National Extension Education Workshop: Current and Future Impact of Issues Facing Animal Agriculture

1 Introduction. Richard Reynnells*¹, ¹USDA/CSREES/PAS.

There is insufficient understanding by society of our food supply network. Our agricultural system is simultaneously robust and fragile, so must be protected, but is taken for granted. Our agricultural future requires mutual respect and a search for truth, versus special interests and myopic agendas.

Technological advances at the molecular level demand we deal with bioethical issues. We require an honest evaluation of the consequences of progress. Our keynote speaker will address GMO's in the Food Chain. Society's demand for inexpensive food, coupled with competition and grocery store's efforts to fulfil those requirements eliminated many good farmers. Consumers are appalled at the consolidation of farms, yet show little concern about the consolidation of grocery and other stores. These issues will be discussed by two speakers and an industry panel. ADDS, Inc. personnel will discuss and demonstrate their unique educational program.

Activist groups protest vigorously, and some may be considered a secular religion. Can animal rights dogma be promoted as originally intended, or must it be sold on welfare or a reduced version of "rights"? Can industry withstand the crucible of common decency in dealings with animals? Do they deal progressively with societal issues? Prescriptive Production Issues will be discussed by a panel, then there will be comments on Farm Level HACCP. Animal agriculture is presented as the major contributor of water pollutants. Is the USEPA moving toward acceptable agricultural pollution through credits that allow pollution? The final session is a panel of environmental experts. Full papers will be available in independently published proceedings.

Key Words: GMO's, Prescriptive Production, Agricultural Consolidation

2 A Rational Discussion of GMOs in the Animal Food Chain. S.K. Harlander*, *BIOrational Consultants, Inc.*

In the relatively short time since their commercial introduction in 1996, genetically modified (GM) crops have been rapidly adopted in the U.S. Over 25% of the corn, 54% of the soybeans, 61% of the cotton and 70% of the canola grown in the U.S. and Canada in 2000 were GM varieties. These crops are treated as commodities and have found their way into the vast majority of ingredients used for human food products and animal feed. Because FDA considers these crops "substantially equivalent"

to their traditional counterparts, no special labeling is required for ingredients derived from GM crops in the U.S. Crops are typically not identity preserved or segregated from their non-GM counterparts and co-mingling is common in the supply chain. Certain consumers who wish to avoid GM foods have raised concerns about the use of GM crops in animal feed. They question the safety and fate of DNA and protein derived from GM crops once they are consumed by animals. Some have suggested that animals that have consumed GM crops should be labeled as such. International scientific organizations agree that GM crops are as safe or safer than conventional crops. The DNA and protein present in GM crops is digested in the same manner as endogenous DNA and protein present in the food supply. Numerous studies have also demonstrated that protein and DNA from GM crops is not detectable in various organs, meat, milk or eggs. Animal feeding studies in a variety of animal model systems have confirmed that GM crops are nutritionally equivalent to their conventional counterparts. Further, animal performance is equivalent for conventional and GM varieties. The techniques of genetic engineering can be applied to animals in a variety of ways to improve animal performance, alter composition, or to engineer animals to produce pharmaceuticals in their milk or blood. This presentation will provide a rational discussion of the broad applications of genetic engineering to the animal food chain and the logistical, regulatory and consumer acceptance issues created by this emerging capability.

Key Words: Genetically modified crops, Fate of DNA and protein, Labeling

3 The Economics of the Animal Protein Chain. A Barkema*¹, M Drabentott¹, and N Novack¹, ¹Federal Reserve Bank of Kansas City.

One of the most striking developments in the animal protein industry in recent years is its rapid consolidation, highlighted by three recent events. First, recent census data indicate just a tenth of the nation's farms account for fully two-thirds of U.S. agriculture's output of food and fiber. Second, the share of the nation's steers and heifers slaughtered by the four largest meat processors edged up to more than 81 percent in 1999, up from slightly more than a third in 1980. Third, Wal-Mart recently took the lead as the nation's largest food retailer, boosting the market share held by the four largest food retailers to about a third.

The industry's increased consolidation presents an important trade-off to both consumers and producers. On one hand, the consolidation heightens concern that big food companies could gain market power, pushing up food prices for consumers while pushing down commodity prices for producers. On the other hand, the consolidation could be beneficial, enabling more efficient product development and delivery systems while wringing out industry costs. Consumers could gain a wider selection of higher quality food products at lower prices. Producers could boost margins and manage risks by entering supply chain relationships with food companies. In either event, rural areas could see a new patchwork of growth and decline emerge as traditional farm-dependent communities wither and a comparatively small number of supply-chain hubs emerge.

These dramatic shifts in the economics of the animal protein chain pose big questions for policymakers. How much concentration is too much, and how do regulators know? What policy changes will help producers participate most profitably in the industry's new business structures? And how do rural communities position themselves to capture the benefits of the new livestock industry while minimizing any negative impacts? All of these questions point to the need to rethink the traditional approach to regulatory, farm, and rural policies that were built around commodities, a model that looks out of step with where the industry is headed.

Key Words: consolidation, concentration, food industry

4 Pork value chain economic concerns. Steve Meyer*, National Pork Producers Council, Des Moines, IA USA.

There is no "food" value chain. There is not even "a" pork value chain. In fact, there are hundreds of parallel value chains delivering foods of various varieties to consumers. They compete for consumer food dollars; a pool which has gotten smaller by opportunity, not necessity, in the U.S. New technology and the ability to apply it rapidly has allowed some producers, processors and retailers to gain cost advantages over competitors thereby enabling them to sell for less and create extreme economic pressure for rival firms. This pressure has, not surprisingly, forced many from the industry. The resulting consolidation has caused producer sector turmoil and political decisions aimed at economic problems. The issues for the future will be twofold. First, will the pork industry look to the consumer or producer end of the chain to decide who is "rightfully" served? Second, will value chain systems that equitably distribute the total consumer value be derived and, if so, will they provide enough income and profit to producers of live animals?

Key Words: value chain, consumer, equitably

5 Current and future challenges in the dairy food marketing chain. R. D. Yonkers*, International Dairy Foods Association.

All segments of the dairy marketing chain have undergone significant structural change in the past decade, a trend likely to continue. Increasing concentration exists among milk marketing cooperatives, dairy product processors and retailers and other outlets for dairy products. The dairy industry is characterized by low profit margins at all points in the marketing chain. In addition, the substantial level of government regulation of the dairy industry inhibits innovation at all levels, especially minimum price regulations and strict standards of identity for consumer products. The future growth of the U.S. dairy industry depends on successfully addressing the following challenges:

- 1) Transition current dairy industry regulations, which are nearly the same as those first developed in the 1930's and 1940's, to reflect current market realities.
- 2) Increase the dairy industry's cost competitiveness with other global dairy players as well as other domestic competitors for their share of the consumer stomach.
- 3) Successfully adopt existing and emerging technologies and develop product innovations designed to meet the changing consumer marketplace.

Key Words: Dairy markets, Dairy regulation, Cost competitiveness

6 The ADDS Program: facilitating cooperation and national leadership for agricultural knowledge delivery. J.M. Mattison*¹, M.B. Opperman¹, B.R. Eastwood², R.M. Kattnig³, and M.J. Joyce⁴. ¹ADDS Center, ²USDA-CSREES, ³University of Arizona, ⁴Wisconsin Milk Marketing Board.

The ADDS Program is a cooperative effort between USDA/CSREES, the Land Grant University system, producer commodity organizations and the private sector to develop information resources for decision support. These resources, or InfoBases, can be used by extension personnel, educators, producers and support personnel to facilitate the development of a decision support mechanism to benefit all of agriculture. Each InfoBase product is organized by a national committee of specialists representing Cooperative Extension, commodity producer groups and private industry. This committee sets the organizational structure of the InfoBase, including determining a project leader, organizing an editorial committee and developing review teams. The committee also develops guidelines for the information that will appear in an InfoBase, including subject areas, content requirements and review schedule. Standard operating procedures for the continuous updating and review of content are also outlined by the committee. This committee structure provides a forum for national leadership and cooperation for the development of specific commodity-based decision support tools. Each InfoBase committee selects three representatives to the ADDS, Inc board of directors. This board represents all active InfoBase groups, encompassing beef, poultry, dairy, pig, sheep, goat, catfish, FARAD and food safety industries. This groups maintains the policy and structure of the ADDS Center, which is the service bureau charged to facilitate the development, production and marketing of InfoBase products.

Key Words: Infobase, Decision, Knowledge

7 Prescriptive production issues - a UK / European perspective. Malcolm Mitchell*¹, ¹Roslin Institute.

In Europe, public and political concern relating to animal welfare and commercial production has increased dramatically. In particular, public awareness of the issues has been raised by extensive media coverage and the high profile activities of both animal welfare (e.g. UK Farm Animal Welfare Council) and animal rights organizations. Inextricably linked to the animal welfare concerns is the perception that modern intensive production systems have influenced food hygiene and human health (e.g. spongiform encephalopathies and salmonella infections). The result is an ever-changing background of interrelated legislation, codes of practice and quality assurance schemes regulating animal production, handling, transport, slaughter and processing. There are many participants in the development, implementation and policing of the regulations and codes. A major driving force for improvement is general public concern although the animal welfare lobby has drawn attention to specific problems. Much of the pertinent legislation originates at European level in the form of European Community Regulations and Directives. These are binding upon member states and must be implemented, by governments, through "domestic law". The standards defined in this manner may often come in to conflict with World Trade Organization agreements. Superimposed on this legal framework is the influence of the food retailers who in the UK can exert tremendous economic influence on animal producers. These retail organizations can achieve commercial advantage by promoting higher welfare standards and production systems. There are many recent examples of changes in agricultural practice resulting from all of these prescriptive pressures, including the abolition of pig farrowing cages and tethers, the phasing out of battery cages and the prohibition of amputation procedures. The increased costs of higher welfare standards and better production systems are generally borne by the producers and few subsidies for this purpose are available. A major challenge to the scientific community is to provide the sound, objective basis for improvements in welfare regulations and methods of production, which consider the well being of the animals but allow for the economic supply of high quality animal products.

Key Words: animal production, welfare, legislation

8 Government perspective on animal production food safety. Alice Thaler*, *USDA/FSIS, Washington, DC/USA.*

The Food Safety and Inspection Service (FSIS) is committed to ensuring food safety for meat, poultry and egg products using a farm-to-table approach. Issues affecting producers include regulatory requirements at slaughter, humane handling, and residues. FSIS has no direct regulatory authority on the farm; however, regulatory requirements at slaughter establishments will impact the relationship between producers and processors. The FSIS has 35 cooperative agreements with state regulatory officials and universities to educate producers about these impacts. These educational efforts in animal production are part of a larger change whereby FSIS will redefine the role of its veterinarians who will become public health professionals overseeing the effectiveness of farm-to-table food safety systems.

Humane issues potentially impact producers. FSIS considers humane methods of handling animals and humane slaughter operations a priority, and is committed to ensuring that there is compliance with the Humane Methods of Slaughter Act in federally inspected establishments that slaughter livestock. FSIS participates in the USDA Animal Well Being Task Group, which is comprised of agencies with regulatory authority over humane treatment of animals under prescribed circumstances, such as animals under exhibition. FSIS plans to develop objective criteria for determining whether observed handling and stunning practices for livestock are humane. Also, beginning with School Year 2000-2001 purchase, USDA will no longer accept ground beef that includes product from non-ambulatory cattle.

Residues continue to be an important issue in the minds of consumers. FSIS is developing an approach to regulatory enforcement that will be compatible with a HACCP environment. This may include condemnation of carcasses whenever a target tissue is found to exceed the regulatory tolerance for a pesticide or drug.

All in all, responsibility to prevent, reduce or eliminate hazards will be shared throughout the farm-to-table continuum. Industry quality assurance programs are expected to address more food safety issues in the future. This will be a major change for producers who do not currently have programs in place to address microbiological, chemical, and physical hazards.

Key Words: residues, HACCP, food safety

9 Overview of environmental protection concerns and potential solutions. H. F. Tyrrell*, *U. S. Department of Agriculture, CSREES, PAS.*

The impact of livestock production on the environment has evolved into a major issue confronting livestock producers in the United States. The U.S. Environmental Protection Agency has proposed new regulations for Animal Feeding Operations which will have major impact if enacted as proposed. The Supreme Court has upheld new Air Quality Standards which, for the first time, will include ammonia as a criteria pollutant under the National Ambient Air Quality Standards. The bottom line is that it will not be business as usual for livestock producers. The livestock industry is going to have to factor in the cost of dealing with nutrients entering and leaving the animal feeding operation by whatever route. The starting point for the development of nutrient management

systems has to be the application of mass balance principles to the total livestock production system. We have to be able to accurately identify source and fate of each nutrient as it moves through the production system. Route of loss will be different for each nutrient. Loss of nitrogen to the atmosphere, for example, can be the primary route from the production system to the environment whereas phosphorus loss via this route would be negligible. Only when one considers total mass flow of all nutrients through a livestock production system can realistic comparisons of alternative nutrient management strategies be made.

Key Words: Nutrient, Regulation, Environment

10 EPA's Vision—the Next Steps. Roberta Parry*, *U.S. Environmental Protection Agency, Washington, D.C..*

The U.S. Environmental Protection Agency (EPA) proposed new Confined Animal Feeding Operation (CAFO) regulations in January 2001. The regulations focus on preventing animal manure from reaching surface waters. Nutrients are the major pollutants of concern, since they are the number one cause of water quality impairments in lakes and the number three cause in rivers. Pathogens and sediment are also important pollutants from CAFO operations. In order to update the 25-year old CAFO regulations, EPA has proposed several changes to better protect water quality. These changes focus on three major areas: 1) who needs a permit (all CAFOs including dry poultry, immature swine and heifer operations, and integrators with substantial operational control over growers); 2) feedlot requirements (existing beef and dairy CAFOs and all new CAFOs—zero discharge to groundwater that is hydrologically connected to surface water),(veal, swine, and poultry—zero discharge with no overflow allowance); and 3) land application of manure (Permit Nutrient Plans including rate, timing, and method of application; 100' setback from water; maintaining records on manure transferred off-site). EPA has taken public comment on the proposal and will be revising the regulation for final action by December 2002. In addition to the CAFO proposal, the Total Maximum Daily Load regulation may require animal operations to adopt additional practices if the operations are in watersheds where agriculture impairs water quality. Livestock producers will need assistance from many different sources to understand their responsibilities under these regulations and implement changes on their operations.

Key Words: Confined Animal Feeding Operation, Water Quality, EPA Regulations

11 Industry View of Environmental Issues. C. H. Iltis*,¹ *National Milk Producers Federation.*

As a result of various federal, state, and local environmental initiatives, livestock producers are having to become increasingly aware of minimizing any potential environmental impacts on their farms. This presentation will review various initiatives to manage livestock waste from both regulatory and educational/technical assistance standpoints. In addition, we will discuss producer-led efforts to address their environmental concerns.

Key Words: Environmental, Livestock

Current Concepts of Animal Growth X: Metabolic and Cellular Regulation of Protein Deposition

12 Amino Acids: Regulators of Global and Specific mRNA Translation. S.R. Kimball*¹, ¹*Pennsylvania State University.*

A continuous supply of a complete complement of essential amino acids is a prerequisite for maintenance of optimal rates of protein synthesis in both liver and skeletal muscle. Deprivation of even a single essential amino acid causes a decrease in the synthesis of essentially all cellular proteins through an inhibition of the initiation phase of mRNA translation. However, the synthesis of all proteins is not repressed equally. Specific subsets of proteins, in particular those encoded by mRNAs containing a 5-terminal oligopyrimidine (TOP) motif, are affected to a much greater extent compared to most proteins. The specific decrease in TOP mRNA translation is a result of an inhibition of the ribosomal protein S6 kinase, S6K1, and a concomitant decline in S6 phosphory-

lation. Interestingly, many TOP mRNAs encode proteins involved in mRNA translation, such as elongation factors eEF1A and eEF2, as well as the ribosomal proteins. Thus, deprivation of essential amino acids not only directly and rapidly represses global mRNA translation, but also potentially results in a reduction in the capacity to synthesize protein.

13 Cellular Control of Protein Degradation. Didier Attaix*¹, Lydie Combaret¹, M-Noelle Pouch¹, and Daniel Taillandier¹, ¹*Human Nutrition Research Center of Clermont-Ferrand and INRA.*

A few years ago protein degradation was considered to be a global, non-selective and poorly regulated metabolic process that was mainly involved in housekeeping functions. This area of research has developed exponentially in the last decade, and it is now clear that many major biological functions are controlled by the breakdown of specific proteins. In

this respect, the ubiquitin-proteasome-dependent pathway is the most elaborate protein-degradation machinery known. The formation of a polyubiquitin degradation signal is required for proteasome-dependent proteolysis. Several families of enzymes, which may comprise hundreds of members to achieve high selectivity, control this process. The substrates tagged by polyubiquitin chains are then recognized by the 26S proteasome and degraded into peptides. However, the 26S proteasome also recognizes and degrades some non-ubiquitinated proteins. Indeed, several ubiquitin- and/or proteasome-dependent systems degrade specific classes of substrates and single proteins by alternative mechanisms and are presumably interconnected. They may also interfere or cooperate with other proteolytic pathways.

Key Words: Protein breakdown, Proteasome, Ubiquitin

14 Stress and Muscle Cachexia. P.O. Hasselgren*¹, ¹University of Cincinnati.

One of the metabolic hallmarks of sepsis and severe injury is a catabolic response in skeletal muscle. Muscle cachexia in these conditions is mainly caused by increased protein breakdown, although inhibited protein synthesis contributes to the negative nitrogen balance in skeletal muscle. Muscle protein breakdown during sepsis and following severe injury mainly reflects degradation of the myofibrillar proteins actin and myosin. There is evidence that a calcium-calpain-dependent release of the myofilaments from the sarcomere provides substrates for the ubiquitin-proteasome proteolytic pathway. Proteins degraded by this pathway are ubiquitinated and subsequently degraded by the 26S proteasome. Research in our laboratory has provided evidence that the gene expression of calpains as well as various components of the ubiquitin proteasome pathway is upregulated in skeletal muscle during sepsis and following severe injury. In addition, proteasome inhibitors block the increase in muscle protein breakdown seen in these conditions. Muscle cachexia in patients with stress has important clinical implications because it can prevent or delay ambulation, increasing the risk for thromboembolic complications and prolonging rehabilitation. In addition, when respiratory muscles are affected, there is an increased risk for pulmonary complications and a need for prolonged ventilatory support.

Key Words: Muscle, Proteolysis, Sepsis

15 Developmental Regulation of Protein Metabolism. T.A. Davis*¹, M.L. Fiorotto¹, and A. Suryawan¹, ¹USDA/ARS Children's Nutrition Research Center.

Growth and development are characterized by high rates of protein turnover that support rapid rates of protein accretion. The rate of protein deposition varies among tissues, with the growth rate of the skeletal musculature being amongst the highest. The efficiency with which dietary amino acids are utilized for protein deposition is high in neonates and decreases as the animal matures. This high efficiency is likely due to the enhanced stimulation of protein synthesis after feeding. The rise in protein synthesis in response to feeding and its developmental decline are more pronounced in skeletal muscle than for other tissues. In the neonatal pig, the postprandial rises in insulin and amino acids independently stimulate protein synthesis in skeletal muscle, whereas amino acids are the principal anabolic stimulus for liver. These developmental changes in protein synthesis are regulated by alterations in the expression and activity of components of the signaling pathway that controls the initiation of translation.

Key Words: Protein Synthesis, Insulin, Amino Acids

16 Muscle Wasting and Protein Metabolism. C. Castaneda-Sceppa¹, ¹Jean Mayer USDA Human Nutrition Research Center on Aging.

Accelerated muscle proteolysis is the primary cause of muscle wasting in many catabolic diseases such as diabetes mellitus, renal and liver failure, HIV infection and AIDS, and cancer. In individuals with catabolic diseases, as it is the case of fasting states (anorexia and starvation), protein breakdown increases while protein synthesis declines resulting in negative muscle protein balance. The pathway responsible for accelerated proteolysis in catabolic conditions is the ubiquitin-proteasome dependent system. Muscle proteolysis increases under conditions of acidosis,

up-regulation of branched-chain ketoacid dehydrogenase, the presence of catabolic hormones (glucocorticoids, thyrotoxic states), insulin resistance, and multiple cytokines (interleukin-1 and 6 and tumor necrosis factor). In contrast, factors that suppress muscle proteolysis and wasting leading to a state of adaptation include dietary protein deficiency with adequate energy intake, use of anabolic agents, and resistance exercise training. The understanding of the biochemical adaptation that reduce protein degradation and improve nitrogen balance are important for the development of effective therapies to combat muscle wasting and improve protein homeostasis with catabolic illnesses.

Key Words: Skeletal muscle loss, Protein turnover, Catabolism

17 Hormonal Regulation of Regional and Tissue Protein Turnover. S. Nair*¹, ¹Endocrinology Unit, Mayo Clinic.

Hormones are major regulators of protein turnover in humans. Whole body protein balance and tissue concentrations of specific proteins are determined by the balance between synthesis and degradation of proteins. Most of the hormonal actions are tissue and protein specific and the same hormone may inhibit synthesis of one protein but directly or indirectly stimulate synthesis of another protein. Hormonal effects are targeted at different levels of regulation of protein synthesis and degradation. Examples of hormonal imbalance resulting in profound changes in protein turnover is evident in type I diabetes. Insulin deficiency results in elevated glucagon and growth hormone levels in human. Insulin deficiency has been shown to result in profound muscle wasting by a net increase in muscle protein breakdown. High glucagon causes increased metabolic rate and accelerated leucine oxidation thus contributing to the catabolic state in diabetes. Other catabolic hormones such as cortisol also may contribute to catabolism. Insulin also is a key hormone involved in regulating the trafficking of amino acids across organs especially making amino acids available for synthesizing essential proteins in between meals. Recent interest has focused on insulin specific effects on certain proteins with specific functions such as mitochondrial proteins. Hormones also act in conjunction with substrates which modulates hormonal effect on protein turnover.

18 Exercise and Protein Metabolism. R.R. Wolfe¹, ¹University of Texas Medical Branch and Shriners Burns Hospital.

Resistance exercise training produces an anabolic effect on muscle, yet during exercise muscle protein synthesis is not stimulated, and muscle protein breakdown may be accelerated. The anabolic response begins after the exercise is completed. Muscle protein synthesis is elevated by about one hour after exercise, and remains elevated for as long as 48 hours. A simultaneous increase in muscle protein breakdown blunts the effect of the stimulation of synthesis on the net protein balance. Net muscle protein balance is improved after exercise, but remains negative unless nutrients are ingested. Thus, the "anabolic" response to resistance exercise occurs in the fed state, where ingested amino acids are incorporated into muscle protein to a greater extent than when ingested at rest.

19 Nutritional Regulation of Protein Metabolism. P.J. Garlick*¹, ¹State University of New York at Stony Brook.

Protein homeostasis depends on the balance between protein synthesis and protein degradation. In muscle of growing animals, feeding is accompanied by an increase in protein synthesis, resulting in net protein deposition. This has been shown to depend on amino acid supply and insulin secretion. In contrast, in the liver, protein deposition after feeding results mainly from an inhibition of protein degradation. At the whole body level, increasing nutrient intake in human preterm neonates has been shown to be associated with increased protein deposition, resulting from enhanced protein synthesis. In healthy adults there is no growth, but there is a need to retain protein after meals to counter the protein loss that occurs postabsorptively. The adult rat shows little stimulation of muscle protein synthesis by food intake or insulin infusion, whereas in human muscle the responses to nutrients or insulin remain controversial. Pathological conditions such as trauma and infection are characterized by muscle protein loss and a decrease in muscle protein synthesis, and much effort has been spent on strategies for reversing muscle wasting by nutritional and pharmacological means. However, nutritional support, even when supplemented with branched chain amino acids or glutamine, have not yet been shown to be effective.

ADSA Dairy Foods Graduate Student Paper Competition

20 Temperature effect on structure-opacity relationships of nonfat Mozzarella cheese. A.J. Pastorino^{*1}, R.I. Dave², C.J. Oberg³, and D.J. McMahon¹, ¹Utah State University, ²South Dakota State University, ³Weber State University.

Our objective was to determine the effect of heating on the structure of nonfat Mozzarella cheese, and then to relate changes in structure to changes in cheese opacity. Cheese was made according to a direct-acid, stirred-curd procedure. Cheese samples, at 4°C, were taken on d 1 and placed into glass bottles, which were sealed and heated. Once the cheese reached 10°C or 50°C, the bottles were placed on a scanner and color values measured. Samples of cheese at 10°C and 50°C were also taken on d 1 for structural analysis. Scanning and transmission electron micrographs of cheese were scanned and digitally analyzed. Applying heat increased cheese opacity, as measured by L-values (91.5 versus 78.0; $P < 0.001$), and induced changes in cheese structure. Larger protein aggregates (7.0 nm² versus 1.9 nm²; $P = 0.074$) and increased protein concentration in the protein matrix were observed in cheese at 50°C (i.e., increased aggregate density, 157 versus 91; $P = 0.008$). Applied heat would favor hydrophobic interactions, and possibly, re-association of β -casein and calcium with the protein matrix, promoting protein-to-protein interactions. Thus, the protein matrix contracted, occupying less cheese matrix area (69 versus 99%; $P = 0.022$) and microphase separation occurred, causing serum pockets to grow in size (from a maximum diameter of 1.0 μ m to 7.0 μ m), and microstructural heterogeneity increased. It is proposed that the increased size of aggregates and heterogeneity of the cheese at 50°C promote light reflection, thus increasing cheese opacity. We concluded that applying heat alters protein interactions in the cheese matrix, which is manifest as changes in cheese structure. Such changes in structure help provide an understanding of changes in cheese opacity.

Key Words: Cheese, Structure-Opacity, Temperature

21 Rheological properties of rennet-induced gels made from coagulants of vegetable origin and chymosin. C. L. C. Esteves^{*1,2}, J. A. Lucey¹, and E. M. V. Pires², ¹University of Wisconsin-Madison, Madison, ²University of Coimbra, Coimbra, Portugal.

The type of coagulant used in cheese-making plays an important role in the characteristics of the final product. In Portugal, the flowers of *Cynara* sp have been used for a long time in the production of vegetarian cheeses that are considered of high quality, because of their distinctive flavor and texture. However, little is known about the textural properties of rennet-induced gels made with vegetable coagulants. The rheological properties of rennet gels made from the vegetable coagulants *Cynara cardunculus* L. and *Cynara humilis* L. were compared with those of recombinant chymosin, using dynamic low amplitude oscillation. The large deformation properties of gels were studied by subjecting set gels to a constant shear rate (0.01 s⁻¹), up to yielding of the gel. Gelation experiments were performed at 32°C using NFDM reconstituted for 2 and 16 h, at 32°C. The general pattern of gelation curves was similar for the three coagulants. After 6 h of gelation, the storage modulus of chymosin and vegetable coagulants were 79±0.4 and 66±1.9 Pa, respectively for milk dissolved for 2 h and 74±0.2 and 57±2.4 Pa, respectively for milk dissolved for 16 h. The lower storage modulus in gels made from milk dissolved for 16 h was probably due to casein hydrolysis by plasmin. The effect of the time scale of the applied deformation on the rheological properties was determined by a frequency sweep (0.002 - 1 Hz). At low frequency (0.002 Hz), regardless of time allowed to dissolve the milk, loss tangent values for chymosin (0.54±0.01) were higher than those for *Cynara cardunculus* L. (0.49±0.01) and *Cynara humilis* L. (0.50±0.01). Higher loss tangent values indicate susceptibility to syneresis. The shear stress at yielding was higher for chymosin (53±2.2 Pa) than vegetable rennets (46±2.3 Pa), for milk dissolved for both periods. The shear strain at yielding was similar for all coagulants (0.98±0.11) except for chymosin (1.17±0.05) when milk was dissolved for 16 h. The rennet-induced gels made with *Cynara cardunculus* L. and *Cynara humilis* L. were alike, probably due to the similarity in their proteolytic enzymes.

Key Words: Vegetable coagulants, Rennet-induced gels, Rheology

22 Evaluation of Quality Properties of Butter and Ice Cream with a High Content of Linoleic and Oleic Acid. S Gonzalez*, S.S. Duncan, S.S. Sumner, S.F. O'Keefe, and J. Herbein, Virginia Tech, Blacksburg, VA/USA.

Milk fat composition determines specific rheological, sensory and physicochemical properties of dairy products such as texture, melting point, flavor, color, oxidation rates, and viscosity. Previous studies have shown that milkfat containing higher levels of long chain polyunsaturated fatty acids have lower melting point and decreased solid fat content which leads to softer textured products. An increased risk of higher oxidation rates can be a disadvantage of high levels of polyunsaturated fatty acids. Three different milkfat compositions were obtained through dietary manipulation of cows: high oleic content, high linoleic content and standard milkfat. Ice cream and butter were processed from the treated and control milk. The samples were then analyzed to measure differences in texture (firmness), oxidation rate and sensory perception. Textures of butter and ice cream were performed by doing compression measurements. No significant difference was found between control and treated ice cream samples. However untreated butters were firmer (10.54 J) than butters containing higher amounts of unsaturated fatty acids (6.09-6.95 J) in a temperature range of 4.3-5.5 C. Peroxide values in ice cream were measured before freezing and after sensory testing to monitor oxidation behavior of the three treatments. Initial peroxide values were similar between the treatments, however after 3 months of storage the values increased at a higher rate for the linoleic treatment. Sensory analyses included a scooping test on the three treated ice creams at -18C to detect differences in texture. An overall difference test was conducted to determine if consumers could taste a difference between the three ice cream treatments. The overall difference test showed significant difference between the control and the oleic treatment as well as the control and linoleic treatment at a p= 0.05. No significant difference was found in the scooping test.

Key Words: Ice cream , Texture, Linoleic and Oleic Acid

23 Effect of high-pressure on two strains of *Lactococcus lactis* subsp. *cremoris* in a phosphate buffered saline (PBS) cell suspension. A. S. Malone*, T.H. Shellhammer, and P. D. Courtney, Food Science and Technology, Ohio State University.

Cellular lysis or membrane permeability of cheese starter cultures is thought to play an important role in cheese ripening due to release of intracellular enzymes. Thus, researching a method, such as high-pressure processing, to induce or prohibit cell lysis or membrane permeability may provide a path to accelerate or arrest cheese maturation. Two strains of *Lactococcus lactis* subsp. *cremoris*, MG1363 and SK11, were grown to early stationary phase at 30°C in GM17 and LM17 broth, respectively. Cells were washed and resuspended in sterile phosphate buffered saline (PBS) at pH 7.0 to concentrations of approximately 6 X 10⁸ to 1 X 10⁹ cfu/ml. Cell suspensions were examined for their response to five minute, high-pressure treatments (100 to 800 MPa) at 25±4°C. Cell viability was assessed as cfu/ml immediately after pressure treatment. Both strains were completely inactivated at pressures of 400 to 800 MPa. There was no significant effect on cell viability at pressures of 100 and 200 MPa. At 300 MPa, the MG1363 population decreased by 7.3 log cycles, whereas the SK11 population decreased by 2.5 log cycles. Cell lysis was monitored by recording suspension absorbance at 600 nm (A₆₀₀) after pressure treatment for time intervals up to 24 hours. Pressure treated MG1363 cell suspensions decreased in A₆₀₀ over time when compared with non-pressure treated controls. Twenty-four hours after pressure treatment, the A₆₀₀ decreased by 0.15 to 0.30. The A₆₀₀ of pressure-treated SK11 suspensions did not differ significantly from non-pressure treated controls. These data indicate that high pressure can induce subsequent cell lysis and that lysis is strain dependent. Further studies are aimed at the extent of membrane permeability and autolysin activity in each strain after pressure treatment.

Key Words: *Lactococcus lactis*, high-pressure, lysis

24 Alpha-galactosidase as a novel molecular tool for the genetic modification of *Lactococcus lactis*. I. Boucher*¹, M. Parrot¹, C. Vadeboncoeur¹, and S. Moineau¹, ¹*Universite Laval, Quebec, Quebec, Canada.*

Atypical sugar fermentation phenotypes represent an attractive alternative to antibiotic resistance as a selection marker on plasmid vectors used for the genetic modification of lactic acid bacteria (LAB). For instance, melibiose is an alpha-galactoside rarely fermented by LAB. This disaccharide is hydrolyzed into galactose and glucose by alpha-galactosidase. The resulting monosaccharides are subsequently degraded through metabolic pathways that are commonly found in LAB. Using a degenerated oligonucleotide probe, the alpha-galactosidase gene (*aga*) and a gene coding for a transcriptional regulator from the LacI/GalR family (*galR*) of *Lactococcus raffinolactis* ATCC43920 were located on a 4 kbp DNA restriction fragment. When transferred into various *Lactococcus lactis* strains using the plasmid vector pNZ123, *aga* conferred the ability to ferment melibiose. A *Pediococcus acidilactici* strain also became melibiose-positive when transformed with the *L. raffinolactis* *aga* gene. Sequences coding for homologues of *L. raffinolactis* *aga* and *galR* products were also obtained from a raffinose-fermenting *L. lactis* subsp. *lactis* strain. The genes of both organisms displayed a similar organization on the chromosome and their nucleotide sequences were over 90% identical. *L. raffinolactis* *aga* was finally associated to the minimal region essential for the maintenance of a *L. lactis* natural plasmid to create a functional cloning device. Detection of melibiose-positive *L. lactis* transformants on a solid medium was made possible by first culturing transformed cells into an enrichment medium containing melibiose as the unique energy source. Constituted entirely of lactococcal DNA and exempt of antibiotic resistance determinants, this plasmid construction should be appropriate for food-grade applications. Lactococcal alpha-galactosidases represent a valuable new molecular tool suitable for the genetic modification of lactococci and other LAB.

Key Words: *Lactococcus raffinolactis*, alpha-galactosidase, selection marker

25 Influence of proteolytic enzymes from thermophilic lactic acid bacteria on the functional properties of Mozzarella cheese. B. S. Oommen*¹, D. J. McMahon¹, J. R. Broadbent¹, and C. J. Oberg², ¹*Utah State University*, ²*Weber State University*.

Part-skim Mozzarella cheeses were manufactured from 2%-fat milk using *Streptococcus thermophilus* as the starter and three different strains of *Lactobacillus delbrueckii* ssp. *bulgaricus* as adjunct starter culture to make three treatments and one without the addition of adjunct starter culture as the control. Three strains of the bacteria differed in their proteolytic specificity on α_{s1} -CN (f1-23) and their extent of proteolysis in milk. Based on their specificity, they were grouped as R2I, R6III, and R13V (this also represents the decreasing order of their extent of proteolysis) and the cheeses with those cultures were designated CR2I, CR6III, and CR13V respectively. Four replicates of these cheeses were aged and tested for functional attributes at 7, 14, and 21 d. Moisture, fat, and protein content in cheeses ranged from 45.2 to 48.4%, 19.9 to 20.5%, and 26.80 to 28.55% respectively. Salt content were not different ($P > 0.05$) among treatments. Cheese meltability increased ($P < 0.05$) from 58.05% in control to 81.86% in CR13V (CR2I, 73.20%; CR6III, 74.19%). TPA-hardness was 168.20 N for control and similar ($P > 0.05$) for CR2I (88.77), CR6III (101.45), and CR2I, CR13V (80.34 N). Melt strength, a measure of strand forming ability was highest ($P < 0.05$) for control (3.17 N) and lowest ($P < 0.05$) for CR13V (1.42 N). The ability of cheese strands to remain as a cohesive mass while being pulled called stretch quality was highest ($P < 0.05$) in control (0.6438 N) and lowest ($P < 0.05$) in CR13V (0.2113 N). Stretch quality and melt strength were similar ($P > 0.05$) for CR2I and CR6III. Meltability and TPA-cohesiveness increased ($P < 0.05$) with age while melt strength and stretch quality decreased ($P < 0.05$) with age. Water soluble peptides in cheese as measured by the total area under the peaks on HPLC correlated highly with meltability and stretch characteristics. Proteolytic specificity of lactic acid bacteria may be used as an indicator of the functional properties of the resultant cheese.

Key Words: Mozzarella, proteolysis, functionality

26 Fluorescence microscopy and recrystallization rate of model ice cream solutions as influenced by stabilizer type. A. Regand* and H.D. Goff, *University of Guelph, Guelph, Ontario, Canada.*

Stabilizers are known to retard ice recrystallization in frozen systems during storage at fluctuating temperatures, however the mechanism is not clear. Stabilizers were labelled with rhodamine isothiocyanate (RITC) and incorporated into solutions of sucrose (24%) and sucrose (16%) with skim milk powder (SMP) (14.7%). Solutions contained either no stabilizer or 0.3% of carrageenan, carboxymethyl cellulose (CMC), xanthan gum, sodium alginate, locust bean gum (LBG) or gelatine. The solutions were quenched frozen to -50°C, precycled to get similar ice crystal size at t=0 ($p \leq 0.05$), and cycled between -3.5°C and -6°C, 5 times. Different precycling treatments were required for samples with or without SMP due to lower initial values of ice crystal size in the presence of SMP. Digital brightfield and fluorescent images were acquired at t=0 and -3.5°C on each cycle. Recrystallization rate was calculated as the slope of the linear regression of the ice crystal median diameters obtained by the brightfield data. Location of the stabilizer was observed using fluorescence microscopy. Of the sucrose solutions, only the sample containing LBG showed a gel-like structure after cycling. Nevertheless, its recrystallization rate was not different from the control ($p \leq 0.05$). Lowest rates of recrystallization were detected with xanthan or alginate in sucrose solutions ($p \leq 0.05$). Cryo-gel formation and/or phase separation of proteins were identified by fluorescence microscopy after cycling in all solutions containing SMP. In the presence of proteins, all stabilizers retarded recrystallization compared to the control ($p \leq 0.05$). The most effective stabilizers in this case were alginate, CMC and carrageenan ($p \leq 0.05$), but they did not show any distinguishing structural features. These results suggest that molecular interactions between polysaccharides and proteins play an important role in retarding ice recrystallization. In the absence of proteins, cryo-gel formation is not essential to slow recrystallization.

Key Words: Ice Cream, Stabilizers, Fluorescence Microscopy

27 Monoclonal antibodies raised against native structural proteins of *Streptococcus thermophilus* bacteriophage DT1. C. Bart*¹, A. Darveau¹, C. Vadeboncoeur¹, and S. Moineau¹, ¹*Universite Laval, Quebec, Quebec, Canada.*

Streptococcus thermophilus is a lactic acid bacterium widely used for the production of yogurt and speciality cheeses. The manufacture of these dairy goods has risen sharply over the past years. A known fact about increased productivity within existing facilities is that milk fermentation processes may be delayed due to lytic bacteriophages. *S. thermophilus* phages are currently classified into two groups based on the number of major structural proteins (MSP) and their mode of DNA packaging. Phages with two MSP and cohesive genome extremities (costype) appear to occur more frequently. To better understand phage-host interactions, our laboratory recently sequenced the first genome of a costype lytic phage of *S. thermophilus*. The sequence analysis of DT1's genome revealed several open reading frames (ORF) coding for putative structural proteins. To confirm the presence of these proteins on the phage structure, monoclonal antibodies were produced using bacteriophage DT1 as the antigen. Furthermore, two different approaches were utilized, the classical method using mice spleen hybridoma cells and the phage-display technology. One antibody raised against the major capsid protein of DT1 was obtained by the first strategy and its specificity was confirmed by immunoelectron microscopy. An ELISA assay showed that this antibody has affinity for two out of the three 2MSP phages tested (DT1, MD4) and none for the two 3MSP phages tested. On the other hand, the phage-display technology allowed us to create a library of antibody fragments (ScFv) expressed as fusion proteins on the filamentous *E. coli* phage M13. Following two rounds of panning using complete DT1 phages as the antigen, four ScFv were chosen for further characterization. The phage-display library can be a useful tool in understanding the proteomic of phage DT1 and other phages of *S. thermophilus* since members of the same phage group (2MSP) share a high level of similarity in structural proteins.

Key Words: Monoclonal antibodies, Bacteriophages, *Streptococcus thermophilus*

28 Effect of linoleic and conjugated linoleic acids on *Lactobacillus* species in broth and milk. J. K. Jenkins* and P. D. Courtney, *The Ohio State University, Columbus, Ohio.*

Conjugated linoleic acid (CLA) is formed by the enzymatic or chemical isomerization of linoleic acid (LA). CLA is reported to reduce cancer cell growth, improve immune response and reduce body fat composition. Both CLA and LA are found in dietary triacylglycerols which are hydrolyzed by lipases in the human gastrointestinal tract. CLA content is highest among fatty dairy foods due to microbial activity in the rumen. Several bacteria have the ability to enzymatically isomerize linoleic acid to CLA. It has been hypothesized that bacteria may counteract the toxic effects of linoleic acid by converting it to a less toxic form, CLA. Studies directly comparing bacterial inhibition by both fatty acids are lacking. Five *Lactobacillus* strains from mammalian intestines or fermented dairy products were grown in MRS broth or UHT milk containing various concentrations of linoleic acid or CLA. All strains were inhibited to a greater extent by the fatty acids in broth than in milk. In MRS broth, fatty acid concentrations were 0, 250, 500, 750, or 1000 $\mu\text{g/ml}$ linoleic acid or CLA, whereas in UHT milk higher concentrations were used (0, 500, 1000, 3000 and 5000 $\mu\text{g/ml}$). Both fatty acids were more inhibitory at higher concentrations. CLA was consistently less inhibitory or less lethal than linoleic acid. The population of the most linoleic acid-sensitive strain was reduced by 3 log cycles after 10 hours in MRS broth containing 750 $\mu\text{g/ml}$ LA, whereas a slight increase (0.5 log) in population was observed with the same concentration of CLA. Free fatty acids can be present in foods and in the ileum, cecum and colon of humans, thus these results have implications regarding survival of *lactobacilli* in foods and human intestinal tract.

Key Words: *Lactobacillus*, conjugated linoleic acid

29 Development of two analytical methods to quantify the concentrations of insoluble and soluble Calcium in Cheddar cheese. A. V. Hassan* and J. A. Lucey, *University of Wisconsin-Madison.*

Two methods were developed, which could be routinely used to quantify the proportions of soluble and insoluble Ca in cheese. The concentration and type of residual Ca greatly influences cheese texture and functionality. The first method ("titration"), involved the use of a novel computer controlled, acid-base titration system to quantify buffering properties of milk and cheese. During acidification of milk, there was a well-defined buffering peak with a maximum at pH 5.1, due to the solubilization of colloidal calcium phosphate (CCP). When cheese was acidified there was a strong buffering peak at pH 4.8 which was due to residual CCP of milk that was not solubilized during cheese making. The area of this buffering peak in cheese was expressed as a percent of the original area of this peak in milk and was used to estimate the concentration of residual CCP (insoluble Ca) in cheese. Cheddar cheese homogenates were prepared for titration by mixing 8 g of cheese with 40 g of distilled water at 50°C in a homogenizer for 3 min. Cheese homogenates and milk samples were titrated from initial pH of cheese and milk to pH 3.0 with 0.5 M HCl and then back titrated to pH 9.0 with 0.5 M NaOH at 25°C on a Mettler DL50 Autotitrator. Total area under this buffering peak was analyzed using a program developed with MatLab software. Proportion of soluble Ca in cheese increased from 36% to 44% of total Ca during the first four wk of ripening. The second method was based on extracting the aqueous phase ("juice") of cheese under high pressure (Morris et al., 1988) and determining the concentration of soluble Ca in juice using atomic absorption spectroscopy. 800 g of freshly grated cheese was thoroughly mixed with 1000 g of sand and placed in a specially designed stainless steel mould, and subjected to pressures up to 8 MPa, over a period of 3 h. To remove fat, the juice was centrifuged at 1650 g for 10 min at 4°C. By this "juice" method the proportion of soluble Ca in cheese increased from 33 to 38% of total Ca during the first four wk of ripening. Both methods gave similar results for the proportions of soluble and insoluble Ca in cheese. These methods will be very useful tools in monitoring changes in the detailed mineral composition of cheese during ripening.

Key Words: Calcium, Buffering, Cheese texture

30 The effects of NaCl, CaCl₂, lactose and pH on the interfacial behavior of β -lactoglobulin. J P Davis* and E A Foegeding, *North Carolina State University, Raleigh NC/USA.*

Changes in the dynamic surface tension of aqueous β -lactoglobulin (10 μM) solutions, with varying concentrations (0-0.4 M) of either NaCl, CaCl₂ or lactose, were investigated using a pendant drop technique. Surface tension was measured over a time scale of 0 to 1200 s with a 2 s resolution. For all treatments, two distinct regions of protein adsorption were observed: 1) an initial rapid and nonlinear decrease in surface tension (0 to 250 s) followed by a 2) more gradual, linear decrease in surface tension (250 to 1200 s). The rate of decline for the second region was very similar for all treatments and no treatment had reached equilibrium by 1200 s. Therefore, the final values of surface tension for any treatment depended mainly on the processes occurring during the first 250 s. At pH 5.0, which is near the isoelectric point of 5.2 for β -lactoglobulin, the initial rate of adsorption was greatest for all treatments due to the reduction of an electrostatic energy barrier at the air/aqueous interface. At pH levels above (pH 7.0) and below (pH 3.0) the isoelectric point of β -lactoglobulin, the initial adsorption was significantly slower. The addition of either NaCl or CaCl₂ at levels up to 0.1 M increased the initial rate of adsorption due to a reduction of the electrostatic barrier to protein adsorption. The effect of lactose concentration was minimal.

The success of any protein-based food foam ultimately depends on the initial rapid adsorption of the protein and its subsequent behavior, i.e. unfolding and protein-protein interactions. Our results suggest that pH, NaCl and CaCl₂ mainly alter the rate and extent of surface tension decrease. Once β -lactoglobulin is adsorbed, the gradual unfolding and lowering of interfacial tension is the same regardless of pH or co-solute.

31 Isolation and Analysis of Glycomacropeptide from Goat Sweet Whey. Eryck Silva*, Takuo Nakano, and Lech Ozimek, *University of Alberta, Edmonton, Alberta, Canada.*

Glycomacropeptide (GMP) found in cheese whey (or sweet whey) is the hydrophilic C-terminal peptide released from k-casein by the action of chymosin during cheese making. GMP has been the subject of growing interest in recent years. Because of its various biological activities, and unique amino acid composition having no phenylalanine, GMP is thought to be a potential ingredient for dietetic foods and pharmaceuticals. Bovine GMP has been studied in many laboratories. There is, however, very limited information available on goat GMP. This study was, therefore, undertaken to purify GMP from goat sweet whey, and to determine its chemical composition. A sample of sweet whey was prepared from pasteurized goat milk by chymosin treatment. After dialysis, the whey sample was applied to an anion-exchange column of DEAE-Sephacel (Pharmacia Biotech Inc.) equilibrated with water adjusted to pH 3.0. Most GMP, accounting for 97 % of total recovered sialic acid (a carbohydrate moiety of GMP), was adsorbed on DEAE-Sephacel and eluted from the column by applying 1 M NaCl. The GMP fraction obtained after DEAE-Sephacel chromatography was further purified using hydrophobic interaction chromatography on phenyl-agarose (Sigma Chemical Co.) equilibrated with 0.01 M sodium phosphate, pH 6.8 containing 5 M NaCl. The final preparation of GMP, corresponding to 0.06 % (w/v) of sweet whey, was of considerably high purity with its amino acid composition showing a trace (0.4 mol % or < 1 residue/peptide) of phenylalanine. The overall amino acid composition in goat GMP is, in general, comparable to that in bovine GMP. The content of sialic acid was, however, approximately three times lower in goat (25 mg/mg dry weight) than in bovine (80 mg/mg dry weight) GMP. It was concluded that goat sweet whey is a potential source to prepare GMP to partially substitute amino acids used for the dietary treatment of phenylketonuria.

Key Words: Glycomacropeptide, Goat whey, Sialic acid

32 Effects of NutriDenseTM and waxy corn hybrids on site and extent of starch and protein disappearance and efficiency of microbial N production in sheep. V. Akay*, J. A. Jackson, and D. L. Harmon, *University of Kentucky, Lexington.*

Corn grains harvested from the corn hybrids, Exsegen 617 (conventional yellow dent corn), Exsegen 404ND (NutriDenseTM corn, high oil and protein), and Exsegen ESX4WX (waxy corn, high amylopectin) from ExSeed Genetics L.L.C. (Decatur, IL) were used in a study to investigate their effects on site and extent of starch and protein disappearance, and efficiency of microbial N production. Six wether lambs surgically fitted with ruminal, duodenal, and ileal cannulas were fed three diets in a 3 x 6 Latin rectangle design with 21 d periods. Diets were: 1) conventional yellow dent corn (CC), 2) NutriDenseTM corn (NC), and 3) waxy corn (WC). Diets contained approximately 44.0% cracked corn grain, 39.0% cottonseed hulls, 15.0% soybean meal, and 2.0% mineral and vitamin mix (DM basis). Chromic oxide (0.21% of DM) was used as a marker. Lambs were fed twice daily in the amount of 1.8 x NE_m requirement. Data were analyzed using GLM procedure of SAS. True starch disappearance in the rumen was higher for WC than CC (86.9, 91.4 and 98.5% for CC, NC and WC, respectively). Apparent starch disappearance in the small intestine was higher for NC and WC than CC (88.3, 93.8 and 95.9% of duodenal starch flow for CC, NC and WC, respectively). Apparent daily starch disappearance in the hindgut was higher for CC than WC (7.61, 1.79 and 0.24 g/d for CC, NC and WC, respectively). Apparent total tract starch disappearance was highest for WC and lowest for NC (99.8, 99.7 and 99.9% for CC, NC and WC, respectively). Daily flow of total N, bacterial N, NH₃-N, and non-NH₃ nonbacterial N at the duodenum were similar among diets. Bacterial N production efficiencies, (gram of bacterial N per kg of true or apparent OM disappearing in the rumen) were similar among diets. Apparent N disappearance from the small intestine was also similar among diets. However, apparent N disappearance from the hindgut was -0.81, -1.06 and -1.46 g/d for CC, NC and WC, respectively, and demonstrated a statistically significant effect between CC and WC diets. Total tract apparent N disappearance was similar among diets. Results suggested that starch in waxy corn grain is more digestible in the rumen than conventional yellow dent corn. This higher starch digestion, however, did not increase bacterial N production compared to conventional yellow dent corn.

Key Words: NutriDenseTM, Waxy, Disappearance

33 Synthetic conjugated linoleic acid may cause mammary involution in dairy cows. J.A. Bell* and J.J. Kennelly, *University of Alberta, Edmonton, Canada.*

In view of the potential of synthetic CLA as a means to increase the CLA content of bovine milk, this study was undertaken to evaluate the effect of synthetic CLA on milk component synthesis. Four Holstein cows received abomasal infusion of: (1) control, no fat infusion (CTL), (2) 150g/day of synthetic CLA, 31.7% c-9, t-11; 30.4% t-10, c-12 (CLA), (3) 150g/day of safflower oil (SAFF), and (4) 150g/day of tallow (TALL). Infusion was carried out for 20-22 hours/day for 11day periods in a 4x4 Latin square design. Data from the last two days of each period was used for statistical analysis. The milk fat concentration of c-9, t-11 CLA was 0.59, 0.58, 0.61, and 1.77% of fatty acid methyl esters for CTL, SAFF, TALL and CLA respectively. The concentration of t-10, c-12 CLA was 0.85% for CLA, but not detected with the other treatments. Milk yield dropped by 35 to 40% with CLA infusion. Percentage and yield of lactose and fat were also significantly lower with CLA. The surprisingly lower concentration of lactose with CLA infusion was counterbalanced by a higher concentration of sodium. Percentage of protein was significantly higher with CLA infusion although the yield of protein was lower compared to the other treatments. Somatic cell count was approximately five to seven times greater as a result of CLA infusion compared to the other treatments. This was unexpected since there were no visible signs of mastitis during milking. Subsequent analysis of the milk revealed no evidence of bacterial infection. During the early stages of drying-off similar changes are seen in the mammary secretion as were observed with infusion of CLA. Although purely speculative, it is possible that infusion of unnaturally large amounts of these synthetic CLA isomers was initiating the involution process in the mammary gland.

Item	CTL	TALL	SAFF	CLA

34 The biohydrogenation of oleic acid to trans monoenes by ruminal microbes in vitro. E. E. Mosley*, T. C. Jenkins, and G. L. Powell, *Clemson University, Clemson, SC.*

According to most reports, oleic acid is directly hydrogenated to stearic acid by ruminal microbes without the formation of *trans* intermediates. However, feeding fat supplements high in oleic acid content to lactating cows has often increased the concentration of *trans* monoenes in ruminal contents and milk. The purpose of this study was to determine if *trans* monoenes are formed from oleic acid biohydrogenation or if oleic acid is directly hydrogenated to stearic acid as depicted in reviews. Oleic-1-¹³C acid and oleic acid were each added to four in vitro cultures of mixed ruminal microbes taken from a ruminally cannulated Holstein cow. Samples were taken at 0, 24, and 48 hours and methylated. Fatty acid methyl esters (FAME) were separated into fatty acid fractions differing in degree of saturation using a silver impregnated solid phase extraction column. The unsaturated FAME fractions were converted to dimethyl disulfide derivatives and analyzed by gas chromatography mass spectrometry. After 48 hours, the concentrations of oleic acid decreased 1.9 mg/5 ml of culture, stearic acid increased 1.3 mg/5 ml of culture, and *trans* monoenes increased 0.3 mg/5 ml of culture. Total *trans* monoenes at 48 hours averaged 0.4 mg/5 ml of culture and consisted of *trans*-9 (49%), *trans*-10 (16%), *trans*-11 (25%), and *trans*-12 (9%) octadecenoic acids. Enrichments were calculated from the mass abundance of ¹³C in major fatty acid fragments and expressed as a percentage of total carbon isotopomers. Enrichment of ¹³C at 0 hours was found in stearic acid (10.9%), oleic acid (85.2%), and *trans*-9 (85.4%) octadecenoic acid. At 24 hours, enrichment of ¹³C was found in stearic acid (37.5%), oleic acid (84.8%), *trans*-9 (85.0%), *trans*-10 (77.4%), *trans*-11 (39.9%), and *trans*-12 (72.7%) octadecenoic acids. At 48 hours, enrichment of ¹³C was found in stearic acid (35.8%), oleic acid (85.3%), *trans*-9 (84.2%), *trans*-10 (77.1%), *trans*-11 (47.4%), and *trans*-12 (73.3%) octadecenoic acids. It can be concluded that the biohydrogenation oleic acid by mixed ruminal microbes involves the formation of several positional isomers of *trans* monoenes rather than only stearic acid as previously described.

Key Words: Oleic acid, Biohydrogenation, *Trans* monoenes

35 Effects of long chain unsaturated fatty acids on palmitic acid metabolism by ruminant hepatocytes. D.G. Mashek*, S.J. Bertics, and R.R. Grummer, *University of Wisconsin, Madison.*

The objective was to determine the effects of long chain unsaturated fatty acids on the metabolism of palmitic acid to oxidation or cellular lipid products. Hepatocytes were isolated from four ruminating calves and exposed in suspension for 3 hours to one of the following treatments: 1 mM palmitic acid (1C16), 2 mM palmitic acid (2C16), or 1 mM of palmitic acid plus 1 mM of oleic (C18:1), linoleic (C18:2), linolenic (C18:3), eicosapentaenoic (C20:5), or docosahexaenoic (C22:6) acid. Oxidation of [1-¹⁴C]palmitic acid to CO₂ and acid-soluble products (ASP), or incorporation into cellular triglyceride (TG), phospholipid (PL), cholesterol (C), and cholesterol ester (CE) were measured. Overall, addition of C20:5 yielded the highest rates of palmitic acid oxidation followed by addition of C18:1 and C22:6. Addition of C18:2 or C18:3 resulted in the lowest rates of palmitic acid metabolism to most metabolic products, whereas addition of C18:1 and 2C16 yielded the highest rates of palmitic acid incorporation into TG and total cellular lipids. Addition of C20:5 and C22:6 yielded the highest rates of palmitic acid incorporation into C and, similar to C18:2 and C18:3, decreased TG formation from palmitic acid compared with the addition of C16 or

C18:1. These results show that long chain unsaturated fatty acids can have a direct affect on palmitic acid metabolism by bovine hepatocytes. Values in the table below represent incorporation of [^{14}C]palmitic acid into metabolic products (pmol/ μg DNA/3 h).

36 Programmed exercise altered carbohydrate and lipid metabolism of dairy cows. J. A. Davidson* and D. K. Beede, Michigan State University, East Lansing.

Objective was to determine the effects of a programmed exercise regimen (PER) and pregnancy of dairy cows on blood glucose (GLU), lactate (LACT), non-esterified fatty acid (NEFA), β -hydroxybutyrate (BHB) concentrations and glucose tolerance. Holstein non-lactating, multiparous pregnant or non-pregnant cows (n=52) were blocked by parity and expected calving date and assigned randomly to treatments: no exercise or exercise at a walk (3.25 km/h) every other day for 1.25 h, d 0 to 30; and, 1.5 h, d 31 to calving (d 70 of PER) in a mechanical walker with a circular lane (33.8 m circumf.). All cows completed treadmill exercise tests (ET) on d 0, 30 and 60 of PER. Treadmill ET consisted of walking 4 km/h for 3 min followed by 5 km/h with incremental increases in incline every 3 min until cows refused to walk. Jugular blood was sampled every 3 min during ET and 18 min recovery period (RP) after ET. Venous plasma concentrations of GLU and LACT were higher for non-exercised compared with exercised cows and increased as time increased during ET ($P < 0.05$). Plasma LACT concentrations were slightly higher for exercised pregnant cows compared with exercised non-pregnant cows ($P < 0.05$). Concentrations of NEFA during ET were higher for pregnant cows compared with non-pregnant cows and higher for non-exercised compared with exercised cows ($P < 0.07$). Concentrations of BHB declined faster for exercised cows compared with non-exercised cows as time during ET increased ($P < 0.05$). During RP, plasma concentrations of GLU, LACT, and NEFA decreased as time increased ($P < 0.01$). Exercised cows had lower plasma LACT than non-exercised cows during RP for d 60 ET compared with d 0 and d 30 ET ($P < 0.05$). Concentrations of BHB during RP were higher for exercised compared with non-exercised cows as time increased ($P = 0.05$). During the RP following d 60 ET, concentrations of NEFA were highest for pregnant cows as compared with non-pregnant cows ($P < 0.01$). The PER did not affect glucose tolerance. During glucose tolerance tests, pregnant cows had lower basal concentrations of GLU and insulin compared with non-pregnant cows. When given a GLU bolus (150 mg/kg BW), plasma insulin increased less for pregnant compared with non-pregnant cows ($P < 0.05$). The PER altered GLUC, LACT, BHB and NEFA metabolism during ET, but did not alter glucose tolerance.

Key Words: Exercise, Pregnancy, Dairy cows

37 Bovine lymphocytes express prolactin receptor (PRL-R) mRNA: a potential mechanism for PRL effects on immune function. T. L. Auchtung*, P. E. Kendall, and G. E. Dahl, University of Illinois, Urbana-Champaign.

Photoperiod is known to influence prolactin (PRL) secretion in cattle and has been implicated in enhancement of the immune system in rodents. Such enhancement is potentially through the actions of PRL, which is known to have cytokine-like activity. Lymphocytes of humans and rodents are known to express PRL-R mRNA, however no studies

have been performed to show the existence of PRL-R mRNA in lymphocytes of cattle. In addition, whether photoperiod has an effect on expression of PRL-R in cattle has not been studied. The objective of this study was to determine the existence of PRL-R mRNA in lymphocytes and to gain initial insight into the possibility that photoperiod influences the immune function in cattle. Blood was collected from Holstein calves via jugular venipuncture and lymphocytes were separated by centrifugation on Ficoll hypaque density gradients. Total RNA was isolated from lymphocytes using TRIzol reagent, and converted to cDNA. Real-time polymerase chain reaction (PCR) was performed using an ABI PRISM[®] 7700 Sequence Detector, with 18S as the endogenous control. Bovine lymphocytes expressed PRL-R mRNA suggesting that PRL may have direct action on these immune cells. Thus it is likely that PRL, as mediated by photoperiod, may have an impact on immune function in cattle via its receptors in lymphocytes. Further studies are underway to begin to elucidate the effects of photoperiod on PRL-R expression in lymphocytes.

Key Words: Cattle, Prolactin receptor, Lymphocytes

38 Trends in milk production and composition in dairy herds in Saskatchewan: August, 1997 to July, 2000. C.R. Richardson* and D.A. Christensen, University of Saskatchewan.

The objective was to study trends of milk production and milk composition in dairy herds in Saskatchewan, Canada over three years. The first two years of the study, the province was on a volume based pricing system and quota system. Both multiple component pricing (MCP) and a quota system based on kilograms of butterfat were implemented on the first day of the final year of the study. From August 1, 1997 to July 31, 2000 farm numbers decreased from 402 farms to 381 farms. However, total milk production for the province increased linearly each year. In the 1997-1998 dairy year milk fat percentage, milk protein percentage and other solids percentage were 3.63, 3.25 and 5.51 % respectively. In 1998-1999 the milk composition was 3.64% for milk fat, 3.26 % for milk protein and 5.52 % for other solids. During the final year of the study, milk fat, milk protein and other solids percent were 3.66, 3.23 and 5.51 % respectively. Results show that during the 1999-2000 dairy year, milk fat percentage was higher ($P < 0.05$) than in 1997- 1998 and 1998- 1999. Milk protein percentage was significantly lower ($P < 0.05$) in 1999-2000 than in the previous two years of the study. Seasonal variation for milk production and milk fat percentage was similar for all years. Milk protein and milk fat percentages were highest in the October, November and December (fall) and lowest in the June, July and August (summer). Milk protein percentage was similar for 1997-1998 and 1998-1999 dairy years with the exception of November 1998, which was significantly higher than in other years. In the 1999- 2000 dairy year, milk protein percent was lower than other years from November to March. Changes in milk production and composition may have reflected a change in policy of milk pricing and quota allocation. Because of the economic advantage to producers, it would be expected that milk production would go up. However, it was unexpected for milk fat percentage to go up and milk protein percentage to go down.

Key Words: milk composition, multiple component pricing, trends

39 The effects of dietary protein fractions and levels on performance and nitrogen utilization and excretion in early lactation dairy cows. S. Davidson*, B.A. Hopkins, D.E. Diaz, S.M. Bolt, C. Brownie, and L.W. Whitlow, North Carolina State University.

Treatment diets varying in crude protein (CP) and rumen undegradable protein (RUP) and calculated to supply a duodenal Lys:Met ratio of about 2.9:1 were corn silage based and fed as a TMR to sixty-five Holsteins from 21 to 120 days in milk to determine effects on performance and nitrogen utilization. Diets contained %CP and calculated %RUP (of CP) as follows: 1) 19.4%, 40% (CON), 2) 16.5%, 34% (LPLU), 3) 16.8%, 40% (LPMU), 4) 16.8%, 46% (LPHU), 5) 17.2%, 43% (LPHU+UREA), which is the result of adding 1% urea to LPHU. Diets contained approximately 24% ADF, 1.5 Mcal/kg NE_L, and 6.5% fat. Milk urea nitrogen (MUN) values were used to calculate predicted amounts of urinary nitrogen (UN) using the relationship: UN (g/d) = 12.54 X MUN (mg/dl). CON cows had greater CP and RUP intake, plasma urea nitrogen, rumen ammonia, MUN and predicted UN. Milk yield, fat yield, fat percent, protein yield and protein percent were not significantly different

($P > 0.05$). Cows on CON gained more weight than cows on other treatments ($P < 0.025$). Parity by treatment was not significant ($P > 0.05$). In this study, cows fed LPHU had lower MUN and predicted UN without limiting production.

Item	CON	LPLU	LPMU	LPHU	LPHU + UREA	Treatment P <	Parity P <
DMI (kg/d)	23.32	22.88	23.12	23.39	24.08	.823	.001

40 The effect of increasing alfalfa haylage particle size on physically effective NDF values. P.J Kononoff^{*1}, A.J Heinrichs¹, H.A Lehman¹, and M.R Long¹, ¹*Pennsylvania State University*.

Physically effective NDF (peNDF) is defined as that dietary fiber source which effectively stimulates rumination and salivation. The peNDF value of feed has been determined by measuring the amount of NDF retained on a 1.18 mm screen. Changing cut length of forage results in changes in the proportion of large particles (>19.0 mm). The Penn State Particle Separator (PSPS) was modified to measure both small (<1.18 mm) and large particles. The objective of this experiment was to evaluate effective fiber requirements of cows in early lactation based on measurements of the PSPS. Eight cannulated, multiparous cows averaging 19 DIM and 642 kg BW were assigned to one of two 4X4 Latin Squares. During each of the 23 d periods animals were offered one of four diets, which were chemically identical but included alfalfa haylage of different particle size; short (SH), mostly short (MSH), mostly long (MLG), and long (LG). Total peNDF was similar across diets (27.2, 27.7, 27.9, 28.1) but the amount of particles >19.0 mm increased with increasing particle size (3.0, 12.4, 21.9, 31.3%). Increasing haylage particle size decreased DMI linearly (23.3, 22.0, 20.9, 20.8 kg for SH, MSH, MLG, LG respectively; $P < 0.05$). Milk production and percent fat did not differ across treatments ($P > 0.10$; 35.5 kg milk, 3.32% fat). Ruminal pH increased quadratically (6.04, 6.15, 6.13, 6.09; $P < 0.05$) but A:P ratio increased linearly (2.75, 2.86, 2.88, 2.92; $P < 0.0001$) with increasing particle size. Total time ruminating increased quadratically (467, 498, 486, 468 min/d; $P < 0.05$) but time eating increased linearly (262, 253, 298, 287 min/d; $P < 0.05$) with increasing particle size. Both eating and ruminating efficiency increased with increasing particle size (11.2, 11.5, 14.1, 14.1 min/kg DM; 20.5, 23.2, 23.4, 23.9 min/kg DM; $P < 0.05$). Based on rumen pH and total time ruminating, these results suggest higher effective fiber values should be assigned to rations with 12-22% of the particles >19.0 mm and that peNDF values should be adjusted based on the proportion of larger particles in the diet.

Key Words: NDF, pH, Rumination

41 Rumen inert lipids and glucose precursors lessen prepartum feed intake depression and improve carbohydrate status in periparturient dairy cows. C. E. Sorenson^{*1}, A. R. Hippen¹, D. J. Schingoethe¹, and R. S. Patton², ¹*South Dakota State University, Brookings*, ²*Galisteo, NM*.

In a trial to determine the effects of dietary fat and glucose precursors on ketosis and postpartum health of dairy cows, 24 multiparous Holstein cows were divided into two groups. The treatment group (T) received 0.45 kg/d MetaxerolTM, a specific combination of rumen inert lipid, calcium propionate, propylene glycol, and niacin (Pestell, Inc., Ontario Canada), and the control group (C) received 0.45 kg/d of a 50:50 mixture of calcium salts of fatty acids and ground barley. Treatments were added to the diet from 14 d before until 21 d after calving. Liver samples were collected by puncture biopsy at -14 and -2 d prepartum and at 2, 7, 14 and 28 d postpartum. Blood samples were taken via tail venipuncture immediately prior to each liver biopsy and at -7 d prepartum and 21 d postpartum. Production of milk and milk fat, protein, and lactose were not different. A numerical, but not significant, decrease was observed in milk fat percentage from T cows during the first week of lactation (5.5 vs. 6.4% for T and C, respectively, $P = 0.20$). The DMI for T cows was greater than for C cows during the last week prior to calving (15.4 vs. 13.4 kg/d $P = 0.05$). There was no decrease in DMI for T cows during the prepartum period; whereas DMI of C cows during the last week prepartum decreased by 3.2 kg/d compared with the previous week. Although liver lipid concentrations were numerically decreased in T cows on d 7, differences were not significant (8.1 vs. 9.6% wet wt, $P = 0.17$) and glycogen concentrations of livers did not differ also. The T cows had greater blood glucose concentrations, pre-calving (70.75 vs. 62.1 mg/dl) and post-calving (60.06 vs. 56.24 mg/dl, $P = 0.04$). Accordingly, total number of days of ketosis was less for T cows than for C cows (11 vs. 29 d). Feeding MetaxerolTM for 2 wk before parturition until 3 wk postpartum helped avoid periparturient feed intake depression, increased carbohydrate status as evidenced by increases in blood glucose, and may be beneficial in prevention of ketosis.

Key Words: Periparturient, Ketosis, Fatty Liver

42 Differences in resistance to heat shock between 2-4 cell Brahman and Holstein embryos produced in vivo. C.E. Krininger III^{*1}, J. Block¹, Y.M. Al-Katanani¹, R.M. Rivera¹, C.C. Chase Jr.², and P.J. Hansen¹, ¹*University of Florida, Gainesville*, ²*USDA, ARS, Brooksville, FL*.

Exposure of in vitro produced embryos to elevated culture temperature (heat shock) reduces development. Heat shock effects were greater for Holstein (H) embryos than for Brahman (B) at d 4 after fertilization. Objectives were to test if embryos produced in vivo are susceptible to heat shock, if breed differences in this response exist at the 2-4 cell stage, and to determine breed effects on estrous synchronization and superovulation. Holstein (n=24) and B (n=29) cows with a corpus luteum were injected with 100 µg GnRH (d 0) and 12.5 mg PGF_{2α} (d 7 and d 8). The proportion of cows displaying standing estrus was higher ($P = 0.08$) for H (50 vs 29%) - there was no significant difference for estrus based on tail paint (71 vs 58%). Forty cows detected in estrus were superovulated using FSH. Luteolysis was induced with PGF_{2α} and cows were inseminated 36 and 48 h later using semen from the same breed as the donor. At first insemination, 100 µg GnRH was given. Ten cows of each breed were killed 48 h after GnRH and oviducts flushed. Embryos were cultured for 24 h. Then, 2-4 cell embryos were cultured at either 38.5°C or 41°C for 4.5 h. Thereafter, all embryos were cultured at 38.5°C. There were no breed effects on ovulation rate (16.6 vs 15.2 for H and B, respectively) or embryo recovery rate (69 vs 66%). Cleavage rate (CR) at slaughter was lower ($P \leq 0.001$) for H than B (16±3.5 vs 43±3.8%) but CR at the time 2-4 cell embryos were separated was higher ($P \leq 0.001$) for H than B (74±3.8 vs 63±4.1%). Heat shock reduced development but there were no significant breed by temperature interactions. For example, the proportion of embryos that developed to blastocyst was 16.2±5.0% vs 0.0±4.1% for H at 38.5°C and 41°C, respectively, and 13.05.2% vs 0.0±5.3% for B (temperature, $P \leq 0.05$). In conclusion, 2-4 cell embryos produced in vivo can be disrupted by heat shock. There was no evidence that H embryos were more sensitive to heat shock than B embryos at this stage in development.

Key Words: Breeds, Heat shock, Embryo

On-Farm Certification Programs

43 Auditing procedures. David Meisinger*¹, ¹National Pork Producers Council.

Any certification program must have audits in order to ensure that the product, process or system meets the requirements intended for the program and that they continue to follow these procedures. Audits are intended for control or compliance. This paper will deal with the different types of audits, how they are conducted and who usually conducts them. The procedures used in any audit have been standardized by the American Society of Quality and will be outlined in this paper. These procedures include preparation for the audit including the phases in the process and the steps in preparation. These steps include performance standards and the checklist to be used in the audits. The second phase is performance of the audit including how facts are gathered and how conclusions are reached. The next phase involves reporting of the results in a meeting and in a formal report. The last phase is closure with corrective action and formal closure. This brief presentation will provide attendees with a quick view of these accepted procedures used in auditing for certification purposes.

Key Words: Audits, Quality audits, certification

44 Certification programs on farm animal care issues. John McGlone*, Texas Tech University.

Farm animal care involves both animals at institutions who teach and conduct research (such as universities & companies) and on commercial farms. The public demands – to varying degrees – that farm animals be treated humanely both in publically-funded activities, most notably teaching and research, and in production systems that supply animal products. The main question is not if the public demands will be met, but how best to meet the consumer wants and wishes for humane treatment of farm animals. Animals used in biomedical research are now overseen by an ACUC and a number of checks and balances are in place to assure adequate animal care. These assurances extend to vendors who produce laboratory animals (lab animal “farms”). Furthermore, veterinarians can be board-certified in laboratory animal medicine. Parallel assurances and certifications are only partly in place for farm animals at public institutions and on commercial farms. FASS has recently taken the leadership in developing peer-reviewed animal care training materials. Commodity groups have developed quality assurance programs – most of which lack third-party verification – that often include a small animal care component. ARPAS has an opportunity now to participate in new areas of certification that might include new programs such as (a) institutional professional board certification in farm animal care, (b)

farm animal worker certification, perhaps on at least two levels, and (c) on-farm worker certification.

Key Words: Animal Care, FASS, ARPAS

45 Certification of nutrition professionals. L. E. Chase*¹, ¹Cornell University.

The American Association of Feed Control Officials (AAFCO) has proposed licensing of nutrition professionals. In response to this proposal, the American Registry of Professional Animal Scientists (ARPAS) established a work group to examine this issue and develop a position statement. The work group agreed that the concept of licensing is appropriate. The rationale for licensing should be to provide assurance of professional competency of nutrition professionals. The work group indicated that the licensing process must include measures of knowledge, experience and expertise. It was proposed that an examination process be used as part of the licensing process. This would require development of a new exam. An initial or temporary license could be granted to individuals until the licensing program and exam were fully developed. The work group concluded that a college degree should not be a requirement for obtaining a license. Continuing education credits would also be required to maintain the license. The ARPAS group indicated a willingness to work with AAFCO and others to move this licensing process ahead.

Key Words: Certification, Licensing, Nutrition professionals

46 Verification of good production practices which reduce the risk of exposure of pigs to *Trichinella*. D.G. Pyburn*¹, H.R. Gamble², L.A. Anderson¹, and L.E. Miller¹, ¹USDA, APHIS, VS, ²National Research Council.

Control of *Trichinella* infection in pork has traditionally been accomplished by inspection of individual carcasses at slaughter or by post-slaughter processing to inactivate parasites. Declines in prevalence of this parasite in domestic swine during the last twenty to thirty years coupled with improvements in pork production systems offer the opportunity to document pork safety at the farm level. We report here on a certification pilot study using an on-farm audit to document good production practices for swine relative to the risk of exposure to trichinae. Based on the results, improvements in the program have been made and further studies will be undertaken prior to launching the voluntary *Trichinae* Certification Program in the United States.

Key Words: Pre-harvest Pork Safety, *Trichinae*, Food Safety

Conservation and Management of Animal Genetic Resources

47 Managing Genetic Diversity, Selection and Inbreeding in Livestock. P Bijma*, Wageningen Institute of Animal Sciences (WIAS).

Genetic drift is caused by random sampling of alleles that contribute to the next generation, and results in loss of genetic diversity in populations. There are two sampling processes. First, sampling between families, i.e. some families become parents of the next generation, whereas others don't. Second, Mendelian sampling of alleles within individuals. Without selection, both processes contribute approximately equal to loss of diversity. With selection (e.g. livestock), between family sampling causes the majority of the loss of diversity. Thus maintenance of diversity requires restriction of between family selection. Drift per unit of time is quantified by the variance of gene frequency change that can be attributed to a single generation or cohort, σ_q^2 . Drift causes homozygosity by descent (inbreeding), and drift variance and rate of inbreeding (ΔF) are equivalent measures of the loss of diversity, $\sigma_q^2 = q(1-q)\Delta F$. In livestock, the challenge is to genetically improve populations while maintaining diversity, i.e. to maximize gain (ΔG) while restricting ΔF . The long-term genetic contribution theory reveals a relationship between ΔG and ΔF ; $\Delta G = \Sigma a_i$ and $\Delta F = \Sigma r_i^2$, where r is the long-term genetic contribution of an individual, a is its Mendelian sampling term and the sum is taken over all individuals per unit of time. It follows that the theoretical maximum gain with restricted inbreeding is achieved by a linear increase of r with a . This provides a general

measure of genetic efficiency of selection programs. Selection tools that maximize gain while restricting inbreeding try to establish this linear relationship by determining the optimum contribution of selection candidates to the next generation, which implicitly restricts between family selection. With restricted ΔF , minimum coancestry and factorial mating increase ΔG . In addition, molecular markers enable reduction of Mendelian sampling drift, but benefits are small for livestock. Thus it is technically feasible to maximize ΔG while restricting ΔF . The commercial situation, however, may prohibit this. In particular in dairy cattle, global competition, availability of genetic material, and information on genetic quality (Interbull) causes breeding companies to focus on short-term improvement.

Key Words: Genetic Diversity, Inbreeding, Selection

48 Identification of germplasm for preservation from pedigreed populations. M. D. MacNeil*¹, W. R. Lamberson², and B. L. Golden³, ¹USDA-ARS, Fort Keogh LARRL, Miles City, MT, ²University of Missouri, Columbia, ³Colorado State University, Fort Collins.

Cryogenic conservation programs seek to maximize genetic diversity in the conserved sample of germplasm. Breed associations record and maintain extensive pedigree databases for a wide variety of livestock

populations. The objective of this research was to develop methods for identifying genetically diverse samples of animals from pedigree databases. Candidates for cryopreservation can be initially identified by appropriate criteria. Given the list of candidates and their pedigrees, coefficients of relationship (R) among them can be calculated. For large numbers of candidates, one suitable approach is to generate a list of "pseudo progeny" from all possible pairs of candidates and compute the inbreeding coefficient for each of them. The R for each pair of candidates is then twice the inbreeding coefficient of their pseudo progeny. The R can be used directly as in a procedure proposed for use in swine. That algorithm is initiated with an arbitrary animal or a set of preselected animals (perhaps ones that already have pools of semen available) and sequentially selects the animal with the lowest cumulative relationship to the previous set until a desired complement is attained. This procedure was tested on a simulated set of relationships among 100 animals. Repeated sets of 10 animals were chosen from the population by three methods: 1) random sampling; 2) use of the algorithm initiated with a random seed animal; and 3) use of the algorithm initiated with a set of five random seed animals. The mean of the relationships for the three procedures were: 0.102, 0.067, and 0.076, respectively, and SD were 0.014, 0.005, and 0.006, respectively. Alternatively, the R may be transformed (reciprocal, 1-R, etc.) to distance measures. A cluster analysis procedure can then be used to identify a set of animals for cryopreservation. Alternative distance measures and clustering methods need to be evaluated as does the similarity of outcome using pedigree vs using allelic frequencies at several loci.

