating dairy cows in favor of accepting that AA may be bioactive to the extent of changing animal performance, even when they are not limiting.

Key Words: urine spot samples, amino acids, allantoin

1533 (M247) Ruminal degradation and intestinal digestibility of crude protein and amino acids and correction for microbial contamination in rumen-undegradable protein.

H. A. Paz Manzano[*1], E. Castillo-Lopez[2], T. J. Klopfenstein[1], and P. J. Kononoff[3], *[1]University of Nebraska-Lincoln, Lincoln, [2]University of Saskatchewan, Saskatoon, Canada, [3]University of Nebraska, Lincoln.*

Two Holstein cows fitted with ruminal and proximal duodenal cannulas were used to determine crude protein (CP) and AA ruminal degradation using an in situ incubation of 16 h and intestinal digestibility using the mobile bag technique (pore size 50 μm). Bacterial contamination of the rumen-undegradable protein (RUP) was corrected using purines or DNA as bacterial markers. The feedstuffs evaluated were: three sources of blood meal (BM1, BM2, and BM3), canola meal (CM), low-fat distillers dried grains with solubles (LFDG), soybean meal (SBM), and expeller soybean meal (ESBM). Data were analyzed as a randomized complete block. Ruminal degradation of CP varied ($P < 0.001$) across feedstuffs, 85.3, 29.8, 40.7, 75.7, 76.9, 68.8, and 37.0 ± 3.93% for BM1, BM2, BM3, CM, LFDG, SBM, and ESBM, respectively. Ruminal degradation of both total essential AA and nonessential AA followed a similar pattern to that of CP. Based on the ratios of AA concentration in the RUP to AA concentration in the original feed, ruminal incubation decreased (ratio < 1; $P < 0.001$) the concentrations of His, Lys, and Trp and increased (ratio > 1; $P > 0.001$) the concentrations of Ile and Met across feedstuffs. Estimations of BCP contamination using purines were 0.75 ± 0.86, 0.65 ± 0.88, 0.55 ± 0.91, 2.50 ± 0.88, 6.45 ± 0.91, 2.61 ± 0.88, 10.8 ± 0.91% CP and using DNA were 0.68 ± 0.86, 0.18 ± 0.88, 0.63 ± 0.91, 4.52 ± 0.88, 2.58 ± 0.91, 1.36 ± 0.88, and 2.49 ± 0.91% CP for BM1, BM2, BM3, CM, LFDG, SBM, and ESBM, respectively. Intestinal digestibility of RUP could not be estimated for BM1, BM3, and SBM due to insufficient recovery of residue. For the remaining feedstuffs, intestinal digestibility of RUP was highest ($P < 0.001$) for ESBM, followed by BM2 and LFDG, and lowest for CM, 98.8, 87.9, 89.7, 72.4 ± 1.40%, respectively. Intestinal absorbable dietary protein was higher ($P < 0.001$) for BM2 compared to CM and LFDG, 61.7, 17.9, and 20.7 ± 2.73% CP, respectively. Ruminal degradation and intestinal digestibility of AA determine the supply of intestinal absorbable AA across feedstuffs. These factors are not constant across AA within feedstuffs and nutrition models need to account for them to increase the accuracy to predict the AA supply to the animal.

Key Words: rumen degradation, intestinal digestibility, amino acids, bacterial CP contamination

1534 (M248) Validation of the bioavailability of the second generation AjiPro-L using the in vivo plasma lysine response method.

N. L. Whitehouse[*1], A. F. Brito[1], A. Crowther[1], A. B. D. Pereira[1], C. G. Schwab[2], I. Shinzato[3], and M. Miura[4], *[1]University of New Hampshire, Durham, [2]Schwab Consulting, LLC, Boscobel, WI, [3]Ajinomoto Heartland Inc., Chicago, IL, [4]Ajinomoto Co., Inc., Kawasaki, Japan.*

Six lactating multiparous Holstein (DIM = 64 to 314) equipped with ruminal cannulas were used in a 6 × 6 Latin square study with 7-d periods. The treatments were: 1) 0 g/d Lys, 2) 60 g/d of infused Lys, 3) 30 g/d of fed Lys from AjiPro-L, 4) 60 g/d fed Lys from AjiPro-L, 5) 30 g/d fed Lys from AjiPro-L 2G, and 6) 60 g/d fed Lys from AjiPro-L 2G. The infusion treatments consisted of Lys-HCl and were infused continuously into the abomasum via the ruminal cannulas. To ensure complete consumption, the AjiPro-L and AjiPro-L 2G were mixed with 1 kg of TMR and placed in tubs in front of the cows 30 min before each of the 3 daily feedings. Blood samples were obtained from each cow on the last 3 d of each period every 2 h, four times daily, from the tail vein, centrifuged, deproteinized, and composited into one daily sample/cow. Deproteinized plasma was analyzed for AA. Data for plasma AA concentrations (μmol basis) were analyzed using the PROC MIXED and PROC REG procedures of SAS. The bioavailability of AjiPro-L, calculated by comparing the slopes of the infused and fed AjiPro-L (Lys as % of total AA), was lower than previous evaluations using the same methodology. The infusion slope observed herein, obtained from two doses (0 and 60 g/d), was larger than those obtained previously, which were obtained using three doses (0, 30, and 60 g/d); this may explain the discrepancies among studies. To increase precision, it is recommended that at least 1 additional dose of infused Lys between 0 and 60 g/d should be used. It is important to note that the slope for the AjiPro-L 2G (i.e., 0.01011; $P < 0.01$) was greater than the slope for the AjiPro-L (i.e., 0.00682; $P < 0.01$) resulting in a 48% improvement in bioavailability of Lys from the AjiPro-L 2G based on the ratio of the 2 slopes. It can be concluded that the bioavailability of Lys from AjiPro-L 2G was better than that from AjiPro-L. Further research is needed to test these 2 RP-Lys products.

Key Words: AjiPro-L, bioavailability, lysine

1535 (M249) Comparison of duodenal nitrogen and amino acid flows in dairy cows fed a corn straw or mixed forage diet. C. Qin[1,2], P. Sun[1], D. P. Bu[*1], J. Q. Wang[1], P. Zhang[2], and P. An[1], *[1]State Key Laboratory of Animal Nutrition, Institute of Animal Science, Chinese Academy of Agricultural Sciences, Beijing, China, [2]Hunan Provincial Key Laboratory for Genetic Improvement of Domestic Animal, College of Animal Science and Technology, Hunan Agricultural University, Changsha, China*.

Knowledge to duodenal nitrogen and amino acid flows may provide guidance to nutritionists with dairy rations. This study was conducted to evaluate the effects of dietary factors that alter ruminal fermentability on duodenal flows of nitrogen and amino acids (AAs). Twenty-four primiparous, lactating, ruminally and duodenally fistulated Holstein cows were used in this study. Cows were randomly assigned to high forage diet (HF, forage:concentrate = 60:40) with Chinese wildrye, alfalfa hay and corn silage as the forage source or low forage diet (LF, forage:concentrate = 40:60) with corn straw as the forage source. This study lasted for 11 wk with 2-wk of preliminary period and 9-wk of trial period. Co-EDTA, Cr_2O_3 and $YbCl_3 \cdot 6H_2O$ were used as indicators in the last 3 wk. Samples were collected in the last three trial days and all samples were kept at -20°C for further analysis. Data were analyzed using the PROC MIXED (SAS 9.1) and expressed as gram per day (g/d). The HF diet had positive effect on flows of duodenal total nitrogen (369.75 and 539.39), Arg (90.53 and 136.20), His (37.65 and 55.97), Ile (100.24 and 150.44), Leu (157.25 and 234.10), Lys (132.31 and 202.80), Met (26.63 and 40.31), Phe (92.81 and 145.96), Thr (79.00 and 123.04), Val (110.39 and 168.14), Asp (183.23 and 277.74), Ser (59.45 and 91.31), Glu (253.40 and 372.30), Ala (118.30 and 178.80), Cys (16.83 and 23.67), Tyr (55.99 and 84.45), Pro (82.58 and 120.45), essential AA (826.82 and 1256.97), non-essential AA (903.03 and 1339.11) and total AA (1729.85 and 2596.08) ($P < 0.05$). Duodenal Gly flow tended to be higher in cows fed with HF diet (133.26 and 190.40, $P = 0.07$). Flows of duodenal bacterial nitrogen (215.93 and 263.27), endogenous nitrogen (37.82 and 37.95) and non-degradable nitrogen (136.35 and 183.61) were not affected by dietary treatments ($P > 0.05$). In conclusion, dietary systems played a role in duodenal nitrogen nutrition flows, and duodenal total nitrogen and amino acid flows were depressed when cows fed a low forage diet.