Key Words: Genetic Distance, Diversity, Conservation

49 DNA sequence diversity and haplotype relationships at gene loci in U.S. beef cattle populations. M. P. Heaton*, *USDA, ARS, U.S. Meat Animal Research Center.*

Single nucleotide polymorphisms (SNPs) are useful as DNA markers because they occur at a high density in U.S. cattle populations, they are genetically stable over evolutionary time scales, and they are amenable to a variety of high-throughput technologies developed from the Human Genome Project. To capture the breadth of sequence diversity in U.S. beef cattle, a panel of 96 cattle DNA samples was designed for automated DNA sequencing of small amplicons at gene loci. The beef breeds comprise greater than 99% of the germplasm used in the U.S. beef cattle industry, based on the number of registered progeny for each breed. This beef cattle diversity panel (MBCDP2.1) is expected to allow a 95% probability of detecting any allele with a frequency greater than 0.016 in the group. Because the information content of an individual SNP is inherently low (biallelic), the set of SNP alleles residing on a specific segment of a chromosome may be used as a group (i.e., DNA segment haplotype) to discern additional allelic variants and thereby enhance measurements of genetic diversity. Defining the relationships between DNA segment haplotypes allows them to be considered in an evolutionary context and provides an objective means of identifying potentially ancient DNA segments.

50 Cryopreservation of rooster sperm. S.P. Gill*¹ and Guy Barbato², ¹*BioPore Inc, State College, PA.*, ²*The Pennsylvania State University, University Park, PA.*

Cryopreservation of poultry sperm likely can benefit individuals interested in maximizing fertility with sperm from males of lines that are on the verge of extinction or elimination. In the past, fertility of cryopreserved chicken sperm has been unacceptably low, unless impractically high numbers of sperm per insemination and frequent artificial insemination (AI) are combined. There are at least 2 reasons. First, cryoprotectant (e.g., glycerol) must be present at >13% (v/v; 1.8 M) concentration for retention of motility or viability, but has to be reduced to <0.7% (v/v; 0.1 M) before AI due to its contraceptive effect. Second, a protein important in sperm-egg binding is stripped from sperm during cryopreservation and that causes greater reduction in fertility than predicted on the basis of post-thaw sperm motility. Most procedures tried with rooster sperm rely on slow dilution of thawed semen plus centrifugation and resuspension of sperm in a small volume, to reduce glycerol concentration. A new method for cryopreservation uses special containers with major faces formed from "gated-pore" membranes. It allows automated removal of cryoprotectant and circumvents the need for dilution or centrifugation. Sperm from different lines of layers and broilers was frozen with this method. Sixty-seven percent of eggs laid had a viable embryo after AI of only $\sim 170 \times 10^6$ sperm every 4 days. However,

significant differences were observed within lines to the amount of cryoprotectant and fertility. Exposure of thawed rooster sperm to synthetic pro-fertility peptides increased ($P < 0.01$) fertility by 20-40% above that obtained with untreated (control) sperm. Through non-surgical intramaginal insemination, it was possible to obtain some fertility from line whose sperm did not tolerate cryopreservation very well. Rare or experimental lines, whose sperm quality and fertility is exacerbated by cryopreservation can be recovered using intramaginal inseminations and addition of pro-fertility peptides to the thawed sperm before AI.

Key Words: Sperm, Cryopreservation, Intramagnum

51 Preserving/conserving germplasm by incorporating embryo-related technologies. R.S. Prather*, *University of Missouri-Columbia, Columbia, MO.*

Embryo-related technologies, for the purpose of this talk, is defined as any technology that uses the unfertilized egg or early embryo. These technologies may include preservation of sperm, unfertilized eggs, embryos, or cells. Haploid genetic material might be preserved in the form of sperm or unfertilized eggs, while diploid genetic material might be preserved in the form of pre-attachment stage embryos or as cells harvested from live animals. Term development has resulted from cryopreservation of unfertilized eggs followed by fertilization and embryo transfer. Preservation of sperm is no longer limited to cryopreservation, as freeze-dried sperm have been rehydrated and injected into unfertilized eggs. This technology is termed intracytoplasmic sperm injection (ICSI). Nuclear transfer (NT) technology, i.e. the transfer of diploid nuclei to enucleated eggs, has also resulted in the production of offspring. These latter two technologies, ICSI and NT, are dependent upon adequate numbers of mature unfertilized eggs being readily available. While ICSI will permit the production of offspring from half of the desired genotype, NT will result in offspring that are entirely derived from the nucleus of the donor cell. While both of these technologies offer great promise, there are a number of limitations. The first limitation is that large numbers of meiotically mature unfertilized eggs are required. The second limitation is that these eggs influence the entire genetic makeup of the resulting animal. This is because the eggs contain mitochondria that have their own genome. Thus, if there is an incompatibility between the proteins whose production is directed by the nucleus and proteins whose production is directed by the mitochondria, then the resulting embryo could fail to develop, or fail to reproduce the desired phenotype as an adult. A third limitation, observed in cattle, is the production of animals that fail to thrive, and up to half die during the first few weeks postnatally. When considering the use of such technology, one should remember that phenotype is directed by both genetic makeup and environment.

Key Words: Cloning, Nuclear Transfer, Embryo-Technologies

52 Conservation and preservation of poultry genetic resources: a review of issues and progress. Mary Delany*, *University of California, Davis CA 95616.*

The landscape of extant poultry genetic resources is complex and thus considerations for conservation and preservation are complicated by a number of interwoven issues. Issues for consideration include but are not limited to: (1) the variety of species, (2) the types of populations, (3) the heterogeneity of purposes, (4) inherent difficulty in predicting future utility and needs, (5) financial resources, (6) paucity of genetic diversity assessment, (7) only the male germplasm can be cryopreserved. We know that (1) hundreds of research genetic lines have been eliminated over the last two decades and such elimination is ongoing, (2) the number of independent primary breeder companies has declined through industry mergers and anecdotal discussion indicates entire groups of lines are often dropped in the process, (3) several recent molecular genetic studies suggest reduced diversity for industry White-Leghorn based populations, (4) U.S. poultry breed population status is currently unknown although assessment is underway by the American Livestock Breeds Conservancy. The National Animal Germplasm Program poultry species committee consists of academic, industry and government geneticists, researchers and administrators committed to improving the status quo of poultry genetic resources. Many of the committee members are directly involved in maintaining and managing poultry genetic resources. Committee work during the last 12 months focused on assessing what our committees' priorities should be and the two top areas include promotion of cryopreservation research and preservation of living-stocks

collections. In regard to the latter, a recognition letter has been designed to alert university-based administrators of the value of poultry genetic resources. The committees' present administrative goals include development of priority guidelines for repository deposits of semen at the Ft. Collins NAGP facility, development of poultry-specific parameters for the GRIN database, establishment and distribution of useful guidelines/advice for handling and cryopreservation of semen by non-experts.

Key Words: Poultry, Conservation, Genetic resources

53 Dairy cattle contributions to the National Animal Germplasm Program. L. B. Hansen*, *University of Minnesota, St. Paul.*

Genetic diversity within the six recognized breeds of dairy cattle in the US was viewed as the key area of concern for the dairy cattle committee of the National Animal Germplasm Program. The ten-member dairy

cattle committee has a membership roster as follows: two from the land-grant universities (L. Hansen, U. of MN, Chair, and M. Schutz, Purdue U.), two from USDA/ARS (M. Ashwell and C. Van Tassell), two from AI companies (D. Funk, ABS Global, and C. Sattler, Select Sires), one from NAAB (to be named), one from a breed association (C. Wolfe, American Jersey Association), the USDA/ARS Executive Secretary for NAGP (H. Blackburn), and an ex officio member from USDA/CSREES (R. Frahm). Committee members will have terms with fixed years of service, and the terms will have staggered years for final year of service. The key goal of the dairy committee is for each A.I. organization in the US to submit 30 units of frozen semen from progeny test sires to the repository for the germplasm program at Ft. Collins, CO. Frozen semen is requested from each 10th Holstein sire entering progeny testing as well as every bull entering progeny test for the other five breeds. The dairy cattle committee will be charged with the responsibility of reviewing requests for use of dairy cattle germplasm in the repository.

Key Words: Germplasm preservation, Dairy cattle, Genetics

Energy Nutrition of Ruminants

54 Energy nutrition of ruminants: keeping books. C.L. Ferrell*, *USDA, ARS, Roman L. Hruska U.S. Meat Animal Research Center, Clay Center, NE.*

Goals of energy metabolism research with ruminants have historically been to 1) develop an accurate means for evaluating feedstuffs and stating animal requirements, and 2) establish the tissue and biochemical origin of heat production or energy expenditures. Techniques employed in nutritional energetics of ruminants have classically been concerned with the partitioning of dietary energy into fecal, urinary, methane, heat, and recovered or product energy. Attributes of feeds that influence the partition of dietary energy has received limited attention recently. Indirect respiration calorimetry and comparative slaughter techniques continue to be important energetics research tools. Carbon dioxide entry rate techniques have found application in goat, sheep, and cattle studies. The use of heart rate as an index of energy expenditure may have application to the free ranging animal. Techniques utilizing blood flow, thermal dilution and gas analyses to quantify and separate heat generated from the GI tract into aerobic and anaerobic origins has been successfully applied to ruminants. Assessment of tissue energy metabolism from blood flow and substrate flux across the PDV, liver, gravid uterus, fetus, mammary gland, and hind limb have contributed substantially to our understanding of tissue energy expenditures and sources of their variation. Studies at the organ, tissue, cellular, and subcellular levels, including substrate turnover and channeling, ion transport, proton leakage, and uncoupling proteins have increased our understanding of the biochemical processes involved. Regulation of those processes through hormonal and other means is beginning to be understood. A major challenge of the future lies in not only establishing the biological and biochemical bases for energy expenditures, but also in determining the genetic and biological bases for differences among animals. It is equally critical that we be able to translate fundamental knowledge gained through these endeavors to functional understanding that can be applied to the whole animal.

Key Words: Cattle, Heat, Energy metabolism

55 Economics of visceral nutrient metabolism in ruminants - toll keeping or internal revenue service? C. K. Reynolds*, *The University of Reading, UK.*

Measurements across a range of productive states show that the portal-drained viscera (PDV) and liver, or the total splanchnic tissues, account for 40 to 50 % of body oxygen consumption or heat. This high rate of metabolism is in part attributable to high rates of protein turnover and thus amino acid utilization, as well as other 'service' functions supporting nutrient assimilation and 'waste management'. This metabolic intensity and the anatomic position of absorptive and liver tissues has led to the assumption that the tissues that assimilate and process incoming nutrients from the diet exact a toll in payment for their entry. This 'toll' is believed to reduce the extent to which absorbed nutrients gain admission to the arterial blood pool and reach 'productive' organs such as the mammary gland or skeletal muscle. Measurements of net nutrient flux generally support this concept of splanchnic metabolism 'restricting entry' and thus dictating supply, as on a net basis the appearance of the major carbon-based nutrients absorbed into the portal

vein is typically low compared to their rate of disappearance from the gut lumen. An alternative interpretation is that this low net recovery of absorbed nutrients across splanchnic tissues is attributable to extensive metabolism of nutrients from the arterial pool, which masks true rates of absorption. In this scenario any tax to support community services is paid using internal funds. Measurements of nutrient kinetics based on isotopic labelling support the latter scenario. In the case of the liver, catabolism of amino acids is driven in part by supply and demand, with over-population dealt with by depopulation, restructuring or the metabolic equivalent of cremation. Similarly, relative rates of amino acid metabolism by the gut and mammary gland vary with requirement. Organ metabolism of many energy-yielding nutrients varies with supply, demand and the need for waste management and other community services.

Key Words: Organ metabolism, Energy, Amino acids

56 Endocrine and gene expression profiles in relation to energy metabolism. G. Murdoch¹, W.D. Dixon¹, V.E. Baracos¹, E.K. Okine¹, D. Balcezak¹, J.A. Moibi¹, B.T. Li¹, R.J. Christopherson^{*1}, and R.J. Christopherson¹, ¹*University of Alberta, Edmonton, Canada, T6G 2P5.*

In order to test hypotheses regarding regulation of energy metabolism, heat production (HP) was examined in response to adrenergic agonists and/or blocking agents in ruminants. Low doses of adrenaline, acting via β adrenoceptors, increases HP ($P < .05$) in cattle (40%) and in sheep (30-45%). Increases in HP of sheep in response to adrenaline averaged 32% ($P < .05$) while increases in the portal drained viscera and hindquarter metabolic rates were 50 % ($P < .05$) and 61 % ($P < .05$) respectively and were abolished by beta adrenergic blockade. Increases in whole body and hindquarter HP during acute cold exposure were reduced by 20-50 % by β blockers. Alpha-2 selective agonists suppress heat production in ruminants by 20-23 % ($P < .05$), suggesting a role in energy conservation. HP was positively related to β receptor density in the heart muscle, but a negative relationship was observed in non-cardiac tissues. Lipogenic enzymes (ACC and FAS), in subcutaneous and mesenteric adipose were positively correlated ($P < .05$) to HP. Expression of other target genes have recently been determined in skeletal muscle, adipose depots, rumen, abomasum and duodenum in cattle, using PCR. The expression of leptin receptor and NPY receptor type II genes were correlated ($P < .05$) in peripheral tissues, such as Biceps femoris ($r=0.91$) and subcutaneous adipose ($r=0.70$). These were not as well correlated in mesenteric adipose and perirenal adipose. Receptor gene expression was not detected in GI tissues. The expression levels of UCP1, UCP2, and UCP3 in tissues that we have screened using RT-PCR, ranged from undetectable to 100 densitometric units. We observed variable expression of leptin mRNA in adipose depots which may pertain to various functions of this peptide. Positive correlations between HP and urinary excretion of 3-MH ($P < .39$) and hydroxyproline ($P < .51$) paralleled changes in expression of genes for proteolytic enzymes. Compilation of information relating to the expression of specific genes

linked to energy expenditure will help elucidate the physiological basis for variations in energetic efficiency.

Key Words: Endocrines/Genes, Energy Metabolism, Ruminants

57 Cellular energy expenditure and the importance of uncoupling. M-E. Harper*¹, A. Antoniou¹, V. Bezaire¹, and S. Monemdjou¹, ¹*University of Ottawa.*

Just as total body energy expenditure in animals can be classified into that which supports resting energy metabolism, work, growth, etc., cellular energy expenditure can similarly be classified. Our overall objective is to examine the metabolic origins of cellular energy expenditure, differentiating between metabolic states where cells are at relative rest, and where cellular energy expenditure is high. In most situations when energy expenditure is high, mitochondrial ATP production (oxidative phosphorylation) is coupled and efficient. Uncoupling refers to the dissociation of the oxidation of energy substrates, such as fatty acids, from the synthesis of ATP by mitochondria. Uncoupling can occur during

states of high energy expenditure or during states of metabolic rest. In brown adipocytes, uncoupling protein 1 (UCP1) activity can cause very high rates of energy expenditure for the purpose of thermogenesis (heat production). UCP1 is found exclusively in brown adipocytes. While uncoupling also occurs in other cells of the body, it is of greatest importance during periods of relative metabolic rest. The latter form of uncoupling is referred to as mitochondrial proton leak, and accounts for roughly one quarter of the resting metabolic rate of the rat. The mechanisms of mitochondrial proton leak are not well understood. The recently identified uncoupling proteins may play some role, but may also have some other physiological functions. Our recent findings from transgenic mice with altered expression of UCPs will be reviewed. Proton leak activity scales roughly in proportion with metabolic rate in mammals of different body size, and is related to thyroid hormone status. Proposed functions for mitochondrial uncoupling include thermogenesis, control of oxidative phosphorylation efficiency and protection from reactive oxygen species. Support: NSERC of Canada.

Key Words: thermogenesis, proton leak, uncoupling

Meat Science in an International Marketplace

58 Global meat research initiatives. R.B. Sleeth*¹, ¹*Consultant.*

The International Congress of Meat Science and Technology (ICoMST) is a very extraordinary and dynamic organization. A brief review will highlight the history, structure, and function to enable participants to better understand and appreciate its uniqueness as a scientific entity. It is imperative that we foster worldwide cooperation in meat science and technology research to be better informed and to minimize duplication. Within the USA, scientists access the Current Research Information System (CRIS) to determine the status of ongoing research. One purpose of the ICoMST is to provide a global forum for discussing research concepts and accomplishments but proceedings are not available for the majority of the scientific community. The presentation will briefly highlight related meat research programs from several countries which hopefully will provide the impetus to develop an implementation plan to foster greater worldwide exchange of meat science and technology.

59 U.S. Pork Products in the International Marketplace. J.W. Cravens*, *National Pork Producers Council, Des Moines, Iowa.*

In 2000, the United States exported 1.25 billion pounds of pork and pork variety meats, worth 1.316 billion dollars, an increase of 213 percent by volume and 224 percent in value since 1991. Exports now represent 6.8 percent of domestic production. According to the USDA Foreign Agriculture Service, pork represented 41 percent of global meat protein consumption in 1999. Global pork trade is projected to continue increasing as global populations and per capita incomes increase and trade barriers fall.

Although the United States is one of the world's lowest cost producers of pork, to maintain rapid growth in exports, the United States industry must continue to supply safe, high quality pork that meets the needs of varied customers around the globe. The demands of the export market can vary significantly from those of the U.S. market. The United States exported pork or pork variety meats to 85 different countries in 2000.

Frequently the demand for various pork cuts or byproducts are unique to these individual markets. And just as frequently, unique requirements or standards exist in areas such as processing, carcass fabrication, labeling, food safety, sanitation and hygiene. This presentation will look at the demands of the export market for U.S. Pork and explore a number of these issues. It will contrast the specifications and customer requirements in the domestic market with those of the export market in an attempt to present both the opportunities that exist for increasing exports and the barriers that must be overcome. It will also explore some of the advantages our competitors have over the U.S. industry.

Key Words: Pork, Exports, Trade, Variety meats, Offals

60 Poultry products and processing in the international marketplace. S.F. Bilgili*¹, ¹*Auburn University.*

Globally, consumption of poultry meat products has increased dramatically during the last decade. As a result, production of young meat chickens (broilers), turkeys and other poultry (spent layers, ducks, geese, guinea-fowl, pheasants, ratites, etc.) continues to grow and expand in many parts of the world. Nutritional profile, taste, versatility, convenience, availability and relative value are the major reasons why consumers prefer poultry meat products. Adoption of new production and processing systems and technologies, and development of new and novel products have enabled the poultry industry to continually innovate and respond to market demands. Although poultry products vary greatly in many countries, ranging from live poultry markets to consumer packaged, ready-to-eat entrees, there has been a clear trend of diversification in the marketplace. The most obvious change has been the steady shift in product forms, from a primarily "homogenous, generic commodity" to a "well differentiated, name-branded, value-added" products. Value-adding by cut-up and further-processing not only meets the changing needs of the consumers, but also improves the net returns and profitability. Given this trend, the future challenge in product development will be preservation and/or incorporation of unique cuisine and preferences of diverse cultures.

ASAS/ADSA Animal Behavior and Well Being

61 Effect of genetic selection for loin-eye area on belly-nosing and plasma cortisol in weanling Landrace pigs. S. Torrey*¹, E. Pajor¹, S. Weaver², D. Kuhlers³, and T. Stewart¹, ¹*Purdue University*, ²*USDA-ARS Livestock Behavior Research Unit*, ³*Auburn University.*

Two genetic lines of Landrace gilts, selected for differences in loin-eye area, were studied for behavioral and physiological differences during Segregated Early Weaning (SEW). The select line, selected for increased loin-eye area (n = 30), differed from the contemporary random control line (n = 32) by 10.6 cm². The gilts were weaned at an average age of 15 d and transported from Auburn University to Purdue University. Litters were blocked by farrowing date to minimize age differences and trans-

ported on two dates, 2 wk apart. Litters were videotaped continuously while in nursery to record frequency of belly-nosing. Individual blood samples were collected in late afternoon 9, 20 and 30 d after arrival into the SEW facility to measure plasma cortisol levels. Frequency of belly-nosing was examined on d 2, 3 and 4 post-weaning using scan sampling. Significant differences in frequency of belly-nosing were seen only on d 4 between the two lines (select 2.43 ± 0.44% of time; control 0.61 ± 0.43% of time; p < .02). This is in agreement with previous literature that found differences in belly-nosing occurring several days after weaning. Blood samples were assayed for cortisol levels using GammaCoat RIA. Cortisol concentrations in the select pigs (29.34 ± 3.12 ng/ml) were significantly higher (p < .02) than in the control pigs (23.11 ± 3.00 ng/mL). Previous results showed that the select pigs spent more time active and

had higher whole blood serotonin levels than control pigs. Our results suggest that a genetic relationship exists for lean pigs with an increased loin-eye area and a pig's ability to handle the stress of weaning. As weaning is a stressful event in a pig's life, this decreased ability to handle the stress related to weaning may have negative implications on the welfare of pigs selected for lean growth.

Key Words: belly-nosing, cortisol, genetics

62 Savaging in gilts and second parity sows: a study of seven commercial farms. M.J. Harris^{*1,2,3}, Y. Li¹, and H.W. Gonyou¹, ¹*Prairie Swine Centre Inc., Saskatoon, Saskatchewan, Canada*, ²*University of Saskatchewan, Saskatoon, Saskatchewan, Canada*, ³*Present address: Purdue University, West Lafayette, Indiana, USA.*

Savaging of piglets by their mothers is a harmful and costly behavior, the extent and causes of which are largely unknown. A study was conducted to investigate the incidence and correlates of savaging behavior on seven new 600- or 2400-sow units (n = 4 and 3, respectively) during their first two farrowing cycles. Females were subject to a light (continuous or intermittent light) and sound (newborn piglet vocalizations or no vocalizations) treatment before and during farrowing. Behavior records were collected for the first farrowing of 6625 gilts (first farrowing cycle) and 2175 gilts and 5232 sows (second cycle). The incidence of savaging and number of piglets killed or injured by it were recorded.

During the first farrowing cycle 331 gilts (5.3%) displayed some piglet-directed aggression, and of these, 201 (2.9%) fatally savaged one or more of their young; 392 piglets (.6%) were killed by savaging and a further 114 (.14%) were non-fatally injured. Savaging levels were similar for the gilts in the second farrowing cycle, while the problems were reduced to approximately half among the sows. During the second parity, females that had savaged as gilts were more likely to behave aggressively again (14%) than those that had not (<1%; p<0.05). There was considerable variation among farms in reported incidence of savaging and numbers of piglets affected. During the first farrowing cycle, percentages of gilts killing one or more of their offspring ranged from .8% to 5.8%, and percentages of piglets killed by savaging ranged from .1%-1.1%.

During the first farrowing cycle, continuous light resulted in a reduction in the proportion of piglets fatally savaged (.47 vs. .77%; p<0.05) and reduced total reported mortality (.62 vs. .74 piglets/litter; p<0.05) compared to intermittent light. Gilts farrowing in crates in the center of rooms receiving the vocalization playback fatally savaged more piglets (.12 piglets/litter) than did those in the front (.05 piglets/litter) or back (.07 piglets/litter; p<0.05). We theorize that increased illumination allowed gilts to better see approaching piglets, reducing their fear response. The sound treatment may have disturbed the gilts, and thus extraneous sounds should be minimized during farrowing.

Key Words: Pig, Savaging, Mortality

63 Behavior of outdoor sows 72 h after parturition: relation to piglet mortality. A. K. Johnson^{*1}, J. L. Morrow², J. W. Dailey², and J. J. McGlone¹, ¹*Pork Industry Institute, Texas Tech University, Lubbock, TX, 79409-2141*, ²*USDA-ARS, TTU, Lubbock, TX, 79409-2141.*

The majority of piglet deaths occur in the first 72 h after parturition, with the main cause attributed to crushing by the sow. The objectives of this study were to determine 1) time spent outside the farrowing hut by the sow and 2) sow behavior one hour prior to the piglet death in relation to piglet mortality. Records were used to identify PIC USA sows that crushed (CR) N=10 or did not crush (NC) N=10 piglets and for these sows the time spent inside and outside the hut was determined. Records from 10 of these sows (N=5 CR and N=5 NC) were used for further behavioral analysis. Sows were housed in an English style-farrowing hut with chopped wheat straw bedding and a metal fender. Multiparous sows were fed a completely balanced milo-soy diet once daily. Behavioral data were collected by time-lapse video using 2.5 frames/s. Nine behaviors were collected: walk, stand, sit, lateral lying, sternum lying, lying while rooting, stand while rooting, nurse and outside of the farrowing hut. Sows did not differ in the amount of time spent outside the farrowing hut (P > .05) over the first two days. On day three, CR spent less (P < .01) time than NC outside of the hut (20.2 4.7 vs. 40.4 4.8 min/d) and showed an increased (P < .01) time lying on their sternum (9.7 3.1 vs. 0.7 3.1 min/h). Before crushing a piglet, 78 % of the CR were lying on their side and 56 % moved from lying on their sternum to

lying on their side. Only 11 % of NC showed these sequences of behavior with 67 % nursing, then remaining on their side. In conclusion, CR sows spent more time inside the farrowing hut on day three and spent more time lying on their sternum. The behavioral sequence associated with crushing piglets was a shift in lying postures rather than transitions from sitting or standing to lying down.

Key Words: Piglet, Behavior, Mortality

64 The lying behavior of pigs; a basic study. E.D. Ekkel¹, H.A.M. Spoolder², and B. Hulsege³, ¹*Wageningen University, Wageningen, The Netherlands*, ²*Research Institute for Animal Husbandry, Lelystad, The Netherlands*, ³*ID-Lelystad, Lelystad, The Netherlands.*

An experiment was carried out in which the lying behavior of pigs was studied. It is well known that pigs housed in groups prefer to lie down together for many hours per day, but little is known about their lying posture and the total space they occupy. Moreover, the extent to which pigs tend to huddle was studied, since this affects their total space occupation. Information about these lying characteristics is necessary in order to be able to assess the space requirements for pigs, e.g. in the event (inter)national authorities pass legislation on minimum space requirements for pigs. The study included two replicates of 8 groups. Each group consisted of 8 pigs. Pigs were housed at thermoneutral conditions in 8 m² pens. Two types of flooring were studied: pens with 60 % solid sloped floor and 40 % slatted floor and pens with 60 % solid arched floor and 40 % slatted floor. Lights were on from 0630 until 1830. Feed and water were available ad libitum. Behavior of the pigs was recorded for 48 h on video at approximate 30, 50, 80 and 100 kg live weight. General activity (lying, sitting, standing), lying posture (sternum, half-sternum, lateral recumbent) and percentage of space-sharing (as a consequence of huddling behavior) were scored by 20 min scan-sampling. The results confirmed that pigs lie down for a great part of the day. During the behavioral period, on average > 80 % of the pigs lie down. There were no differences (P > .05) between replicates or floor types. The weight category did affect the lying behavior of the pigs (P = .027): the percentage of pigs that lie down, increased with weight. During the night (1840 to 0620), the fully lateral recumbent lying posture was predominant and unaffected (P > .05) by floor type. A significant interaction was found between replicate and weight category. The percentage of space that is shared with other pigs was on average 33.7, 28.1, 28.3 and 31.0 for 30, 50, 80 and 100 kg pigs respectively. Average space occupation for these weight categories when lying was 0.30, 0.46, 0.64, 0.76 m² per pig. In conclusion, pigs lie down for most of the time and the fully lateral recumbent position is predominant. Regulations for minimum space requirements for pigs should take this into account.

Key Words: Pigs, Lying Behavior, Space requirements

65 Effects of transportation and relocation on plasma glucose, triglyceride and cortisol concentrations in Brahman and Hereford steers. R. Browning, Jr., T. Payton, N. Whittingham, and C. Bradley, *Tennessee State University.*

In Exp 1, Hereford (n = 7) and Brahman (n = 7) steers were hauled round trip (344 km, 243 min) or maintained in holding pens on the farm in a crossover design to assess physiological responses to transportation. Steers were bled on afternoons 6 and 3 d before treatment, immediately after treatment, and 1, 3, and 6 d after treatment. Plasma was harvested to determine glucose, triglyceride and cortisol concentrations. No breed × treatment × day interactions were evident. Treatment × day interaction affected (P < 0.05) all three blood constituents. Glucose, triglyceride and cortisol concentrations immediately after transportation (81 ± 2 mg/dL, 52.4 ± 0.8 mg/dL, and 174 ± 14 ng/mL) differed (P < 0.01) from concentrations at 3 d before (57, 57 and 72) and 1 d after transportation (59, 55 and 61) and compared to non-transported steers (62, 56 and 92). In Exp 2, Hereford (n = 7) and Brahman (n = 7) steers were hauled one-way (55 km, 40 min) to a new farm or hauled round trip an equal distance in a crossover design to assess physiological responses to relocation. Relocated steers were maintained at the new farm for 6 d. Steers were bled on afternoons 6 and 3 d before transit, immediately after transit, and 1, 3, and 6 d after transit. Plasma was harvested to determine glucose, triglyceride and cortisol concentrations. No breed × treatment × day or treatment × day interactions were evident that would have indicated an influence of relocation. Day affected (P < 0.01) all three blood constituents. Glucose, triglyceride

and cortisol concentrations immediately after transportation (88 ± 2 mg/dL, 43.9 ± 0.4 mg/dL and 407 ± 15 ng/mL) were higher ($P < 0.01$) compared to 3 d before (65, 47.0 and 94) and 1 d after transportation (66, 45.4 and 126). Results indicate that plasma glucose and cortisol increased, whereas triglyceride concentrations were reduced in response to transportation in steers. However, the responses were transient and not influenced by breed or relocation.

Key Words: Cattle Breeds, Transportation, Stress

66 Shade effects on performance, carcass traits, and behavior of heat-stressed feedlot cattle. F. M. Mithlner*, M. L. Galyean, and J. J. McGlone, *Texas Tech University*.

In earlier studies on heat stress in feedlot cattle, we found that the use of water (sprinkling or misting) was largely ineffective, but shade minimized some negative effects of heat stress. Past studies were conducted in concrete floored pens under experimental feedlot conditions. To determine whether shade also improves performance, physiology, and carcass traits under conditions similar to those in commercial feedlots, we used a total of 168 heifers in 12 dirt-floored pens. Six pens were shaded (SHADE) with a tin-roofed shade construction (4 m height), allowing for 2.04 m² shade per heifer and six pens served as the unshaded control (CONT). The performance variables that were measured or calculated were DMI, BW, ADG, feed:gain (F:G), and dietary concentrations of NEm, and NEg. Carcass measurements were yield grade, kidney, pelvic, and heart fat, longissimus muscle area, hot carcass weight, quality grade, liver abscess rate, and incidence of dark cutters. The respiration rates of the heifers were measured, as well as the behaviors of feeding, drinking, walking, standing, lying, agonistic, and bulling. Heifers in SHADE compared with CONT had higher DMI (9.80 vs 9.52 ± 0.05 kg/d, $P < 0.01$), ADG (1.74 vs 1.64 ± 0.03 kg/d, $P < 0.05$), and final BW (565.47 vs 554.15 ± 2.97 kg, $P < 0.05$). The F:G, and NEm and NEg concentrations did not differ between treatments. Carcass traits were similar between treatments, but more carcasses of heifers in SHADE graded Choice, (55.84 vs 36.23% , $P < 0.01$) and the incidence of dark cutters (8.33 vs. 19.05% , $P < 0.05$) was decreased in carcasses from SHADE heifers. Respiration rates were decreased among SHADE compared with CONT heifers (73.8 vs 105.3 ± 1.2 breaths/min, $P < 0.01$). Most behaviors were not different between treatments, but cattle in SHADE showed less agonistic behavior than CONT heifers (0.34 vs $1.40 \pm 0.33\%$, $P < 0.05$). During heat, shade improves well-being of feedlot cattle and the profitability of the operation in West Texas.

Key Words: Feedlot Cattle, Heat Stress, Shade

67 Behavioral and adrenal response of cows tail docked with a rubber ring with or without local anesthesia. D. S. Schreiner* and P. L. Ruegg, *University of Wisconsin, Madison*.

The practice of tail docking dairy cattle is controversial. Dairy farmers justify tail docking by claiming it improves cleanliness and reduces mastitis. Behavioral and physiological effects of tail docking are unknown. The objective of this study was to determine the behavioral and hormonal affects of tail docking with rubber rings in dairy cattle. Twenty-four pregnant Holstein heifers 20-25 months of age were randomly assigned to four treatment groups: control, rubber ring docked, control plus epidural, or rubber ring docked plus epidural. Docked animals were banded three to four inches below the vulva. Blood samples were obtained -45, -15, 0, 15, 30, 60, 90, 120, 180, 240, 360 and 720 minutes from treatment for cortisol analysis. Blood samples were obtained at -45 minutes and 7, 14 and 21 days for complete blood count (CBC). Animals were observed -60, -45, -30, -15, -1 before treatment and every 5 min. for the first hour, every 15 min. for hours 2-4 and every 30 min. for hours 5-12 after treatment. Additional behavioral observations were taken three times daily for weeks 1 and 2, twice daily for weeks 3 and 4, and once daily for weeks 5 and 6. Animals were observed for the following behaviors: eat, ruminate, standing, walking, tail shake, vocalization, foot stomping, grinding teeth, posture, restlessness, and tail tucking. There were no significant differences in cortisol levels between treatment groups ($P = .49$). CBC results remained in normal ranges for all animals during all time periods. There were no significant differences in the proportions of behaviors observed between treatment groups ($P > .14$). Tail shaking was observed more frequently for both docked and control animals before and after treatment as compared to other time periods ($P < .01$). The application of rubber rings and the process of

tail atrophy did not significantly affect observed patterns of behavior or selected physiologic variables during the period of this study.

Key Words: Behavior, Docking, Stress

68 Development of a bovine lameness index that correlates visual lameness scores to measurable limb movement variables - a pilot study. P. G. Rajkondawar*¹, N. Neerchal¹, M. A. Varner², B. Erez², A. M. Lefcourt³, R. M. Dyer⁴, and U. Tasch¹, ¹UMBC, ²UM, ³Biomedical Engineer, ⁴Univ of Delaware.

Lameness in dairy herds has been reported to be a critical economic factor and a vital animal-welfare issue for the dairy industry around the world. Various lameness evaluation schemes that assess the severity of the ailment have been suggested. These schemes are based on visual observations of individual cattle. A lameness scoring scale that focuses on the shape of the cattle's back in posture and gait has been proposed. This scheme is easy to implement under field conditions, however it is observer dependent and non-quantitative in nature.

In an effort to objectively characterize the status of hoof and leg ailments, a system that measures various limb movement characteristics was developed. This system can be used to measure multiple variables representative of limb movements, including: (a) peak value of ground reaction force (GRF) of individual limbs, (b) integral of GRF with respect to time, (c) stance time, (d) average GRF, (e) step size, (f) integral of the Fourier transformation of the GRF signature with respect to frequency, and (g) the integral with respect to frequency of the Fourier transform of the GRF signature multiplied by the frequency. To allow comparisons among different cows, variables were normalized with respect to body weight. The objective of this study was to examine the relationship between a visual scoring scale and the 7 listed limb movement variables. The visual lameness score and all movement variables were measured for 23 mature Holstein cows.

Logistic regression and discriminant analyses (LOGISTIC, STEPDISC procedures in SAS) indicate that visual lameness scoring scale can be captured by the average GRF values ($p < 0.05$) of individual limbs. The model predicts probabilities that a cow is sound, mildly lame, and lame. An estimated lameness index is derived as the weighted sum of these probabilities. In this pilot study, the results of the visual scoring scale and the new lameness index matched for lame cows. However the visual scores and lameness index of 6 out of 16 mildly lame and sound cases exhibited discrepancies. Future studies will compare visual scores, limb movement variables, and clinical lameness diagnoses of individual limbs to enhance objective measures of dairy cow lameness.

Key Words: Lameness, Dairy Cattle, Limb Movement Variables

69 Utilization of a small animal model of fescue toxicosis to evaluate the potential benefit of *Ascophyllum nodosum*. P. A. Eichen*¹, D. E. Spiers¹, G. Rottinghaus¹, and D. P. Colling², ¹University of Missouri, Columbia, MO, ²Land O'Lakes Farmland Feed, Kansas City, MO.

Cattle grazing endophyte-infected tall fescue (EIF) during summer months display symptoms of fescue toxicosis that include hyperthermia, decreased feed intake and growth, and death in extreme cases. An economical rat model of fescue toxicosis shows changes in internal body temperature, feed intake and weight gain that are similar to those seen in cattle fed EIF. Adding seaweed extract (*Ascophyllum nodosum*; SWE) to the diet may reduce stress associated with EIF consumption during summer heat. An initial study was performed to determine a level of SWE (range of 0 to 2% of diet) that might reduce symptoms of fescue toxicosis in male rats ($n=36$) fed control or EIF diets ($90\mu\text{g}$ ergovaline/kg BW). Telemetric temperature transmitters (Mini Mitter, Bend, OR) were implanted into one of the 3 rats from each of the 12 treatment groups to measure core body temperature (Tc). Rats were housed at 21°C for 5 days and then heat-challenged (HC) at 31°C for 21 days. Rats fed diets containing more than 0.25% SWE tended to have a lower Tc during initial HC at about 3 days. A second, shorter study was conducted to verify the thermal-relief effect of SWE, using control and EIF diets from Study 1, and SWE (0 or 1% of diet). Rats fed EIF diet with 1% SWE exhibited lower Tc ($P < .0001$) during HC. In both studies, EIF-fed rats had a larger decrease in feed intake ($P < .0001$ and $.0007$) and a smaller gain in body weight ($P < .0001$) than control rats. Decreased blood levels of cholesterol ($P < .002$ and $.03$), alkaline phosphatase ($P < .0001$ and $.009$) and amylase ($P < .002$ and $.01$), together with reduced liver weight ($P < .0001$), were seen in EIF-fed rats in both

studies, with no effect of SWE treatment. Although SWE, at 1% of diet, is effective in reducing the hyperthermia associated with fescue toxicosis, it does not appear to reverse other known disorders associated with fescue toxicosis.

Key Words: Fescue toxicosis, Heat stress, Seaweed

70 Use of *Ascophyllum nodosum* to reduce problems associated with fescue toxicosis in cattle during heat challenge. M. J. Leonard^{*1}, D. E. Spiers¹, G. Rottinghaus¹, and D. P. Colling², ¹University of Missouri, Columbia, MO, ²Land O'Lakes Farmland Feed, Kansas City, MO.

Cattle grazing endophyte-infected tall fescue (EIF) during summer months are at increased risk of heat-related stress. Previous studies have reported that cattle grazed on EIF pastures sprayed with seaweed extract (*Ascophyllum nodosum*) (SWE) exhibit reduced internal temperature compared to cattle grazing EIF pastures without the SWE. The objective of this study was to determine if supplemental SWE would reduce symptoms of fescue toxicosis in cattle. Twelve Angus x Simmental steers (238±10 kg) were randomly divided into 3 treatment groups consisting of 0, 0.5, or 1% SWE. Steers were housed in environmental chambers with a feedlot starter diet and water *ad libitum*. Air temperature and percent relative humidity (%RH) were recorded continuously. Steers were exposed to thermoneutral conditions (19°C, 50% RH, days 1-5 and 27-31) and heat challenge (HC) (26-33°C, 50% RH, days 6-26) during the trial. EIF seed and SWE were fed daily in the diet at a concentration that would ensure 10µg ergovaline/kg BW/day and the appropriate SWE dose. Rectal temperature, respiration rate, and skin temperatures were recorded three times daily to monitor thermal status. Feed intake was recorded daily. Blood was drawn prior to treatment and weekly thereafter for analysis of blood constituents. Feed intakes were reduced during HC for all treatments; however, this reduction was greater for 1% SWE steers (P <0.05). Rectal temperature for 1% SWE was also lower than the other treatments (P <0.05). Respiration rates and skin temperatures were similar for both 0.5 and 1% SWE groups, however, respiration rates for 1% SWE steers were lower than 0% SWE (P <0.05). Blood levels of total and free triiodothyronine and total thyroxine were lower in 1% SWE steers after removal from heat challenge (P < 0.05). Addition of 1% SWE reduced heat-related stress in steers. Further studies are needed to determine the effect of SWE on metabolic function during long-term heat challenge.

Key Words: Fescue toxicosis, Heat stress, Cattle

71 Effects of an intermittent altrenogest regimen on behavioral, hormonal, and testicular parameters of three-year-old stallions. H.A. Vartorella^{*1}, H.A. Brady¹, A.D. Herring¹, S.D. Prien¹, N.L. Heninger¹, and A.L. Neumann¹, ¹Texas Tech University, Dept. of Animal Science and Food Technology.

Overly sexual/aggressive stallions within the performance horse industry create a hazardous working environment and several training challenges. To suppress these behaviors without surgical castration, oral altrenogest (Regu-Mate[®], Intervet, Millbro, DE) is being administered to stallions by trainers in an off-label application. Previous research has studied the use of altrenogest in continuous application. The objective of this study was to evaluate the testicular, hormonal, and behavioral capacity of three-year-old stallions receiving a short term, repetitive dosage of oral altrenogest. Nine, three-year-old Quarter Horse stallions were initially blocked by sire, and then randomly designated to two groups, treatment (n=5) and control (n=4). The treatment group received an oral daily 0.088 mg/kg BW dose of Regu-Mate[®] for 10 d, followed by 10 d of recuperation (no treatment). This process was repeated three times over 60 d, followed by a recovery period of 36 d. All animals went through interval evaluations for steroid hormones, physical condition, testicular parameters, and sexual/aggressive behavior (including Flehmen response, biting/chewing, sniffing/licking, erection of penis, dropping of penis, and vocalizations). The altrenogest dosages had no significant effects on body weight or condition scores. Of the testicular parameters analyzed, scrotal width, testis composition, and gross testicular parameters were unaffected, although a significant decrease (P<0.05) was found in the mean number of spermatids. No differences

were observed between treatment groups for either estrogen or testosterone concentrations. However, there was a significant time by treatment interaction for estrogen levels (P<0.05). No significant differences were seen for any of the sexual/aggressive behavioral parameters analyzed based on frequency, latency, or duration, at any point of the study. Nevertheless, several areas assessed in this study showed large variations between individual stallions. Further research of altrenogest in the stallions is needed to determine a practical dosage amount and sequence to produce a manageable animal, which takes age and fertility effects in consideration.

Key Words: Stallion, Altrenogest, Behavior

72 Social structure and behavior of laying hens in large groups. R. Freire^{*}, F. Short, and C.J. Nicol, *Bristol University, Bristol, United Kingdom.*

There has been a recent trend in Europe towards large group systems for the commercial housing of laying hens. The aim of this study was to obtain information about the spatial interaction and social cohesion of birds in large groups. A group of 1000 birds was housed in a perchery pen providing littered areas, individual nest boxes and a central frame of perches. Eighty birds were tagged with transponders that emitted a unique identification number each time they walked near antennae placed at 16 locations at each of 4 heights. Over a four-month recording period, approximately 85% of the tagged birds restricted their movement to particular areas (i.e. within a home range, chi-squared P<0.001). We tested the possibility that birds that occupy the area under the perches (i.e. the slats) for long periods of time are in poor health and retreat to this location as a means of avoiding social encounters. Increased use of the slats was significantly related to reduced weight (third order polynomial fitted line, F_{1,67}=6.6, P<0.0001) and poorer back feather condition (ANOVA, F_{1,67}=4.2, P<0.05). However, latency to move away from a group of birds and distance reached was not significantly correlated to time spent on the slats (multiple regression, P>0.1). In conclusion, the health and condition of a few individuals that become restricted to unfavorable areas may be compromised in large group systems.

Key Words: Social, Behavior, Hens

73 Survey of auction and slaughter horses. K. McGee¹, J. L. Lanier¹, and T. Grandin^{*1}, ¹Colorado State University.

Surveys of 10 non-cataloged auctions (n=1,473) and at 3 slaughter plants (n=1,348) were used to characterize the types of horses typically found. Informal interviews with industry people were conducted to gain an insight into why certain types of horses are more prevalent in auctions than in slaughter plants. Soundness of horses was based on guidelines in the U.S. Pony Club Guide to Conformation, Movement and Soundness, and foot condition and body condition was scored with a four-point and five-point scale, respectively. Interviews indicated that horses are typically not sold to a slaughter plant if there is potential for that horse to continue as a riding or working horse. Usable horses have a greater economic value at an auction than at a slaughter plant. The frequency for types of horses seen at slaughter and auction plants, respectively was riding horses 63% and 68%, mules, donkeys, ponies and miniatures 2% and 18%, racehorses 4% and 1%, feedlot horses fed for slaughter 9% and 0%, draft horses 7% and 2%, male horses (stallions, gelding, and colts) 50% and 57%, sound riding or working horses 13% and 47%, gray horses (70-90% have melanosis tumors) 10% and 10%, and horses with an official Bureau of Land Management freeze brand were 2% of the slaughter horses and less than 1% of all auction horses. Body condition for slaughter and auction horses, respectively was emaciated 3% and 2%, thin 27% and 20%, good 59% and 67%, and fat or obese 11% and 11%. Slaughter plant horses had substantially poorer foot condition than the auction horses. Neglected hooves that had damage of the coronary band were 10% of the slaughter horses versus 2% of the auction horses. Moderately neglected hooves accounted for 54% and 26%, acceptable hooves for 31% and 54% of slaughter and auction horses, respectively. More horses sold at auctions were sound usable riding/working horses than those sold to the slaughter plants. Slaughter plants in the United States assist in maintaining a level of horse welfare by preventing old and (or) unsound working/riding horses from being neglected.

74 Myofibrils isolated from red and white porcine muscles respond differently to pH. B. C. Bowker^{*1}, D. R. Swartz², A. L. Grant¹, and D. E. Gerrard¹, ¹Purdue University, West Lafayette, IN, ²Indiana University Medical School, Indianapolis, IN.

The pH-dependent ATPase activity of myofibrils from muscles varying in fiber type is thought to modulate postmortem muscle metabolism. The objective of this study was to determine the effects various conditions, simulating postmortem conditions, have on myofibrillar ATPase activity of red semitendinosus (RST) and white semitendinosus (WST) porcine muscle. The ATPase activity of myofibrils was measured at 39°C, 10-4 M Ca²⁺, and pH ranging from 5.0 to 7.5 at 0.25 unit intervals. To test if decreased pH irreversibly alters myofibrillar ATPase activity, activity was measured using myofibrils incubated 90 min at 39°C at pH 7.0, then pH 5.0 or 6.0, and back to pH 7.0. Maximum activity was at approximately pH 7.0 with WST myofibrils exhibiting greater ($P < .0001$) ATPase activity than RST myofibrils (0.621 vs. 0.445 nmole Pi/mg protein/min). Activity of both RST and WST myofibrils declined from maximum rates to approximately zero between pH 6.25 and 5.5. Activity declined to half-maximal levels at pH 5.95 in both RST and WST myofibrils. After incubation at pH 5.0, activity was not recovered in RST or WST myofibrils. Following incubation at pH 6.0, ATPase activity recovered to a higher ($P < 0.05$) percent of maximum activity in RST than WST myofibrils. These data suggest that postmortem muscle pH and muscle fiber type affect overall myofibrillar ATPase activity and that low pH may irreversibly alter myofibrillar proteins causing a loss in ATPase activity, with this pH sensitivity being more pronounced in WST than RST.

Key Words: Myofibrils, ATPase activity, pH

75 Relationship between muscle fiber type and pork quality traits of pigs selected for leanness and growth efficiency. C.R. Kerth^{*}, A.A. Helm, D.L. Kuhlert, L.B. Cagle, L.K. Blair-Kerth, and W.R. Jones, Auburn University, Auburn AL.

Progeny from the sixth generation of Duroc pigs selected for leanness and growth efficiency or a control line of pigs maintained from the base population were tested to determine the relationship between muscle fiber types and muscle quality traits. Random samples of pigs from each genetic line with mixed sexes ($n = 31$) were slaughtered at 114 kg. Longissimus muscles were measured for postmortem pH at 0.5, 1, 2, 3, 4, and 22 to 24 h postmortem. Chops were removed to determine Hunter L*, a*, and b* values, drip loss, water holding capacity, and fiber typing. Muscle fiber type samples were stained for acid-stable ATPase activity to determine muscle fiber type. Correlation and regression analyses were conducted to determine the relationship between muscle fiber type and muscle quality traits. No significant correlation existed ($P > 0.05$) between muscle fiber type and percent drip loss, Hunter a* and b* values, percent moisture, or postmortem pH at 0.5, 1, 2, 3, 4, and 22 to 24 hours. Genotype did not affect ($P > 0.05$) mean fiber type percentage. Hunter L* values were negatively correlated with slow-twitch oxidative (SO) fiber types ($r = -0.39$) and positively correlated with fast-twitch glycolytic (FG) fiber types ($r = 0.49$, $P < 0.05$). No correlation existed ($P > 0.05$) between percent free water and SO or FG fiber types. However fast-twitch oxidative, glycolytic (FOG) fiber types were negatively correlated ($r = -0.40$) with percent free water and positively correlated with percent bound and immobilized water ($r = 0.40$ and 0.40 respectively, $P < 0.05$). Regression analysis showed that percent FG muscle fiber types accounted for 23.8% and SO muscle fiber types accounted for 14.9% of the variation in Hunter L* ($P < 0.05$). The percentage of FOG fiber types accounted for 16.1% ($P < 0.05$) of the variation in percent free water. These data indicate that a relationship exists between muscle fiber type and objective muscle quality traits of pigs selected for increased leanness and growth efficiency.

Key Words: Muscle Fiber Type, Water-holding, Muscle Color

76 Variation in color and pH measurements throughout boneless pork loins. C. L. Lorenzen^{*1}, J. L. Norman¹, G. K. Rentfrow², C. A. Stahl², E. P. Berg², and M. R. Ellersieck³, ¹Food Science and Engineering Unit, ²Animal Sciences Unit, ³Department of Statistics, University of Missouri - Columbia.

Color is an extremely important consideration for merchandising pork both domestically and internationally. The objective of this study was to characterize the changes in color and pH throughout the length of the boneless pork loin. Center cut boneless pork loins ($n = 93$) were obtained commercially and segmented according to NPPC color standards assessed at the sirloin face of bone-in loins. Treatment 1 included NPPC color standards 1 and 2; treatment 2, standards 3 and 4; and treatment 3, standards 5 and 6. Loins were cut into 2.54 cm chops and allowed to bloom for at least 10 min. Hunter color L*, a*, b* values and pH measurements were taken on all chops in the loin starting at the sirloin end. Treatment affected ($P < .05$) all measures of color. Hunter color L*, a*, and b* values for chops differed ($P < .05$) by position of chop in the loin. All regression equations used to predict color values were polynomial with R² values of 0.71, 0.87, and 0.95 for L*, a* and b*, respectively. A treatment by position interaction ($P < .05$) existed for pH values with treatment 3, sirloin end being the highest and treatment 1, blade end the lowest. The center of the loin is typically merchandized as the high-value, high yield portion of the loin most popular with consumers. This study indicates that there is variation in color and pH throughout the loin; therefore, a single measurement at the end of the loin may not accurately predict the color of pork in the portion of the loin that creates retail demand.

Treatment	L*	a*	b*
1	58.17 ^a	6.35 ^b	15.18 ^a
2	51.48 ^b	6.99 ^{ab}	14.27 ^b
3	45.55 ^c	7.36 ^a	12.77 ^c

^{a,b,c}Means within a column lacking a common superscript differ ($P < .05$)

Key Words: Pork, Color, pH

77 In-home consumer acceptance of boneless pork loins varying in color. J. L. Norman^{*1}, C. L. Lorenzen¹, C. A. Stahl², G. K. Rentfrow², E. P. Berg², and H. Heymann¹, ¹Food Science and Engineering Unit, ²Animal Sciences Unit, University of Missouri - Columbia.

The objectives of this study were to determine the effects of color and light reflectance on Warner-Bratzler shear force values and (or) on consumer preferences for pork. Center-cut boneless pork loins ($n = 60$) were divided into three groups based on NPPC color standards. Treatment 1 included NPPC color standards 1 and 2; treatment 2, 3 and 4; and treatment 3, 5 and 6. Loins were cut into 2.54 cm chops. Two chops obtained from the center section of each loin were used to determine Warner-Bratzler shear force, Hunter color L*, a*, b*, and pH values. The "in-home" portion of this study consisted of two three-week repetitions where consumers prepared, consumed, and evaluated specific pork chops. Chops were allotted randomly for both treatment and week of repetition. Consumers used a nine-point sensory hedonic scale for the attributes overall likeness, tenderness liking, juiciness liking, and flavor liking; where 1 = dislike extremely and 9 = like extremely. A total of 47 households completed both repetitions of the study. Hunter color L*, a*, b*, and pH measurements differed ($P < .05$) by treatment. L* means were 57.01, 50.24, and 45.54 for treatments 1, 2, and 3, respectively. Warner-Bratzler shear force values were not affected by treatment ($P > .05$), but the percentage cook yield of dark pork was 3.5 % higher than light pork ($P < .05$). Consumers detected differences in juiciness and tenderness liking ($P < .05$) due to treatment. Warner-Bratzler shear force values were negatively correlated with a* and b* values ($P < .0001$; $r = -0.295$ and -0.314 , respectively). Neither, Warner-Bratzler shear force values nor consumer preferences were affected ($P > .05$) by color grouping or light reflectance.

Key Words: Pork Quality, Tenderness, Light Reflectance

78 Muscle glycogen and lactate content and pork quality traits as affected by available dietary carbohydrate in pigs. G. Bee*, ¹Swiss Federal Research Station for Animal Production.

The aim of the study was to determine whether muscle glycogen content and pork quality traits could be modified by availability of carbohydrates in the diet. Biopsy samples of longissimus (LM) from 48 Swiss Large White pigs (25 gilts; 23 barrows) weighing 70 kg were collected, and the glycolytic potential (GP = 2[(glycogen + glucose + glucose-6-phosphate) + lactate] was determined to vary from 111 to 187 $\mu\text{mol/g}$ wet weight. At 90 kg pigs were moved into individual pens and assigned (blocked by GP and sex) to be fed 2.8 kg of a diet either high (H) or low (L) in available carbohydrate up to 104 kg. Pigs were fasted over night (15 h) before slaughter. Glycogen and lactate content were determined in samples of LM (predominately glycolytic) collected 30 min and 24 h after stunning, and in samples of the dark part of the semitendinosus (ST, oxidative muscle) collected 24 h after stunning. Measurements of pH were carried out in the LM 30 min and 24 h after slaughter. Hunter L*, a*, b* values and drip losses were assessed the day after dissection. Overall glycogen and lactate levels 24 h postmortem were higher in the LM compared to the ST (19.5 vs. 11.5 $\mu\text{mol/g}$; 95.4 vs. 74.8 $\mu\text{mol/g}$; $P < 0.05$). Diets did not affect pH, color, drip losses, or glycogen and lactate concentrations of the LM. The diets affected the glycogen content of the ST in gilts (H: 14.7 vs. L: 9.2 $\mu\text{mol/g}$) but not in barrows. Lactate concentrations in the ST were also higher in pigs fed the H diet (H: 76.3 vs. L: 73.4 $\mu\text{mol/g}$; $P = 0.03$). Compared to diet L, Hunter L* values tended to be lower (H: 42.6 vs. L: 43.6; $P = 0.07$) in the ST of animals fed diet H, and b* (H: 6.8 vs. L: 5.6; $P < 0.05$) and drip losses (H: 4.8 vs. L: 3.1%; $P \leq 0.05$) were higher in gilts but were unaffected in barrows. Hunter L*, a*, b* and drip losses were positively correlated with glycogen (0.36; 0.34; 0.57; 0.59; $P < 0.05$) and lactate content (0.36; 0.28; 0.34; 0.27) in the ST, whereas the correlations were not significant in the LM. In conclusion, dietary treatment affected quality traits of the ST, but not of the LM muscle, and the effects were more pronounced in gilts than barrows.

Key Words: pigs, glycolytic potential, pork quality

79 Influences of nutritional levels on porcine muscle development and meat quality. Daiwen Chen*, Keying Zhang¹, Zhuyu Hu¹, Feiyun Yang², and Zuohua Liu², ¹Institute of Animal Nutrition, Sichuan Agricultural University, PR.China, ²Academy of Swine Research of Chongqing, PR.China.

This study was to investigate the growth models of pigmeat traits at high (HL) and low (LL) nutritional levels. Landrace x Rongchang barrows (n = 90) with 18 kg bodyweight (BW) were randomly allotted into two treatments with 3 replicates each. Pigs were fed with diets containing DE 14.2 MJ/kg and CP 18%, 15.5% and 13.2% for the stage of 18-50, 50-80 and 80-100 kg, respectively (HL) or diets with DE 12.1 MJ/kg and CP 15.5%, 13.2% and 11.2% for each stage (LL). For each replicate, 3 pigs were killed at 20, 35, 50, 80 or 100 kg BW to examine meat measurements. Quality traits were measured at 45 min postmortem. The amount (kg) of lean deposition increased linearly with BW ($= 0.4156 + 0.3299 \text{ BW}(\text{kg})$, $R^2 = 0.9997$, $P < 0.001$), but didn't vary with nutritional levels ($P > 0.05$). There were no differences for color score of longissimus muscle (LM) among treatments. LM area, lean percentage (LP) in carcass, intramuscular fat (IMF) content and water loss (WL) of meat after 5-min pressure under 35-kg force responded quadratically to BW (x, kg) ($P < 0.001$) as follows. Analyses of these equations showed that the effects of HL and LL on LM area and LP differentiated from 70 kg on, and those on IMF and WL from 40 kg. It was concluded that nutritional levels did not influence development models of meat traits and meat quality until pigs reach a certain bodyweight.

Key Words: Meat Quality, Development Model, Nutritional Level

80 Effects of dietary supplementation of copper and Vitamin E on pigmeat quality. Daiwen Chen*, Keying Zhang, Yongyi Li, Fangqun Li, Zhuyu Hu, and Xuwei Li, Institute of Animal Nutrition, Sichuan Agricultural University, Yaan, Sichuan 625014, PR.China.

Copper (Cu) is widely used as growth promoter for growing-finishing pigs in China. Whether Cu application has impacts on meat quality and vitamin E (VE) needs to be supplemented in Cu-containing diets are not

known. Two experiments were conducted in this study to investigate the effects of Cu or/and VE supplementation in diets on pigmeat quality. In Exp.1, 250 ppm Cu in form of copper sulfate or 200ppm VE or Cu and VE together were added into corn-soybean-meal basal diet(control) which contained DE 13.8MJ/kg, CP 16.5-14%, Cu 16-20 ppm, and VE 27-40 ppm. In Exp.2, 200 ppm VE was supplemented into 250-ppm-Cu basal diets(control) when pigs reached 20, 60 or 80 kg liveweight (LW). For each Exp., 36 Large White x Landrace barrows with initial LW of 20 kg were randomly allotted into 4 treatments with 3 replicates each. Pigs were slaughtered at 100kg LW. Cu supplementation tended to increase ($p < 0.1$) average daily gain (ADG), feed conversion rate (FCR), area of longissimus muscle, and decrease backfat thickness. No significant differences were observed for color scoring, marbling, pH, drip loss and the contents of protein, lipid, collagen, Cu, Fe and VE for both fresh meat and meat chops stored at -4°C up to 9 days. VE supplementation in diets either with or without Cu supplementation tended to improve ($p < 0.1$) ADG, FCR, color scoring, and decrease drip loss of fresh meat. Fe, Cu and VE contents in fresh meat were enhanced ($P < 0.05$). After meat chops were stored at -4°C for 9 days, VE content and color scoring were higher, and drip loss and lipid oxidation, reflected by thiobarbituric acid reaction value, were lower for VE supplementation ($p < 0.01$) compared to the control. The extent of effects was greater when VE was included at 20 kg LW than at 60 kg or 80 kg. There were no interactions between Cu and VE. It is concluded that Cu supplementation in growing-finishing diets has no adverse effects on pork quality and VE supplementation was able to improve pork quality and extend pork shelf life.

Key Words: Meat Quality, Copper/Vitamin E, Pigs

81 Effects of dietary levels of ideal protein on pig meat quality. Keying Zhang*, Daiwen Chen, Xianmei Luo, Xuwei Li, Fangqun Li, and Zhuyu Hu, Institute of Animal Nutrition, Sichuan Agricultural University, Yaan, Sichuan, PR. China.

There are no investigations on the relationship between dietary ideal protein (IP) levels and pork quality up to now. In this study, sixty Large White x Landrace barrows with initial live weight (LW) of 20 kg were used to examine the effects of dietary IP levels on meat quality. Five dietary IP levels were designed as 8, 11, 14, 17 and 20% on as-fed basis (DM 89%). Corn-soybean-meal diets were formulated to contain DE 14.2MJ/kg, digestible lysine 4.75 g per 100 g of N x 6.25, and a ratio of lysine: sulfur-containing amino acids: threonine and tryptophan on digestible basis of 100:61:64:20. Pigs were randomly assigned into each treatment with 4 replicates each and given ad libitum access until 100 kg LW, when 1 pig of each replicate was slaughtered to check carcass quality. The results were showed in the table. There were no significant differences among treatments in terms of meat pH, color scoring. However, as IP increased, area and drip loss of longissimus muscle significantly improved, while marbling and intramuscular fat decreased. Because marbling, intramuscular fat and drip loss are related to meat tenderness, juiciness and overall acceptability, this study indicates that appropriately low level of dietary ideal protein may be favorable to eating quality of pig meat.

Key Words: Meat Quality, Ideal Protein, Pigs

82 Validation of three cookery methods to eliminate Listeria monocytogenes on short versus long term aged country ham slices. J.S. Kotrola*, W.B. Mikel, and M. C. Newman, University of Kentucky, Lexington, KY.

Newly implemented USDA regulations dictate that all ready-to-eat products, of which Country-cured hams are classified, have validated cooking instruction on the label to be considered not ready to eat. Recent research indicates that if the USDA process for curing country hams is not strictly adhered to, then Listeria may possibly be present in sufficient numbers to cause illness in immuno-compromised individuals. Therefore, three cookery methods were evaluated on short versus long term aged country ham slices to determine mean temperature at which Listeria monocytogenes was no longer viable. Country-cured hams slices were inoculated with a cocktail of 5 strains of Listeria monocytogenes at 3.70×10^5 CFU/ml, 1.33×10^5 CFU/ml and 7.10×10^5 CFU/ml in preparation for cookery by microwave, oven and griddle respectively. Heating times were as follows: microwave (1000 watts) for 1, 2, 4, 6, 8 min.; oven (350°F) for 2, 4, 8, 12, 16, 20 min.; and Griddle (350°F) for 30, 45, 60, 90, 120, 150 sec. There were nine observations per cook

method and time combination. After the heat treatment, 25 gm of meat was rapidly mixed with 225 ml chilled UVM broth to terminate heating effect. Microwave heating effectively eliminated the *Listeria monocytogenes* cultures after 2 minutes for the long term ham and 1 minute for short term ham slices. Oven heating resulted in no viable cultures remaining after 8 minutes for the long term and short term cured products. Griddle heating eliminated populations after 45 sec for short term aged slices and after 60 sec for long term aged sliced. The efficacy of eliminating *Listeria monocytogenes* from country cured ham slices is dependent upon time, temperature, and cookery method used.

Key Words: *Listeria monocytogenes*, Country-cured ham, cookery

83 Analysis of postmortem tenderization in porcine *longissimus dorsi* muscle. C.P. Allison*, R.J. Tempelman, and M.E. Doumit, Michigan State University, East Lansing, MI.

Our objective was to quantify the rate and extent of postmortem tenderization in porcine *longissimus dorsi* (LD) muscle and determine if proteolysis of desmin corresponds to mechanical measures of tenderness. Berkshire (n=32) and Yorkshire (n=16) sired pigs were harvested on two days at a commercial abattoir. Four 5.72-cm sections of the LD were removed at d 1 from the 11th rib to the 3rd lumbar vertebrae. Loin sections were randomly assigned to aging treatments of 1, 3, 7 and 14 d, vacuum packaged and stored at 4°C. After storage, two 2.5-cm thick chops were cooked to an internal temperature of 71°C on Farberware Open Hearth™ broilers. Chops were cooled overnight at 4°C and three 1.27-cm diameter cores per chop were sheared with a Warner-Bratzler Shear (WBS) machine. No differences in WBS values were observed between breed or loin location (P>.05). Shear values decreased (P<.0001) from 4.1 kg at d 1 to 3.6 kg and 3.2 kg at d 3 and d 7, respectively. Chops aged for 7 and 14 d had similar WBS values (P>.05). Western blot analysis of desmin from 4 tender (<4 kg) and 4 less tender (>4.7 kg) samples at d 1 revealed that desmin degradation paralleled decreases in WBS. Intact desmin was typically undetectable in tender samples by d 7 and in less tender samples by d 14. Tenderization of most pork loin chops is complete by d 7, however some chops exhibit additional tenderization and desmin degradation between 7 and 14 d postmortem.

Key Words: Pork, Tenderness, Desmin

84 Desmin degradation influences water-holding capacity and tenderness of fresh pork. L.J. Rowe*¹, E. Huff-Lonergan¹, and S.M. Lonergan¹, Iowa State University Ames, Iowa.

Proteolysis of desmin and troponin-T has been related to increased tenderness of meat. Degradation of desmin may also influence water-holding capacity (WHC) by disrupting linkages among adjacent myofibrils as well as myofibrils and the sarcolemma which would allow more space for fluid to reside in the tissue. We hypothesized decreased proteolysis of the myofibril-associated protein desmin would result in reduced WHC and tenderness. The objective was to determine if degradation of desmin was related to WHC and/or tenderness of pork. Halothane negative Duroc pigs (n=82) were harvested and pH measurements of the *longissimus dorsi* (LD) were taken at 45 min and 24 h postmortem (PM). Drip loss was measured on LD chops taken at 24 h and held at 4°C for an additional 24 h. Warner-Bratzler shear (WBS) force measurements were made on chops held 5 d PM at 4°C. LD samples taken at 1 d PM and 5 d PM were analyzed by immunoblotting using antibodies for desmin and troponin-T. Immunoreactive bands were quantified using densitometry. Desmin degradation was indicated by a decrease in intensity of an approximately 55 kDa immunoreactive band while troponin-T degradation was indicated by an increase in a 30 kDa band. 24 h drip loss was significantly correlated with 45-min pH (-.372) and 24 h pH (-.329). Drip loss at 24 h was not correlated with 5 d troponin-T degradation (-.119, P=.28) but was correlated with desmin degradation (.437, P < .01) indicating that products with less desmin degradation may have greater drip loss. 45 min pH and 24 h pH measurements were also significantly correlated with 5 d desmin degradation (-.254, -.377 respectively) indicating higher pH products tended to have greater desmin degradation. WBS at 5 d was significantly correlated with 5 d desmin degradation (.295) and 5 d troponin-T degradation (-.295). These results indicated increased drip loss and decreased tenderness of pork may be related to reduced proteolysis of proteins like desmin. (This work was supported by the National Pork Producers Council.)

Key Words: Water-holding capacity, Tenderness, Desmin

85 Dietary Conjugated Linoleic Acid and IGF-I Transgene Effects on Pork Quality. J. S. Eastridge*¹, M. B. Solomon¹, V. G. Pursel¹, A. D. Mitchell¹, and A. Arguello², ¹USDA-ARS, BARC, ²Univ. de las Palmas de Gran Canaria, Spain.

Transgenic (T) pigs produced with a fusion gene composed of avian skeletal α -actin regulatory sequences and cDNA encoding human IGF-I have exhibited increased lean tissue and less fat than normal (N) controls. While the use of T-pigs for meat production has not yet been approved, it is worthwhile to explore the quality of the meat from these pigs. Thirty pigs (14 T and 16 N siblings) were finished on a control (CO) growing-finishing diet or with added conjugated linoleic acid (CLA) to 120 kg. Carcass weight for N pigs was heavier (P<.01) than for T (92.5 vs 87.4 kg, respectively); however T loin eye area (38.1 cm²) was 16% larger than in N (32.5 cm²). Backfat thickness was lower (P<.05) for T-CLA-fed pigs (21.4 mm) than for N-CO, N-CLA and T-CO pigs (29.8, 27.5 and 27.0 mm, respectively). Although pH at 45 min was higher (P<.01) in N (6.10) compared to T (6.01), there were no differences detected in ultimate pH (N=5.65 vs T=5.59). CLA affected pH at 45 min (5.99 vs 6.13 for CO and CLA, respectively) but not ultimate pH (CO=5.58; CLA=5.66). Gene and diet effects on pork quality traits of ultimate pH, amount of purge after 21 d, cook yield and shear force values were not different. Shear force for N vs T (6.3 vs 5.8 kg) and for CO vs CLA (6.1 vs 5.9 kg) was not different. Malonaldehyde (TBARS) formation after 5 d fresh, 21 d fresh and 6 mo frozen storage was not influenced by gene or diet. CLA added to growing-finishing diet may help reduce carcass fatness. Based on the present study, the muscle hypertrophy induced by the IGF-I transgene has no detrimental effects on quality of meat as compared to control.

Key Words: Pork quality, IGF-I transgenic pig, Conjugated linoleic acid

86 Enhanced rates of postmortem muscle glycolysis differ across porcine genotypes. M. D. Spire*¹, B. C. Bowker, J. E. Hammelman, A. P. Schinckel, A. L. Grant, and D. E. Gerrard, Purdue University, West Lafayette, IN.

Pork quality development varies with genotype. Mechanisms responsible for this variation likely involve postmortem muscle metabolism. Curiously, many genotypes do not develop adverse pork quality unless they are subjected to pre-slaughter stress or postmortem mishandling. The objective of this study was to challenge pork carcasses of different genotypes using electrical stimulation (ES) to determine if some genotypes are more susceptible than others to exaggerated postmortem muscle metabolism. Three different genotypes, fifty pigs each, were slaughtered, then subjected to ES (100V or 200V, 13 pulses, 2 sec on / 2 sec off) at 15 or 25 min post-exsanguination, or no stimulation (NS). *Longissimus* muscle (LM) pH and temperature were recorded at 1, 10, 20, 30, 40, 50, and 60 min, and 24 h postmortem. Samples were collected from LM at 1, 30, and 60 min, and 24 h and analyzed for glycogen, glucose, glucose-6-phosphate (G6P), and lactate concentration. Muscle pH, but not temperature, differed (P < .05) across genotype. Genotype altered (P < .05) muscle glucose, glycogen, G6P, and lactate concentrations postmortem. In particular, G6P decreased (P < .05) from 1 to 60 min postmortem for all genotypes; however, G6P at 24 h accumulated to concentrations equivalent to 1 min levels for one genotype, but only accumulated to concentrations equivalent to 30 min levels for the other genotypes. Genotype effects were not observed for color, firmness, drip loss, 24 h pH, or CIE L*, a*, b* values. These data show that genotypes respond differently to postmortem perturbation by altering muscle glycolysis.

Key Words: Genotype, Pigs, Muscle Metabolism

87 Effect of processing plant on pork quality. E. Hambrecht*¹ and M.W.A. Verstegen², ¹Nutreco, ²Wageningen University.

The objective of the present study was to compare meat quality of pigs processed at three different plants. Plant A and B worked with head-to-heart electrical stunning (Midas[®], Stork) while plant C had a CO₂-dip-lift system (87% CO₂, Butina). Line speed varied from 420 (plant B) to 500 pigs/hour (plant A and C). In plant A carcasses passed through a 3-phase rapid chilling tunnel (-15/-10/-1°C, air velocity (AV) 2-3m/s, 90 min), in plant B through a pre-cooling tunnel (4-5°C, AV 3-3.5m/s, 30

min), and in plant C carcasses were directly transported to the cold storage (1-3°C, AV 2m/s). All carcasses were chilled until 20 h postmortem when meat quality was measured in the loin (3rd/4th lumbar vertebra). From October to March, 9 batches of ~150 pigs each (halothane-negative, average carcass weight 87kg) were purchased at commercial farms, divided in three and sent to the plants on three consecutive days. Feed withdrawal, transport and lairage time were identical for the three plants within batch. At 30 min postmortem pH was measured: plant A and C showed a lower pH₃₀ than plant B (A: 6.50 and C: 6.53 vs. B: 6.70, P<.001). After 4 h, pH was highest at plant B and lowest at plant C (A: 6.06 vs. B: 6.12 vs. C: 5.99, P<.001). Ultimate pH (pH_u) was lowest for plant C (5.62), intermediate for plant B (5.68) and highest for plant A (5.71, P<.001). In agreement with other measurements, drip losses (DL) differed between plants (P=.057) with highest DL found at

plant C (C: 5.2% vs. A: 4.8%, P<.05, B: 5.0%, P>.10). The plants ranked the same with regards to conductivity as with DL (A: 5.5 vs. B: 6.5 vs. C: 7.4 mS, P<.001). Although instrumental color measurement (Minolta) did not show significant differences, visual scoring (Japanese color scale, 1-6, 6 being darkest) revealed a paler color for plant C (A and B: 2.9 vs. C: 2.7, P<.001). Correlations (corrected for plant, batch and day of slaughter) were low to moderate: DL showed highest correlation with conductivity (r=.63) but lower correlations with pH₃₀, pH_{4h} and pH_u (pH₃₀: r=-.38, pH_{4h}: r=-.38, pH_u: r=-.45). It is concluded that processing plant can affect meat quality with differences being most likely related to pre-slaughter stress, stunning and/or cooling systems.

88 Use of menhaden oil to alter n-6:n-3 fatty acid ratios in nursery pig diets. T. A. Meyer*, M. D. Lindemann, G. L. Cromwell, and H. J. Monegue, *University of Kentucky, Lexington, KY.*

Weanling pigs (n=125, 21.4 d of age, and 6.8 kg BW) were used in two 28-d experiments to evaluate five dietary n-6:n-3 fatty acid (FA) ratios on performance, cell-mediated immunity, and intestinal morphology. Pigs were blocked by weight and randomly allotted to five pigs/pen. Complex diets with 5% oil (menhaden, corn, or a mixture) and calculated n-6:n-3 FA ratios of 0.7, 1.9, 6.9, 35.5, and 70.0 were then randomly allotted to pens within a replicate. Diets were formulated to contain 1.28% lysine; all other nutrients met or exceeded requirement estimates (NRC, 1998). Pig weights and feed consumption were recorded weekly. Cell-mediated immunity was assessed on d 14 and 28 by measuring the inflammatory response to an intradermal injection of phytohemagglutinin solution in the ear. One pig/pen was euthanized on d 28 and sections of duodenum and jejunum were taken to measure villi height and crypt depth. No overall differences (P = 0.10) in ADG (402, 448, 433, 456, and 428 g/d), ADFI (608, 677, 694, 709, and 656 g/d), or F/G (1.52, 1.51, 1.61, 1.56, and 1.53) occurred with increasing n-6:n-3 ratios. The inflammatory response (1.02, 1.00, 0.99, 0.93, and 0.96; 0.90, 0.86, 0.83, 0.95, and 0.85 mm) did not differ (P = 0.10) with increasing n-6:n-3 ratios on d 14 or 28, respectively. Duodenum crypt depth did not differ with increasing n-6:n-3 ratios (220, 215, 231, 213, and 225 mm; P = 0.10), but a quadratic effect occurred in jejunum crypt depth (239, 244, 252, 259, and 233 mm; P < 0.05). The duodenum and jejunum villi height (394, 394, 411, 407, and 364; 408, 432, 431, 415, and 424 mm), and villi height:crypt depth ratios (1.92, 1.93, 1.89, 2.07, and 1.70; 1.78, 1.86, 1.77, 1.68, and 1.91) did not differ (P = 0.10) among dietary treatments. Alteration of dietary n-6:n-3 FA ratios did not influence performance or skin inflammatory response to PHA, but did have a small effect on intestinal morphology.

Key Words: Pigs, Fatty acids, Performance

89 Response of early-weaned pigs to pea protein isolate-based diets supplemented with chicken egg-yolk anti-E. coli (K88) antibody. A. Owusu-Asiedu*¹, R. R. Marquardt¹, C. M. Nyachoti¹, and S. K. Baidoo², ¹University of Manitoba, Winnipeg, Manitoba/Canada, ²University of Minnesota, Minneapolis, Minnesota/USA.

In practical swine production, enterotoxigenic *E. coli* (ETEC) infection and resulting scours is a major problem for young pigs especially where purified plant proteins compared to spray-dried porcine plasma (SDPP) are fed. The effect of supplementing a pea protein isolate (PPI)-based diet with egg-yolk antibodies (EYA) obtained from laying hens immunized with ETEC K88 on piglet performance and incidence of scours was studied in a 14-d experiment. Ninety 10-d old weaned pigs were assigned to 5 dietary treatments in a completely randomized design to 6 replicate pens per treatment. The treatments were PPI, PPI + EYA, SDPP, SDPP + EYA and PPI + SDPP. All diets were formulated to similar nutrient levels and provided for ad libitum consumption. On d 7, piglets were orally challenged with 6 ml of ETEC K88 dose of 10¹² CFU ml⁻¹. Piglets were weighed on d 7 and every other d after ETEC challenge. Weekly feed intake, BW change and number of piglets with scours and scour score were recorded. Fecal swabs from 10 pigs per treatment were taken for polymerase chain reaction (PCR) test to detect *E. coli* K88.

Feed efficiency ranged from 1.3 to 1.4 and was not affected (P>0.05) by dietary treatment. Mean daily feed intake was lower (P<0.05) in piglets fed diet PPI (64.3 g/d) compared to PPI + EYA (94.8 g/d) during WK 1. Piglets fed PPI without EYA had lower (P<0.05) ADG (84.0 g/d) compared to those fed PPI + EYA (123.0 g/d) or SDPP-based diets. Scour appeared in all groups of pigs 4-6h after ETEC K88 oral challenge. However, piglets fed PPI + EYA or SDPP-based diets recovered after 10h post-challenge, whereas those fed PPI continued to have severe diarrhea resulting in 46.5% mortality. PCR results showed that all PPI fed piglets continued to shed ETEC K88 at the end of the 14-d experimental period. It was concluded that specific EYA and SDPP can provide passive control of ETEC (K88) infection and potentially improve feed intake and weight gain in early-weaned pigs fed PPI

90 High levels of dietary ascorbic acid on liver gulonolactone oxidase activity, serum and liver ascorbic acid concentration, and growth performance of postweaning pigs. S. Ching*¹ and D.C. Mahan, ¹The Ohio State University.

Pig liver ascorbic acid synthesis activity was found to be suppressed while nursing the sow, but increased during the initial 2 wk postweaning. Blood and tissue ascorbic acid concentration declined postweaning and continued at a low concentration for several weeks. This experiment therefore evaluated the effects of feeding high dietary vitamin C levels on liver gulonolactone oxidase (GLO) activity, tissue ascorbic acid contents, and growth performance during a 38 d postweaning period. A randomized complete block design was conducted with four levels of dietary ascorbic acid (0, 500, 1000, 3000 ppm) in 12 replicates. Diets were comprised using typical Phase 1, 2, and 3 starter pig diets, except that a stabilized form of vitamin C (Stay C ? 35%) was used. A total of 260 crossbred pigs was weaned at 17 d of age and averaged 6.2 kg BW. At the end of each phase (10, 24, and 38-d postweaning) pigs were weighed and feed consumption measured. Pigs were bled at each period with the serum analyzed for ascorbic acid. Two pigs per treatment group were killed at the end of each period and liver GLO activity and ascorbic acid concentration determined. Daily gains (P < 0.05) and G/F ratio (P < 0.10) increased linearly as dietary ascorbic acid increased during the 0 to 10-d period, but not thereafter. Liver GLO enzyme activity decreased linearly (P < 0.01) at 10, 24, and 38 d as dietary vitamin C increased. As dietary vitamin C levels increased, serum ascorbic acid (P < 0.01), liver ascorbic acid (P < 0.01), and urinary ascorbic acid (P < 0.01) increased at 10, 24, and 38-d postweaning. These results indicate that high levels of dietary vitamin C suppressed vitamin C synthesis in the pig, but stimulated pig growth and feed efficiency during the initial 10-d postweaning with higher serum, tissue, and urinary ascorbic acid concentrations.

92 Effects of brewers dried yeast as a source of mannanoligosaccharides and of carbadox on total, *Escherichia coli* K88, and carbadox-resistant coliform populations in early-weaned pigs. L. A. White*, M. C. Newman, G. L. Cromwell, and M. D. Lindemann, *University of Kentucky, Lexington, KY.*

Effects of brewers dried yeast, as a source of mannanoligosaccharides (MOS), and carbadox on enteric microbial populations in young pigs were evaluated. In two trials, pigs ($n = 12$ /trial) were weaned at 11 d of age (4.1 kg BW) and placed in isolation chambers (two pigs/chamber) equipped with individual air filtering systems and excrement containers. Treatments were a non-medicated basal diet, a diet with 55 mg/kg of carbadox, and a diet with 3% yeast. Diets were fortified corn-soy-dried whey-lactose-animal plasma and contained 1.5% lysine (total). Diets were fed for 29 d, then each pig was bled and orally dosed with approximately 9.5×10^8 CFU of *E. coli* K88. Fecal swabs were collected daily from inoculation (d 0) to d 10. Total, K88, and carbadox-resistant coliforms were enumerated daily, and total serum protein levels were measured from blood sampled on d 0 and d 10. All pigs were killed on d 10 (18.5 kg BW) and bacterial samples were obtained from the intestinal wall of the small intestine, cecum, and colon. Agglutination tests confirmed adsorption of K88 and other serovars of *E. coli* and *Salmonella* spp. with yeast. A few differences among pigs fed the basal, carbadox, or yeast diets were detected in total coliform (2.9, 2.6, 2.6 log CFU/g tissue), *E. coli* K88 (1.6, 1.4, 1.6), and carbadox-resistant (1.7, 1.3, 1.6) populations in the small intestine, cecum (5.7, 4.6, 5.2 [$P < 0.05$]; 2.4, 2.6, 3.1; 2.8, 2.4, 2.5), and colon samples (5.8, 5.4, 5.4; 2.7, 3.2, 2.9 [$P < 0.05$]; 3.1, 3.4, 3.2). Daily fecal K88 counts were not different ($P > 0.05$) among treatments, but counts of carbadox-resistant coliforms were higher ($P < 0.05$) throughout the 10-d period in the carbadox vs basal or yeast treatments. Serum protein levels were higher ($P < 0.05$) for the yeast group on d 0 (2.4, 3.1, 3.4 g/dl serum) but not at termination (4.7, 5.0, 4.7). In this trial, brewers dried yeast and carbadox had minimal effects on microbiological and immunological traits in early-weaned pigs.

Key Words: Pigs, Coliforms, Yeast

93 The effect of feeding spray-dried porcine plasma and egg immunoglobulins with anti-bacterial or anti-somatostatin specificities on the performance of weaned pigs. M. D. Drew* and A. E. Estrada, *University of Saskatchewan, Saskatoon SK Canada.*

A total of 120 weanling pigs (18 d of age; 6.0 Kg mean weight) were used to evaluate the effect of feeding porcine plasma (PP) with two different egg immunoglobulin (Ig) products. The first egg Ig was produced by immunizing laying hens with a bacterin containing *E. coli* F4, *Pseudomonas aeruginosa*, *Proteus vulgaris*, *Enterococcus faecalis*, *Klebsiella pneumoniae* and *Clostridium perfringens*. The second egg

Ig was produced by immunizing hens against a somatostatin (SRIF)-bovine serum albumin conjugate. The eggs were spray-dried before use. Thirty pigs (5 per pen) were randomly assigned to one of four diets: 1) Control-containing no plasma or egg, 2) Plasma-control diet with 2.5% PP added, 3) Bacterial Egg-control diet with 1.0% PP; 0.5% anti-bacterial egg added and 4) SRIF Egg-control diet with 1.0% PP; 0.5% anti-SRIF egg added. The diets were not pelleted and provided equal crude protein, lysine, methionine, threonine and digestible energy. Pigs were fed ad libitum and pig weights and feed intakes were measured on days 0, 7 and 14. During the first 7 days, pigs receiving the SRIF egg diets had significantly higher average daily gains (ADG) ($P < 0.05$) compared to the controls (143 g/d vs 83 g/d). Plasma or Bacterial Egg fed pigs had ADG (121 g/d and 128 g/d respectively) which were not significantly different from the Controls or SRIF egg groups. The Plasma fed pigs had higher ($P < 0.05$) average daily feed intakes (ADFI) than the other three groups during the first week of the experiment. Feed:gain ratios (F:G) were reduced ($P < 0.05$) in the pigs fed the Bacterial or SRIF egg diets (1.19 and 1.09 respectively) compared to the controls and Plasma diet fed pigs (1.79 and 1.50 respectively). No significant differences were seen during the second week of the experiment. The results suggest that anti-bacterial or anti-SRIF egg Igs combined with low levels of plasma can increase the growth and feed efficiency of weaned pigs.

Key Words: Pig, Immunoglobulin, Somatostatin

94 Pre- and postweaning performance of piglets fed pre-weaning diets containing either spray-dried porcine plasma, whey protein concentrate or whey powder. A.J. Van Dijk*¹, M. Ubbink-Blanksma¹, J.G.P. Van der Palen¹, and A.C. Beynen², ¹Co-operative Central Laboratory Nutritional Control, P.O. Box 107, 5460 AC Veghel, The Netherlands, ²Dept. Nutrition, Utrecht University, Veterinary Faculty, P.O. Box 80152, Utrecht, The Netherlands.

We studied the effect of the addition of either delactosed whey powder (WP), spray dried porcine plasma (SDPP) or whey protein concentrate (WPC) to creep feed on pre- and post-weaning performance and health of piglets. Inclusion levels in the diets were 17.7, 5.0 and 13.1 %, respectively. SDPP or WPC were exchanged for WP in the control diet on an isonitrogenous basis. During the period from thirteen days before weaning until weaning, the piglets (17 litters per treatment) were offered one of the three experimental creep feeds followed by a weaner diet after weaning, that was identical for all three treatment groups. During the pre-weaning period there were no significant differences in feed intake and daily gain between the treatment groups (Table 1). During the first week after weaning, the piglets that had been fed the SDPP diet before weaning, had a significantly higher average daily feed intake (ADFI) than did the piglets that were fed the WPC diet before weaning. During the fourth week after weaning, the piglets given the creep feed with SDPP diet before weaning had a significantly higher average daily gain (ADG) and lower feed conversion ratio (FCR) than the piglets that were fed the creep feed with WP. For the entire post-weaning period there were no major differential effects on ADG, ADFI and FCR as mediated by either SDPP, WPC or WP in the creep feed. It is concluded that the type of protein in creep feed can have carry-over effects on post-weaning growth performance.

Diet	WP	SDPP	WPC	SEM
ADG (g/day)				
14 days before weaning until weaning	295	310	314	9
After weaning, days:

95 Evaluation of Termin-8[®] addition to spray-dried animal plasma or base mix on growth performance of nursery pigs. J.M. DeRouche¹, R.E. Musser², W.N. Cannon³, M.D. Tokach¹, J.N. Nelssen¹, R.D. Goodband¹, and S.S. Dritz¹, ¹Kansas State University, Manhattan, ²The Pork Group, Rogers, AR, ³NutraBlend, Neosho, MO.

A total of 1698 pigs (BW of 5.0 kg and 17 d of age) were used in a 13 d growth assay to determine the effects of Termin-8[®] (Anitox Corp.) addition to the spray-dried animal plasma (SDAP) or base mix portion of a SEW diet on growth performance in nursery pigs. Termin-8[®], an antibacterial feed additive, contains a mixture of aliphatic acids, formaldehyde, and natural terpenes. Pigs were housed in a commercial research nursery with 12 to 19 pigs per pen (uniform within each block) and 36 pens per treatment. Pigs were allotted to one of three SEW dietary treatments. The treatment diets included: 1) control diet (1.67% lysine, 7% SDAP); 2) control diet with Termin-8[®] application (3 g/kg) to the SDAP portion of the diet; and 3) control diet with Termin-8[®] application (3 g/kg) to the base mix portion (specialty protein products, milk products, oat groats, vitamins, minerals, and antibiotic) of the diet. All pigs were fed 2.27 kg of their respective treatment diet and then a common transition diet (1.47% lysine) for the remainder of the treatment period. For d 0 to 8, pigs fed diets containing Termin-8[®] in the SDAP or base mix portions had increased ($P < .01$) ADG and gain/feed compared to the pigs fed the control diet. Also, pigs fed SDAP with Termin-8[®] treatment had greater ADG ($P < .01$) and tended to have improved gain/feed ($P < .07$) compared to pigs fed Termin-8[®] treated base mix. Overall (d 0 to 13), ADG ($P < .01$) and gain/feed were greater ($P < .05$) for pigs fed diets containing Termin-8[®] treatment to the SDAP or base mix portion compared to pigs fed the control diet. In conclusion, adding Termin-8[®] to the SDAP or base mix at 3 g/kg before diet manufacturing improved pig performance.

96 Dietary supplementation of different organic acids as an alternative to the use of antibiotics in the diets of early-weaned piglets. M. Borysenko^{*}, M.Z. Fan, T. Archbold, J.L. Atkinson, C. Dewey, and H. Engelhardt, *University of Guelph, Guelph, Ontario, Canada.*

The objective of this study was to evaluate the use of organic acids as alternatives to antibiotics in the diets of early-weaned piglets. Average daily gain, feed efficiency, organ weight gain, diarrhea scores, white blood cell counts and blood urea nitrogen (BUN) were the endpoints measured. A total of 216 Yorkshire piglets, weaned at the age of 14 d with an average BW of 4.71 kg, were used in the study. A randomized complete block design was used. Pigs were blocked by replication time, equalized for gender, allotted to one of six treatments using six pigs per pen and six replicate pens per treatment. Animals were housed in a nursery in raised pens with rubberized woven wire floors with free access to feed and water. Six diets were used: control diet (CD, antibiotic Lincomix 44 at 1 kg/tonne of feed), negative control (NC, no antibiotic) and lactic (LAD), formic (FAD) and fumaric acid (FUM) diets containing 0.65% organic acid. A low cost diet (LCD) contained 0.2% of each acid. Piglets were fed the diets from d 1 to 20 post-weaning. All endpoint measurements were taken at d 10 and 20. One representative male and female piglet from each treatment group were sacrificed and

samples (blood, stomach, liver, spleen, proximal and distal small intestine) taken. The CD group had a higher ($P < 0.05$) growth rate at d 20 post-weaning than the NC, LAD, FAD, FUM and LCD groups (146.7 vs. 133.5, 136.6, 133.1, 133.2 and 117.1, SEM = 2.4g/d). BUN at d 20 was lower ($P < 0.01$) in the CD group than in the other treatment groups (4.33 vs. 5.39, 5.85, 5.67, 6.60 and 7.27, SEM = 0.44 mmol/L). There were no differences ($P > 0.05$) between treatment groups for the remaining measurements. In conclusion, organic acid supplementation does not improve growth performance of early-weaned piglets under our experimental conditions. BUN is a more sensitive indicator of growth and protein metabolism than the other parameters examined.

Key Words: Organic acids, Early-weaned piglets, Antibiotics

97 Effects of ractopamine on pigs fed diets with and without vitamin and trace mineral premixes in late finishing (90 kg to slaughter). C. W. Starkey^{*}, J. D. Hancock, G. A. Kennedy, C. L. Jones, D. J. Lee, C. M. Dodd, and J. D. Dunn, *Kansas State University, Manhattan.*

A total of 192 pigs (avg initial BW of 90 kg) were used to determine the effects of ractopamine (RAC) on finishing pigs fed diets with and without vitamin and trace mineral premixes (VTM). The pigs were blocked by sex and weight and allotted to 16 pens with 12 pigs per pen. Treatments were arranged as a 2 x 2 factorial with main effects of VTM status (with vs without) and RAC treatment (none vs 19.8 g/ton of feed). The treatments were administered for the last 25 d before slaughter. Diets were corn (ground to 600 microns)-soybean meal-based with 1% lysine, 0.65% Ca, 0.55% P, and 2% added fat. The diets were fed in meal form and consumed on an ad libitum basis. Deletion of VTM did not affect growth performance ($P > 0.2$) or last rib backfat thickness ($P > 0.9$), but addition of RAC increased ADG ($P < 0.03$), tended to increase gain/feed ($P < 0.06$), and decreased last rib backfat thickness ($P < 0.01$). There was a tendency, however, for the beneficial effects of RAC on backfat thickness to be expressed only when the VTM were in the diets (VTM x RAC interaction, $P < 0.06$). The number of broken vertebrae was decreased when RAC was added to diets with VTM but was largely unaffected when RAC was added to diets without VTM (VTM x RAC interaction, $P < 0.02$). Deletion of VTM and additions of RAC did not affect scores for stomach ulcers ($P > 0.33$). In conclusion, there was no evidence to suggest negative effects in either growth performance or carcass measurements when RAC was added to diets without VTM.

98 Effects of ractopamine on pigs fed diets with and without vitamin and trace mineral premixes in the finishing phase (70 kg to slaughter). C. W. Starkey, J. D. Hancock^{*}, G. A. Kennedy, C. L. Jones, D. J. Lee, C. M. Dodd, and J. D. Dunn, *Kansas State University, Manhattan.*

A total of 192 pigs (avg initial BW of 70 kg) were used to determine the effects of ractopamine (RAC) on finishing pigs fed diets with and without vitamin and trace mineral premixes (VTM). The pigs were blocked by sex and weight and allotted to 16 pens with 12 pigs per pen. Treatments were arranged as a 2 x 2 factorial with main effects of VTM status (with vs without) and RAC treatment (none vs 19.8 g/ton of feed). The treatments were administered for the last 50 d before slaughter. Diets were corn (ground 600 micron)-soybean meal-based with 1.2% lysine, 0.65% Ca, and 0.55% P, for 70 to 90 kg BW and 1% lysine, 0.65% Ca, and 0.55% P for 90 to 118 kg BW. The diets were fed in meal form and consumed on an ad libitum basis. No interactions were observed among the VTM and RAC treatments for ADG, ADFI, or gain/feed ($P > 0.2$). Deletion of VTM premixes from 70 kg to slaughter decreased overall ADG ($P < 0.01$) with no effects on ADFI ($P > 0.09$) or gain/feed ($P > 0.23$). Addition of RAC did not affect overall ADG ($P > 0.23$), but decreased ADFI ($P < 0.01$) and increased gain/feed ($P < 0.04$).

There were no interactions among the VTM and RAC treatments for last rib backfat thickness, broken vertebrae, or scores for stomach ulcers ($P > 0.21$). Also, deletions of VTM premixes did not affect these same measurements ($P > 0.22$). However, RAC decreased ($P < 0.01$) backfat thickness by 8% and tended to decrease scores for stomach ulcers ($P < 0.06$). In conclusion, there were no interactions to suggest that the effects of RAC on growth performance and carcass leanness were altered by deletion of VTM.

ASAS/ADSA Breeding and Genetics: Breeding Strategies for Dairy Cattle

99 Evaluation of corrective mating programs for dairy cattle in the U.S. E.N. Sonnek*, L.B. Hansen, and A.J. Seykora, *University of Minnesota, St. Paul, MN.*

Corrective mating programs have been popular with dairy producers for many years, and recently they have been promoted as tools to avoid inbreeding. Six AI companies, two breed associations, and one commercial vendor answered a 42-question survey on the details of their corrective mating programs. The total number of cows mated annually in the US is about 2.7 million with individual programs ranging from about 90,000 to about 600,000. Corrective mating programs use phenotypes and PTAs for multiple traits (including production and type) to optimize mate selection. All of the programs mate heifers by PTAs from pedigrees, by phenotype on linear type traits, or a combination of the two. Most of the programs are run on a laptop on the farm or on a PC in the evaluator's office. Two programs are run strictly from the organization's headquarters. All programs are flexible regarding which traits of animals are used as well as methods for sire selection. When gathering pedigrees on females, six of the programs use only sire and maternal grandsire (MGS). Of these six, five programs use three-generation pedigrees of the selected mate, the female's sire, and MGS to check for common ancestors. Of these five, three check for common ancestors only among the males of these three-generation pedigrees. The sixth program (that gathers only the female's sire and MGS) utilizes complete pedigrees back to the 1960's. Two programs gather the maternal great-grandsire of the female in addition to the sire and MGS. One of these programs uses a three-generation pedigree including males and females while the other uses a five-generation male only pedigree when checking for common ancestors. Finally, only one program uses full pedigrees of selected mates and females back to the 1960's when calculating inbreeding coefficients. Obviously, great differences exist on the depth of pedigrees utilized to accurately prevent inbreeding depression. A significant portion of potential inbreeding is not detected if only a few generations are used, especially considering that the two bulls with highest relationship to the breed would appear several generations back in pedigrees.

100 Analysis of the relationship between linear type traits, inbreeding, and survival in US Jersey cows. Daniel Z. Caraviello*, Kent A. Weigel, and Daniel Gianola, *University of Wisconsin, Madison WI/USA.*

The ability of a dairy cow to resist involuntary culling is of high economic importance to the dairy farmer. Genetic improvement of survival can lead to lower replacement costs, decreased veterinary costs, more opportunities for voluntary culling, and a higher proportion of cows producing at a mature level. The objective of this study was to evaluate the relationship between linear type traits and survival in Jersey cattle. Because some traits may have an intermediate optimum or a threshold above which there is little impact on culling, we were interested in both linear and nonlinear relationships. Data for this study were obtained from USDA Animal Improvement Programs Laboratory, and these included 124,953 Jersey cows in 2258 herds with first calving between January 1, 1981 and December 31, 1993. Average age at termination was 1978 days. Our model included the effects of herd, year of calving, season of calving, age at first calving, and within-herd quartiles for mature equivalent milk, fat, and protein yield in the terminal lactation. Linear and quadratic regression coefficients corresponding to inbreeding coefficients and thirteen linear type traits were added to the

model one at a time. Linear regressions on strength, dairy form, foot angle, rear legs side view, rump angle, thurl width, fore udder, rear udder height, rear udder width, udder depth, suspensory ligament, and front teat placement were all positive and significantly different from zero. Quadratic effects of strength, foot angle, rear legs side view, rump angle, thurl width, fore udder, rear udder height, rear udder width, udder depth, suspensory ligament, and front teat placement were all significant and negative, indicating the likelihood of nonlinear relationships between type traits and survival. Inbreeding had a highly significant negative relationship with survival; a one percent increase in inbreeding resulted in a decrease in survival of approximately 40 days. Results of the linear model analysis will be verified using survival analysis methodology.

Key Words: Survival, Type Traits, Inbreeding

101 Effects of information in pedigrees on estimates of inbreeding depression for days to first service and summit milk yield. B. G. Cassell* and V. Adamec, *Virginia Polytechnic Institute and State University.*

Data from Holstein cows processed by DRMS Raleigh were used to estimate inbreeding depression in number of days to first service and summit milk yield. Pedigree information on all cows in this study was retrieved from AIPL, Beltsville, MD and combined with cow records. A procedure based on contribution of each ancestor in a five-generation pedigree to inbreeding coefficient was used to evaluate percentage of information present in cow pedigrees. Four groups of herds with about 50,000 cows each were randomly selected from the data. Group one included herds of grade cows where at least 85% of cows had 0-30% of available pedigree. Groups two (grade, 31-70%), three (grade, 71-100%) and four for herds with registered cows above 70% pedigree were formed similarly with 7% of herds contributing data to both group 3 and group 4. Inbreeding was calculated using standard methods and averaged 0.03%, 1.8%, 2.0%, and 3.7% for groups 1 to 4, respectively. Standard deviations were 0.7%, 2.0%, 2.2%, and 2.4% for the same groups. Mixed models for the two traits included herd-year-season (random), lactation number, inbreeding covariate, animal and permanent environmental effects associated with a cow. Three generations of pedigree were used in the numerator relationship matrix. Estimates of inbreeding depression from MTDFREML analysis of days to first service were -0.23 ($p=0.10$), 0.07 ($p=0.13$), 0.15 ($p=0.003$) and 0.03 ($p=0.27$) days for groups 1 to 4. Summit milk yield averaged between 36-38 kg in all groups, with estimated inbreeding depression of -0.12, -0.06, -0.06, and -0.07 kg. Effects of inbreeding were significantly different from zero ($p<0.001$) with significance increasing from group 1 to group 4. Estimates of inbreeding depression for days to first service were greater from grade herds with more pedigree data, a trend not confirmed in registered cows.

Key Words: Days to first service, Summit milk, Inbreeding depression, Pedigree

102 Minimization of rate of inbreeding for populations with overlapping generations combining live and frozen genetics. A.K. Sonesson* and T.H.E. Meuwissen, *Institute of Animal Science and Health, Lelystad, The Netherlands.*

We present a method that minimizes the rate of inbreeding (ΔF) for small unselected populations with overlapping generations. It minimizes the increase of coancestry of parents and optimizes the contribution of

each selection candidate. The carrying capacity of the population is limited to a fixed number of animals per year. For survival rates <100 % the algorithm has to optimize the use of few old and less related animals with many young and higher related animals. For a scheme where the oldest animals were selected, ΔF increased with 18-52 % compared with the proposed method. When freezing semen of all sires in a gene bank and assuming that each sire can be used infinitely, the relationships are set in the first 2-3 years, and thereafter the average coancestry of the population stays about the same, such that ΔF is approximately zero. Thus, the relationships among the live animals converges to that of the cryo-conserved sires. The level of inbreeding in the optimal schemes with 6 new-born animals per year (3 sires + 3 dams) is 0.060, which is lower than the expected level of inbreeding when simply the 3 founder sires were cryo-conserved, i.e. this would result in an inbreeding coefficient of 0.083 ($=1/(4*3)$). The latter implies that the optimal method also conserves genes of the founder dams by using frozen semen of their male offspring.

Key Words: Minimization of Rate of Inbreeding, Overlapping Generations, Genebank

103 Non-random mating schemes for selection with restricted rates of inbreeding. A.K. Sonesson* and T.H.E. Meuwissen, *Institute of Animal Science and Health, Lelystad, The Netherlands.*

Non-random mating has been shown to decrease rate of inbreeding (ΔF), but have no effect on genetic gain for BLUP and phenotypic selection. However, with optimum contribution selection, ΔF is restricted and the improved family structure due to non-random mating is instead used to increase selection differential, i.e. increase genetic response. For schemes with discrete generations, ΔF restricted to 1.0% and 100 selection candidates per generation, minimum coancestry mating with only one offspring per mating pair (MC1), increased genetic gain with 22% compared with random (RAND) mating. The increased genetic gain is mainly because MC1 mating results in more independent selection within and over generations. Compensatory mating on either the average relationship or the genetic contributions, which reduces the Q^2 effect of Robertson by connecting successful with unsuccessful families, resulted in just somewhat higher genetic gain than RAND mating. For schemes with a less stringent constraint on ΔF (2.5%) or more candidates (200), the genetic superiority of MC1 mating was reduced to 5-6%. Schemes with overlapping generations are mostly larger than schemes with discrete generations, because there are several reproductive age classes, which would decrease the effect of non-random mating for schemes with overlapping generations. There are however also more different family structures over the age classes, which would increase the effect of non-random mating. We compared the effect of non-random mating for discrete and overlapping generations at the same ΔF (0.25%) and genetic gain per generation. This comparison resulted in 17 and 3 % higher genetic gain for MC1 for schemes with overlapping and discrete generations, respectively.

Key Words: Selection, Inbreeding, Non-random Mating

104 Implementation of an approximate multitrait BLUP evaluation to combine production traits and functional traits into a total merit index. V. Ducrocq*, D. Boichard, A. Barbat, and H. Larroque, *Station de Génétique Quantitative et Appliquée, INRA, Jouy-en-Josas, France.*

The new total merit objective function for French dairy breeders combines information on production traits (50% of the total weight in Holstein) and functional traits (with weights of 12.5% for somatic cell count, female fertility, functional longevity and overall type). Traditionally, total merit indexes are constructed based on index selection theory, for bulls and cows separately, and often neglecting correlations between records from one same cow or differences in reliability between traits. In order to approximate an optimal evaluation procedure in a general, yet simple framework, a multiple trait BLUP evaluation applied to an animal model was implemented: pre-adjusted records for production traits, somatic cell scores, female fertility, length of productive life and some (4-6) type traits considered as good predictors of functional longevity and somatic cell scores were derived from each trait evaluation, eliminating the influence of environmental factors. It was checked that in the case of functional longevity, the newly defined pre-adjusted record and its associated weight led to univariate BLUP EBVs for bulls very close to those obtained with the survival analysis mixed model currently used.

Then for each trait, the pre-adjusted record for each cow could just be described as an overall mean plus an additive genetic effect. The combination of this simple model and of a canonical transformation of the data applicable to situations with missing records and variable weights made the multiple trait BLUP evaluation computationally feasible. The total merit index for males and females was obtained as a linear combination of the resulting EBVs, based on the true economic weights of the traits. An interesting by-product of this strategy was the production of improved EBVs for functional longevity combining direct information with information from early predictors.

Key Words: Total merit index, Dairy cattle, Multiple trait evaluation

105 Is Crossbreeding the Answer to Questions of Dairy Breed Utilization? A J McAllister*¹, ¹University of Kentucky.

The current interest in crossbreeding in the commercial dairy industry, even though it is quite limited, raises questions of breed utilization. Less than 5 percent of U.S. dairy cattle are other than purebred or grade Holsteins. The large advantage of Holsteins for additive genetic merit for lactation milk yield is apparently responsible. Why then is there this interest in crossbreeding? The economic importance of traits such as reproduction, health and survival in dairy production systems is likely the basis for the interest in crossbreeding, even though these traits are secondary to milk yield. Several U.S. studies and a Canadian study confirmed that while several crossbred groups were equivalent to Holsteins for lactation milk yield none was superior. Two crossbred groups in the Canadian study had equivalent lifetime yields, milk value and net returns to Holsteins. In the New Zealand study, Friesian-Jersey reciprocal crossbreds were predicted to exceed Friesians in first lactation fat yield. Crossbred performance is dictated by a combination of additive and non-additive genetic effects. Evidence exists for direct, maternal, heterosis and cytoplasmic maternal effects. Heterosis of 15-20% for lifetime traits was found in two studies. Results from previous crossbreeding studies have something to recommend for inclusion of Holstein, Ayrshire, Brown Swiss and Jersey breeds in a crossbreeding scheme. However, multiple generation lifeline performance on an array of purebreds and crossbreds under U.S. condition does not exist. Full unique identification of individual animals, including breed, permits the use of DHIA data to examine field data for the traits recorded therein. Survival data from birth and health data would need to be fully recorded to provide complete data on lifetime performance. Self-propagation of crossbred replacements is mandatory if any crossbreeding system is to be successful. At present a two breed rotational crossing systems appears to be the most viable system to maximize economic merit. Full-scale long term breeding experiments or analysis of field data paired with a comprehensive modeling of use of alternative breed utilization strategies for U.S. conditions are recommended.

Key Words: crossbreeding, breed utilization

106 Heterosis and breed differences for yield and somatic cell scores of US dairy cattle in the 1990s. P.M. VanRaden*, *Agricultural Research Service, USDA, Beltsville, MD.*

Yields and somatic cell scores (SCS) of 8806 F1 crossbreds and 81,409 purebreds were examined using test-day data from 320 US herds that each had ≥ 10 crossbred cows born since 1990. Comparisons were made within herd, year, and 3-mo calving season, although some groups contained only purebreds or only crossbreds. The model included effects of age and lactation stage, parent breeds, regression on sire predicted transmitting ability, and general heterosis. Estimates of heterosis for first parity were 4.6% for milk yield, 5.3% for fat yield, 4.9% for protein yield, and 0.6% (unfavorable) for SCS. Corresponding estimates for all parities were 4.7, 5.0, 4.9, and 0.3%. A model without an adjustment for sire merit produced slightly lower estimates. For Brown Swiss X Holstein crossbreds, daily fat yield (1.08 kg) and protein yield (0.88 kg) equaled yields for Holsteins, but milk yield was slightly lower (27.6 versus 28.9 kg). For Jersey X Holstein crossbreds, fat yield was equal to Holsteins, but protein yield (0.85 kg) and milk yield (25.7 kg) were lower. With cheese yield pricing, crosses of Brown Swiss or Jerseys with Holsteins may be more profitable than purebred Holsteins if heterosis for health, fertility, and mortality traits are considered. Yields for all other breeds and breed crosses were lower than yields for purebred Holsteins, but feed costs are lower for breeds with smaller body size. Because inbreeding coefficients are increasing by 2 to 3% per decade, heterosis for yield should increase by .6 to .9%. Although genetic progress is slower

within the less numerous breeds, increasing breed differences, current heterosis for yield traits is sufficient to make some dairy breed crosses worth considering. Animals should receive credit for heterosis when considered as mates for another breed. A combined national evaluation of data for all breeds and crossbreds may be desirable but would require an extensive programming effort.

Key Words: Crossbreeding, Heterosis, Dairy cattle

107 Strategies for continual application of MAS in an open nucleus population. A. Stella*¹, G. Jansen², G. Pagnacco³, and P. Boettcher⁴, ¹CERSA-FPTP, Italy, ²CGIL, University of Guelph, Canada, ³University of Milan, Italy, ⁴ANAFI, Italy.

The objectives of this study were to develop and simulate the implementation of several strategies for repeated application of quantitative trait loci (QTL) detection and marker assisted selection (MAS) and to compare the short-term and continual genetic responses. A finite locus model was simulated with 20 QTL randomly distributed across 30 chromosome. Three hundred markers with 6 alleles were evenly spaced across the genome. Allelic effects were sampled from a double exponential distribution. A daughter design was used, every generation, to determine the marker alleles associated with QTL effects. Within family MAS was applied to young bulls, prior to progeny testing, as part of an open nucleus. Young bulls were selected using strategies based on a) the single marker with greatest contrast (BEST1), b) the sum of n greatest contrasts (BESTn), c) the best n contrasts, limited to one per chromosome (LIMn), d) the sum of all contrasts exceeding a given threshold (THRES), and e) the sum of contrasts exceeding a threshold, but limited to one per chromosome (LIMT). Maximum progress was achieved by strategies that selected upon several markers flanking multiple QTL in each generation. When THRES was applied, the mean TBV of selected bulls was increased by 11.98% over conventional selection versus 6.73% for BEST1 in the first generation. On average, 19 marker locations exceeded the 1.96 critical value for THRES. For all approaches, the advantages of MAS decreased to roughly a half by generation five. These decreases occurred because selection decreased the amount of genetic variability in the population and the expected difference between sire alleles at the QTL. The QTL accounting for the greatest proportion of genetic variance in the commercial population was often not selected for in the nucleus, because many nucleus sires were homozygous at that locus. Applying a full genome scan in each generation allowed selection for different QTL across time. By selecting for multiple QTL over time, MAS maintained superiority over conventional selection for many generations.

Key Words: QTL detection, Marker Assisted Selection

108 Superiority of QTL-assisted selection in different dairy cattle breeding schemes. Gamal Abdel-Azim* and A. E. Freeman, Iowa State University.

The effect of varying the system of dairy cattle breeding on the superiority of QTL-assisted selection (QAS) over QTL-free selection is investigated. Stochastic computer simulation was used with realistic structure and proportional parameters to the US Holstein population. QTL-assisted selection was based on breeding values that were estimated by an animal model that accounted for the identified QTL as fixed factors and QTL-free selection was based on a conventional animal model. Three aspects of the superiority of QTL-assisted selection were evaluated: genetic response, accuracy of evaluation, and selection pressure on the favorable QTL allele. Aspects of superiority were examined for active sires, young bulls, bull dams, and commercial cow population. The breeding systems compared were: first a conventional progeny testing plan against a progeny testing plan that employed a nucleus herd. The nucleus herd simulated was a hybrid closed nucleus herd with a hierarchical mating design. Second, early selection of young bulls at the age of 3 and 4 years was compared against conventional waiting plans of 5 years. QAS performed potentially better in nucleus herds than in conventional two-stage selection, and in early selection plans than conventional plans. It was found that QAS performed the poorest for the 4-year plan. In addition, QAS superiority for the favorable allele frequency was very similar to its superiority in terms of genetic response. On the contrary, accuracy superiority trends did not parallel response superiority trends across the systems or across the paths of selection. QAS accuracy superiority consistently decreased with time because of the accumulation

of pedigree and phenotypic information. The study shows that the superiority expected from QAS is highly dependent on the breeding system implemented. The low superiority of QAS observed in conventional progeny testing schemes suggests that limited benefit is to be expected from using QTL information in genetic evaluation without modifying such schemes to maximize the superiority of QAS.

109 Optimal selection on two quantitative trait loci with linkage. J. C. M. Dekkers*¹, R. Chakraborty¹, and L. Moreau², ¹Iowa State University, Ames, IA, ²INRA, Gif-sur-Yvette, France.

Methods have been developed to optimize selection on a single identified quantitative trait locus (QTL) over multiple generations but in practice multiple QTL must be selected on simultaneously. Our objectives were to develop a method to optimize selection on multiple QTL and to apply it to selection on two linked or unlinked additive QTL. Effects of the QTL were .25 and .375 phenotypic standard deviations for a trait with heritability .25. Initial frequencies of the favorable QTL alleles were .1. Strategies to maximize total or cumulative discounted response (CDR, 10% discount rate) over ten generations were compared to standard QTL selection on the sum of breeding values for the QTL and an EBV for polygenes, and to phenotypic selection. For unlinked QTL, optimal selection resulted in 6.9% greater total and 2.6% greater CDR than standard QTL selection and 2.4% greater total and 5.6% greater CDR than phenotypic selection. Linkage (recombination rate 0.05) between the QTL slightly reduced response for standard QTL and phenotypic selection but increased response for optimal selection, which capitalized on linkage by emphasizing selection on favorable haplotypes. When the objective was to maximize total response after ten generations and QTL were unlinked, optimal selection increased QTL frequencies to fixation in a near linear manner and equal emphasis was given to each QTL, regardless of a difference in effects of the QTL and regardless of linkage. The average emphasis given to individual QTL was, however, not additive. These results demonstrate the ability of optimal selection to capitalize on information on the complex genetic basis of quantitative traits that is forthcoming as a result of advances in molecular genetics.

110 Real options analysis applied to dairy cow breeding and replacement decisions. H Groenendaal* and D.T. Galligan, University of Pennsylvania, School of Veterinary Medicine, Kennett Square, PA, USA.

Many investments allow for active management decisions that can improve their value. However, traditional discounted cash flow (DCF) analysis assumes a passive management (as in the marginal net revenue approach) or attempts to value real investment opportunities that have discretionary asymmetrical cash flows by using an inappropriately constant risk-adjusted discount rate (as in dynamic programming). Therefore DCF neglects the value of active management and under-estimates the true value of investment opportunities. However, the real option approach, developed in the financial markets, captures the value of managerial flexibility.

The goal of this presentation is to describe the real options approach. In addition, this analysis will be applied to the evaluation of a simplified hypothetical breeding and replacement decision of a dairy cow. The conclusion from the traditional DCF method was not to invest in breeding the dairy cow and cull her at the end of the current lactation because the value of the next lactation, if the cow got pregnant, was negative (- US dollar 5). In contrast, the real option approach showed insemination was economically attractive, the value of the pregnant cow's next lactation value was positive (US dollar 34). The difference between the value calculated with both methods, (US dollar 39) was attributable to the extra value of active management.

It was concluded that the real options analysis provided an analytical infrastructure that is more appropriate to be used in situations where managerial flexibility exists. Due to the active role of management as well as the volatility in many livestock investments, real option analysis will allow for better valuation than DCF.

ASAS/ADSA Food Safety: Bacteria Detection

111 Ionizing radiation effectively destroys Mycobacterium paratuberculosis in milk. Judith Stabel*¹, Charles Waldren², and Frank Garry², ¹USDA-ARS, National Animal Disease Center, Ames, IA, ²Colorado State University, Fort Collins, CO.

Crohn's disease in humans has strong similarities to Johne's disease in cattle, but with a poorly defined etiology. Mycobacterium paratuberculosis, the causative agent of Johne's disease, has been linked as a causal agent of Crohn's disease in humans. However, evidence to date does not prove that Crohn's disease is caused by M. paratuberculosis and may, in fact, be a multifactorial disorder. Regardless, it has become a concern for the dairy industry as consumer confidence has been influenced by reports that pasteurization may not destroy the bacterium. Efforts to eliminate M. paratuberculosis from the food chain would require rigorous control and management programs for this disease on the farm. Although voluntary programs are in place in many states in the US, it will still be many years before the spread of this disease is attenuated. In the meantime, we must rely on methods that guarantee that potential contaminating agents such as M. paratuberculosis are destroyed in food products post-harvest. Studies to determine optimal methods of pasteurization by heat treatment are underway in many countries, including the US. An alternative method of destruction is the use of ionizing radiation. In the present study, we examined the effects of radiation on milk experimentally inoculated with 10⁴ and 10⁸ cfu M. paratuberculosis/ml of milk. Milk was exposed to either 0, 5 or 10 kGy of radiation (1.2 kGy/hr) and cultured for viable M. paratuberculosis. Results from this study demonstrate that M. paratuberculosis was effectively destroyed by gamma radiation at either dose. Thus, ionizing radiation may prove to be an alternative method for destruction of potential contaminants in dairy foods.

Key Words: Mycobacterium paratuberculosis, Milk, Radiation

112 Microbiological and Rheological Characteristics and Their Association with Shelf-life of Fresh Soft Goat Milk Cheese. Young W. Park*¹, Aref Kalantari¹, Diane L. Van Hekken², and M. H. Tunick², ¹Agricultural Research Station, Fort Valley State University, Fort Valley, GA, ²Eastern Regional Research Center, USDA/ARS, Wyndmoor, PA.

Microbiological and rheological characteristics of commercial fresh soft goat milk cheeses were evaluated for their food safety and shelf-life for an extended refrigerated storage period. The soft goat cheeses were purchased from a farmstead grade A goat dairy, and stored at 4°C for 0, 7, 14, and 21 days. Microbiological assays for total aerobic, *E. coli* and coliform, yeast and mold, and *Staphylococcus aureus* counts were performed using 3M petrifilm plates techniques according to the manufacturer's recommended procedures. Rheological parameters were determined using a universal testing machine and a small strain oscillatory analyzer. Total aerobic counts of the soft goat cheeses were too numerous to count (TNTC) regardless of treatments and lengths of storage periods, probably due to the lactobacilli counts. The respective ranges of yeast and mold counts were 10⁴ -10⁶ cells/g and 10³ -10⁴ cells/g cheese, and both counts were increased with storage time. Coliforms, *E. coli* and *S. aureus* were not detectable, while non-coliform organisms such as *Pseudomonas* and many unidentified presumptive *Staphylococcus* species appeared to be present. Rheological properties revealed that cohesiveness of the soft goat cheeses significantly decreased, while viscoelastic properties remained unchanged as aging time progressed. An inverse correlation was observed between the yeast and mold counts and cohesiveness of the tested cheeses. The significant increase in deterioration of the cheese quality at 21 days storage may be attributed to the elevated *Pseudomonas*, yeast and mold counts, which might have accelerated the lipolytic and proteolytic processes in the stored products.

Key Words: Goat, soft cheese, microbiology, rheology, shelf-life

113 Real-time Assessment Of The Microbial Quality Of Fluid Milk Using A Simple Noninstrumental Microrespirometer. Y-H.P. Hsieh*¹, Z. Ren¹, and Y.P. Hsieh², ¹Auburn University, Auburn, AL, USA, ²Florida A & M University, Tallahassee, FL, USA.

An innovative approach using a recently developed non-instrumental microrespirometer for detection of spoilage bacteria in pasteurized fluid

milk was studied. The microrespirometer, which sensitively measures the minute amounts of CO₂ (l/h) evolved by bacterial respiration, efficiently determined the total spoilage bacterial activity in real time (within one hour). The technique was validated using the official Petrifilm total aerobic count (TAC) method in conjunction with the sensory characteristics of the milk sample. In the low microbial growth range (10² - 10³ CFU/ml), the rate of CO₂ evolution was more consistent and sensitive in assessing the microbial quality of the milk than the TAC. The cut-off point for milk suitable for human consumption was set at a CO₂ rate of 25 l/ml/h, corresponding to a viable count approaching 10⁷ CFU/ml. This research demonstrated a novel and economic means of improving the speed of microbial detection and ensuring the high quality and safety of perishable foods such as milk.

Key Words: milk, real-time assessment, microbial quality

114 Comparisons of meat carcass surface bacterial collection efficiencies utilizing a novel wet-vacuum Microbial Sampler and the Sponge method. J. Bruce Bradley* and S. Filomena Saddler, Rocky Mountain Resource Labs, Inc., Jerome, Idaho/USA.

A novel wet-vacuum sampler, Microbial-VacTM (M-Vac), currently under development with NIH funding, was compared to the Sponge (SP) method for collection efficiency of surface bacteria off chilled beef carcasses. The M-Vac allows contained application of sterile, food safe Surface Rinse Solution (SRS) and subsequent retrieval of the liquid and suspended microbes off food surfaces. Microbes present in high numbers (APC) may be detected in recovered liquid aliquots (ca 50ml/100cm²) of SRS. For improved recovery and detection of bacteria present in low numbers, the collected liquid may be filtered through the M-Vac's 0.45µm final filter for rapid or conventional detection and quantification directly on the removable filter. Twenty-four samples were separately collected off adjacent sites of brisket, flank and rump (100 cm²) using the two methods. Sponge samples, pummeled in peptone and M-Vac SRS aliquots were plated on Petrifilm for APC, TCC and ECC. Following SRS filtration, M-Vac filters were removed and placed directly on EMB media for TCC. Results indicate there were no differences (P ≥ 0.05) among sampling sites within methods but the M-Vac collected higher mean APC/s than SP (log₁₀), 3.91 ± 0.51 vs 3.11 ± 0.57 (all sites) P ≤ 0.05 in all cases. No coliforms were detected in diluted liquid samples from either method but low level (1-5 CFU/100 cm²) *E. coli* was confirmed on the M-Vac's filter in 8 of 12 samples. These observations indicate the M-Vac may provide a more efficient, non-destructive sampling method for low-level pathogen collection and detection on meat carcasses, as well as food-prep and processing equipment surfaces.

115 Novel Biosensors for the Rapid Detection of Campylobacter in Various Food Matrices. Richard Obiso* and Jill White, IGEN International, Inc., Gaithersburg, MD.

Campylobacter is considered to be the leading cause of enteric illness in the United States. Symptoms of a Campylobacter infection include mild to severe diarrhea, including loose and watery stools followed by bloody diarrhea. *C. jejuni*, *C. lari*, and *C. coli* represent the three main species that lead to enteric disease in humans, however, procedures to detect these Campylobacter species may take as long as 5 days to complete. Therefore, more rapid methods are required to determine the presence of Campylobacter in food. In this study, the utility of an ORIGEN[®]-based Campylobacter test was evaluated in different food matrices. This technology is based on a technique called electrochemiluminescence, which permits the detection of Campylobacter within an extensive array of samples. The food matrices tested included, poultry products, fruits and vegetables, shellfish, cheese products, milk products, and water samples. These food matrices (100 samples) were tested by microaerophilic incubation in Bolton broth using both 24 h and 48 h enrichment methods, followed by testing using the PATHIGENTM Campylobacter test or B.A.M. standard plating methods. Food samples representative from each matrix were also inoculated with known levels of *Campylobacter jejuni* and tested using the Campylobacter test. The Campylobacter test was able to detect the equivalent of less than 100 CFU/25 g of sample. Detection of Campylobacter was possible in 24 h or in 48 h. The PATHIGEN test performed equivalently when compared

to B.A.M. standard plating methods, however, detection was reduced to 24-48h. Each assay takes approximately 1.5 h after enrichment and can be run simultaneously with other PATHIGEN tests.

Key Words: Campylobacter, Diagnostic, Detection

116 Novel Biosensors for the Rapid Detection of Salmonella Species in Various Food Matrices. Eddie Jefferies*, Shelia Rowe, and Jill White, IGEN International, Inc., Gaithersburg, MD.

Salmonella are implicated in causing 2 to 4 million cases of salmonellosis annually in the United States. Symptoms of a Salmonella infection include nausea, vomiting, abdominal cramps, diarrhea, fever and headache. *S. typhimurium* and *S. enteritidis* represent the two main species that lead to enteric disease in humans, however, procedures to detect these Salmonella species may take as long as 4 days to complete. Therefore, more rapid methods are required to determine the presence of Salmonella in food. In this study, the utility of an ORIGEN[®]-based Salmonella test was evaluated on different food matrices. This technology is based on a technique called electrochemiluminescence, which permits the detection of Salmonella species within an extensive array of samples. Food matrices included, poultry products, fruits and vegetables, shellfish, cheese products, milk products, chocolate, and water samples. 100 samples were tested by pre-enrichment in buffered peptone water followed by selective enrichment in Rappaport Vassiliadis soya peptone broth and testing using the PATHIGEN[™] Salmonella test or B.A.M. standard plating methods. Food samples representative of each matrix were also inoculated with known levels of *Salmonella typhimurium* and tested using the Salmonella test. The Salmonella test was able to detect the equivalent of less than 1 CFU/25 g of sample. The sensitivity of the PATHIGEN test was equivalent to the B.A.M. standard plating methods, however, detection time was reduced to 24-30 h. Each assay takes approximately 1.5 h after enrichment and can be run simultaneously with other PATHIGEN tests.

118 Cyclic stretch influences p21^{WAF1} promoter activity in myoblasts and myotubes. M.K. Webster*¹ and J.M. Reecy¹, ¹Iowa State University, Ames, IA.

The ability of skeletal muscle to adapt to an imposed workload has been well characterized, while the molecular events underlying this process are less defined. Cyclin dependent kinase inhibitors, such as p21^{WAF1}, play an important role in cell cycle progression. These cell cycle regulators, in conjunction with members of the MyoD family, have been shown to induce the terminal differentiation of myoblasts. In previous studies, p21 expression was dramatically increased after as little as 12 hours of overload, as well as during terminal differentiation. These results suggest that either myoblasts differentiate, thereby increasing p21 expression, or p21 expression in the existing myofibers increases in response to work overload. We hypothesized that there was a stretch-responsive element within the p21 promoter. C2C12 myoblasts, plated at 1250 cells/cm², were transiently transfected with a p21-Luciferase construct. The construct was made by inserting 2.1 kb of 5' p21 promoter upstream from the firefly luciferase gene. Cells were cyclically stretched for 24 or 48 hours with a Flexercell-3000 machine, or no stretch as a control. The stretch protocol consisted of a 20% sine stretch for 3 seconds, followed by ten seconds of rest. This cycle was repeated three times, after which the cells were allowed to rest for 30 minutes. This series was repeated for the duration of the experiments. The promoter activity in myoblasts appears to decrease in response to cyclic stretch. Additionally, C2C12 myoblasts were plated at 20,000 cells/cm², transiently transfected, and induced to differentiate with low serum media for 15 hours. The differentiating myoblasts were then cyclically stretched for up to 48 hours. There was a 6.5-fold increase in promoter activity during differentiation. In addition, p21 promoter activity appeared to increase in response to stretch. We are currently examining the mRNA abundance of p21 un-

117 Comparison of cultivation to PCR-hybridization for detection of Salmonella in porcine fecal and water samples. Ingrid Feder¹, Jerome C. Nietfeld², John Galland³, Teresa Yeary², Jan M. Sargeant³, Richard Oberst³, Mark L. Tamplin¹, and John B. Luchansky¹, ¹U. S. Department of Agriculture, Wyndmoor, PA/U.S.A., ²College of Veterinary Medicine, KSU, Manhattan, KS/U.S.A., ³Food Animal Health and Management Center, KSU, Manhattan, KS/U.S.A..

Salmonella in swine is an economic concern to swine producers and a human health risk. A reliable and rapid technique for *Salmonella* detection in swine feces and water exposed to swine feces would be useful. The purpose of this research was to compare cultivation methods and PCR-based methods for the detection of *Salmonella* in the feces of healthy pigs and in water. In the present study, three cultivation techniques were compared to a polymerase chain reaction (PCR)-hybridization technique for the detection of *Salmonella*. A total of 150 fecal and water samples were tested for the presence of *Salmonella*: 1) 92 fecal samples were pre-enriched overnight in tryptic soy broth (TSB) followed by overnight enrichment in Rappaport-Vassiliadis R10 (RV10) broth; 2) 34 fecal samples were enriched overnight in RV10 broth with no additional enrichment; and, 3) 24 water samples were pre-enriched overnight in 3MC broth followed by overnight enrichment in RV10 broth. For the PCR detection of *Salmonella*, samples were tested after the first overnight enrichment. The DNA was extracted via boiling and concentrated using a Sepharose CL-6B spin column. A total of 65 samples tested positive by both cultivation and the PCR or either method alone. *Salmonella* was detected by both methods in 68.8% of the positive samples pre-enriched in TSB, in 73.3% of the positive samples pre-enriched in 3MC, and in 24.0% of the positive samples enriched in RV10. Using the kappa statistic, agreement was 76% between cultivation with pre-enrichment and the PCR for *Salmonella* detection but was 5.7% when using cultivation without pre-enrichment compared to the PCR. These data provide evidence that the PCR could be used in combination with cultivation to improve *Salmonella* detection as the PCR worked as well or better than culture for delineating positive samples. However, the PCR detected only 72% of those samples which culture identified as positive, indicating that additional improvements are warranted before the PCR replaces cultivation as the gold standard for detection of *Salmonella* from swine.

Key Words: *Salmonella*, PCR-hybridization, Swine

der these same conditions. Based on these results, it would appear that the p21 promoter responds differentially in myoblasts and myotubes to cyclic stretch.

Key Words: p21^{WAF1}, cyclic stretch, skeletal muscle

119 Effect of intramuscular plasmid delivery and electroporation on circulating concentration of the plasmid-encoded reporter gene in the pig. A.G. Van Kessel*¹, B.G. Goldade¹, B.R. Krishnan², M.A. Morsey², L.D. Nelson², and P.J. Gaynor³, ¹University of Saskatchewan, Saskatoon, SK, Canada, ²Pfizer Global Research and Development, Groton, CT, ³Pfizer Global Research and Development, Terre Haute, IN.

The effect of electroporation of skeletal muscle following plasmid injection on expression of a reporter gene was examined using 24 pigs (103.6 ± 0.79 kg BW). Pigs were assigned to one of four treatment groups including a vehicle control (CON) group, a group administered 2 mg plasmid in each of 2 sites (2P), a group administered 2 mg plasmid in each of 2 sites followed by electroporation (2PEP) and a group administered 1 mg plasmid in each of 2 sites followed by electroporation (1PEP). Prior to treatment, all pigs were sedated. The plasmid encoded secreted alkaline phosphatase (SEAP) driven by the CMV promoter and was injected in the right *biceps femoris* muscle suspended in 1 mL Na₂HPO₄ (150 mM, pH 7.2). Twelve electrical pulses (200 volts for 20 msec) were delivered across (1 cm gap) the injection site such that 6 pulses were delivered parallel with muscle fibres and 6 pulses were delivered perpendicular to muscle fibres. Polarity was reversed for 3 pulses delivered in each orientation. Electroporation had no adverse effects on the pigs. SEAP was detected in blood by day 2 following plasmid injection in electroporated pigs with maximal circulating SEAP activity observed

at day 10 and returned to baseline by day 21. Serum SEAP activity, measured in relative light units (RLU), was not significantly increased in CON (88 137) versus 2P (459 131) pigs. Comparison of 2P and 2PEP groups indicated electroporation increased SEAP activity 3.9-fold ($P < 0.001$). SEAP activity was different ($P < 0.05$) on day 7 only, between 1PEP (657 725 RLU) and 2PEP (1 005 619 RLU) treatment groups. Electroporation enhanced plasmid-encoded gene expression and may be an alternative approach to *in vivo* protein delivery.

Key Words: Swine, Electroporation, Gene Therapy

120 Muscle-derived insulin-like growth factor-I alters postnatal growth. J. K. Armstrong*, P. V. Malven, A. L. Grant, and D. E. Gerrard, *Purdue University, 1151 Smith Hall, West Lafayette, IN 47907.*

Insulin-like growth factor-I (IGF-I) regulates postnatal growth in most mammals. The source of this growth factor, however, is a point of much debate as some suggest the primary action of IGF-I results from GH-dependent release from the liver, yet the ability of peripheral tissues to produce IGF-I independently from GH may play an equally important role in growth. Therefore, we crossed three lines of mice: (1) *Little* mice (GH deficient), (2) IGF-I knock-out mice deficient in endogenous IGF-I (eIGF-I), and (3) mice with a muscle-specific actin promoter-driven human IGF-I transgene (tIGF-I), to evaluate the role of muscle-derived IGF-I in GH and/or IGF-I deficient mice. Body weights were recorded at 1, 10, 20, 30, 40, and 60 d postnatal. Progeny were genotyped using PCR. Serum GH and IGF-I concentrations were determined by radioimmunoassay. eIGF-I +/- mice had lower ($P < .01$) body weights than eIGF-I +/+ (wild type) mice after d20. *Little* (-/-) mice were smaller ($P < .0001$) than *Little* wild-type or heterozygotes after d20. Presence of the tIGF-I transgene resulted in increased ($P < .10$) body weights in eIGF-I +/+ mice (d60), eIGF-I +/- mice (d40), *Little* +/- mice (d40), and *Little* -/- mice (d60). The tIGF-I transgene did not change serum GH or IGF-I concentrations, but eIGF-I +/- mice had lower ($P < .0001$) serum IGF-I than wild-type eIGF-I mice. These data suggest both IGF-I alleles are necessary for normal body growth and serum IGF-I concentrations in mice, and that muscle-specific production of IGF-I is capable of increasing body weights in GH and IGF-I deficient mice.

Key Words: Growth hormone, Insulin-like growth factor-I, Mice

121 Effect of an IGF-I transgene on tissue accretion rates in pigs. VG Pursel*¹, AD Mitchell¹, RJ Wall¹, ME Coleman², and RJ Schwartz³, ¹USDA-ARS, Beltsville, Maryland, ²Valentis, Inc., The Woodlands, Texas, ³Baylor College of Medicine, Houston, Texas.

The objective of this research was to determine whether directing expression of IGF-I specifically to striated muscle would alter the rate of lean and fat tissue accretion. Founder transgenic pigs were produced with a fusion gene composed of avian skeletal alpha-actin regulatory sequences and the cDNA encoding IGF-I. A founder transgenic boar (hybrid dam line) was mated to 12 non-transgenic gilts from two hybrid sire lines to produce G1 transgenic (TG) and sibling control progeny (CN). Pigs were provided feed ad libitum from weaning to 120 kg BW. At 90 and 120 kg BW, 31 TG and 39 CN pigs were anesthetized and scanned by dual-energy x-ray absorptiometry (DXA) to estimate fat and lean body composition of the live pigs. At 90 kg TG gilts had 16.4% less fat and 6.2% more lean tissue and TG barrows had 21.1% less fat and 8.4% more lean tissue than respective CN pigs ($P < 0.01$ for each). During subsequent growth from 90 to 120 kg, the rates of fat accretion were 20.6% and 23.7% lower for TG gilts and barrows than for respective CN pigs. Rates of lean tissue accretion were 30.3% and 31.7% higher for TG gilts and TG barrows, than for respective CN pigs. The rates of lean tissue accretion were 632 and 485 g/d for TG and CN gilts and 696 and 529 g/d for TG and CN barrows, respectively (TG vs. CN, $P = 0.0001$). The rates of fat tissue accretion were 242 and 305 g/d for TG and CN gilts and 300 and 393 g/d for TG and CN barrows, respectively (TG vs. CN, $P = 0.0001$). The IGF-I transgene affected progeny of both sire lines similarly in regard to enhancement of lean tissue accretion and reduced fat deposition. These results confirm our earlier findings that the targeting of IGF-I expression to striated muscles had a major impact on lean tissue accretion.

Key Words: Swine, IGF-I, Transgenic

122 IGF-I and analogues can increase growth in artificially-reared neonatal pigs. F. R. Dunshea*¹, C. S. Chung², P. C. Owens³, F. J. Ballard³, and P. E. Walton³, ¹Agriculture Victoria, Victorian Institute of Animal Science, Werribee, Australia, ²Department of Animal Science, Chungbuk National University, Republic of Korea, ³Cooperative Research Centre for Tissue Growth and Repair, Adelaide, Australia.

Exogenous insulin like growth factor-I (IGF-I) has been shown to increase growth rate in neonatal pigs while an analogue of IGF-I, LR3IGF-I, has been shown to be more potent than IGF-I in the rat. Therefore a study was conducted to determine whether IGF-I and LR3IGF-I increase growth in the artificially reared neonatal pig. Eighteen pigs (2 kg initial weight) pigs were infused with control, IGF-I (8 $\mu\text{g/h}$) or LR3IGF-I (8 $\mu\text{g/h}$) via osmotic pumps. After 9 days an additional pump was inserted to increase the infusion rates of each of the growth factors (16 $\mu\text{g/h}$) for a further 9 days, after which time the pigs were slaughtered. Pigs were offered bovine milk ad libitum. Neither IGF-I nor LR3IGF-I had any effect upon daily gain over the first 9 days of the study. However, over the second 9 days of the study, daily gain was increased in LR3IGF-I infused pigs (386 v. 457 g/d, $P < 0.01$), and tended to be increased in pigs infused with IGF-I (386 v. 413 g/d, $P = 0.15$). As a result pigs infused with LR3IGF-I were heavier than the control pigs at slaughter. Milk intake was not different during the first 9 days of the study but was significantly greater in pigs infused with growth factors over the second half of the study (2905 v. 3407 g/d, $P < 0.01$). Pigs treated with LR3IGF-I had a larger spleen (18.9 v. 27.5 g, $P < 0.001$) and tended to have a larger liver (286 v. 319g, $P = 0.078$), small intestine (329 v. 383 g, $P = 0.10$) and combined small intestine and liver (614 v. 701 g, $P = 0.062$) weight. Plasma IGFBP3 concentrations were highly correlated ($R = 0.85$) with average daily gain over the 3 days preceding blood sampling. In conclusion, exogenous IGF-I and particularly LR3IGF-I can increase growth rate and visceral development in ad libitum fed artificially-reared pigs. At least part of the cause was an increase in milk consumption of infused piglets.

Key Words: IGF-I, Pig, Neonate

123 A GnRF vaccine (Improvac[®]) and porcine somatotropin have synergistic and additive effects on growth performance in group-housed boars and gilts, respectively. W. T. Oliver*¹, I. McCauley², R. J. Harrell¹, D. Suster², and F. R. Dunshea², ¹North Carolina State University, Raleigh, NC, ²Agriculture Victoria, Victorian Institute of Animal Science, Werribee, Australia.

Two hundred and twenty four pigs (112 boars, 112 gilts) were used in a 2x2x2 factorial design, with the factors being vaccination with a GnRF vaccine, Improvac[®] (I; 0 or 2 ml at 13 and 17 wks of age), porcine somatotropin (pST; 0 or 5 mg/d from 17 wks of age), and gender. Pigs were weighed and feed disappearance was measured from 17 wks of age until slaughter at 21 wks of age. Body composition was measured by dual-energy X-ray absorptiometry at 17 and 21 wks of age. At slaughter, boars were heavier than gilts (100.7 vs 95.1 kg, $P < 0.008$). ADG was increased by both I (1109 vs 1244 g/d, $P < 0.001$) and pST (1109 vs 1199 g/d, $P < 0.001$). Boars treated with both I and pST gained at a faster rate (1404 g/d) than control and pST treated pigs ($P < 0.001$), and tended to grow at a faster rate than pigs receiving I alone ($P < 0.08$). Overall, I increased ADG in gilts (1000 vs 1166 g/d, $P < 0.001$). However, ADG for gilts treated with both pST and I was not significantly different from I or pST treated pigs. Treatment with I increased feed intake by 18 % ($P < 0.01$), but treatment with both I and pST resulted in feed intakes similar to pigs receiving neither treatment ($P > 0.5$). Treatment with I increased fat gain (217 vs 301 g/d, $P < 0.001$), while fat gain for pST treated pigs was reduced (170 g/d, $P < 0.001$). Pigs receiving both I and pST had fat accretion rates similar to control pigs ($P > 0.4$). While treatment with I or pST alone had no effect on lean gain in boars ($P > 0.2$), boars treated with both I and pST tended to have higher lean accretion rates than control boars (707 vs 782 g/d, $P < 0.09$). Treatment of gilts with pST increased lean gain (485 vs 652 g/d, $P < 0.001$), but no difference was observed in gilts treated with I. Gilts treated with I and pST accrued lean mass at a rate similar to pST treated pigs (703 vs 652 g/d, $P > 0.2$). In conclusion, the concomitant use of I and pST improves growth performance in boars and gilts.

Key Words: GnRF, pST, Swine

124 Regulation of selection-induced growth hormone expression in porcine single trait selection lines. M.F.W. te Pas*, J.W.M. Freriksen, A.J.H.M. van Bijnen, C.L.M. Gerritsen, T.J. van den Bosch, F.J. Verburg, A.H. Visscher, and K.H. de Greef, *Institute for Animal Science and Health, ID-Lelystad.*

Selection for increased growth rate or decreased fat deposition in pigs is associated with changed growth hormone (GH) plasma levels. The molecular mechanisms regulating selection-induced changes remain largely unknown. This study aims at investigating selection-related changes in individual components of the GH expression. Associations between performance and GH expression parameters were evaluated in 2 pig selection lines selected for increased growth rate (F-line), or decreased back fat thickness (BFT) (L-line). We investigated changes in the mRNA levels of GH and its pituitary-specific transcription factor (Pit-1) in the pituitaries of slaughter pigs. In both lines GH and Pit-1 mRNA levels increased 50 % each generation. GH mRNA levels are pulsatile in vivo. GH mRNA levels were associated with BFT and growth rate in both lines. Pit-1 mRNA level was associated to BFT in the L-line. When GH and Pit-1 were fitted together in the model GH mRNA levels were significantly associated with growth rate and BFT. GH mRNA levels are directly associated with genetic constitution for BFT, but less or not with growth rate. GH blood plasma pulsatile pattern is characterized by (1) maximum peak value, (2) area under the curve, (3) pulse width, and (4) pulse interval. Both lines showed a declining GH peak maximum level and area under the GH curve. GH pulse width was not affected by selection. In both lines the pulse interval declined during selection, indicating that the number of pulses per day increased during selection with 1 pulse per 24 h per generation. Growth rate was associated with the GH plasma baseline value in both lines. Area under the curve and GH baseline level was significantly related to BFT. Line-specific effects were found for the baseline levels in the F-line. The results suggest that selection-induced GH synthesis is probably not sufficient for demanded blood plasma secretion resulting in smaller GH peaks and increased peak numbers per day.

125 Cloning, mapping, and functional analysis of porcine pituitary homeodomain transcription factor genes. S.J. Rhodes*¹, K.W. Sloop¹, G.E. Parker¹, T.P.L. Smith², A.D. Showalter¹, A.L. McCutchan Schiller¹, J.R. Blanton Jr¹, and G.A. Rohrer², ¹Indiana University Purdue University Indianapolis, ²US MARC Nebraska.

Hormones secreted from the pituitary gland mediate regulation of growth, lactation, reproduction, the stress response, and metabolic homeostasis. Recent studies have identified transcription factors that regulate the development and function of the pituitary gland in mice and humans. Our goal is to understand the molecular events that regulate pituitary development in swine. We have cloned, mapped, and analyzed the genes encoding the porcine Lhx3 (pLhx3) and Prop-1 (pProp-1) homeodomain transcription factors. In mice, Lhx3 is expressed in the developing nervous system, and then is restricted to the pituitary. Prop-1 expression is pituitary-specific in rodents. The pLhx3 and pProp-1 proteins are conserved within their protein/protein interaction and DNA-binding domains but exhibit less conservation outside these motifs. Assay of gene expression in whole early porcine embryos by RT-PCR revealed that the pLhx3 gene is activated at the time of neurogenesis. It then displays a biphasic expression pattern with expression increasing during the establishment of the pituitary and at the time of hormone gene activation. By contrast, pProp-1 is only observed at the times of pituitary organogenesis and then is down regulated to low levels. Northern analysis demonstrated that the pLhx3 gene produces a rare transcript in the adult pituitary. RNase protection analysis detected several pProp-1 mRNAs at low levels in the pituitary gland; expression was not found in other endocrine organs. Porcine Lhx3 activated the alpha-glycoprotein and prolactin promoters in transfection assays. Recombinant pLhx3 and pProp-1 proteins specifically bound to DNA sites in gelshift assays, and the pLhx3 protein specifically interacted with Pit-1 and other partner proteins in solution binding assays. We have mapped the protein elements required for the nuclear localization of pLhx3 and have demonstrated that pLhx3 is associated with the nuclear matrix. Genetic mapping experiments placed the pLhx3 and pProp-1 genes on the q arms of pig chromosomes 1 and 2, respectively.

The mapping and analysis of swine pituitary regulatory genes will provide candidate genes for genetic analysis of growth, reproductive, and metabolic traits. Supported by USDA.

126 Purification of porcine β -casein from milk by liquid chromatography, N-terminal sequencing, and antisera development. Adam C.W. Kauf* and Ronald S. Kensinger, *Pennsylvania State University, University Park, Pennsylvania.*

Sow's milk is not capable of supporting the genetic potential for growth of modern piglets. A better understanding of the regulation of milk protein synthesis is desirable to improve sow milk, but is hindered by a lack of reagents to directly measure porcine milk proteins. Our objective was to purify porcine β -casein from sow's milk, determine N-terminal amino acid sequence, and develop specific polyclonal antisera against porcine β -casein. Milk was collected by hand milking from an oxytocin-treated crossbred Yorkshire sow on d 27 of lactation. Milk was defatted by centrifugation (5,000 x g, 15 min), and the casein fraction precipitated by incubation at pH 4.6. A casein-enriched fraction was isolated by centrifugation (5,860 x g, 60 min), washed three times, and lyophilized for storage at -20 °C. For further fractionation, it was then dissolved (24 mg/ml) in 4 M Urea and 0.01 M Imidazole at pH 6.75. A volume of 1.5 ml was applied (1 ml/min) to a 5 ml Mono Q anion-exchange column (Bio-Rad Laboratories), and eluted by a stepwise gradient of NaCl between 0 and 500 mM in Urea/Imidazole buffer. Fractions from the 165 mM NaCl step were collected and pooled from five chromatographic runs. β -casein (9 mg) was isolated and assessed by electrophoresis (SDS-PAGE with 4 M Urea) to be greater than 95 % pure. Direct sequencing of the 14 N-terminal amino acids by Edman degradation yielded RA-KEELNASGETEV, which confirms the sequence predicted by Alexander and Beattie (1992) from cDNA analysis. β -casein (400 ug) was mixed with complete Freund's adjuvant and injected into rabbits, followed by three boosters (200 ug) with incomplete Freund's adjuvant at four week intervals. Antiserum from one rabbit on day 112 after primary immunization detected 100 ng β -casein by Western blot procedure when used at dilution of 1:2,000,000. A goal is to use this antiserum to detect subtle changes in β -casein secretion by porcine mammary tissue.

Key Words: porcine β -casein, anion-exchange chromatography, polyclonal antisera

127 Effect of dexamethasone treatment on growth in neonatal swine. J. S. Seaman*¹, E. P. Berg¹, T. J. Safranski¹, and J. A. Carroll², ¹University of Missouri, Department of Animal Sciences, ²Animal Physiology Research Unit, ARS-USDA, Columbia, MO.

We have previously reported that dexamethasone (Dex) treatment at birth enhances pre-weaning growth in piglets. The objective of the present study was to evaluate the effects of Dex treatment at birth on post-weaning piglet growth. Sixty-four crossbred piglets were assigned according to birth weight and sex to receive either sterile saline (Control; n=16 males and 17 females) or Dex (2 mg/kg body weight; n=14 males and 17 females) i.m. within 1 hour of birth. Using ANOVA, the statistical model included analysis of treatment, sex, and treatment x sex interactions for weight and ADG. Birth weights ($1.543 \pm .270$ kg) did not differ between Dex and Controls ($P > .99$) or males and females ($P > .67$). Weaning weights (21 days of age) were increased ($P < .03$) for Dex piglets (7.72 ± 1.10 kg) compared to Controls (7.14 ± 1.15 kg). At 7 weeks of age, piglets were moved out of the nursery. There was a treatment x sex interaction in 7-week weight ($P < .07$) such that no difference existed between Dex and Control females; however, Dex males (17.65 ± 2.20 kg) were heavier ($P < .08$) than Control males (15.97 ± 2.67 kg). ADG through weaning was increased ($P < .03$) in Dex piglets ($.293 \pm .048$ kg/d) compared to Controls ($.267 \pm .047$ kg/d). There was a treatment x sex interaction ($P < .08$) for ADG from birth to 7 weeks of age. No effect of Dex treatment was observed in females ($P > .59$), however, a trend was observed in males ($P < .08$) such that Dex increased ADG compared to Controls. Further research is underway to determine if this growth increase is maintained through the grow-finish phase, and if there are effects associated with carcass quality in Dex treatment. Given that the growth rate of the neonatal pig is considered to be less than half of its potential, the use of hormonal therapies such as Dex at birth to enhance growth rates could prove to be of significant economical importance to the swine industry.

Key Words: Dexamethasone, growth, piglets

128 Involvement of the type I and type II glucocorticoid receptors (GR) in growth hormone (GH) cell differentiation (GHDIFF) during chicken embryonic development. I. Bossis* and T.E. Porter, *University of Maryland, College Park MD USA.*

GHDIFF occurs around day 14 of chicken embryonic development (e14) and is coincident with maturation of the adrenal glands. We have previously shown that corticosterone (CORT) can induce premature GHDIFF both *in vitro* and *in vivo*. In the present study, the GRs mediating the effects of CORT on GHDIFF were identified. Pituitary cells isolated from e12 embryos were cultured in the presence of vehicle (A), CORT at 1 nM (B), the type II GR antagonist ZK-98299 at 10 μ M (C) and B + C in combination (D). Immunocytochemistry for GH was used to assess GHDIFF. Treatment with CORT significantly increased the population of somatotrophs, but the effect was not blocked by ZK-98299 (1.2 ± 0.3 , 22.0 ± 2.1 , 1.0 ± 0.2 and 19.8 ± 1.9 % of all pituitary cells for A, B, C and D, respectively; $P \leq 0.05$, $n=4$ experiments). However, treatment with ZK-98299 clearly reduced the intensity of GH staining. Subsequently, several steroids were tested for their ability to induce GHDIFF *in vitro*. Only glucocorticoids (CORT and dexamethasone) and aldosterone (ALDO) were effective, suggesting that both the type I (mineralocorticoid) and type II (glucocorticoid) GR might be involved. To test this hypothesis, e12 pituitary cells were cultured in the presence of vehicle (A), CORT at 1 nM (B), ALDO at 0.1 nM (C), CORT plus the mineralocorticoid receptor antagonist spironolactone (SPIRO) at 10 μ M (D), ALDO plus SPIRO (E), ALDO plus ZK-98299 at 10 μ M (F), CORT plus ZK-98299 and SPIRO at 10 μ M each (G) and ALDO plus ZK-98299 and SPIRO (H). Induction of GHDIFF by CORT and ALDO was not blocked by SPIRO or ZK-98299 alone. However, it was completely abolished in the presence of both GR antagonists (1.8 ± 0.3 , 23.6 ± 3.1 , 21.7 ± 2.6 , 20.9 ± 2.3 , 23.0 ± 2.3 , 22.7 ± 2.9 , 3.4 ± 0.6 and 2.5 ± 0.5 % of all pituitary cells for A, B, C, D, E, F, G and H, respectively; $P \leq 0.05$, $n=4$ experiments). We conclude that both the type I and type II GR mediate steroid-induced GHDIFF and that either GR type is sufficient for this response.

129 Gene expression in sexually dimorphic muscles in sheep. R.G. Mateescu* and M.L. Thonney, *Cornell University, Ithaca, NY.*

Testosterone is known to act differentially on skeletal muscle from different regions. Two genes likely to mediate the testosterone effect are insulin-like growth factor-I (IGF-I), an important growth regulator acting in an autocrine and paracrine way, and androgen receptor (AR), as receptor density could account for differential muscle growth. Another muscle-specific gene that may play a role in differential muscle growth is myostatin (MSTN), a member of the transforming growth factor-beta superfamily, shown to be a negative regulator of skeletal muscle mass. The objective of this study was to quantify and compare the expression of these three genes in two different skeletal muscles in sheep. Eleven Dorset rams were slaughtered after reaching puberty and total RNA was extracted from samples of semitendinosus (ST) and splenius (SP) muscles. IGF-I mRNA was measured using competitive reverse-transcription-polymerase chain reaction (RT-PCR). AR and MSTN mRNA were measured by ribonuclease protection assay (RPA) with standard curves. The means (attomoles/ μ g RNA) for SP and ST muscles were 1.39 and 1.02 (SE = 0.14), 4.05 and 2.96 (SE = 0.24), and 4.30 and 3.85 (SE = 0.37) for IGF-I, AR, and MSTN respectively. The difference between the two muscles was significant for IGF-I ($P < 0.1$) and AR ($P < 0.01$) mRNA levels with higher expression in the SP but not for MSTN ($P > 0.4$). Our results show that locally produced IGF-I and the regulation of AR expression may be important for sexually dimorphic muscle growth patterns.

130 The Effect of Stage of Growth and Implant Exposure on Carcass Composition and Quality in Steers. K.W. Bruns*, R.H. Pritchard, and T.A. Wittig, *South Dakota State University, Brookings, SD.*

Angus and Angus x Limousin steers ($n=45$) were used to evaluate the influence of an estradiol-trenbolone acetate implant (revalor-s) on the

relationship between percent intramuscular fat content (PIMF) and carcass composition when administered at specific stages of growth. Treatments were as follows: NI) control No Implant; EI) Early Implant, d 1, BW=295 kg; or DI) Delayed Implant, d 56, BW=385 kg. Steers were procured at weaning and were backgrounded (40 d) prior to the trial. Steers were fed a 90% concentrate diet for 150 d. Serial harvest was conducted at d 1 ($n=5$), d 56 ($n=10$) and at the end of the trial ($n=30$). Rib sections (9-10-11) were removed and analyzed for fat, protein, and moisture content to predict whole carcass composition. Regression equations were developed to quantify changes in carcass characteristics and composition throughout the feeding phase. At d 56 ($n=10$) EI increased HCW vs. NI (NI 227 vs. EI 243 kg; $P < .05$). Backfat, REA, YG, marbling score as well as whole carcass protein (%) and whole carcass fat (%) were not different. At harvest implants (I) increased ($P < .10$) final body weight (532 vs. 541 kg) and HCW (341 vs. 349 kg). Implants increased REA (75.4 vs. 82.74 cm^2 ; $P < .01$) and decreased KPH (3.5 vs. 3.2%; $P < .10$). Yield grade components HCW, BF, REA, and KPH increased linearly. The subjective maturity and marbling scores were not affected by treatment and increased in a linear fashion. Treatment had no effect on the whole carcass proportions of fat, protein, or water. The PIMF of the L. dorsi was reduced ($P < .10$) by EI and was unaffected by DI (NI 5.1, EI 4.0, DI 4.8%). The PIMF content increased linearly and the slope of development was greater ($P < .10$) for NI vs EI. These data indicate that implanting will improve carcass weight and REA with no effect on carcass composition. Early implant exposure tended to reduce the rate of PIMF development but delaying implant until 385 kg BW increased carcass production without decreasing PIMF content.

131 Lipogenic activity and adipose tissue cellularity in steers fed casein-formaldehyde-protected starch and(or) canola lipid. C. D. Gilbert*, D. K. Lunt, and S. B. Smith, *Texas A&M University, College Station, TX.*

Eighteen Brangus steers of similar live weight were assigned randomly to one of three dietary treatment groups: cracked corn (Corn), casein-formaldehyde-protected Canola Lipid (CL), or casein-formaldehyde-protected Marble Plus (MP). The purpose of the study was to determine if feeding protected starch and lipid increased lipogenic enzyme activities in i.m. adipose tissue more than in s.c. adipose tissue, thus increasing marbling scores without increasing yield grade. All diets were equally balanced for ME (291 Mcal/kg), crude protein (12.5%), and dry matter (89%). Ether extract was 3.7, 6.9, and 6.9% for the Corn, CL, and MP diets, respectively. The CL and MP diets provided equal amounts of protected lipid (3.3%). The MP also contained 3.7% protected starch. Steers were fed their respective diets for 126 to 130 d before slaughter. Beef carcasses from steers fed Corn, CL, or MP did not differ in yield grade or marbling score ($P \geq 0.23$). Percentage KPH fat was higher ($P < 0.05$) for CL and MP carcasses than for Corn carcasses. Peak diameter (154 vs 98 μ m) and volume (160 vs 112 pL) were greater in s.c. than in i.m. adipose tissue ($P < 0.05$). Subcutaneous adipocyte peak diameter tended ($P < 0.08$) to be greater in CL steers (130 μ m) than in Corn steers (120 μ m), but peak volume did not differ ($P = 0.55$) among treatments. There were no treatment x tissue interactions for adipocyte volume or cells/g ($P > 0.59$). The addition of lipid to the diets (CL and MP combined effects) increased peak adipocyte diameter ($P = 0.03$). The activities of 6-phosphogluconate dehydrogenase, glucose-6-phosphate dehydrogenase, NADP-malate dehydrogenase, and fatty acid synthetase did not differ among treatment groups for either s.c. or i.m. adipose tissue ($P > 0.05$). We were not able to demonstrate a direct effect of protected starch and lipid on i.m. or s.c. lipogenic enzyme activities, marbling score, or yield grade.