Key Words: forage pattern, dairy cow, duodenal nutrition flow, nitrogen nutrition

1536 (M250) Comparison of mammary amino acid utilization in dairy cows fed a corn straw or mixed forage diet. C. Qin[1,2], P. Sun[2], D. P. Bu[2], J. Q. Wang[*1,2], P. Zhang[3], and P. An[2], *[1]Heilongjiang Bayi Agricultural University, Daqing, China, [2]State Key Laboratory of Animal Nutrition, Institute of Animal Science, Chinese Academy of Agricultural Sciences, Beijing, China, [3]Hunan Provincial Key Laboratory for Genetic Improvement of Domestic Animal, College of Animal Science and Technology, Hunan Agricultural University, Changsha, China.*

It is reported that changes in mammary amino acid (AA) utilization associate with dietary systems. In this study, we investigated AA transformation efficiency (AATF) from mammary gland to milk production in dairy cows fed different diets. Twenty-four first lactating Holstein cows were used in this study. Cows were randomly assigned to high forage diet (HF, forage:concentrate = 60:40) with Chinese wildrye, alfalfa hay and corn silage as the forage source or low forage diet (LF, forage:concentrate = 40:60) with corn straw as the forage source. This study lasted for 11 wk with 2 wk of preliminary period and 9-wk of trial period. Milk samples, blood in perineal artery and jugular vein were collected on the last morning of the trial, respectively. All samples were kept at -20°C for further analysis. To estimate AATF data were fitted to the model AATF = A/(B*C), where: A (g/d) was milk AA yield; B (g/L) was the concentration difference of plasma AA in perineal artery and jugular vein; C (L/d) was blood flow volume in mammary gland. Data were analyzed by PROC MIXED (SAS 9.1). The results showed that transformation efficiency of Phe increased in cows fed HF diet (0.72 vs. 0.88, $P < 0.01$). We observed that transformation efficiency of Thr (0.77 vs. 0.61), Asp (16.84 vs. 7.62) and Ser (2.01 vs. 1.26) was lower in HF group ($P < 0.05$), and HF diet tended to have a negative effect on non-essential AA transformation efficiency (1.95 vs. 1.45, $P = 0.08$). However, transformation efficiency of Arg (0.35 vs. 0.34), His (1.04 vs. 1.07), Ile (0.57 vs. 0.61), Leu (0.68 vs. 0.72), Lys (0.80 vs. 0.73), Met (0.74 vs. 0.60), Val (0.64 vs. 0.67), Glu (1.81 vs. 2.06), Gly (1.06 vs. 0.99), Ala (0.71 vs. 0.70), Cys (1.09 vs. 2.64), Tyr (0.80 vs. 0.84), Pro (3.75 vs. 3.32), essential AA (0.65 vs. 0.65) and total AA (1.01 vs. 0.97) were not affected by dietary treatment ($P > 0.05$). These results indicated that feeding a high forage diet to cows depressed mammary utilization of some amino acids but improved phenylalanine conversion efficiency.

Key Words: diet system, mammary gland, amino acid utilization

1537 (M251) Plasma L-methionine and supplemental L-methionine precursor responses to rumen administration of a rumen protected DL-methionine source or different levels of 2-hydroxy-4-methylthio-butanoic acid. *G*. I. Zanton*, S. E. Bettis, and M. Vazquez-Anon, *Novus International, Inc., St. Charles, MO.*

The L-enantiomer of methionine (Met) is the form that can be used for biological functions. Supplemental precursors of L-Met such as D-Met or 2-hydroxy-4-methylthio-butanoic acid (HMTBa) must be converted to L-Met to be incorporated into protein. The objective of this study was to evaluate the plasma response of L-Met and supplemental L-Met precursors to a rumen pulse dose of protected DL-Met (Smartamine M, Adisseo, France; RPM) or different levels of HMTBa. Six rumen cannulated Holstein steers (initial BW = 250 ± 6 kg SD) were fed a common basal diet and pulse dosed with different treatments according to a partially replicated Latin square design. Treatments administered to the rumen were 80 (H80), 120 (H120), or 160 (H160) mg HMTBa/kg BW (Provided as MFP feed supplement, Novus International, St. Charles, MO) or RPM at 80 mg DL-Met/kg BW (RPM80); where, based on previous research, H160 and RPM80 were hypothesized to provide similar levels of absorbed Met activity (64 mg/kg BW). Ruminal pulse dose coincided with morning feeding and occurred at t = 0 with 11 plasma samples taken from the coccygeal vein over the ensuing 48 h and analyzed for HMTBa, D-Met, and L-Met. Statistical contrasts were linear and quadratic effects of level of HMTBa and H160 vs. RPM80 with significance declared at $P < 0.05$. Baseline L-Met was not different between treatments averaging 2.75 mg/L; L-Met precursors were not detected in baseline samples. Plasma profiles of L-Met and supplemental L-Met precursors differed between levels and sources ($P < 0.01$). The change in L-Met from baseline area under the response curve through 48 h (AUC) was linearly increased ($P < 0.02$) as HMTBa increased; L-Met AUC for H160 did not differ from RPM80 (128 vs. 147 ± 17 mg·h/L, respectively; $P > 0.40$). Likewise, supplemental L-Met precursor AUC linearly increased as HMTBa level increased; HMTBa AUC for H160 did not differ from RPM80 D-Met AUC (140 vs. 117 ± 11 mg·h/L, respectively; $P > 0.14$). When not separated on a chiral column, D- and L-Met are combined during plasma Met analysis; when analyzed values for D-Met or HMTBa were added to analyzed values for L-Met, there was no difference between AUC for H160 and RPM80 (268 mg·h HMTBa + L-Met/L vs. 264 mg·h D- + L-Met/L ± 24, respectively; $P > 0.90$). It is concluded that supplying a pulse dose of 64 mg methionine activity/kg BW as RPM or HMTBa resulted in plasma L-Met concentrations that were not different.

Key Words: methionine, dairy, bioavailability

1538 (M252) Effects of the ideal profiles of lysine, methionine, threonine, phenylalanine, histidine, and valine on milk protein synthesis gene network expression in bovine mammary epithelial cells. S. Li[1,2], W. Zhao[2,3], A. Hosseini[4], J. X. Liu[1], and J. J. Loor[*2], *[1]Zhejiang University, Hangzhou, China, [2]University of Illinois, Urbana, [3]Northwest A & F University, Yangling, China, [4]University of Bonn, Germany.*

Amino acids (AA) are essential precursors for milk protein synthesis in mammals. In recent years it has become evident that the AA-mediated protein synthesis response within mammary cells is partly regulated through the mTOR pathway. Thus, AA not only are building blocks of proteins but also are one of the key molecules that serve as upstream components of the signaling pathways that regulate protein synthesis. Although the effects of AA on signaling through mTOR in mammary cells have been explored, little is known about the transcriptional response, particularly regarding the 6 essential AA [lysine (Lys), methionine (Met), threonine (Thr), phenylalanine (Phe), histidine (His), and valine (Val)] for which ideal recommendations have been proposed. The specific objective of this study was to investigate how changing the ratio of Lys to Thr, Lys to His, and Lys to Val affected the expression of genes associated with pathways of insulin, mTOR, and Jak2-Stat5 signaling and also glucose and AA transport in MacT cells. Target genes plus three internal controls were measured using qPCR. Triplicate cultures with the optimal AA ratio (OPAA; Lys:Met 2.9:1; Thr:Phe, 1.05:1; Lys:Thr, 1.8:1; Lys:His, 2.38:1; Lys:Val, 1.23:1) plus the mTOR inhibitor rapamycin (OPAARMC, control) or OPAA, 2.1:1 Lys:Thr (LT2.1), 1.3:1 Lys:Thr (LT1.3), 3.05:1 Lys:His (LH3.0), and 1.62:1 Lys:Val (LV1.6) were incubated for 12 h. Compared with OPAARMC the OPAA treatment upregulated SLC1A5, SLC7A5, and RPS6KB1, and downregulated expression of IRS1, AKT3, TSC2, and EEF1A1. Greater expression of SLC1A5, SLC7A5, SLC2A1, SLC2A8, STAT5B, and RPS6KB1 and lower expression of TSC2 and EEF1A1 were observed in response to LT2.1, LT1.3 and LH3.0 compared with OPAARMC. Treatment with LV1.6 as compared with LT2.1, LT1.3 and LH3.0 had similar effects on expression of SLC1A5, SLC7A5, SLC2A1, SLC2A8, STAT5B, and RPS6KB1. In addition, treatment with LV1.6, LH3.0, and LT2.1 compared with OPAA and control led to greatest upregulation of mTOR. However, only LV1.6 up-regulated TSC1 and TSC2 and downregulated EIF4EBP1 relative to OPAA and control. Overall, our study revealed unique effects of essential AA ratios, and particularly Lys:Val, on the molecular phenotype associated with milk protein synthesis regulation in mammary cells.

Key Words: mTOR, nutrigenomics, milk protein synthesis

1539 (M253) Changes in plasma methionine concentrations after administration of two different doses of rumen protected methionine.

P. D. Carvalho[*1], N. E. Lobos[2], M. Z. Toledo[2], E. Trevisol[2], V. G. Santos[2], R. V. Barletta[2], G. M. Baez[2], A. Garcia-Guerra[2], J. N. Guenther[2], A. H. Sousa[2], D. Luchini[3], P. M. Fricke[2], R. D. Shaver[1], and M. C. Wiltbank[1], *[1]University of Wisconsin, Madison, [2]Dep. of Dairy Science, University of Wisconsin–Madison, Madison, [3]Adisseo, Alpharetta, GA.*