Key Words: Steers, Lipogenesis, Protected Fat

132 Novel effects of nutrition on reproduction in lactating dairy cows. M. C. Wiltbank*, R. Sartori, S. Sangsritavong, H. Lopez, J. M. Haughian, P. M. Fricke, and A. Gumen, *Department of Dairy Science, University of Wisconsin-Madison.*

A number of reproductive parameters are altered in lactating dairy cows including: twinning rate, expression of estrus, conception rate, pregnancy loss, and incidence of anovulation. We hypothesized that the high feed consumption associated with lactation has fundamentally altered reproductive physiology due to increased metabolism of steroids. We evaluated liver blood flow and steroid metabolism under different physiological conditions using continuous infusion of bromosulfothalein (90% metabolized by one pass through liver) and/or estradiol and progesterone. In lactating or non-lactating cows, acute feeding produced an increase in liver blood flow of 20-30% that was maximal by 2 h after feeding. There was a corresponding decrease of 30% in circulating estradiol and progesterone concentrations following acute feeding of cows continuously infused with steroids. The baseline liver blood flow was much greater in lactating (1600 l/h) as compared to non-lactating (800 l/h) cows. Similarly, estradiol and progesterone metabolism was much greater in lactating as compared to non-lactating cows. Analysis of normal estrous cycles showed striking differences in lactating cows vs. heifers that are consistent with high steroid metabolism. Peak serum estradiol near estrus was lower in single-ovulating lactating cows (7.15 pg/ml) than heifers (9.46) in spite of larger preovulatory follicle diameter in cows (17.45 mm) than heifers (14.8.2). Similarly, circulating progesterone concentrations were lower for cows than heifers from d 5 to 14 of the estrous cycle (on day 14: 4.1.3 vs. 6.1.4 ng/ml); whereas, luteal volume was greater for cows than heifers (on day 14: 8272932 vs. 5415276 mm³). There were also differences in double ovulation rate (cows-25.0%; heifers-1.8%) and embryo quality on day 5 after normal ovulation (n = 27-28 per group each flushed 3 different times). The percentage of degenerated embryos (Grade 5) was greater (p<0.05) in lactating cows (61.9%) vs. heifers (6.3%) during summer or comparing lactating (41.7%) vs. non-lactating cows (17.6%) during winter. Thus, changes in reproductive physiology may be a consequence of the high feed consumption, high liver blood flow and resulting increase in steroid metabolism associated with high milk production.

Key Words: Reproduction, Liver blood flow, Progesterone

133 The influence of nutrient intake on ovarian form and function in meat-type chickens. F. E. Robinson*¹, R. A. Renema¹, and M. J. Zuidhof², ¹University of Alberta, ²Alberta Agriculture, Food and Rural Development.

The chicken is an ideal model in which to examine ovarian form and function, including follicular steroidogenesis, recruitment, yolk deposition, atresia and ovulation rate. Meat-type chickens that have been intensively selected for appetite exhibit very fast rates of growth. These stocks are reproductively unfit when allowed to feed ad libitum. Our research has focussed on the degree of feed restriction during rearing and lay, as well as the rate of change in feed intake during sexual maturation (SM) on the above mentioned ovarian parameters in breeding stock. During SM, dietary energy allocation to pullets is increased from approx. 285 kcal/day (20 wk) to 460 kcal/day (30 wk). Birds that are allocated this increase quickly, and early during this period have at least one extra large yellow follicle (LYF). This excess follicular development is associated with a reduction of about 10 eggs, as under estrogen domination following photostimulation (PS), hepatic vitellogenesis partitions excess dietary energy to follicular development. Considering the increased gonadotrophin levels seen in over-fed pullets, it is hypothesized that increased estrogen output was stimulated. Increased estrogen levels stimulate hepatic fatty acid synthesis and the formation of phospholipids and proteins to package lipid for yolk deposition. Recently, the consequences of over-feeding BB females for one of seven 14-d periods during the period from 18 to 32 wk of age were investigated. It was observed that the most critical period for exposing pullets to a bonus feeding allocation (30 g more feed/bird/d) was between 14 and 28 after PS. It is proposed that this period represents the time of maximal sensitivity of hepatic lipogenesis to circulating estrogen. Plasma levels of FSH and LH increase within 48 h of PS in all birds and levels are higher in heavy weight birds. These heavy birds reach sexual maturity more quickly and have a greater number of LYF than do small birds.

Increased plane of nutrition can double the initial increases in plasma levels of FSH and LH and further accelerate SM. Increased follicular development is not advantageous, as evidenced by significantly lower egg output in aggressively fed flocks.

Key Words: Chicken, Ovarian morphology, Follicular recruitment

134 Relationships between Bovine follicular steroids and components of the extracellular matrix. C.M. Field*¹, A.R. Williams¹, A.B. Moore¹, J.N. Oyarzo², M.E. Bellin², and R.L. Ax², ¹Mississippi State University, Starkville, MS, ²University of Arizona, Tuscon, AZ.

Objectives were to confirm presence of TIMP-2 (T2) on surface membranes of bovine follicular cells, determine the relationship of estradiol-17 β (E), progesterone (P), and glycosaminoglycans (GAGs) to T2 in follicular development, and quantify binding of T2 in follicular content. Ovaries were obtained within 30 minutes of slaughter or by ovariectomy. Follicles (n=441) were aspirated from ovaries and follicular fluid and follicular cells separated by centrifugation, and frozen. E and P concentrations in individual follicles were determined by RIA from follicular fluid. Follicles were classified into 4 groups by high/low E and P and large/small size (n=40). Atresia was defined by low E concentration. Follicular fluid GAGs were determined spectrophotometrically using an Alcian blue dye procedure. Granulosa cell content per follicle was quantified using a Pierce BCA protein assay and spectrophotometry. The quantity of T2 present was measured with a fluorometer after incubation with fluorescent-labeled human T2 antibody at 210 μ g/ml per sample. Data were analyzed using SAS GLM procedures to determine relationships of E and P to GAGs and T2 expression and correlation procedures to establish relationship of T2 to GAGs. An inverse relationship between T2 and GAGs to E and P was revealed (P<.05). Regardless of size, high E and P follicles had low GAGs and T2 binding, while low E and P follicles displayed elevated GAGs and T2 binding. The amount of T2/ μ g protein indicated a trend toward additional T2 binding on follicular cells from large atretic follicles, compared to healthy large follicles and small atretic follicles (P<.10). A strong relationship (r=0.85) between T2/ μ g protein and GAGs existed in large, high E follicles. Results confirmed follicle health was related to T2 and GAG expression, with atretic follicles, on the basis of steroid concentrations, displaying higher GAGs and T expression.

Key Words: Bovine, Follicle, TIMP-2

135 Relationship between preovulatory follicle growth and postovulatory luteal function in the cow. GE Mann*¹, ECL Bleach², GR Starbuck¹, and MD Fray³, ¹University of Nottingham, Sutton Bonington, Loughborough, UK, ²University of Reading, Whiteknights, Reading, UK, ³Institute for Animal Health, Compton, Newbury, UK.

In dairy cows the timing and strength of the postovulatory progesterone rise is a key determinant of early embryo development and survival. The aim of this study was to determine whether postovulatory luteal function is related to preovulatory follicle development. Luteal regression was synchronized in 25 non-lactating Holstein Friesian cows which subsequently underwent daily trans rectal ultrasonography to determine the growth pattern and size of the ovulatory follicle. Following ovulation, daily plasma samples were collected for 6 days to determine progesterone concentrations. The mean (sem) diameter of the ovulatory follicle rose from 10.9 \pm 0.8 mm at luteolysis to 15.9 \pm 0.5 mm at ovulation 4.0 \pm 0.2 days later. There was a significant relationship between initial follicle diameter and time to ovulation with smaller follicles taking longer to ovulate (r² = 0.63; p<0.001). The mean plasma concentration of progesterone (from days 4-6 post ovulation) increased significantly with increasing initial (r² = 0.34; p<0.01) and final (r² = 0.24; p<0.05) diameter of the ovulatory follicle and decreased with increasing time from luteolysis to ovulation (r² = 0.22; p<0.05). The mean interval from ovulation to the onset of the postovulatory progesterone rise (>1ng/ml) decreased with increasing initial (r² = 0.34; p<0.01) and final follicle diameter (r² = 0.22; p<0.05) and increased with increasing days to ovulation (r² = 0.34; p<0.01). The results demonstrate that increased progesterone secretion by the developing corpus luteum is related to the ovulation of a larger follicle that took less time to ovulate. Whether it is

follicle size or time to ovulation that is the more important determinant of subsequent luteal function remains to be determined.

Key Words: Cow, Follicle, Corpus Luteum

136 Effects of Acute Nutritional Restriction of Beef Heifers on LH in serum and Anovulation. C. A. Lents*, F. J. White, L. N. Floyd, N. H. Ciccioli, I. Rubio, and R. P. Wettemann, *Department of Animal Science, Oklahoma Agricultural Experiment Station.*

Angus x Hereford heifers (BCS = 5.5 ± 0.1 ; 387 ± 7 kg BW) exhibiting normal estrous cycles at 15 mo of age were used to determine the effects of acute nutritional restriction on LH in serum and the incidence of anovulation. Heifers were maintained in individual pens and adapted to a 1.2 x maintenance (M) diet for 10 d. On d 0, heifers were randomly assigned to 0.4 M (n = 16) or 1.2 M (n = 7). Heifers were treated with PGF 2α on d -10, 0, and 10. Daily blood samples were obtained by tail venipuncture and progesterone in plasma was quantified. Jugular catheters were inserted on d 8. Blood samples were collected every 10 min for 8 h on d 9, 10 and 11, and LH in serum was quantified. Beginning on d 12, blood samples were collected from 0.4 M (n = 9) and 1.2 M (n = 4) heifers every 4 h for 48 h to quantify estradiol in plasma and the ovulatory surge of LH. Heifers with plasma progesterone less than 0.5 ng/mL on d 14 to 21 were classified as anovulatory. On d 12, 0.4 M heifers weighed less ($P < 0.01$) than 1.2 M heifers (353 ± 9 kg vs 391 ± 7 kg, respectively), but BCS was similar for 0.4 M and 1.2 M heifers (5.4 ± 0.1). On d 14, 44% (4 of 9) of 0.4 M heifers were anovulatory and all 1.2 M heifers ovulated. Concentrations of LH in serum and frequency of LH pulses on d 9, 10, or 11 were not influenced by treatment. Anovulatory heifers lacked an ovulatory surge of LH and concentrations of estradiol were similar and minimal on days 2, 3, and 4 after PGF 2α (1.1 ± 0.1 pg/mL). Heifers on 1.2 M had a preovulatory increase in plasma estradiol (2.7 ± 0.4 pg/mL) preceding the ovulatory surge of LH. In conclusion, acute nutritional restriction for 14 d induced anovulation in 44% of heifers, did not influence serum concentrations of LH or frequency of LH pulses during follicular growth, but inhibited the proestrous increase in estradiol and the ovulatory surge of LH.

Key Words: Heifers, Nutrition, LH

137 Estradiol benzoate (EB) inhibits secretion of LH and induces atresia of dominant follicles within 36 hours in cyclic heifers. C.R. Burke*^{1,2}, S. Morgan², M.L. Mussard¹, D.E. Grum¹, and M.L. Day¹, ¹The Ohio State University, Columbus OH, ²Dexel Ltd, Hamilton, New Zealand.

The aim of this study was to characterize LH secretion and timing of functional atresia in dominant follicles (DF) of cyclic heifers treated with EB. At $5.6 \pm .1$ d after estrus, heifers received 1 mg EB/500 kg BW (designated h 0; T; n=15) or remained untreated (C; n=15). Ovarian structures were monitored by ultrasonography at least daily from estrus to ovariectomy or new follicle wave emergence. Blood samples were collected every 20 min for 12 h beginning at h -12, 0, 24 and 48 from seven heifers in each treatment to characterize LH secretion. Four heifers from each of these groups were ovariectomized 12 h after new wave emergence. The remaining eight heifers per treatment were ovariectomized at either h 12 or 36. Concentrations of estradiol-17 β (E $_2$) and progesterone (P $_4$) were determined in the fluid of DF. Maximum diameter of DF was less in the T ($12.0 \pm .8$ mm) than the C ($14.0 \pm .4$ mm) treatment (treatment x time; $P < .01$) but the interval to new wave emergence ($4.6 \pm .2$ d) was similar among treatments. Mean E $_2$ and E $_2$:P $_4$ ratio in DF of T heifers at 36 h (48.6 ± 4.25 ng/ml and $2.37 \pm .6$) was less ($P < .01$) than in C heifers at 36 h (258.13 ± 26.7 ng/ml and $7.3 \pm .7$), and comparable ($P > .1$) to that in C heifers after a new follicle wave had emerged (27.8 ± 17.6 ng/ml and 1.3 ± 1). Mean concentrations of LH and amplitude of LH pulses were lower in the T than C treatment at h 24 and 48 (treatment x time, $P < .05$) while LH pulse frequency was similar between treatments. Maximum P $_4$ in plasma after treatment was lower ($P < .01$) in T ($3.2 \pm .2$ ng/ml) than C treatment ($4.87 \pm .5$ ng/ml). The results indicate that EB-induced atresia of dominant follicles is achieved by 36 h and is accompanied by a reduction in LH pulse amplitude and mean concentration. It is also suggested that the interval from EB treatment to emergence of a new follicle wave is not entirely dependent on the functional status of the present DF.

Key Words: Estrous synchronization, Follicular atresia, Estradiol

138 Effect of Heat Stress in Follicular Development of Dairy Cows in Intensive Production in North-Central Mexico. R.R. Lozano-Dominguez¹, C.F. Arechiga², and E. Gonzalez-Padilla*¹, ¹Universidad Nacional Autonoma de Mexico, Mexico, ²Universidad Autonoma de Zacatecas, Zacatecas, Mexico..

To assess the effect of heat stress in lactating dairy cows in intensive farming conditions, on ovarian follicular development, a study was carried out with 56 Holstein cows located in different farms in the state of Aguascalientes, Mexico. Daily ultrasound observations of both ovaries were performed between two estrous cycles. Average production of the herds was around 9500 kg per cow per year and studied cows were cycling regularly and had 71.2 ± 17.9 d in milk. Measurements were taken at four different times of the year according to temperature-humidity index 60 days prior or during the studied cycle. Therefore there were stressful (S) or neutral (N) conditions before or during evaluation: SN (n = 24), NN (n = 11), NS (n = 11) and SS (n = 10). The variables studied were: number of follicular waves per cycle (FW: 1, 2, and 3); maximum diameter of the dominant follicle (DF) in each wave (DDF, mm); growth rate of each DF (GRDF: 1 - first dominant follicle and 2 - second dominant follicle, mm/d); and growth length of each DF (GLDF, d). Data were analyzed by least square analysis of variance. Chi-square was utilized for analysis of proportions. In NN the DDF of FW1 was larger (20.9 ± 0.6 , $P < 0.05$) than in the other groups (SN, 19.1 ± 0.6 ; NS, 18.0 ± 0.8 ; SS, 18.6 ± 0.9). In FW2, the DDF of NS (16.9 ± 0.7) and SS (16.7 ± 0.8) were smaller ($P < 0.05$) than those of the SN (18.9 ± 0.6) and NN (19.2 ± 0.8). There were no differences in GRDF1 between groups ($P < 0.05$); however GRDF2 in SS (2.2 ± 0.3) was larger than in the other groups (SN, 1.4 ± 0.2 ; NN, 1.5 ± 0.3 ; NS, 1.3 ± 0.3) and had GLDF shorter (4.7d, $P < 0.05$) than SN (8.6d), NN (9.1d) or NS (7.1 d). Estrous cycles in SS group had more FW (2.6) ($P < 0.05$) than the rest. In SS + NS, in 36% of the cycles the ovulated follicle was of FW3 while this occurred in 9.1% of the cycles of NN+SN ($P < 0.05$). Thermal-humidity stress induces shorter periods of follicular growth and dominance and increases estrous cycles of three follicular waves, which may be related with lowered fertility in the warmer seasons of the year.

Key Words: follicular development, dairy cow, Mexico

139 Expression of insulin-like growth factor-binding protein-2, -3, -4, and -5 messenger RNA in fresh versus cultured bovine granulosa and theca cells. J.L. Voge*, D.T. Allen, J.R. Malayer, and L.J. Spicer, *Oklahoma State University.*

The objective of this study was to determine the presence of messenger RNA (mRNA) for IGF-binding protein (IGFBP)-2, -3, -4, and -5 in fresh versus cultured bovine granulosa and theca cells. Granulosa cells (GC) from small follicles (1-5 mm) and theca cells (TC) from large follicles (>7.9 mm) were collected from cattle and RNA isolated either before or after in vitro culture. For in vitro derived RNA, GC and TC were cultured for 2 d in medium with 10% fetal calf serum and an additional 2 d in serum-free medium. RNA from fresh and cultured cells was isolated using the Trizol extraction method. The presence of mRNA for IGFBP-2, -3, -4, and -5 was assessed using reverse transcriptase-PCR. IGFBP-2 mRNA was detected in 2 of 2 fresh and 4 of 5 cultured GC samples, and in 2 of 2 fresh and 4 of 6 cultured TC samples; the proportion of TC (85.7%) and GC (75%) samples that had detectable IGFBP-2 mRNA did not differ ($P > 0.50$, chi-square). IGFBP-3 mRNA was not detectable in either fresh or cultured GC, whereas IGFBP-3 mRNA was detectable in all fresh and cultured TC samples ($P < 0.005$). IGFBP-4 mRNA was expressed in 1 of 2 fresh GC samples and 3 of 5 cultured GC samples. IGFBP-4 mRNA expression was found in all fresh TC samples and in 4 of 6 cultured TC samples; the proportion of TC samples (87.5%) that had detectable IGFBP-4 mRNA tended to be greater ($P < 0.10$) than that of GC samples (42.9%). IGFBP-5 mRNA was detected in 1 of 2 of the fresh and 3 of 5 of the cultured GC. All of fresh TC and 4 of 6 cultured TC samples had IGFBP-5 mRNA; the proportion of TC (75%) and GC (57%) samples that had detectable IGFBP-5 mRNA did not differ ($P > 0.25$). These results indicate that IGFBP-3 may be produced by TC and not GC, whereas IGFBP-2, -4, and -5 are produced by both TC and GC. Furthermore, in vitro culture had no effect on whether or not IGFBP-2, -3, -4, and -5 mRNA was expressed in small GC or large TC.

Key Words: Insulin-like Growth Factors, Binding Proteins, Ovarian Follicles

140 Insulin plays a key role in re-coupling the IGF-somatotropin axis in the early postpartum dairy cow. S.T. Butler* and W.R. Butler, *Cornell University, Ithaca, NY.*

Negative energy balance associated with the onset of lactation results in hypoinsulinemia, uncoupling of the IGF-somatotropin axis, attenuation of gonadotropin release and delayed first ovulation. Our objectives were to examine the effects of elevated insulin during the immediate postpartum period on circulating IGF-I concentrations, ovarian follicular growth, estradiol secretion and LH pulse profiles. Holstein cows (n=14) were subjected to either a hyperinsulinemic-euglycemic clamp (INS) or saline infusion (CTL) for 96 hours starting on day 10 post-calving. Blood samples were taken on days 8-9 to establish baseline glucose values. Insulin was infused continuously (1 µg/kg BW/hr) via a jugular catheter. Blood samples were collected hourly, and euglycemia was maintained by infusion of exogenous glucose. During infusion, insulin concentrations were increased 8-fold in INS cows over those in CTL cows (2.4 ± 0.1 vs. 0.3 ± 0.1 ng/ml; P<0.001), while blood glucose concentrations were not different between the treatments (45.4 ± 2.2 vs. 41.7 ± 2.3 mg/dl; P=0.27). Plasma IGF-I increased continuously during the insulin infusion, and reached the highest values at the end of the clamp, being almost 4-fold higher in INS compared with CTL cows (122 ± 11 vs. 33 ± 2 ng/ml; P<0.001). Ultrasound measurements of ovarian follicular growth revealed that 2 cows ovulated, both of which were CTL cows. Among non-ovulatory cows, the dominant follicle reached a greater maximum diameter in the INS cows compared with CTL cows (13.4 ± 0.5 vs. 11.6 ± 0.6 mm; P=0.04). Excluding ovulatory cows, no difference in plasma estradiol was observed between groups during the infusion period (1.3 ± 0.2 vs. 1.1 ± 0.3 pg/ml; P=0.69). Blood samples collected every 10 minutes for 8 hours prior to and at the end of the infusion periods showed no differences between groups in LH pulse frequency, pulse amplitude or area under the curve. In conclusion, insulin appears to be a key metabolic signal in coupling the IGF-somatotropin axis, orchestrating the observed marked elevation in circulating IGF-I.

Key Words: Insulin, IGF-I, Ovary

141 Postpartum nutrition influences concentrations of leptin, IGF-I, and pregnancy rate of primiparous beef cows. N. H. Ciccio¹, R. P. Wettemann¹, L. J. Spicer¹, D. H. Keisler², C. A. Lents¹, and F. J. White¹, ¹Oklahoma Agricultural Experiment Station, Stillwater, ²University of Missouri-Columbia.

The influence of nutrition on plasma concentrations of leptin and IGF-I and reproductive function was determined at the first estrus in Hereford x Angus spring calving primiparous cows. At parturition, cows (BCS = 4.3 ± 0.1; BW = 385 ± 17 kg) were blocked by BCS and calving date and randomly assigned to gain 0.45 (M; n = 17) or 0.90 (H; n=17) kg/d for 11 wk. Then, all cows were fed the same (M) diet until the first estrus. A second replication was added to assess pregnancy rate (M; n = 13; H; n=17). Leptin and IGF-I were quantified weekly and progesterone thrice a week in blood plasma. Estrous behavior was detected with Heatwatch[®] and ovulation was determined using plasma progesterone. The dominant follicle was measured by ultrasonography at 4 to 14 h after onset of estrus. All cows were AI between 12 and 20 h after onset of estrus. During treatment, H cows gained (P < 0.01) BW

and BCS and had greater (P < 0.01) concentrations of leptin and IGF-I compared with M cows. From the end of treatment to first estrus, concentrations of IGF-I were greater (P < 0.01) in H cows; however, concentrations of leptin decreased (P < 0.01) in H cows after treatment termination and did not differ (P = .16) from those of M cows through the first estrus. Cows that exhibited estrus and ovulated on or before 19 wk postpartum had greater (P < 0.06) concentrations of leptin on wk 13 to 15 than anestrus cows. During treatment, leptin and IGF-I concentrations were positively correlated (P < 0.05) with changes in BW and BCS. H cows had a larger (P < 0.05) dominant follicle, more mounts (P < 0.06), and a shorter (P = 0.06) interval to estrus than M cows. Pregnancy rate at the first postpartum estrus was greater (P < 0.01) for H (n=34; 82.3 %) than for M (n=30; 60 %) cows. We conclude that increased nutrient intake after calving results in increased concentrations of IGF-I in plasma, and increased follicle size and pregnancy rate at the first estrus.

Key Words: IGF-I, Leptin, Reproduction

142 Concentrations of leptin and insulin like growth factor-I (IGF-I) during acute nutritionally induced anovulation and realimentation. F.J. White^{*1}, C.A. Lents¹, N.H. Ciccio¹, R.P. Wettemann¹, L.J. Spicer¹, and D.H. Keisler², ¹Oklahoma Agricultural Experiment Station, Stillwater, ²University of Missouri, Columbia.

Luteal activity and concentrations of leptin and IGF-I were evaluated during acute nutritional restriction and realimentation of beef heifers. Angus x Hereford heifers (14 mo old; n=19) were housed in individual pens and fed a diet supplying 1.2 x maintenance (M) for 1 wk. Then heifers were randomly allotted on d 0 to either 0.4 or 1.2 M. Heifers were treated with PGF2α on d -10, 0, and 10 to synchronize ovulation. After 30 d, 0.4 M heifers were gradually increased to 1.2 M during 10 d. Blood was collected 23 h after feeding on alternate days during restriction and 3 x per wk during 100 d realimentation. Heifers with progesterone <0.5 ng/mL for 8 d were classified as anovulatory. Seventy percent (7 of 10) of 0.4 M heifers did not ovulate on d 14 while all 1.2 M heifers had normal luteal function. Plasma IGF-I in 0.4 M heifers decreased from 49 ± 3 ng/mL on d 0 to 33 ± 4 ng/mL on d 14; however, 1.2 M heifers had similar concentrations on d 0 and 14 (57 ± 3; day x diet effect, P < .01). During restriction, heifers on 0.4 M tended (P = 0.1) to have decreased concentrations of leptin (14 % less) in serum compared with 1.2 M. Five of the anovulatory heifers had luteal activity by 16 to 51 d of realimentation at 1.2 M (mean = 35 d); however, two heifers did not ovulate by 100 d. Realimentation with 1.2 M for 2 wk increased concentrations of IGF-I in 0.4 M heifers (day x diet effect, P < 0.05) to concentrations similar to 1.2 M heifers. During realimentation, concentrations of leptin in blood samples taken after 23 h of fasting were similar (P > 0.1) in 0.4 and 1.2 M heifers. Concentrations of IGF-I in plasma decreased with acute nutritionally induced anovulation and were similar to those in control heifers (1.2 M) by 2 wk of realimentation at 1.2 M. Systemic concentrations of IGF-I were more indicative of nutritional status than concentrations of leptin in these acute nutritionally restricted heifers.

ASAS/ADSA Ruminant Nutrition: Feed Additives

143 Influence of length and ramification of the alcohol radical of esters of methionine and of 2-hydroxy-4 (methylthio) butanoic acid on methionine bioavailability. J.C. Robert^{*1}, B.K. Sloan², G. Etave¹, and B. Bouza¹, ¹Aventis Animal Nutrition, Antony, France, ²Aventis Animal Nutrition, Alpharetta, USA.

In a series of five experiments, Methionine bioavailability from 8 DLmethionine and 3 HMB esters were tested according to the blood kinetics method based on determining the Area Under the Curve (AUC). The alcohol radical varied in number of carbons but all were arranged in a linear form. SmartamineTM M (a methionine coated with a pH sensitive polymer based coating) of which the methionine bioavailability is 80%, was used as a reference. Non lactating rumen cannulated Holstein cows, receiving 10 kg / animal / day of a ration comprising 75% hay and 25% concentrate delivered in equal quantities twice a day, were used. A single dose, 50 g of methionine equivalent, was supplied directly

into the rumen at 0800 on day two (D2) for the esters and at 1600 on day one (D1) for SmartamineTMM. Blood samples were obtained, on D2 at 0900,1000, 1100, 1300, 1500h and, thereafter, every three hours from 0900 to 1500h on D3 and D4. For SmartamineTMM, blood samples were collected every two hours on D2, starting at 0600 until 1000h and, thereafter, every three hours on D3 and D4 from 0600 until 1500h. Blood plasma methionine concentration (BPMC mg/100g) for base line determinations were measured on D1 at 0900,1100 and 1500h. Modelization of the AUC results for BPMC for the 11 esters resulted in the following relationship : Y = 40.6787 exp.(-0.2272 X)(R² = 0.89)(SED =6.13) Y = bioavailability as a percentage of methionine equivalent ingested. X = alcohol carbon number. It shows that methionine bioavailability decreases with increasing number of carbons in the alcohol. Three esters with branched alcohol radicals were tested vs. their corresponding linear forms using the same methodology described above. In all cases, methionine bioavailabilities with the corresponding branched alcohol were higher.

Products	Alcohol carbon numbers	Branching	Methionine bioavailability (%)
Methionine n-propyl ester	3	1	20.7
Methionine isopropyl ester	3	2	43.9
Methionine n-butyl ester	4	1	7.9
Methionine sec.-butyl ester	4	2	28
HMB n-butyl ester	4	1	17
HMB sec.-butyl ester	4	2	31

Key Words: Methionine, Bioavailability, Chemical derivatives

144 Investigation of the site of absorption and metabolism of a novel source of metabolisable methionine: 2 hydroxy 4 (methyl thio) butanoic acid isopropyl ester (HMBi). J.C. Robert*, C. Richard, T. D'Alfonso, N. Ballet, and E. Depres, *Aventis Animal Nutrition, Antony, France.*

In 2 tests, HMBi was delivered in a single dose, 50 g of methionine equivalent directly into the rumen. Two and four non lactating rumen cannulated Holstein cows were used in trials 1 and 2, respectively. They were offered 10 kg/cow/day of a ration comprising 75% hay and 25% concentrate delivered in 2 equal meals. Blood samples were obtained after supplementation at intervals of about 2h except in trial 2 where, during the interval 0-2h, more frequent blood samples were taken. Blood plasma HMB (BPHC) and blood plasma methionine concentrations (BPMC) were measured. In the two tests, a peak of HMB was observed (1h) followed by a methionine peak (4h) relative to ruminal delivery of HMBi. The appearance of HMB and methionine in plasma were found to be best described by a gamma function $Y = a + bX \exp(-cX)$ ($Y = \text{BPC}$ and $X = \text{hours post-supplementation}$). In trial 2, more frequent measurements during the 1st hour showed the virtually immediate appearance of HMB in peripheral blood after HMBi supply to the rumen. BPHC, zero before supplementation, rose quickly 1.41-1.73-2.05 mg/100g at times 10,20,30 min after supplementation. In parallel, BPMC increase from 0.35 to 0.45,0.66 and 0.83 mg/100g at the same times. This indicates HMBi is being absorbed through the rumen wall, subsequently dissociates to give HMB which is ultimately transaminated into methionine.

Assay	Meta-bo-lites	Intervals of time (h)	Peak hours	Max BPC (mg/100 g)	$y = a + bX \exp(-cX)$		
					Coefficients	R ²	SED
1	HMB	0 ≥ 10	1.3	1.48	a=0 b=3.13 c=0.7790	0.99	0.08
	Methio-nine	0 > 25	4.3	3.26	c=0.231	0.98	0.24
2	HMB	0 ≥ 24	1.3	2.64	c=0.7631	0.78	0.79
	Methio-nine	0 > 24	4.4	2.16	a=0.2850 b=1.1556 c=0.2267	0.93	0.22

Key Words: Methionine, Rumen absorption, Chemical derivative

145 Feeding 2-hydroxy-4-(methylthio)-butanoic acid to transition dairy cows improves milk production but not hepatic lipid metabolism. M. S. Piepenbrink*¹, A. L. Bork¹, M. R. Waldron¹, T. R. Overton¹, M. Vazquez-Anon², and M. D. Holt², ¹Cornell University, Ithaca, NY, ²Novus International, Inc., St. Louis, MO.

Forty-eight Holstein cows entering second or later lactation were utilized to determine the effects of 2-hydroxy-4-(methylthio)-butanoic acid

(HMB; Alimet[®] feed supplement, Novus International, Inc. St. Louis, MO) on milk production and hepatic lipid metabolism during the transition period. Cows were fed one of three diets as TMR starting 21 d before expected calving. These diets contained 0 (CON), 0.1 (+HMB), or 0.21 (++)HMB% HMB. From parturition to 84 DIM, cows were fed diets that contained 0, 0.15, or 0.23% HMB. The CON diets were formulated to be low in Met (1.98 and 1.77% of MP for pre- and postpartum diets) but adequate in Lys (7.23 and 7.00% of MP for pre- and postpartum diets). Prepartum (12.9, 12.8, 12.7 kg/d) and postpartum (18.6, 19.8, 19.7 kg/d) DMI were similar among cows fed CON, +HMB, and ++HMB ($P > 0.20$). Feeding +HMB increased milk yield (42.0, 45.0, and 42.0 kg/d for CON, +HMB, ++HMB; P (quadratic) < 0.05). Percentages of fat, protein, and total solids in milk were not affected by treatment. Trends ($P < 0.15$) for increased yields of 3.5% FCM, lactose, and total solids by cows fed +HMB were related to milk yield. Differences in plasma NEFA (495, 514, 446 $\mu\text{Eq/L}$) and β -hydroxybutyrate (13.72, 12.04, 11.92 mg/dl) were not significant ($P > 0.25$). Liver triglyceride content was similar on d 1 postpartum (7.24, 6.61, 6.75%) and was increased for +HMB on d 21 postpartum [(8.87, 13.68, 11.07%) treatment \times d; $P < 0.04$]. Differences in rates of [¹⁻¹⁴C]palmitate oxidation [27.9, 23.7, 25.4 nmoles/(hour \times g wet weight)], and formation into stored esterified products [318, 316, 338 nmoles/(hour \times g wet weight)] were not significant. The data suggest that adding HMB to low Met but adequate Lys diets at 0.1% prepartum and 0.15% postpartum is beneficial for increasing milk production. The underlying mechanism does not appear to be associated with hepatic lipid metabolism as measured in this experiment.

Key Words: HMB, Methionine, Liver

146 Use of milk protein concentrations to estimate the "methionine bioavailability" of two forms of 2-hydroxy-4-methylthio butanoic acid (HMB) for lactating cows. C. G. Schwab*¹, N. L. Whitehouse¹, A. M. McLaughlin¹, R. K. Kadariya¹, N. R. St-Pierre², B. K. Sloan³, R. M. Gill³, and J. C. Robert⁴, ¹University of New Hampshire, Durham, ²The Ohio State University, Columbus, ³Aventis Animal Nutrition, Alpharetta, GA, ⁴Aventis Animal Nutrition, Antony, France.

Forty multiparous Holstein cows (58 to 167 DIM) were assigned randomly to a balanced split-plot 5 \times 5 Latin square design involving two replicates of four squares. Experimental periods were 14 d with the last 7 d for measurements. Each square consisted of five concentrations of a single methionine (Met) source in a Met-deficient diet. The four Met sources were: 1) Smartamine M-TM (SmM, Aventis Animal Nutrition), 2) HMB, 3) the isopropyl ester of HMB (HMBi), and 4) a combination of HMB and HMBi (HMB/HMBi). Treatment levels were (g Met equivalents/d per 25 kg of DMI): SmM (0, 10, 15, 20, and 25), HMB and HMBi (0, 15, 20, 25, and 30), and HMB/HMBi (0/0, 5/10, 8.3/16.7, 11.7/23.3, and 15/30). Because treatment levels within source were not spaced equally, appropriate orthogonal coefficients were generated using PROC IML of SAS. Corrected LSM for milk protein percentages were: SmM (2.99, 3.08, 3.15, 3.15, and 3.13; quadratic effect, $P < 0.01$), HMB (3.04, 3.02, 3.03, 3.06, and 3.03), HMBi (3.05, 3.11, 3.16, 3.17, and 3.19; linear effect, $P < 0.001$), and HMB/HMBi (3.07, 3.13, 3.12, 3.16, and 3.18; linear effect, $P < 0.001$). Inspection of the LSM indicated that a broken line model of response to Met sources was more adequate than smooth function models. Thus, PROC NLIN of SAS was used to identify the optimum level of supplementation (breakpoint) and the slope of the dose-response relationships prior to breakpoint for SmM, HMBi, and HMB/HMBi. Based on differences of slope, and the assumption that 80% of the Met in SmM is available, the bioavailability of Met from HMBi and HMB/HMBi was estimated to be 42% and 34%, respectively. Results indicate that HMB provided little or no Met for milk protein synthesis and that HMBi was 50% or more as effective as SmM.

Key Words: Methionine, HMB, Ruminant

147 Performance of high producing dairy cows fed methionine hydroxy analog or D, L-methionine in a total mixed ration during early lactation. K. Uchida¹, P. Mandevu², C. J. Sniffen^{*2}, C. S. Ballard², and M. P. Carter², ¹Zen-Noh National Federation of Agricultural Co-operative Associations, Tokyo, Japan., ²W. H. Miner Agricultural Research Institute, Chazy, NY.

Effect of feeding two methionine supplements was compared using high producing Holstein cows during early lactation. Pregnant cows housed in a free-stall barn at the Miner Institute in northeastern New York, were blocked and at calving, were assigned randomly to one of two TMR containing a liquid form of methionine hydroxy analog (MHA; Novus Intl., Atlanta, GA), or D,L-methionine (D,L-Met), and group-fed for ad libitum intake. Cows spent 3315 days in the fresh group (FG), after which they were moved to the high producing group (HG) where they stayed up to 8 wk postpartum. The TMR had on DM basis a forage to concentrate ratio of 40 to 60% for FG cows with predicted DMI of 21.7 kg/d, and 42 to 58% for HG cows with predicted DMI of 26.5kg/d. All TMR contained on DM basis 33% NDF and 18% CP. The TMR were formulated using the CPM Dairy# model to meet the methionine and lysine factorial requirement, and the methionine and lysine ratios of 2.20 and 6.89% of metabolizable protein, respectively. The concentrations of methionine and lysine, respectively, in all TMR were 0.25, 0.75 (% of DM). In order to provide the same amount of methionine postruminally from the two methionine supplements, cows fed TMR containing MHA and D,L-Met, respectively, were fed approximately 14.2 g of MHA and 25.7 g of D,L-Met for FG and 17.1 g of MHA and 31.0 g of D,L-Met for HG, assuming a rumen escape value of 40% for MHA and 22% for D,L-Met. The average daily DMI by the group-fed cows across treatments was 22.5 kg/cow for the FG, and 27.2 kg/cow for HG. Cows that were fed TMR containing MHA and D,L-Met, respectively, had similar ($P>0.18$) milk yield (49.0, 49.8 kg/d; SE=0.32), milk fat (4.03, 4.21%; SE=0.051), milk CP (3.13, 3.21%; SE=0.019), linear SCC (4.08, 4.55; SE=0.072), body condition score (3.17, 3.17; SE=0.019), days to first service (68.7, 65.1; SE=6.61), and first service conception rate (36.9, 35.0%) during wk 1 to 8 postpartum, and different milk fat (3.64, 3.93%; SE=0.07, $P=0.07$) during wk 5 to 8 postpartum. Average milk yield was 45.5 kg during wk 1 to 4 postpartum and 53.3 kg during wk 5 to 8 postpartum. In conclusion, D,L-Met performed as well as MHA in promoting milk yield and contents of milk fat and CP when fed at levels aimed at achieving similar amounts of methionine postruminally as supplied by MHA.

Key Words: dairy cow, methionine hydroxy analog, milk yield and reproductive performance

148 Effect of two levels of crude protein and supplementation of methionine on performance of dairy cows. C. Leonardi^{*1}, L.E. Armentano¹, and M. Stevenson², ¹University of Wisconsin-Madison, ²Degussa Canada Ltd., Ontario, Canada.

Sixteen lactating Holstein cows (4 primiparous and 12 multiparous) were used in a 4 x 4 Latin Square, with periods of 35 days. At the beginning of the study animals averaged 95 DIM and produced 44.5 kg/d of milk. The effect of supplemental methionine at two levels of CP (16.1 vs. 18.8%) was tested. The two levels of protein and methionine supplementation were such that the lower level of CP supplemented methionine was sufficient to cover the requirements of amino acids, according to the Mepron Dairy Ration Evaluator ver. 2.1 (Degussa Huls Corp., Allendale NJ). The high level of protein (HP) was selected to meet the amino acids requirement without the supplementation of methionine. A low protein (LP) diet without methionine was added as negative control and the high protein diet plus methionine (HPM) as a positive control. All four diets contained 16.2% alfalfa silage, 38.6% corn silage, 16.2 % of corn grain, 8.1% soybean roasted, 5.7 % cottonseed, 2% soyplus, 1% blood meal, 0.8% animal fat, and 1.8 % minerals and vitamins mix (DM basis). The remaining 9.6% of the diet was either corn grain plus urea in the low protein diet, or soybean meal in the high protein diet. We anticipated an interaction where low protein responded to methionine more than the high protein diet, but no interactions were significant. The only methionine main effect was an increase in milk protein %, while increased dietary protein decreased milk protein %. Milk fat was depressed across diets. Low dietary NDF (27.2 % of DM), and high levels of vegetable oil (4.5 % fatty acids) may have been the cause of the low milk fat test. These dietary conditions may also have caused microbial protein synthesis to differ from the values predicted by the model used.

A main effect of dietary protein was to elevate milk fat concentration and yield.

149 Effects of rumen undegradable protein digestibility and supplemental methionine on production parameters and nitrogen efficiency of Holstein cows in early lactation. S. Noftsker* and N. St-Pierre, *The Ohio State University.*

A production trial followed by a collection trial was conducted to assess the effects of post-ruminal undegradable protein (RUP) digestibility, metabolizable protein supply and Met supplementation on production efficiency and N utilization of lactating dairy cows in early lactation. Treatments were: 1) 18.5 % crude protein (CP) with low estimated intestinal digestibility RUP (Control); 2) 18.5 % CP with high digestibility RUP (HiCP); 3) 17 % CP with high digestibility RUP (LowCP); and 4) 17 % CP with high digestibility RUP and supplemental Met (LowCP + Met). Thirty-six multiparous and 24 primiparous cows were assigned at random to one of the four dietary treatments 3 weeks post-freshening. At week 13, six cows from each treatment were placed in metabolic stalls for a digestibility study, each cow remaining on the same treatment as during the production trial. Treatments had a significant effect on dry matter intake (21.7, 23.3, 23.2, 23.6; SE = .05 kg/d), milk production (40.8, 46.2, 42.9, 46.6; SE = 0.7 kg/d), protein production (1.20, 1.38, 1.28, 1.44; SE = 0.02 kg/d) and milk protein content (2.95, 2.99, 3.00, 3.09; SE = 0.03 %) for Control, HiCP, LowCP, and LowCP + Met respectively in the production trial. Nitrogen balance results are reported in the following table. Lowering the CP in diets in early lactation in conjunction with selection of RUP sources selected for higher estimated post-ruminal RUP digestibility can improve the efficiency of N utilization. The supplementation of Met did not improve the efficiency of N utilization during the digestibility study, in contrast to what was estimated during the production trial.

Key Words: RUP digestibility, methionine, N efficiency

150 Ruminal escape and response of serum methionine to 25 and 50 grams of methionine hydroxy analog in dairy cows. K. M. Koenig^{*1}, M. Vazquez-Anon², C. D. Knight², and L. M. Rode¹, ¹Agriculture and Agri-Food Canada, Research Centre, Lethbridge, AB, Canada, ²Novus International, Inc., St. Louis, MO, US.

Ruminal escape of various amounts of methionine hydroxy analog [D,L-2-hydroxy-4-(methylthio)-butanoic acid (HMB), Novus International Inc., St. Louis, MO] was measured in an experiment designed as a 4 x 4 Latin square using four lactating dairy cows with cannula in the rumen. The cows were fed a diet composed of corn silage, alfalfa haylage, rolled barley grain, canola meal, and blood meal, three times per day. The cows were fed the liquid analog each day for one week prior to the initiation of the experiment. On the day of the experiment, each

cow received an oral bolus dose of 0, 25, or 50 g of the liquid analog (Alimet[®] feed supplement, 88% HMB) or 51.2 g of a dry calcium salt of the analog (86% HMB; MHA[®]) mixed with 0.5 kg of ground barley grain. After a period of 30 min, any remains of the carrier grain and treatment were placed in the rumen. A liquid phase marker (Co-EDTA) was administered as a bolus dose into the rumen at the time of oral administration of the methionine analogs. Rumen contents and blood serum were collected at 0, 1, 3, 6, 9, 12 and 24 h relative to the time of dosing. Rumen samples were analyzed for Co and HMB, and serum was analyzed for free methionine. Fractional rate constants for the passage of the liquid marker (k_p) and the decline of HMB concentration in the rumen (k_{rHMB}) were determined by non-linear regression. Liquid passage from the rumen was similar among the four analog treatments (0.136 ± 0.022 /h; mean \pm SEM). Ruminal escape of HMB as a percentage of the dose ($100\% \times k_p/k_{rHMB}$) did not differ between cows receiving 25, 50, and 51.2 g of the methionine analogs (42.5, 41.0, and $34.9 \pm 9.0\%$, respectively) and averaged 39.5%. Serum methionine concentration peaked at 3 and 6 h after dosing and increased in proportion to the amount of the analog administered. It was concluded that 39% of the methionine hydroxy analog escaped rumen degradation, the percentage of the dose that escaped the rumen was not affected by the amount or form of the methionine analog fed, and the analog that escaped ruminal degradation was absorbed and metabolized to methionine.

Key Words: HMB, Methionine, Ruminal escape

151 Carbohydrate fermentation and nitrogen metabolism of a finishing diet by ruminal microbes in continuous cultures as affected by ethoxyquin and (or) supplementation of monensin and tylosin. H. Han^{*1}, H. S. Hussein¹, H. A. Glimp¹, D. H. Saylor², and L. W. Greene³, ¹University of Nevada - Reno, ²Solutia Inc., ³Texas A&M University.

Long-term feedlot studies have shown positive effects (i.e., improved ADG and gain/feed; reduced morbidity and mortality) of dietary supplementation with ethoxyquin (AGRADO[®]). This may be due to improving the antioxidant capacity at the ruminal, post-ruminal, or post-absorption levels. This study was designed to investigate the potential antioxidant role of ethoxyquin at the rumen level. A finishing diet (12.5% CP; DM basis) was formulated to contain (on a DM basis) 77.5% flaked corn, 10% corn cobs, 10% protein/vitamin/mineral supplement, and 2.5% animal fat. In a randomized complete block design experiment, the treatments were arranged as a 2×2 factorial. The main factors were 2 ethoxyquin treatments (without or with 150 ppm) and 2 monensin/tylosin treatments (without or with monensin and tylosin at .0028 and .0014% of dietary DM, respectively). Eight dual-flow continuous culture fermenters were used in two experimental periods (blocks; 8 d each with 5 d for adjustment and 3 d for sample collection) to allow for 4 replications for each treatment. No interactions ($P > .05$) were detected for any of the measurements evaluated. Therefore, results of the main factors were summarized. Ethoxyquin supplementation improved ($P < .05$) true digestibility of DM (from 40.7 to 47.1%) and OM (from 38.8 to 45.0%) but it did not alter ($P > .05$) concentrations of total VFA (averaging 131.4 mM) or acetate (averaging 58.8 mM). Ethoxyquin decreased ($P < .05$) propionate concentration from 51.1 to 42.4 mM and increased ($P < .05$) butyrate concentration from 18.4 to 22.9 mM. Digestion of total nonstructural carbohydrates was not altered ($P > .05$) by the treatments and averaged 86%. With the exception of increased ($P < .05$) concentration of propionate (from 42.0 to 51.5 mM) and decreased ($P < .05$) concentration of butyrate (from 25.9 to 16.3 mM), no effects were detected for monensin/tylosin. Ruminal N metabolism including efficiency of bacterial protein synthesis (averaging 21.2 g N/kg OM truly digested) was not affected ($P > .05$) by the treatments. Results suggest positive effects of ethoxyquin on ruminal digestion of DM and OM and unique changes in VFA production.

152 Comparison of different methods of administration on the effect of fibrolytic enzymes on digestive processes in lactating cows. J.D. Sutton^{*1}, R.H. Phipps¹, D.E. Beever¹, D.J. Humphries¹, G.F. Hartnell², and J.L. Vicini², ¹University of Reading, UK, ²Monsanto Co, St Louis, MO.

To clarify the site of action of fibrolytic enzymes extracted from *Trichoderma longibrachiatum*, four multiparous Holstein x Friesian cows with cannulas in the rumen and proximal duodenum were used in a 4 x

4 Latin square experiment with 5-wk periods. From lactation wk 5, the cows were given ad libitum a TMR composed of (DM) 57% forage (3:1 maize silage:grass silage) and 43% concentrates. The TMR contained (g/kg DM): 274 NDF, 295 starch, 180 CP. Treatments were TMR alone (T1) or TMR with the enzymes added (2 g/kg TMR DM) either sprayed on the TMR 1 h before the morning feed (T2), sprayed only on the concentrate the day before feeding (T3), or infused into the rumen for 14 h/d (T4). Xylanase and endoglucanase activities of the enzymes were 26,483 and 2,645 mol.min⁻¹.g⁻¹. There was no significant effect on feed intake (T1-T4: 20.7, 21.1, 20.9, 20.4 kg DM/d, s.e.m. 0.43) or milk yield (34.0, 35.5, 34.5, 35.0 kg/d, s.e.m. 0.52) but both were highest on T2. Rumen digestibility of DM (0.321) and starch (0.843) was unaffected. Digestibility of NDF was lowest on T2 in the rumen (0.449, 0.335, 0.402, 0.492, $P < 0.05$) but highest on T2 post-ruminally (0.090, 0.247, 0.161, 0.006, $P < 0.05$). Total tract digestibility was highest on T2 for DM (0.714, 0.724, 0.707, 0.714, $P < 0.05$) and starch (0.970, 0.977, 0.970, 0.972, $P < 0.05$) but treatment differences were non-significant for NDF (0.503). Maize silage stover passage rate out of the rumen was increased by all enzyme treatments (0.025, 0.030, 0.033, 0.032 h⁻¹, $P < 0.05$) but gut transit time was also increased (12.5, 16.7, 16.1, 15.9 h, $P < 0.05$) so the decline in total tract retention time (61.2, 58.3, 54.5, 55.7 h, s.e.m. 2.57) was not significant. Although inclusion of these enzymes by all three methods altered digesta kinetics, it was only when they were sprayed on the TMR that diet utilisation was improved with higher DM digestibility and a numerical increase in milk yield.

Key Words: Enzymes, Dairy Cows, Forage

153 Effects of liquid feed supplementation and (or) cellulolytic enzymes on dry matter disappearance of either legume or grass hay. G. V. Pollard^{*1}, W. T. Wright¹, T. C. Bramble¹, C. R. Richardson¹, and C. W. Cobb², ¹Texas Tech University, Lubbock, ²Loveland Ind., Inc., Greeley, CO.

The objective of this research was to determine if pH of a suspension liquid feed product and (or) cellulolytic enzyme supplementation increases the digestibility of forage as indicated by in vitro dry matter disappearance (IVDMD). Liquid feed suspensions (32% CP, as fed) and cellulolytic enzymes (CE) were added as aqueous solutions and sprayed directly onto ground (1mm) .5 g samples of alfalfa, wheat, or grass hay. Treatments were negative control (CON); enzyme only (ENZ); liquid supplement, pH 4 (LS); liquid supplement plus enzyme (LE); liquid supplement plus enzyme buffered to pH 5 (LE5). Levels of CE were equivalent to 185 g per 907 kg of forage DM and liquid feed supplement levels were equivalent to intakes of 1 kg as fed/hd/d. The IVDMD of samples was determined following a 24 h incubation in 100-mL in vitro tubes containing 50-mL of a buffer and rumen fluid mixture. Rumen fluid was obtained from a cannulated steer fed a roughage diet. Alfalfa hay samples had greater ($P < .05$) overall IVDMD than either wheat or grass hay samples. Alfalfa hay IVDMD was improved ($P < .05$) by ENZ, LS, and LE, however, alfalfa hay was unaffected ($P > .05$) by LE5. Wheat hay samples were unaffected ($P > .05$) by dietary treatments, however LE5 tended ($P = .09$) to improve IVDMD over CON. Also, ENZ tended ($P = .08$) to have lower IVDMD when compared to LS in wheat hay, and reduced ($P < .05$) IVDMD in alfalfa hay. In contrast, grass hay samples were unaffected ($P > .05$) by either LS or ENZ, while both LE and LE5 improved ($P < .05$) IVDMD. Treatments containing liquid feed supplements and (or) CE resulted in greater overall IVDMD in both alfalfa and grass hay samples. These results indicate that the addition of CE and liquid feed supplements either separately or in combination, improves digestibility of alfalfa and grass forage. However, buffering liquid feed supplements containing CE from pH 4 to pH 5 appears to be unwarranted.

Key Words: Enzymes, Liquid feed, Dry matter disappearance

154 Effects of ruminant feed enzyme additives on digestibility evaluated in vitro. G. R. Bowman^{*1}, K. A. Beauchemin², and J. A. Shelford¹, ¹University of British Columbia, Vancouver, Canada, ²Agriculture and Agri-Food Canada, Lethbridge, Canada.

A study was conducted to determine if fibrolytic enzymes increase feed digestion by ruminants. A revolving digestion incubator and mesh bags (9.5 X 19.5 cm) were used to evaluate the dry matter digestibility (DMD,%) and neutral detergent fiber digestibility (NDFD,%) of a TMR for dairy cows consisting of barley silage and barley grain or the same

TMR treated with a fibrolytic enzyme product (Promote, Agribands Intern., St. Louis, MO). The objectives were: 1) determine whether enzymes improve DMD or NDFD, and 2) establish whether increased digestibility was due to feed-treatment effect or an enhancement of the hydrolytic capacity of the ruminal fluid. Two cannulated lactating Holstein cows were fed a sequence of four TMR: no enzymes (-E), enzymes added to the concentrate portion of the TMR (C+E), enzymes added to the supplement portion of the TMR (S+E), or enzymes added to the premix portion of the TMR (P+E). The same cows served as rumen fluid donors, which was composited by diet. Fresh, unground TMR was incubated in vitro for 12 or 48 h. At 12 h, when rumen fluid from the respective diets was used, -E showed the lowest DMD (41.2^a), followed by S+E (43.2^{ab}), C+E (44.7^b), and P+E (44.8^b). However, there were no differences ($P > 0.05$) among treatments for NDFD at 12 h (20.08±12.0). There was no effect of treatment ($P > 0.05$) at 48 h for DMD (59.83±3.8) or NDFD (40.88±9.3). When the -E TMR was incubated with the various inoculates, there was no improvement in its DMD or NDFD at 12 or 48 h. We did not test the effects of incubating the enzyme-treated TMR in ruminal fluid from cows fed -E. This study indicates that fibrolytic enzymes increase DMD during the early stages of digestion. However, enzyme supplementation has no effect on feed digestibility at longer incubation times, which may indicate that enzymes improve rate, rather than extent, of digestion. Enzymes must be in physical contact with the feed to improve digestibility.

Key Words: Enzyme, Digestibility, in vitro

155 The effect of different levels of yeast culture inclusion in the concentrate diet on calf performance. R.J. Fallon*¹ and B. Earley¹, ¹Teagasc.

The recent banning of a number of in-feed antibiotic digestive enhancers within the European Union has generated the need to find suitable non-antibiotic alternatives. Yeast culture (YeaSacc 1026) as a supplement has been evaluated in several growth studies in calves, steers and bulls. There is however, little information available on the optimum level of YeaSacc 1026 for inclusion in the calf concentrate ration. The aim of this study was to determine the optimum level of YeaSacc 1026 inclusion. The following experiment was undertaken using 80 Friesian male calves (average initial weight of 54 kg) to determine the optimum inclusion rate of YeaSacc 1026 in a barley soyabean meal ration. Calves were allocated at random to 1 of 4 treatments: 1) 0, 2) 0.625, 3) 1.25 and 4) 2.5 kg YeaSacc 1026 per tonne of ration. The concentrate ration was available ad libitum throughout the 84 day experimental period and the calves were offered 25 kg of calf milk replacer by bucket over the initial 42 day period. Calf liveweight gain in the period 1-42 days was 0.58, 0.65, 0.65 and 0.68 (s.e.d 0.029) kg/d for treatments 1 through 4, respectively. The corresponding liveweight gain for the period 1 to 84 days were 0.84, 0.92, 0.92 and 0.89 (s.e.d 0.026) kg/day, respectively. Concentrate intake (1 to 42 day) were 25, 29, 30 and 31 (s.e.d 2.1) kg, respectively the corresponding values for the period 43 to 84 days was 129, 138, 138 and 140 kg. It was concluded that the inclusion of 0.625 or 1.25 kg of YeaSacc 1026 per tonne of ration increased calf liveweight gain by 5 kg in the period 1 to 84 days.

Key Words: Yeast Culture, YeaSacc, Calves

156 The effect of different levels of YeaSacc 1026 inclusion on the lifetime performance of cattle offered an ad libitum concentrate ration. R.J. Fallon*¹ and B. Earley¹, ¹Teagasc.

The recent banning of a number of in feed antibiotic digestive enhancers within the European Union has generated the need to find suitable non-antibiotic alternatives. Yeast culture (YeaSacc 1026) as a supplement

has been evaluated in several growth studies in calves, steers and bulls. There is however, little information available on the optimum level of YeaSacc 1026 for inclusion in the diet on the lifetime performance of bulls offered an ad libitum concentrate diet. The aim of this study was to determine the optimum level of YeaSacc 1026 inclusion. The following experiment was undertaken using 80 Friesian male calves (average initial weight of 54 kg) to determine the optimum inclusion rate of YeaSacc 1026. Calves were allocated at random to 1 of 4 treatments: 1) 0, 2) 0.625, 3) 1.25 and 4) 2.5 kg YeaSacc per tonne of ration using individual bulls as the experimental unit. The concentrate ration consisted of rolled barley, soya bean meal plus minerals and vitamins was available throughout the 329 day experimental period. The crude protein content was 168 g/kg to 12 weeks and 151 g/kg there after. In addition the animals were offered a fixed daily allowance of straw (80g/kg of concentrates). Bull liveweight gain in the period 1 to 168 days was 1.11, 1.14, 1.20 and 1.15 (s.e.d 0.022) kg/day from treatments 1 through 4, respectively. The corresponding liveweight gains for the period 169 to 329 days were 1.32, 1.36, 1.34 and 1.36 (s.e.d 0.043) respectively. The corresponding concentrate dry matter intakes were 548, 562, 583 and 565 for the period 1 to 168 days and 1122, 1161, 1208, 1143 for the period 169 to 329 days. The corresponding carcass weights were 233, 239, 242 and 239 kg. It was concluded that the 1.25 kg/tonne inclusion rate for YeaSacc 1026 resulted in a response in the 1 to 168 day period, but was not significant

Key Words: Yeast Culture, Cattle, Dose Response

157 The effects of feeding a fungal extract (Amaferm) to ewes 60 days prepartum through weaning on milk protein, fat, lactose and yield. S. L. Campbell*, S. P. Jackson, A. D. Herring, M. L. Galyean, and D. R. Niemann, Texas Tech University Lubbock, TX/US.

The objectives of this study were to determine differences in milk protein, fat, lactose and milk yield in ewes either fed whole corn and CSM (control) or the same diet plus Amaferm (AMF), which contains the fungal extract *Aspergillus oryzae*. Sixty-two Rambouillet ewes from ages 3 to 7 yr. were randomly assigned to four pens, and treatments were randomly assigned to each pen. Milk protein, fat, and lactose were measured in milk samples taken at parturition (time 0), 6 h and every 12 h thereafter for the first 36 h and additionally at 3 wk and 6 wk. Milk yield was measured at 3 and 6wk postpartum. Milk yield was not affected by treatment at the 3 or 6 wk milking time. Milk protein decreased linearly through lactation. Percent milk protein was 11.63, 10.99, 9.19, 7.06, 6.38, 5.12, and 5.12 at time 0, 6 h, 12 h, 24 h, 36 h, 3 wk, and 6 wk, respectively. Percent milk fat increased from 8.50 at time 0 to 9.69 at 6 h, then decreased to 8.75 by 36 h., and 5.06 at 3 wk., but increased to 5.34 by 6 wk postpartum. Percent milk lactose increased linearly through lactation (3.28, 3.54, 3.90, 4.33, 4.46, 5.37, and 5.31 at time 0, 6h, 12 h, 24 h, 36 h, 3 wk, and 6 wk, respectively). There were no differences in milk protein between ewes fed AMF or the control diet over the entire lactation, but there was a trend at 6 h, suggesting the control group had a slightly higher milk protein content ($P = .06$) than the AMF group. Ewes on AMF had higher milk fat than ewes on the control diet at 0 h. ($P = .004$) and 3 wk ($P = .02$) and tended to have higher milk fat at 6 h ($P = .10$). Milk lactose was lower in ewes consuming AMF at 6 h. ($P = .02$) and tended to be lower at 12 h ($P = .08$) than for ewes in the control group. In this study, Amaferm addition to the diet did not affect milk yield, but it increased milk fat and decreased milk lactose at certain stages of lactation.

PSA Environment and Management: Broilers

158 Impact of Aflatoxin in the feed on Coccidial infection in broiler chicks. V.G. Stanley¹, D. Spiller*¹, W. Kruger², and A. Sefton³, ¹Prairie view A&M University, ²Texas A&M University, ³Alltech, Guelph Canada.

An experiment was conducted to examine the effects of aflatoxin on male broiler chicks infected with *Eimeria acervulina*. The experimental design was a 2 x 2 factorial, consisting of two levels of aflatoxin (0; 3 mg/kg) and two levels of coccidia (0; 500,000 oocysts/chick). Chicks

were fed an aflatoxin-treated or non-aflatoxin-treated diet (control) from 1 d of age through 28 d of age. At 14 d of age, the chicks were infected with *Eimeria acervulina*. At 14 d post-infection the effects of treatments were assessed on weight gains, relative organs (liver, pancreas, gizzard, proventriculus, heart and cecal) weights, and gross lesion scores. Blood was collected for serum chemistry values, and enzyme activities. Weight gain in chicks fed the aflatoxin-treated diet infected with *E. acervulina* was significantly lower ($P < .05$) than the control by 26.8 percent. Chicks fed an aflatoxin-treated diet had a 20.46 percent

reduction in weight gain, whereas those infected with the coccidia only had 19.12 percent reduction in weight gain. Combined effects of aflatoxin and coccidiosis significantly increased the relative weight of the liver, gizzard, and the serum concentration of triglycerides. The toxicity of aflatoxin and coccidiosis was expressed mainly through decreased serum concentration of uric acid, albumin, total protein, cholesterol and the activity of alanine aminotransferase. Significant increase in relative cecal weight was seen in both aflatoxin and coccidiosis treatments. Intestinal lesion scores were observed in both groups, but were more severe in the chicks fed aflatoxin and later infected with coccidia. It was concluded that coccidial infection was intensified by the presence of aflatoxin in the feed.

Key Words: Chicks, Aflatoxin, Coccidiosis

159 The impact of methionine source on poultry fecal matter odor volatiles. C. Chavez*¹, T. P. Niemeyer¹, P. L. Reynolds¹, R. A. Russo¹, R. E. Lacey², and J. B. Carey¹, ¹Department of Poultry Science, Texas A&M University, College Station, TX, ²Department of Agricultural Engineering, Texas A&M University, College Station, TX.

Trials were conducted using straight run broiler chicks raised in battery cages. Chicks were randomly distributed into 3 replications of 4 treatment groups with 16 birds per pen. The treatment groups were dry methionine hydroxy analogue (52% methionine activity), sodium methionine aqueous solution (45.9% methionine activity), liquid methionine hydroxy analogue (89% methionine activity), and no supplemental methionine (control group). All diets were formulated to contain 3,135 Kcal ME/kg, 23% crude protein, 0.8% total methionine activity and otherwise met NRC nutrient requirements. Diets were fed *ad libitum* from day 1 to termination of the study (5-6 weeks). Feed consumption and feed conversion were measured daily and all birds were weighed weekly. There were no significant differences in body weight, feed consumption, and feed conversion among the treatments in any trials. All excreta was collected in litter pans lined with aluminum foil. Weekly, litter pans for each pen were individually transferred to a separate room for odor volatile analysis. A Cyranose 320[®] (Cyranose Sciences, Inc., Pasadena, CA) electronic nose was used to capture 3 to 4 air samples from various locations for each pan of broiler excreta resulting in a total of 10 air samples from each treatment group. All data taken from the Cyranose 320 were evaluated using principal component analysis and indicated that there were significant differences in volatiles in the broiler excreta for all treatment groups. These data indicate that different methionine sources may result in the production of different odor related compounds in broiler excreta.

Key Words: Methionine, Broiler excreta, Odor

160 Impact of Farm Management Practices on the Microbial Profile of Processed Broilers. Marcos Sánchez*¹, Wade Fluckey, Mindy Brashears, Eva Wallner-Pendleton, Marcela Tamayo, Adriana Aguilar, and Shelly Mckee, ¹University of Nebraska-Lincoln, Lincoln, NE.

Bacterial loads on birds coming into the processing plant impact the presence of pathogens on processed broilers. Conditions during growout including farm management practices, water source and environmental parameters were investigated. Four farms were tested every 3 months over a 1 year period. Farms were evaluated based on survey data and microbial testing. Farm surveys examined building and age condition, litter management, house ventilation, routine sanitation between flocks, biosecurity measures, bird density, bird strain, vaccination history, incidence of disease and mortality, growing season temperatures, water source and water system conditions. In addition, airflow readings, ammonia levels, water activity, relative humidity and house temperature were determined for each house tested. Drag swab (DS) samples of litter and ceca samples from birds were aseptically obtained to determine levels of pre-harvest contamination with pathogens. Sampling locations were determined by differentiating between wet and dry areas of the litter based on water activity readings. DS and ceca samples were tested for *Salmonella*, *Campylobacter*, aerobic populations, coliforms and generic *E. coli*. Results suggested that water activity in the litter, airflow in the poultry house and water source appeared critical to controlling microbial levels on the farm. Open pond water as a drinking source for birds was correlated to higher levels of *Salmonella* and *Campylobacter* on the farm and in the processing plant. DS and ceca

samples obtained in areas of high Aw on the farm had higher bacterial populations and a higher incidence of pathogens. High numbers of pathogens on farms were equated to a higher incidence of *Salmonella* and *Campylobacter* on broilers when sampled during processing. These data suggest that improving environmental conditions and management practices may enhance the safety of birds supplied to the processing facility.

Key Words: Poultry farm management, *Salmonella*, *Campylobacter*

161 Estimation of the growth potential of six commercial strains of broiler chickens. M. J. Zuidhof*¹, D. Eisenbart¹, Z. Wang¹, and G. Hinse², ¹Alberta Agriculture, Food and Rural Development, ²University of Alberta.

In order to model the growth of any animal, there must be an appropriate description of the type of animal being grown. A study was conducted to determine the growth potential of six strains of commercial broiler chickens. Gompertz growth parameters were determined for males and females of each strain. An assumption of the Gompertz model is that the birds must be able to achieve their genetic potential for growth. Therefore utmost care was taken to ensure that ideal environments were provided. Careful attention was spent to ensure appropriate temperatures, pen hygiene, nutrition, and other potential environmental constraints to growth were eliminated. A total of 984 (82 males and 82 females) of six strains of broilers were placed at 0 d of age and reared to 16 wk. Every week from 0 to 8 wk, and every second week thereafter, two birds closest to the mean body weight of each strain by sex combination were dissected and carcass composition was determined on the plucked empty (feed removed from gut) carcasses by chemical analysis. Gompertz parameters are reported as asymptotic weights (Wmax) and rates of maturing (b) expressed in the units g and d⁻¹, respectively. Body weight asymptotes ranged from 2679 to 2950 for the females (b = 0.0461 and 0.0427, respectively) for females, and from 3385 to 3811 (b = 0.0417 and 0.0396, respectively) for males. Protein asymptotes ranged from 341 to 393 g in females and 466 to 514 in males (b = 0.0493, 0.0396, 0.0446 and 0.0423, respectively). Fat asymptotes ranged from 17.7 to 21.7% of the mature weight asymptotes in females, and from 13.9 to 16.2% in males.

Key Words: Gompertz, Growth model, Broiler strains

162 Temperature gradients in trailers transporting broilers under Canadian winter conditions. T.D. Knezacek*, G.P. Audren, H.L. Classen, E.M. Barber, T.G. Crowe, and S. Stephens, University of Saskatchewan, Saskatoon, SK, Canada.

Five commercial scale broiler transport trailers, using Anglia Autoflow modules, were monitored under Canadian winter conditions to investigate the development of horizontal and vertical temperature gradients during transportation. Five evenly distributed stacks of modules were each equipped with nine data loggers recording the temperature and relative humidity of the microenvironment at one-minute intervals. In one stack of modules, loggers were placed in each of the top, middle and bottom rows of crates to determine the vertical temperature gradients. Horizontal temperature gradients were recorded in each of these rows by placing loggers in the center of the middle crate and at the extreme edges of the outside crates. Temperature heterogeneity was found among modules in all loads with average temperatures ranging from -2 to 18, -4 to 19, -4 to 18, -4 to 21, and -2 to 26 C for journey lengths of 155, 171, 152, 184, and 229 minutes and ambient temperatures of -7, -11, -13, -10, and -9 C, respectively. Temperatures within the modules increased 5-35 C above ambient recordings due to low levels of passive ventilation on the tightly tarped trailers. Loggers along the rear outside edges of the trailer recorded temperatures closest to ambient conditions, indicating that air entered in this area. Horizontal temperature gradients, from tarp to tarp, and vertical temperature gradients between the roof and floor of the trailer were generated. However, the degree of variation was dependent upon the ventilation configuration, which was altered according to ambient temperature. In conclusion, the results suggest that passively ventilated transport trailers expose broilers to less than optimum microenvironments, with the greatest imposition occurring along the rear outside edges of the trailer.

Key Words: Broiler, Transportation, Temperature Gradients

163 Effect of cyclic heat stress on voluntary water consumption, Efficiency of feed utilization and thyroid activity of broiler chicks. Miriam ELDeeb*¹ and A. Abou-Elmagd², ¹College of Agriculture, ²College of Vet. Medicine.

The effect of cyclic heat stress temperature (24-35-24°C) on voluntary water consumption and efficiency of feed utilization as well as microscopic structure of thyroid gland were studied in broiler chicks growing on litter from hatch till 6 wk-old. Results indicated that heat stress chicks markedly increased ($P \leq .01$) voluntary water consumption (ml/kg BW^{0.75}) over the control during growing period (3-6 wk-old). Water:feed ratio indicated higher ($P \leq .01$) ratio for birds subjected to 7h. daily heat stress 35°C at both periods; 3 and 6 wk-old. Body weight of chicks subjected to heat stress was significantly ($P \leq .01$) lowered by about 24.6% at 6 wk-old. Consequently, overall reduction in body gain during exposure to heat stress was about 25.2%. The depression in body gain of broiler were 5 and 42g/ bird/ 1°C from 24-35°C at 3 and 6 wk-old, respectively. Also, feed consumption were reduced in heat stress birds by about 10.3 and 48.5g/ bird/ 1°C above the control at 3 and 6 wk-old, respectively. Hence, feed conversion ratio was significantly ($P \leq .01$) decreased clearly at 6 wk-old. The percentage of abdominal fat was significantly ($P \leq .05$) reduced in birds subjected to heat stress. Neither, RBC count nor Hb was affected by heat stress. Furthermore, total moisture and expressible fluids in breast muscles; pectoralis major and minor were not influenced by heat stress treatment. Microscopic examination and morphometric measurements revealed remarkable decrease in the thyroid activity after 6 week exposure to the heat stress compared with the control group. The reduction in thyroid activity was represented by significant increase in the area percentage of follicular colloid in treated group (24.1±3.07) than that in control group (6.9±3.35), and decreased in follicular epithelium percentage in treated group (36.5±5.46) compared with control group (68.6±7.15). Additionally, the area percentage of the large follicles significantly increased ($P \leq .01$) as well as the area percentage of small follicles significantly decreased ($P \leq .01$) at end of the experiment in comparison with that in the control group. In conclusion, heat stress exposure resulted in lower activity of the thyroid gland that may be responsible for lower performance of broiler chicks.

Key Words: broiler chicks, heat stress, thyroid activity

164 Sources of Salmonellae in typical Delmarva broiler operations. J. deGraft-Hanson*, E. LaBreque, A. Dorsey, A. Evangelista, R. Porreca, and L. Baker, *University of Maryland, Princess Anne, Md. USA.*

Two typical broiler houses on Delmarva were sampled every two weeks beginning at placement and continuing to processing. The objective was to determine animate and inanimate sources of salmonellae in the grow-out system. Samples collected included feed, litter, drag swabs, drinking and outside standing water, beetles, flies, flying insects, boot swabs, feces from chickens, animals, wild birds and chick pads. All samples were pre-enriched in BPW, selectively enriched in TTH and RV broths, isolated on XLT4, MLIA and BGSA, screened biochemically on TSI and serogrouped for confirmation. When chick pads were positive there was a tendency for the flocks to be positive throughout the life cycle as evidenced by positive litter, drag swabs and chicken feces. Beetles and flies were also positive on occasion. Outside samples that were positive were water, mud, animal and bird feces. Of an average number of 70 samples per visit positive samples ranged from 0 to 88%. When chick pads were negative, flocks usually had low levels of salmonellae. The higher the number of positive chicken feces the more the positive samples taken inside the houses. Negative inside samples at placement indicated effective cleaning of houses between flocks. In the processing plant, crates and carcasses were positive with carcasses ranging from 0 to 96%. Both pre and post chill water were usually negative.

Key Words: Broiler houses, Processing plant, Salmonellae

165 The effect of adding ozone into an intensive broiler production unit on performance, mortality, ammonia levels, and bacterial levels as compared to a non-ozone treated environment. K. Schwan*, H. L. Classen, A. A. Olkowski, E. M. Barber, and C. Riddell, *University of Saskatchewan, Saskatoon, SK Canada.*

Ozone (O₃) is an unstable and reactive molecule that can readily oxidize many organic and inorganic substances. As a consequence, it is also known to be an effective biocide. For these reasons, the use of ozone in a commercial poultry unit could potentially offer two advantages: a reduction in ammonia due to oxidation, and a lower environmental bacterial population. This experiment studied the effect of adding atmospheric ozone (target level of 0.05 ppm) to rooms housing broilers. Broilers (three rooms of five replicate pens, each containing 110 birds) were grown in either a normal environment or an environment with added ozone. Ozone levels were monitored once daily in each pen subjected to ozone. Bird weight and feed consumption were examined on a pen basis at 21 and 40 d of age; mortality was collected daily, and necropsies were performed. Total aerobic bacteria colonies from air samples were plated and counted at 11, 19, and 34 d of age, as well as enterobacteriae at 34 d. Environmental ammonia levels were measured at 15, 20, 28, 32, and 38 d. The addition of ozone caused a near-significant decrease ($P=0.06$) in ammonia levels at 38 d (12.7 vs 25.7 ppm) and total bacterial count at 19 d (142 vs 225 colonies/plate; $P=0.09$). A significant improvement in mortality corrected gain to feed ratio was noted in the ozone-treated birds (0.553 vs 0.535). Birds exposed to ozone grew significantly slower (1.255 vs 1.353 kg gain), ate less (3.695 vs 3.953 kg), and had a higher mortality (11.46 vs 7.33%) and condemnation percentage (10.36 vs 3.39%) than normal environment broilers. These major increases in morbidity and mortality of the ozone-subjected birds make the use of this gas unacceptable for use in a commercial broiler unit, and raise serious health issues for both producers and birds.

Key Words: Ozone, Toxicity, Broiler

166 A Demonstration of Sand as an Alternative Bedding in Commercial Poultry Houses. G.W. Malone*¹, M. Salem¹, D.J. Hansen¹, and M.K. Eckman², ¹University of Delaware, Georgetown, DE/USA, ²Auburn University, Auburn, AL/USA.

Masonry-grade sand (S) is being compared to pine shavings (PS) as an alternative bedding material in paired-house farms under Delmarva production practices. Initial bedding depth was 3.8 cm (S) and 7.6 cm (PS) on 1 paired-house broiler farm, and 8.9 cm (S) and 10.2 cm (PS) on 2 paired-house roaster farms. Following cake removal, no additional bedding has been added since starting this demonstration on the broiler and roaster farms in February and June 2000, respectively. Production parameters (body weight, feed conversion, livability, condemnations, production cost); coccidial lesions and litter oocyst counts; litter quality (gram-negative bacteria, darkling beetle population, temperature, moisture and water activity); and air quality (ammonia and total dust) have been monitored on all farms. Based on the 9 paired-house observations (5 broiler flocks and 2 roaster flocks on 2 farms) to date, initial bedding type has had no consistent influence on most litter quality, air quality and bird performance parameters. However, there are several significant ($P < .05$) treatment effects. For proprietary reasons, all results are reported as the percentage deviation from the control (PS) value. Compared to PS houses, S houses averaged 85% fewer darkling beetles and the litter surface (top 2.5 cm) moisture was 53% and 23% less during the first and last week of production, respectively. Since the moisture determination was a gravimetric procedure, part of these differences can be explained by S having an initial 9-fold higher bulk density than PS. Although total dust was 18% greater in the S houses, birds processed from S houses had 30% fewer total condemnations. Other trends that approached significance ($P < .07$) included; S houses having 2% warmer litter temperatures and 26% higher atmospheric ammonia concentrations during the first week, and 14% higher body weights at market age compared to the PS houses. Although promising, the suitability of S as an alternative bedding for Delmarva production practices can not be fully assessed until a minimum of one year's data is available from these paired-house farms.

Key Words: Broiler, Litter, Sand

167 Effects of density and perch availability on aggressive behavior in broilers. Inma Estevez*, Rosemary Pettit-Riley, and Estelle Russek-Cohen, *University of Maryland*.

Aggressive interactions can both divert energy from growth and potentially reduce well-being of domestic animals. However social behavior, particularly aggressive interactions, has been poorly studied in broiler chickens, perhaps due to the relatively low occurrence as compared to laying hens. Aggressive behavior has been reported to change with varying stocking density. It has also been suggested that perch availability may reduce aggression by providing a place for threatened individuals to retreat. To test the hypothesis that the frequency of aggression in broilers will change with changing stocking density and availability of perches within the environment, groups of broilers were observed from 2 to 6 weeks of age. Both the type of aggression and the pen region in which the interaction occurred were recorded. Birds were housed at densities of 10, 15 and 20 birds/m² corresponding to group sizes of 45, 67 and 90 birds, respectively. In a nested design the birds within each density treatment were assigned to one of the following perch treatments: Horizontal (three 0° perches), 10° angled (three 10° angled perches), mixed angle (one 0° perch, one 10° angled perch and one 20° angled perch) and control (no perches). Results indicate that levels of aggression per bird decreased ($P < 0.05$) with increasing stocking density from 10 to 15 birds/m² (but not from 15 to 20). The main effect of perch treatment was significant for the frequency of threats ($P < 0.05$), but only approached significance for other types of aggression ($P = 0.0584$). Aggression peaked early during week 3 ($P < 0.05$), a result similar to those reported in other studies examining aggression in broilers. Aggressive interactions occurred more frequently in those regions of the pen that were either open or contained perches, rather than in the regions around the feeder or drinker. Results indicate that levels of aggression are dependent on stocking density, and that perch design influence the frequency of aggressive interactions.

Key Words: Broilers, Density, Aggression

168 Effectiveness of a terpene-based product as a broad-spectrum antimicrobial. Julio L. Pimentel*¹ and W. Douglas Waltman², ¹G.V.D. Corporation, ²Georgia Poultry Laboratory.

Two in vitro studies were developed in order to determine the effectiveness of a terpene-surfactant based product (Amibaf). In the first study, seven microorganisms, *E. coli*, *S. typhimurium*, *P. mirabilis*, *P. aeruginosa*, *S. aureus*, *C. albicans*, and *A. fumigatus* adjusted to 10⁵ organism/ml were incubated in BHI broth containing the terpene product diluted at 1:500, 1:1000, 1:2000, 1:4000, 1:8000, 1:16000, 1:32000 and 1:128000. Three replicates of each series of dilutions were used for each microorganism. After adding 0.5 ml of test organisms, tubes were incubated at 35-37 °C for 18-24 hours, growth onto blood agar was observed after incubating for an additional 18-24 hours. The results showed that the terpene product has a broad-spectrum inhibitory or killing activity. *E. coli*, *P. mirabilis*, *S. aureus* and *C. albicans* (yeast) were all inhibited at 1:1000. *S. typhimurium* was inhibited at 1:500 and *A. fumigatus* (fungi) at 1:13,000. In a second study the objective was to determine the inhibitory effect of various dilutions of terpenes against *E. coli* over time. The terpene product was diluted to 1:500, 1:1000, 1:2000, 1:4000, 1:8000, 1:16000, 1:32000 and 1:64000 in BHI and tested at 30, 90, 150 and 450 min. The product was also diluted in saline at the same concentration and tested at 60, 120, 180 and 480 min. At each respective time, 0.5 ml of each dilution was spread onto MacConkey agar plate an incubated overnight at 35-37 °C. The results showed an inhibitory effect of terpenes in broth and saline. In BHI *E. coli* was killed at 1:500 and 1:1000 after 30 min, growth was reduced at 1:2000, 1:4000, 1:8000 and 1:16000 after 90-min incubation. There was a greater effectiveness in saline, *E. coli* was killed at 1:500 after 60 min, at 1:1000 and 1:2000 showed a dramatic reduction at 60 min. After 480 min *E. coli* was completely killed in the 1:500, 1:1000, 1:2000 and 1:4000 dilutions and reduced at 1:8000. The results show that the terpene product has antimicrobial properties and can have several uses in the animal industry because of its GRAS status.

Key Words: Terpenes, Antimicrobial, Biocide

169 Strain and age effects on skeletal growth in two commercial broiler strains. I. Toure*, J. Nixon, and M. Lilburn, *The Ohio State University/OARDC*.

Selection for growth and yield traits in broilers have had positive effects on traits of economic importance but not all aspects of growth and development have been enhanced. There is considerable data in the literature on various aspects of skeletal development in modern broilers but much of the data incorporates measurements with the tibia but not the femur. In the present experiment, broiler chicks from two commercial strains were killed at multiple ages throughout growth for carcass and skeletal measurements. The tibia and femur were removed from each bird for length, width @50% of length, and dried wt determination. The absolute length and width of each bone continued to increase through the entire study (49 d) and there were significant strain differences throughout the study, although the magnitude of these changes varied with age. At 21 d, there were significant strain differences in tibia length ($P \leq .012$) and femur length ($P \leq .014$) but only the tibia length differences carried through to 36 d. At the latter age, however, there were significant differences in both tibia width ($P \leq .011$) and femur width ($P \leq .022$). The data suggest that while there are acknowledged differences in growth and yield characteristics between commercial broiler strains, there are differences in the support structure (i.e. skeleton) as well. These changes in relative support need to be further studied, particularly as bone breakage continues to be of concern in broilers reared to heavier body weights.

Key Words: Broiler, Tibia, Femur

170 Artificial neural network prediction of the weight gain and feed conversion of broilers raised under a range of environmental temperatures. T. L. Cravener*¹, W. B. Roush¹, J. D. May², and B. D. Lott², ¹The Pennsylvania State University, Department of Poultry Science, University Park, PA 16802-3501, ²USDA, ARS, South Central Poultry Research Laboratory, Mississippi State, MS 39762-5367.

Data describing the effects of altering environmental temperature (T) on the BW gain (BWG) and feed conversion (FC) of male and female broilers were gathered over 3 trials. Previously, May et al., (1998; Poultry Sci. 77(Suppl. 1):4) analyzed the data and calculated regression equations (REG) for BWG and FC for both genders. The same data inputs (BW and T) were used in the current study to predict BWG and FC with Artificial neural networks (ANN). Chicks were reared in a common environment until 3 wk of age. At 3 wk they were randomly assigned to 1 of 10 environmental chambers. Each chamber was maintained at a constant T throughout the study; with the T in the 10 individual chambers ranging from 12 to 30 C in two degree increments. Dewpoint was maintained at 18 C and relative humidity was $\leq 82.9\%$. BWG and FC were calculated on a wky basis for 4-7 wk. NeuroShell[®] Predictor software was used to train the four ANN. The REG and trained ANN were placed in a spreadsheet. The difference between the actual value in the database and either the REG or ANN prediction was calculated. The absolute differences were statistically analyzed for significance using a paired t-test. ANN prediction of FC resulted in higher training R² values than BWG. Females tended to have higher R² values than males. The ANN training R² for predicting BWG was 0.83 for females and 0.72 for males. The ANN training R² for predicting FC was 0.91 for females and 0.84 for males. When predictive ability was compared, the ANN predicted more accurately ($P < 0.05$) than the REG. ANN prediction of BWG and FC is a successful alternative to REG and may allow a manager to make critical decisions concerning scheduling and feed inventory requirements on a timely basis.

Key Words: Artificial Neural Networks, Environmental Temperature, Broiler Performance

171 Genetic characterization of commercial broiler lines experimentally infected with Subgroup J Avian Leukosis Virus (ALV-J). M Karaca*, J. K. Rosenberger, and S. S. Cloud, *University of Delaware, Newark, DE*.

This study was initiated to determine the genetic basis for weight gain or immune response in chickens infected with ALV-J. Embryos from 4 genetic lines of chickens were inoculated with the UD-4 isolate of ALV-J by the yolk sac route at 3 days of incubation. An equal number of embryos were sham inoculated. At hatch chicks were vaccinated with NDV and IBV and during grow-out exposed to infectious bursal disease virus, reovirus and chicken anemia virus to simulate commercial conditions. Body weights were measured every 2 weeks. At 5 weeks, chickens were assessed for their ability to clear *E. coli* following intravenous inoculation. This was done because ALV-J is believed to compromise resistance to bacterial infections. Biweekly body weights and *E. coli* blood clearance assays were analyzed using the GLM procedure of SAS. A total of 129 (A=42, B=40, C=47) chickens were genotyped using 33 microsatellite markers. The association of genotype with the phenotypic measurements of body weight and *E. coli* clearance were determined for sham vs ALV-J inoculated chickens. The heterogeneity of each locus was calculated within lines. The average observed heterogeneity of line A, B and C over 33 loci was 30.65 %, 33.31 % and 31.29 % with 3.24, 2.97 and 3.45 alleles per locus, respectively. The average allele sharing between lines A and B was 72.23 %, between lines A and C it was 66.07 % and 61.91 % between lines B and C. Overall, the lines shared 55.38 % of their alleles. The genetic distance between line A and B or C was found to be 25.82 or 27.41 % respectively. Both suggestive ($P < 0.10$) and significant ($P < 0.05$) associations of marker genotypes with quantitative trait loci (QTL) affecting biweekly body weights and clearance of *E. coli* were detected. Two marker loci were found to be significantly ($P < 0.05$) associated with body weight at 2 and 4 weeks of age for line A. One marker genotype had a significant effect ($P < 0.05$ - $P < 0.10$) on clearing pathogenic *E. coli*. Further characterization of the genetic lines is continuing by genotyping progeny tested sires with 100 microsatellite markers.

172 Relationships between skeletal growth and body weight in Japanese quail selected for 4 week body weight. J. M. Reddish*, A. El-Keredy, K. E. Nestor, and M. S. Lilburn, *Dept of Animal Science, The Ohio State University, Ohio Agricultural Research and Development Center.*

A weight selected strain of quail (HW) selected for increased 4 week body weight was compared with a randombred control to investigate the relationship of skeletal growth and selection for body weight. The heavy weight (HW) strain was derived from the randombred control strain (RBC). Body weight differences (HW>RBC) between strains were consistent throughout the experiment. The objective was to investigate the growth of the tibia and femur and determine if selection for resulted in differences between the HW and RBC strains. Measurements were taken of body weight, length and width of both the tibia and femur at weekly intervals from 1 to 35 days of age. Body weight difference (50%) was consistent throughout the experiment (HW>RBC) and growth patterns were similar. Differences in skeletal measures and body weight were only 15% for both RBC and HW ($p < .01$). Correlations for skeletal traits and body weight were positive, and significant ($p < .01$) for RBC thru day 28 but HW showed disruption in this pattern. The results suggest that selection for body weight and skeletal growth are symmetrical in the RBC, but different in HW. The HW strain has proportional growth but does not have symmetry between skeletal traits and body weight as noticed in the RBC strain.

Key Words: selection, quail, growth

173 The effect of selection for increased egg production in turkeys on incubation characteristics of embryos. A. L. Antonelli*, K. E. Nestor, and M. S. Lilburn, *Department of Animal Sciences, Ohio State University/OARDC, Wooster, OH.*

In strains of turkeys selected for egg production (E; Nestor et al., 1980, 1995), genetic increases in egg production are proportional to decreases

in the weight of the albumen and yolk, as well as the total egg weight when comparisons are made to a randombred control line (RBC1). In the present study, E line hens were mated to E line toms or RBC1 toms, and RBC1 hens were mated to RBC1 toms. Egg weight at set was $67.2 \pm .39$ g for E/E eggs, $65.6 \pm .32$ g for E/RBC1 eggs, and $87.16 \pm .68$ g for RBC1/RBC1. At 21 days of incubation, E/E yolk-free embryo weight was 5% less than in E/RBC1 embryos, yet at 25 days there was no differences. At hatch, E/E yolk-free embryo weight was 5% greater than that of E/RBC1 embryos. Overall, the E/E line embryos had a 64% increase in yolk-free weight between 21 and 25 days with overall weight gain of 95%. E/RBC1 had only a 56% increase in yolk-free weight between 21 and 25 days with overall weight gain of 70%. RBC1/RBC1 embryos had an 80% increase in yolk-free weight between days 21 and 25 with an overall weight increase of 118%. At 21 days of incubation, RBC1/RBC1 yolk-free embryo weight was 11% heavier than the E/E line and these differences increased to 25% and 26% at 25 d and hatch (28 d), respectively. The data suggest that genetic differences in embryonic development are maximally expressed from 21 to 25 days of incubation, concomitant with the period of maximal yolk lipid transfer to the development embryo.

Key Words: Turkey, Incubation, Embryo

174 Germ-line transmission of a *lacZ* gene in chickens using an avian Spleen Necrosis Virus-based vector. S. Borwornpinoy*, D.W. McCoy, P.E. Mozdziak, and J.N. Petite, ¹*North Carolina State University.*

Replication-defective retroviral vectors based on the avian spleen necrosis virus (SNV) have been successfully used to produce transgenic chickens. One particular vector, SNTZ, expresses nuclear-directed beta-galactosidase. The SNTZ vector has been used as a cell lineage marker for the analysis of early embryonic development of the chick. The purpose of the present study was to produce transgenic chickens using SNTZ. High titers (2.0×10^7 virion/ml) of SNTZ were injected into the subgerminal cavity of 66 stage X white Leghorn embryos followed by *ex ovo* embryo culture. Of the 66 infected embryos, 16 hatched (24%). To date, of the 16 hatched chicks, 12 have reached sexual maturity. Genomic DNA from blood and semen samples from these G₀ birds were tested for the presence of *lacZ* sequences using the polymerase chain reaction in combination with primers specific for *lacZ*. Out of 7 hens, 2 birds had detectable *lacZ* sequences in their blood. Of the 5 cockerels, 3 were carrying the bacterial *lacZ* gene in the semen. To date, test mating of males and females yielded germ-line transmission from one male at a frequency of 1 out of 20 offspring. No correlation was observed between the presence of *lacZ* sequences in circulating red blood cells and semen. The results of this study suggest that the SNTZ vector can be used to develop a line of transgenic chickens that expresses nuclear-directed bacterial beta-galactosidase. Support was provided through funds under projects NC05293 (PEM), NC06590 (PEM), and NC0168 (JNP).

Key Words: retroviral vectors, germ-line transmission, transgenic

175 Molecular characterization of the genomic chicken prolactin receptor (cPRLR) gene from a native Chinese chicken (Wai Chow strain). Angela Hui* and Frederick Leung, *University of Hong Kong.*

The aim of this study is to clone and characterize the genomic cPRLR gene from a native Chinese chicken (Wai Chow strain). Prolactin receptor (PRLR) participates in a number of physiological functions in birds including reproduction, maternal behavior and osmoregulation. It is widely distributed in many tissues including the brain, the testis and, particularly abundant, in hypothalamus and the anterior pituitary gland. The cDNA of PRLR has been previously shown to consist of an extracellular ligand-binding domain, a single transmembrane and an intracellular domain involved in signal transduction. However, the genomic molecular structure of the cPRLR gene is still lacking. We used the Polymerase Chain Reaction (PCR) trapping method. By designing different pairs of primers flanking the possible intron splice sites, fragments of introns can subsequently be amplified for subcloning and further sequencing analysis. Three introns have been successfully trapped, and the estimated sizes are 1.4kb, 1.5kb and 1.7kb. These DNA fragments were subcloned and further confirmation by DNA sequencing. Consequently, these sequences will be analysed in the databank for any

significance discovered, which helps further understanding of the gene expression pattern and to reveal important pieces of evidences on the gene diversity. Tissue culture will also be carried out to further characterize the promoter region using deletion expression approach.

Key Words: Chicken, Prolactin receptor, Intron

176 Molecular characterization of the chicken prolactin (PRL) gene:genomic gene structure, its polymorphism and promoter analysis. Florence Au* and Frederick Leung, *University of Hong Kong.*

Prolactin (PRL) is a polypeptide hormone of the anterior pituitary gland and has been shown to have a diverse spectrum of biological activities and functions in all vertebrates. Characterization of the chicken PRL gene and its polymorphism is the first step in establishing the genotypes and traits association. Polymerase chain reaction (PCR), cloning and sequencing were used to obtain the four intron sequences of the chicken PRL genomic gene. PCR products indicated that the sizes of the four introns are of 1.5 kb, 0.5 kb, 1.3 kb and 2.0 kb respectively. Sequence analysis of the four PRL introns of the chicken PRL gene revealed that they share high homology with that of the turkey PRL gene and the other strains of chicken PRL gene. In addition, PCR-restriction fragment length polymorphism (PCR-RFLP) was used to identify polymorphic sites within the four introns. An Ava II enzyme cut site in the first intron was found to be polymorphic in Chinese native (Guangdong Xing Hua) chickens. PCR-RFLP was also applied to other chicken strains such as broiler, layer and other native Chinese strain (Shek kai). However, No polymorphism was identified. Present results enable extended study in the PRL gene diversity. In addition, an approximated 2 kb 5' flanking of the cPRL was also obtained by PCR and confirmed by DNA sequencing. Deletion analysis and luciferase reporter gene assay will be used to characterize and define the promoter region in PRL gene expression.

Key Words: Chicken, Prolactin, Polymorphism

177 Detection of a single nucleotide polymorphism in exon 10 of the chicken growth hormone receptor gene. Joanna Lau* and Frederick Leung, *University of Hong Kong.*

Interaction of Growth Hormone (GH) with its receptor (GHR) is required for normal growth in both mammalian and avian species. Defect in GHR gene functions caused by mutation is one of the major causes of genetic disorder, eg. Laron Syndrome and Dwarfism in human and chicken respectively. Recent studies suggest that polymorphisms on both the GH and GHR genes in chicken might serve as genetic markers for phenotypes of commercial values. In this study, a new restriction fragment length polymorphism (RFLP) at exon 10 of the GHR gene has been identified in native Chinese strain chicken, using polymerase chain reaction (PCR) and Alu I restriction enzyme digestion. The same study has been extended to broiler and layers strains and no RFLP was detected. The PCR-RFLP results were further verified by direct sequencing analysis and confined to a single nucleotide polymorphism (SNP) silent mutation at position 924th nucleotide (GA) counting from the translational start site on the published cDNA sequence, resulting in no change in the amino acid. Future studies will be set up to examine whether such mutation has any association with phenotypic traits.

Key Words: Chicken growth hormone receptor, Restriction fragment length polymorphism (RFLP), Single nucleotide polymorphism (SNP)

178 Candidate genes and reproductive traits in a commercial broiler breeder population, an association study. I C Dunn*¹, Y-W Miao¹, A Morris², M N Romanov¹, D Waddington¹, P W Wilson¹, and P J Sharp¹, ¹*Roslin Institute, Roslin, Midlothian EH25 9PS, Scotland,* ²*The Cobb Breeding Company, East Hanningfield, Essex, CM3 8BY, England.*

To take advantage of programmes to identify candidate genes for variation in traits of economic importance, methods to test these genes in selected pedigree populations need to be developed. To this end we have carried out a study of association between candidate genes and reproductive traits in a pedigree line of broiler breeders. Gonadotropin releasing hormone (GnRH), its receptor (GnRHR), growth hormone receptor (GHR) and neuropeptide Y (NPY) were selected for their role in controlling aspects of reproduction. Genetic markers for NPY, GnRHR and

GHR alleles were detected using bulk PCR-restriction fragment length polymorphism or BESS-T Scan (Epicentre Technologies). Genotyping of 772 hens from one generation was by PCR-restriction fragment length polymorphism. Total number of eggs, age at first egg (AFE) and number of double yolked eggs (DY) for each hen were recorded. Additive and dominance effects were fitted for the autosomal GnRHR and NPY genes; additive effects were fitted for the sex linked GHR gene. To control for some of the background genetic variation, candidate genes were assessed within heterozygous sire families. A dominance effect of NPY (14 sire families) on AFE and an additive effect of GnRHR (36 sire families) on DY, were found ($P < 0.02$). If the latter effect were true, selection could increase overall flock performance by 0.13 usable eggs per hen. A simplified model, omitting sires, was also fitted. This analysis gave four significant associations ($P < 0.05$), a surprisingly large number. In conclusion it is possible to detect association between economic traits and candidate genes in a population undergoing selection, and test if a candidate gene explains some of the trait variation. However, statistical associations between trait and genes require to be treated with caution and models should account for as many genetic and environmental variables as possible.

Key Words: Reproduction, Candidate genes, Association

179 Mapping QTL Loci Affecting Growth And Disease Resistance to Avian Coccidiosis. J Zhu*¹, H Lillehoj¹, C Van Tassel², M Emara³, P Allen¹, H Cheng⁴, D Pollock⁵, M Sadjadi⁵, and T Sonstegard², ^{1,2}*U.S.Department of Agriculture, BARC, Beltsville, MD,* ³*University of Delaware, Newark, DE,* ⁴*U.S.Department of Agriculture, ADOL, East Lansing, MI,* ⁵*Perdue Farms, Inc., Salisbury, MD.*

Selection of commercial poultry stocks with improved disease resistance using classical genetic breeding techniques has been unsuccessful due to technical difficulties. Although selection based on progeny tests can be used, this is labor-intensive, time consuming, and costly. In order to develop a DNA marker-assisted selection strategy to improve disease resistance against avian coccidiosis in commercial breeder chickens, chicken genes controlling resistance to coccidiosis are being identified. Three hundred and twenty four F2 offspring for mapping quantitative trait loci (QTL) affecting disease resistance were produced from 12 full-sib families of a commercial broiler breeder. The F2 offspring were inoculated with 104 sporulated oocysts of *Eimeria maxima* at 4 weeks of age. Body weight gain and fecal oocyst shedding were determined as a measure of infection. One hundred and twenty chicken microsatellite markers with an average genome distribution of 20 cM were used for genotyping the F1 and F2 generations. Genotypic data were analyzed with CRIMAP version 2.4 to construct a marker linkage map. A minimum LOD score of 3.00 was used as the statistically significant threshold for declaring linkage. The QTL analysis was conducted using SOLAR on genotypes of the F1 and F2 and the phenotypes of the F2 chickens. A locus on chromosome 1 was identified that was significantly associated with reduced oocyst shedding and 3 potential loci affecting growth were identified on chromosomes 1 and 6. (Supported by Fund for Rural America, Grant No 9704985 and partially by ARS CRIS).

Key Words: Coccidiosis, QTL mapping, Disease resistance

180 The use of molecular markers to associate feather color alleles with tissue pigmentation in broiler chickens. R Okimoto*, *University of Arkansas.*

Consumers dislike black melanin pigment in the abdominal skin and fascia. It has been demonstrated that certain feather color alleles are associated with this pigmentation. The dominant white allele (*I*) and sex-linked barring allele (*B*) are known to reduce the incidence of abdominal pigmentation when coupled with the extended black allele (*E*) of the *E* locus. Since most commercial broilers are white feathered the cryptic feather color alleles that are segregating within the population cannot be determined without test mating. Molecular PCR based markers would facilitate selection against unwanted alleles. We have developed PAMSA (PCR amplification of multiple specific alleles) tests that can distinguish the various *E* locus alleles. These tests detect specific nucleotide substitutions in the melanocortin 1-receptor gene that result in amino acid substitutions in the receptor sequence associated with specific alleles of the *E* locus. In order to test the efficacy of using these tests in selection against tissue pigmentation a cross between two broiler dam lines was made to create an F₁ population that was nearly

fixed for recessive white (*cc*), segregating for sex-linked barring (*B*) and heterozygous for the *I* and *E* loci (*IiEe^b*). F₂ chicks were hatched and 345 were typed for tissue pigmentation at 15 days of age and 1700 were typed at 5+ weeks of age. All F₂ chicks were white feathered due to recessive white (*cc*). Pigmentation ranged from no visible pigment to pigmented birds with a few spots around the navel to large areas of the abdominal region having intense pigmentation. Total incidence of abdominal tissue pigmentation was 27% at 15 days and 23.6% at 5+ weeks. At this time, 79 F₂ chicks have been PAMSA genotyped for their *E* locus alleles, and were found to segregate 1:2:1, as expected, for the *EE:Ee^b:e^be^b* genotypes. As expected, the *EE* genotype was associated with the least abdominal pigmentation (8.7%), while 18.4% of the *Ee^b* chicks and 44.4% of the *e^be^b* chicks were pigmented. Results indicate that selection for the *E* allele in dominant white broiler stocks would decrease the incidence of abdominal tissue pigmentation, and that molecular based tests would facilitate this selection.

181 Effect of dietary protein, photoperiod, and genetic background on growth and sexual maturity in Japanese quail. A. El-Karedy, K. Nestor, and M. Lilburn*, *The Ohio State University/OARDC, Wooster, OH.*

Japanese quail are a valuable species for genetic studies in poultry due to their short generation interval and relative ease of maintenance. The current study included two lines of Japanese quail, a large-bodied line (HW) selected for increased BW at 4 wk of age and a rambred control line (R1) from which the HW line was developed. The selection environment includes a period of reduced daylength and this environment results in sexual maturity (age at first egg) at about 53 d in both lines (Anthony et al., 1993), whereas continuous lighting can reduce sexual maturity by approximately 10 d (Lilburn et al., 1992). The selection diet contains 28 % CP and, in previous experiments, this diet resulted in a significant line by diet interaction for growth and onset of sexual maturity (Lilburn et al., 1992). In the present study, HW and R1 quail were fed one of three diets (21, 24, or 27 % CP) and exposed daily to either an 8- or 24-h photoperiod from hatch to 28 d of age and 24 h thereafter. The R1 hens reached sexual maturity about 2 d earlier than HW hens (49.8 vs 51.9 d; $P \leq 0.004$). The 8-h photoperiod delayed sexual maturity by 12 d (56 vs 44 d; $P \leq 0.0001$) and the 27 % CP diet enhanced sexual maturation by 4 d compared with hens fed either 24 or 21 % CP diets (47.3 vs 51.5 d; $P \leq 0.0001$). There were no significant two-way interactions. As would be expected, the 24-h photoperiod significantly reduced BW at sexual maturity in both lines but there were no significant diet effects. The 24 and 27 % CP diets increased oviduct weight at sexual maturity in HW hens compared with the 21 % CP diet (10.24 vs 9.3 g) and there was no diet effects in the R1 line (5.6 g), resulting in a significant line by diet interaction ($P \leq 0.031$). There was a linear decrease in ovary weight in both lines with each incremental increase in dietary CP but no significant effects due to photoperiod. The data suggest that dietary CP and photoperiod had independent effects on various traits measured at sexual maturity and these effects were not necessarily similar within the two genetic backgrounds.

Key Words: Japanese quail, sexual maturity, genetics

182 Is improved feed conversion associated with increased lethargy and docility in broiler chickens? D. O. Skinner-Noble*¹, R. B. Jones², and R. G. Teeter¹, ¹Oklahoma State University, Stillwater, OK 74078, ²Roslin Institute (Edinburgh), Midlothian EH25 9PS.

An experiment was conducted to test the hypothesis that broilers classified as good rather than poor feed converters (high versus low gain-to-feed ratios, respectively) would show decreased activity (increased lethargy) and reduced fear of human caretakers. The birds (450 large broiler-type) were reared straight run to 36 d of age when they were sexed. Of the 227 males that were then weighed and subjectively evaluated for breast conformation and leg defects, 192 were placed into individual-bird cages (46 x 60 cm) at 40 d of age and their feed conversion ratio (FCR) was measured over the next 7 days. During this time the birds were subjected to three behavioral tests. Firstly, we scored their approach / avoidance responses to a novel object placed in the feeder at a time when feeding would be expected. Secondly, in an assessment of the general behavior patterns of individual birds we recorded feeding, drinking, walking, pecking, preening, standing and

resting. Thirdly, the 20 birds showing the best FCR and the 20 showing the worst were induced into tonic immobility (TI); this test of underlying fearfulness is an anti-predator reaction to manual restraint. We found that feed conversion was not related to either the novel object or the TI measures of fearfulness. Neither was FCR related to feeding, drinking, walking or pecking. However, gain-to-feed ratio was positively correlated with both standing and preening, and negatively correlated with resting behavior. Therefore, contrary to expectations, the present results suggest that broilers that showed good feed conversion ratios were actually less lethargic and no more fearful than those that showed poor FCR values.

Key Words: Feed conversion, Lethargy, Fearfulness

183 Level and pattern of DNA sequence variation in the chicken genome. Edward Smith*, *Virginia Tech.*

Variation among chickens for metabolic and physiological factors are significant indicators of differences in performance and health. Individual variation in physiological and metabolic factors can be influenced by differences in candidate genes. Identification of mutations in these candidate genes as well as the determination of the distribution and structure of the variants in different populations are essential in properly defining their roles. Here results of a DNA sequence-variation screen of five metabolically important chicken genes including type X collagen (*col10*), aggrecan (*agg1*), cyclin D3 (*cycD3*), ovalbumin A (*ovbA*) and chicken PepT 1 (*cpept1*) are described. For each gene, a panel of 48 unrelated birds from six commercial layer-type breeder lines were used without regard to their health or performance status for resequencing of PCR-amplified diploid products. Variable DNA sites or single nucleotide polymorphisms were identified in iterative stages that involved alignment of multiple sequence traces and the identification of heterozygous loci based on context-specific patterns of the individual sequences. Each variable site was re-sequenced at least once and most were aligned in more than one contig. As expected and have been observed in human and mouse, there was significant variation among genes. For example, within the 800-bp sequence evaluated from the 3d end of *cpept1*, a total of 16 variable sites were detected and confirmed. From the *cycD3* gene, however, no variable sites were detected within the coding sequences. Within a total of 40 kb of DNA sequence screened, an average of 1/150 bp of variable sites were detected. The value of this information is at several levels: First, SNP discovery within these functionally important genes will now make it easier to carryout association studies designed to identify genes that influence disease and performance traits. Second, the high frequency of variable sites suggest that biallelic markers may be useful for the construction of a third generation chicken genetic map that can be used for quantitative trait locus identification. (Acknowledgment: Hong Chen, Yuan Pan, Kenny Webb and Eric Wong are gratefully acknowledged for sharing the PepT1 sequence with me prior to publication).

184 Novel Randomly Amplified Polymorphic DNA Markers for the Turkey Genome. Amy Spellerberg* and Edward Smith, *Virginia Polytechnic Institute and State University, Blacksburg Virginia/USA.*

Though it is a commercially important meat animal species, our knowledge of the turkey genome, relative to the chicken and other species, remains limited. To address this limitation, a publicly available and widely disseminated turkey genome map is necessary. The utility of such a map includes gene discovery and quantitative trait loci identification for economically important traits. To support the development of a turkey genome map, randomly amplified polymorphic DNA (RAPD) markers may be a useful resource. Here we describe a novel set of RAPD markers developed by screening parental samples from members of a turkey DNA reference panel. Using conventional PCR techniques, ninety-six RAPD primers were used in the screening. Amplified products were separated on agarose gels and analyzed for the presence of informative fragments based on Mendelian inheritance. A total of thirty-two primers, or 33.3% of the primers used for screening, revealed polymorphic fragments that showed Mendelian inheritance. These fragments ranged in size from 400 bp to 3 Kb and cumulatively represented the analysis of a 46.8 Kb

portion of the turkey genome. This study establishes that RAPD markers may be a reliable and efficient resource for constructing a genomic linkage map of the turkey genome.

Key Words: Turkey genome linkage map, RAPD markers, polymorphic loci

185 Use of AFLP DNA markers to evaluate genomic diversity and genetic distances in Japanese quail lines divergently selected for stress responsiveness. F. M. Odeh*¹ and G. G. Cadd¹, ¹*Department of Poultry Science, Louisiana State University Agricultural Center, Baton Rouge, LA 70803.*

The secretion of corticosterone is a classic endocrine response to stress in avians. In this study, the genomic diversity and genetic distances in Japanese quail lines divergently selected for stress responsiveness were evaluated using an amplified fragment length polymorphism (AFLP) technique to generate DNA markers. DNA from individuals of extreme performance within each selected line was extracted and pooled for analysis. DNA from five different individuals was pooled for each replicate. Four replicates from each selected line and two replicates from a randomly bred (RB) line were screened by DNA fingerprinting. The enzyme combination *EcoRI/TaqI* was used for a double digestion of the DNA

pools. Fragments with *EcoRI/TaqI*-end were radioactively labeled, separated by molecular weight by gel electrophoresis, and apposed to X-ray film for visualization. Ninety-seven *EcoRI/TaqI* primer combinations generated 20,416 bands with 5,089 of them being polymorphic. The AFLP procedure amplifies a high number of restriction fragments (52 bands, on average, in a single primer combination) and produces markers that are scored as the presence or absence of a band. The average band sharing (BS) values produced from AFLP fingerprinting within lines were 0.590, 0.631, and 0.581 for HS, RB, LS lines, respectively, whereas the average BS values between the lines were 0.573, 0.550, and 0.572 for HS-RB, HS-LS, and LS-RB respectively. The BS values within each given line and between the lines were, however, very sporadic, regardless of primer-combination used and the line analyzed. In this study, 5.5% of the genomic variation was attributed to mutation rate, 0.57% to genetic drift, and 0.057% to bidirectional selection. There were insignificant differences in average genetic distances between the selected lines. Although AFLP failed to resolve genetic diversity between the selected lines, it clearly identified fragments of DNA that may help determine the major genes involved in the stress responsiveness phenotype.

Key Words: Stress responsiveness, AFLP, Genetic distance, Japanese quail

PSA Nutrition: Amino Acids

186 Impact of phase-feeding on growth performance of broilers fed diets adjusted every other day for decreased amino acid content. H.R. Pope*, J.A. Townsend, and J.L. Emmert, *University of Arkansas.*

An experiment was conducted during the finisher period (42 to 56 d) to determine the effects of decreasing dietary amino acid levels as often as every other day using the phase-feeding (PF) approach. Experimental diets were formulated using either NRC recommendations for lysine (Lys), sulfur amino acid (SAA) and threonine (Thr) or recommendations from linear regression equations generated from estimates of Lys, SAA and Thr requirements. To facilitate implementation of PF, two diets were prepared that contained Lys, SAA and Thr levels matching the predicted requirements for birds at 42 d (high nutrient density) and 56 d (low nutrient density). After being properly mixed and pelleted, the high and low nutrient density diets were blended in variable quantities to produce rations containing amino acid levels that matched the predicted PF requirements over two day intervals (42-44 d, 44-46 d, 46-48 d, 48-50 d, 50-52 d, 52-54 d, 54-56 d). Birds were fed either a single NRC diet from 42 to 56 d or a series of PF diets that were switched every other day to supply a gradual decrease in Lys, SAA and Thr. Weight gain, feed intake, and feed efficiency of birds fed the PF regimen were unaffected ($P > 0.05$) relative to birds fed the NRC diet. An evaluation of digestible Lys, SAA, and Thr intake revealed a significant decrease ($P > 0.05$) in Thr intake for those birds given the PF diets, however no differences ($P > 0.05$) in digestible Lys or SAA intake were observed between the NRC and PF diets. These data indicate that dietary Lys, SAA, and Thr content maybe reduced as often as every other day under a PF program in which high and low nutrient density diets are blended without adversely affecting growth performance. Moreover, because dietary Lys, SAA, and Thr levels are decreased under the PF system substantial dietary cost savings may be available with such a program.

Key Words: Broiler, Phase-feeding, Amino Acids

187 Evaluation of lysine and arginine needs in broiler finisher diets. E. A. Oviedo-Rondon*, C. A. Fritts, and P. W. Waldroup, *University of Arkansas.*

Two studies were conducted in floor pens to examine response of male broilers to combinations of Lys and Arg in broiler finisher diets. In the first study, a diet was formulated with 0.75% Lys and 1.0% Arg. Aliquots of the diet were supplemented with Lysine HCl and arginine free base to provide a 3 x 4 factorial arrangement with three Arg levels (1.0, 1.2, and 1.4%) in combination with four Lys levels (0.75, 0.85, 0.95, 1.05%). Each treatment was fed to four pens of 50 male Ross 308 broilers from 42 to 63 d. In the second study, three Arg levels (1.0, 1.1, and 1.2%) were fed in combination with four Lys levels (0.75, 0.85, 0.95, and 1.05%) with each treatment fed to four pens of 50 male Cobb 500

broilers from 42 to 56 d. Body weight gain and feed conversion (FC) were determined and birds were processed for dressing percentage (DP), breast yield (BY) and abdominal fat (AF) content. The level of Arg had no significant effect on BW gain, FC, DP, BY, or AF in either study, indicating that the NRC (1994) recommended level of 1.0% is adequate for this age period. No significant interactions occurred between levels of Lys and Arg for any criteria in either study. In the first study, conducted in moderate temperature, Lys had no significant effect on BW, FC, or DP; BY was increased by 0.85% Lys but higher levels gave no further advantage. In the second study, conducted in high temperatures, BW gain, FCR, and BY were significantly improved by increasing Lys from 0.75 to 0.85% but higher levels gave no further advantage. These data suggest that current NRC (1994) levels of Arg and Lys are satisfactory for broilers during the finisher period of 6 to 8 or 9 wks of age under periods of moderate or high temperatures.

Key Words: Arginine, Lysine, Broilers

188 The influence of dietary labile methyl donors on arginine requirement of young broiler chicks using growth and muscle creatine as parameters. M. Chamrusspollert*, G.M. Pesti, and R.I. Bakalli, *Department of Poultry Science, The University of Georgia, Athens, GA 30602-2772.*

Two experiments were conducted to investigate the effect of methyl donors on the arginine requirement of young broiler chicks. One-day-old Ross x Ross chicks were fed corn-whey based diets for 14 days. Four replicate pens of ten chicks each were randomly assigned to each treatment. At 14 d, two birds from each pen were killed and breast muscles were collected for creatine analysis. In Experiment 1, six levels of arginine (ARG) (0.95, 1.05, 1.15, 1.25, 1.35, or 1.45%) were fed with two levels of methionine (MET) (0.45 or 0.65%). Based on body gain data, the ARG requirement was $1.19 \pm 0.07\%$ or $1.16 \pm 0.06\%$ when chicks were fed the 0.45 or 0.65% MET diet, respectively. The requirement was $1.16 \pm 0.04\%$ or $1.19 \pm 0.06\%$, respectively, based on muscle creatine. However, based on FCR, the ARG requirement of chicks fed 0.45% MET was higher ($1.25 \pm 0.04\%$), compared with those fed with 0.65% MET ($1.16 \pm 0.04\%$; $P < 0.05$). In Experiment 2, two sources of methyl donors, MET or betaine (BET) were compared on an equal percentage basis. Eighteen treatments with 6 levels of ARG (as above) were factorially arranged with no methyl donor supplementation, or 0.2% MET supplementation (0.65% total) or 0.2% BET supplementation (0.2% total). There was no significant interaction ($P > 0.05$) between ARG and methyl donor source on body weight gain and feed intake. The body gain data were pooled to calculate the ARG requirement. Therefore, based on body gain, the ARG requirement was $1.20 \pm 0.05\%$. Based on FCR, we found the interaction between ARG and methyl donor source ($P < 0.05$). Based on FCR, the ARG requirement of chicks fed the unsupplemented diets was $1.29 \pm 0.06\%$, fed diets supplemented MET was $1.24 \pm 0.04\%$,

and fed supplemental BET was $1.15 \pm 0.04\%$. Based on muscle creatine, the requirement was $1.29 \pm 0.06\%$, $1.27 \pm 0.03\%$ or $1.18 \pm 0.04\%$ when chicks fed unsupplemented diets or diets supplemented with MET and BET, respectively.

Key Words: Arginine requirement, Methionine, Betaine

189 Influence of maillard reaction products on *Escherichia coli* amino acid lysine auxotroph growth-based assay response. X. Li* and S. C. Ricke, *Texas A&M University, College Station, Texas/USA.*

Lysine availability in poultry feeds can be rapidly assessed by measuring the growth response of an *Escherichia coli* lysine auxotroph. Maillard reaction formation commonly occurs during food or feed processing that involve heating and can reduce the availability of lysine. It is not clear whether formation of Maillard reactions products (MRP) would inhibit *E. coli* growth and influence the accuracy of the assay. The objective of these studies was to examine the effect of MRP formation on *E. coli* mutants *lys*⁻ and *met*⁻, and wild type K12 growth in model systems. Three different types of MRP were generated by autoclaving glucose with either lysine, arginine, or histidine for more than 3 hours. In model systems, combinations among types of MRP and different concentrations of MRP were added to an M9 minimal medium. The growth response of different *E. coli* strains were examined in the model systems supplemented with 4 µg/ml of required amino acid. Different types of MRP were added to determine the effect of MRP on the lysine assay. There were significantly ($p < 0.01$) different growth rates due to bacterial strain difference, however, addition of different types of MRP or different concentrations of MRP did not cause significant ($p > 0.01$) differences in growth rate. Linearity of the standard curve without adding MRP (control) was not significantly ($p > 0.01$) different from those of the standard curves adding MRP for the lysine assay. The result indicated that the presence of the MRP should not lead to errors in the *E. coli* lysine availability assay of foods or feeds containing Maillard reaction products.

Key Words: Maillard reaction products, Growth rates, Lysine assay

190 Development of a rapid whole cell biosensor for assessing methionine availability by insertion of genes encoding for green fluorescent protein into an *Escherichia coli* methionine auxotroph. C. A. Froelich*, I. B. Zabala Díaz, and S. C. Ricke, *Texas A&M University, College Station, TX/USA.*

The need to accurately measure the levels of bioavailable methionine in poultry and animal feeds remains an important issue in animal nutrition. Techniques ranging from animal, chemical, and microbial assays exist to measure this nutrient's utility. The objective of this study is to develop a rapid microtiter methionine assay for feeds and feed components using a fluorescent *Escherichia coli* methionine auxotroph strain (ATCC# 23798). Initially an *E. coli* methionine auxotroph strain was transformed with plasmid *p519ngfp*, containing a green fluorescent protein gene (*gfp*) coupled to a constitutive promoter that confers a fluorescent phenotype. Transformation was achieved by conventional CaCl₂ method. Plasmid presence was confirmed by antibiotic markers and by gel electrophoresis. Microbial assay was started by placing fully grown and depleted *E. coli* cells in minimal mineral media containing increasing concentrations of methionine and cells were then incubated at 27°C with constant agitation. Fluorescence was monitored using a multi-label counting fluorometer (Victor2V, PerkinElmer, Massachusetts) every 15 minutes for 2 hours set at an excitation/emission wavelength of 485nm/535nm for 1 second. Measuring absorbency at 585nm assessed bacterial growth. Since the bacterial assay was performed at 27°C, cells never left lag phase and A585nm correlated poorly with varying methionine concentrations ($0.5\text{-}2.0 \mu\text{g/ml}$, $R^2 \geq 0.1$). However, bacterial fluorescence during this time assayed correlated with methionine concentrations at lower levels ($\leq 0.25 \mu\text{g/ml}$, $R^2 \leq 0.98$). The proposed method allows more sensitive measurements than conventional microbial assays for methionine bioavailability.

Key Words: *Escherichia coli*, Green Fluorescent Protein, Methionine

191 Sulfur amino acids requirement of slow- and fast-feathering male broilers from 0-21 days of age. A. Kalinowski* and E.T. Moran, *Auburn University, Auburn, AL.*

Corn-soybean meal based diets (C-SBM) are limiting in total sulfur amino acids (TSSA) for broiler development. Differences in feather development are thought to influence the demand for cystine (Cys) thus, TSAA requirement. Two experiments were conducted with fast (Ross x 3F8) and slow (Ross x 308) feathering males from 0 to 3 wk of age. For each experiment, chicks were randomly assigned to 72 battery cages (6 birds/cage) and fed a C-SBM diet (21.5% CP; 3050 kcal ME/kg). A 2 x 4 FAT was used, consisting of feathering rate (fast and slow) in combination with four levels of methionine (Met) (Exp. 1) and Cys (Exp. 2). In Exp. 1 diets contained 0.50% Cys with 0.35%, 0.40%, 0.45%, and 0.50% total Met. Feed conversion (FC) responded linearly ($P \leq .01$) to progressive Met level but not weight gain (WG). No significant interaction occurred between feathering and Met level for either WG or FC suggesting a similar need by both sources of males. The second experiment examined the response to Cys level with feeds having marginal total Met (0.45%) to minimize sparing of Cys. Total dietary Cys progressed from 0.35% to 0.50%. Increasing Cys led to improved FC with fast (cubic response; $P \leq .02$) but not slow feathering birds, whereas WG was unaffected. Nitrogen balance studies conducted concurrently (from day 20 to 21) also failed to establish an interaction between Met level and extent of feathering (Exp.1), but an optimization at 0.45% with both broiler sources was apparent (quadratic response; $P \leq .0001$). Differences in the need for Cys attributable to feathering was detected in nitrogen retention ($P \leq .0001$), and slow feathering males attained an optimum at 0.45% (quadratic response; $P \leq .08$), whereas fast feathering males exhibited continuous improvement to the highest level of Cys (linear response; $P \leq .05$). Although present results indicate a Met requirement approximating 0.50% is appropriate, regardless of feather rate, and agrees with NRC (1994); the advocated Cys requirement is more a reflection of need for slow than fast feathering males.

192 Influence of dietary sodium level on response to source and level of methionine in broiler diets. M. A. Motl*, C. A. Fritts, and P. W. Waldroup, *University of Arkansas.*

Numerous studies have compared DL-methionine (DL-Met) and the hydroxy-methyl analogue 2-hydroxy-4-methylthiobutanoic acid (HMB) as sources of methionine for young chicks with variable results. One possible explanation for differences in results is the sodium content of the test diet, as absorption of DL-Met appears to be Na-dependent while absorption of HMB does not. A study was conducted in which a Met-deficient (0.28% Met) diet based on grain sorghum and soybean meal with 0.15% Na and 0.20% Cl was divided into three aliquots and fortified with additional Na from sodium bicarbonate to provide dietary Na levels of 0.15, 0.20, and 0.25%. Within each Na level, either DL-Met (99%) or HMB (88%) were added in amounts sufficient to provide either 0 or 0.30% Met activity. These diets were then blended in amounts calculated to provide 0, 0.04, 0.08, 0.12, 0.16, 0.20, 0.24, and 0.28% supplemental Met from each source at each level of sodium. Each of the 48 test diets was fed to six replicate pens of six male chicks in electrically heated battery brooders from 1 to 21 d posthatch. Source of Met had no significant ($P < 0.05$) effect on either BW or feed utilization (FU). Sodium level significantly influenced both BW and FU, with an interaction of Met level but not with Met source. At the lower levels of Met, the highest level of Na significantly reduced both BW and FU. As Met level increased no significant differences among Na levels were observed. These data suggest that Na level does not appear to influence the response to DL-Met or HMB as sources of Met under thermoneutral conditions.

Key Words: Methionine, Hydroxy Analogue, Sodium

193 Lysine need of broiler males from 42 to 56 days of age under terms of an ideal amino acid pattern. A. Corzo*¹, E. T. Moran, Jr.¹, and M. E. Jackson², ¹*Auburn University, Auburn, AL*, ²*Degussa-Huls, Kennesaw, GA.*

An "ideal" relationship of amino acids one to the other optimizes utilization of dietary protein. Dietary lysine has been used as the standard in this relationship, and its level prior to slaughter is known to influence final live performance as well as breast meat yield. An experiment

was conducted to measure lysine response by broilers to a finishing feed with the protein formulated to approximate an ideal amino acid pattern (Mack et al., 1999). A total of 1050 Ross x Ross 308 male broilers were randomly distributed into 30 floor pens of an open-sided house and provided common diets from placement until 6 weeks of age. From 6 to 8 weeks birds were fed a corn-soybean meal diet (18% CP and 3250 Kcal/kg ME) having essential amino acids "ideally" related to one another within the limits of practicality based on lysine at 0.85%. Five lysine levels from 0.75 to 1.15% were provided. Birds had continuous access to feed, water and light. Body weight gain was similar among treatments; however, feed conversion improved between the 0.75 and 1.15% lysine levels with an optimum approximating 0.85%. All birds were processed, and no significant differences were observed for abdominal fat, carcass yield without fat, and skinless boneless breast meats. The lysine requirement of 0.85% as advocated by NRC (1994) is in agreement with present results.

Key Words: Broiler, Lysine, Protein

194 Lysine, threonine, and arginine supplementation and effects on performance of young tom turkeys raised in a summer environment. J. Kalbfleisch^{*1}, V. Stangeland², J. Brannon¹, and S. Noll¹, ¹University of Minnesota, St. Paul, MN, USA, ²Stangeland Feed Consulting, Willmar, MN, USA.

The purpose of this study was to determine the response to lysine and threonine in diets of young tom turkeys, and any interaction among levels of lysine, threonine, and arginine to 11 wks of age. At 5 wks of age, 980 male Nicholas turkey poults were randomly sorted into 98 pens so that average starting weights were equal. Performance data was collected at 3-wk intervals. The basal diet was formulated to 92% NRC (1994) threonine, 95% NRC lysine, and 110% NRC TSAA at 3-wk intervals and all diets were supplemented with isoleucine, valine, and tryptophan. The basal diet was primarily composed of corn, soybean meal 47%, meat and bone meal, and canola meal. Diet protein in the basal diet was set by desired threonine level, and sources of L-lysine HCl, DL-methionine, L-arginine, and L-threonine were used to obtain desired supplemental levels of each amino acid. A factorial arrangement was used with three levels of lysine (0, .12%, .24%), two levels of threonine (0, .075%), and two levels of arginine (0, .12%). Average daily temperature ranged from 21°C to 26°C from 5-8 wks and 23°C to 29°C from 8-11 wks of age. At 11 wks of age, body weights were significantly affected ($P < 0.05$) by dietary lysine supplementation, where the .12% supplemented lysine diet performed better than the non-supplemented lysine diet. Threonine supplementation improved body weight by 1.05% ($P < 0.03$). During 8-11 wks of age, feed efficiency was improved by 1.83% with supplemental threonine ($P < 0.002$). The .12% supplemented lysine level, representing 105% NRC lysine, provided a better BW response over the basal lysine level (95% NRC) and high lysine level (113% NRC). Diets supplemented with threonine to 100% NRC provided a better BW response and feed efficiency compared to the non-supplemented threonine level, representing 92% NRC threonine. Interactions among amino acids were not detected except for feed efficiency during 8-11 wks for lysine and arginine.

Key Words: Turkey, Lysine, Threonine

195 Lysine needs of starting chicks and subsequent effects during the growing period. M. T. Kidd^{*1}, J. B. Yeatman¹, and B. I. Fancher², ¹Department of Poultry Science, Mississippi State University, Mississippi State, MS 39762, ²Aviagen North America, Inc., Huntsville, AL 35805.

The lysine requirement for broiler chicks has been studied extensively. Many factors such as protein quality, experimental conditions, dietary nutrients, and genetic strain affect lysine needs of chicks. Because lysine increases protein synthesis and decreases protein degradation in chicks, its requirement may vary as meat-type broiler genetics are improved. We conducted two experiments to evaluate lysine needs during the starter period in a broiler strain cross selected for enhanced white meat yield (Ross x Ross 508). Male broilers were randomly placed in 30 floor pens in two experiments (14 birds/pen in Experiment 1 and 30 birds/pen in Experiment 2). There were six dietary treatments representing graduations of lysine from 80 to 130% of NRC in 10% increments from Days 1 to 18. The lysine deficient diets (0.88% total lysine or 80% of 1994 NRC specifications) were similar in both experiments and were created by blending corn, soybean meal, corn gluten meal, wheat middlings,

poultry fat, and crystalline amino acids. All broilers received a common diet from Days 19 to 41 and Days 19 to 42 in Experiments 1 and 2, respectively. Growth responses were measured for the starter period and birds were processed and deboned at termination to determine effects of starter lysine on breast meat development. Quadratic response curves were fitted to growth performance criteria of chicks. Broilers fed lysine levels below NRC specifications as chicks had reduced growth and carcass attributes at Day 41 and 42. The lysine level required (95% of the upper asymptote) for chick growth responses was between 107 and 111% of NRC (1994).

Key Words: Lysine, Broiler, Amino Acid

196 Broiler growth and carcass responses to diets containing L-threonine versus diets containing threonine from intact protein sources. M. T. Kidd^{*1}, C. D. Zumwalt¹, D. W. Chamblee², M. L. Carden², and D. J. Burnham³, ¹Department of Poultry Science, Mississippi State University, Mississippi State, MS 39762, ²South Central Poultry Research Unit, USDA-ARS, Mississippi State, MS 39762, ³Ajinomoto Heartland, Inc., Chicago, IL 60631.

The third limiting amino acid for broilers is typically Thr and meeting its minimum in least cost formulation with L-Thr results in reduced CP. This experiment evaluated if diets formulated utilizing the supplemental amino acids Met, Lys, and Thr could achieve the same performance as commercially fed diets utilizing supplemental Met and Lys. Ross x Ross 308 broilers (1,440 of each sex) were randomized across 72 floor pens (40 birds/pen). The experimental design consisted of a 2 (sex) x 6 (dietary Thr) factorial arrangement (12 treatments and 6 replications/treatment). Two basal diets, with and without L-Thr, were formulated using identical minimum digestible amino acid values. This resulted in one diet with 600g/ton of L-Thr and one with no L-Thr. These two diets were blended together to make the intermediate treatments which consisted of: 1) a control diet with no L-Thr; 2) as 1 plus 150g/ton of L-Thr; 3) as 1 plus 300g/ton of L-Thr; 4) as 1 plus 450g/ton of L-Thr; 5) as 1 plus 600g/ton of L-Thr; and 6) as 5 with a digestible Thr/Lys ratio of 0.65. Dietary treatments were implemented from Days 1 to 20, 21 to 35, and 36 to 48. Growth responses were measured for each period and carcass responses were measured at Day 49. There were no significant Thr x sex interactions. Also, dietary Thr treatment differences did not occur for any parameter measured. BW gain, feed intake, and carcass parts weights were improved ($P < 0.05$) in male broilers versus female broilers, but female broilers had optimal ($P < 0.05$) feed conversion and livability. Although all treatment diets met adequate minimum levels of essential amino acids, treatment diets containing L-Thr had lower nutrient levels of CP, Ile, Arg, Val, and Trp. Formulating diets adequate in essential amino acids to contain up to 600g/ton of L-Thr does not affect growth or carcass attributes of commercial broilers.

Key Words: Threonine, Broiler, Amino Acid

197 Male and female broiler responses to low and adequate dietary threonine on nitrogen and energy balance. W. A. Dozier, III^{*1}, E. T. Moran, Jr.¹, and M. T. Kidd², ¹Auburn University, AL, ²Mississippi State University, MS.

Mucus associated with the intestine and digestive enzymes from the pancreas have extensive amounts of threonine. Presumably, mucus and enzyme formation would decrease when birds receive feeds low in threonine to adversely affect nutrient recovery. This study compared nitrogen and energy utilization of male and female broilers fed diets previously shown to be either deficient or adequate in threonine for males late in development. A total of 750 male and female broilers were randomly distributed into 30 floor pens of an open-sided house and provided diets that met NRC (1994) nutrient recommendations from placement until 6 wk of age. At 42 d, 48 birds (24/sex) were removed from the floor pens and individually caged in raised wire batteries. Each bird was given feed that was formulated to contain either 0.52 or 0.74% total threonine with 18% CP and 3,200 kcal ME/kg. The treatment structure consisted of a 2 x 2 factorial arrangement with 12 replications per treatment. Two 24-h excreta collection periods were conducted on Days 46 and 54 to measure nitrogen and energy recovery. On Day 46, males receiving 0.74% threonine had an advantage in retention of nitrogen (38.8 vs. 21.5%; $P \leq 0.05$) and recovery of AME_n 3.40 vs. 3.24 kcal/g; $P \leq 0.05$) but energy retention was not significantly ($P \leq 0.05$) different from those given the lower level. Dietary threonine did not affect nitrogen retention with females at Day 46, but contrary to expectation low threonine at 54 d

provided an advantage in nitrogen utilization (19.9 vs. 8.8%; $P \leq 0.05$) over females consuming the higher level. Dietary ME measurements with females were similar at both threonine concentrations and ages. Threonine need appears to be considerably more extensive with males than females, and inadequacies with males that exceed repercussion on N-balance also create conditions that reduce the recovery of ME.

Key Words: Amino Acid, Broiler, Threonine

198 Ideal ratio (relative to lysine) of tryptophan and threonine for chicks during the second and third week of life. A.B. Batal*, T.M. Parr, N.R. Augspurger, C.M. Parsons, and D.H. Baker, *University of Illinois, Urbana, IL USA.*

Three bioassays were conducted to determine the ideal ratios of Trp and Thr to Lys. Young male crossbred chicks (New Hampshire x Columbian) were fed diets based on corn gluten meal and synthetic amino acids (AA) that could be made singly deficient in Lys, Trp, or Thr. Diets for all assays contained 3,400 kcal ME/kg, and L-glutamic acid was used to make all diets (within and among assays) equal in protein at 23.8% of the diet. When fully fortified with each limiting AA, growth performance of chicks fed the corn gluten meal diet was equivalent to that observed with a 23% CP Met-fortified corn-soybean meal diet. True digestibility assessment of corn gluten meal in cecectomized roosters facilitated dose-titration studies (six dose levels for each AA) so that least squares fitted one-slope broken-lines and quadratic regression equations could be calculated to establish inflection points for both weight gain and gain:feed. Four battery pens of four chicks were fed one of six AA dose levels during the period 8 to 22-d posthatching. Weight gain and gain:feed responded quadratically ($P < 0.01$) to increasing doses of digestible Lys (0.68 to 1.28%), Trp (0.09 to 0.24%), and Thr (0.41 to 0.81%). Broken-line least squares analysis predicted breakpoints for gain and gain:feed, respectively, of: Lys (0.85, 0.96%), Trp (0.16, 0.16%), and Thr (0.53, 0.53%). Requirement estimates based on quadratic regression fits (90% of upper asymptote) predicted requirements for gain and gain:feed, respectively, of: Lys (0.97, 1.03%), Trp (0.19, 0.18%), and Thr (0.61, 0.62%). Regardless of curve-fitting method, gain:feed requirements for Lys (but not Trp or Thr) were much higher than weight gain requirements. Using the higher of the broken-line requirement estimates for gain and gain:feed, ideal ratios (% of Lys) were: Lys (100), Trp (17), and Thr (55). The

Trp ratio is similar but the Thr ratio is lower than previous estimates made in our laboratory.

Key Words: Tryptophan, Lysine, Threonine

199 Ideal ratio (relative to lysine) of isoleucine and valine for chicks during the second and third week of life. T.M. Parr*¹, A.B. Batal¹, N.R. Augspurger¹, and D.H. Baker¹, ¹*University of Illinois.*

Three bioassays were conducted to determine the digestible Lys, Ile and Val requirement of male crossbred (New Hampshire x Columbian) chicks during the period 8-20 days posthatching. The chicks were fed semi purified diets based on corn gluten meal (CGM) and amino acids (AA) that could be made singly deficient in Lys, Ile or Val. Diets for all assays contained 3,400 kcal ME/kg, and L-glutamic acid was used as a source of non-specific amino nitrogen to make all diets (within and among assays) equal in protein at 23.8 % of the diet. When fully fortified with each limiting AA, growth performance of chicks fed the CGM diet was equivalent to that observed with a 23% CP Met-fortified corn-soybean meal diet. True digestibility assessment of CGM in cecectomized roosters facilitated dose-titration studies (six dose levels for each AA) so that least squares fitted one-slope broken lines could be calculated to establish inflection points for both weight gain and gain:feed. Each AA dose level in each assay was fed to four battery pens of four chicks. Quadratic ($P < 0.01$) responses to each AA occurred when graded levels of digestible Lys (0.68 to 1.28 %), Ile (0.45 to 0.95 %) or Val (0.51 to 1.06 %) were fed. Breakpoint requirement estimates for gain and gain:feed, respectively, were : Lys (0.85, 0.97 %), Ile (0.59, 0.58 %) and Val (0.74, 0.74 %). Using the higher of requirement estimates for gain and gain:feed, ideal ratios (% of Lys) were : Lys (100), Ile (61) and Val (76). The Ile ratio was lower but the Val ratio was similar to previous estimates made in our laboratory. Breakpoint requirement estimates for gain and gain:feed were similar for all AA evaluated except Lys, where the requirement for feed efficiency was substantially higher than that for weight gain. Quadratic regression fits to the data so that 90 % of the upper asymptote could be calculated predicted higher requirements than those predicted from the breakpoint of the broken-line responses.

200 Bioavailability of zinc and copper lignosulfate complexes in broiler chicks. J.L. Grimes, J.W. Spears, and J.L. Godwin*, *North Carolina State University, Raleigh, NC, USA.*

Chickens are usually fed inorganic minerals to meet their mineral requirements. However, organic chelated minerals have been shown to be more bioavailable in some studies than inorganic forms. Two trials (T1 & T2) were conducted to determine the bioavailability of Zn and Cu from lignosulfate complexes (LSC) relative to feed grade sulfate forms. In each trial there were 24 pens with 7 male chicks per pen. In T1, the treatments were as follows: 1) Control - no supplemental Zn (10.1 ppm Zn analyzed); 2) 7.5 ppm supplemental Zn from ZnSO₄; 3)15 ppm supplemental Zn from ZnSO₄; 4)7.5 ppm supplemental Zn from Zn LSC; 5)15 ppm supplemental Zn from Zn LSC, and 6) 7.5 ppm supplemental Zn from Zn proteinate. In T2, the treatments were as follows: 1) no supplemental Cu (2.22 ppm Cu analyzed); 2) 1 ppm supplemental Cu from CuSO₄·5H₂O; 3)3 ppm supplemental Cu from CuSO₄·5H₂O; 4)1 ppm supplemental Cu from Cu LSC, 5)3 ppm supplemental Cu from Cu LSC, and 6)1 ppm supplemental Cu from Cu proteinate. The experimental design was a completely randomized design. In T1 on d 21, tibia Zn (TZ) and plasma Zn (PZ) were determined using four chicks per pen. In T2 on d 21, blood hemoglobin (Hb), liver Cu (LCu), bile Cu (BCu), and plasma Cu (PCu) were determined using four chicks per pen. Feed consumption, by pen, and BW were measured at d 0, 7, 14, and 21. Orthogonal contrasts were made to compare the effect of level and source of mineral on performance parameters in each trial. In T1, increasing dietary levels of Zn from all sources resulted in increased BW, BWG, TZ, and PZ. There was no effect of source on BW, BWG, TZ, or PZ. FC was improved by supplemental dietary Zn while source had no effect. In T2, there was no effect of level or source of Cu on BW, BWG, FC, or LCu. Both level and source of Cu increased BCu. Chicks fed the lower CuSO₄ level had higher BCu than those fed a similar level of Cu LSC. Hb and PCu were increased by supplemental Cu from both

sources. Dietary Zn and Cu LSC were similar in bioavailability to feed grade Zn and Cu sulfates.

Key Words: Zinc, Copper, Bioavailability

201 Evaluation of tetrabasic zinc chloride and tribasic copper chloride for growth promotion and toxicity in chicks. M.E. Persia*, C.M. Parsons, and D.H. Baker, *University of Illinois, Urbana, IL USA.*

Concerns associated with increasing antibiotic resistance of bacteria have cast a negative shadow on the use of sub-therapeutic levels of antibiotics as growth promoters in animals. With increasing legislation prohibiting the use of antibiotic growth promoters, other methods of growth promotion should be explored. High levels of both Zn and Cu have been used in swine diets to promote growth, and high levels of Cu have been used to a lesser extent in poultry diets. The objective of this study was to evaluate two new Zn and Cu compounds, Tetrabasic zinc chloride (TBZC) and Tribasic copper chloride (TBCC), for growth promoting effects and maximum tolerable levels that can be fed in corn-soybean meal diets to chicks. In the first experiment, TBZC (61.8% Zn) was fed at levels of 0, 0.05, 0.10, 0.15, 0.30, 0.50, and 1.00% added Zn. In a second experiment, TBCC (59.8% Cu) was fed at levels of 0, 0.015, 0.025, 0.05, 0.075, and 0.10% added Cu. Feed grade CuSO₄ was also added to supply 0.10% Cu for comparison. In both experiments, four replications of five New Hampshire x Columbian chicks were fed each diet from 8 to 22 days of age. The experiments were conducted in batteries that were left dirty from previous chick exposure. In the TBZC experiment, no differences were seen in weight gain or feed efficiency from feeding up to 0.15% supplemental Zn. A significant reduction in weight gain and feed efficiency occurred at 0.30% added Zn and higher levels. The 1.00% Zn treatment also resulted in increased mortality. In

the second experiment, the addition of 0.015 to 0.050% Cu from TBCC had no effect on chick weight gain, feed intake or feed efficiency. Levels of Cu above 0.050% decreased growth performance. The growth depressions from TBCC and CuSO₄ (0.1% added Cu) were similar in magnitude. Our results indicate that at least 0.15% supplemental Zn from TBZC and 0.05% supplemental Cu from TBCC can be safely fed to chicks.

Key Words: Tetrabasic Zinc Chloride, Tribasic Copper Chloride, Growth Promotion

202 The application of egg by-products as valuable protein supplements in broiler chicken diets. L.D. Schmidt*, B.A. Slominski, D. Boros, L.D. Campbell, and W. Guenter, *University of Manitoba, Winnipeg, MB, Canada.*

Egg by-products have received little attention as a poultry feedstuff despite their excellent amino acid profile, energy content and the presence of anti-bacterial proteins. The nutritive value of the egg by-products was evaluated in two experiments. The first experiment was a completely randomized design in which birds were fed corn-soy diets containing 8% of either fish meal (control), spray-dried technical albumen (SDTA), heat treated (hot room storage at 70°C for 72h) SDTA or heat treated spray-dried whole egg (SDWE). Similar body weight gains (529, 520, 480, 514 g/bird/14days) and feed conversion ratios (1.33, 1.34, 1.38, 1.32) were observed although a negative affect of heat treatment on the nutritive value of SDTA was evident. This was substantiated by reduced TME_n content of SDTA following hot room storage (5.32 vs 4.54 Mcal/kg). Amino acid digestibility, as determined at the terminal ileum, averaged 80-90% for lysine, methionine, cystine and threonine. Based on the results of the first trial a long-term production trial was conducted. Five replicates of 60 birds were fed one of four wheat-soy diets: a positive control containing fish meal and antibiotic (PC), a negative control with no antibiotic added (NC), NC+SDTA and NC+SDWE. The test proteins were included at 6% in the starter phase and 5% in the grower phase. The body weight gain and feed conversion averaged 2.14, 2.12, 2.18, 2.25 kg/bird and 1.68, 1.66, 1.61, and 1.60 for PC, NC, NC+SDTA and NC+SDWE, respectively. The high performance observed for the SDWE diet was substantiated by an increased AME over the PC diet (3212 vs 2956 kcal/kg). In comparison to the PC diet, a trend towards reduced populations of Gram-negative *Enterobacteriaceae* was observed for NC+SDTA (7.78 vs 6.15 Log CFU/g feces). It is evident from this study that the substitution of fish meal with egg by-products could further improve broiler chicken performance.

Key Words: Egg by-products, Nutritive value, Broiler chicken

203 Nutritional value of hydrolyzed whole swine for turkey poults. S. D. Crow*¹, P. R. Ferket, and T. F. Middleton², ¹NC State University, Raleigh, NC USA, ²Ag ProVision, Kenansville, NC USA.

Hydrolyzed whole swine (HWS) meal is produced by an alternative rendering method: ground carcasses were blended with soybean hulls then processed by flash dehydration and dry extrusion. Two experiments were conducted to evaluate the feeding value of HWS for poults. In both experiments, 400 hen poults were randomly assigned to one of five dietary treatments with 10 poults/pen. Four isocaloric and isonitrogenous corn-soy meal based diets, containing different levels of HWS (0,5,10,15%), were formulated to contain 90% of NRC (1994) recommendation for amino acids. A positive control (C) corn-soy diet was formulated to meet 100% NRC (1994) recommendations. All diets contained 0.5% titanium dioxide as an indigestible marker. Poults were housed in Petersime battery cages and fed the experimental diets *ad libitum* from 0 to 18 d of age. Body weights and feed intake were measured at 7, 14, 18 d of age, and fecal samples collected 14-18 d to determine apparent metabolizable energy (AME) content of all experimental diets. Treatment effects were not observed in experiment 1: however, significant effects were observed between the HWS test diets and the C diet for feed to gain (1.37 vs 1.29 P<.006) and g protein intake/gain (2.81, 2.84, 2.83, and 2.76, P<.006). There were no significant differences in growth performance observed among the HWS test diets. In experiment 2, there were no treatment effects observed on weight gain; however, FCR was significantly different P<.001 among the 4 test treatments and the C, respectively (1.24, 1.23, 1.30, 1.36, 1.22), indicating AME of the HWS was over estimated. Based on the AME data, the HWS produced for experiments 1 and 2 was estimated to be above 5250 Kcal AME/kg and

5109 kcal AME/kg, respectively. This study demonstrated that HWS is a high-value feed ingredient that can be included up to 15% in poult diets without adverse effects on growth performance, provided accurate knowledge of energy value.

Key Words: Flash dehydration, Extrusion, Hydrolyzed whole swine

204 Canola meal toasting can be eliminated as it has no positive effects on broiler performance. R.W. Newkirk*¹ and H.L. Classen, ¹University of Saskatchewan, Saskatoon, SK, Canada.

Elimination of toasting during the desolventization of canola meal (CM) would result in higher and more uniform amino acid availability but it is not known if such processing is required to reduce anti-nutritional or toxic factors in the meal. Therefore, the objective of this research was to study the effects of canola meal toasting on broiler chicken performance. Conventional toasted meal (TCM) and a hexane laden, non-toasted meal (NTCM) were collected from a crushing plant. NTCM was desolventized in a research desolventizer toaster without the use of sparge steam. The resulting meal contained low residual hexane and was yellow in color. The meals were fed to 3240 broiler chickens in a 2*2*6 factorial (2 sexes* 2 types of meal* 6 levels) with 45 birds per floor pen from 0-39 d. TCM and NTCM replaced 0, 20, 40, 60, 80 and 100% of the soybean meal (SBM) in wheat based diets. Elimination of toasting increased body weights from 0.606 and 2.148 to 0.618 and 2.181 Kg in 19 and 39 d chickens, respectively. It also improved gain to feed ratio (0-19 d) from 0.637 to 0.642 but did not affect mortality. Replacement of up to 80% and 60% of the SBM in the starter and finisher diets, respectively did not affect growth rate. Higher levels of TCM or NTCM significantly reduced growth rate and feed intake. Total mortality from 19 to 39 d and chronic heart failure (CHF) increased with level of CM addition from 5.19% to 13.89% and 1.85% to 9.63%, respectively. CHF in males, but not females was increased from 3.33 to 17.40% with CM level. In conclusion, elimination of toasting improved broiler growth and feed efficiency and was at least equal to TCM for other parameters. Therefore the production of NTCM may be commercially viable. The highest levels of TCM and NTCM reduced performance and increased mortality indicating maximum inclusion levels of 20 and 15% in starter and finisher diets, respectively.

Key Words: Canola meal, Toasting, Chronic heart failure

205 Nutritional, physiological, and metabolic significance of canola meal sinapine in broiler chickens. H. Y. Qiao*¹ and H. L. Classen¹, *University of Saskatchewan, Saskatoon, Saskatchewan, Canada.*

Sinapine (SNP) is the predominant phenolic compound found in canola meal (CM) and has been considered an anti-nutritional factor in laying hens. Research in broilers has not been known. An experiment was conducted to study the effect of level and source of dietary SNP on male broiler chickens (120 in total). SNP was fed in pure (SB; sinapine bisulphate), semi-purified (EE; CM ethanol extract) or in its native form in CM at three levels equivalent to 15, 22.5 and 30 % CM, and compared to a corn-soybean meal diet. Performance was measured from 0 to 18 days of age, after which birds were killed for measurement of all internal organs and collection of digesta samples for the study of nutrient retention, SNP digestibility, and volatile fatty acid (VFA) production. Feces was collected during the last two days of the experiment. Data were analyzed according to a one-way ANOVA. Dietary treatment did not affect growth rate, feed intake or weight of most organs. Exceptions were that feeding CM increased liver weight, and all diets containing SNP had lower empty cecal weight in comparison to the control. Dietary treatment did not affect VFA production in either the ileum or ceca. Both SB and EE treatments improved fecal AME and protein digestibility in comparison to the control. Digestibility of SNP ranged from 27 to 46 % and 54 to 75 % in the ileum and feces, respectively, and was affected by dietary source and level of diet inclusion. No SNP could be found in the ceca suggesting microbial hydrolysis in this area. Sinapic acid was found in feces samples from birds fed various sources of SNP indicating it is a hydrolysis product of SNP. Dietary SNP in three forms had no impact on the palatability of diets or demonstrate any anti-nutritional effects in the broiler chicken; SNP in SB form may actually provide a beneficial nutritional effect.

206 Nutrient characterization of guar meal fractions. S.R. Conner, J.T. Lee*, J. Carey, and C.A. Bailey, *Texas Agricultural Experiment Station.*

The annual legume, guar (*Cyamopsis tetragonoloba*) flourishes in arid climates such as north Texas. Currently guar is grown for its galactomannan polysaccharide gum that is utilized as a thickening agent in cosmetics, foods, feeds and oil field drilling mud. Guar meal is the by-product of gum production and has been used successfully in limited quantities as a source of vegetable protein in animal feeds. In the separation of the gum containing endosperm, two distinct fractions are obtained. The first fraction from the splitting of the guar bean has higher germ content and the second fraction removes the hull from the remaining endosperm. A third fraction results from a combination of approximately 22% fraction one and 78% fraction two. Nutrient profiles for the three fractions were determined by proximate and amino acid analysis. The crude protein content of the guar by-product meals averaged 45, 36, and 38% for fractions one through three, respectively. Methionine concentrations averaged 0.53, 0.44 and 0.45% while lysine averaged 2.00, 1.54 and 1.64%, respectively. Dry matter averaged about 91, 94 and 93%. Feeding studies suggest that guar meal can be a viable source of protein for poultry feeds.

207 Evaluation of the feeding value of a non-GMO high-protein soybean meal in broiler diets. B. Lenfestey*, R. Wilson, J. Burton, and J. Brake, *North Carolina State University, Raleigh, NC USA.*

This study was conducted to establish the relative feeding value in broiler diets of a high protein, non-GMO soybean meal (cv. Prolina). Meals were made at a commercial plant from a commercial variety of soybean (Soy-48) and Prolina grown in the same geographical region. Prolina meal possessed higher fiber due to the relatively small lot of beans being air-dried while the standard soybeans were mechanically dried. The difference in soybean moisture caused more hulls to be retained during crushing. Toasted soy hulls or Solka Floc powdered cellulose were used to dilute the Soy-48 to a similar fiber level as that found in Prolina meal. Broiler starter (1.13 kg per bird) and grower diets were formulated to meet or exceed NRC (1994) minimums. Dietary treatments contained the soybean meal sources as follows: Soy-48, Soy-48 diluted with soy hulls (Soy-48+SH), Soy-48 diluted with Solka Floc (Soy-48+SF), and Prolina. The study consisted of four dietary treatments with 8 replicate pens of 25 male broilers per pen. The results showed that Prolina produced a larger BW throughout the study when compared to the appropriate controls, Soy-48+SH and Soy-48+SF, but not different from undiluted Soy-48. The 42-day BW for the Soy-48, Soy-48+SH, Soy-48+SF and Prolina diets were 2.73 kg, 2.67 kg, 2.68 kg, and 2.72 kg, respectively. Unadjusted feed conversion ratio (average = 1.83) showed a slight advantage for the Prolina as well. Percentage mortality was not different across the dietary treatments. The results demonstrate that Prolina SBM has potentially beneficial nutritive traits.

Key Words: Broiler, Body Weight, Feed Conversion

208 Genetically modified rice containing lactoferrin and lysozyme as an antibiotic substitute in broiler diets. Brooke Humphrey*¹, Ning Huang², and Kirk Klasing¹, ¹*University of California, Davis*, ²*Applied Phytologics, Inc.*

Lactoferrin and lysozyme have antibacterial properties, and when combined together their activity is effective against bacteria along the epithelia. Two experiments were done to determine if genetically modified rice expressing human lactoferrin (LF) or lysozyme (LZ) protects the intestinal tract similar to sub-therapeutic antibiotics. Experiment one consisted of ten treatments: corn-soy diet (CS) + 15% conventional rice (control); CS + 0.1% LF; CS + 1.0% LF; CS + 5% LF; CS + 0.2% LZ; CS + 10% LZ; CS + 0.1% LF + 0.2% LZ; CS + 5% LF + 10% LZ; CS + antibiotics (Roxarsone at 0.025%, and Bacitracin at 0.05%). There were no differences in rate of gain or feed intake between any of the experimental rice diets compared to control or antibiotic diets. CS + 5% LF + 10% LZ had significantly better feed efficiency than the control rice diet. Chicks fed CS + 5% LF + 10% LZ had thinner lamina propria in the duodenum and jejunum compared to all other diets ($p < 0.05$). The number of leukocytes per villi was lower in chicks fed lactoferrin, lysozyme, antibiotic, and combination diets compared

to controls ($p < 0.05$). Experiment two had five diets: CS + 15% conventional rice; CS + 10% LZ; CS + 5% LF + 10% LZ; CS + antibiotic (Roxarsone at 0.025%, and Bacitracin at 0.05%); CS without rice. There was no effect of diet on rate of gain. Chicks fed CS + 10% LZ and CS + 5% LF + 10% LZ had significantly lower feed intake and significantly better feed efficiency than those fed the control rice diet ($p < 0.05$). The results from these experiments demonstrate a potential of genetically modified lactoferrin and lysozyme rice to be used as a substitute for antibiotics.

Key Words: Lactoferrin, Lysozyme, Chicken

209 Evaluation of high available phosphorus corn with and without phytase in diets for growing turkeys. C. A. Fritts*¹, F. Yan¹, H. L. Stilborn², and P. W. Waldroup¹, ¹*University of Arkansas*, ²*DuPont Specialty Grains.*

This study was conducted to compare normal yellow dent corn (YDC) and high available phosphate corn (HAPC), fed with and without phytase, in diets fed to growing turkeys. The HAPC contains approximately 0.27% P of which 0.17% is estimated to be available to the poult. The YDC contains approximately the same total P but only 0.03% available P. Substitution of YDC with HAPC will reduce the amount of phytate-bound P in the diet and consequently reduce the amount excreted. Diets were formulated with either YDC or HAPC to contain NRC recommended levels of nonphytate P levels to 20 wk. By removal of dicalcium phosphate and adjusting limestone, test diets were produced that contained reduced levels of P (-0.0%, -0.05%, -0.10%, and -0.15% of NRC) for both the YDC and HAPC. Each of these was fed with or without 1000 units/kg phytase (Natuphos, BASF) for a total of 16 treatments. Each treatment was fed to three pens of 20 male turkeys to 20 wk. At 4, 8, 12, 16, and 20 wk birds were weighed, feed consumption determined, and two birds per pen killed for tibia ash determination. Source of corn had no significant effect on BW, feed conversion, or mortality during the study. Birds fed diets with HAPC had significantly greater tibia ash than those fed YDC at 4, 8, and 12 wk. Addition of phytase significantly improved BW at 4, 8, 12, and 16 wk; at 20 wk turkeys fed phytase were heavier but difference was not significant. Tibia ash was significantly improved at all ages by phytase. No interactions were observed between source of corn and phytase supplementation. Although no fecal samples were taken in this study, the use of HAPC in conjunction with phytase supplementation and reduced P levels should play an important role in a program to reduce P excretion by turkeys.

Key Words: High available phosphorus corn, Phytase, Turkeys

210 Effect of dietary conjugated linoleic acid (CLA) on the growth and fat accumulation of broilers. M. Du*, K. C. Nam, S. J. Hur, H. Ismail, D. U. Ahn, and J. L. Sell, *Iowa State University.*

Two experiments were conducted to investigate the influence of dietary conjugated linoleic acid on the growth and fat accumulation in broilers. In experiment I, 50 three-week-old broilers (total 200 birds) were assigned to one of the diets containing 0%, 0.25%, 0.5%, or 1% CLA and fed for three weeks. In experiment II, 40 three-week-old broilers (total 120 birds) were assigned to one of diets containing 0%, 2%, or 3% CLA and fed for five weeks. Results showed that dietary CLA did not influence the growth, feed consumption, and abdominal fat accumulation in broilers. At the end of 3-wk feeding trial, the average body weight of broilers for Experiment I was about 2.20 kg per bird. For experiment II, after 5-wk feeding trial, the average body weights of birds were 4.04kg, 3.99 kg, and 3.93 kg for control, 2%, and 3% CLA groups, respectively, and were not significantly different. There were no differences in abdominal fat weight, liver fat content, serum triglyceride and cholesterol levels, and feces extractable lipid content. However, dietary CLA reduced monounsaturated fatty acid content, but increased saturated fatty acid content in tissues. Abdominal and subcutaneous fats from birds fed high levels of CLA (2% and 3%) were much firmer than those from control diet. The result of this experiment was unexpected, because dietary CLA has been consistently shown to reduce fat accumulation in rats, mice, and pigs. The reason for the ineffectiveness of CLA in reducing fat accumulation in birds is not clear. However, the major difference in fat metabolism between birds and rodents, where liver plays a central role in synthesizing triglycerides in birds and fat

tissues play a major role in rodents and pigs, could have contributed in part to the ineffectiveness of CLA in reducing fat accumulation in birds.