Feeding rumen-protected limiting amino-acids, such as methionine (MET), to dairy cows may allow feeding of diets with lower amounts of crude protein while increasing milk protein and feed efficiency. Information on the changes of circulating MET concentrations after feeding may provide valuable information on both its usage and its metabolism, which could then be used by field nutritionists. The objective of the present experiment was to determine changes in plasma MET concentrations after administration of a single bolus of rumen-protected methionine (RPM). Non-lactating, non-pregnant dairy cows (n = 16) weighing 694 ± 16 kg were randomly assigned to three treatments: 1) untreated control (n = 4); 2) bolus containing 10 g of RPM (Smartamine; 6 g of metabolizable MET; n = 6); and 3) bolus containing 20 g of RPM (Smartamine; 12 g of metabolizable MET; n = 6). Blood samples were collected at 12h before treatment, immediately before treatment, and at 6, 12, 18, 24, 36, and 48h after treatment. Plasma was assayed for free amino acid by gas chromatography using a commercial kit (EZ:faast-GC-FID Physiological, Phenomenex). Data were analyzed by repeated measures using the PROC MIXED of SAS. Plasma MET concentrations tended to differ among treatments (P = 0.08) and were greater for cows receiving the 20 g bolus, intermediate for cows receiving the 10 g bolus, and least for control cows (peak average 57.5 ± 0.8μM, 26.9 ± 0.2μM, and 20.3 ± 0.2μM, respectively). Before treatment, all cows had low MET concentrations (21.4 ± 0.5μM), and MET concentrations remained low throughout the experimental period in controls. At 12 and 18h, MET concentrations increased (P = 0.09) by 30% in cows receiving the 10 g bolus (26.5 ± 0.2μM) compared to control cows (20.3 ± 0.1μM); however, cows receiving the 20 g bolus increased more than 100% (50.4 ± 4.1μM) and were greater than either controls (P < 0.01) or cows treated with the 10 g bolus (P < 0.01). By 24 h after treatment, MET concentrations differed among treatments (P < 0.001) and were least for controls (22.7 ± 0.1μM), intermediate for cows receiving the 10 g bolus (23.7 ± 0.1μM), and greater for cows receiving the 20 g bolus (29.6 ± 0.1μM). Methionine concentrations did not differ among treatments (P = 0.85) at 36 and 48 h. Lysine concentrations did not differ among treatments (P = 0.52) and were 143.3 ± 5.2μM, 133.3 ± 5.4μM, and 139.6 ± 6.8μM for controls, cows receiving 10 g of RPM, and cows receiving 20 g of RPM, respectively. In conclusion, plasma MET concentrations were affected by treatment dose and time after treatment. Time after treatment should be considered when evaluating effectiveness of MET supplementation. *Supported by Hatch project WIS01240 and Adisseo USA, Inc.*

Key Words: methionine, dairy cow, amino acids

1540 (M254) A three-step in vitro procedure for evaluating rumen-protected lysine products.

Y. Miyazawa[1], M. Miura[*2], T. Fujieda[2], I. Shinzato[3], S. W. Fessenden[4], and M. D. Stern[4], *[1]Ajinomoto Co., Inc., Kawasaki, Japan, [2]Ajinomoto Co., Inc., Tokyo, Japan, [3]Ajinomoto Heartland, Inc., Chicago, IL, [4]University of Minnesota, St. Paul.*

The three-step in vitro procedure is used for estimating intestinal digestibility of the RUP fraction of feedstuffs. However, rumen protected amino acid products have been evaluated in various ways for estimates of bioavailability. The objective of this study was to propose a three-step in vitro procedure for rumen-protected Lysine products (RPL), which is composed of buffer solutions with enzymes and can be developed as a standardized method to evaluate RPLs. Three grams of six different RPLs were weighed into nylon bag (5 × 7 cm, pore size 53 ± 10 μm). Bags were incubated using a dissolution apparatus for drug evaluation with rotating paddles at 100 rpm at 39°C. Three individual vessels were allocated to each RPL as ruminal, abomasal and duodenal phases, respectively. Modified McDougal's buffer containing lipase (900 mL) was used to simulate ruminal conditions (pH 6.8). A hydrochloride buffer containing pepsin (900mL, pH 2.0) and a phosphate buffer containing pancreatin and gall powder (900 mL, pH ≈ 7.9) were used to simulate abomasal and intestinal conditions, respectively. After a 20-h incubation in ruminal vessels, aliquot samples of solution were taken, and bags containing each RPL were transferred from ruminal to abomasal vessels. These procedures were repeated after a 2-h incubation followed by incubation in duodenal vessels for 8 h; aliquot buffer samples were taken again. Each buffer sample was analyzed for Lys, and amount of lysine escaping dissolution was calculated by subtracting buffer lysine from original feed lysine provided to the assay. Residual Lys under ruminal conditions was compared with extent of in situ ruminal protection. Statistical differences (P < 0.05) were tested by a one-way ANOVA. In vitro ruminal protection measured by this procedure correlated (P < 0.05) with in situ ruminal protection with a correlation coefficient of > 0.9. The RPLs showed various characteristics; high/medium/low ruminal protection and high/low post-ruminal Lys release. However, when pH of the ruminal buffer was reduced, one of the RPLs showed an increase (P < 0.05) in ruminal protection using in vitro procedures (46.2 ± 9.3% at pH 6.8, 90.0 ± 4.0% at pH 6.2, n = 3). Results from this study indicate that a buffer-based three-step in vitro procedure can be a useful tool to evaluate RPLs, but further research is needed to optimize pH of ruminal conditions.

Key Words: rumen-protected lysine, in vitro procedure, rumen pH

1541 (M255) Histidine requirement of dairy cows determined by the indicator amino acid oxidation (AAO) technique. D. R. Ouellet[*1], G. E. Lobley[2], and H. Lapierre[1], *[1]Agriculture and Agri-Food Canada, Sherbrooke, QC, [2]Rowett Institute of Nutrition and Health, University of Aberdeen, UK.*

The indicator AAO technique has been used successfully to quantify AA requirements in pigs and poultry. This technique was used to evaluate His requirement in dairy cows. Six lactating dairy cows were used in a 6 × 6 Latin square design, with 7-d periods. Cows were fed a TMR balanced to provide 110% and 75% of energy and metabolizable protein (MP; 1653 g/d) requirement, respectively. All AA (813 g/d; casein profile), excluding His, were infused into the abomasum to supply 105% of MP requirement. Treatments were abomasal infusion of His at 0, 7.6, 15.2, 22.8, 30.4 and 38.0 g/d, representing 1.50, 1.83, 2.15, 2.46, 2.78, and 3.09% of MP. On d6, [1-^{13}C]leucine was infused intravenously for 5 h (4.0 mmol/h; prime dose 4.0 mmol). Six blood samples were collected every 20 min during the last 2 h of infusion and the isotopic enrichment of plasma keto-isocaproic acid and CO_2 used to estimate whole body (WB) Leu irreversible loss rate (ILR) and oxidation. On d 7, $NaH^{13}CO_2$ was infused (2 mmol/h; prime dose 2.8 mmol) intravenously, with a similar schedule as d 6, to estimate the WB ILR of CO_2. Leucine and CO2WB ILR were not affected by treatments and averaged 126.8 ± 2.15 mmol/h and 23.4 ± 0.98 mol/h, respectively. Yields of milk and milk protein, and Leu oxidation (indicator AAO) all indicated that a His supply of 1.83%MP was sufficient to meet requirement. However, the consistent decrease in plasma concentrations of carnosine (β-alanyl-His dipeptide) below 2.46%MP suggests provision of His from endogenous pools; this could temporarily mask a dietary deficiency. The indicator AAO method is sensitive and provides similar estimates of requirement to those based on milk protein yield. Nonetheless, to accurately estimate His requirements needs consideration of changes in endogenous pools of His.

Key Words: dairy cow, amino acid oxidation, histidine

1542 (M256) Estimation of histidine requirement in lactating dairy cows. H. Lapierre[*1], D. R. Ouellet[2], and G. E. Lobley[3], *[1]Agriculture and Agri-Food Canada, Sherbrooke, QC, [2]Agriculture and Agri-Food Canada, Sherbrooke, QC, [3]Rowett Institute of Nutrition and Health, University of Aberdeen, UK.*

Although in lactating dairy cows, His and Met show similar hepatic and mammary behaviour, with similar concentration in milk, requirement for His has been variously estimated as 2.4% (Doepel et al., 2004, JDS 87:1279), 2.7% (CPM-Dairy) and 3.2% (Rulquin et al., 2001, INRA ProdAnim 14:265) of metabolizable protein (MP) supply. Such variability may be

explained by depletion or replenishment of endogenous pools of His, including intramuscular carnosine and anserine and blood hemoglobin. To test this hypothesis, five multiparous Holstein cows (674 ± 36 kg BW, 92 ± 18 DIM) were used in a 4 × 4 Latin square plus one cow, with 14-d periods. Cows were fed a diet balanced to supply 103% of NEL requirement but only 72% of MP requirement (1610 g/d) providing 34 g/d of digestible His (NRC, 2001). Treatments were abomasal infusion of His at 0, 7.6, 15.2 or 22.8 g/d in addition to a mixture of AA (595 g/d, casein profile). His represented 1.60, 1.95, 2.30 and 2.65% of MP supply, respectively. At the end of each period, six arterial blood samples plus muscle biopsies from the semimembranous muscle were collected. Milk yield plateau was reached at a higher His supply (2.30%MP) than milk protein yield (1.95%MP). Between these supplies, however, milk protein yield could be sustained from depletion of endogenous pools. Observed reductions in muscle carnosine and anserine plus plasma hemoglobin could supply 3.2 g of His/d. Compared with other essential AA, the unique peculiarity that His has additional endogenous labile pools means that depletion and/or replenishment of these pools over short periods may bias estimate of true requirement.

Key Words: histidine, carnosine, dairy cow

1543 (M257) Effects of different protein sources on milk performance and amino acid profile in early lactating dairy cows. X. Q. Zhou[*1,2], D. P. Bu[1], Y. D. Zhang[1], M. Zhao[1], P. Sun[1], and J. Q. Wang[1], *[1]State Key Laboratory of Animal Nutrition, Institute of Animal Science, Chinese Academy of Agricultural Sciences, Beijing, China, [2]Northeast Agricultural University, Harbin, China.*

Protein content of feed plays an important role in dairy amino acid profile of bovine milk protein. This study was aimed to investigate different protein sources on milk production performance and milk amino acid profile. Thirty-two Chinese Hostein dairy cows were blocked based on DIM (60 ± 25 d) and milk yield (31.0 ± 3.17kg/d) and randomly divided into group soybean (diet protein, soybean meal 11.29%, extruded soybean 2.06%, whole cottonseed 10.44%, rapeseed meal 4.19%, beet pulpand 4.16% and cottonseed meal 2.13%) and group non-soybean (whole cottonseed 10.44%, rapeseed meal 9.63%, cottonseed meal 6.71% and beet pulp 7.49%). Two diets contained similar forage with the same concentrate-to-forage ratio of 65:35 (DM basis).Experiment lasted for 12 wk with first 2 wk as adaption period. Milk samples were collected weekly and analyzed for milk composition and amino acid profile. Data were analyzed as repeated measurements using PROC MIXED of SAS. Milk yield, milk protein content, milk fat content, milk protein yield and milk fat yield showed no difference between two groups. Compared with group soybean, Cows in group no-soybean increased DMI (20.31vs 17.43kg/d, $P < 0.01$) and milk Pro content (8.48 vs. 8.37 g/100 g AA, $P = 0.04$) but decreased milk Phe content (5.54 vs. 5.60 g/100 g AA, $P = 0.02$) and BCAA (23.49 vs. 23.68 g/100 g AA, $P = 0.08$), especially Leu content (11.69 vs. 11.88 g/100 g AA, $P < 0.01$) in milk protein. There were no difference on content of EAA, NEAA between 2 groups. Results suggest that soybean meal can be partly replaced by miscellaneous meal (rapeseed meal, cottonseed meal and beet pulp) in diets for lactating dairy cows.

Key Words: protein source, milk amino acid profile, dairy cow

1544 (M258) Lipogenic gene network expression in bovine mammary epithelial cells in response to the "ideal" profile of Lys, Met, Thr, Phe, His, and Val. S. Li[1,2], W. Zhao[1,3], A. Hosseini[4], J. X. Liu[2], and J. J. Loor[*1], *[1]University of Illinois, Urbana, [2]Zhejiang University, Hangzhou, China, [3]Northwest A & F University, Yangling, China, [4]University of Bonn, Germany.*

Amino acids (AA) not only are building blocks of proteins but also are key factors regulating protein synthesis. In regards to milk protein synthesis, the 6 essential AA (EAA) for which ideal recommendations have been proposed are Lys, Met, Thr, Phe, His, and Val. We hypothesized that the essential AA profile could affect the mRNA expression of genes regulating lipogenic gene networks in bovine MAC-T cells. The specific objective of this study was to study how changing the ratio of Lys to Thr, Lys to His, and Lys to Val affects the expression of lipogenic target genes. Triplicate cultures with the optimal AA ratio (OPAA; Lys:Met 2.9:1; Thr:Phe, 1.05:1; Lys:Thr, 1.8:1; Lys:His, 2.38:1; Lys:Val, 1.23:1) plus rapamycin (OPAARMC, control), OPAA, 2.1:1 Lys:Thr (LT2.1), 1.3:1 Lys:Thr (LT1.3), 3.05:1 Lys:His (LH3.0), and 1.62:1 Lys:Val (LV1.6) were incubated for 12 h. The expression of lipogenic gene networks was evaluated via quantitative PCR of 15 genes plus three internal control genes measured using qPCR. Data were log-transformed and statistically analyzed using the GLM of SAS with treatment as a fixed effect and replicate as random effect. The multiple comparisons were corrected using Tukey's and significance set a $P < 0.05$. Responses to LT2.1, LT1.3, LH3.0, and LV1.6 relative to the OPAARMC included greater expression of ACSS2, FABP3, ACACA, FASN, SCD, LPIN1, INSIG1, SREBF1, PPARD, and NR1H3. Furthermore, LV1.6 increased expression of ACSL1, DGAT1, and RXRA and reduced PPARG expression. Although no effect of OPAA on expression of PPARG was observed, OPAA increased expression of ACSS2, FABP3, ACACA, FASN, SCD, LPIN1, INSIG1, and SREBF1 compared with OPAARMC. Gene network analysis using Ingenuity Pathway Analysis revealed a potentially important role of EAA ratios in the coordination of milk fat synthesis via PPARG and SREBF1. The upregulation of lipogenic gene

networks observed underscore a role of EAA in the regulation of milk fat synthesis during lactation.

Key Words: nutrigenomics, milk fat synthesis, mTOR

1545 (M259) Rumen-protected methionine and choline supplementation during the transition period enhance the proinflammatory cytokine response of whole blood. M. Vailati Riboni[*1,2], Z. Zhou[2], D. N. Luchini[3], A. Minuti[1], E. Trevisi[1], and J. J. Loor[2], *[1]Università Cattolica del Sacro Cuore, Piacenza, Italy, [2]University of Illinois, Urbana, [3]Adisseo S.A.S., Alpharetta, GA.*

The immune system of dairy cows declines in responsiveness during the transition period. In spite of this, there are several factors that can stimulate immune cells and induce the production of proinflammatory cytokines (PIC). The objective of this study was to investigate the effect of supplementing rumen-protected methionine or choline on the production of the proinflammatory cytokine IL1-β by whole blood challenged with *E. Coli* lipopolysacharide (LPS). Twenty-four multiparous Holstein cows were dried off at −50 d from parturition (DFP) and allocated to 1 of 3 treatment groups (n = 8/group) starting on -24 DFP; control (CON; fed a basal diet with a 3.4:1 Lys:Met), methionine (MET; basal diet plus Smartamine M with a 2.9:1 Lys:Met), and choline (CHO; basal diet plus ReaShure, 60 g/d). Blood samples for LPS challenge were collected on -15, −7, 2, 7, and 20 DFP into evacuated tubes containing lithium-heparin and kept at 38°C. An ex vivo whole blood (1 mL) stimulation assay was performed within 30 min using LPS at three different doses, 0 (negative control, CTR), 0.01, and 5 μg/mL blood. Samples were incubated for 3.5 h. At the end of incubation the plasma was collected after centrifugation and used to analyze IL-1β concentration via ELISA. The data were analyzed as a factorial design with repeated measures using PROC MIXED in SAS. There was an overall diet effect ($P < 0.05$) associated with greater IL1-β in cows fed MET and CHO (1812 pg/mL) compared with CON (1043 pg/mL). Similarly, there was an overal LPS effect ($P < 0.05$) with control incubations averaging 52 pg IL1-β/mL compared with 1621 and 3013 pg IL1-β/mL in response to 0.01 and 5 μg LPS. The three-way interaction ($P < 0.05$) revealed that the high LPS dose induced a marked response in IL1-β in both MET or CHO regardless of DFP. In contrast, whereas the high dose of LPS induced a similar response (1500–2,000 pg IL1-β) in CON on -15, −7, 7, and 20 DFP, the response on 2 DFP was markedly greater to the point that IL1-β concentration was similar for CON, MET, and CHO. Overall, results confirmed the responsiveness of blood cells to an inflammatory challenge even in a period of immune suppression. More importantly, data revealed that supplemental methionine or choline during the transition period enhances the PIC response, hence, potentially enhancing the responsivennes to invading pathogens.

Key Words: inflammation, transition period, nutrition

1546 (M260) Amino acid analysis in dairy cow plasma by chloroformate derivatization and gas chromatography. N. E. Lobos[*1], G. A. Broderick[2], P. D. Carvalho[3], D. N. Luchini[4], R. D. Shaver[3], A. H. Souza[5], and M. C. Wiltbank[3], *[1]Dep. of Dairy Science, University of Wisconsin–Madison, Madison, [2]Broderick Nutrition & Research, LLC, Madison, WI, [3]University of Wisconsin, Madison, [4]Adisseo S.A.S., Alpharetta, GA, [5]University of California, Cooperative Extension, Tulare.*

The objective of the experiment was to evaluate gas chromatography (GC) after chloroformate derivatization of AA to quantify dietary effects on plasma AA concentrations in dairy cows. Plasma was obtained from 72 cows participating in a previous trial [Souza et al., J. Dairy Sci. 95(Suppl. 2):353, 2012, abstract] where positive performance effects to Met supplementation were reported. Starting at calving, cows were fed isoenergetic diets formulated to deliver equal metabolizable protein (2875 g MP/d). The control diet (CTR) provided 1.89% Met (% of MP), while the treatment diet (MET) was supplemented with sufficient Smartamine M to increase Met to 2.43% of MP. Results indicated increased milk concentrations of protein (2.92 vs. 2.75%, $P < 0.01$) and SNF (8.73 vs. 8.54%, $P < 0.01$) in cows fed MET. Plasma was harvested from blood samples collected at 50 DIM, and kept frozen at -18°C until analysis. Samples were separated by treatment group (supplemented = 37, control = 35) and combined randomly within parity, into seven plasma composites of four to six cows on each diet. Composites were prepared for GC analysis by using a commercial kit (EZ:faast GC-FID Physiological, Phenomenex). This method involves amino acid collection using solid phase extraction (SPE), derivatization with chloroformate, GC separation in a mid-polar capillary column and flame ionization detection. Quantification was based on area under the curve, using the internal standard ratio method (norvaline). Consistent with performance data, analysis of variance indicated higher plasma free Met levels in MET cows vs. CTR cows (22.9 vs. 16.8 μM, $P < 0.001$). Although the kit manual indicated deproteinization was not required, untreated plasma was difficult to work with because variable plasma concentrations of proteins and phospholipids clogged the SPE resin. Mixing plasma at a 1:1 volume ratio with 5% trichloroacetic acid, followed by centrifugation (12,000 × g), allowed satisfactory SPE of all composites. Ion exchange chromatography coupled with ninhydrin quantification is currently the gold standard for AA analysis. The drawbacks of that methodology are high cost and long runtimes. The modifications to the GC-chloroformate method here presented allow rapid (15 minute) determination of differences in free amino acids in cow plasma at a reasonable cost.