Key Words: Broiler, Conjugated Linoleic Acid, Fat Accumulation

211 Conjugated linoleic acid alters egg yolk fatty acid composition and hepatic histopathology of laying hens. Gita Cherian^{*1}, Troy B. Holsonbake¹, Mary P. Goeger¹, and Rob Bildfell², ¹*Department of Animal Sciences, Oregon State University,* ²*College of Veterinary Medicine, Oregon State University.*

The effect of dietary conjugated linoleic acid (CLA) along with n-3 polyunsaturated fatty acid (n-3 PUFA) on yolk fatty acid profile and hepatic lipid accumulation was investigated. Single Comb White Leghorn laying hens (n=40) were randomly assigned to four experimental diets containing 0, 0.5, 1.0, or 2.0% CLA. Menhaden oil was used as the source of n-3 PUFA. The total fat content of the diet was 3%. Hens were fed the diets for a period of six weeks. Six birds from each treatment were sacrificed and histopathological evaluation of the hepatic tissue was determined. Total lipid and fatty acid composition of the eggs were determined on day 1, 3, 6, 9, 12 and 15. Dietary CLA did not affect the total lipid content of egg yolk (P >.05). Addition of CLA resulted in an increase in saturated fatty acids (P <.05) with a concomitant reduction in monounsaturated fatty acids (P <.05) in the yolk. The amounts of CLA isomers (cis-9 trans-11, trans-10 cis-12) in the egg yolk were proportional to the levels of CLA in the diet (P <.05). The total CLA content in the egg yolk constituted to 0, 1.4, 2.7 and 5.4%, respectively (P <.05) on day 15 of feeding. Dietary CLA at all concentrations resulted in an increase (P <.05) in the total number of fat vacuoles in hepatocytes. The number of cells with 75% or higher lipid vacuolation in the cytoplasm were also increased (P <.05) by 2.0% CLA. Dietary CLA at all levels resulted in an increase (P <.05) in the total lipid content of hepatic tissue.

Key Words: Conjugated Linoleic Acid, Egg Fatty Acid, Liver Histopathology

212 Feeding various dietary levels of high oleic high oil corn and typical yellow dent corn to laying hens. 1. Live performance and egg production. H. L. Stilborn*, M. Araba, D. W. Rice, M. Hinds, and B. L. Smith, *DuPont Specialty Grains, Des Moines, Iowa, USA.*

High oleic high oil corn (HOHOC) contains an elevated level of oleic acid compared to typical yellow dent corn (YDC), in addition to the increased oil (energy) present in the kernel. The benefit of HOHOC would be not only the increased metabolizable energy present but also the increased oleic acid, which may improve the oxidative stability and fatty acid profile of eggs. A study was initiated to examine if varying the percentages of HOHOC and YDC in layer diets would affect hen performance and egg production. Eighteen-week old hens were randomly assigned to cages and given a standard pre-conditioner diet prior to starting the study. Fifteen cages with 5 hens per cage were utilized per treatment. The corn-soybean meal based diets involved blending the corns at different levels to provide 5 diets: 100/0, 75/25, 50/50, 25/75 and 0% YDC/100% HOHOC. Isocaloric and isonitrogenous mash diets were fed ad-libitum for seven periods (28 days/period). Live performance and egg production parameters were measured during the study. Results indicate body weights of hens were not influenced by the blending level of each corn used in the study, since the diets were formulated to the same nutrient requirements. Feed intake/hen/day, feed/dozen eggs and feed/kg of egg were not affected by corn source or the blending level of each corn. Egg production increased as dietary HOHOC increased. The greatest egg production came from hens fed diets containing at least 50% of the corn source as HOHOC. Further additions of HOHOC to 75 or 100% of the dietary corn source numerically improved egg production compared to hens fed the 50/50 blend. Feeding HOHOC to laying hens in isocaloric and isonitrogenous diets supports similar live weights, feed efficiency (per dozen eggs or per kg of egg) and optimum egg production versus hens fed diets containing only YDC as the corn source.

Key Words: High oleic high oil corn, Laying hens, Live performance, Egg production

213 Feeding various dietary levels of high oleic high oil corn and typical yellow dent corn to laying hens. 2. Egg quality parameters. H. L. Stilborn*, M. Araba, D. W. Rice, M. Hinds, and B. L. Smith, *DuPont Specialty Grains, Des Moines, IA USA.*

A study was initiated to examine how varying the inclusion levels of high oleic high oil corn (HOHOC) and typical yellow dent corn (YDC) in layer diets would influence egg quality parameters. Eighteen-week old hens were randomly assigned to cages and given a standard pre-conditioner diet prior to starting the study. Fifteen cages with 5 hens per cage were utilized per treatment. Corn-soybean meal based diets involved blending the corns at different levels to provide 5 diets: 100/0, 75/25, 50/50, 25/75 and 0% YDC/100% HOHOC. Isocaloric and isonitrogenous mash diets were fed ad-libitum for seven 28 day periods. Egg quality parameters, egg cholesterol, TBA values, yolk vitamin E content and fatty acid profiles were measured. Feeding hens diets containing HOHOC at 75 to 100% of the dietary corn source supported the heaviest egg weights compared to the treatment fed hens. Shell thickness, Roche color score as well as Minolta l, a and b values were not affected by corn source or the degree of corn blending. Albumen height was greatest from eggs of hens fed 25/75 and 0% YDC/100% HOHOC diets. Yolk and albumen weights were heavier from hens fed diets with at least 75% of the corn source represented by HOHOC. Egg TBA values generally increased with increased storage time. However egg TBA levels increased at a slower rate as dietary HOHOC inclusion increased, particularly during days 6 and 12 of storage. Yolk vitamin E levels increased and egg cholesterol content decreased as dietary HOHOC content increased. Yolk oleic fatty acid increased, linoleic decreased, oleic:linoleic ratio increased, conjugated linoleic acid decreased and monounsaturated fatty acid levels increased as dietary HOHOC inclusion level increased. Feeding HOHOC, especially at 75% of the dietary corn source, in isocaloric and isonitrogenous diets supported optimum egg quality parameters. Blending level between HOHOC and YDC tended to influence some egg parameters.

214 Nutritional evaluation of Bt (MON810) and Roundup Ready[®] corn compared with commercial hybrids in broilers. A.M. Gaines*, G.L. Allee, and B.W. Ratliff, *University of Missouri-Columbia.*

Experiments were conducted to compare the nutritional value of insect protected (containing CryIA (b)protein, Bt) corn, glyphosate-tolerant (Roundup Ready, RR) corn, their near isogenetic parents (BtC and RRC) and three commercial corn hybrids (C1, C2, and C3). In a 14-day growth assay, 3-day old male broiler chickens were weighed and allotted into 50 pens (6 birds/pen) using a complete randomized design. For each treatment, the five corn hybrids (Bt, BtC, C1, C2, and C3) were included in the diets at the same percentage. The performance parameters of ADG, ADFI, and G:F were determined. No differences were observed in terms of ADG; however, differences (P <.05) were detected for ADFI and G:F. Birds on the BtC diet had a lower ADFI while birds on the C1 diet tended to have poorer G:F. Subsequent to the 14-day growth assay experiment, 35 pens (6 birds/pen) were used to evaluate apparent metabolizable energy values. Diets consisted of only the corn hybrid supplemented with vitamins and minerals. Feed disappearance and fecal output were determined. Dry matter and gross energy values were obtained for the feed and fecal matter. No differences in apparent metabolizable digestibility coefficients were observed (P >.05) due to corn hybrid. In an additional 14-day growth assay, 3-day old male broiler chickens were weighed and allotted into 50 pens (5 birds/pen) using a complete randomized design. For each treatment, the five corn hybrids (RR, RRC, C1, C2, and C3) were included in the diets at the same percentage. The performance parameters of ADG, ADFI, and G:F were determined. No differences (P >.05) in performance parameters were observed. Following the growth assay, 35 pens (5 birds/pen) were used to evaluate apparent metabolizable energy values. No differences in apparent metabolizable digestibility coefficients were observed (P >.05) due to corn hybrid. In conclusion, Bt and RR corns were nutritionally equivalent to their near isogenetic parents; however, there were slight performance differences among the three commercial corn hybrids tested.

Key Words: Corn, Broiler, Growth

215 Application of lactic-acid-producing bacterial cultures to skin of live broilers. J. A. Cason*, R. J. Buhr, A. Hinton, Jr., M. E. Berrang, and N. A. Cox, *Russell Research Center, Athens, GA USA.*

In four trials, lactic-acid-producing bacterial cultures were applied to the skin of live broilers 24 h before slaughter to determine whether inoculation of the cultures could affect the numbers of bacteria that are normally found on the skin of processed broiler carcasses. The cultures contained 10,000 to 100,000 cfu/mL and were sprayed in 250 mL of a pH 6.0 nutrient medium (including glucose, peptone, beef extract, yeast extract, a surfactant, and salts) to enhance the growth and survival of the cultures. With broilers suspended by the feet, feathers were moved aside to apply as much of the liquid as possible directly to the skin. Sprayed broilers were then returned to a pen. In each trial, 4 five-wk-old broilers were sprayed and 4 broilers were kept as untreated controls. The following day, broilers were processed in a research processing facility and defeathered carcasses were sampled by rinsing for 1 min in 100 mL of peptone water after removal of heads and feet. Coliforms, *E. coli*, lactic-acid bacteria, and *Campylobacter* were enumerated by standard methods. After removal of aliquots for plating, the remaining sample volume was enriched to detect salmonellae. No differences were found in log₁₀(cfu/mL) of coliforms, *E. coli*, or lactic-acid bacteria between the treated and control carcasses. All carcasses were *Campylobacter*-negative. Salmonellae were present on some carcasses, but with no differences between treatments. Spraying lactic-acid-producing bacteria with nutrients on the skin of live broilers appears to have no effect on numbers of bacteria that are present on the skin after defeathering.

Key Words: Lactic acid bacteria, Skin, Broilers

216 Microbiological consequences of skin removal prior to evisceration of broiler carcasses. M. E. Berrang*, R. J. Buhr, and J. A. Cason, *USDA-ARS-Russell Research Center.*

The skin of broilers can harbor high numbers of bacteria. If broiler processing could be altered such that the skin is removed early like feathers, feet and heads, perhaps a large proportion of these bacteria could be left behind. The objective of this project was to determine if removal of skin prior to evisceration lowers the number of bacteria that can be recovered by whole carcass rinse or outer surface sponge sampling. Two sets of experiments were conducted, one with each type of sampling (rinse or sponge). On each of three replicate sample days, ten New York dressed carcasses were obtained from a commercial broiler processing plant, five were aseptically skinned and five were left with skin intact. On each carcass, the esophagus was tied and cut above the proventriculus allowing the crop to be removed toward the head to prevent contamination of the body cavity. The carcasses were then aseptically eviscerated by hand. Carcasses were either rinsed in 100 mL sterile water or sampled by moist sponge over the outer surface. Serial dilutions from the rinse or sponge were plated on Campy cefex agar, *E. coli* petrifilm plates and plate count agar. Data are reported as mean log₁₀ cfu per sample. When sampled by rinse, 5.4 *Campylobacter*, 4.4 *E. coli* and 6.7 total aerobic bacteria were recovered from carcasses with intact skin. Significantly less *Campylobacter* (4.7) and total aerobic bacteria (5.8) were recovered from skin-off carcasses. No difference in *E. coli* counts was noted for whole carcasses rinsed without skin (3.9). When sampled by sponge, 4.5 *Campylobacter*, 3.7 *E. coli* and 5.6 total aerobic bacteria were recovered. Significantly less *Campylobacter* (2.0), *E. coli* (2.3) and total aerobic bacteria (3.3) were recovered from carcasses without skin. Although not commercially practical, it is possible to lower the level of bacteria including *Campylobacter* on the outside of broiler carcasses by removal of the skin prior to evisceration.

Key Words: Broiler skin, *Campylobacter*, *E. coli*

217 In Plant Microbial Profile of Air Chilled Chickens. W. M. Fluckey*, M. X. Sanchez, M. M. Brashears, E. Wallner-Pendelton, A. Aguilar, M. Tamayo, and S. R. McKee, *University of Nebraska, Lincoln, NE.*

Many factors influence the microbial profile of chicken carcasses at retail. These factors include growout conditions at the farm as well as plant processing methods. To date there has been little data available to establish a microbial baseline for the air chilling poultry process in

the U.S. because this method of chilling is primarily used in Europe. In a one-year period, birds representing 24 farms were evaluated for total aerobic microorganisms, coliforms, psychrotrophs, generic *E. coli*, *Salmonella* spp. and *Campylobacter* spp. Broilers were sampled at three sites during processing: before evisceration (BE), after evisceration (AE), and after chill (AC). Approximately a 0.5 log reduction in aerobes, coliforms and generic *E. coli* was observed AE compared to BE. An additional 0.5-1-log decrease in these populations was observed AC. *Salmonella* spp. and *Campylobacter* spp. enumeration was more variable. When *Salmonella* and *Campylobacter* counts were high, decreases in populations occurred AE and AC. Most often, higher prevalence of *Salmonella* and *Campylobacter* in the plant was related to flocks that came from farms with an open pond water source contaminated with these pathogens. This data suggest that water source contamination on the farm may play a larger role than higher counts of *Salmonella* and *Campylobacter* found in the plant and that numbers of bacteria on chicken carcasses are reduced as the birds proceed through the processing environment. Although there is a reduction in bacteria during processing, high initial loads of bacteria on carcasses entering processing facilities equates to higher bacterial loads after processing.

Key Words: Air chilling poultry, *Salmonella*, *Campylobacter*

218 Development of Time/Temperature Indicator Tags for Tracking Poultry Product Quality Throughout the Cold Chain. C.M. Moore*¹ and B.W. Sheldon¹, ¹*North Carolina State University, Raleigh, NC/USA.*

Time-temperature integrators (TTIs) offer a means of continuously monitoring the temperature of a food product from the point of manufacture to the consumer's refrigerator. TTIs readily indicate temperature abuse and are used to clearly indicate the end of shelf life based on the product's temperature exposure. Currently, no work has been published on the application of TTIs to poultry products. This study was conducted to develop and validate VITSAB-Cox-brand TTIs for monitoring fresh chicken quality throughout the cold chain. VITSAB-Cox TTIs change color from green to yellow to indicate the end of shelf life. Chroma [$\sqrt{(a^2 + b^2)}$] was used to objectively indicate TTI progress. Total bacterial plate counts and *Pseudomonas* species counts were used as quality indicators for chicken drumsticks. Raw chicken drumsticks (n = 4) and VITSAB TTIs (n = 5) were stored at four constant temperatures to identify their Arrhenius activation energy (E_a) which is a measure of temperature sensitivity. The E_a for *Pseudomonas* and for the total indigenous population were determined to be 21.7 ($r^2 = 0.94$, SE=3.8) kcal per mole and 22.5 ($r^2 = 0.97$, SE = 2.9) kcal per mole, respectively. The E_a for the TTI based on its chroma was determined to be 19.8 ($r^2 = 0.98$, SE = 2.2) kcal per mole. Shelf life studies were conducted at constant temperatures (3C and 4.5C) and under fluctuating temperature conditions (stepwise change between 4.5C and 14.5C) with TTIs attached to individual packages of drumsticks. For both constant and variable temperature studies, the TTIs correctly indicated the end of the drumsticks' shelf life. The chroma readings were significantly correlated ($p \leq 0.0001$) to *Pseudomonas* populations [$r = 0.85$ (4.5C), $r = 0.93$ (3C), $r = 0.77$, 0.87(variable temperatures)] and total microbial growth [$r = 0.86$ (4.5C), $r = 0.93$ (3C), $r = 0.8$, 0.91(variable temperatures)]. These findings demonstrated that the VITSAB-Cox TTIs were effective in predicting the end of shelf life of refrigerated and temperature-abused chicken drumsticks as defined by *Pseudomonas* and total aerobic bacterial populations.

Key Words: Time Temperature Indicators, Poultry Products, Shelf Life Prediction

219 Effects of three packaging systems on the natural microflora and acceptability of fresh broiler breast meat. Nadege Charles and Sally K. Williams*, *University of Florida, Gainesville, FL/U.S.A..*

A study was conducted to investigate the effects of three packaging systems on the spoilage microflora, objective color and sensory characteristics of fresh commercial broiler chicken breast meat packaged for retail marketing. Fresh chicken broiler breasts were purchased from a local poultry processing plant and packaged in either (1) conventional styrofoam tray with polyvinyl chloride over-wrap and absorbent pad (PAD), (2) styrofoam tray with polyvinyl chloride over-wrap minus the

pad (PAD), or (3) Fresh-R Pax™ container (FRP) equipped with absorbent liner-gel system. All packages were heat sealed and stored at 1.21 C for 8 d. At each sampling period (0, 2, 4, 6 and 8 d), three packages from each treatment were analyzed for *Pseudomonas sp.* and psychrotrophic organisms, objective color and sensory characteristics. The data revealed similar results for all packaging systems. In general, the *Pseudomonas sp.* and psychrotrophic counts increased as storage time increased for all packaging systems. The color and sensory characteristics (i.e., odor and overall appearance) were similar for all packaging systems. While the absorbent pad used in the conventional tray-pack system and the absorbent liner-gel system incorporated into the Fresh-R Pax™ did not function to control microbial growth, they maintained aesthetic appeal by absorbing all visible moisture released from the meat during storage. This study also suggested that the Fresh-R Pax™ system would function well in reducing free purge in bulk packaged fresh meat and poultry, especially during transport.

Key Words: Packaging, Microbiology, Shelf life

220 Effect of packaging systems on bacteria survival on processed poultry. J. A. Byrd*¹, A.R. Sams², D.J. Caldwell^{2,3}, L.F. Kubena¹, and B.M. Hargis^{2,3}, ¹USDA-ARS, Southern Plains Agricultural Research Center, College Station, TX, 77845, ²Texas A&M University, Department of Poultry Science, ³Texas A&M University, Department of Veterinary Pathobiology, Texas Agricultural Experiment Station.

Previously, we evaluated the effects of modified atmosphere packaging (MAP) gases on the survival of naturally occurring *Campylobacter* on raw poultry and found that O₂ was the most effective in reducing the bacteria. Presently, we evaluated the effects of packaging methods on the survival of naturally occurring *Campylobacter*, aerobes, and psychrophiles on whole or parts of raw poultry. Whole or parts from broiler carcasses (400) were packaged with MAP, ice pack, chill pack, vacuum pack or frozen and sampled for detection of *Campylobacter*, psychrophiles, and total aerobes at 0, 2 and 14d of refrigerated (2°C) storage. MAP gases evaluated were 100% O₂ and a standard mixture (5% O₂ + 10% CO₂ + 85% N). The rinse fluid was recovered, pooled from 5 individual rinses, and serial dilutions made for examination of *Campylobacter* (campy-cefex, 42°C, 48h), psychrophiles (plate count agar, 4°C, 7d), and total aerobic bacterial populations (plate count agar, 37°C, 24h). *Campylobacter* counts for all treatment were reduced during the 14d storage period but the O₂ and frozen treatments caused a significantly (P<.05) greater reduction than the other treatments. Storage for 14d in chill or ice packs resulted in the greatest growth of psychrophilic (spoilage) bacteria. Psychrophilic growth was reduced by frozen, O₂, and gas mixture methods with the mixture having the greatest reduction. Freezing, followed by storage in MAP gas mixture, O₂, and chill pack parts, caused the greatest reduction of aerobes through 14d. These data suggest that O₂ may be a preferred MAP environment because it actually reduced *Campylobacter* detection and retarded both psychrophile and aerobe growth during storage.

Key Words: *Campylobacter*, Modified atmosphere packaging, Storage

221 Application of Active Packaging Films to Inhibit *Salmonella* Typhimurium on Broiler Drumstick Skin. B.W. Sheldon*¹ and P.L. Dawson², ¹North Carolina State University, Raleigh, NC/USA, ²Clemson University, Clemson, SC/USA.

The incorporation of bacterial inhibitors in biodegradable primary packaging films that are applied to fresh poultry products has the advantage of not only providing a hurdle for controlling pathogenic organisms at the processing plant but also throughout the entire marketing and distribution cold chain. The objective of this study was to develop and characterize the inhibitory activity of casted corn zein and heat-pressed wheat gluten packaging films containing varying combinations and concentrations of nisin, lauric acid, citric acid, and Tween 80 on inactivating a nalidixic acid-resistant strain of *Salmonella* Typhimurium on broiler drumstick skin. Following application to the skin and subsequent refrigeration, triplicate skin samples were taken at 42, 88, and 168 hours and the population of surviving *S. Typhimurium* cells estimated following a skin rinse and surface plating technique on BHI agar supplemented with 800 ppm nalidixic acid (37C, 48h). In comparison to control samples that were overlaid with films lacking any inhibitors, a significant reduction in the *S. Typhimurium* populations was detected in the films containing the inhibitors. The maximum inhibition detected was 1.23

(168 h) and 2.17 logs (44 h) for the corn zein and wheat gluten films, respectively. Those films containing multiple inhibitors such as nisin and lauric acid or nisin, lauric acid, citric acid, and Tween 80 produced the greatest inhibition. Reduction of microbial pathogens and spoilage microorganisms on fresh poultry products by safe and naturally occurring antimicrobials (i.e., bacteriocins and organic acids), achieved in a practical and economical way such as by packaging films, could contribute to a significant decrease in the incidence of human disease and the attendant costs. Furthermore, these active package delivery systems could also be utilized at the retail level to further assure the safety and quality of poultry products throughout retail marketing.

Key Words: Inhibitory Packaging, Nisin, *Salmonella* Typhimurium

222 Effect of electron beam irradiation on poultry meat safety and quality. S. J. Lewis*, A. Velásquez, S. L. Cuppett, and S. R. McKee, University of Nebraska-Lincoln Lincoln, NE.

FDA approved the use of irradiation for the control of salmonellae in poultry in 1990. Doses of 1.5 to 3.0 KGy in raw packaged poultry were established as guidelines in 1992. The purpose of this study was to determine whether electron beam irradiation doses of 1.0 and 1.8 KGy could eliminate bacteria in boneless, skinless chicken breasts. Microbial testing was done in triplicate with each treatment consisting of 10 samples. Four breast fillets in a covered/polystyrene tray constituted one sample. Results show that the average populations for coliforms, generic *E. coli*, and psychrotrophs were 11.0, 11.6, and 21.4 CFUs/ml, respectively, in the control samples. However, no populations were detected after the samples were irradiated at a dose of 1.0 or 1.8 KGy. An average level of 254.8 CFUs/ml was detected for aerobic bacteria in the control samples. Irradiation doses of 1.0 and 1.8 KGy reduced the levels to 1.3 and 0.4 CFUs/ml, respectively. Irradiation also rendered the breast fillets free of *Salmonella* and *Campylobacter*. Consumer taste panels were also conducted using a 9-point Hedonic scale to evaluate quality parameters of irradiated poultry. Three sets of each treatment group were randomly selected, individually packaged, and stored for 0, 14, and 28 days at -4°C. Results indicated that the irradiated samples stored for 28 days were less appealing with increased drying and a decrease in the texture, flavor, and overall acceptability. Degree of oxidation was also tested in the breast fillets using TBAR analysis. Within each storage period, TBAR values increased as the level of irradiation increased. In addition, as storage time increased, the TBAR values also increased. Results also indicated that the irradiated samples had higher "a" values, indicating they were "pinker" in color when compared to the controls. In this study, irradiation of the breast fillets proved to be effective in the elimination of bacteria with an improvement in the breast fillet color, but quality of irradiated samples decreased with increasing storage time.

Key Words: irradiation, electron beam, quality of poultry meat

223 Consumer poultry preparation habits and opinions concerning food safety, irradiation, and hormones in El Paso, TX and Las Cruces, NM. K. G. Maciorowski*¹, S. G. Birkhold², and S. C. Ricke², ¹Delaware State University, ²Texas A&M University.

One hundred and fifty supermarket shoppers were surveyed at random in El Paso, TX and Las Cruces, NM to determine poultry preparation habits and opinions concerning food safety, irradiation, and hormones. The respondents were generally older than 26 and 60% were female. The respondents were mostly either Hispanic (70%) or Caucasian (21%), and the majority (68%) possessed a high school education or less. Consumers believed that either pork (26%) or poultry (21%) was the most dangerous meat, with 27% citing no difference. A majority (57%) of consumers believed that bacterial issues were paramount for poultry, but 67% did not use a meat thermometer. Thermometers were most often used for whole birds (11%) or during holidays (12%). Poultry was generally frozen (48%) and thawed in a refrigerator (41%) before use. Television (29%) and family (20%) were most often cited as the most influential source of food safety information. Fifty-five percent of respondents claimed to have had foodborne illness, with either bacteria (17%) or spoiled food (13%) thought to be the culprit. Thirty percent would eat irradiated poultry, while 66% believed that hormones are used in poultry production. Educational programs could be best targeted via television, or by family nutrition counseling.

Key Words: Consumer, Survey, Meat Preparation

224 Egg production and quality response of commercial laying hens molted with alfalfa diets. K Medvedev*¹, C Woodward¹, X Li¹, L Kubena², D Nisbet², and S Ricke¹, ¹Texas A&M University, Department of Poultry Science, ²USDA-ARS, Food and Feed Safety Unit.

Molting is a process that is used throughout the commercial egg industry to extend production in older laying hens. Common industry practices usually involve the removal of feed for a period of several days. It has been shown that molting by feed deprivation can cause a higher risk of *Salmonella* contamination in eggs. This coupled with the increasing awareness of molting practices by consumers has led to the need for alternative molting procedures. One such alternative is feeding alfalfa as an insoluble fiber source during molt. In this study, hen egg production and several quality factors were evaluated in hens that were feed deprived or fed alfalfa meal or pellets for a period of nine days. Hens were kept on a 8h:16h (light:dark) lighting program during the molting period. After the molting period, all hens were placed on layer ration *ad libitum* and a 16h:8h lighting program. Factors investigated include: date of reentry into production, air cell size, egg length, egg weight, egg circumference, albumin height, and yolk height. Post molt egg production in alfalfa pellet (61.24%) and alfalfa meal (55.14%) was shown to be significantly higher ($p \leq 0.05$) than feed deprivation (54.38%). All other quality measurements were consistent across all molting treatments in this study. This data suggests that birds molted using an alfalfa diet will produce eggs in comparable quality and number to birds molted by feed deprivation.

Key Words: Alfalfa, Egg production, Molt

225 Conjugated Linoleic Acid Alters Egg Yolk Fatty Acid Composition and Volatile Compounds in Raw, Cooked and Irradiated Eggs. Gita Cherman*¹, Troy B. Holsonbake¹, Mary P. Goeger¹, and Dong U. Ahn², ¹Department of Animal Sciences, Oregon State University, ²Department of Animal Science, Iowa State University.

The effect of dietary conjugated linoleic acid (CLA) along with n-3 polyunsaturated fatty acid (n-3 PUFA) on yolk fatty acid composition and volatile compounds in raw (R), hard boiled (HB) or hard boiled eggs irradiated (HBI) at 2.5 kGy were investigated. Single Comb White Leghorn laying hens ($n = 40$) were randomly assigned to four experimental diets containing 0, 0.5, 1.0, or 2.0% CLA. Menhaden oil was used as the source of n-3 PUFA. Eggs collected after six weeks of feeding were analyzed for fatty acids ($n = 6$) and volatile compounds ($n = 4$). The content of C22:6 n-3 was reduced ($P < 0.05$) in eggs from hens fed high CLA diet. The contents of cis-9 trans-11 CLA and trans-10 cis-12 CLA in the egg yolk were 3.2 and 1.6%, respectively, for 2.0% CLA diet, and 0.9 and 0.35%, respectively, for 0.5% CLA diet ($P < 0.05$). Total volatiles were reduced in R eggs from 1.0 and 2.0% CLA diets. 2-Propanone, hexane and methyl cyclopentane were the major volatiles in R eggs and were reduced by dietary CLA at 1.0% and 2% levels. Acetaldehyde, pentane, propanol, acetic acid methyl ester, acetic acid ethyl ester, propionic acid methyl ester, 2-methyl-methyl propionic acid, 2-propanone and octane were the major volatiles in HB eggs and was reduced by 2.0% CLA ($P < 0.05$). No difference was observed in the acetaldehyde, pentane, propanol, acetic acid ethyl ester, octane and total volatile content of HBI eggs ($P > 0.05$).

Key Words: Conjugated linoleic acid, Yolk fatty acids, Egg volatiles

226 Effect of electrostatic application of MaxSpray on *Salmonella* Enteritidis attached to the surface of eggs. S. M. Russell*¹, ¹The University of Georgia.

A study was conducted to evaluate the effect of MaxSpray (N-Alkyl dimethyl benzyl ammonium chloride) in combination with an electrostatic spraying system (ESS) on populations of *Salmonella* Enteritidis (SE) coated onto the surface of eggs. Forty eggs were washed and sanitized using a chlorine based sanitizer. The eggs were rinsed thoroughly in deionized water to remove any residual sanitizer. Eggs were submerged into 1% peptone broth containing actively multiplying SE. Thirty of the eggs were placed into a plastic egg flat in the ESS chamber. MaxSpray solution (3600ppm) was prepared using sterile deionized water and electrostatically sprayed onto the eggs using two-10s bursts every hour for 6 h. A total of approximately 800mL of MaxSpray solution was used. The remaining 10 control eggs were treated by electrostatically spraying them with tap water using the same procedure as

for the MaxSpray. Three eggs were also evaluated after immersion into SE and drying to determine how many SE attached to the egg. After treatment, the contents of each egg were aseptically removed and each shell was placed into a neutralizing solution. One mL of this solution was then placed into 9 mL of brain heart infusion broth (BHI) and vortexed. One mL of this solution was then placed into Bactometer module wells in duplicate. Bacterial growth was monitored using the Bactometer Microbiological Monitoring System 128. Three replicate trials were conducted. Microbiological tests indicated that for the three replicate trials, the initial inocula averaged 185, 370, and 120 SE/mL, respectively. SE was recovered from all control eggs, which had an average impedance detection time (DT) of 8.8, 8.7, and 8.0 for unsprayed control eggs, respectively, and 9.8 h for controls sprayed with tap water. Results demonstrated that MaxSpray was able to completely eliminate all SE on 19/30 (63%), 28/30 (93%), and 24/30 (80%) eggs in trials 1, 2, and 3, respectively. For eggs that remained contaminated with SE, the average DT significantly increased from 9.8 for the controls to 10.6, 11.1, and 13.3 (MaxSpray treated) in trials 1, 2, and 3, respectively, indicating a significant decrease in the number of SE. Thus, MaxSpray, in combination with ESS, appears to be an effective means of eliminating SE from egg surfaces.

Key Words: *Salmonella* Enteritidis, MaxSpray, Electrostatic Spraying System

227 Why the Haugh Unit is wrong. F. G. Silversides*¹ and T. A. Scott², ¹Agriculture and Agri-Food Canada, Charlottetown, Canada, ²Agriculture and Agri-Food Canada, Agassiz, Canada.

The Haugh Unit was developed in the 1930s as a means of measuring the quality of an egg by measuring the height of the inner thick albumen. The Haugh Unit formula converts the height to a log scale because albumen height declines in a logarithmic fashion with storage, it uses a scale between 0 and 100, and it adjusts the height for the weight of the egg. The difficulties are in adjusting the height for egg weight, and in using a measure of the height of the inner thick albumen as a measure of egg quality. Eggs from ISA-White and ISA-Brown hens between 25 and 59 wk of age were stored at room temperature for 1 to 7 d to produce a data set with known variation in the three most important determinants of albumen height. Age and storage had the expected effects on egg size, yolk, shell and albumen weights, and albumen height. Regressions of albumen height on egg weight calculated for groups of eggs separated by age of hen and storage period for each strain varied between -0.058 and 0.102 mm per gm egg wt. The Haugh Unit formula uses a fixed regression of 0.05 mm in albumen height per gm egg weight and in this sample of eggs would have introduced a bias into the measurement of egg quality. The use of the log scale in the Haugh Unit suggests that early researchers used albumen height as a measure of freshness, and it is clear that albumen height decreases with storage. The height of the inner thick albumen is associated with levels of the protein ovomucin, which is extremely viscous. However, only 1.5 to 3.5 % of the total protein in albumen is ovomucin and other proteins with good foaming properties make up much larger proportions of the albumen. It is not clear from the scientific literature that moderate differences in albumen height are associated with altered functional characteristics of the egg, suggesting that the most appropriate use of albumen height is to measure freshness. In this sample of eggs, storage, strain of hen, and age of the hen all affected albumen height, imposing a bias on the measure of freshness which was not seen for albumen pH. Measuring freshness of eggs by the height of the inner thick albumen introduces a bias against old hens and some strains of hen, and adjusting the albumen height by applying the Haugh Unit formula further confounds the problem.

Key Words: Egg quality, Albumen height, Haugh unit

228 The effect of cryogenic cooling with carbon dioxide on the USDA grade and microbial load of shell eggs in the commercial setting. L.A. Hughes*¹, K.E. Anderson¹, and P.A. Curtis¹, ¹North Carolina State University.

To determine the effects of cryogenic cooling on the USDA grade and microbial quality of shell eggs, a commercial scale prototype CO₂ cooling unit was placed in a commercial processing facility. Shell eggs were processed using an 8400 Diamond Washer/Grader. Eggs were washed, candled, and sorted for size then passed through the cryogenic prototype cooler prior to packaging. Eggs were packaged automatically and palletized prior to storage in a walk-in cooler (7C). Two trials were conducted, 12 and 15 week periods, respectively. On a weekly basis 18 dozen

of eggs were selected for grading samples based on USDA random sample selection process. Physical quality of intact shell eggs was significantly improved using cryogenic cooling. The difference in the percentage of AA, A, and B eggs began to differentiating after approximately 5 weeks of storage. Eggs cooled cryogenically maintained a higher AA quality throughout the storage period. A random sample of eggs was also selected to evaluate the shell surface and interior content microbial level. The microbial counts of the content of the cryogenically cooled eggs were significantly higher ($p < 0.0001$) compared to traditionally cooled eggs in trial one. It was determined that the cooler sanitation was lacking during the first trial. A cleaning and sanitation protocol was developed for the cooler then the trial was repeated. Internal microbial loads between the two treatments were not significantly different in trial two, after the improvements were made. External microbial counts were higher for cryogenically cooled eggs ($P < 0.002$) in both trials. The increased internal microbial level of cryogenic cooled eggs in trial 1 was due to the lack of cleaning and sanitizing of the cryogenic cooler. The physical quality of the eggs was better in the cryogenically cooled group, with no difference in apparent microbial quality. These trials led to improvements in the design of the equipment, which have been made in the commercial unit. These improvements will facilitate cleaning the equipment, reduce the shell surface microbial load, and improve the physical quality of the eggs.

Key Words: Cryogenic cooling, Shell eggs, Microbial load

229 Comparison of quality and functionality of traditionally and cryogenically cooled shell eggs. K.C. McAvoy^{*1}, P.A. Curtis¹, K.M. Keener¹, K.E. Anderson², and D.E. Conner³, ¹Department of Food Science, North Carolina State University, ²Department of Poultry Science, North Carolina State University, ³Department of Poultry Science, Auburn University.

Previous studies have found that cryogenic cooling of shell eggs results in, a lower Salmonella enteritidis level, a higher quality egg, and a longer

shelf-life than traditional cooling. This research was designed to compare quality and functionality of traditionally cooled eggs to cryogenically cooled eggs from a commercial egg processing plant. Three replicate runs of each of the two treatments were processed to give a total of six treatment reps. Data for cooling curves was obtained by inserting temperature probes attached to data recorders into an egg from each treatment rep. Two hours after processing the cryogenically cooled eggs had reached 11.6°C while the traditionally cooled eggs were at 28°C. Eggs from both treatments were held in refrigerated storage (4°C) during the fifteen-week testing period. Functionality and quality tests conducted include: Haugh units, displacement and specific gravity measurements of angel food and sponge cakes, emulsion stability of mayonnaise, shell and vitelline membrane strength, pH, whipping height and overrun. Haugh unit values were measured every week; all other functional and quality tests were conducted tri-weekly. Data was analyzed using the General Linear Model (GLM) of SAS (1996). Means were separated using the least square method. Cryogenic cooling of shell eggs with carbon dioxide increased the percentage of AA quality eggs compared to traditional cooling. The traditionally cooled eggs dropped from Grade AA to Grade A approximately one week prior to those from the cryogenic treatment. The average Haugh unit values for the fifteen-week testing period were 69.8 and 67.6 for the cryogenically and traditionally cooled eggs, respectively. There were no statistical differences in functionality measurements between the two treatments. Cryogenic cooling of shell eggs with carbon dioxide gas is a viable option for improving safety and quality of shell eggs. This enhanced safety and quality should have significant economic benefit to egg producers.

Biotechnology, Animal Products, and the Food Industry

230 Is DNA or protein from feed detected in live-stock products? Kevin Glenn*, Chair, ABSTC Subcommittee on DNA Detection.

With the advent of highly sensitive analytical technology such as polymerase chain reaction (PCR), the need for documentation regarding the potential for the detection of DNA and protein from biotech crops in meat, milk, and eggs (MME) is critical. This is not a concern over the safety of the transgenic DNA or protein in MME since the introduced proteins undergo rigorous review prior to approval, and the UN FAO and WHO, the U.S. FDA and the U.S. EPA have all stated that DNA in food, including transgenic DNA in biotech crops, is a safe, natural component of food. However, it is well recognized that significant logistical problems would be incurred for meat, poultry, egg, and milk processors if labeling and segregation of products from animals fed biotech crops could occur using new detection methods. The scientific studies that have attempted to detect transgenic DNA or protein in MME derived from animals fed biotech crops will be reviewed. To date, the scientific evidence clearly shows that the transgenic DNA and proteins cannot be detected in MME products and that these products are equivalent in every way to products from animals fed conventional feeds. In addition, new data will be presented from studies in which DNA and protein were extracted from chicken breast samples from animals fed YieldGard[®] or conventional corn. PCR followed by Southern blot hybridization was used to analyze the DNA for the presence of specific fragments from the Bt cry1Ab gene and the gene encoding the corn protein ADP glucose pyrophosphorylase (sh-2). None of the extracted DNA samples was positive for cry1Ab or sh-2. The extracted DNA was shown to be of high quality and amendable to PCR amplification of the chicken ovalbumin gene. In addition, data from a new competitive immunoassay sensitive to both intact and partially digested Cry1Ab protein will be presented, showing that this transgenic protein or immunoreactive fragments of the protein cannot be detected in the breast samples from chickens fed YieldGard[®] grain.

Key Words: Polymerase Chain Reaction, Transgenic DNA, YieldGard[®]

231 Preventing food allergy - The impact of biotechnology. James D. Astwood*, Monsanto Company, St. Louis, MO.

People who suffer from food allergies manage their condition by avoidance strategies such as diet eliminations and careful examination of ingredient labels. Unexpected exposures and resulting adverse reactions to food allergens represent the main challenge in food atopy. Unlike hay fever and respiratory allergies, immunotherapy has achieved only limited success because of the potency of food allergens - i.e., immunotherapy with food allergens can often trigger serious side effects, including anaphylaxis. Biotechnology has had a positive influence on the science of food allergy by facilitating the discovery and characterization of allergens using recombinant DNA methods. Today, it is generally accepted that most major allergens have been identified and described. Subsequently, biotechnology has enabled the development of diagnostics based on recombinant allergens and more recently has been used to engineer potentially safer immunotherapeutic versions of food allergens - the creation of de-allergized variants. This will allow safer immunotherapies since the de-allergized variants of food allergens should produce fewer, if any, side effects. In addition, DNA vaccines based on these variants are being tested presently, with a view of providing long-lasting immunotherapeutic options for food allergy patients. Biotechnology is also providing prophylactic options through the development of hypoallergenic foods which have either been engineered to contain fewer endogenous allergens, or have been modified by the presence of proteins like thioredoxin, to render endogenous food allergens less potent and less allergenic. Hypoallergenic foods could reduce the incidence of new food allergies on a global basis.

Key Words: Biotechnology, Allergy, Food

232 The risks of going non-biotech. Thomas P. Redick*, Law Offices of Thomas P. Redick, Del Mar, CA.

Many companies see product lines that are free from modern biotechnology (non-biotech) as necessary to satisfy consumers who may want "non-GMO" foods, including meat, eggs and milk from animals fed non-GMO feed. Before making this leap, however, companies should analyze

potential liability risks of non-GMO products. Product liability risks include potential increases in carcinogenic mycotoxins, such as aflatoxin, which may concentrate in milk or meat (unlike the rDNA in digested GMO (“biotech”) feeds). The comparative product liability risks of rDNA (“biotech”) and non-biotech choices may actually dictate the use of biotech. Moreover, environmental liability risks may be reduced by biotech feeds (e.g., low-phytate soybean meal to reduce phosphorus in animal waste); the EPA could require such feeds as the “best available control technology”. Companies may find that rDNA plant breeding, on a case by case basis, minimizes the environmental impacts of the traditionally bred crops and their associated inputs. Finally, assuming equal safety profiles for biotech and non-biotech feed, a company that goes “non-biotech” risks consumer fraud liability. An affirmative “non-biotech” representation should follow an agreed standard acceptable to all stakeholders. Without careful legal and scientific management of the process behind “non-biotech” representations, companies face fraud suits over unwanted “biotech” content. Until regulators endorse a process for non-biotech certification, dropping the “tolerances” for DNA content in food or feed (i.e., a process standard comparable to USDA’s new Organic Rule), the risks of going non-biotech may often outweigh the benefits. Consumers know about biotech content from intensive media campaigns, so biotech content without a non-biotech claim is not a fraud risk. Since some consumers will ignore reduced mycotoxins and improved environmental performance in favor of non-biotech sources of food, regulations should ensure peaceful co-existence between organic farming and commercial agriculture, but ensure continuing innovation that reduces product liability risks, environmental impacts, and consumer fraud.

Key Words: Food biotechnology, Food safety, GMO

233 Economic and practical considerations of using non-biotech grain in U.S. livestock and poultry feed. Scott Richman*, *Sparks Companies, Inc., Memphis, TN.*

Given concerns about the continuing acceptance of agricultural biotechnology among U.S. consumers, some companies may consider offering for sale meat and poultry produced from animals which were fed only non-biotech grains and protein meals. This avenue may be considered as a way to protect a company’s market share in the event that U.S. consumer attitudes toward biotechnology turn negative, or it may be seen as an opportunity for a company to serve a niche market of consumers who prefer “natural” foods and are willing to pay a premium. Yet, there are practical considerations which constrain the ability of livestock and poultry firms to offer meat and poultry certified as coming from animals fed only non-biotech corn and SBM. At the farm level, biotech varieties of corn and soybeans have been adopted widely across the U.S.

Genetics of Disease Resistance

235 Transgenic approaches to prevent bovine mastitis. D. E. Kerr*¹, K. D. Wells², and R. J. Wall², ¹*University of Vermont, Burlington, VT,* ²*USDA-ARS, Beltsville, MD.*

Transgenic animal technology is a strategy likely to play a major role in the prevention of animal disease. One approach is to enable the production of novel antibacterial proteins by the mammary gland as a means to enhance mastitis resistance. To this end, we have produced transgenic mice that have the ability to produce a bioactive variant of lysostaphin in milk. Lysostaphin, which is normally produced by *Staphylococcus simulans*, has potent staphylococcal activity. The lysostaphin-transgenic mice exhibit substantial resistance to staphylococcal mastitis. Fortification of milk as a strategy to enhance disease resistance has also resulted in reports of transgenic mice whose milk contains human lysozyme, bovine tracheal antimicrobial peptide, or a neutralizing antibody to a strain of murine hepatitis virus. We are currently evaluating additional antimicrobial proteins as candidates to be secreted by the mammary glands of transgenic animals. Our selection strategy is based on a number of parameters. First, there must be no indication of toxicity to eukaryotic cells. Second, the selected protein or peptide must be effective in milk in reducing the growth of mastitis pathogens. Milk components such as negatively charged casein micelles, and milk fat globule membranes can markedly reduce the activity of cationic antimicrobial peptides. Third, antibacterial activity must have limited or no enzymatic activity against milk proteins to ensure product quality. Fourth, the mammary epithelium must be able to produce the protein of interest in an active form.

At the grain elevator, corn mills and soybean crushing facilities, grain from different sources is commingled. Many animal feeding operations would face challenges unless they switched entirely to non-biotech feeds. There would be difficulty in keeping the resulting meat separate from commodity meat in packing and processing plants. The objectives of this talk are to describe the constraints which exist in the current supply chain, to indicate the steps which must be taken if those constraints are to be overcome, and to estimate the costs involved with undertaking such an effort.

Key Words: Economic, Biotechnology, Livestock

234 Effects on Global Trade: Setting International Food Standards via Codex Alimentarius. Mark Mansour*, *Attorney and Partner, Keller and Heckman LLP, Washington, DC.*

Although the Codex Alimentarius Commission has functioned as part of the U.N. Food and Agriculture Organization since 1962, its activities, until recently, were of little more than incidental interest to the international food and feed industries, especially U.S.-based multinationals. However, with the advent of the World Trade Organization (WTO) and the establishment of NAFTA and other regional trading blocs, Codex’s deliberations became significantly more important to government and industry alike. As manufacturers realized that Codex, in the absence of any other mutually acceptable arbitral mechanism, would be enshrined in the WTO as the means by which disputes over trade in food products would be resolved, member countries also realized that the Commission would provide a solution to the growing gaps in their food regulatory structures. Lesser developed countries lacking both the expertise and the budgets to fully develop food regulatory structures adequate for both the protection of public health and streamlining the free flow of goods found such expertise through the 37 year long deliberative process, during which period they have institutionalized in their own regulatory regimes the experience gleaned from delegates representing the industrialized countries of North America and Europe. Despite the progress made in many countries toward developing coherent food legislation and regulatory structures, there remain significant gaps in the laws of many jurisdictions, particularly in Asia, the Middle East and Latin America, as well as persistent confusion about the legality of ingredients, additives and preservatives, and the propriety of various types of claims. In no functional area have these developments been as vital as in the area of biotechnology where, during the course of the next year, Codex is poised to make a series of decisions that will have a significant, and perhaps irreversible impact on the future of the global trade in food and feed products derived from biotechnology.

Key Words: Biotechnology, WTO, Food trade

For many antibacterials this will likely require additional genes to enable post-translational processing and activation. Fifth, activity against bacteria normally used in the production of fermented dairy products must be considered. Lastly, the potential exists for the development of resistant microbial strains. This potential should be reduced by the simultaneous production of multiple antibacterial proteins. Transgenic mice producing lysostaphin in milk represent a proof of concept for the generation of mastitis resistant transgenic cows. Additional proteins will be needed to prevent coliform and streptococcal mastitis.

Key Words: Lysostaphin, Milk

236 Immunogenomics and the periparturient dairy cow: letting leukocytes tell us their own story about disease susceptibility. J.L. Burton*¹, ¹*Michigan State University.*

Despite rigorous management practices aimed at environmental cleanliness, good nutrition, and even vaccination, mastitis remains a problem in periparturient dairy cows. This is partly due to well-known leukocyte dysfunctions that occur during periparturition and jeopardize immune defenses against mastitis-causing organisms. To better understand and control mastitis susceptibility in periparturient cows we need detailed understanding of the genes that regulate and orchestrate leukocyte development, trafficking, and immune defense against the bacteria that infected mammary glands and cause mastitis. We have begun to use combinations of DDRT-PCR, cDNA dot blots, and cDNA microarrays

to identify these genes in leukocytes. Using these techniques we have simultaneously monitored from a few to hundreds of expressed leukocyte genes for differential expression patterns during mid-lactation and periparturition. In this way, we have allowed the leukocytes to tell us their own story about disease susceptibility during periparturition by displaying and quantifying changes in global gene expression patterns. Further physiological studies of interesting differentially expressed genes will help us gain new knowledge about the behavior of gene expression during interesting scenarios such as parturition, intramammary infection, vaccination, and genetic selection. Results of these studies to date will be presented. It is hoped that the new knowledge generated from our work will enable targeted nutritional and drug studies focused on development of novel immunomodulators and mastitis preventatives and therapeutics for periparturient dairy cows. Identified genes will also be studied in our laboratory for the presence of harmful and beneficial mutations that could be taken advantage of using traditional genetic selection to improve mastitis resistance. If highly beneficial genes and alleles are identified, these could be used in the future to develop lines of transgenic cows whose mammary glands have been programmed to specifically target and eliminate intramammary infections. These genetic approaches to bolster immunocompetence should help us counteract any negative effects of selection for high milk yield on mammary immunity

Key Words: Functional Genomics, Periparturition, Mastitis

237 Genetics and Genomics of Susceptibility to Mycobacterial Infection in Cattle. P.M. Coussens^{*1}, B. Tooker¹, W. Nobis¹, and M.J. Coussens¹, *Michigan State University, East Lansing, MI 48824.*

The Mycobacteria are responsible for significant diseases in man and most animals. In cattle, Mycobacteria are responsible for Johne's dis-

ease (*M. paratuberculosis*) and bovine tuberculosis (*M. bovis*). As obligate intracellular bacteria, the Mycobacteria have devised ways of surviving in macrophages, one of the animals first lines of defense against such infections. The ability to survive in this hostile environment is a key step in the pathogenesis of Mycobacterial diseases. We have begun studies aimed at understanding interactions of Mycobacteria with the bovine macrophage, using both genetic and genomic tools. Clues from studies in mice and humans have been used to highlight possible genetic elements controlling susceptibility to Mycobacterial infection and to examine various bovine populations for genetic differences in these elements. One such element is the NRAMP 1 gene. In mice the NRAMP 1 gene is directly linked to susceptibility to infection by intracellular Mycobacteria. To evaluate potential roles of NRAMP 1 mutations in the outcome of mycobacterial infections in cattle, we have searched for polymorphisms within the bovine NRAMP 1 coding sequence and analyzed the bovine NRAMP 1 gene structure. These studies suggest that the NRAMP 1 gene is polymorphic in cattle and open the way for analysis of linkage to susceptibility to Mycobacterial infection. To better understand Mycobacterial survival in bovine macrophages, we have applied the tools of functional genomics, using a combination of DD RT-PCR and cDNA microarrays to identify key genes whose expression is altered upon macrophage uptake of Mycobacteria. Gene expression patterns have been cataloged into those genes whose expression is affected by the general process of phagocytosis and those genes whose expression appears to be specifically altered by uptake of Mycobacteria. Differentially expressed genes are then classified according to the deduced function or pathway to which their protein products belong. By this process, we hope to elucidate particular pathways within the normal course of macrophage activation that are adversely affected by Mycobacteria. Results of these studies to date will be presented and discussed.

Latest Development in On-Farm Ultrafiltration

238 Latest Development in On-Farm Ultrafiltration
1. History of On-Farm Ultrafiltration of Milk. John Bruhn^{*1},
¹*University of California, Davis.*

Research in the use of membrane processing of milk started in the early 1970's when dairy researchers saw a potential for this technology that was being used to make potable water from saltwater. At that time, the concentration of milk was possible, but problems with fouling, flux rates and difficulties with cleaning and sanitizing of the membrane kept it from being used in the dairy industry. In the early 1980's, the on farm use of reverse osmosis was explored. The farm milk was pasteurized before concentrating in a single pass unit. When the cheese plant received this concentrated milk, it was again pasteurized. The double pasteurization decreased cheese yields, but the on farm process was shown to work. In the 1990's, the on farm membrane processing was installed with a dairy producer cooperative in New Mexico. The concentrating process was evaluated extensively before the regulatory agencies would approve the use in grade A dairy foods. Research established that the concentrating process did not convey any special resistance to the pathogens in the raw milk to standard pasteurization. Nor did pathogens grow faster in the raw milk concentrate. No special resistances or growth advantages were noted. The operating parameters were also defined by the regulatory agencies. With the approval of the regulatory agencies, the membrane concentrated, raw milk became a marketplace reality. The raw milk concentrate is used to fortify solids in milk for cheese making. It also has application in the manufacture of frozen dairy desserts. It has potential for use in any dairy foods where a high quality, milk solid concentrate is needed. Potentially, it also could be used to make a grade A fluid milk product with the addition of water. The advantages of the raw milk concentrate to the dairy and food processor are just being realized.

Key Words: UF, RO

239 Regulatory Issues: Processing and Quality. Alfred Reeb, *New Mexico Department of Agriculture.*

Approximately 20 years ago, the dairy industry first proposed the on-farm ultrafiltration of milk. Initially, the regulatory concerns about the quality of raw milk, temperature of processing, and other processing conditions limited ultrafiltration of milk products to in-plant usage. When

on-farm ultrafiltration of unpasteurized milk was proposed in 1994, regulatory concerns about processing conditions and product quality were again expressed. The dairies, the membrane equipment supplier, and regulatory agencies worked together to arrive at an answer for the concerns on the processing conditions of the on-farm ultrafiltration and product quality of the retentate. These regulatory issues concerning the On-Farm Ultrafiltration of Unpasteurized Milk will be addressed in this presentation. Proper design of the Grade A Dairy Plant for Ultrafiltration of the milk was required. The review of the equipment included the monitoring and recording of the temperature of ultrafiltration processing. If the temperature during the ultrafiltration process was greater than 8 °C (45 °F), product was diverted through a flow diversion valve. Testing of equipment and the placement of regulatory seals will be discussed. Bacteriological quality of unpasteurized milk for concentration and unfiltered milk is in compliance with the Grade A Standard. Conformance of this concentrated product to Grade A Standards will be also discussed.

Key Words: Regulatory Issues, Quality of Unpasteurized UF Milk, Processing

240 Applications of membrane filtered cold milk as an ingredient. P. Tong^{*1} and H. Vyas¹, ¹*Dairy Products Technology Center, California Polytechnic State University, San Luis Obispo.*

Membrane processing of milk at low temperatures results in a concentrated and/or fractionated milk stream which has been obtained with little to no heating. Such concentrates can then be delivered to an ingredient user and only heat processed once to obtain the final pasteurized product. As a result, any undesirable changes associated with heat processing (e.g., protein denaturation, cooked flavors, etc.) can be minimized. When ultrafiltration membranes are used, modification in protein to lactose ratios, and mineral composition of the concentrate are possible. Therefore, such membrane processed milk concentrates will be desirable as ingredients for cheese manufacture, ice cream manufacture and specialized dairy based beverages and other foods. Use of these ingredients may improve finished product composition control (standardization to more optimum protein to fat or protein to lactose ratios), plant throughput/efficiency, and product overall quality (flavor, texture, etc.).

Key Words: ultrafiltration, membrane, milk

Hot Topics in Meat Processing

241 Developing Validation Models for E. Coli 0157 Inactivation in Dry Fermented Sausages. Shai Barbut* and Mansel Griffiths, ¹University of Guelph.

After the 1994 E. coli 0157:H7 outbreak associated with the consumption of semidried fermented sausage in Washington State, the USDA-FSIS has required processors to either validate their processes or include a step that will assure a 5 log reduction of the pathogen. The presentation will illustrate the work done in our laboratory to validate sausage fermentation (i.e., inoculated studies) for different commercial processes, and the initial development of three models to validate the process when the USDA-FSIS two log E. coli reduction option is chosen. The models include variables such as water activity, pH, fermentation and drying time, as well as the interactions among these variables. The predictive abilities of the models were confirmed by linear regression, comparing values for E. coli survival derived from the models with experimental values obtained from data that were not used to construct the models. Response surface diagrams were also produced to demonstrate the effects of the different variables.

Key Words: Fermented Sausage, E. Coli 0157, Validation models

242 Use of carbon monoxide in retail meat packaging. O. Sorheim*¹, H. Nissen¹, T. Aune², and T. Nesbakken³, ¹MATFORSK - Norwegian Food Research Institute, Aas, Norway, ²Norwegian School of Veterinary Science, Oslo, Norway, ³Norwegian Meat Research Centre, Oslo, Norway.

Centralised pre-packaging of fresh retail meat in modified atmospheres is common in many countries in Europe, but to a less extent in the USA. The predominating gas mixture for retail meat contains approx. 70 % O₂ and 30 % CO₂ enabling an extended, but still limited shelf life. Carbon monoxide (CO) binds strongly to myoglobin and maintains a bright red color of meat. The Norwegian meat industry has for 15 years been using a gas mixture of approx. 0.3 - 0.5 % CO, 60 - 70 % CO₂ and 30 - 40 % N₂ (CO mix). The market share of pre-packaged retail meat in the CO mix in Norway is 60 %. CO is presently not permitted for meat packaging in the EU or USA. However, CO is temporarily allowed in Norway, and an application for permanent use in the EU and Norway is under evaluation. Research on aspects of the CO mix has demonstrated several benefits. Consuming meat exposed to the CO mix does not pose a toxic hazard, because the meat contains only negligible amounts of CO. The CO mix is safe to use in meat plants, as the CO is delivered in a concentration of maximum 1 %. The combination of a stable, bright red color and a long microbiological shelf life of the meat is unique for the CO mix. The shelf life extension is achieved by the high CO₂ concentration and absence of O₂. Growth of *Yersinia enterocolitica*, *Listeria monocytogenes* and *Escherichia coli* O157:H7 was more inhibited by the CO mix than other packaging methods. Ground beef containing carboxymyoglobin required a higher temperature by cooking to develop a gray, well-done color than other forms of myoglobin. The main reason for resistance against CO relates to its ability to mask spoilage by color stabilization beyond the time of microbiological deterioration. A reliable shelf life of MAP meat can only be obtained through proper quality control of meat handling, packaging and chill chain.

Key Words: Carbon Monoxide, Packaging, Retail Meat

243 Use of the AMI Process Lethality Spreadsheet to Validate the Safety of Cooking Procedures. T. A. Freier*, Cargill.

Producers of cooked meat and poultry products are increasingly being required to produce documented, science-based validations of thermal processes. Traditional thermal death-time studies require relatively extensive laboratory facilities, time and expertise. When D and Z values are known (through experimentation or by obtaining published values), there remains the question of how to apply these variables to an actual thermal process. The American Meat Institute Foundation (AMIF) has sponsored the development of a process lethality spreadsheet that can

be used to estimate the effectiveness of specific heat processes in destroying microorganisms of concern. This model is readily available for downloading from the AMIF's web site. With the input of the proper variables, this spreadsheet can quickly indicate the total kill potential of a specific cooking process for any of the common food-borne pathogens of concern. This presentation will provide a practical introduction to the use of this model and will discuss the appropriate use of the data that is generated.

Key Words: Thermal Process, Computer Model, Critical Control Point Validation

244 Predictive models for growth of foodborne pathogenic spore-formers at temperatures applicable to cooling of cooked meat. Vijay Juneja*¹, ¹USDA-ARS-ERRC.

Inadequate cooling of foods in retail food operations is a major safety problem. Accordingly, the objectives of these studies were to determine a safe cooling rate for cooked beef and develop models to predict the germination, outgrowth and lag (GOL), and exponential growth rates (EGR) of *Clostridium perfringens* and *Clostridium botulinum* from spores. First, we demonstrated the effectiveness and validity of "square-root model" under non-isothermal conditions. Next, we developed two models, one each for *C. perfringens* and proteolytic *C. botulinum*, to predict their growth from spores at temperatures applicable to the cooling of cooked meat. It was found that for *C. perfringens*, the use of the logistic function provided a better prediction of relative growth than the use of the Gompertz function. For *C. botulinum*, growth curves were determined by fitting Gompertz functions to the data. From the parameters of the Gompertz or logistic function the growth characteristics, GOL times and EGR, were calculated. These growth characteristics were subsequently described by Ratkowsky functions using temperature as the independent variable. By applying multivariate statistical procedures, the standard errors and confidence intervals were computed on the predictions of relative growth for a given temperature. Closed form equations were developed that allow prediction of growth for a general cooling scenario. The predictive models should aid in evaluating the safety of cooked product after cooling and thus, with the disposition of products subject to cooling deviations.

Key Words: Predictive models, Spores, Cooling of cooked meat

245 Case ready red meat-demand and technology. Scott Eilert*¹, ¹Excel Corporation.

The demand for case ready red meat continues to grow at a pace unmatched in previous years. Suppliers of red meat are focusing a great deal of their growth around meeting these demands and providing solutions for retailers. The demand is being fueled by several factors, most notably the need to reduce labor and costs at the retail outlet. As the retail market is quite diverse (volumes, distribution methods, product lines, branding) so are the solutions that are required by retailers. There is no one ideal business or packaging model for case ready today. The proper solution for a retailer will vary with the factors listed previously. The goal of this presentation will be to present the various models of case ready, primarily focusing on the packaging formats that can be employed. Specifically, the various high oxygen and low oxygen formats will be presented. The advantages and disadvantages of each format will be discussed. In closing, this presentation will address key technological challenges as the industry moves to more central processing of red meat products for retail.

Developing and Sustaining International Agriculture Experiences in Animal Science Curricula

246 The nuts and bolts of student exchange programs. John C. Forrest*, Terry S. Stewart, Bud G. Harmon, and Michael H. Stitsworth, *Purdue University*.

Exchange programs prepare animal sciences students to participate in the emerging global economy. Purdue's successful international undergraduate exchange developed from a long history of international programs and faculty exchanges. Emphasis on student exchanges during the last decade stems from recognition that economic development of the agricultural sector depends upon a better understanding of the cultures that drive international trade. The first formal undergraduate animal agriculture exchange program developed out of a faculty sabbatical to Australia. Prior to that several animal sciences students participated in general agricultural exchange programs sponsored by International Programs in Agriculture.

Exchange programs that provide the most beneficial experiences for students are well organized by participating institutions. When possible equal numbers of students from each university should be recruited. A great economic deterrent to recruitment was overcome when university administrators allowed students to pay tuition to their home institution while participating in exchanges, and revenue remains constant for both institutions. Mentors with a strong interest in students and knowledge of the programs at the collaborating institution help programs go smoothly at both ends of an exchange. This is especially important in initial exchanges. When exchanges are ongoing, students tend to form networks between universities that are beneficial to new students.

Exchanges take many forms, from formal funded programs that generally include one full semester of courses at a host university, to summer work experiences. In some cases a work experience is either preceded or followed by a semester of resident instruction. Exchanges with developing countries generally require funding to allow students from those countries to participate, host families often help offset housing costs for students coming to the US, and provide cultural understanding beyond the normal university experience. Exchanges with developed countries are fostered by agreements that allow students to pay tuition at their home campus. Scholarships and other financial assistance are often provided to assist students with travel and extra expense of living in a foreign country.

247 The Linkage Project: a partnership in international educational development. M. D. Kenealy*, *Iowa State University, Ames*.

The Linkage Project was developed to create a model for US and international universities to align curricula to improve access to undergraduate and graduate programs for international students. The project proposal was driven by the need for increased globalization of education. If universities throughout the world are to capitalize fully on available knowledge and methodologies, they must prepare students who can move seamlessly through educational systems worldwide. Representatives of seven agriculture or veterinary medicine disciplines from Iowa State University (ISU) and National Agriculture University of Ukraine (NAUU)

partnered for a four-year effort funded by the United States Information Agency. Disciplines represented were: agricultural education, agricultural engineering, agronomy, animal science, economics, forestry, and veterinary medicine. Procedural steps were: 1. year one: one month exchanges of faculty counterpart teams from each discipline to study educational programs at the cooperating institutions and develop aligned bachelor of science (BS) programs; 2. year two: exchanges to finalize curricular proposals at ISU, open forums at NAUU to promote new BS programs to faculty and administration, and curricular implementation; 3. year three: on-site evaluation of the first year of implementation of BS programs and initiation of development of new master of science (MS) programs at NAUU; 4. year four: final adjustments and implementation of MS programs at NAUU. Faculty and students from the two universities involved in the Linkage Project benefited from accomplishment of the primary project objective of aligning curricula to enhance the process of student exchange, transfer, and graduate enrollment. Secondary benefits included internationalization of faculty and students, increased awareness of education on a global scale, and new opportunities for research partnerships. Additionally, the project positioned NAUU as a lead institution and model for preparing agricultural students for the changing economic system of the countries of the former Soviet Union.

248 Developing/funding of exchanges of faculty and other international symposia related to teaching and research. J. F. Keown*¹, ¹*University of Nebraska, Lincoln, NE*.

The Institute of Agriculture and Natural Resources at the University of Nebraska is a member of the Mid America International Agricultural Consortium. This Consortium consists of the Agricultural Colleges located at the University of Missouri, Iowa State University, Kansas State University and Oklahoma State University. The main focus of this group is to work with Mexican Institutions to further research, teaching and extension with Mexican Universities, Governmental Research Centers, private industry and producer groups. The sole focus of this group is to work in the agricultural sectors of livestock and meats, biotechnology, wheat, maize, natural resources and current women's issues. This group has formed "sister university" relations with several Mexican Universities, held symposia in Mexico in the biotechnology, conservation tillage, exploring women's issues and by-product feeding. This consortium in previous years has spent considerable time and effort working overseas with USAID grants. With the reduction in USAID funding, the consortium took a different mode of action and decided to work mainly with Mexico. The Board of Directors, comprised of the Agricultural Deans at all five universities, changed due to the importance of the agricultural exports that flow to Mexico from this five-state region, as well as the increasing number of Mexican workers currently working in this five-state region in the meat packing, construction and general agricultural areas. The consortium feels that an exchange of scientific knowledge and of students and faculty will enhance economic development of both countries.

ADSA Dairy Foods: Dairy Products—Chemistry and Physical Properties

249 Methods to Prepare Glycomacropeptide from Cheese Whey. Takuo Nakano* and Lech Ozimek, *University of Alberta*.

Glycomacropeptide (GMP) found in cheese whey (or sweet whey) is a biologically active compound, and thought to be a potential ingredient for dietetic foods and pharmaceuticals. Thus, much attention has been given to the development of techniques to isolate and purify this glycopeptide. The objective of this study was to develop techniques to prepare GMP from sweet whey under a laboratory scale. We have developed the following techniques: 1) gel chromatography on Sephacryl S-200 in 0.1 M sodium acetate at pHs 7.0 and 3.5; 2) cetylpyridinium chloride treatment, and gel chromatography on Sephacryl S-200 in 0.1 M sodium acetate (associative condition) and on Sephadex G-75 in 6 M guanidinium chloride (dissociative condition); and 3) deproteinization with trichloroacetic acid and gel chromatography. In all the techniques

used, we obtained high purity GMP with amino acid composition having a trace (< 1 residue/ peptide) of phenylalanine (amino acid that does not occur in GMP). These techniques are useful to prepare GMP as a research chemical. The purified GMP may be used as a standard in chromatography and electrophoresis, and may also be used to test various known or unknown biological activities of this glycopeptide.

250 Scale up and mass balance of affinity purification of native β -lactoglobulin. Harit K. Vyas*, J. M. Izco, and R. Jimenez-Flores, *Dairy Products Technology Center, Cal Poly*.

The process of affinity purification of β -lactoglobulin in its native form using all-trans-retinal immobilized on Celite R-648TM was scaled up and applied to fractionate industrial sweet whey. Three different ways

of mixing the Celite R-648TM and whey for the interaction between all-trans-retinal and β -lactoglobulin were tried at pilot scale. The three methods used were (1) a continuous operation using a column packed with Celite R-648TM, (2) a batch operation in a stirred tank and (3) a continuous operation using a fluidized Celite R-648TM column. Adsorption and desorption of β -lactoglobulin were carried out at pH 5.1 and 7.0, using 0.01 and 0.1M phosphate buffers, respectively. The phosphate buffer containing desorbed β -lactoglobulin was concentrated 20 times using ultrafiltration and then freeze-dried. The packed column, stirred tank and fluidized column produced β -lactoglobulin with purity of 80, >95 and >95%, and recovery of 0.65, 2.88 and 2.88g per kg of Celite R-648TM, respectively. The comparative poor purity and recovery of β -lactoglobulin in the case of the packed column was attributed to insufficient contact between the passing fluids and the Celite R-648TM during adsorption, desorption and intermittent washing. The fluidized column method being a continuous operation with a gentle mixing action, was considered the best suited for further scale up to the industrial level.

Key Words: Process scale up, affinity purification, β -lactoglobulin

251 Separation of proteins from acid whey using clay minerals. J. Su and D. W. Everett*, *University of Otago, Dunedin, New Zealand.*

The adsorption and desorption behavior of whey proteins on clay minerals was investigated. Bentonite, halloysite, and kaolinite from New Zealand and eckalite from Australia were suspended in 1% (v/v) H₂O₂(aq) and stirred over a period of 6 days to oxidize organic surface impurities. To create a homoionic surface, minerals (except bentonite) were washed 4X in 1M NaCl at pH 2.6-3.0. Bentonite was washed 4X in 1M CaCl₂ at pH 2.6-3.0 to avoid mineral coagulation. All four mineral samples were then washed in deionized water until the conductivity approached that of the water. Acid whey (HCl, pH 4.6) was added to each clay sample in the ratio of 20:1 (v/w) for kaolinite, eckalite, and halloysite, and 10:1 (v/w) for bentonite. The pH was adjusted for each of eight samples of the four mineral-protein complex series in the range pH 3-10. Samples in triplicate were agitated for 60 min, centrifuged at 11,000 X g for 5 min at 4°C, and the supernatant examined for protein composition by SDS-PAGE and densitometry.

Proteins (α -LA, β -LG, and lactoferrin+BSA) were completely adsorbed up to pH 4 onto kaolinite, eckalite, and halloysite and up to pH 7 for bentonite, dropping to 10% adsorption onto kaolinite, 20-40% onto halloysite, 30-70% onto eckalite, and 60-95% onto bentonite at pH 10, the level of adsorption depending upon the protein. Adsorption of β -LG onto eckalite was significantly higher (70%), and significantly lower for α -LA onto bentonite (60%) compared to other proteins. Adsorption of 60kDa IgG was 100% complete over the range pH 3-10 on all four mineral surfaces. The level of desorption of bound proteins was measured by agitating for 60 min and washing the complexes in (1) distilled water, (2) 0.1, 0.2, 0.5, 1 and 2M NaCl, (3) 0.1% β -mercaptoethanol + 2M NaCl, (4) 6M urea, or (5) 6M urea + 2M NaCl. Washing the pH 3 complexes with solutions 1-3 did not result in any measurable protein desorption. Washing the pH 3 complexes with solution 4 resulted in 3-12% desorption of β -LG, and up to 25% desorption of β -LG in solution 5 from all clays. Desorption of other proteins was not detectable. Clay minerals may afford an inexpensive method to isolate β -LG from acid whey.

Key Words: Clay Minerals, Whey Proteins

252 Effect of β -casein addition on MFGM-stabilized soy oil emulsions. K. Hutchby and Everett D. W.*, *University of Otago, Dunedin, New Zealand.*

The binding and aggregating effects of β -CN addition to soy oil emulsions coated with milk fat globule membrane (MFGM) material were examined. Raw cream was phase-inverted and buttermilk collected. Casein micelles were dissociated by citrate addition and the MFGM recovered by centrifugation at 100,000×g for 50 min at 15°C followed by freeze drying. MFGM-stabilized soy oil emulsions (1% MFGM, 10% soy oil, w/w) were prepared using a MicrofluidizerTM (40 passes) at an effective outlet pressure of 75 MPa. Globule diameter was determined by photon correlation spectroscopy at pH 4.8 to 5.8 in 0.2 unit increments in a 20 mM sodium acetate buffer, and at pH 7.0 in a 20 mM Tris-HCl buffer, before and after β -CN addition. Emulsion dilution factor was 1 μ L per 2 mL of filtered buffer. Ten measurements were made every 5 min for duplicate samples.

Hydrodynamic diameter was 600±50 nm at pH 7 and remained in the range 550-725 nm down to pH 5.4. Below this pH the diameter increased, rising to 1060±175 nm at pH 4.8. Addition of β -CN reduced the diameter within a 5 min period, the greatest decrease at pH 5.2 from 725±150 to 150±30 nm. Decreases in diameter at the pH extremes was of order 100 nm. Trypsin (3 μ L of 0.01 g/mL in 20 mM Tris-HCl at pH 7) was added to the MFGM-stabilized globule and to the emulsion after β -CN addition, both at pH 5.2. There was no effect on diameter when β -CN was not previously added. The diameter increased from 160 to 330 nm over a 15 min period after β -CN addition, followed by a rapid increase to 1100 nm over 5 min after trypsin addition, indicating extensive aggregation after the initial dispersing. Emulsions stabilized with MFGM aggregated over the pH range 4.8 to 7.0, with more loose and extensive aggregates forming at pH 4.8 nearer the pI of MFGM. β -CN may bind to the MFGM surface and disperse the aggregates by a steric stabilization mechanism. Hydrolysis of the hydrophilic flexible "tail" of β -CN by trypsin caused the globules to aggregate again. These results show that it is feasible to disperse a food emulsion coated with MFGM using β -CN. In addition, it is likely that fat globules in cheese interact with the β -CN of the casein matrix, holding the globules into place.

Key Words: Emulsions, Casein, Photon Correlation Spectroscopy

253 Characterization of dephosphorylated β -Casein. F. Haidari*, L.E. Metzger, and D.E. Smith, *University of Minnesota, St. Paul, MN.*

A method for isolation of β -casein, developed at the University of Minnesota, has allowed access to large quantities of purified β -casein. In this research, β -casein was isolated using the aforementioned method and then dephosphorylated utilizing a known method for dephosphorylation of caseins with slight modification. In this procedure, β -casein is enzymatically dephosphorylated with potato acid phosphatase (28 units per 1 g protein) for 72 hours at pH 7 at 4°C. The reaction takes place in a dialysis tube (12400 M.W. cutoff) against water which removes free phosphates that inhibit the enzyme activity. The protein solution is heated to 85°C to inactivate the enzyme and then lyophilized. This experiment was repeated with three separate lots of isolated β -casein. The degree of dephosphorylation was confirmed by ³¹P-NMR spectroscopy, inductively coupled plasma spectroscopy, and fast protein liquid chromatography. The results indicated that the extent of dephosphorylation was more than 90 percent. The dephosphorylated β -casein was further purified with anion exchange chromatography. The secondary structure of the highly purified dephosphorylated β -casein was studied and compared to that of the native β -casein by utilizing FT-IR spectroscopy. Furthermore, the calcium binding ability of the dephosphorylated β -casein was measured against varying concentrations of calcium solution.

Key Words: β -Casein, Dephosphorylation, Characterization

254 Effects of added plasmin on the rheological properties of rennet-induced skim milk gels. M Srinivasan* and J.A. Lucey, *University of Wisconsin-Madison*.

Elevated activity of plasmin enzyme (EC 3.4.21.7) results in reduced cheese yields and texture defects and this can occur in mastitic and late-lactation milks. The effects of exogenous plasmin on the rheological properties, at small and large deformations, of rennet-induced skim milk gels were studied. Rennet gels were made from 9% (w/w) NFDM, which was reconstituted for 3 h at 32°C. Porcine plasmin (0.01 mg/ml milk) was added to milk and samples incubated for 1, 2, 3, 4, 6 and 8 h at 37°C. The reaction was terminated using soy bean trypsin inhibitor. Samples with no added plasmin were also incubated (controls). Extent of degradation of caseins was determined by SDS-PAGE. Gelation properties were determined at 32°C using dynamic low amplitude oscillation and rheological parameters were monitored for a period of 6 h after rennet addition. Extent of breakdown of α_s - and β -caseins increased with incubation time with plasmin. After 8 h of incubation, the amounts of intact α_s - and β -casein were 24.30.5 and 13.60.3%, respectively. Rennet gels made from milk with no added plasmin had storage moduli of 751 Pa. Storage moduli of rennet gels decreased with increasing degradation of caseins. After incubation of milk with plasmin for 8 h, storage moduli decreased to 102 Pa. Loss tangent values of rennet-induced gels after 8 h incubation increased to 0.61 from 0.35 in control milk, indicating a more liquid-like gel character. In contrast to previous studies, we found that storage moduli of gels decreased even when a small amount of breakdown of caseins occurred, e.g. after 1 h incubation with plasmin the amounts of intact α_s - and β -caseins were 84 and 80%, respectively, and this resulted in 20% reduction in the storage modulus. Gelation time hardly changed until 3 h of incubation, thereafter gelation time increased considerably. Fracture properties were determined by subjecting the gels to a low shear rate (0.01 s^{-1}). Fracture stress (force required for fracture) of gels decreased with increasing casein breakdown and after 8 h incubation with plasmin the fracture stress was only 103 Pa, whereas control milk was 786 Pa. Low levels of plasmin activity influences the texture of rennet gels which could have significant effects on the yield and texture of cheese.

Key Words: Plasmin, Rennet coagulation, Rheology

255 Effect of Homogenization Pressure and Selected Additives on Particle Size Properties of Retort Sterilized Dairy Beverages During Storage. C. Lin* and R. Richter, *Texas A&M University, College Station, TX*.

The objective of this study was to determine the effect of homogenization pressure and six mineral salts and hydrocolloids on the particle size properties of dairy beverage processed in a retort. Skim milk, cream, nonfat dry milk, and sucrose were mixed to make beverages containing either 0.1% sodium salts (sodium citrate, sodium tripolyphosphate, or sodium hexametaphosphate), 0.05% hydrocolloids (locust bean gum, iota-carrageenan, or kappa-carrageenan), or combinations of the salts and hydrocolloids. The mixtures were heated, homogenized at either 20, 50, or 90 MPa, canned, and sterilized with a retort at 121°C for 6 min. The processed products were stored at 36°C and tested after 1, 10, 20, and 30 days of storage. Particle size distribution of the sample was determined with a Coulter LS130 particle size analyzer. Particle size index was calculated as the ratio of mean particle size (D(4,3)) of the top and bottom layers. Both mineral salts and hydrocolloids significantly affected particle size index. Samples containing sodium tripolyphosphate or iota-carrageenan had the particle size index values closest to 1.00 but samples that contained sodium citrate or locust bean gum had the smallest mean particle size. Nevertheless, samples that contained both sodium tripolyphosphate and kappa-carrageenan had a better particle size index than samples that contained sodium tripolyphosphate and iota-carrageenan. The mean particle size decreased as the homogenization pressure was increased. This effect became more apparent as storage time increased. The mean particle size increased as storage time increased for samples homogenized at 20 MPa but did not change significantly in samples homogenized at 90 MPa.

Key Words: Homogenization Pressure, Hydrocolloids, Particle Size

256 The Effect of Stabilizers and Emulsifiers on the Rheological Properties of Ice Cream Model Systems. J.V. Patmore* and H.D. Goff, *University of Guelph, Guelph, Canada*.

Ice cream contains many ingredients that influence quality of the final product. Locust bean gum (LBG) and guar gum (GG) are two stabilizers used in ice cream to modify texture and enhance shelf life. Emulsifiers help create ice cream structure because they form a thin interface around fat globules, which allows fat to partially coalesce during whipping. During homogenization and aging, emulsifiers adsorb to the fat globule surface, displacing milk proteins and thus leaving more proteins in the aqueous phase. The purpose of this research was to determine the rheological properties of model ice cream mixes to understand how different ingredients affect aqueous structure formation during freezing, and ultimately ice crystal growth during ice cream storage. A controlled stress rheometer measured yield stress and frequency sweeps for solutions comprised of skim milk powder (SMP) (4% protein), sucrose (10%) and LBG or GG (0.25%), with or without fat (10%) and emulsifier (0.1%). Measurements were made at -1°C after being quiescently frozen and temperature cycled (-15°C to -1°C to -15°C) for a total of five cycles. Rheological data showed that LBG/SMP/sucrose solutions developed a more elastic network during temperature cycling, as shown by significantly increasing yield stress and decreasing $\tan \delta$ values ($P \leq 0.05$), while GG/SMP/sucrose solutions did not. Emulsifiers enhanced solution rigidity after temperature cycles. Junctions form more easily between LBG molecules than GG molecules because of their structures, which may explain why LBG forms weak networks during temperature cycling. When LBG or GG are mixed with milk proteins, concentrations of both stabilizer and protein increase because LBG and GG are thermodynamically incompatible with milk proteins. This effect is further enhanced when water is frozen out of solutions at subzero temperatures or when protein concentration in solution is increased. The above evidence suggests that freezing and phase separation with milk proteins enhances the ability of LBG to form weak networks, which may explain why LBG has been shown to slow down recrystallization rates better than GG.