Key Words: rumen-protected, methionine, chromatography

[1] Contrasts: 1 = 16 vs. 14.9; 2 = 16 vs. 13.5; 3 = 14.9 vs. 14.9+EAA; 4 = 13.5 vs. 13.5+EAA

1547 (M261) Effects of supplementing limiting amino acids in diets with reduced CP on nitrogen excretion. M. A. C. Danes*[1], G. A. Broderick[2], and C. Parys[3], *[1]University of Wisconsin–-Madison, Madison, [2]Broderick Nutrition & Research, LLC, Madison, WI, [3]Evonik Industries AG, Hanau, Germany.*

Lowering dietary CP content while supplementing limiting essential amino acids (EAA) has potential to increase N efficiency and decrease N excretion. Ten Holstein cows were blocked by DIM into two 5x5 Latin squares with 5 treatments: (1) positive control (16% CP); 14.9% CP with (2) or without (3) EAA infusion; or 13.5% CP diet with (4) or without (5) EAA infusion. Diets contained alfalfa silage, corn silage, high moisture corn, canola meal, soybean meal and soybean hulls. The infusion solutions were prepared according to AminoCow to provide all limiting EAA and infused continuously into cows' abomasum. Amounts of Met, Lys, His, Leu and Val were, respectively, 11, 11, 5, 5, and 0 g/d for treatment 2 and 15, 27, 11, 22, and 6 g/d for treatment 4. Data from the last 4 d of each 14-d period were analyzed using Proc Mixed. Dry matter intake was not different among treatments ($P > 0.10$) and was highly variable. Therefore, DMI was included in the model to isolate treatment effects. Significance was declared at $P < 0.10$. Contrasts and LS-means are reported. There was no difference among treatments for fecal N excretion. Increasing CP level increased urinary N content and proportion of urea in total urinary N. The EAA infusion on 14.9% CP increased urinary N excretion relative to the same diet without infusion. However, when infused on the 13.5% CP diet, EAA decreased urinary N excretion relative to the same diet without infusion. This suggested that the 14.9% CP diet provided sufficient EAA for milk protein synthesis, while the 13.5% CP diet was EAA deficient and supplementation improved N utilization.

Key Words: amino acid infusion, nitrogen excretion, protein

1548 (M262) Effects of rumen-protected ã-aminobutyric acid on immune function and antioxidant status in heat-stressed dairy cows. J. Cheng[1,2,3], N. Zheng[1,3,4], X. Sun[1,2,3], D. P. Bu[3], L. Pan[3], and J. Wang*[1,3,4], *[1]Ministry of Agriculture–Laboratory of Quality and Safety Risk Assessment for Dairy Products, Beijing, China, [2]College of Animal Science and Technology, Anhui Agricultural University, Hefei, China, [3]State Key Laboratory of Animal Nutrition, Institute of Animal Science, Chinese Academy of Agricultural Sciences, Beijing, China, [4]Ministry of Agriculture– Milk and Dairy Product Inspection Center, Beijing, China.*

This experiment was conducted to investigate the effects of rumen-protected γ-aminobutyric acid (GABA) on immune function and antioxidant status in heat-stressed dairy cows. Sixty Holstein dairy cows (141 ± 15 DIM, 35.9 ± 4.3 kg of milk/d) were randomly assigned to 1 of 4 treatments according to a randomized complete block design. Treatments consisted of 0, 40, 80, or 120 mg GABA/kg DM from rumen-protected GABA. The trial lasted 10 wk. The average temperature-humidity indices at 0700, 1400, and 2200 h were 78.4, 80.2 and 78.7, respectively. Blood samples were collected from all of animals via tail vein before the morning feeding on d 0, 21, 42, and 56. Data were analyzed by MIXED model procedure of SAS. Concentrations of immunoglobulin (Ig) A (0.18 and 0.25 vs. 0.16 mg/mL) and IgG (64.62 and 62.14 vs. 32.08 μg/mL) increased ($P < 0.05$) in cows fed 80 or 120 mg/kg GABA, while IgM level showed no difference ($P > 0.05$) when compared with control cows. Compared with control, concentrations of IL-2 (10.84 and 9.37 vs. 6.37 ng/mL) and IL-4 (76.72 and 85.64 vs. 56.63 pg/mL) were higher ($P < 0.05$) in cows fed 80 or 120 mg/kg GABA, and the IL-6 level was higher (124.24 vs. 77.53 pg/mL; $P < 0.05$) in cows fed 120 mg/kg GABA, tended to be higher (89.42 vs. 77.53 pg/mL; $P < 0.10$) in cows fed 80 mg/kg GABA. The TNF-α level was higher (68.50 and 80.82 vs. 49.18 fmol/mL; $P < 0.05$) in cows fed 80 or 120 mg/kg GABA, and tended to be higher (62.29 vs. 49.18 fmol/mL; $P < 0.10$) in cows fed 40 mg/kg GABA. The proportions of $CD4^+$ (9.26 and 9.88 vs. 7.03%) and $CD8^+$ (6.41 and 6.26 vs. 5.15%) T lymphocyte were higher ($P < 0.05$) in cows fed 80 or 120 mg/kg

GABA compared with control, but ratio of $CD4^+/CD8^+$ was not different ($P > 0.05$) among treatments. Compared with control, the activities of SOD (9.59 and 9.52 vs. 8.54 U/mL) and T-AOC (6.11 and 5.64 vs. 3.20 U/mL) increased ($P < 0.05$) in cows fed 80 or 120 mg/kg GABA, but the activities of GSH-Px and MDA were not affected ($P > 0.05$) by GABA supplementation. These results indicate that rumen-protected GABA supplementation to heat-stressed dairy cows can improve the immune function and enhance antioxidant activity.

Key Words: γ-amino butyric acid, immune function, antioxidant activity

1549 (M263) Effects of supplemental rumen-protected methionine and histidine on performance of lactating dairy cows. W. D. Weich*[1], K. F. Kalscheur[1], K. J. Herrick[2], and K. E. Griswold[3], *[1]South Dakota State University, Brookings, [2]Kemin Industries, Inc., Des Moines, IA, [3]Kemin Animal Nutrition and Health, Des Moines, IA.*

Objectives were to determine the effects of rumen-protected methionine (MET) and histidine (HIS) on lactation performance. Twenty-seven multiparous and sixteen primiparous dairy cows blocked by parity, milk production, DIM and breed were assigned a treatment in a randomized complete-block design. Cows were fed a covariate diet for 10 d followed by 4 wk of experimental diets. Treatments were: 1) control diet (CON; formulated for 50.5 g MP MET), 2) CON + encapsulated MET (EM; 18 g of product, +10.8 g MP MET), 3) CON + spray-freeze MET (SFM; 33 g of product, +10.8 g MP MET), 4) SFM + encapsulated HIS (SFMH; 120 g of product, +10.1 g MP HIS). Diets were formulated using AMTS (Version 3.4.7.1). The control diet was balanced to contain 14.7% CP (91% of MP requirements) and maintained a LYS:MET ratio of 3.46:1. Addition of MET products reduced the LYS:MET ratio to 2.85:1. The control diet was created as a single batch in a vertical mixer and rumen-protected amino acids were added to CON at the Data Ranger to create treatments. Amino acid supplementation did not affect DMI, milk yield, feed efficiency, milk protein content or yield. Milk fat concentration and yield were greater ($P < 0.05$) for CON compared with EM and SFM. Differences in MUN among EM, SFM, and SFMH may be related to rumen digestibility of the products. Addition of rumen-protected MET or HIS for cows fed a 14.7% CP diet did not alter production performance.

Key Words: histidine, metabolizable protein, methionine, rumen-protected amino acid

1550 (M264) Canola meals from different plants over two production years differ in rumen-undegraded protein. G. A. Broderick*[1], S. Colombini[2], A. Faciola[3], and M. A. Karsli[4], *[1]Broderick Nutrition & Research, LLC, Madison, WI, [2]University of Milan, Italy, [3]University of Nevada, Reno, [4]Kirikkale University, Turkey.*

Lactation trials showed improved production and N efficiency when dietary soybean meal was replaced with equal CP from canola meal. Three canola meal samples were collected from each of 12 Canadian production plants over 2 yr (total = 72) and analyzed for chemical composition and ruminal protein degradability. The Michaelis-Menten inhibitor in vitro method was used to quantify protein degradation rates and rumen-undegraded protein (RUP), assuming passage rates of 0.16/h and 0.06/h for soluble and insoluble proteins. Differences among plants were assessed using the SAS Mixed model; LS-means for plants over both years, and for each year, are reported in Table 1550. Although CP concentration and NDIN and RUP proportions were unaffected by year ($P \geq 0.21$), NDF and soluble N were lower ($P \leq 0.01$) in canola meal produced in 2011 than 2012. Proportions of NDIN ranged from 18 to 28% of total N but were unaffected by plant ($P = 0.15$). However, differences were detected among plants in CP and NDF concentrations ($P \leq 0.03$) and proportions of soluble N and RUP in total N ($P < 0.01$). Plant x year interactions ($P \leq 0.04$) also were found for concentrations of CP and NDF and proportions of NDIN and RUP, but not for soluble N ($P = 0.19$). Results indicated that differences in canola meal RUP concentration were consistent over 2 production years and, depending on plant of origin, ranged from 38 to 50% of CP, a difference of 30%.

Key Words: canola meal, inhibitor in vitro, rumen-undegraded protein

1551 (M265) Rumen-undegradable protein of blood meal, canola meal, low-fat distillers dried grain with solubles, soybean meal, and expeller soybean meal determined using in situ and in vitro ammonia release procedures. H. A. Paz Manzano*[1], T. J. Klopfenstein[1], and P. J. Kononoff[2], *[1]University of Nebraska-Lincoln, Lincoln, [2]University of Nebraska, Lincoln.*

Two Holstein cows (days in milk 70 ± 17 and milk yield 27.3 ± 8.00 kg) fitted with ruminal cannulas were used to determine rumen-undegradable protein (RUP) using an in situ incubation of 16. In addition, the in vitro ammonia (NH_3) release procedure was used to estimate RUP. The in vitro NH_3 release procedure involves the incubation of equal amounts of N from each feedstuff in ruminal fluid and the measurement of the NH_3 and total VFAs produced. Concentrations of $NH_3$and total VFA were adjusted for a blank (only inoculum). The feedstuffs evaluated were: 3 sources of blood meal (BM1, BM2, and BM3), canola meal (CM), low-fat distillers dried grains with solubles (LFDG), soybean meal (SBM), and expeller soybean meal (ESBM). Data from the in situ procedure were analyzed as a randomized complete block design and the model included the fixed effect of feedstuff and the random effects of replicate and load within feedstuff and data from the in vitro ammonia release were analyzed as a complete randomized design and the model included the fixed effect of feedstuff and the random effect of load within feedstuff. Based on the in situ procedure, RUP was 70.2, 63.0. 59.3, 31.2, 24.3, 23.1, 14.7 ± 3.93% crude protein (CP) for BM2, ESBM, BM3, SBM, CM, LFDG, and BM1, respectively. Based on the in vitro ammonia release procedure, RUP was 67.6, 67.5, 65.8, 48.8, 32.5, 32.3, 32.1 ± 3.46% CP for BM2, BM3, ESBM, LFDG, BM1, SBM, and CM. Compared to RUP values obtained from the in situ procedure, values of RUP from the in vitro ammonia release procedure were greater ($P = 0.01$) for BM1 and LFDG and similar ($P \geq 0.10$) for the remaining feedstuffs. The in vitro ammonia release procedure is a promising method for measuring RUP that avoids the use of cannulated animals and errors that may emerge with washout of residue from the polyester bags, and allows for uniform settings; however, more research is needed to elucidate the factors that cause variability when using this procedure.

Key Words: rumen-undegrabable protein, in situ, in vitro

1552 (M266) Sources of protein and protected methionine on in situ ruminal degradability of crude protein of feed ingredients. F. D. O. Scarpino van Cleef*[1,2], J. M. Bertocco Ezequiel[1], E. Neves Muniz[3], R. L. Galati[4], and E. H. C. B. Van Cleef[1,5], *[1]UNESP, Jaboticabal, Brazil, [2]CNPq, Brasilia, Brazil, [3]Embrapa Tabuleiros Costeiros, Aracaju, Brazil, [4]Federal University of Mato Grosso, Cuiaba, Brazil, [5]FAPESP, Sao Paulo, Brazil.*

The objective of this study was to evaluate crude protein degradability of feed ingredients in diets containing corn gluten or starea as protein sources, with or without 2 g/d protected methionine. Eight male ruminally-cannulated sheep (12 mo old, 51.3 kg BW) were assigned to a replicated 4 × 4 Latin square design with a 2 × 2 factorial arrangement of treatments (two sources of protein— corn gluten or starea— and with or without protected methionine). The in situ nylon bag technique was used in this trial. Samples of feed ingredients were ground to 5 mm (corn silage), and 2 mm (extruded corn and soybean hulls), and incubated for 6, 12, 24, 48, 72, and 96 h for corn silage, and 1, 6, 12, 24, and 48 h for extruded corn and soybean hulls. Data were fitted to exponential model to estimate degradation parameters, and effective degradability was calculated with passage rates of 2, 5, and 8%/h. Data were analyzed as a replicated 4 × 4 Latin square with PROC MIXED of SAS. There was no interaction of protein sources and protected methionine, thus only the main effects were studied. Variations from 23 to 91% (corn gluten, and starea, respectively) on protein degradability of protein sources do not affect degradability parameters, potential degradability, and effective degradabilities (2, 5, and 8%/h passage rates) of corn silage and soybean hulls. The average potential degradabilities of crude protein observed were 75.9% (corn silage), and 73.6% (soybean hulls). The average effective degradabilities of crude protein for 3, 5, and 8%/h passage rates were respectively 71.6, 68.8, and 67.7% (corn silage), and 66.1, 58.0, and 53.1% (soybean hulls). The addition of protected methionine improves in 4% the potential crude protein degradability and in 2.8, 2.1, and 1.5% the effective degradabilities of corn silage, for 2, 5, and 8%/h passage rates, respectively. It was concluded that regarding fibrous in-

gredients, the variation of 68% units in crude protein degradability of protein sources is not enough to modify the ruminal utilization of crude protein of these ingredients. Furthermore, the protected methionine inclusion improves crude protein degradation parameters for low protein ingredients.

Key Words: degradability, methionine, protein sources

1553 (M267) Supplementation of lysine and methionine in the starter concentrate or milk replacer of dairy calves.

J. T. Silva*, M. R. De Paula, G. Santos, G. Slanzon, and C. M. M. Bittar, *University of Sao Paulo, Piracicaba, Brazil.*

Concentrate and milk replacer available in Brazil are deficient in lysine and methionine for dairy calves, which may benefit from supplementation. Forty-five newborn Holstein male calves were used in a randomized complete block designed experiment and assigned into one of three treatments: 1) Control: no amino acid (AA) supplementation; 2) Starter concentrate: supplementation of lysine and methionine in the concentrate starter to reach daily intakes of 17 g/d and 5.3 g/d, respectively; and 3) Milk replacer: supplementation of lysine and methionine in the milk replacer to reach daily intakes of 17 g/d and 5.3 g/d, respectively. Calves were housed in individual shelters, with free access to water, and were fed starter concentrate and 6 L/d of milk replacer (20% CP, 16% ether extract, and 12.5% solids), divided into two meals, until the 8 wk of life, when they were weaned. Starter concentrate and milk replacer intakes, as well as fecal scores were monitored daily. Body weight, withers height, heart girth and hip width were weekly measured. Data suggest that amino acid supplementation in the concentrate decreased solid feed intake, reducing total dry matter intake after weaning and consequently calves' final body weight (Table 1553). Amino acid supplementation have no beneficial effects on dairy calves' performance.

1554 (M268) Evaluating the plasma free amino acid dose–response method to determine the content of metabolizable methionine in a rumen-protected methionine supplement.

N. L. Whitehouse*[1], C. G. Schwab[2], M. C. Blais[1], A. F. Brito[1], and B. K. Sloan[3], [1]*University of New Hampshire, Durham,* [2]*Schwab Consulting, LLC, Boscobel, WI,* [3]*Adisseo, Alpharetta, GA.*

The plasma free AA dose–response approach has been proposed as the standardized method for evaluating rumen-protected Lys supplements. The method has the advantage of providing animal-derived estimates of efficacy under conditions of commercial use. However, before using the approach for evaluating rumen-protected Met (RP-Met) supplements, it is necessary to confirm that a positive linear relationship exists between increasing amounts of absorbed Met and plasma Met concentrations. The primary objective of this experiment was to confirm linearity in plasma Met response with up to 24 g/d of supplemental MP-Met by abomasal infusion or feeding a RP-Met product. A secondary objective was to determine if technique precision could be improved by including the other plasma sulfur AA (cystine, cystothionine + allocystothionine, homocystine and taurine) with Met (total sulfur AA) as an indicator of Met absorption. Five rumen-cannulated lactating Holstein cows (90–155 DIM), fed a Met-deficient diet, were assigned to a 5 × 5 Latin square with 7-d experimental periods. Treatments (*P*er 25.0 kg/d of DMI) were 0 g/d Met (neg-

ative control), 12 and 24 g/d abomasally infused Met, and 12 and 24 g/d of assumed MP-Met from a RP-Met supplement. Blood samples were taken from the tail vein every 2 h, 4 times daily, the last 3 d of each period, centrifuged, deproteinized, and composited into 1 daily sample/cow. Data for plasma AA concentrations were analyzed using the PROC MIXED and PROC REG procedures of SAS 9.2. The basal diet was confirmed to be Met-deficient by observed increases in milk protein concentration (+0.10 and 0.12% units for infused and fed Met, respectively; $P < 0.05$) with the first level of both infused and fed Met. All plasma sulfur AA responded in a significant linear fashion to both infused and fed Met ($P < 0.05$). Estimates of the MP-Met content of the RP-Met supplement were the same using either plasma Met or plasma total sulfur AA. The plasma free AA dose–response method is applicable for determining the MP-Met content of RP-Met supplements.

Key Words: rumen-protected, methionine, evaluation

1555 (M269) Amino acids supplementation in the milk replacer for dairy calves.

J. T. Silva*, N. B. Rocha, E. Miqueo, T. Manzoni, G. Santos, S. Baldassin, and C. M. M. Bittar, *University of Sao Paulo, Piracicaba, Brazil.*

This study evaluated the performance and fecal scores of dairy calves receiving milk replacer supplemented with lysine and methionine (EAA) to reach daily intakes of 17 g/d and 5.3 g/d, respectively; and two levels of AminoGut (Ajinomoto Animal Nutrition; 10% Glutamine and 10% Glutamic acid). Forty-five newborn Holstein male calves were utilized in a randomized blocks experimental design, and distributed into three treatments: 1) Control: no amino acid supplementation; 2) AminoGut 0.6%: supplementation of EAA and 0.6% AminoGut; and 3) AminoGut 1%: supplementation of EAA and 1% AminoGut. Calves were individually housed, with free access to water and starter concentrate, and received 6L/d of milk replacer (20CP:16EE; 12.5% solids), until the eighth week of life, when weaned. Calves were followed up to the 10 wk of life. Feed intakes and fecal scores were monitored daily; while body weight and body measurements were weekly measured. Even though AminoGut has been proven to benefit animals affected diarrhea, there were no supplementation effects on fecal scores. Supplementation of 0.6% of glutamate increased starter intake, which may benefit animals going through the transition period. However, the low intake observed for all treatments resulted in modest daily gains and final weight, as it has been seen in other trials during summer tropical conditions. *Supported by Fapesp, São Paulo, Brazil.*

1556 (M270) Effects of maternal nutrition and arginine supplementation on characteristics of wool quality in offspring.