Key Words: stabilizer, emulsifier, rheology

257 Measurement of temperature dependent changes in process cheese viscosity. L. E. Metzger* and M. L. Leman, *University of Minnesota, St. Paul, MN*.

A ten-minute test which measures temperature dependent changes in the viscosity of process cheese was developed utilizing a rapid visco analyzer (Newport Scientific, Warriewood, Australia). The rapid visco analyzer is capable of adjusting sample temperature between 0 and 99°C with stirring speeds of 0 to 2000 rpm and measures viscosity from 50 to 50,000 cps. During the test the sample is heated to a set temperature in five min, held for three min, and cooled to a set temperature in 2 min. The sample is stirred from four minutes until the end of the test. The initial hot viscosity, time at minimum viscosity, change in viscosity during holding at maximum temperature and change in viscosity during cooling were determined. Three commercial samples (14 g cheese and 1 g propylene glycol) were evaluated in triplicate utilizing a variety of operating conditions including stirring speeds of 100, 200, and 300 rpm, maximum temperatures of 80, 85, and 90°C and cooling temperatures of 65, 70, and 75°C. Initial hot viscosity, change in viscosity during holding at maximum temperature, and change in viscosity during cooling were significantly ($p \leq .05$) affected by stirring speed, maximum temperature, and cooling temperature. Suggested operating conditions are heating from 25 to 85°C in five min, holding for 3 min, and cooling to 65°C in two min with a stirring speed of 200 rpm. Under these operating conditions significant ($p \leq .05$) differences in initial hot viscosity, change in viscosity during holding at maximum temperature, and change in viscosity during cooling were observed between the three samples. The rapid visco analyzer can be used to measure temperature dependent changes in viscosity of process cheese and has potential as a quality control technique.

Key Words: process cheese, viscosity

258 On-farm factors influencing the tenderness of pasture-fed beef raised commercially in New Zealand. B.C. Thomson*, K.V. Gilbert, and N.J. Simmons, *AgResearch Limited, Hamilton, New Zealand.*

This survey aimed to identify the amount and factors contributing to the variation in tenderness of strip loins from New Zealand beef animals. Strip loins (longissimus dorsi) were collected 24 hours post-slaughter from 10 beef animals from four abattoirs every fortnight over the killing season for a year (n=740). Producers were asked about the history of their animals. Shear force was determined 2 and 7 days post-slaughter in samples cooked to an internal temperature of 75°C in a boiling water bath, using a MIRINZ tenderometer. The influences of the different variables were analysed and the least square means presented. Although, there was a wide range of tenderness values (1.5 to 16.6 kgF 7 days post-slaughter), 91% of the samples were below 8 kgF 7 days post-slaughter. Possible reasons for the variation were examined. There was a strong seasonal effect on tenderness 2 days post-slaughter; samples in the spring were tougher than those in summer, winter and fall (8.7, 8.2, 8.0 and 7.2 kgF respectively, $P < 0.009$), this effect was reduced by day 7 of storage. This effect appeared to be at least partially due to the producer's perception of weather conditions immediately prior to slaughter; animals that were slaughtered when the weather was classified as colder than normal for the period were tougher than when it was warmer, hotter or normal (9.5, 8.6, 7.1 and 6.0 respectively, $P < 0.03$). Heifers were tougher than steers at both time points (9.1 vs 6.5 and 6.4 vs 5.0 kgF for 2 and 7 days post-slaughter respectively, $P < 0.005$), an effect unrelated to ultimate pH (5.56 vs 5.61 for heifers and steers respectively, $P < 0.30$). Poor growth rates as classified by the producer, buying from the saleyard vs buying direct from another producer, and low levels of contact with humans also reduced tenderness, but the effects were smaller. The identification of key factors like the above, will allow the development of appropriate measures for handling animals and carcasses of different backgrounds on-farm and during processing to reduce the variation in the tenderness of the final product. Work is currently underway to examine the effects of factors immediately prior to slaughter.

Key Words: Tenderness, Sex, Season

259 National Beef Quality Audit-2000: Survey of producers, packers, and end-users. D. L. Roeber*¹, D. R. McKenna², P. K. Bates³, T. B. Schmidt⁴, K. E. Belk¹, J. W. Savell², J. B. Morgan³, T. H. Montgomery⁴, and G. C. Smith¹, ¹Colorado State University, Fort Collins, CO, ²Texas A & M University, College Station, TX, ³Oklahoma State University, Stillwater, OK, ⁴West Texas A & M University, Canyon, TX.

National Beef Quality Audits (NBQA) in 1991 & 1995 provided benchmark data on quality challenges for the beef industry. Face-to-face interviews in 1991 & 1995 identified hide defects and lack of uniformity in live cattle as leading quality challenges for packers, and external fat and low overall uniformity and consistency as leading quality challenges for purveyors, retailers, and restaurateurs. For NBQA-2000, face-to-face interviews were replaced with questionnaires to solicit opinions of seedstock generators, cow-calf producers, stockers/backgrounders, and feedlot operators and to increase data collected from packers, purveyors, retailers, and restaurateurs. The most frequently cited ($P < 0.05$) management changes made since 1991 in the seedstock and cow-calf sectors (n = 2,308) were improved genetics using EPDs, changed injection-site location, and improved genetics using physical characterization. The most frequently cited ($P < 0.05$) management changes in the stocker/backgrounder and feeder sectors (n = 740) were changed injection-site location, improved handling, and changed genetic types of cattle. Identified changes coincided with those quality challenges for which packers (n = 29) and end-users (n = 113) have seen the greatest improvement. Seedstock and cow-calf producers said results of the previous audits had a "strong" (18.7%) or "moderate" (57.6%) impact on changes in beef quality since 1991; comparable responses were, for stocker/backgrounders plus feedlot operators (15.3% or 62.7%), for packers (6.9% or 55.2%), and for end-users (9.5% or 71.8%). Aggregated responses of the production sectors revealed the greatest quality challenges facing the beef industry were lack of uniformity in live cattle, inadequate tenderness, and insufficient marbling in carcasses and cuts. Aggregated responses of end-users revealed that the greatest quality challenges for the beef industry were insufficient marbling, lack of

uniformity in cuts, and inadequate tenderness. These findings should be useful to the beef industry and those who provide educational and research services in seeing where progress has been made and challenges still exist.

Key Words: Beef quality, Market survey

260 National Beef Quality Audit-2000: Results of slaughter floor assessments. P.K. Bates*¹, D.R. McKenna², D.L. Roeber³, T.B. Schmidt⁴, J.B. Morgan¹, J.W. Savell², T.H. Montgomery⁴, D.B. Griffin², D.S. Hale², and G.C. Smith³, ¹Oklahoma State University, ²Texas A&M University, ³Colorado State University, ⁴West Texas A&M University.

In order for the beef industry to improve quality and consistency of beef, the current state of the industry must be assessed. The National Beef Quality Audit-2000 was conducted as a sequel to previous audits in 1991 and 1995. Plants (n = 30) were audited from May to November 2000. Each university team (n = 4) surveyed seven or eight plants for the equivalent of one day's production. Fifty percent of each lot was audited in each plant resulting in a total sample size of 43,415 carcasses for hide-on and 43,595 carcasses for bruise evaluations. For condemnation data, approximately 10% of each lot was sampled, resulting in a total sample size of 8,588. Slaughter floor data was segmented into three categories: hide-on, bruise, and condemnation. Hide-on data consisted of evaluations of hide color, mud/manure characteristics, horns, and brands. Bruise data consisted of the frequency, location, and severity of bruises. Offal and carcasses were evaluated for the incidence of condemnation. Data indicated that 45.1% of cattle were predominately black hided, 31.0% were red and 8.0% were yellow. Of the cattle surveyed, 18.0% had no mud/manure, while 55.8% had a small amount. The frequency of cattle without horns was 77.3%. Data revealed 49.3% of the cattle were not branded, 46.2% had one brand, and 4.4% had multiple brands. Of the cattle surveyed, 36.3%, 13.7%, 3.6% had brands located on the butt, side and shoulder, respectively. Data indicated that 53.3% of cattle had no bruising, while 30.9% had one bruise and 15.8% had multiple bruises. Of the cattle with bruises, 14.9%, 25.9%, 19.4%, 28.2%, and 11.6% were located on the round, loin, rib, chuck and brisket, flank and plate, respectively. Offal and carcasses were evaluated for the incidence of condemnation and corresponding reasoning for condemnation. Head, tongue, liver, lung, tripe, and carcass condemnations were 30.3%, 13.8%, 11.6%, 6.2%, 7.0% and 0.1%, respectively. Results from the slaughter floor assessment indicate quality and consistency improvements have been made in the fed-beef cattle industry since previous the audits.

Key Words: Beef Quality, Slaughter, Market Surveys

261 National Beef Quality Audit-2000: Results of carcass assessments. D.R. McKenna*¹, P.K. Bates², D.L. Roeber³, T.B. Schmidt⁴, D.S. Hale¹, D.B. Griffin¹, J.W. Savell¹, J.B. Morgan², T.H. Montgomery⁴, and G.C. Smith³, ¹Texas A&M University, College Station, TX, ²Oklahoma State University, Stillwater, OK, ³Colorado State University, Ft. Collins, CO, ⁴West Texas A&M University, Canyon, TX.

The National Beef Quality Audit-2000 was conducted to assess the current status of the quality and consistency of the U.S. fed steer and heifer population. Previous audits, conducted in 1991 and 1995, have been used as a baseline to pinpoint inadequacies and problems that the industry needs to improve upon. Plants (n = 30) were audited during a seven-month period (May to November, 2000). Each university team (n = 4) surveyed seven or eight plants for the equivalent of one day's production. Ten percent of each lot for each shift was audited in each plant, resulting in a total sample size of 9,396 carcasses. USDA grade factors and other data were collected in the cooler. Mean (SD) USDA yield grade traits were as follows: USDA yield grade, 3.0 (0.87); carcass weight, 356.9 (42.7) kg; adjusted fat thickness, 1.24 (0.53) cm; longissimus muscle area, 84.5 (10.8) cm²; and kidney, pelvic, and heart fat, 2.35 (0.76) %. The distribution of USDA yield grades were as follows: yield grade 1, 12.2%; yield grade 2, 37.4%; yield grade 3, 38.6%; yield grade 4, 10.4%; and yield grade 5, 1.3%. Carcasses weighing over 431 kg were 3.9% and carcasses having ribeyes greater than or equal to 96.8 cm² were 13.2% of the carcasses surveyed, respectively. Mean (SD) USDA quality grade traits were as follows: USDA quality grade, Select⁸⁵ (60.6);

marbling score, Small²³ (101.0); overall maturity, A⁶⁶ (23.8); lean maturity, A⁶⁴ (19.9); and skeletal maturity, A⁶⁷ (30.5). The distribution of USDA quality grades were as follows: Prime, 2.0%; Choice, 49.1%; Select, 42.3%; Standard, 5.6%; and Commercial, Utility, Cutter, and Canner, 0.9%. The incidence rates of dark cutters, blood splash, and yellow fat were 2.3%, 0.5%, and 0.4%, respectively. B-maturity carcasses were 2.5%, and C-maturity and older carcasses were 0.9% of the population surveyed. Steers were 67.9%, heifers 31.4%, and bullocks 0.3% of the fed-beef population evaluated. Results indicate a trend toward heavier carcass weights and larger ribeyes, however, other yield grade factors, and quality grade factors were similar to previous audits.

Key Words: Beef quality, Meat grades, Market surveys

262 National Beef Quality Audit-2000: Consensus of the beef industry. T. B. Schmidt¹, D. L. Roeber², P. K. Bates³, D. R. McKenna⁴, T. G. Field², T. H. Montgomery¹, J. B. Morgan³, J. W. Savell⁴, and G. C. Smith², ¹West Texas A & M University, Canyon, TX, ²Colorado State University, Fort Collins, CO, ³Oklahoma State University, Stillwater, OK, ⁴Texas A & M University, College State, TX.

Representatives of the beef industry, as participants in the Strategy Workshop of the National Beef Quality Audit-2000 (NBQA-2000), reached consensus regarding the leading quality challenges for the industry. Participants (n = 40) included seedstock generators, cow-calf producers, stockers/backgrounders, feedlot operators, packers, purveyors, restaurateurs, retailers, and academicians. Participants ranked the top ten quality challenges, by severity of the problem for the industry, based upon results of questionnaires and in-plant audits. Severity of quality challenges was determined on an 11-point scale (-5 = severe problem, +5 = above expectations). Leading quality challenges were (1) low overall uniformity and consistency of cattle, carcasses, and cuts (-3.0 ± 0.5); (2) inappropriate carcass size and weight (-2.9 ± 0.2); (3) inadequate tenderness of beef (-2.2 ± 0.3); (4) insufficient marbling (-2.0 ± 0.4); and (5) reduced Quality Grade and tenderness due to growth-promoting implants (-2.0 ± 0.3); all different from zero (P < 0.05). Participants developed strategies, tactics, and goals to overcome quality shortfalls by 2005. Goals included (1) eliminate USDA Standard carcasses, (2) eliminate USDA Yield Grade 4 and 5 carcasses, (3) eliminate injection-site lesions from whole muscle cuts, including the chuck, (4) eliminate side brands, (5) reduce horns to less than 5% of fed cattle supply, (6) develop and implement a standardized electronic identification system, (7) develop information systems that allow producers to conduct a quality audit of their own herd, (8) eliminate major and critical bruises that result in subprimal devaluation, (9) improve transportation, (10) market seedstock animals with meaningful genetic data for production and end-product traits, (11) train all producers in Beef Quality Assurance, and (12) continually improve the eating quality of beef. Beef producers can begin to recapture a portion of the \$100.10 (Waste = \$50.96, Taste = \$24.45, Management = \$18.23, Weight = \$6.46) in quality losses per fed steer/heifer harvested if they develop, implement, and manage cattle using a total quality management approach.

Key Words: Beef quality, Market survey

263 Incidence of injection-site lesions in top sirloin butts of fed steers and heifers. D. L. Roeber¹, R. C. Cannell², K. E. Belk¹, J. N. Sofos¹, J. A. Scanga¹, G. L. Cowman³, and G. C. Smith¹, ¹Colorado State University, Fort Collins, CO, ²ConAgra Beef Company, Omaha, NE, ³National Cattlemen's Beef Association, Englewood, CO.

Damaged beef muscle tissue resulting from intramuscular injections of animal-health products represents a "quality control" problem and an economic loss to the beef industry. Injection-site lesion audits commenced in 1990 when the incidence was documented to be 21.6%. Such lesions are unsightly and the wound-healing process causes toughening of muscle in a radius of 7.6 cm around the injection-site. Fifteen individual and sequential national audits of injection-site lesions in beef top sirloin butts were conducted at the steak provisioner/cutting level between November 1995 and July 2000. The national incidence of injection-site lesions in the top sirloin butts audited (n = 240,080) decreased (P < 0.05) between November 1995 (11.4%) and July 2000 (2.1%). From November 1995 to July 1997, mean injection-site lesion weight, across all lesion classes, increased (P < 0.05) from 192.5 g to 435.8 g, respectively; mean lesion weight subsequently decreased (P < 0.05) to 249.8 g in July

2000, but was still heavier (P < 0.05) than in November 1995. The increase from 1995 to 1997 coincided with a response by steak cutters to the release of data confirming the "toughening response" in tissues surrounding injection-site lesions. Results of these audits indicate that producers have changed injection practices; probably due to the efforts of the National Cattlemen's Beef Association and state beef quality assurance programs to heighten awareness of the injection-site lesion issue. Analyses of results for lesion classes, partitioning lesions according to chronological stages of the healing process, suggested that the majority of lesions were induced at times which coincide with cow-calf, stocker, or early finishing-period stages of cattle production.

Key Words: Injection-site lesion, Top sirloin butt, Incidence

264 Incidence of injection-site lesions in beef and dairy cow rounds. D. L. Roeber¹, R. C. Cannell², K. E. Belk¹, J. A. Scanga¹, J. N. Sofos¹, G. L. Cowman³, and G. C. Smith¹, ¹Colorado State University, Fort Collins, Co, ²ConAgra Beef Company, Omaha, NE, ³National Cattlemen's Beef Association, Englewood, CO.

While incidence of injection-site lesions in top sirloin butts and rounds in fed cattle has been well documented, incidence and severity of lesions in rounds of beef and dairy cows has not been reported. This study determined incidence and type of injection-site lesions in beef and dairy cow rounds. Audits were conducted in 1998, 1999, and 2000 on 3,190 gooseneck rounds (beef: n = 1,695; dairy: n = 1,495) in seven states. Rounds were cut into 1.25-cm slices to determine the number of lesions present and the type of lesion. In 1998, 31.1% of beef rounds and 60.1% of dairy rounds had an injection-site lesion. The frequency of lesions in beef rounds declined (P < 0.05) nearly 6 percentage points between 1998 and 1999 and an additional 6 percentage points between 1999 and 2000 (P < 0.05). The frequency of lesions in dairy rounds did not change (P > 0.05) from 1998 (60.1%) to 1999 (51.0%). However, the incidence in dairy rounds declined (P < 0.05) over 16 percentage points between 1999 and 2000. In 1998, 1999, and 2000 the incidence in beef rounds was lower (P < 0.05) than the incidence in dairy rounds. In all rounds, 95.2% and 89.0%, of all lesions were clear lesions (older lesions comprised primarily of connective tissue) or woody calluses (infiltrated with connective tissue and fat), respectively. Incidence of clear lesions and woody calluses in beef and dairy rounds in 1998, 1999, and 2000 was higher (P < 0.05) than incidence of cystic, nodular, or metallic lesions. However, still of concern were the 4.8%, 3.3%, and 4.1% of cystic lesions (encapsulated lesions containing fluid) that were found in beef rounds in 1998, 1999, and 2000, respectively, and the 4.1%, 2.3%, and 2.2% of cystic lesions that were found in dairy rounds in 1998, 1999, and 2000, respectively. Incidence of cystic lesions in beef vs. dairy rounds did not differ (P > 0.05). Monitoring of the incidence of injection-site lesions in beef and dairy rounds allows educational efforts of state and national BQA programs to target, more definitively, management practices of producers that can minimize occurrence of such defects in end-products.

Key Words: Injection-site lesion, beef and dairy rounds, tissue damage

265 Bison grain fed and grass fed top loin taste test. J. L. Lanier¹, C. D. Smith¹, P. Chapman², and T. Grandin³, ¹Lanier Animal Systems, ²Dept. of Statistics, Colorado State University, ³Grandin Livestock Handling Systems, Ltd..

A study was conducted to determine consumer preference/acceptance for grass-fed and grain-fed bison steaks. Twenty-five top loin steaks, (longissimus lumborum) from each treatment group (grass-fed or grain-fed; 6 producers each treatment), were cooked to an internal temperature of 60°C. Warner-Bratzler shear force values were determined on 21 steaks (10 grass-fed, 11 grain-fed). Customers (n=144; 53% women) of two Alfalfa's Market in northern Colorado participated in an "untrained consumer taste panel" to evaluate overall like or dislike, flavor, tenderness, and juiciness. Ninety percent of the panelists were Caucasians and the average age was late 30's. Contribution to health was the primary factor in choosing products for a main meal, while taste was the primary factor for a special meal ingredients. Interest in purchasing bison meat to be cooked at home was slightly greater than ordering bison meat at a restaurant. Sixty-two percent of the panelists would prefer to purchase grass-fed bison steaks rather than grain-fed steaks, with the most frequent reason given as "grass-fed are more natural". Grain-fed steaks had a greater acceptance rating for flavor (P<.01) adjusted for thickness of the steak and income of the panelist, and overall

acceptance ($P=.02$), adjusted for thickness. There was evidence of variability among animals from different producers within both feed-types for tenderness (est. $\sigma = .075$; glm test $P=.02$), and juiciness (est. $\sigma = .017$; glm test $P=.02$). A lack of consistency within grass-fed and grain-fed producers for juiciness and tenderness ($P=.02$), as well as marginal consistency for flavor and overall acceptability within feed-types was found. Thicker grain-fed steaks had a higher probability of preference ($P=.02$) than thinner grain-fed steaks. Thickness was not a condition of acceptance for grass-fed steaks. If a customer was male, the odds of not preferring grass-fed steak decreased by a multiple of .471 ($P=.03$). Mechanical analysis of tenderness found all bison loin steaks grilled to an internal temperature of 60°C to be tender, with no difference between feed-types.

Key Words: Bison, Consumer taste test, Meat

266 Influence of feeding malting industry byproducts to feedlot cattle on longissimus muscle sensory traits and tenderness. C. R. Dahlen*¹, K. Hachmeister⁴, C. M. Zehnder¹, M. Dikeman⁴, G. C. Lamb³, L. R. Miller¹, H. Chester-Jones², and A. DiCostanzo¹, ¹University of Minnesota, St. Paul, ²Southern Research and Outreach Center, Waseca, ³North Central Research and Outreach Center, Grand Rapids, ⁴Kansas State University, Manhattan.

Loins from 48 crossbred steers were used to evaluate effects of feeding malting industry byproducts (MBP) on sensory traits, color, and Warner-Bratzler (WB) shear force. Pens (two heavy and two light replicates; 5 steers/pen) were allocated to receive one of four dietary treatments consisting of a corn grain-based diet (Control) where corn gluten feed (CGF), MBP, or MBP and thin stillage (MBPTS) substituted for a portion of corn silage and/or corn. Steers in heavy or light replicates were harvested after 110 or 138 d on feed, respectively; 97 d after receiving a single steroid implant. Loins were aged at 2 C for 14 d postmortem, cut into steaks (2.54 cm thick) and analyzed for WB shear force, sensory, and color evaluation. Neither cooking loss nor WB shear force were affected ($P > .05$) by treatment. Steaks from steers fed CGF had more desirable scores for myofibrillar tenderness than those from steers fed Control ($P = .004$) or MBPTS ($P = .08$). A similar trend ($P = .06$) was observed for overall tenderness. Steaks were found to be moderately juicy and intense in flavor, with practically no connective tissue or off-flavors regardless of treatment ($P > .05$). Steaks from steers fed MBPTS tended ($P = .06$) to be redder (higher 630/580 ratios) during display than those from CGF steers, whereas steaks from steers fed Control tended ($P = .06$) to be darker (lower L* values) than those from MBPTS steers. Steaks from steers fed CGF tended ($P = .07$) to be less red (lower a* values) than those fed Control, and less red ($P < .05$) than steaks from steers fed MBPTS. Feeding steers MBP had no adverse effects on longissimus muscle tenderness or sensory traits.

Key Words: Tenderness, Beef, Byproducts

267 Tenderness improvement through prerigor muscle stretching of Holstein cow carcasses. J.R. Claus¹, H. Wang², and N.G. Marriott*², ¹University of Wisconsin-Madison, ²Virginia Polytechnic Institute and State University.

The objective was to determine if prerigor muscle stretching would improve the tenderness of beef from Holstein cow carcasses. In a commercial packing plant, carcasses were suspended in the common vertical position and nine carcasses (approx. 365 kg each) were selected, with one side randomly designated for the Tendercut treatment (TC) with the counterpart as a control (C). After 35 min postmortem, the 12th thoracic vertebra, Multifidus dorsi, and connective tissues of the TC sides were completely severed, leaving only the Longissimus muscle (LM) intact in this area. Both sides were chilled in a cooler that utilized spray chilling at 4 C for 24 h. The LM between the 2nd lumbar and 9th thoracic vertebrae was removed, vacuum packaged, and aged for 10 days (4 C). After aging, samples were frozen and stored (-31 C). The LM was cut into 25.4 mm steaks. Steaks were thawed and cooked to an internal temperature of 70 C. The LM of TC treated carcasses had longer ($P<0.05$) sarcomeres than the C samples in both the anterior (2.55 vs. 1.70 μm) and posterior regions (2.13 vs. 1.62 μm). In the anterior portion of the LM, the Warner-Bratzler shear force (WBS) of the TC steaks (4.75 kg) was lower ($P<0.05$) than the C samples (5.54 kg). The posterior region of the LM was not different ($P>0.05$) in WBS between TC and C which was attributable to the farther distance from the treatment site. Lee-Kramer shear force data were similar to the results of

WBS. Trained sensory panelists determined that TC steaks had higher (14.8%, $P<0.05$) scores for myofibrillar tenderness and overall tenderness (13.9%) than C steaks. TC steaks were not different ($P>0.05$) in sensory juiciness or connective tissue score compared to the C samples. Prerigor carcass muscle stretching can improve the tenderness of beef from Holstein cows.

Key Words: Holstein, Prerigor, Tenderness

268 Composition and consumer perception of fresh beef bonded with Activa™ TG-RM. D.S. Kollé*, B.L. Kollé, and J.W. Savell, Texas A&M University, College Station, TX.

Objectives were to determine the effects of removing kernel fat from ribeye rolls ($n = 24$ treated; $n = 24$ control) and connective tissue from top blades ($n = 24$ treated; $n = 24$ control) on percent dissectible components, chemical analyses, energy measurements, and consumer evaluations of steaks. For treated cuts, the kernel fat that lies within the ribeye between the *Spinalis dorsi* and the *Longissimus thoracis* was removed. For the top blade, the *Infraspinatus* was cut open and the heavy connective tissue within the muscle was removed. Control cuts were left intact. A 0.5% dry-sprinkle application of Activa™ TG-RM/sodium caseinate mixture was applied to treated cuts to serve as a binding agent. Steaks were assigned randomly to: 1) raw analysis; 2) cooked analysis; or 3) in-home sensory evaluation. Steaks were dissected into separable lean, fat, connective tissue, and inseparable tissue. Chemical analyses were conducted to determine moisture, fat, and protein content, and results were determined for protein calories, fat calories, and total calories. Additional ribeye rolls ($n = 12$ treated; $n = 12$ control) and top blade roasts ($n = 10$ treated; $n = 10$ control) were used for a consumer retail case study. Modified raw ribeyes were higher ($P < 0.05$) in percent dissectible lean, chemical protein, and chemical moisture, in addition to being lower in percent dissectible fat, chemical fat, and total energy. Treatment increased the percent dissectible lean and percent chemical protein, while reducing the percent dissectible connective tissue for raw top blades. Cooked data for both cuts were similar to the findings for the raw data. In-home sensory evaluations showed consumers rated modified ribeye steaks higher for leanness. The removal of kernel fat did not negatively affect evaluations for tenderness, juiciness, and flavor. Consumers rated treated top blade steaks higher than controls for all sensory characteristics. Consumer case data suggested that consumers chose treated ribeyes over control ribeyes due to leanness, and treated top blade steaks over control steaks because of perceived marbling. Modifying retail cuts to remove excessive seam fat and connective tissue appears to be an effective tool in increasing the nutritional composition and purchasing characteristics of steaks.

Key Words: Beef, Consumer preferences, Composition

269 The effects of calcium loading on tenderness of beef Longissimus, Supraspinatus and Semitendinosus muscles. D.J. Hanson*¹, C. R. Calkins¹, and J.M. Horton², ¹University of Nebraska-Lincoln, ²Kemin Industries, Inc., Des Moines, IA.

Calcium is needed for postmortem proteolysis of muscle. This experiment was designed to evaluate the hypothesis that high calcium, oral drench administered immediately prior to slaughter would hasten the effects of aging and/or increase overall muscle tenderness of beef *Longissimus*, *Semitendinosus*, and *Supraspinatus* muscles. Forty-two ($n=14$ /treatment) crossbred steers were treated 35 to 125 min prior to slaughter with one of three solutions. One group served as a control and received 1 L of distilled water; the other two groups were drenched with 1 L of calcium chloride or calcium propionate (NutroCAL™), that provided 150 g of elemental calcium. The muscles were removed about 24 h postmortem and 2.54 cm steaks were removed after 2, 5, 7, 14, and 21 d postmortem for Warner-Bratzler shear force determination, except that the size of the *Supraspinatus* prevented sampling after 7 d. Calcium chloride-treated steers had higher serum calcium levels ($P<.10$) than controls or calcium propionate treated steers. *Longissimus* muscles from calcium propionate-treated steers tended to have higher levels of muscle calcium than controls and calcium chloride-treated steers and numerically lower shear force values at 2, 5, 7, and 14 d than controls. No differences in muscle calcium or shear force values were detected among treatments for *Semitendinosus* and *Supraspinatus* muscles. Sarcomere lengths were not different among treatment groups, indicating that differences in muscle calcium did not create differences in muscle

shortening. These data suggest subtle benefits to *Longissimus* tenderness from calcium propionate (NutroCALTM) treatment of steers prior to slaughter.

270 Inhibition of lipid oxidation with encapsulated phosphates in muscle foods. J.R. Claus^{*1}, H. Wang², N.G. Marriott², and W.N. Eigel², ¹University of Wisconsin-Madison, ²Virginia Polytechnic Institute and State University.

The objective was to determine if encapsulation would improve the antioxidative property of phosphate in cooked muscle foods. Encapsulation of phosphate was done to protect the phosphate from endogenous phosphatases during the raw meat manufacturing steps. An initial experiment involved incorporation of encapsulated phosphates (0.5% sodium tripolyphosphate, STP or 0.5% sodium acid pyrophosphate, SAPP; meat weight basis) into ground beef patties that were immediately heat processed before storage (3 C). Phosphates were encapsulated with a hydrogenated vegetable oil designed to melt at 74 C (STP) or 60 C (SAPP). Unencapsulated STP samples had the lowest (P<0.05) cooking loss. Thiobarbituric Acid Reactive Substances (TBARS) were lower (P<0.05) for the phosphate treatments compared to control samples (no phosphate) on day 0 and 6. Unencapsulated STP samples had lower (P<0.05) TBARS than the other phosphate treatments on day 0. However, there were no differences (P>0.05) in TBARS among the phosphate treatments on day 6. A subsequent experiment involved delay of heat processing after phosphate encapsulation. Ground turkey meat with 1% NaCl was incorporated with unencapsulated STP (0.3% or 0.5%), encapsulated STP (0.3% or 0.5% phosphate), or a blend of unencapsulated (0.3%) and encapsulated (0.2%) phosphate and compared to a control. Treated ground turkey was stored (4 and 24 h, 3 C) before cooking to two different endpoints (74 and 79 C). Cooked turkey was stored (3 C) for 0, 5, and 10 days. An improvement of 77% and 80% in the reduction of TBARS was found with the 0.3% and 0.5% encapsulated STP, respectively, in comparison to the unencapsulated STP. TBARS on day 10 from samples stored 24 h before cooking were higher (P<0.05) than the samples stored 4 h prior to cooking. Encapsulation

ASAS Nonruminant Nutrition: Amino Acids, Vitamins, and Minerals in Finishing Pigs

272 Evaluation of synthetic L-Lysine use in finishing pigs. D.C. Kendall^{*1}, G.L. Allee¹, and J.L. Usry², ¹University of Missouri-Columbia, ²Ajinomoto Heartland Inc..

An experiment was conducted with finishing pigs (n=150 PIC C-22 x 337; initial BW = 70 kg) to evaluate the use of synthetic L-Lys on pig performance and carcass characteristics. Pigs were fed one of five dietary treatments with 6 replicates and housed at 5 pigs/pen. Pigs were fed an early finishing diet (EF) until 93 kg and late finishing diets (LF) until 115.5 kg. Diets consisted of a corn-soy positive control, a corn-soy negative control, .15% added L-Lys, .225% added L-Lys, and .30% added L-Lys. Dietary CP for the EF period were 16.1, 14.8, 13.1, 12.3 and 11.5%, respectively, and 13.9, 13.0, 11.2, 10.5, and 9.7%, respectively, for the LF period. True ileal digestible (TID) lysine levels were .71 and .57% for the positive control in the EF and LF. All other diets were formulated at .63 and .51% TID Lys for EF and LF. Ratios of TID Thr and Trp values were maintained relative to lysine of .63 and .20 in EF, .68 and .185 in LF with the addition of synthetic L-Thr or L-Trp. All diets were formulated to be equal on a modified ME basis. Pigs were weighed biweekly to determine average daily gain, average daily feed intake and feed efficiency. In addition, ultrasound measurements were taken on d 0 and at slaughter to determine tenth rib backfat depth and loin eye area. During the EF phase, no differences were observed in ADG or ADFI, however G:F was poorer in pigs fed diets containing .225 and .30% added L-Lys (.335) compared to the positive control (.353; P<.05). During the LF phase and for the overall finishing period, no differences in growth performance were detected between the diets. Ultrasound measures of tenth rib back fat depth, loin eye area, and percent lean at slaughter did not differ between treatments. At no point were the growth performance or carcass characteristics different between the negative control and diets with added L-Lys. This study shows that finishing swine diets

of phosphates has the potential to retard lipid oxidation in further processed meats that required an extended raw meat processing time prior to cooking.

Key Words: Encapsulated phosphate, Lipid oxidation, Meat

271 Future for red meat consumption cannot be accurately evaluated by using per capita: A different approach, per adult human unit versus per capita. S. Hasimoglu^{*1}, ¹Continental Analytical Services Inc. Salina, KS.

While the world's population has doubled in the past century, its appetite for meat quadrupled reaching 200 million tons. Even though the World Bank is discussing normalization of per capita (PC) consumption, its erroneous use has rarely been challenged, as if it is the most viable unit that should be used in the evaluation of meat consumption. However, PC does not address detailed anthropometrics criteria. When data are presented on PC basis, the assumption must be made that a 6-month-old baby will consume as much meat as a mature person. Aiming to reduce the magnitude of errors inherent PC, a method has been developed for analyzing production and consumption in populations that accounts for variations among age groups within populations. Per adult human use (PAHU) allows standardization of any population and eliminates the "one size-fits-all" PC concept. Application of the PAHU and calculated age groups conversion factors are used in obtaining data presented below. The calculation of the PAHU of the USA population (1985 and 1995) indicated that consuming and producing 239 and 265 million PC was reduced to standardized 199 and 222 million PAHU populations, respectively. Considering equally populated Sweden and Zimbabwe (8.3 million in 1985) and the world PC average meat consumption 29.6 kg/yr, their meat requirements would be 240 000 and 167 000 t/yr respectively. Percentage unit (PU) deviations of PAHU red meat consumption from PC were significantly different; 14.8 and 32.8 PU for Sweden and Zimbabwe respectively. The methodology underlying PC estimate of red meat consumption is an indirect procedure of arriving at a conclusion by disregarding not only the younger but the older portion of the population and the calculated unintended faulty level is not less than 15.86 PU as compared to PAHU. Simply, on the red meat consumption and production predictions, we are trying to find the right answer with the wrong unit, PER CAPITA.

containing up to .30% synthetic L-Lys, supplemented with L-Thr and L-Trp, does not affect growth performance or carcass characteristics.

Key Words: Pigs, Reduced crude protein, Lysine

273 Heat-damaged protein has reduced ileal true digestibility of cystine and aspartic acid in chicks. E.L. Miller^{*1}, Y.X. Huang¹, S. Kasinathan¹, B. Rayner¹, U. Luzzana², V.M. Moretti², F. Valfr², K. R. Torrissen³, H.B. Jensen⁴, and J. Opstvedt⁵, ¹University of Cambridge, ²Universit degli Studi di Milano, Italy., ³Institute of Marine Research, Norway., ⁴University of Bergen, Norway., ⁵Norwegian Herring Oil and Meal Industry Research Institute, Norway.

Low temperature fish meal (LT) has better digestibility than regular fish meal (R) in mink. Model systems have shown heat processing of fish muscle between 70 and 120C reduces SH groups and causes racemization of L to D aspartic acid. The objective was to determine the SH content, the extent of racemization of aspartic acid and ileal true digestibility (TD) of amino acids in chicks of Norse LT 94[®] compared with regular NorSeaMink[®]. Reactive SH was determined using three methods: 1) reaction with dithiodipyridine, 2) reaction with monobromobimane, and 3) reaction with 4-vinyl pyridine and HPLC separation. Values (mmoles/100 g CP) were LT 2.38, 2.57, 2.11; R 0.62, 0.70, 0.13 by methods 1, 2, 3 respectively. The proportion of D-aspartate (D/D+L) was determined by HPLC separation of the isomers following hydrolysis with 6M HCl at 100C for 6 h to minimize hydrolysis-induced racemization. D/D+L aspartate was 0.004 in freeze dried fish muscle compared with 0.030 in LT and 0.056 in R. Hydrolysis corrected values were LT 0.026, R 0.052. Ileal true digestibility was determined by slaughter of 11 day old chicks fed diets with 0 (200 enzyme hydrolysed casein plus amino acids), 150, 200, 250 g CP/kg of each fish meal as the sole protein

source and chromic oxide as marker. TD was calculated as 1-slope of the regression of ileal N or amino acid on diet N or amino acid. TD for N, cyst(e)ine (as cysteic acid), aspartate, D-aspartate, indispensable amino acids were: LT 0.930.009, 0.890.015, 0.920.007, 0.760.029, 0.940.009; R 0.870.012, 0.750.021, 0.800.013, 0.330.053, 0.880.011. LT meal had more SH and less S-S bonds and D-aspartate than R. TD of all amino acids was better for LT especially cyst(e)ine and aspartate. TD of D-aspartate was particularly low in R.

Key Words: Fish meal, Sulfhydryl, Racemization

274 Effect of increased levels of crystalline essential amino acids on growth performance and nitrogen retention of broiler chicks fed low-CP diets. K. Bregendahl* and D.R. Zimmerman, *Iowa State University, Ames.*

Bioavailability of crystalline AA (cAA) in low-CP diets may be lower due to destruction before consumption (i.e., Maillard reactions) or inefficient use during digestion/absorption. Therefore, an experiment was conducted to investigate whether increased dietary levels of cAA improve the growth performance and N retention of broiler chicks fed low-CP diets. A total of 306 day-old broiler chicks was fed a common corn-soybean meal (SBM) diet (24% CP) for 1 wk, after which the chicks were allotted to one of five diets (D) in a completely randomized design (10 chicks per pen, 6 replications; 146 g initial BW). Chicks had free access to the isoenergetic diets (3.20 Mcal ME_n/kg), which consisted of a control diet (D1; 24.0% CP), D2 (18.5% CP), D3, D4, and D5. The CP content of D2 was reduced by altering the corn:SBM ratio in D1 and adding cAA (Arg, Ile, Lys, Met, Thr, and Val) to 105% of NRC (1994) AA levels. Diets D3, D4, and D5 were formulated by increasing the cAA levels in D2 by 15, 30, and 45%, respectively, replacing Glu (making D2 though D5 isonitrogenous). After 2 wk on test, chicks were weighed, fasted for 24 h, and two chicks per pen were euthanized. The whole-body N contents of the chicks fed D1 through D5 as well as six baseline chicks were determined. Treatment means were compared using orthogonal contrasts. ADG (52.2, 50.6, 49.9, 49.3, 49.6 g/d for D1, D2, D3, D4, and D5, respectively), ADFI (68.6, 72.1, 71.2, 70.7, 69.8 g/d), feed utilization (G:F; 0.762, 0.701, 0.701, 0.697, 0.711), and N retention (1.45, 1.31, 1.30, 1.26, 1.26 g/d) of chicks fed D1 were superior ($P < 0.05$) to that of chicks fed D2 through D5. No linear or quadratic effects ($P > 0.10$) of increasing the cAA levels were observed on ADG or G:F, while ADFI ($P = 0.01$) and N retention ($P = 0.06$) decreased linearly. Based on these data, growth performance and N retention of chicks fed low-CP diets are not improved by increasing the amounts of dietary cAA above that needed to supply essential AA at NRC (1994) recommended levels

Key Words: Low Crude Protein, Performance, Crystalline Amino Acids

275 Supplemental fat and/or reduced dietary crude protein effects on growth performance, carcass characteristics, and meat quality of late finishing barrows reared in a controlled hot environment. J.D. Spencer*¹, A.M. Gaines¹, G. Rentfrow¹, W. Cast², J. Usry³, and G.L. Allee¹, ¹University of Missouri-Columbia, ²Premium Standard Farms, ³Ajinomoto Heartland Inc..

A total of 196 barrows (88 kg) were housed in a finishing facility (7 pigs/pen) with temperatures cycling between 29.4 and 35°C. A 2x2 factorial with two CP levels (13.6 or 11.3%) and two added fat levels (1 or 8%) allowed for 7 replicates (pens)/trt. All diets were corn/sbm and formulated to the same digestible lysine:ME ratio. Diets were fed until pigs approached 114 kg. Pigs were ultrasound for 10th rib backfat (ultBF) initially and before slaughter. Fat-o-meter fat depth (FOMBF), ham and loin 45 minute pH (45pH), ultimate ham pH(ultHpH), ham Hunter score (Ham L*), and total body electrical conductivity of the cut ham were taken from all pigs after slaughter. The right loin from 25 pigs/trt was subjected to pH measurement (ultLpH), loin intramuscular-fat content (IM), Hunter score (loin L*), and storage (14-d vacuum-sealed whole loin and 7-d retail display). Pigs fed the high CP/low fat (control) grew slower than all other trts ($P \leq .08$). However, high fat resulted in improved G:F regardless of CP level ($P \leq .01$). High fat diets had greater FOMBF, while high fat or lower protein both increased ultBF ($P \leq .05$). Reduced protein decreased ham weight and ham lean weight ($P \leq .04$). There was no difference in loin or ham 45 pH ($P \geq .05$), but low CP diets had lower ultHpH ($P \leq .05$). Pigs fed high fat diets had lower (darker) L* values at the ham face, as well as on the cut loin surface prior to

and after the 14-d vacuum seal and 7-d retail display. UltLpH was also higher with high fat inclusion ($P \leq .10$). Low CP fed pigs displayed less purge loss after the 7-d retail display ($P \leq .06$) and 14-d storage ($P \leq .19$). There was no difference in IM among treatments. These results suggest that 8% added fat or reduced dietary CP content (2.3%) improves finishing pig growth rate in hot environments, and fat inclusion improves G:F and meat quality regardless of CP level.

Key Words: Pigs, Temperature, Meat quality

276 A rapid method to determine “true metabolic availability” of amino acids in feedstuffs for pigs. R.O. Ball*, R.F.P. Bertolo, P.B. Pencharz, and S. Mhn, *University of Alberta.*

Some digested and absorbed amino acids (AA) in feeds cannot be used for protein synthesis by the pig. True ileal digestibility does not account for metabolically unavailable AA (eg Maillard products). The proportion of these unavailable AA varies with the growing and processing conditions for feedstuffs, preventing accurate diet formulation. We developed a rapid method (2 weeks), based on the indicator AA oxidation technique, to determine the “true metabolic availability” (MA) of AA for protein synthesis. Increasing AA intake below the requirement decreases indicator AA (phenylalanine, PHE) oxidation inversely to protein synthesis. Per unit AA intake, the MA of a feedstuff is equivalent to the decrease in oxidation relative to that supported by the free form of the test AA. Four catheterized barrows were fed a base diet for 7 d at 95 g/kg^{0.75}. Test diets were then fed for 2 d after which PHE oxidation was determined twice on subsequent days. The 5 test diets were: low lysine (LYS, 56% of requirement), low LYS + free LYS (90% of requirement), low LYS plus either raw peas or heated peas or heated peas + LYS (90% of requirement). PHE oxidation was quantified during 4h primed constant infusions of 425.0 (SE 6.9) kBq/h of L-[1-¹⁴C]-PHE. The first 2 diets provided the change in oxidation per g added free LYS, which is deemed 100% available, to predict MA of lysine in the other diets. In raw peas, MA was 65.3%, and in heated peas, MA was -2.9% of that of free LYS, indicating that the heating rendered the LYS in peas totally unavailable. When adding back free LYS to the level in raw pea diet, LYS MA was 64.9%, similar to raw pea diet. This indicates that the change in oxidation due to heating was entirely due to the change in dietary available LYS content. The present rapid method can be used to determine the MA of LYS and other AA in feeds. Using such information to formulate pig diets more accurately would result in more consistent performance and cost-efficient production.

Key Words: Pig, Lysine availability

277 A method to measure the amino acid requirement of individual pigs. S. Mhn*, R.F.P. Bertolo, and R.O. Ball, *University of Alberta.*

Although amino acid requirements for growing pigs are well established, there are no estimates of their variation in the population determined by measurements on individual pigs. We chose the indicator amino acid oxidation method (IAAO) to determine the lysine (LYS) requirement in individual pigs for an estimate of the mean requirement and its variation. When LYS intake increases, the relative excess and oxidation of the indicator (phenylalanine, PHE) diminishes. PHE oxidation remains constant once the LYS intake exceeds the requirement for protein synthesis. Oxidation is measured by quantifying the ¹⁴CO₂ release from a primed, constant infusion of L-[1-¹⁴C]-PHE. Four individually housed barrows (18.0kg SE 1.8) were surgically implanted with venous catheters for isotope infusion. They were offered, in random order, isonitrogenous and isoenergetic diets with 7 lysine concentrations (56, 67, 78, 90, 101, 123 and 145% of requirement, NRC, 1998) at 95 g/kg^{0.75}. After a validated minimum adaptation time of 2 days, indicator oxidation was determined for each dietary lysine level during 4 h primed, constant infusions of L-[1-¹⁴C]-PHE at a rate of 470.9 kBq/h (SE 17.1). The LYS requirement was calculated using a linear broken line model within individual pigs. For each pig, PHE oxidation decreased linearly ($P < 0.05$) as the LYS level increased until the requirement was reached; thereafter, PHE oxidation remained constant. The LYS requirement was 94, 99, 101, 117% of the NRC (1998) values for the four individual animals. The mean requirement for all pigs was 103.10%, in agreement with the estimate by NRC (1998). The IAAO method gives values for LYS requirements similar to conventional methods. The short (<3 weeks) experimental period allows, for the first time, the generation of an estimate of population variability. This allows the calculation of the effect of choosing a

specified safety factor on herd performance. This method is suitable to use with all dietary indispensable amino acids.

Key Words: Growing pig, Lysine requirement, Variation

278 Protein requirement re-evaluated for juvenile rainbow trout (*Oncorhynchus mykiss*). Zongjia Cheng*, R.W. Hardy, E.L. Brannon, and M. Casten, *University of Idaho, Hagerman, ID.*

Seven experimental diets (3,600 kcal DE/kg diet) were made with CP levels ranged from 27 to 45% (as fed basis) at 3% increment to evaluate the protein requirement for juvenile rainbow trout (initial BW 11.3 g) using practical feed ingredients. Fish were stocked into twenty-one 150 L fiberglass tanks with 3 tanks per treatment (diet), each tank was supplied with 4 L/min of untreated, constant temperature (14.5 C), spring water at the Hagerman Fish Culture Experiment Station, University of Idaho. Fish were fed 3 time/d and 6 d/wk to apparent satiation for a period of 6 weeks. Results showed that there were significant differences among treatments in weight gain (WG, $P < .0001$) and feed conversion ratio (FCR, $P < .01$). WG was 14.9.8, 16.21.2, 17.91.0, 19.8.8, 21.1.6, 22.31.9 and 21.11.3 g; FCR was 1.4.1, 1.4.1, 1.3.1, 1.2.0, 1.1.0, 1.1.1 and 1.1.1 g feed/g gain, for fish fed 27, 30, 33, 36, 39 and 42 and 45% CP diets, respectively. Quadratic regression based on WG revealed that the CP requirement for juvenile rainbow trout was 42.24% (as fed basis), the relationship can be expressed as: $WG = -0.026(CP)^2 + 2.1963(CP) - 26.122$ ($R^2 = .8959$); The CP requirement for juvenile rainbow trout was 44.08% (as fed basis) based on FCR, and the relationship can be expressed as: $FCR = 0.0012(CP)^2 - 0.1058(CP) + 3.3932$ ($R^2 = .9537$). These data showed that the CP requirement for juvenile rainbow trout fed practical diets was higher than NRC (1993) recommended values of 38% (as fed basis).

Key Words: Protein requirement, Rainbow trout, Weight gain, Feed conversion ratio

279 Effect of genotype and dietary lysine content during the grower phase on growth performance, serum urea N, and carcass and meat quality. J. Fabian*, L. I. Chiba, D. L. Kuhlers, L. T. Frobish, C. R. Kerth, K. Nadarajah, W. H. McElhenney, and B. L. Anderson, *Auburn University, Auburn, AL.*

A total of 32 select line (SL) and 32 control line (CL) Duroc pigs were used in two trials to determine the effect of selection for lean growth efficiency and dietary lysine content during the grower phase on pig performance. In each trial, pigs weighing 20 kg were assigned to 16 pens with two gilts or two barrows per pen, and pens were randomly assigned within genetic lines to one of the four grower (G) diets (0.5, 0.7, 0.9, or 1.1 g lysine/kg diet). After 50 kg BW, all pigs were fed finisher 1 (F1; 50-80 kg BW) and finisher 2 (F2; 80-105 kg BW) diets formulated to meet the NRC nutrient requirements. Pigs were allowed ad libitum access to feed and water. Blood samples were taken from each pig at 20, 50, and 105 kg BW. Pigs were subjected to ultrasound backfat (UBF) measurement at 50 and 105 kg BW. The initial statistical analyses revealed that variances between the two trials were homogeneous, thus the data were combined. During the G phase, pigs consumed less feed [linear (Ln), $P < 0.001$] and grew faster (Ln, $P < 0.05$) and more efficiently (Ln, $P < 0.001$) as the dietary lysine level increased. With the increasing dietary lysine content, pigs had lower UBF (Ln, $P < 0.001$) and higher serum urea N (Ln, $P < 0.001$) at the end of the G phase. However, during the F1 and F2 phases, pigs grew faster (Ln, $P < 0.01$ and $P = 0.07$, respectively) and more efficiently (Ln, $P < 0.05$) as the lysine content of the G diets decreased, resulting in no differences in overall growth performance or carcass and meat characteristics. The SL pigs grew faster ($P < 0.01$), and had lower 10th rib backfat ($P < 0.001$) and larger longissimus muscle area ($P = 0.08$) than the CL pigs, which were reflected in higher estimated daily lean gain ($P < 0.001$). The SL pigs had lower meat color ($P < 0.05$) and firmness ($P = 0.07$) scores. These results indicate that pigs exhibited compensatory growth after dietary lysine restrictions during the G phase, and were able to compensate fully. Although SL pigs had superior growth rate and body composition, both genetic lines responded similarly to the dietary restrictions.

Key Words: Pigs, Genotype, Compensatory growth

280 Lysine level required to optimize the growth response of Paylean™ in PIC pigs. R. D. Boyd*¹, M. E. Johnston¹, J. L. Usry², C. E. Fralick³, A. A. Sosnicki¹, and B. Fields¹, ¹PIC USA, Franklin, KY, ²Heartland Lysine Inc, Chicago, IL, ³Swine Tek, Van Wert, OH.

A trial was conducted with 456 PIC 337 × C22 pigs to determine the lysine level that allows full growth expression to Paylean™ (9g/909 kg). This dose was expected to yield about 70-85% of the maximum growth and carcass response. Females (240) and castrated males (216) were allocated by gender and weight to groups of 10 or 9 pigs/pen, respectively. Individual weights were taken at the start (92 ± 3 kg) and at the end of the 28 day trial. Corn-soy diets were used to formulate to 0.78% total lysine (Control, without Paylean™) and with Paylean™ (diets 2-5) having 0.78%, 0.90%, 1.02% or 1.14% lysine from intact protein. Diets 6 and 7 also contained Paylean™, but were formulated to 0.90% and 1.02% total lysine using 0.225%, 0.030% and 0.077% synthetic lysine, methionine and threonine, respectively. Pigs fed the Control diet had an ADG of 1.095 kg/d and a feed conversion ratio (G:F) of 0.34. The G:F ratio was improved ($P < .01$) with addition of Paylean™ to the 0.78% lysine diet (2). However, ADG was not improved when compared to pigs fed the Control diet. A linear improvement in ADG ($P < .05$) and G:F ($P < .01$) was observed for pigs fed diets containing Paylean™ with increasing lysine (diets 2-5): 1.145 and 0.371; 1.250 and 0.393; 1.195 and 0.398; 1.268 and .407, respectively. Pigs fed diets formulated with intact protein (3, 4) performed identical to those formulated with practical levels of synthetic amino acids (6, 7, $P > .50$). The lysine level that optimized growth declined in a step-wise manner. Using G:F ratio: week 1, 1.14% (0.562 vs 0.400); week 2, 1.02% (0.439 vs 0.366); week 3, 0.90% (0.327 vs 0.287); 0.90% total lysine approximated the requirement for the 28 day period. This level resulted in about 4 kg of added body weight and 1.8% carcass yield with 1.5 mm less backfat. Response to Paylean™ is dependent on adequate amino acid intake. The decreasing lysine requirement coincides with a declining response to Paylean™ with time.

Key Words: Pigs, Ractopamine, Lysine

281 Effects of supplemental trace mineral levels on carcass characteristics and carcass value. E. van Heugten*¹, P. R. O'Quinn², D. W. Funderburke², W. L. Flowers¹, and J. W. Spears¹, ¹North Carolina State University, Raleigh, ²Cape Fear Consulting LLC, Warsaw, NC.

A total of 6,024 pigs was used to determine whether reducing supplemental trace mineral (TM) levels during the grower-finisher phase has a negative impact on carcass traits and economic value. Pigs were randomly distributed into 4 blocks of 2 barns, ensuring that each block of barns was filled at the same time. Barns were then allotted within block to receive either diets with low or high TM supplementation. Four diet phases were fed with 135, 125, 105, and 85 ppm added Zn, 13.5, 12.5, 10.5, and 8.5 ppm added Cu, and 113, 104, 87.5, and 70 ppm added Fe for the high TM diets and 30 ppm added Zn, 6 ppm added Cu, and 30 ppm added Fe for all low TM diets. Diets were analyzed to contain 181, 155, 142, and 135 ppm Zn, 17, 21, 19, and 18 ppm Cu, and 506, 477, 352, and 299 ppm Fe for the high TM diets and 80, 75, 79, and 80 ppm Zn, 12, 8, 10, and 10 ppm Cu, and 389, 368, 270, and 271 ppm Fe for the low TM diets. Pigs averaged 19.1 and 21.2 kg for the high and low TM treatments, respectively ($P = 0.19$), at placement. Pigs were slaughtered at a commercial plant and sex and carcass data were determined for each individual pig. Data were analyzed by split-plot analysis using treatment as whole plot and sex as split-plot. Barrows had greater carcass weight (90.1 vs 87.7 kg; $P < 0.003$), fat depth (20.1 vs 17.3 mm; $P < 0.001$), carcass weight payment (\$110.52 vs 108.55; $P < 0.04$) and lower % lean (53.6 vs 55.4%; $P < 0.001$) and lean premium payment (\$1.50 vs 3.55; $P < 0.001$). Pigs fed low TM diets had greater carcass weight (89.5 vs 88.3 kg; $P < 0.06$), carcass weight payment (\$110.54 vs 108.53; $P < 0.04$), and total payment (\$112.98 vs 111.07; $P < 0.02$) compared to pigs fed high TM diets. Backfat thickness, loin depth, % lean, and lean premium payment were not affected ($P > 0.10$) by dietary treatments. Results indicate that reducing trace mineral levels in diets for grower-finisher pigs had no negative effects on carcass characteristics or value of the carcass.

Key Words: Swine, Minerals, Carcass

282 Differential response from feeding high levels of vitamin E on quality of stored pork from two genotypes. J. L. Hasty*, E. van Heugten, and M. T. See, *North Carolina State University, Raleigh.*

This study examined the effects of feeding high levels of vitamin E on the quality of stored pork from different genotypes. Pigs (n=240; initial BW=87 kg) were allotted by weight to one of ten treatments (8 pens/trt, 3 pigs/pen) in a 2 x 5 factorial arrangement. Factors included: 1) genotype (Berkshire sired and Hampshire sired) and 2) supplemental levels of vitamin E (0, 75, 150, 300 and 600 mg/kg). Corn-SBM basal diets containing 2.5% added fat, 0.83% lysine and 15 mg/kg vitamin E were fed for 6 weeks. Drip loss, color, and TBARS were measured in loin chops displayed for 0, 2, 4, 6, and 8 d at 4°C. Drip loss from Hampshire crosses was greater (3.16 vs. 1.77%; $P < 0.001$) compared to Berkshire crosses, but was not affected by vitamin E level ($P > 0.10$). Chops from Berkshire crosses were darker (L^* : 52.4 vs. 54.3; $P < 0.05$), less red (a^* : 7.87 vs. 8.94; $P < 0.001$), and less yellow (b^* : 7.87 vs. 8.71; $P < 0.05$) compared to Hampshire crosses, but were not affected by vitamin E level ($P > 0.10$). Greater oxidation (TBARS) occurred in Hampshire cross display chops (day x genotype; $P < 0.01$) on d 0 (0.77 vs. 0.65; $P < 0.02$), d 4 (1.09 vs. 0.83; $P < 0.001$), d 6 (0.62 vs. 0.47; $P < 0.002$) and d 8 (1.31 vs. 1.17 mg MDA/kg sample; $P < 0.01$). TBARS (day x vitamin E; $P < 0.06$) decreased linearly on d 4 (1.13 to 0.79; $P < 0.001$), d 6 (0.76 to 0.48; $P < 0.02$) and d 8 (1.40 to 1.04 mg MDA/kg sample; $P < 0.001$) with increasing levels of vitamin E. TBARS in display chops from Hampshire cross (genotype x vitamin E; $P < 0.02$) decreased linearly (from 1.02 to 0.66 mg MDA/kg sample; $P < 0.001$) with increasing vitamin E level. These data reinforce that Hampshire crosses produce paler, more exudative pork that is more susceptible to oxidation than Berkshire crosses. However, increasing supplemental vitamin E levels will improve storage as indicated by reduced oxidation of lower quality pork, but will not impact oxidation in higher quality pork.

Key Words: Vitamin E, Pork, Quality

283 The effects of niacin on growth performance and meat quality in grow-finish pigs. D. E. Real*¹, J. L. Nelssen¹, M. D. Tokach¹, R. D. Goodband¹, S. S. Dritz¹, J. A. Unruh¹, and E. Alonzo², ¹*Kansas State University, Manhattan*, ²*Lonza Inc., Fair Lawn, NJ.*

Two experiments were conducted to determine the effects of additional dietary niacin on growth performance and meat quality in finishing pigs. All pigs were blocked on weight and assigned to one of six dietary treatments. Pigs were housed with 2 pigs per pen (6 pens/treatment/sex) in Exp. 1 and approximately 26 pigs per pen (4 pens/treatment/sex) in a commercial research barn in Exp. 2. In both trials, dietary treatments consisted of a corn-soybean meal-based control diet or the control diet with 27, 55, 83, 110, or 550 mg/kg additional niacin. In Exp. 1, 144 pigs (initially 51.2 kg) were fed diets in two phases from d 0 to 25 and d 25 to 62 that were formulated to 1.00 and 0.75% lysine, respectively. In Exp. 2, 1243 pigs (initially 35.9 kg) were fed diets in four phases (d 0 to 28, d 29 to 56, d 57 to 84, and d 85 to 117). Diets were formulated to 1.25, 1.10, 0.90, and 0.65% lysine in the respective phases and contained 6.0% added fat in the first three phases. In both trials, gilts grew slower ($P < 0.001$), were leaner at the tenth rib ($P < 0.03$), and had higher fat-free lean percentages ($P < 0.01$) than barrows. Overall, in Exp. 1, feeding additional niacin had minimal effects on growth performance. However, niacin tended to increase ($P < 0.06$) 24 hr pH (5.44, 5.49, 5.49, 5.46, 5.49, and 5.48). In the commercial environment in Exp. 2, increasing niacin increased (quadratic, $P < 0.05$) ADG (760, 775, 762, 775, 754, and 753 g/d) and improved (quadratic, $P < 0.01$) G/F (.352, .362, .357, .375, .367, and .366). Niacin supplementation also decreased (linear, $P < 0.04$) carcass shrink and drip loss percent (2.00, 1.90, 1.93, 1.90, 1.23, and 0.80) and increased (linear, $P < 0.01$) subjective color scores, L^* values, and ultimate pH (5.67, 5.73, 5.77, 5.76, 5.85, and 5.94). Results from these two studies show that additional dietary niacin can be

284 Role of pantothenic acid as a modifier of body composition in pigs. T. S. Stahly and T. R. Lutz*, *Iowa State University, Ames, IA.*

Fifteen sets (7 barrows, 8 gilts) of four individually penned, littermate pigs were utilized to determine the effect of pantothenic acid (PA) additions on growth, body composition and meat quality in pigs fed from 10 to 118 kg BW. Pigs from a high lean strain were reared via a SEW scheme and self-fed a diet containing 19 ppm PA from weaning to 10 kg BW. Pigs were then fed a basal diet (analyzed 6 ppm PA) and allotted within litter to one of four dietary additions of PA (0, 30, 60, 120 ppm) from d-calcium pantothenate. The basal diet consisted of a corn-SBM-3% choice white grease mixture and contained 1.5, 1.2, and .95% lysine for pigs fed from BW of 10 to 46, 46 to 80 and 80 to 118 kg, respectively. All vitamins except PA were fortified to 600% of NRC (1998) for each stage of growth. As dietary PA concentration increased, longissimus muscle area increased quadratically (43.9, 48.0, 45.4, 47.5 cm², $P < .06$) and tenth rib backfat decreased quadratically (2.25, 2.04, 2.07, 1.95 cm, $P < .05$) resulting in a quadratic increase in fat-free lean (51.4, 53.4, 52.5, 53.6%, $P < .04$). The magnitude of these responses were larger ($P < .09$) for barrows than gilts. Daily body weight gain (933, 916, 940, 914 g) and gain:feed (429, 433, 428, 431 g/kg) were not altered by dietary PA. In addition, measures of meat (longissimus) quality including intramuscular fat content (4.4, 4.2, 4.6, 4.0%), Hunter L (54.5, 54.2, 54.3, 54.3) and Hunter a (8.7, 9.1, 8.9, 8.5) color values and water loss under retail storage (4.7, 4.9, 5.1, 4.7%) at 96 hours post-kill were not ($P > .10$) altered by dietary PA. Based on these data, dietary pantothenic acid at concentrations greater than that required to maximize body weight gain elicits reductions in subcutaneous fat thickness while increasing carcass lean content of market weight pigs without altering meat quality.

Key Words: Pigs, Pantothenic acid, Body composition

285 Impact of a targeted B-Vitamin regimen on rate and efficiency of growth on lean growth genotype pigs from 6 to 110 kilograms of body weight. M. Coelho, B. Cousins*, and W. McKnight, *BASF Corporation.*

Four hundred, four week old pigs (5.5 kg initial BW) were utilized in a 5x2 factorial design (10 reps/treatment) to determine the effects of five B-vitamin (riboflavin, pantothenic acid, niacin, B₁₂ and folic acid) fortification levels (NRC, 2X, 4X, 8X, 16X NRC) and two levels of stress (low and moderate) on the performance of 5.5 kg to 110 kg pigs (128 trial days). Diets were formulated to be isocaloric and isonitrogenous. The diets were fed in pellet form. Pigs raised under moderate stress conditions during performance period 1(19 days, 12 kg bw) gained 506^d, 533^{cd}, 544^{bcd}, 559^{abc} and 569^{ab} g/day and had corrected feed efficiency of 1.929^d, 1.899^{cd}, 1.889^{bcd}, 1.871^{abc} and 1.828^a when supplemented with NRC, 2X, 4X, 8X and 16X NRC B-vitamins, respectively. For the overall performance at 128 days pigs raised under moderate stress, had an ADG of 814^c, 829^{bc}, 844^{abc}, 850^{ab} and 865^a g/day had corrected feed efficiency of 2.583^c, 2.499^b, 2.466^{ab}, 2.444^{ab} and 2.419^a when supplemented with NRC, 2X, 4X, 8X and 16X NRC B-vitamins, respectively. Across stress levels, increasing vitamin supplementation increased loin eye area (39.72^c, 40.25^c, 42.96^b, 44.06^{ab} and 44.96^a cm²) and decreased backfat (16.65^d, 16.61^c, 16.41^{bc}, 16.06^a and 16.02^a mm) when supplemented with NRC, 2X, 4X, 8X and 16X, respectively. Pigs fed 16X NRC levels had a \$5.91/pig advantage and 500% return over 2X NRC and \$3.69/pig advantage and 400% return over 4X NRC.

Key Words: Swine, Vitamins, Performance

(growth, backfat, and loin muscle area) of Landrace females and their subsequent first parity reproductive performance. Genetic parameters were estimated from first parity Landrace females (n=5247) for which post-weaning performance had also been recorded. These records rep-

resented 710 sires and 2346 dams. Additive genetic (animal/gilt), common environmental (litter, c^2), mate (service sire for reproduction traits only), and residual variances and covariances were estimated for days to 113.5 kg (DAYS), tenth rib backfat (BF), loin muscle area (LMA), number born alive (NBA), and litter weaning weight (LWT) using the multiple-trait animal model REMLF90 program of Misztal. NBA was pre-adjusted for age and parity of sow and LWT for age of pigs at weaning while post-weaning performance traits were pre-adjusted to 113.5 kg. The model included fixed effects of contemporary group (both post-weaning and reproductive) and random effects of animal, litter, mate, and residual error. Heritabilities were similar to literature estimates. Common litter effects were high (.28) for DAYS. Genetic correlations between post-weaning performance and reproduction traits for first parity were generally low. Post-weaning performance traits have little effect upon subsequent first parity maternal performance.

	DAYS	BF	LMA	NBA	LWT
DAYS	0.33	0.13	0.06	-0.17	-0.15

287 Effects of inbreeding of sow on reproduction and litter performance in a closed population of Landrace pigs. K. Nadarajah^{*1}, D.L. Kuhlers¹, S.B. Jungst², and B.L. Anderson¹, ¹Auburn University, AL., ²PIC, Franklin, KY..

Declines in growth and reproductive performance in livestock often sound the alarm that inbreeding depression may be a causal effect. However, many studies have reported inconclusive results. Five generations of single trait selection conducted in a line of Landrace pigs based on BLUP EBVs for increased ultrasound loin eye area at the Swine Breeding Research Unit in Auburn University resulted in an increase in average inbreeding of sows from zero in base generation to 19.4% and 6.4% in the select and control lines, respectively. The objective of this study was to examine the effects of sow's inbreeding levels on reproduction and performance of her litter. Data from 192 first parity sows that were progenies by 68 sires and out of 135 dams were available for this study. Traits analyzed were litter size at birth (LSB), number born alive (LSBA), number weaned at 21 d (LS21), number weaned at 35 d (LS35), litter weight at birth (LWTB), litter weight at 21d (LWT21) and litter weight at 35d (LWT35). Analyses were carried out using the mixed model procedure in SAS, fitting generation, line and generation by line interaction as fixed effects, inbreeding coefficient of the sow within line as covariate, and sire of the sow, dam of the sow and residual error as random effects. To adjust litter weights to common litter size, LSB, LSBA and LS21 were included as covariate in models for analyzing LWTB, LWT21 and LWT35, respectively. Inbreeding of sow did not significantly affect LSB, LSBA, LS21 or LS35 (P values ranged from .11 to .17) though the slopes of the regression lines for sow's inbreeding effect were negative for litter sizes. Regression slope for LSB in the select line differed from zero (P<0.05). Inbreeding levels of sow had no effect on LWTB and LWT35, but affected the LWT21 (P<0.05). The regression slopes were negative for LWT21 and LWT35 in both select and control lines. The LSB, LSBA and LS21 had significant influence on LWTB, LWT21 and LWT35 (P<0.001). Inbreeding of sow did not seriously affect reproduction or litter performance.

Key Words: Sow's Inbreeding, Reproduction, Litter Performance

288 Correlated responses in sow productivity in a line of Landrace pigs selected for increased ultrasound loin eye area. D. L. Kuhlers^{*1}, K. Nadarajah¹, S. B. Jungst², and B. L. Anderson¹, ¹Auburn University, AL, ²PIC USA, 3033 Nashville Road, Franklin, KY.

Positive genetic changes in lean muscle content in pigs might impose some negative effects on sow's productivity. Five generations of single trait selection conducted in a line of Landrace pigs for increased ultrasound loin eye area (ULEA) at the Swine Breeding Research Unit in AU showed a difference of 10.6 cm² in average EBVs between select (SL) and control (CL) lines for ULEA. The objective of this study was

to examine the impact of increased ULEA on sow productivity. Real-time ULEA data at the 10th rib of 1406 pigs at 168 d of age, and litter performance records for number born (NBORN), litter weight at birth (LITBWT), number weaned at 35 d (NWN35) and litter weight at 35 d of age (LITWT35) from 192 sows that had ULEA were used for this study. Heritabilities and genetic correlations were estimated by the multivariate REML procedure using MTDFREML. For ULEA, the model considered the fixed effects of generation, sex, covariate of 168 d weight, and random effects of animal, litter and error. For sow productivity traits, fixed effect of generation and random effects of animal and error were considered. Estimates of heritabilities for ULEA, NBORN, LITBWT, NWN35 and LITWT35 were .47, .07, .25, .25 and .53, respectively. Genetic correlations of ULEA with sow productivity and litter performance traits ranged from -.01 to -.38. The most undesirable genetic correlation was between ULEA and NBORN (-.38). Genetic correlations of ULEA with NWN35 and LITWT35 were -.20 and -.17, respectively. Genetic correlations among litter sizes and litter weights were all positive and ranged from .20 to .98. Average EBVs of SL sows that produced the fifth generation pigs were 1.31 and 1.04 less pigs/litter than CL sows for NBORN and NWN35, respectively. Compared to CL sows, the average EBVs of SL sows showed differences of -.63 and -12.0 kg/litter for LITBWT and LITWT35, respectively. Selection for increased ULEA appears to have some negative effects on sow productivity.

Key Words: Selection, Loineye Area, Sow Productivity

289 Models for predicting the market weight of finishing pigs based on current age and weight. H. I. Sellers^{*} and R. N. Goodwin, *National Pork Producers Council, Des Moines, IA.*

Data from the National Pork Producers Council's Maternal Line National Genetic Evaluation Program were used to develop prediction equations for weight of finishing pigs. The pigs represented barrows and gilts from six maternal genetic lines mated to a common terminal genetic type to produce four parities. Three replicates were performance tested for finishing growth and feed intake using the Feed Intake Recording Equipment (FIRE) system. Target market weight was 113.4 kg. In each replicate performance tested pigs had an initial and ending weight. In replicates 2 and 3 serial weights were recorded at approximately 21-day intervals. Three regression models were evaluated. In model 1 ending weight was fit to the linear and quadratic terms for initial weight and age and ending age. In Models 2 and 3 growth curve equations were developed by fitting initial, serial and ending weights to their corresponding linear and quadratic terms for age and to a logarithmic function of age, respectively. Model 1 error term was 25.29 kg (R²=0.26). The error terms for models 2 and 3 were 62.90 kg (R²=0.905) and 65.81 kg (R²=0.901), respectively. The computed equations were tested for equality of coefficients across barrows, gilts and each genetic type. For model 1 the hypothesis that the coefficients were the same for each sex and for each genetic type was accepted. For Models 2 and 3 the coefficients for barrows and gilts were significantly different (P<0.05), as were the coefficients for two of the six genetic types. These results suggest that a prediction equation for market weight based on current age and weight and projected market age is reasonably robust in that it is applicable across barrows and gilts and a range of genetic types. Predictions of market weight based on growth curves account for more of the variation and have greater standard errors. However, finishing growth curves tend to be specific for each sex and certain genetic types. This suggests that their application may dictate individual equations for barrows, for gilts and certain genetic types.

Key Words: Finishing, Prediction, Weight

290 Genetic correlations among piglet survival, birth weight and performance traits. E.F. Knol¹, R. Bergsma¹, J.W.M. Merks^{*1}, J.A.M. van Arendonk², and T. van der Lende², ²Animal Breeding and Genetics group, Wageningen, ¹IPG, Institute for Pig Genetics, Beuningen, the Netherlands.

Genetic relations between piglet survival and birth weight on one side and performance traits on the other were studied. Measurements were taken on animals in a commercial sire line. For birth weight and survival traits (farrowing, pre-weaning and total) 29,200 observations were available. Performance traits were measured in two test periods, one beginning at 294 kg and lasting 56 days (Phase1, 2019 observations) and one beginning at the end of Phase1 and lasting another 56 days (Phase2).

Daily gain and backfat thickness were available for both phases and feed intake only was available for Phase2 (1622 observations). Protein and lipid depositions were estimated for both phases and residual feed intake was estimated for Phase2. For birth weight a model with a direct and a maternal animal factor was used; this resulted in heritabilities of 0.05 and 0.20, respectively. The maternal component of birth weight had positive genetic correlations with lifetime daily gain (0.240.12), and estimated protein deposition during Phase2 (0.460.18) and a negative correlation with Phase2 backfat (-0.250.11). For pre-weaning survival a model with a direct (piglet) and a nurse sow animal effect was fitted. Estimated heritabilities were 0.02 and 0.03, respectively. The direct effect of pre-weaning survival had a positive genetic correlation with average daily feed intake (0.440.22), Phase1 backfat (0.410.19), Phase2 backfat (0.510.18), and lipid deposition during Phase2 (0.440.19) and a negative correlation with estimated residual feed intake (-0.640.28). The nurse sow effect of pre-weaning survival had a negative genetic correlation with Phase2 gain (-0.410.21) and especially with estimated protein deposition during Phase2 (-0.630.24). The study indicated that selection against backfat will increase birth weight and decrease piglet survival, while selection for increased pre-weaning survival will increase gain, feed intake and backfat.

Key Words: Piglet Survival, Genetic Parameters, Performance Traits

291 The Association Between the Estrogen Receptor Locus and Growth, Carcass, and Developmental Traits in Pigs. T. D. Leeds*, K. M. Irvin, and S. J. Moeller, *The Ohio State University, Columbus, OH.*

The association between the estrogen receptor (ESR) locus and growth, carcass, and developmental traits in swine was investigated in a population of purebred and crossbred Large White and Yorkshire animals. A total of 724 animals were genotyped at the ESR locus (AA, AB, or BB) via a PCR-RFLP procedure or by pedigree analysis and were measured for traits including teat number (TN), individual birth weight (IBW), weaning weight (WW), age at 109 kg (AGE), average daily gain (ADG), ultrasonic backfat thickness (BF), and loin-muscle area (LMA). WW, AGE, BF, and LMA measurements were adjusted to a standardized weight or age prior to the statistical analysis using guidelines provided by the National Swine Improvement Federation. Data were analyzed using a linear model including the fixed effects of ESR genotype, breed composite, sex, season, and parity and interactions including ESR genotype # breed and ESR genotype # sex. ESR genotype was found to be a significant ($P < 0.05$) contributor to the phenotypic variance for BF and nominally significant ($P < 0.10$) for IBW. Animals possessing at least one copy of the B allele had 0.156 0.059 cm more BF than homozygous A animals ($P < 0.01$). Heterozygous animals were 0.054 0.024 kg heavier at birth than the average of the homozygous animals ($P < 0.05$). There were no detectable ESR genotype effects for TN, WW, AGE, ADG, or LMA ($P > 0.10$). Results of this study give evidence of a QTL in the vicinity of the ESR locus affecting BF and IBW. Utilization of the ESR B allele in a marker-assisted selection program for increased litter size, as suggested in previous studies, may have a detrimental effect on BF.

Key Words: Estrogen Receptors, Backfat, Pigs

292 Estimation of genetic parameters for lactation yields of milk, fat and protein of New Zealand dairy goats. N. Lopez-Villalobos* and D. J. Garrick, *Massey University, Palmerston North, New Zealand.*

The New Zealand dairy goat industry is orientated to the production of dairy products for niche markets. Routine genetic evaluation for the identification of superior animals requires knowledge of the genetic parameters for traits of financial importance. Repeatabilities, heritabilities and genetic and phenotypic correlations for lactation yields of milk, fat and protein were obtained in this study. The data set comprised 22,358 lactation records from 9,443 Saanen, Nubian, Alpine, Toggenburg and crossbred does kidding between 1986 and 1999 in 30 co-operative herds. A total of 296 sires were represented. The raw average yields of milk, fat, and protein were 603.9304.0 L, 20.710.6 kg, and 17.88.8 kg, respectively from an average of 201.864.1 days in milk. Estimates of (co) variances were obtained using the ASREML program (Gilmour et al., 2000) with a multiple-trait repeatability animal model. The model included contemporary group (does kidding in the same herd, year and month), age of the doe, day of the month starting the lactation, proportion of genes from

Saanen, Nubian, British, Toggenburg, and "unknown" breeds, and individual heterosis as fixed effects, and random additive genetic and permanent animal effects. Repeatabilities for milk, fat, and protein yields were 0.420.008, 0.410.008, and 0.420.008, respectively. Corresponding heritabilities were 0.250.019, 0.240.019, and 0.250.019. Genetic correlations were 0.900.002 between milk and fat yields, 0.960.001 between milk and protein yields, and 0.920.001 between fat and protein yields. Phenotypic correlations were 0.810.017 between milk and fat yields, 0.930.007 between milk and protein yields, and 0.880.012 between fat and protein yields. Estimates of (co)variances from this study are currently used for the genetic evaluation of animals from the Dairy Goat Co-Operative (NZ) Ltd. Results from the genetic evaluation allows the selection of animals to be used as parents based on their estimated genetic merit and culling of lactating does based on producing ability.

Key Words: Dairy goats, Milk traits, Genetic parameters

293 Models for birth, weaning and fleece weights, and litter size for a population of Targhee sheep. L. D. Van Vleck*¹, G. S. Snowder², and K. J. Hanford³, ¹USDA, ARS, US-MARC, Lincoln, NE, ²USDA, ARS, USSES, Dubois, ID, ³University of Nebraska, Lincoln, NE.

Many models (17) were compared for birth weight of 33,994 lambs recorded at USSES (1950-1998). Initial intent was to estimate fractions of variance due to cytoplasmic line (c^2 ; 892) and sire by cytoplasmic line interaction (sc^2 ; 17,557). The basic model included direct genetic (fractional variance, a^2 ; 35,684), maternal genetic (m^2 , with correlation r -am), and maternal permanent environmental (p^2 ; 8,418) effects. The model with sc^2 was significantly better than the basic model with and without c^2 . When other random effects were added, sc^2 became zero. Significant effects were associated with dam by year (dy^2 ; 24,801), sire by dam (sd^2 ; 23,924) and dam by number born (dn^2 ; 12,944) random interaction effects. Estimates with all effects in the model were: (a^2 , .24; m^2 , .19; r -am, .11; p^2 , .05; c^2 , .00; dn^2 , .04; dy^2 , .06; sd^2 , .05; sc^2 , .00). Estimates for a^2 , m^2 , and r -am were the same for all models. Estimate of p^2 changed when other effects were added to model. Largest estimates for non-genetic effects were: p^2 , .08; c^2 , .00; dy^2 , .13; sd^2 , .11; and sc^2 , .04. With or without Westell groups (91) in the model, estimates were similar. For weaning weight (120-d, $n = 32,715$) estimates of variances of effects added to the basic model were all near zero (a^2 , .18; m^2 , .12; r -am, -.01; p^2 , .06). For number born (NB, $n = 37,020$) and fleece weight (FW, $n = 36,197$), animal permanent environmental effects were added to the model (ap^2 , 9,871 and 9,760) and r -am was dropped. For neither trait did any effects beyond the basic model have large variances. For NB, non-zero estimates with the full model were: (a^2 , .10; ap^2 , .01; dy^2 , .0; sc^2 , .01) and for FW were: (a^2 , .54; m^2 , .02; ap^2 , .02; dy^2 , .04 and sc^2 , .02). For these traits, cytoplasmic effects were not important. Addition of unusual random effects to the model did not change estimates for the basic model. Although some of these effects were significant, especially for BW, the effects on genetic evaluations are likely to be small.