J. L. Peine*, P. P. Borowicz, J. S. Caton, and R. R. Redden, *North Dakota State University, Fargo.*

The objectives of this study were to measure effects of maternal nutrition and rumen-protected arginine supplementation on postnatal offspring wool quality and follicle development. We hypothesized that lambs from ewes receiving diets fed to nutrient requirements would have a greater density of wool follicles and improved wool quality compared to lambs from nutrient restricted ewes. We also hypothesized that lambs from restricted ewes receiving a rumen-protected arginine supplement would present similar wool follicle numbers and quality to those lambs from adequately fed dams. To test these hypotheses, multiparous Rambouillet ewes ($n = 32$; 67.6 ± 6.2 kg) were randomly assigned to one of three treatments at 54 ± 3.9 d of gestation in a completely random design. Dietary treatments included 100% nutrient requirements (control, CON), 60% of CON nutrients (restricted, RES), and RES with the addition of a rumen-protected arginine supplement dosed at 180 mg/kg of body weight once daily (RES-ARG). Ewes were penned individually in a temperature-controlled facility. Immediately post-lambing, lambs were separated from ewes and raised independent of their dam until necropsy at 54 ± 3 d of age. A wool sample was taken for quality analysis, in addition to skin samples (3 cm^2) from the side (between the 10th and 12th rib) and britch regions. Following histological preparation and stereological analysis all data were analyzed using the PROC MIXED of SAS. No differences were observed in follicle numbers between treatments for skin samples taken from

the side of the lambs ($P \geq 0.17$). However, in the britch samples lambs from RES-ARG ewes had more ($P = 0.02$) follicles present than lambs from CON ewes, with lambs from RES being both intermediate and similar in follicle number (106 vs. 86 vs. 93 ± 6.3 follicles per 1 mm^2, respectively). There were no differences among treatments for wool quality measures of mean fiber diameter, fiber diameter SD, or comfort factor ($P \geq 0.32$). These data partially support our hypothesis that maternal rumen-protected arginine supplementation may increase the number of developing follicles in offspring, and therefore potentially increase wool production. However, we reject our hypothesis that arginine supplementation will increase wool quality in those lambs from restricted-nutrient dams.

Key Words: arginine, wool, developmental programming

1557 (M271) Effects of maternal nutrition and rumen-protected arginine supplementation on postnatal lamb performance and organ mass. J. L. Peine*, G. Jia, S. T. O'Rourke, L. P. Reynolds, and J. S. Caton, *North Dakota State University, Fargo.*

Our hypothesis was that rumen-protected arginine supplementation would overcome the negative effects of restricted maternal intake during the last two-thirds of gestation on lamb organ mass and postnatal performance. To investigate the effects that arginine supplementation would have, $n = 32$ multiparous, Rambouillet ewes were allocated to one of three treatments in a completely random design at 54 ± 3.9 d of gestation. Dietary treatments included either 100% of requirements (control, CON), 60% of control (restricted, RES), or RES plus a rumen-protected arginine supplement dosed at 180 mg/kg BW once daily (RES-ARG). Ewes were penned individually in a temperature controlled facility, and remained on these treatments through parturition. Upon parturition, lambs were immediately removed from their dam and reared independently. At 54 ± 3 d of age, lambs were necropsied and organs were dissected. Birth weights in lambs from CON ewes were greater ($P = 0.04$) than lambs from RES ewes, with lambs from RES-ARG ewes being intermediate (5373, 4553, and 4697 ± 256.0 g, respectively). At 54 ± 3 d of age, curved crown rump measurements were longer ($P = 0.003$) in lambs from RES-ARG ewes than from RES, with a tendency for lambs from RES-ARG ewes to also be longer ($P = 0.06$) than CON (99.8 vs. 93.9 vs. 96.3 ± 1.28 cm, respectively). Organ mass measurements showed lambs from RES-ARG ewes had greater ($P = 0.05$) liver mass than RES, with lambs from CON ewes being intermediate (490.0 vs. 481.2 vs. 429.5 ± 21.08 g, respectively). In addition, lambs from CON ewes had greater ($P = 0.01$) mass of adrenal glands than lambs from RES ewes. These data support that rumen-protected arginine supplementation may partially mitigate negative effects on postnatal lamb performance and organ mass due to restricted maternal intake during the last two-thirds of gestation.

Key Words: arginine, developmental programming, offspring

1558 (M272) Ultrasonography for investigating the effect of supplementing whole milk with plant-derived complex carbohydrates on curd clearance through the abomasum of dairy calves. K. Singh*[1], S. R. Leath[1], H. V. Henderson[1], T. J. Watson[1], D. Pacheco[2], and C. D. McMahon[1], *[1]AgResearch Ltd, Ruakura Research Centre, Hamilton, New Zealand, [2]AgResearch Ltd, Grasslands, Palmerston North, New Zealand.*

Growth rates of dairy heifer calves and their performance at first lactation are enhanced by supplementing a whole milk diet with plant-derived complex carbohydrates and specific amino acids. At present it is unclear how such changes in nutrition from birth to weaning can affect a dairy cow's subsequent lactations. The aim of this study was to establish the use of ultrasound to investigate if the transit time of milk is influenced by a supplement of plant-derived complex carbohydrates to whole milk. Initially, the use of ultrasonography for detecting curd after feeding whole milk in the abomasa of pre-ruminant dairy heifer calves ($n = 10$) was determined. This was conducted using a sectorial probe (M-Turbo with C60x/5.2MHz transducer; Sonosite USA), at -10, 5, 30, 60, and 120 min after feeding. A score system was developed for fullness of the abomasum (0 to 3) and size of the curds (A to C). In trial 2, 22 calves were individually fed whole milk (control group) until weaning (approximately 80 kg live weight); 4L whole milk per day (2L am and 2L pm) using an automated calf feeder. The remaining calves (supplemented group; $n = 21$) were fed as per above, but whole milk was supplemented with a probiotic (X-Factor [XF], Bell-Booth Ltd, New Zealand) until 18 d of age and then XF was replaced with a source of plant-derived complex carbohydrates and selected amino acids (Queen of Calves [QoC], Bell-Booth Ltd) at a starting dose of 25 g/L whole milk, increasing at d 20 of age to 37.5 g/L, and to 50 g/L from d 21 of age until weaning. The groups were balanced for age, weight and breed. Ultrasonography of the abomasum was conducted as above. Supplementing whole milk with XF did not affect average retention time compared with calves fed whole milk. However, milk supplemented with QoC delayed the transit time of curd 1.4 ± 0.28 h (32%) longer ($P < 0.001$) at 4 wk of age and 0.7 ± 0.34 h (14%) longer ($P = 0.05$) at 8 wk of age, compared with calves fed whole milk alone. These data indicate that milk supplemented with QoC slows transit time of curd in the abomasum, which may allow a greater absorption of nutrients to support early growth.

Key Words: curd, transit time, dairy heifer

1559 (M273) Relationship between non-protein nitrogen and true protein in supplements during the post-weaning phase of Nellore steers in the dry-wet season transition.
B. C. Carvalho[1], R. M. Fernandes[2], C. M. D. Almeida[1], N. M. Jerônimo[1], G. F. Berti[1], C. G. C. Marcolino[1], M. H. Moretti[3], I. M. de Oliveira[*4], F. D. D. Resende[4], and G. R. Siqueira[4], *[1]Centro Universitário da Fundação Educacional de Barretos–Unifeb, Brazil, [2]UNESP-FCAV, Jaboticabal, Brazil, [3]Universidade Estadual Paulista, Jaboticabal, Brazil, [4]APTA–Agência Paulista de Tecnologia dos Agronegócios, Colina, Brazil.*

The objective of this study was to evaluate the effect of different levels and rates of protein degradation on the performance of Nellore, recreated on *Brachiaria brizantha* cv. Marandu during the transition period dry water. Seventy-two bulls were used with 412.45 kg body weight (BW) initial, non-castrated Nellore, daily receiving 3 g/kg BW of supplement, these were divided into 12 paddocks. The treatments were: energy protein supplement (SPE) with 25% CP (control), energy protein supplement with 40% CP, one third of the PB of vegetable and two thirds of chemical origin, Supplement energy protein with 40% CP, with two thirds of the PB of vegetable and one third of chemical origin, energy protein supplement with 40% CP, one half PB of plant origin and half of chemical origin. The animals were weighed every 28 d after 16 h of fasting and liquid to obtain the average daily gain (ADG). The experiment took place from September to December 2013, totaling am 84-d evaluation. The experimental unit used was the picket, which is composed of six testeres animals. The experimental design was a randomized block experimental areas and the blocking factor, there were three paddocks per treatment. Data were analyzed using mixed model using the PROC MIXED of SAS software, version 9.2 (SAS, 2008), the 10% level of significance by *t* test. The increase in NNP (40–2/3NNP) depressed ADG ($P = 0.07$) 0.265 kg/day in compared to other treatments with averaged 0.366 kg, 0.419 kg and 0.399 kg for C-25, 40–1/2 NNP and 40–1/3 NNP, respectively. The final body weight was greater ($P = 0.08$) in animals that received 40–1/2 NNP (416.7 kg) compared to those who received C-25 (408.5 kg) or 40–2/3 NNP (404.4 kg). The 40–1/3 NNP treatment with intermediate weight (413.1 kg) did not differ from treatments 40–1/2 NNP ($P = 0.40$) and C-25 ($P = 0.30$). It is concluded that supplementation with 40% CP and one-half NNP is able to generate heavier animals in the transition dry-waters. *Supported by CNPq and Bellman.*

1560 (M274) Sulfur sources in protein supplements and their influence on amino acid profiles.
F. P. Leonel[*1], C. J. Silva[2], L. M. Moreira[1], J. M. Carvalho[1], J. C. Carvalho[3], J. C. Pereira[3], T. C. Nunes[1], and R. A. Vieira[4], *[1]Federal University of São João del Rei (UFSJ), Brazil, [2]National University of Brasília, Brazil, [3]Federal University of Viçosa (UFV), Brazil, [4]Norte Fluminense State University, Campos dos Goytacazes, Brazil.*

The present experiment was performed to evaluate the effect of different sulfur sources in protein supplements for cattle in the amino acids profile with respect to the abomasal digesta. Crossbred steers were fed with *Brachiaria dictyoneura* hay, applying different sulfur sources in the protein supplement: 70S elementary sulfur- byproduct (ES70S); 98S elementary sulfur- flowers of sulfur (ES98S); hydrated calcium sulfate (HCS); anhydrous calcium sulfate (ACS) and ammonium sulfate (AS). The dietary treatments were applied at 11:1 nitrogen:sulfur ratio. Five steers which were fistulated in the rumen and abomasum were used in a 5 × 5 Latin square design. The experiment had five 16-d periods, in which the first 10 d were for adaptation period and the subsequent 6 d were utilized to obtain the experimental data. The concentration of available amino acids in the abomasal digesta (g/kg DM) remained with very similar values ($P > 0.05$) in the evaluated diets. The amino acids evaluated in the abomasal digesta remained with the same quantitative profiles, suggesting that their properties do not depend on the sulfur sources encountered in the respective diets.

1561 (M275) Slow-release urea in diets of crossbred lactating cows. F. P. Leonel[*1], B. T. Santiago[2], S. D. J. Vilella[2], J. M. Carvalho[1], J. C. Carvalho[3], M. M. Assis[1], T. C. Nunes[1], and L. M. Moreira[1], [1]*Federal University of São João del Rei* (*UFSJ), São João del Rei, Brazil,* [2]*Federal University of Vales do Jequitinhonha e Mucuri* (*UFVJM), Diamantina, Brazil,* [3]*Federal University of Viçosa* (*UFV), Brazil.*

This work was performed to evaluate the performance of F1 lactating cows (Holstein x Zebu) in response to different levels of substitution of soybean meal by non-protein nitrogen equivalent protein derived from slow-release urea (SRU). Eight cows were used in a duplicate 4 × 4 Latin square design, according to the following treatments: control (100% soybean meal and 0% SRU), 34SRU (66% soybean meal and 34% SRU), 66SRU (34% soybean meal and 66% SRU) and 100SRU (0% soybean meal and 100% SRU). The forage sorghum silage was used. Intakes of dry matter (DMI), crude protein (CPI), neutral detergent fiber (NDFI) were measured. The apparent digestibility of dry matter (MDad) and neutral detergent fiber (NDFad) were evaluated using chromic oxide as an external marker. Milk production was measured. Data were subjected to analysis of variance using the statistical program SAEG, adopting the 5% level of probability. Treatments did not affect DMI, CPI, and NDFI ($P > 0.05$; Table 1561). The results of apparent digestibility of the dry matter and neutral detergent fiber also do not present differences ($P > 0.05$) between treatments. Milk production and composition demonstrated also similar results ($P > 0.05$), when are compared the treatments evaluated in this work. The replacement of soybean meal by slow-release urea (SRU) does not affect the variables of intake and digestibility of dry matter or milk production of crossbred cows.

Key Words: digestibility, intake, milk production, soybean meal

Table 1561. Intake and digestibility of DM and nutrients and milk production

	Treatments					
Variable	Control	34ULL	66ULL	100ULL	CV (%)	*P*
DMI (kg/dia)	18,20	18,44	18,76	17,99	6898	0555
CPI (kg/day)	2,50	2,65	2,62	2,70	11,207	0678

1562 (M276) Passage rate and efficiency of microbial protein synthesis in buffaloes fed increasing levels of crude protein. E. Machado, L. M. Zeoula*, E. H. Yoshimura, R. B. Samensari, N. W. Santos, B. C. Agustinho, L. D. M. Pereira, and S. C. Aguiar, *Universidade Estadual de Maringá, Maringá, Brazil.*

Optimization of the ruminal passage rate improves the conditions for growth of rumen microorganisms; however, if the dilution rate is too fast, the microbial growth can be reduced. The objective was to evaluate the effect of increasing levels of crude protein (CP) in the diet of buffaloes on the passage rate and efficiency of microbial protein synthesis (EMPS). Four crossbred growing buffaloes were used, weighing 355 ± 3.5 kg of body weight, cannulated in the rumen and distributed in a 4 × 4 Latin square design. The total mixed ration consisted of corn silage (850 g.kg^{-1}) and concentrate (150 g.kg^{-1}) and was formulated to meet the proposed levels of CP (70, 90, 110, and 130 g.kg^{-1}). To determine the dilution rate, a Co-EDTA solution (32 g of Co-EDTA in 500 mL of distilled water) was added via ruminal cannula before the first feeding. Ruminal fluid was collected at time zero (before the first feeding), and 2, 4, 6, 8, 10, 12, 14, 16, and 24 h post-feeding. To estimate the EMPS, spot urine samples were collected. From the concentration of creatinine in the spot urine sample, the urinary volume was estimated and the production of microbial nitrogen was calculated from the amount of absorbed purines, which was estimated as the excretion of purine derivatives in urine using the following equation: $Y = 0.74X + (0.117 W^{0,75})$. The synthesis of microbial nitrogen in the rumen was calculated as a function of absorbed purines: $Y = X70/0.116 \times 0.83 \times 1000$. Data were interpreted using the SAS statistical software (version 9.0). There was a linear effect ($P < 0.01$) for the levels of CP on microbial production, which averaged 244.8, 342.0, 394.8 and 425.2 g of microbial protein for 70, 90, 110, and 130 g.kg^{-1}PB, respectively. According to the regression equation ($Y = 54.62 + 4.70X$, $R^2 = 0.4555$), we observed an increase of 4.70 units in the microbial production for each percentage unit of dietary CP. However, this effect is not observed on the dilution rate and on the EMPS when expressed per unit of fermented carbohydrate, probably due to the relationship between these two parameters. Therefore, if the increase in the dietary CP did not alter the EMPS, it can be concluded that the rumen microorganisms' requirements were met at the lowest level of dietary protein.

Key Words: transit kinetics, nitrogen, purine derivatives

1563 (M277) Effects of test weight and processing method on in vitro intestinal digestibility of barley grain. Y. Zhao[1], S. Yan[2], Z. He[1], U. Anele[1], M. L. Swift[3], T. A. McAllister[4], and W. Yang[*1], *[1]Lethbridge Research Centre, Agriculture and Agri-Food Canada, AB, [2]College of Animal Science, Inner Mongolia Agricultural University, Hohhot, China, [3]Alberta Agriculture and Rural Development, Lethbridge, Canada, [4]Agriculture and Agri-Food Canada, Lethbridge, AB.*

An in vitro study was conducted to investigate the effects of test weight and processing method on intestinal digestibility of barley grain following ruminal incubation. The study was designed as a 2 × 2 × 2 factorial arrangement with treatments: test weight (TW; low vs. high), precision processing (*P*P; control vs. PP), and processing index (*P*I; 75 vs. 85%). Ten barley samples with 5 low (574 g/L) and 5 high (632 g/L) TW were either dry-rolled with single roller setting (control) or sieved into small and large kernels, then dry-rolled based on kernel size of each fraction (i.e., PP). Each sample was dry-rolled moderately or coarsely with PI of 75 or 85%, respectively. Intestinal DM digestibility (iDMD; % of ruminal residue input) of barley grains was determined using the modified three-step in vitro procedure. Barley samples were incubated in the rumen for 12 h to produce ruminal residues using three beef heifers (650 ± 25 kg BW) fitted with rumen cannula and fed a diet consisting of 70% barley silage and 30% barley grain. Ruminal residues were incubated in 1 N HCl containing 1 g/L of pepsin for 1 h, and then in phosphate buffer (*P*H 7.8) containing pancreatin at 39°C for 24 h. An interaction between TW and PP ($P < 0.02$) and between PP and PI ($P < 0.01$) was detected but not between TW and PI ($P > 0.05$). The iDMD was greater ($P < 0.01$) with high (25.6%) than with low (23.1%) TW of barley grain for control barley, whereas the iDMD was not different between the low (20.2%) and high TW (20.4%) for PP barley. Compared to control processing, PP reduced ($P < 0.01$) the iDMD (*P*P vs. control; 13.5 vs. 21.2%) for processed barley with PI of 85% but not for barley with PI of 75% (27.3%). Decreasing PI from 85 to 75% increased ($P < 0.01$) iDMD from 17.3 to 27.4%. These results indicate that the intestinal digestibility of barley grain varied with TW, processing method, and extent of processing. It suggests that manipulating these factors may partly shift grain starch digestion from the rumen to the intestine, thereby potentially reduce rumen acidosis and improve feed efficiency in feedlot beef cattle fed high-grain diet.

Key Words: barley grain, precision processing, in vitro intestinal digestibility