Key Words: Extranuclear Effects, Genetic by Environment, Genetic Evaluations

294 Estimation of genetic parameters of lamb mortality using survival analysis. B. R. Southey*¹, S. L. Rodriguez-Zas¹, and K. A. Leymaster², ¹University of Illinois, Urbana, IL, ²USDA-ARS, U. S. Meat Animal Research Center, Clay Center, NE.

Mortality records from 8,642 lambs from a composite population at the US Meat Animal Research Center were studied using time-to-event Weibull and Cox sire models. To account for the different genetic and environmental sources of variation from birth to 365 d of age (BY), survival from birth to weaning (BW) and from weaning to 365 d of age (WY) were also studied. Records from lambs culled during the study were treated as censored on the day of culling. Male lambs had a significantly ($P < 0.01$) greater hazard of mortality (23 to 40%) than female lambs in all periods. Type of birth was significant ($P < 0.01$) in the BW and BY periods with multiple born lambs having a greater hazard of mortality than single- or twin-born lambs. Age of dam was significant ($P < 0.01$) in the BW and BY periods with lambs from 1-year-old dams having a greater hazard of mortality than those from older dams. Lambs raised by their dams had a significantly ($P < 0.01$) lower hazard than lambs raised in the nursery in all periods. Estimates of sire variance and heritability from the Weibull model were greater than those from

the Cox model in all periods. Modal estimates (and standard errors) of heritability from the Weibull and Cox models in the BW, WY and BY periods were 0.21(0.07) and 0.19(0.12), 0.15(0.05) and 0.16(0.06), 0.18(0.12) and 0.12(0.05), respectively. These estimates indicate potential for effective selection for increased lamb survival, enhancing sheep production and welfare.

Key Words: Sheep, Frailty, Cox and Weibull

295 Effect of duration of feeding on variance component estimation for ADG of lambs. G. D. Snowder*¹ and L. D. Van Vleck², ¹USDA, ARS, USSES, Dubois, ID, ²USDA, ARS, USMARC, Lincoln, NE.

Variance components were estimated from Targhee data collected from 1978 to 1984 on a total of 1,047 ewe and ram lambs at the U.S. Sheep Experiment Station, Dubois, ID. Lambs were fed for 14 wk with ADG recorded every 2 wk. Lambs were provided ad libitum access to a commercial pelleted feed of barley grain and ground alfalfa. ADG for the entire 14-wk period across all years was 249.3 ± 56.5 g. Variance components for ADG were estimated from a single trait animal model using REML for sequential combinations of duration of time on feed ($n = 9$) with a range of 4 to 14 wk. The model included fixed effects for year (1978 to 1984), sex of lamb (ewe or ram), and genetic line (selected or control), and two covariates (age on test and initial weight at beginning of feeding). Phenotypic variances for ADG decreased with extended time on feed: 0.54 and 0.14 g² at 4 and 14 wk on test, respectively. Estimates of direct heritability increased with extended time on feed; 0.20 ± 0.06 and 0.35 ± 0.07 at 4 and 14 wk on test, respectively. There was little increase of direct heritability estimates after 8 wk on feed (0.33, 0.33, 0.38, and 0.35 for 8, 10, 12, and 14 wk, respectively.) Genetic and environmental correlations among duration of feeding combinations ($n = 16$) were estimated from a two-trait model. All genetic correlations among duration of feed groups were greater than 0.82 and infer that all measures of ADG were genetically similar. However, environmental correlations among duration of feeding groups ranged from 0.41 to 1.00 with the smaller environmental correlations occurring between 4 or 6 wk and 12 to 14 wk on feed. These results indicate that a period of 8 wk or

ASAS/ADSA Extension Education and PSA Extension and Instruction: Dairy, Swine, and Poultry

297 BASECOW: An Excel add-in specific for the dairy production consultant. DT Galligan*, H Groenendaal, R Munson, JD Ferguson, and H Aceto, *University of Pennsylvania, School of Veterinary Medicine.*

Basecow is an Excel add-in containing over 100 functions that are useful in animal production medicine consulting and modeling. Basic function categories currently include: epidemiology, nutrition, statistical, reproduction, production, and management. Once installed in Excel as an add-in, the functions can be used in any opened work book. Like any Excel function, Basecow functions require the user to enter a call name and a list of arguments appropriate to a given function: Function Name (argument1, argument n). Example (1) If 30 cows all test negative to a test with a sensitivity of 45% and specificity of 98%, what is the probability that at least 1 or more of the 30 are infected if the underlying prevalence of the disease is estimated at 5%? = **Grouppos(sensitivity, specificity, prevalence, number tested negative)** = Grouppos(.45, .98, .05, 30) = 58%. Example (2) What is the optimal economic order quantity (EOQ) for a feed additive costing \$800/ton, used at 40 tons/year, with an ordering cost of \$20/order and holding cost at 5%/year? = **EOQ(demand, order cost, holding cost/unit/year)** = EOQ(40,20,.05*800) = 6.3 tons/order. Example (3) What is the water intake of a cow weighing 1400 lbs, milking 80 lbs of milk at 3.6% fat? = **Waterlb(weight, milk, fat %, status)** = Waterlb(1400,80,3.6,L) = 289 lbs. The add-in is available for downloading at <http://CAHPWWW.NBC.UPENN.EDU> web site. The program is continually updated with new functions. An on line help system is available for many of the commands. The help menu describes command use through an example application and includes reference sources.

Key Words: Spreadsheet, Functions, Excel Add-in

greater is sufficient to observe differences among animals for ADG due to direct genetic effects under this environment.

Key Words: Gain, Heritabilities, Selection

296 Genetic parameter estimates for prolificacy, growth and wool characteristics of Rambouillet sheep. K. J. Hanford*¹, G. D. Snowder², and L. D. Van Vleck³, ¹University of Nebraska, Lincoln, NE, ²USDA, ARS, USSES, Dubois, ID, ³USDA, ARS, USMARC, Lincoln, NE.

Heritabilities and genetic correlations for prolificacy, growth and wool traits were estimated from Rambouillet data collected from 1950 to 1998 at the US Sheep Experiment Station, Dubois, ID. Number of records ranged from 39,816 to 44,211, 34,114 to 35,604, and 3,574 to 39,821 for prolificacy, growth and wool traits, respectively. Direct heritability estimates from single trait animal model analyses using REML were .09 for litter size at birth (LB), .06 for litter size at weaning (LW), .09 for litter weight weaned (LWW), .27 for birth weight (BW), .20 for weaning weight (WW), .16 for fleece grade (FG, visual spinning count), .51 for fleece weight (FW) and .58 for staple length (SL). Maternal heritability estimates were .19 for BW and .10 for WW. Estimates of genetic correlations among prolificacy traits were positive (.76 for LB-LW, .72 for LB-LWW, .95 for LW-LWW). Between BW and WW both the direct and maternal genetic correlations were positive (.60 for direct and .36 for maternal). FG was negatively correlated genetically with both FW (-.47) and SL (-.52); FW was positively correlated with SL (.46). Estimates of genetic correlations were low to moderate between BW and the prolificacy traits (.24, .00, .37 for LB, LW, and LWW) and moderate between WW and the prolificacy traits (.49, .56, .64 for LB, LW, and LWW). Estimated genetic correlations were small between fleece characteristics and prolificacy traits: for FW (-.08, -.04, .09), for FG (-.11, -.10, -.11) and for SL (-.16, -.04, -.07) with LB, LW and LWW, respectively. Growth traits were positively correlated genetically with FW (.21, .27 for BW and WW); negatively correlated with FG (-.15, -.14 for BW and WW) and positively correlated with SL (.14, .09 for BW and WW). These estimates can be used for multiple-trait, multi-flock genetic evaluations and for deriving selection indexes to optimize profitability of genetic selection.

Key Words: Heritabilities, Genetic Correlations, Selection

298 Helping the dairy producer make decisions 1: evaluating dairy herd production records. L. O. Ely*¹, J. W. Smith¹, W. D. Gilson¹, A. M. Chapa², C. Ramakrishnan¹, S. Chellapilla¹, and W. D. Potter¹, ¹University of Georgia, Athens, ²Mississippi State University, Starkville.

A web-based program, Dairy MAP(Dairy Management Analysis Program), has been developed to assist the dairy producer in the analysis of dairy herd production records and to help set priorities for areas of improvement. The system utilizes DHIA benchmark production parameter values which are specific for region and herd size. General herd information entered by the user includes herd size, state, SCC and component sampling options and percent AI sire usage. The DHI-202 herd summary report is the source of management data including rolling herd average production, summit milk, stage of lactation milk production, standardized milk and management information related to SCC, feed costs, reproduction and genetics. The first output table shows herd input values and percentile rankings of similar size herds in the same region. The percentile rank of the herd value is highlighted. The second output table compares herd inputs for summit milk, stage of lactation milk production and standardized milk to expected mean values by rolling herd average. Herd input values are highlighted by production level. More extensive analysis of SCC, production, genetics and reproduction are accessed in succeeding stages if the dairy producer wishes to proceed. Management input values are compared to expected mean levels by rolling herd average with deviations expressed as percentages. Output tables showing deviations from expected values as a series of asterisks ranging from 1 = poor to 6 = excellent assist in identifying areas for improvement.

Key Words: dairy management, decision making, web

299 Helping the dairy producer make decisions 2: an expert system makes recommendations. L. O. Ely*¹, J. W. Smith¹, W. D. Gilson¹, A. M. Chapa², C. Ramakrishnan¹, S. Chellapilla¹, and W. D. Potter¹, ¹University of Georgia, Athens, ²Mississippi State University, Starkville.

A dairy producer can analyze his dairy herd production records with a web-based program (Dairy MAP) and receive a list of areas for improvement. Often other information not available from the dairy herd production records must be utilized in order to make recommendations for improvement of the area under consideration. The second phase of Dairy MAP, a web-based expert system, will ask the dairy producer for additional information in order to make a recommendation. The expert system will have separate modules for SCC (Mastitis), Production, Genetics and Reproduction. Questions asked will partially depend upon previous analysis of dairy herd production records and the determination of areas of improvement. The SCC module is functioning and development of the other modules is on-going. The grouping of questions for SCC includes milking procedures, type of housing (milking herd, dry cow and/or heifers), cow groups, cleaning, treated cows, dry cow management and bacterial testing. For example, if the analysis of the dairy herd records shows that all cows had a high SCC in the first 40 days of lactation, the grouping of questions would begin with housing for dry cows and heifers, milking procedures and treatments. Recommendations could include dry cow treatment, a change of bedding, more frequent cleaning of housing, predipping or use of paper towels during milking depending on the answers given by the dairy producer. The questions and recommendations were developed by group of dairy scientists and veterinarians.

Key Words: dairy management, decision making, expert system

300 Dairy Farm Sustainability Check Sheet. C. A. Wells¹, J. A. Pennington*², D. W. Kellogg², D. E. Daniel², R. E. Morrow¹, W. K. Coblenz², D. Onks³, T. A. James⁴, C. Whiteside⁴, and R. Crawford⁵, ¹National Center for Appropriate Technology/Appropriate Technology Transfer for Rural Areas, ²University of Arkansas, Little Rock and Fayetteville, AR, ³Middle Tennessee Experiment Station, Franklin, TN, ⁴USDA-NRCS, Fayetteville and Harrison, AR, ⁵University of Missouri Southwest Research Center, Mt. Vernon, MO.

A dairy farm sustainability check sheet was developed as a joint effort by personnel from NCAT/ATTRA, the University of Arkansas Cooperative Extension Service and Experiment Station, NRCS, the Middle Tennessee Experiment Station, and local dairy producers. The objective in developing the check sheet was to produce an assessment tool which allowed producers to assess profitability and sustainability of their dairy operations plus environmental conditions and social impact of the dairy operations. Sections in the check sheet included an introduction, inventory of farm resources and management, sustainability, farm planning and goals, farm management (records, farm planning), facilities (livestock housing, milking parlor, calf raising, and other), livestock and forage program (herd health and reproductive management, breeding, genetics, selection program, and nutrition management), assessment of individual pastures, assessment of soils, assessment of watershed, nutrient management, alternative dairy farming (minor dairy species, seasonal dairies, and organic dairies), marketing, and summary. The dairy farm check sheet was initially patterned after a version of a beef farm sustainable check sheet and was revised following numerous dairy farm visits where representatives from each of the various agencies were present. Overall, the check sheet was designed to stimulate critical thinking when analyzing the dairy operation.

Key Words: Dairy, Sustainability, Check Sheet

301 The economic benefits of reducing age at first calving in dairy heifers. Barry Steevens*, R.L. Randle, Roger Bennett, D.K. Hardin, V.L. Pierce, and Joe Horner, *University of Missouri*.

Problem The Missouri dairy industry experiences a substantial annual loss due to extended age at first calving. This problem can be corrected or at a minimum reduced through management practices. However, these management practices may increase the cost of development of

these heifers. Producers need a methodology to evaluate their specific loss and potential gain from increased effort and expense in a modified management program.

Objectives The objective of this project is to identify and quantify the economic benefits to specific producers available to fund management programs necessary to reduce problems associated with extended age at first calving. These changes may include programs such as implementation of grouping and culling strategies that will provide for uniform groups to insure adequate access to feed.

Data and Methods Eight Missouri dairy producers were selected to participate in the project and submit data on their heifers. Schedules were developed and heifers were weighed, body condition scored and the wither height measured. In addition, udders and teats were evaluated for normality. The participating herds were evaluated every 8-10 weeks. The growth data collected from the participating farms was compared to industry benchmarks derived from the scientific literature. The cumulative growth data for all participating herds is compared to the benchmarks and used as a baseline in developing a profile of potential economic gains from reducing age at first calving. There were 1008 records collected in the program and used to develop the economic profiles in the participating herds. Enterprise budgets coupled with partial budgets were used to estimate potential gains from management changes.

Conclusion: Minimum requirements for weight and height were established according to the guidelines mentioned above from the scientific literature. Heifers were categorized by age and evaluated to determine whether minimum weight requirements were met. As few as 35.5 percent of the heifers at 12 months of age met the standard for weight. The decision tool reports the benefit to a specific producer in managing heifers to optimum age at first calving thus allowing for analysis of the costs and benefits of a management program designed to accomplish this improvement.

Key Words: Dairy Heifer, Economics, Calving

302 The Dairy Employee Education Program of the Michigan State University Extension Dairy Team. D. J. Bolinger*, C. S. Mooney, D. K. Beede, and H. F. Bucholtz, *Michigan State University, East Lansing, MI*.

The Dairy Employee Education Program was developed by the Michigan State University Extension Dairy Team with a grant from Michigan State University. The mission of the Dairy Employee Education Program is to strengthen the Michigan dairy industry by improving the husbandry and management proficiency of employees currently working on Michigan dairy farms. Program instruction emphasizes technical skill training of people not traditionally targeted by extension programs. The Program consists of nine educational modules that target the employee who works directly with the cows. The nine modules are: Feeder Training Program, Milker Training Program, Breeder Training Program, Introduction to Management Skills, Herd Health Skills for Calves and Cows, Heifer and Dry Cow Skills, Milking Herd Skills, Calf Care School, and Hoof Health Clinic. There also is an informational program for employers that discusses "Value Added Employees" and advertises the Dairy Employee Education Program. Students are taught practical skills and technical concepts during one or two day modules. Generally, the morning portion of the programs is lecture and the afternoon portion is laboratory. These modules are hosted by local Extension Dairy Agents and are team-taught by dairy agents, university faculty, and local industry personnel. From the Dairy Employee Education Programs beginning in 1998 through mid-February 2001, 28 modules have been presented across Michigan. Data from 24 of the sites shows a combined participation with limited duplication of 311 dairy farm employees representing 193 dairy farms and 52,260 cows. Dairy Employee Education Program schools, clinics, workshops have been credited with providing employees with the information and skills to not only maintain, but improve animal performance and profitability on their respective farms. Participants and their supervisors also report improved worker morale.

Key Words: extension, education, employee

303 The importance of best management practices and quality assurance programs in development of animal production food safety training/teaching modules. G.M. Jones*¹, B.R. Eastwood², M. Opperman³, and J.M. Mattison³, ¹Virginia Tech, Blacksburg, VA, ²USDA/CSREES, Washington, DC, ³The ADDS Center, Verona, WI.

A set of teaching and training modules in animal production food safety has been developed for training Cooperative Extension System field staff and for their use with animal producers. The project's steering committee of Extension specialists and agents recommended that the modules emphasize management practices known to enhance food safety and then highlight the various commodity quality assurance programs. Since HACCP provides the basis for most animal commodity quality assurance programs, one module describes HACCP compatible practices and why they are important to producing a competitive and safe food animal. These practices include: animal or premise identification, record keeping, residue avoidance, zoonotic and human pathogen disease prevention, maintenance of good sanitation practices in food animal production, and certification or verification by a third party. The modules elucidate good animal production and culling practices that prevent zoonotic and other animal diseases from entering the food supply and promote food safety. The module on best management practices describes sources of hazards and stressors, animal health (immune system, nutrition, environment), management precautions, risk assessment, and pathogen reduction. Another module shows the relationship between animal feedstuffs and food safety: contaminated feed, importance of feed quality, quality assurance in feed mill, biological agents transmitted by feed, and aflatoxin. The value of farm advisory teams and why's, who's, and how's of forming and utilizing effective teams to advise farmers/producers of management practices or problem-solving specific to that operation is explained. There is a description of quality assurance certification programs and why it is advantageous for producers to adopt one. Information is provided for the following commodity quality assurance programs: beef, dairy, pork, sheep, goats, veal, chick and poultry, egg, turkey, and aquaculture.

Key Words: Animal Production Food Safety, Management Practices, Quality Assurance Programs

304 Frequency of the porcine stress gene in show pigs and its effects on meat quality. J.A. Sterle*, C.L. Skaggs, and D.B. Griffin, Texas A&M University, College Station, Texas.

Class winning barrows (n = 97) from two major stock shows in Texas (eligible for the carcass contest) were tested for the presence of the porcine stress gene. Carcass variables such as backfat thickness, loin eye area, muscle pH and Hunter color values were also recorded. The primary objective of this study was to determine the frequency of the porcine stress gene in this population of heavily muscled, extremely lean show barrows. An additional objective was to evaluate the effects of this gene on meat quality. Blood was collected at exsanguination and shipped to a laboratory for analysis. Animals were classified at each show as Berkshire (B), Duroc (D), Hampshire (H), Yorkshire (Y), Poland China/Spot (PCS), Chester White/Landrace (CWL) or crossbred (XB). Frequency of normal (NN), heterozygous (Nn) and stress positive (nn) genotypes were 52.58%, 42.27% and 5.15%, respectively. Heterozygous animals were found in every breed. Genotypes by breed were: B barrows: 3 NN, 1 Nn, 2 nn; CWL: 5 NN, 5 Nn, 0 nn; D: 11 NN, 7 Nn, 0 nn; H: 7 NN, 9 Nn, 0 nn; PCS: 0 NN, 9 Nn, 3 nn; Y: 10 NN, 1 Nn, 0 nn; XB: 15 NN, 9 Nn, 0 nn. Each genotype was represented in B barrows, while every PCS barrow possessed at least one copy of the stress gene (no normals). Average loin eye area was 7.40 sq. in. and average 10th rib backfat thickness was 0.52 in. Hunter a values were 6.73 0.54, 6.00 0.38, 6.52 0.29, 7.81 0.30, 7.86 0.40, 7.98 0.63, and 7.74 0.26 for B, CWL, D, H, PCS, Y and XB barrows, respectively (P = .03). Loin muscle pH values were 5.63 0.04, 5.66 0.03, 5.72 0.02, 5.54 0.02, 5.66 0.03, 5.60 0.05, and 5.58 0.02 for B, CWL, D, H, PCS, Y and XB barrows, respectively (P = .03). Correlations between genotype and Hunter a values were .11, and between genotype and muscle pH were .003. Additional samples will be taken in subsequent years to analyze trends in the frequency of this gene. These results will be utilized to educate youth and adults involved in the show pig industry about the porcine stress gene.

Key Words: porcine stress gene, meat quality, PSS

305 Outreach video - Avian Influenza: Preventing the spread of disease. P. H. Patterson*¹, D. C. Kradel¹, R. M. Hulet¹, and J. H. Schwartz², ¹Penn State University, University Park, PA, ²York County Cooperative Extension, York PA.

Between 1983-1997 there were three introductions of Avian Influenza (AI) in Pennsylvania with the spread of disease resulting in depopulation of over 18 million birds. These experiences established the inseparable link between production flocks and the live bird markets (LBM) of NY and NJ, with these markets serving as a constant reservoir of AI viruses. AI has the potential to become highly pathogenic, devastating a poultry industry, disrupting national and international trade, and becoming a real or perceived threat to public health. The public health issue was highly publicized in 1997 when an H5N1 strain of AI found in the Hong Kong LBM caused human illness and several deaths. For these reasons it is essential that all concerned with the poultry industry understand the risks of AI and what might be done to reduce such risks. Therefore, a grant was submitted for USDA/CSREES Smith-Lever Special Needs funds for emergency situations within a state or region, and awarded in 1998. The objectives of the grant were to: 1. Increase awareness and understanding of the potential seriousness of AI to a state or regions poultry industry, and the real or perceived risk to public health. 2. Develop educational tools, and 3. Encourage procedures, testing and other actions necessary to participate in an AI prevention program. The ultimate goal is to break the cycle of AI infection within the poultry LBM and production facilities. Every effort should be made to reduce the risks of LBM interactions with the larger commercial poultry industry. A 25-minute video was produced documenting: 1. Details about the virus that causes AI. 2. The importance of keeping AI out of flocks. 3. Some of the signs or changes seen in birds with AI. 4. Common diagnostic laboratory tests for AI, and 5. Important steps that can be taken to prevent AI. The video is being distributed as part of the Mid-Atlantic Cooperative Extension (MACE) Poultry Health and Management Units biosecurity training efforts in the region. MACE members are partnering with the USDA/APHIS Live Bird Market Working Group in an education campaign with poultry growers, dealers, haulers, and markets, as well as city government and the press in efforts to break the cycle of AI infection between the LBM and production facilities.

306 Urban peafowl: the Rancho Palos Verdes Peninsula pattern. F.A. Bradley* and C.V. Gallagher, University of California, Davis.

The Blue Peacock (*Pavo cristatus*) has long been an introduced fixture on American estates and the sprawling ranchos of the west. With the demise of the birds' original owners and subdivision of the large properties, uncontrolled flocks started to roam. The Palos Verdes Peninsula covers roughly 22,000 acres south of Santa Monica Bay and north of San Pedro Bay in Southern California. In 1999 the City of Rancho Palos Verdes (PVE) entered into an agreement with the University of California at Davis (UCD). UCD staff were to assess the peafowl population in RPV and develop a management plan. Our research documents the advent and spread of peafowl on the peninsula. Frank A. Vanderlip, Sr. was one of the first developers of the peninsula. He acquired the peninsula's first peafowl (6-16) during the period between 1913 and 1937. The peafowl were managed, along with an extensive avian collection, on his estate within RPV. By 1960, the peafowl were roaming off the estate's northern edge and into Johns Canyon. Between 1960 and 1965 some of the peafowl were introduced into Palos Verdes Estates (PVE) by the City's mayor. By 1974 PVE birds had crossed the municipal boundary into the RPV neighborhood of Vista Grande. Residents of the RPV community of Portuguese Bend, report that the Vanderlip estate peafowl first moved from the estate south into Portuguese Bend in 1978. By 1988 peafowl were visible in the Crestridge region of RPV, having spread from adjacent Johns Canyon. PVE realized that they had a peafowl problem and in 1982 adopted a management plan. The plan has met with many difficulties and has not been successful. Our surveys documented 157 peafowl on the peninsula and the spread of peafowl off the peninsula and into San Pedro. No one claims ownership of the birds, therefore, they are constantly trespassing or traversing public property and thoroughfares. Extensive property damage, including damaged roofs, autos, and landscaping, is caused by the peafowl. Their chilling loud calls disrupt otherwise tranquil communities. A management plan that includes ongoing trapping and relocation by all the peninsula communities has

been presented. As more large ranches and rural properties are subdivided, the problem of uncontrolled flocks of domestic fowl will repeat itself.

Key Words: Peafowl, Rancho Palos Verdes

307 Women's participation in livestock production in Bangladesh: Proshika Experience. Md. Nuru Miah and Md. Nuru Miah, *Proshika Manobik Unnayan Kendra.*

Women's participation in livestock production in Bangladesh: Proshika Experience * Md. Nuru Miah
Livestock provides an employment and income generation opportunity for the poor. Women are traditional rearers of cattle and poultry in Bangladesh and possess most of the livestock population in the rural areas. The ownership per household of cattle, goat and poultry are 1.6, 1.03 and 6.8 respectively. Proshika, a national largest Non Govt. Organization (NGO) in Bangladesh has been operating a comprehensive livestock development programme consisting of milch cow, beef cattle, heifer/calf, sheep/goat, commercial poultry (layer and broiler), duckery production through direct participation of about 0.3 million women beneficiaries who are landless, destitute and divorced. The goal of the programme is to increase the productivity of poor's livestock resources

ASAS/ADSA Production, Management, and Environment: Temperature Effects, Production Schemes, and Housing Influence

308 Effect of summer water application on mound microclimate, performance, and body temperature of feedlot steers. M. S. Davis*¹ and T. L. Mader¹, ¹*University of Nebraska, Northeast Research and Extension Center, Concord.*

Ninety-six Bos taurus (Angus, Angus x Charolais) steers (avg. BW = 477 ± 3 kg) were randomly assigned to one of twelve pens to which one of three treatments (TRT; 4 pens/TRT) were applied: no water application (CON), water applied between 1000–1200 h (AM) and 1400–1600 h (PM). Water was applied via ground (mound) sprinklers when predicted average temperature-humidity index ≥ 74. Water flow rate (34 l/hd/d) and area sprinkled (2.4 m²/hd/d) were controlled using an inline meter and valves. On days 30–33, thermistors attached to data loggers recorded hourly tympanic temperature (TT). Concurrent with TT, temperatures were recorded 1 cm below the surface (Ts) and .15 and 1.52 m above the mound. Relative humidity was recorded at .15 and 1.52 m. Water (WI) and DMI were recorded daily and BW was recorded on days 0, 34 and 82 (termination of trial). Panting (0 = normal, 2 = heavy panting) and bunk scores (0 = ≤ 10% feed remaining, 2 = ≥ 50% remaining) were assigned to individual animals and pens, respectively at bi-hourly intervals from 900–2100 h under thermoneutral (avg THI ≤ 74) and hot environmental conditions (avg. THI ≥ 74) accompanied by sprinkling. Sprinkling did not affect BW, ADG or DMI, however feed efficiencies of AM steers were greater (P ≤ .10) than PM steers from days 34–82 (.190 vs .178 ± .004) and 0–82 (.180 vs .168 ± .004). Day 0–34 WI was greater (P ≤ .01) in AM vs PM steers (38.29 vs 35.29 ± .21 l/d). During water application, Ts was higher (P ≤ .05) for CON vs AM and PM mounds at all times, with PM mounds lower (P ≤ .05) than AM at 730 and 1500–2000 h. Tympanic temperature of AM steers was lower (P ≤ .05) than CON and PM steers from 800–900 and 2300–700 h, and lower than PM steers from 1200–1300 h. From 1600–1900 h, PM steers had lower (P ≤ .05) TT than CON, with AM intermediate. Sprinkling feedlot pens under hot environmental conditions lowers TT and mound temperatures. Morning water application maximized animal efficiency relative to afternoon application.

Key Words: sprinkling, microclimate, feedlot

309 An evaluation of different types of commercial fans with or without misters in cooling high producing cows in the summer months in the sub-tropics. CN Lee*¹ and KS Baek^{1,2}, ¹*University of Hawaii-Manoa, Honolulu, HI 96822,* ²*National Livestock Research Institute, Namwon, S.Korea.*

In Hawaii, data collected from dairies on Oahu showed that when THI increases milk production decreases. The THI can exceed 81 in the hot months. Milk production could decrease by 25% with in high production herds and by 10% in low production herds. However, the use of fans and misters could alleviate this summer slump. This

which contributes substantially to poverty alleviation efforts by raising their income. Extension support like vaccination, deworming, treatment, artificial insemination, fodder production is provided to the involved farmers through well trained vaccinators, paravets, artificial inseminators etc. belong to Proshika target groups. Technical training of farmers on particular skill, credit, follow-up, monitoring and marketing support is provided from Proshika through its 950 technical workers. A central team of 17 livestock experts are providing planning, technical guidance & supervision of the programme. Five poultry breeder's farm alongwith five hatcheries and feed mills are in operation to supply 100000 day old chicks and 80 MT. feed weekly to the beneficiaries. Adaptive research activities are implemented at the farmers level to disseminate appropriate technologies on livestock. The impact of these activities showed that mortality reduced from 10 percent to 3.5 percent incase of cattle and from 20 percent to 5–8 percent incase of poultry in the project areas, farmers have been able to raise their income by 150 percent through livestock raising, women's status increased in the family and society.

study evaluated the efficacy of 4 types of fans with/out misters in cooling cows under heat stress :- Gp.A-Korral-Kool(2hp)+Schaffer fan (n=111), Gp.B-Universal Foggers(1hp)(n=144), Gp.C-Universal Foggers(1.5hp)(n=135)and Gp.D-Schaefer fan(1/2hp) w/o misters(n=103). Cows were housed in open lot under shade. Temperature and humidity readings were taken prior to the start of monitoring respiration rate (RR) and at the end of the each collection period not exceeding 30 min. The avg. THI(n=16) were 77 for am and 78 for pm. No differences in mean RR were observed in Gp. A, B, and C in am; 66.7, 65.2, 63.8 respectively. Gp.D had higher RR, 73.3(p<0.05). Higher RR were observed in pm period for Gp. A,B,C but there were not different between groups; 76.1, 72.7, 73.9. Gp.D had RR of 88.0 (p<0.05). The avg. wind speed (kmh) at 4.8m from the fan and 76 cm from the ground for Gp.A,B,C,D were 3.8, 4.2, 6.3, 4.9 respectively. The data suggest that wind speed and misters are important to cool cows. Milk production slump was alleviated in Gp.A,B and C. Energy cost per fan was evaluated.

Key Words: Respiration rate, Heat stress, Milk production

310 Impact of Fan Location upon Milk Production, Feed Intake and Respiration Rates of Lactating Dairy Cattle Housed in a 4-row Freestall Barn. M.J. Brouk*, J.F. Smith, and J.P. Harner,III, *Kansas State University.*

One hundred mid-lactation Holstein cows averaging 173 DIM and producing 44.25 kg/c/d of milk were blocked by milk production and DIM and randomly assigned to one of 4 pens of a 4-row freestall barn. Two replicates, north and south halves of the barn, contained 2 pens each. Fan treatments were 91.4 cm fans mounted every 6.1 m on the feed line (F) or 91.4 cm fans mounted every 6.1 m on the feed line and over the center of the head-to-head freestalls (F&S). All pens were equipped with feed line sprinklers that operated on a 15 min cycle (3 on and 12 off) when temperatures were above 23.8°C. All fans operated when the temperature was above 21.1°C. A switch back design with 5 two-wk periods was utilized to evaluate fan placement. Cows and treatments were switched at the start of each period within each replicate. Cows were milked 2x and milk production was measured every two weeks throughout the 10 wk trial. All pens received the same diet. Amounts of feeds offered and refused were measured and recorded daily. Dry matter content of the diet and refusal of each was determined twice weekly. Cow respiration rates were measured on three separate days under heat stress. Fifteen cows were randomly selected from the 25 study cows in each pen and respiration rates were measured in the morning (0700–0800 hr), afternoon (1500–1600 hr) and at night (2200–2300 hr) on each of the three days. Cows exposed to treatment FS produced more (P<.01) milk (38.8 vs 36.2 kg/c/d) during the trial than those exposed to the F treatment. Respiration rates were lower (P<.06) in the morning (71.7 vs 79.3

breaths/c/m), at night (76.0 vs 80.1) and daily (79.4 vs 83.2) under the FS treatment compared to the F treatment. Afternoon respiration rates were unaffected by treatment. This study clearly demonstrated that in a 4-row freestall barn greater milk production and a lower respiration rate was obtained by locating fans on both the feed line and over the freestalls. Based on respiration rates, the duration of heat stress was reduced by the FS treatment demonstrated by lower respiration rates in the morning and at night. Appropriate fan location in combination with feed line sprinklers reduced heat stress in lactating dairy cattle housed in a 4-row freestall building.

Key Words: Heat stress, Facilities, Dairy cattle

311 Evaluation of Heat Stress in 4- and 6-Row Freestall Buildings Located in Northwest Iowa. J.F. Smith*, M.J. Brouk, and J.P. Harner, III, *Kansas State University*.

The objective of this trial was to evaluate the effect of 4- and 6-row freestall barns located in Northwest Iowa on barn temperature, humidity, and THI. In addition, respiration rates of lactating Holstein cows were also evaluated. Six freestall barns (three, 4-row and three, 6-row barns) with east-west orientation located on five dairies were utilized in this experiment. Temperature and humidity readings were collected at four locations near cow level in each barn. Ambient temperature and humidity were collected at two locations in close proximity to each freestall barn. Temperature and humidity data were collected continuously at 15 minute intervals from June 9 until September 27, 2000 using HOBO® data loggers. Respiration rates were collected in the morning (06:00-08:00) and afternoon (14:00-16:00) on three different days during August 2000. During each observation period respiration rates were collected from 50 cows, 25 from the north and 25 from south half of each barn. For data analysis, the 25 data points from each of the halves of the barn were averaged by day and observation period. Temperature and humidity data were averaged by 3-hr periods for each day. Data were then analyzed as a replicated single factor experiment with 4-row and 6-row barn as the treatments. Statistical differences were detected ($P < .05$) in difference between ambient and barn conditions with respect to temperature, relative humidity and THI. On the days respiration rates were measured, 6-row barns as compared to ambient conditions were .25° C warmer ($P < .01$), had less ($P < .01$) humidity (.69 %) and greater ($P < .01$) THI (.45) than 4-row barns. Respiration rates were higher ($P < .05$) in 6-row vs. 4-row freestall barns in the morning (65.8 vs. 60.5 breaths/c/m), afternoon (78.4 vs. 73.8) and daily average (72.1 vs. 67.2). Although statistical differences exist in differences between ambient and barn temperature and THI, the magnitude of these differences may not explain the differences detected in respiration rates. It is possible that increasing animal density may change the relationship between social interaction and animal density. It could also be possible that additional mechanical ventilation may be required to keep cows comfortable in 6-row barns.

Key Words: Heat stress, Facilities, Dairy cattle

312 Influence of Freestall Barn Orientation upon Summer Heat Stress in Lactating Dairy Cattle. J.F. Smith*, M.J. Brouk, and J.P. Harner, III, *Kansas State University*.

The objective of this trial was to evaluate the effect of freestall barn orientation (North-South (NS) vs. East-West (EW)) of 4-row freestall barns located near Tulare, California on barn temperature, humidity, and THI. Effects on respiration rates of lactating Holstein cows were also evaluated. Six freestall barns (three NS and three EW barns) on six dairies were utilized in this experiment. Temperature and humidity readings were collected at four locations in each barn. Ambient temperature and humidity were collected at two locations in close proximity to each freestall barn. Temperature and humidity data were collected continuously every 15 minutes from April through August 2000 using HOBO® data loggers. Respiration rates of lactating dairy cattle were collected in the morning (06:00-07:00) and afternoon (15:00-16:00) on three different days during August 2000. During each observation period, respiration rates were collected from 50 cows, 25 from each half of each barn. Individual data points were averaged by day, barn and observation period for analysis. Temperature and humidity data were averaged daily by 3-hr periods. Data collected were analyzed as a replicated single factor experiment with barn orientation (E/W and N/S) as the treatments. The difference between barn and ambient conditions showed that NS barns were .24° C cooler ($P < .01$), humidity .44%

greater ($P < .01$) and THI .26 less ($P < .01$) as compared to EW barns during August 2000. Respiration rates were greater ($P < .05$) in NS vs. EW orientated barns in the morning (56.4 vs. 52.2, breaths/c/m), afternoon (77.4 vs. 68.8) and daily averages (66.9 vs. 60.5). The differences of barn temperature and humidity did not appear to explain differences in respiration rates between the two different types of barn orientation studied. Other factors including exposure to solar radiation, airflow, and animal stress may have contributed to the differences observed in respiration rates.

Key Words: Heat stress, Facilities, Dairy cattle

313 Influence of Headlocks upon Summertime Milk Production and Feed Intake of Lactating Dairy Cattle Housed in 2-row Freestall Barns. M.J. Brouk*, J.F. Smith, and J.P. Harner, III, *Kansas State University*.

Two hundred sixteen Holstein cows in mid-lactation (110 primiparous, averaging 189 DIM and 38.7 kg/c/d milk; and 106 multiparous, averaging 178 DIM and 42.0 kg/c/d milk) were blocked by lactation DIM and production and allotted to two 108 cow 2-row freestall barns. Both barns were equipped with similar equipment and heat abatement systems. A switchback design with two 4 wk periods was utilized to evaluate the effects of headlocks upon milk production and feed intake. Feed line barrier treatments were either standard headlocks (H) or a post and rail (P&R). Treatments were physically switched between barns at the beginning of the second period. Cows were milked 3x and milk production data was captured electronically every milking throughout the trial. Amounts fed and refused were measured and recorded daily. Dry matter content of the diet and refusal was determined twice weekly and daily pen dry matter intakes were determined. Daily milk production and pen dry matter intakes were averaged by pen and week for data analysis. Milk production (35.2 vs 34.7 kg/c/d respectively for H and P&R) was not affected ($P = .16$) by treatment. Primiparous cattle averaged 34.6 kg/c/day of milk when exposed to H versus 34.3 kg/c/d when exposed to P&R. Multiparous cattle averaged 35.7 kg/c/d when exposed to H versus 35.2 kg/c/d when exposed to P&R. While primiparous cattle produced ($P < .01$) less milk than multiparous cattle neither group was affected ($P = .25$) by treatment. Pen dry matter intakes were also unaffected ($P = .08$) by treatment (22.8 vs 23.5 kg/c/d). The use of headlocks did not result in a decrease in feed intake or milk production of primiparous and multiparous cattle in this study. Cattle in this study were previously exposed to headlocks, thus the effects of headlocks upon untrained cattle was not determined. With trained cattle, removal of headlocks did not increase milk production or feed intake. Results of this study showed that headlocks could be used effectively without negatively impacting the performance of lactating dairy cattle.

Key Words: Heat stress, Facilities, Dairy cattle

314 Influence of ambient temperature, humidity and bovine somatotropin (bST) on reproductive performance of postpartum Holstein cows. R. Flores*¹, M. L. Looper¹, J. J. DeRuyter², D. M. Hallford¹, and M. G. Thomas¹, ¹New Mexico State University, Las Cruces, New Mexico, ²Mountain View Dairy, Mesquite, New Mexico.

Seventy-nine estrous cycles of multiparous Holstein cows ($n = 44$) during May to August were evaluated for the effects of ambient temperature, humidity and bST on reproductive performance. At 60 to 75 d in milk (DIM), all cows were fitted with a HeatWatch (DDx Inc., Denver, CO) transmitter and estrous activity was recorded. Cows were randomly assigned to treatment with bST (Monsanto Co., St. Louis, MO; 500 mg, s.c., every 14 d) or without (nbST) beginning at 80 DIM. Milk yield (kg), DIM and body condition score were 42 ± 1.6 , 69 ± 1.5 and 2.8 ± 0.1 for bST cows and 41 ± 2.3 , 72 ± 1.6 and 2.8 ± 0.2 for nbST cows, respectively. Weekly plasma samples were collected and concentrations of progesterone were quantified. Maximum ambient temperatures and relative humidity were recorded daily and a temperature-humidity index (THI) was calculated for the day of estrous onset. Range of THI was 68 to 80. Duration of estrus, number of mounts and quiescent periods between mounts were similar ($P > 0.10$) between treatments. Mean duration of estrus was 6.0 ± 0.7 h for bST cows and 6.2 ± 0.9 h for nbST cows. Mean number of mounts was 10.0 ± 1.0 and 8.0 ± 1.2 for bST and nbST cows, respectively. Quiescent periods between mounts averaged 2.7 ± 0.4 and 2.5 ± 0.5 for bST and nbST cows, respectively. Duration of estrus and number of mounts were not influenced ($P > 0.10$)

by THI. Quiescent periods observed between mounts tended ($P = 0.10$) to be influenced by THI and were 1.7 ± 0.5 , 3.0 ± 0.4 and 3.2 ± 0.5 h for THI 1 (< 74), THI 2 (74 to 77) and THI 3 (>77), respectively. First service conception rates were not influenced by treatment or THI. First service conception rates for bST and nbST cows were 31 and 23%, respectively. Pregnancy rates tended ($P = 0.13$) to be affected by THI. Pregnancy rates were 66, 28 and 35% for THI 1, THI 2 and THI 3, respectively. Treatment of postpartum cows with bST during mild heat stress did not alter estrous characteristics. Time of quiescence between mounts was increased and pregnancy rates were decreased as THI elevated. Reproductive performance of postpartum cows was reduced by increased temperatures and humidity.

315 Getting a handle on costs of production: a quick and easy method for dairy producers. D. Shoemaker* and J. Polson, *The Ohio State University, Wooster, Ohio.*

All dairymen who will be competitive in the U.S. dairy industry must make decisions for their businesses based on the expected impacts of the decisions they make on both milk production and cost of production. Most Ohio dairy farms have not used cost of production information in their regular decision making processes. Additionally, new opportunities are now available to put a floor under or set a dairy farm's milk prices. Dairy farm managers who do not know their costs of production may make inappropriate decisions. Once a dairy farmer calculates their cost of production and integrates known costs into the decision making process, he can begin to fine tune the process of record keeping and cost and return calculations.

A quick and easy worksheet for calculating a farm's historical cost of production and a projected, long-term planning price for milk was developed to help farmers use typical Midwest financial record information in making daily decisions. Six dairy farms, ranging from 65 to 350 cows, were used to pilot the worksheet. These farms' long term planning prices for milk ranged from \$12.50 to \$16.02 per cwt. based on 1999 data. This price would cover the short term costs of producing milk, principal payments, a return to the operator, reinvestment in the business and income taxes. The process for calculating this information was then incorporated into Extension teaching efforts.

316 Comparing dairy herd information with a dynamic web-based tool called DairyMetrics. C.N. Vierhout*¹ and J.S. Clay¹, ¹*Dairy Records Management Systems, North Carolina State University, Raleigh.*

DairyMetrics is benchmarking software for dairy herd performance evaluation. It allows users to select information that will be displayed about an individual herd in comparison to cohort herds. Individual producers, commercial consultants or extension personnel can compare an individual herd to cohorts or analyze an entire group of herds. This web application allows users to select cohorts based on their individual parameters within the classifications of general, production, udder health, reproduction and genetic information. Within the five classes of parameters, there are 76 variables from which to choose. The underlying database includes herd summary information from almost 14,000 herds that are routinely processed by Dairy Records Management Systems. The database is updated nightly to maintain current herd information. DairyMetrics displays information about the specified herd plus the means, standard deviations, minimums and maximums for the cohort herds. It also presents the percentiles for each herd performance parameter in comparison to the cohort group. Users have the option of graphing their herd and its cohorts for the previous 3 months and from data 1-year prior.

Key Words: DairyMetrics, benchmarking, dairy management

317 Developing Six Sigma Quality Management Programs for Dairy Farms. T.P. Tylutki* and D.G. Fox, *Cornell University, Ithaca NY.*

As margins and environmental pressure forces dairy producers and nutritionists to decrease safety factors and nutrient excretion, the potential for animal production variability increases. A robust quality management program is required that will identify and control the variance

sources that result in animal production variability. Attempts have been made utilizing total quality management principles; however adoption rates have tended to be low. Six Sigma is the current quality paradigm with the objectives of: 1.) Business transformation, 2.) Strategic improvement within the business, and 3.) Problem solving. Six sigma combines human resource management, quality control, and quality planning.

The feeding system on a case study farm has been used to develop and implement a six sigma quality management program. Sources of variation were identified (feed dry matter, feed chemical composition, feeder accuracy, mixing and delivery, etc.) and data collected to determine within farm variances for feed dry matter and chemical composition (Table 1). Feed variance results were used to develop a sample frequency schedule based on a 95% confidence interval with varying levels of precision. The feeder has been receiving training in basic animal nutrition, developing quality control charts, and simple statistics. Several components of the feeding system have been targeted as weak points by this study including limitations in current software for feeding, unknown scale accuracy, rapid and reliable dry matter analysis, and training in root cause and statistical analysis. A quality management manual is being developed that will contain: standard operating procedures, feed sampling protocols, mixer reliability and reproducibility studies, control charts (development and interpretation), root cause analysis, record keeping (inventory, equipment service, and diet/weather changes), and professional development plans for staff.

Table 1. Composition of home grown feeds sampled at feeding.

	1998 corn silage	1999 corn silage	Grass	Alfalfa
Mean DM	27.72	31.02	30.75	35.10
DM CV %	6.4	9.1	28.4	23.2
Mean NDF (% DM)	50.46	44.76	59.75	46.67
NDF CV %	8.7	9.8	11.9	12.5

Key Words: Quality management, Six Sigma, Feed variance

318 Programmed exercise improved physical fitness of non-lactating, pregnant and non-pregnant dairy cows. J. A. Davidson*, R. R. Devins, and D. K. Beede, *Michigan State University, East Lansing.*

Objective was to determine the effects of a programmed exercise regimen (PER) and pregnancy of Holstein cows on physical fitness, acid-base status, and blood mineral element concentrations. Non-lactating, multiparous pregnant or non-pregnant cows ($n=52$) were blocked by parity and expected calving date and assigned randomly to treatments: no exercise or exercise at a walk (3.25 km/h) every other day for 1.25 h, d 0 to 30; and, 1.5 h, d 31 to calving (d 70 of PER) in a mechanical walker with a circular lane (33.8 m circumf.). All cows completed treadmill exercise tests (ET) on d 0, 30 and 60 of PER. Treadmill ET consisted of walking 4 km/h for 3 min followed by 5 km/h with incremental increases in incline every 3 min until cows refused to walk. Length of time to refusal during the ET was one indication of physical fitness. Jugular blood was sampled every 3 min during the ET and the 18 min recovery period (RP) after the ET. Physical fitness improved with the PER; exercised cows walked longer during the ET compared with non-exercised cows (21.6 vs. 18.7 min, $P<0.01$). Venous whole blood pH and concentrations of K were lower for exercised compared with non-exercised cows during ET ($P<0.05$). Concentrations of K, hematocrit (HCT) and pO_2 increased during ET as time increased whereas ionized Ca concentrations decreased ($P<0.05$). Normalized ionized Ca (nCa, pH adjusted) concentration during the d 60 ET was higher for exercised compared with non-exercised cows, and was higher for pregnant than non-pregnant cows ($P<0.06$). During ET, pCO_2 was lower for pregnant cows compared with non-pregnant cows and decreased as time increased ($P<0.06$). Concentrations of Na were higher for pregnant compared with non-pregnant cows during d 60 test ($P<0.01$). During RP, venous concentrations of Cl, Na, nCa, and pCO_2 increased as time increased whereas K, HCT and pO_2 decreased ($P<0.01$). However, the magnitude of changes were very small during the RP. The pH of venous blood during RP was lower for non-exercised cows compared with exercised cows ($P<0.10$). Blood volume was not affected by exercise. Pregnant cows had larger blood volumes than non-pregnant cows ($P<0.05$). A PER reduced changes of acid-base status and increased physical fitness of dairy

cows. Pregnancy altered blood volume, pCO₂, and concentrations of nCa and Na during the ET.

Key Words: Exercise, Pregnancy, Dairy Cows

319 Profit maximizing calving interval with limited labor resources. C. C. Risch* and C. A. Wolf, *Michigan State University.*

Many dairy farms consistently exceed the industry benchmark calving interval of 13 months, instead having calving intervals of 14 to 16 months. Previous literature typically supports the 13 month benchmark but does not consider resource constraints (e.g., labor, capital, feed) common to dairy farms. This study examines the profit-maximizing calving interval decision when the managerial and skilled labor are limited. An optimizing linear programming model that explicitly considers managerial and skilled labor constraints was developed to identify the calving interval that maximizes net returns to a dairy herd. The model considered 13 to 18 month calving intervals in terms of lactation stage distribution effects on net returns and labor use. Revenues and expenses associated with calving interval and included in the model are milk, calf and cull revenues, as well as replacement and herd health costs. The model allowed various labor allocations in meeting the herd health and reproductive requirements needed to maintain a given calving interval. Results indicate that, although a 13 month calving interval is associated with the highest revenues, the profit-maximizing calving interval for a farm varies significantly with both managerial and skilled labor constraints. Further, labor allocation across reproductive and herd health activities is crucial in determining the profit-maximizing calving interval. Data from a 200 cow herd was used in the model, which resulted in an optimal calving interval of 14 months, achieved with hired labor contributing substantially to heat detection and breeding activities. Labor skill level and wage rate contribute significantly to the optimal calving interval for a given herd.

Key Words: Calving interval, Labor constraint, Linear programming

320 Dry matter intake of lactating dairy cows housed in freestall barns. D.M. Allen*^{1,4}, J.G. Linn^{1,4}, K.A. Janni^{2,4}, and S.C. Stewart^{3,4}, ¹*Department of Animal Science*, ²*Department of Biosystems and Agricultural Engineering*, ³*Department of Clinical and Population Sciences, College of Veterinary Medicine*, ⁴*University of Minnesota.*

Data was collected from twenty groups of lactating dairy cows on three commercial farms from November 1999 to January 2001. All cows were housed in freestall barns. Groups for all three farms were managed based on stage of lactation, reproductive status and parity. Twelve groups had headlocks at the manger, 5 groups had rail-line feeding and 3 groups were fed in J-bunks. On average, 2075 lactating cows were represented in the milk and DM intake (DMI) data collected each month. Body condition score and body weight (BW) were determined on thirty-five percent of the cows in each group once per month. Feed DM offered each group daily was recorded using EZ Feed™ software. Weighbacks, corrected to a DM basis, were recorded from each group and subtracted from feed DM offered to determine DMI. Group means for milk production and days in milk (DIM) were recorded daily by DairyComp 305™. Bulk tank milk composition was recorded daily from each farm. Group means and standard deviations (SD), categorized by DIM and parity, for BW, milk, and DMI are reported. DMI was predicted using the NRC 2001 equation for DMI from group mean data. The difference between actual and predicted DMI within farm and category is similar to the

mean square prediction error reported for the DMI prediction equation in the NRC 2001.

	Farm A		Farm B		Farm C	
	Mean	SD	Mean	SD	Mean	SD

321 Performance, health, and management of calves housed in a greenhouse barn (GHB) versus traditional wooden hutch (WH) during a Mississippi winter. M. L. Scott* and W. B. Tucker, *Mississippi State University, Mississippi State.*

The primary objective was to evaluate housing based upon management and health of young calves during wintry conditions. Forty dairy calves (32 Holstein; 8 Jersey) were randomly assigned at birth, blocked by breed and calving date, to a traditional WH or novel GHB (December 1997 to April 1998). Incidence and severity of scours, dietary intake, body weight changes, feed efficiency, respiration rate, rectal temperature, morbidity, and mortality were recorded from birth to 56 d. Calving assistance, Ig absorption, and calf vigor (birth to 1 h postpartum) were also recorded. Milk diet was 50% milk replacer (22% CP; 12% fat) and 50% waste milk. Gross energy were determined on daily samples composited by week. Dry feed (16% CP) was offered at 5d. Neither ADG (0.420±0.03, WH and 0.459±0.05 kg, GHB) nor feed efficiency (1.36±0.10, WH and 1.45±1.00 kg, GHB) were significantly different by housing. Weight gain was higher (P<0.05) for GHB than WH postweaning, 0.886±0.06 and 0.622±0.72 kg, respectively. Calves housed in WH consumed grain 1 wk earlier than GHB. Rectal temperatures at birth and overall were similar between housing. Fecal scores were 2.24±0.04 and 2.28±0.04 for WH and GHB, respectively. Observed health requiring medical attention were higher for GHB than WH (scours, respiratory and naval infection). Management and morbidity of GHB is similar to other barns. Nonetheless, GHB appears to be a suitable alternative to classical WH during winter, based upon growth.

ASAS/ADSA Ruminant Nutrition: Ruminal Fermentation

322 The effects of pH on acid resistance of cattle fecal *Escherichia coli* and O157:H7 in continuous culture or pure culture. C. J. Fu*, J. Porter, J. W. Lehmkuhler, E.E.D. Felton, D. Schmidt, M. Huck, and M.S. Kerley, *University of Missouri-Columbia, Columbia, MO 65211.*

Twelve single-phase continuous culture (CC) fermentors with a 0.045/hr dilution rate (D) and pure culture incubations were used to determine the effect of pH on acid resistance of fecal *E.Coli.* and *E.Coli.* O157:H7, respectively. The pH tested was 7.5, 7.0, and 6.5 in CC and 7.5, 7.0, 6.5, and 6.0 in pure culture. The basal diet fed to the CC was corn and

soybean meal (95% + 5% on DM basis). The CC fecal inoculants were combined from 20 feedlot steers. The microflora samples were taken from the CC after 96 h of growth. The media used for the pure culture incubations was tryptic soy broth (TSB) without dextrose. Tubes were inoculated with *E.Coli.* O157:H7 (ATCC 43895) and then sampled after 24 h of incubation. The viable *E.Coli.* was enumerated by multi-tube method using lauryl sulfate trypticase broth (LST) as media. The viability of fecal *E.Coli.* linearly (P < 0.01) decreased (3.5, 0.7, and 0.007%) after extreme acid shock (pH = 2, 1 h) as the culture pH increased in CC. No *E.Coli.* O157:H7 was found in CC. The O157:H7 pure cul-

ture study indicated that the viability of the organisms was higher ($P < 0.01$) after extreme acid shock (pH 2, 4 h) when cultivated in pH 6.0 media than that in the other pH media (9.0 vs 2.4, 2.5, and 2.5%). This study demonstrated that culture pH affected acid resistance of *E. Coli*. as previously hypothesized.

Key Words: *E. Coli.*, Acid resistance, Acid shock

323 Effect of sampling frequency and schedule when determining dietary effects on ruminal pH. K. M. Krause* and D. K. Combs, *University of Wisconsin-Madison*.

Ruminal pH is often used as a response variable when assessing fiber adequacy of dairy rations. The optimal number of samples and the best time to sample in order to detect possible differences in ruminal pH are not known. In order to investigate this question a replicated 4 x 4 Latin square study with two forage particle sizes and two levels of corn grain moisture was used as an example. Ruminal pH was measured continuously for a five day period using indwelling electrodes and cows were fed twice daily. Feeding the cows twice daily caused diurnal variations in pH, so effect of feeding was included in the model along with day and hours post feeding. Data were analyzed as repeated measurements using proc mixed. In this study significant effects of the main variables forage particle size ($P < 0.05$) and corn moisture ($P < 0.001$) on pH were found using continuous measurement of ruminal pH. Also, the two forage particle sizes ($P < 0.001$) and the two daily feedings ($P < 0.005$) affected the decline in pH post feeding differently. Six alternative sampling schedules were investigated: 1) 4 h post am feeding on one day, 2) every 4 h for 24 h, 3) every 2 h for 12 h post am feeding, 4) 4 h post am feeding for five days, 5) every 4 h for five days, and 6) every 2 h for 12 h post am feeding for five days. The different sampling scenarios were simulated by using only the data points specified above from the data set collected using the indwelling electrodes. If sampling only on one day, sampling schedule 3 was the only schedule which detected effects of both dietary variables on pH. Sampling just once daily, but over a five day period (schedule 4), detected only a forage particle size effect on pH. Both sampling schedule 5 and 6 detected significant effects of both dietary variables and also interaction effects between dietary factors and hours post feeding. Based on the current data it can be concluded that when sampling on just one day, taking several samples between feedings is more useful than sampling across feedings. However, in order to detect dietary effects and effects of feeding on diurnal fluctuations in pH, data has to be collected across feedings and across several days.

Key Words: Ruminal pH, Sampling schedule

324 Effects of propionate supply on plasma vitamin B12 in growing lambs. CL Girard*¹, L Majdoub², and I Ortigues², ¹*Dairy and Swine R&D Centre, Agriculture and Agri-Food Canada, Lennoxville, Canada*, ²*INRA, Unite de Recherches sur les Herbivores, Nutriments et Metabolismes, Theix, France*.

In sheep, up to 50% of glucose comes from propionate (Kennedy et al.1994. *Internat.J.Vit.Res.*64:270). Methylmalonyl-CoA mutase, a key enzyme in this metabolic pathway, requires vitamin B12 as a coenzyme. A lack of vitamin B12 induced by cobalt deficiency impaired propionate metabolism in sheep (Smith and Marston.1971.*Br.J.Nutr.*26: 41; Kennedy et al.1991.*Biol.Trace Element Res.*28:233). Within the framework of 2 trials aiming to study the influence of an additional supply of propionate on nutrient partition among tissues, the present work was undertaken to determine if changes in propionate supply modify vitamin B12 status in growing lambs. Four male lambs (32 ± 2.2 kgBW) were fed frozen rye-grass (cut at grazing stage, chopped in 5cm length, frozen at -35°C and stored at -15°C) at an estimated level of 165 kcal ME per kg BW^{0.75} in 12 equal meals daily. The treatments were applied in a cross-over design. In Trial 1, they consisted of 5d continuous intraruminal infusion of saline (C) or propionic acid representing 10% (P1; 0.54 mole propionate/d) or 16% (P2; 0.97 mole propionate/d) of daily ME intake from rye-grass, separated by transition periods of 7d. In Trial 2, the lambs were fed during 2wk the same basal diet than in Trial 1 supplemented or not with barley to increase the estimated absorption of propionate by 0.56 mole/d. At the end of each treatment period, blood samples were taken at 30min intervals during 4h for determination of vitamin B12 in arterial plasma. In Trial 1, plasma vitamin B12 decreased when propionate supply increased ($P = 0.07$); 432.9 ± 69.1 , 236.9 ± 33.4 and 276.8 ± 68.7 pg/ml for C, P1 and P2, respectively. In Trial 2, feeding grass+barley decreased plasma vitamin B12 (551.9 ± 87.5 pg/ml) as compared to grass alone (851.5 ± 173 pg/ml) ($P = 0.08$). Therefore, it seems

that increasing propionate supply decreased drastically plasma vitamin B12, probably through an increased demand for vitamin B12 by tissues involved in propionate metabolism.

Key Words: Vitamin B12, Propionate, Lamb

325 Assessment of phosphorus availability from different sources for ruminal fermentation. V. Fellner*, J. W. Spears, and S. J. McLeod, *North Carolina State University, Raleigh, NC*.

Two experiments were conducted using continuous cultures to (1) study the phosphorus requirements of rumen microorganisms and (2) determine the availability of phosphorus from different sources. Diets consisted of cottonseed hulls, corn starch, urea and an amino acid mixture. In the first experiment ($n=2$) daily additions of 28.3, 19.0, 9.4 and 0 mg of inorganic phosphorus (Pi) supplied as sodium phosphate resulted in culture soluble Pi concentrations of 13.9, 13.6, 8.2 and 2.0 mg/l, respectively. At Pi concentrations of 13.9, 13.6 and 8.2 mg/l total volatile fatty acids did not differ ($P > .10$) and averaged 42.4 mM. Reducing Pi concentration to 2.0 mg/l significantly reduced total volatile fatty acids; acetate and methane production also decreased by 8 % and 35 %, respectively. In experiment 2 ($n=2$), different sources of dicalcium and rock phosphate were evaluated for ruminal availability. Four fermentors were inoculated simultaneously, one received 9.4 mg of Pi (+ control; sodium phosphate) and one received 0 mg of Pi (- control). The other two vessels received 9.4 mg of either a dicalcium source or rock phosphate. Production of total volatile fatty acids averaged 57 mmol/d in the (+) and was reduced ($P < .10$) to 44 mmol/d in the (-). Concentration of Pi in cultures receiving the dicalcium sources averaged 7 mg/l compared with 1 mg/l for cultures receiving rock phosphate. Total volatile fatty acid production for all dicalcium Pi sources was similar ($P > .10$) to the (+) and averaged 61 mmol/d. However, addition of rock phosphate as the Pi source reduced volatile fatty acid production to 36 mmol/d. This was also true for acetate production that was higher for all dicalcium sources compared to rock phosphate. Our data indicate that 6 mg/l of soluble Pi concentration in ruminal cultures supported normal rumen fermentation. Rock phosphate had low phosphorus solubility and resulted in decreased ruminal fermentation compared with dicalcium phosphate.

Key Words: Phosphorus, Rumen microbes, Continuous cultures

326 Effects of natural plant extracts on nitrogen metabolism and fermentation profile in continuous culture. P. W. Cardozo, S. Calsamiglia*, and A. Ferret, *Universidad Autonoma de Barcelona, Spain*.

Eight 1.3-L dual flow continuous culture fermenters were used in two periods (10 d) to study the effects of natural plant extracts on N metabolism and fermentation profile. Fermenters were fed 95 g/d of a 60 to 40 forage to concentrate diet. Treatments (1.5 mg/d per fermenter) were: no extract (C), MX (a mix of all extracts), cassia (CA), garlic (G), anise (A), yucca (Y), marjoram (M) and capsicum (CA). Fermenters were maintained at constant temperature (39°C), pH (6.4) and solid (5%/h) and liquid (10%/h) dilution rates. Each day, a sample was taken 2 h after the morning feeding for the determination of ammonia (NH₃ N) and volatile fatty acids (VFA). During the last 2 days, samples were taken at 0, 2, 4, 6, and 8 h after feeding, and analyzed for peptide (Pep), aminoacid (AA) and NH₃ N concentrations. Data were analyzed using the PROC MIXED (SAS, 1996) and significance declared at $P < 0.05$. Total VFA was similar across treatments (111.3 mM). Acetate concentration (mol/100mol) in A (57.8), M (56.6) and CA (57.4) were higher than C (53.4), and MX (52.4). Propionate concentration (mol/100mol) was lower in Y (26.3), A (25.3), M (25.6) and CA (25.0) versus C (28.4) and MX (28.4). Concentration of NH₃-N (mg/100ml) in A (10.8) was higher versus C (7.9). The Pep-N concentration in hour 2 (mg/100ml) was highest for MX (8.9), CA (8.8), G (10.1) and Y (10.4), and lowest for C (3.3). The AA-N concentration in hour 2 (mg/100ml) was highest in C (12.4), and lowest in G (8.0) and CA (7.7). The NH₃-N concentration in hour 2 (mg/100ml) was highest in A (10.0) and lowest in CA (6.3), G (5.6) and Y (6.0). The effect of individual extracts did not match the action of the MX. The accumulation on Pep-N in MX, CA, G, and Y suggested that peptidolysis was inhibited. The accumulation of AA-N, and the decrease in NH₃-N in G suggested that

deamination was inhibited. Careful selection of these additives may allow to manipulate rate of protein degradation. Acknowledgment: Plant extract and financial support provided by Axiss France SAS.

Key Words: Microbial fermentation, plant extract

327 Comparison between Holstein and Jersey Cows in post-prandial Rumen pH and VFA Concentrations. C.W. Cruywagen*, N. Strickland, and S.J. Schoeman, *University of Stellenbosch*.

The authors have previously reported that Jersey cows on high concentrate diets appeared to be more efficient than Holsteins to digest fibre in the rumen. The reasons for breed differences were not apparent. A study was done under the same conditions to compare post-prandial rumen pH values and volatile fatty acid concentrations in an attempt to explain previously observed differences between breeds. Eight ruminally cannulated cows (4 Holsteins and 4 Jerseys) were used in the trial. All the cows were non-lactating but received a lactating cow TMR from two weeks before, until the end of the trial. The TMR was fed at 08h00 daily (12 kg for Holsteins and 10 kg for Jerseys) and supplementary wheat straw was available *ad libitum*. Samples of rumen liquor were taken at 08h00, 12h00, 16h00, 18h00 and 20h00 on the first day of the trial, representing 0, 4, 8, 10 and 12 hours post-feeding. Initial pH (0h) did not differ between breeds and was 7.48 for Holsteins and 7.72 for Jerseys. A sharp decline in post-prandial rumen pH was observed for Holsteins and pH reached a minimum of 6.08 at 4h post-feeding, which was significantly lower ($P < .01$) than the 6.62 observed for Jerseys at the same time. Values at 8h, 10h and 12h post-feeding did not differ between breeds ($P > .05$) and were 6.18 and 6.2, 6.25 and 6.31 and 6.40 and 6.43 for Holsteins and Jerseys, respectively. Post-prandial molar proportions of acetic acid and propionic acid did not differ between breeds ($P > .05$), but total VFA concentration was higher at 4h ($P < .01$) and 8h ($P < .05$) post-feeding for Holsteins than for Jerseys. Higher total VFA concentrations for Holsteins at 4h post-feeding corresponded with lower pH values. It was observed that the Holsteins ate at a faster rate than the Jerseys and always finished their TMR long before the Jerseys. This could explain the differences observed between the breeds in post-prandial pH profiles. Fibre fermentation in the rumen is suppressed at low pH levels and it was concluded that the lower fibre digestibility values observed earlier for Holsteins could be due to lower pH values observed for at least 6h of the day which was probably caused by a difference in feeding behaviour.

328 Meta analysis of the acidogenicity of ingredients. S. Giger-Reverdin and D. Sauvant, *UMR INRA - INAPG Physiologie de la Nutrition et Alimentation*.

Several studies stressed the large variations in the ability of ingredients to depress rumen pH *in vitro*. The aim of this work was to study the consistency of the ranking of acidogenicity of ingredients between experiments. A meta analysis was performed on a base including data of four already published papers and our own data. All the ingredients studied by at least two authors were retained. Methods differed between teams: the ratio (volume of incubation/sample mass) varied from 10 to 150 ml/g, the percentage of artificial saliva was comprised between 50 and 80. For the 14 most studied ingredients, the ranking was established on adjusted means of pH (lsmeans) which was accompanied for each feed by its standard error. It was the following one from the more acidogenic to the less one: Cassava (5.70, 0.10), Barley (5.77, 0.06), Citrus pulp (5.82, 0.07), Wheat (5.84, 0.06), Corn gluten feed (5.86, 0.07), Oats (5.87, 0.08), Wheat bran (5.87, 0.08), Beet pulp (5.89, 0.06), Rapeseed meal (5.95, 0.08), Coconut meal (5.98, 0.08), Soybean hulls (6.00, 0.07), Soybean meal (6.01, 0.07), Corn (6.04, 0.06), Sorghum (6.10, 0.06). As stressed by the precision of the model, the hierarchy between feeds hardly differ between teams and was conserved through incubation duration. Thus, these values could be included into feed formulation to take into account the potential acidogenicity of compound feeds formulated with these ingredients.

329 Rates of production of the major rumen volatile fatty acids in lactating cows given normal and milk fat depressing diets. J.D. Sutton*^{1,3}, M.S. Dhanoa², S.V. Morant³, D.J. Napper³, and E. Schuller³. ¹University of Reading, UK, ²IGER, Aberystwyth, UK, ³formerly NIRD, Shinfield, UK.

To examine the relation of the production rates of the 3 major rumen VFA to milk fat depression, 5 rumen-fistulated Friesian cows in mid-lactation were given two contrasting diets supplying similar digestible energy (DE) intakes. Cows were fed, in a 2-period cross-over design, a Normal diet of 9.0 kg concentrate (82% rolled barley (RB), 16% soyabean meal (SBM)) and 6.0 kg long hay (total 12.9 kg DM and 161 MJ DE/d) and a low-roughage diet (LR) of 12.9 kg concentrate (87% RB, 11% SBM) and 1.4 kg long hay (total 12.7 kg DM and 171 MJ DE/d) in two equal portions at 12-h intervals. Rates of VFA production were measured by 22-h intra-ruminal infusions of 0.5 mCi 1-¹⁴C-acetic acid (A), 2-¹⁴C-propionic acid (P) or 1-¹⁴C-n-butyric acid (B) at 4-6 d intervals with sampling over the last 12 h. Results were calculated using a 3-pool, non-steady state model. Rumen fluid volume changes were included in the model and were measured by a 2-marker system and also by rumen emptying but were found to have little influence on calculations of VFA production. On Normal and LR respectively, milk yield was unaffected at 17.8 and 19.6 kg/d but fat content was severely depressed by LR at 34.5 and 22.0 g/kg ($P < 0.001$). Net production rates (mol/d) on Normal and LR were 56.8 and 48.3 for A ($P < 0.10$), 16.3 and 36.4 for P ($P < 0.01$), and 6.5 and 4.7 for B ($P > 0.10$). Molar proportions (%) of net VFA production were 71.3 and 54.2 for A ($P < 0.001$), 20.8 and 40.5 for P ($P < 0.001$) and 7.8 and 5.4 for B ($P > 0.10$) and were broadly similar to molar proportions of rumen concentrations at 68.1 and 51.5 for A ($P < 0.001$), 19.2 and 39.2 for P ($P < 0.001$) and 12.7 and 9.3 for B ($P < 0.01$). Net production of these 3 VFA provided 89 and 108 MJ/d, equivalent to 55 and 63% of DE. The milk fat depression was associated with a small reduction in acetic acid production, doubling of propionic acid production, and a small but non-significant reduction in n-butyric acid production.

330 Gas and VFA production during the *in vitro* fermentation of selected organic acids and sugars. D.O. Molina*, A.N. Pell, and P. Schofield, *Cornell University, Ithaca, New York*.

The study aimed to examine gas and VFA production and microbial yield from fermentation of selected organic acids (OA) and sugars. Citric, malic and lactic acids were included in *in vitro* medium at three concentrations, 10, 25 and 40 mM. The experiment was repeated twice: in the first experiment, ruminal fluid was filtered through four layers of cheesecloth and one layer of glass wool. In the second experiment, the ruminal fluid was centrifuged and the resulting pellet was resuspended in fresh medium prior to inoculation. In a third experiment, the same OA and two sugars, glucose and arabinose, were included in the standard *in vitro* medium (40 mM), using an inoculum of centrifuged ruminal fluid. In all cases, fermentations were conducted with the appropriate OA or sugar as the substrate either with or without 25 mg of soy hulls. Differences in fermentation among the OA are clear. Citric acid produced the highest gas volumes but did not always have the highest rate of gas production. It also produced the highest acetate and lowest propionate concentrations. More purines were detected in the lactic acid fermentations although the dry weights of the pellets from the lactic acid were not higher than that of the other acids. Fermentation of sugars resulted in more gas production than OA but the rate of gas production from arabinose was similar to that from lactic acid. It is concluded that significant differences ($P < 0.05$) in fermentation exist among various OA and between OA and sugars.

331 Interaction between FermentenTM or soybean meal and fermentability of carbohydrate source on microbial yield and efficiency in continuous culture. W.H. Hoover^{*1}, T.M. Miller¹, J.E. Nocek², and W.E. Julien², ¹West Virginia University, ²Bioavance Technologies Inc..

A continuous culture study was conducted to evaluate the effect of protein and carbohydrate sources on rumen microbial yield and efficiency. Within the dual flow continuous culture system, liquid and solids dilution rates were 0.13 hr⁻¹ and 0.05 hr⁻¹ respectively. Culture pH was not controlled and feeding frequency was 2x/d. The design was a 2 x 2 factorial with protein and carbohydrate as the main effects. There were three replications with eight d fermentations per replication. The forage:concentrate ratio of the basal diet was 56:44. Treatments were: 1) ground corn and SBM, GC-SBM; 2) ground corn and FermentenTM (Bioavance Technologies Inc. Omaha, NE), GC-F; 3) steam-flaked corn-barley and SBM, SF-SBM; and 4) steam-flaked corn-barley and FermentenTM, SF-F. Microbial growth (g N/d) and efficiency (g microbial N/kg OM fermented) were 2.36 and 45.4, 2.28 and 43.8, 2.51 and 48.6, 2.78 and 51.6 for GC-SBM, GC-F, SF-SBM and SF-F respectively. Substituting steam flaked corn-barley for ground corn resulted in increased microbial growth and efficiency (P<0.02). There was a carbohydrate x protein interaction for microbial growth (P<0.05) and efficiency (P<0.15) whereby the combination of steam flaked corn-barley and FermentenTM increased microbial N production by 11% compared to steam flaked corn-barley/SBM and 17 and 22% more than ground corn with either SBM or FermentenTM respectively. These data suggest that the combination of steam flaked corn-barley and FermentenTM acted synergistically in enhancing microbial protein yield and efficiency compared to any other combinations tested.

Key Words: microbial protein synthesis, rumen

332 Selection of *Propionibacterium* strains capable of utilizing lactic acid from *in vitro* models. T.D. Parrott^{*1}, T.G. Rehberger¹, and F.N. Owens², ¹Agtech Products, Inc., Waukesha, WI, ²Oklahoma State University, Stillwater, OK.

Forty-four strains representing four species of *Propionibacterium* were screened for lactic acid utilization to examine their potential for use in a direct-fed microbial to prevent lactic acidosis in cattle consuming large amounts of highly fermentable carbohydrate. Strains were tested for utilization of lactic acid and growth in a nutrient broth supplemented with 80 mM lactic acid at two different pH values - one representing the pH of an acidic rumen (5.0) and the other that of a forage-fed ruminant (7.0). No differences (p>.05) in growth and lactic acid utilization were detected among strains at pH 7.0. Data from pH 5.0 experiments showed *P. freudenreichii* strains P49 and P99 utilized 76.90 mM and 78.59 mM of lactic acid respectively, which was significantly (p<.05) more compared to other strains. Compared with strains of *P. acidipropionici*, *P. jensenii* and *P. thoenii*, *P. freudenreichii* strains reached higher cell densities and utilized more lactic acid at pH 5.0. Rumen fluid simulation models were used to examine the ability of fifteen selected propionibacteria strains to survive and utilize lactic acid produced by native ruminal

microorganisms. Eleven of the fifteen propionibacteria strains tested utilized lactic acid in the rumen model. Compared with other strains, P42 had the highest rate of pH increase (.0377 units/h), but was not different (p>.05) from strains P63, P54, P25, and P41. Strain P42 also had the highest rate of lactic acid utilization (1.61 mM/h) compared to others, but was not different (p>.05) from strains P63, P54, P25, P41, P111, P81, and P104. Gompertz non-linear curve fitting equation revealed that strains P54 and P63 increased (p<.001 and p<.01 respectively) the lag time for lactic acid accumulation and suppressed the rate of H+ concentration. These results suggest that *Propionibacterium* may be able to utilize ruminal lactic acid, thus preventing ruminal pH decline in cattle consuming high concentrate rations.

Key Words: *Propionibacterium*, Rumen, Lactic acid utilization

333 Quantitative analysis of *in situ* starch degradation in the rumen. A. Offner^{*1}, D. Sauvant¹, P. Chapoutot¹, J. Van Eys², and A. Bach², ¹INRA - INA PG, Paris, ²Agribands International, St. Louis.

The objective of this study was to predict ruminal starch degradation for various feedstuffs. The equation ED = a + b x c / (c + k) was generally used to calculate starch effective degradability. The parameters a, b and c represent the rapidly degradable fraction, the potentially degradable fraction and the degradation rate of fraction b, respectively. The passage rate (k) was considered to be equal to 6%/h. A database on starch degradation including the parameters (a, b, c) and also the kinetic values was built from 47 references (291 observations). Data were analyzed using the GLM procedure. The model took the effects of laboratory (lab) and raw materials (rm) into account, these two factors being significant (P < 0.001). This model predicted the effective degradability with an R² of 82% (rsd=7.9, sd_{lab}=16.2 and sd_{rm}=32.5). A similar model predicted starch "a" fraction with an R² of 72% (rsd=16.0, sd_{lab}=40.2 and sd_{rm}=41.6). The least squares means were collected and results with at least 3 observations are presented. This approach can be used to predict ED with standard deviations ranging from 1.8 to 4.9%.

Ingredients	a, %starch*	Starch ED, %*
Corn	22.1 (27, 3.7)	60.2 (28, 1.8)
Ground Corn	32.5 (6, 7.5)	71.6 (5, 4.1)
Extruded Corn	39.4 (3, 10.3)	77.5 (4, 4.4)
Pelleted Corn	21.0 (3, 9.9)	64.9 (3, 4.9)
Corn Gluten Feed	53.3 (6, 7.4)	86.5 (6, 3.7)
Corn Silage	54.0 (14, 5.4)	83.8 (14, 2.7)
Sorghum	25.4 (8, 6.3)	59.5 (9, 3.0)
Barley	46.1 (25, 3.9)	88.7 (26, 1.9)
Ground Barley	62.9 (3, 11.6)	99.8 (3, 5.7)

334 Influence of post-ruminal partially hydrolyzed starch and casein on pancreatic α-amylase expression in calves. K. C. Swanson^{*}, J. C. Matthews, C. A. Woods, and D. L. Harmon, University of Kentucky, Lexington.

The objective of this experiment was to examine the effects of post-ruminal partially hydrolyzed starch (SH) and/or casein on the expression of pancreatic α-amylase mRNA, protein, and enzyme activity in calves. Twenty-four Holstein calves (88 ± 3 kg), fitted with abomasal infusion cannulas, were randomly assigned within block (wk of infusion) to one of four abomasal infusion treatments. Calves were fed an alfalfa-based diet to supply 1.2 x NEm requirement and to exceed requirements for ruminally degradable intake and metabolizable protein for a steer gaining 0.33 kg/d. Abomasal infusion treatments (3000 mL total volume infused/d) were control (water), SH [4 g/(kg BWd)], casein [0.6 g/(kg BWd)], and SH+casein. Treatments were infused abomasally for 10 d

before tissue collection. Casein infusion increased pancreatic weight by 74% and α -amylase mRNA expression by 69% in the absence of SH, but did not influence pancreatic weight and α -amylase mRNA expression in the presence of SH (SH \times casein, $P < 0.10$). Infusion of SH decreased ($P = 0.02$) pancreatic α -amylase protein expression by 67% and activity (U/g pancreas) by 63%. Casein infusion did not influence pancreatic α -amylase protein expression and activity (U/g pancreas). Casein infusion increased total α -amylase activity (kU/pancreas) by 148% in the absence of SH, but did not influence total α -amylase activity (kU/pancreas) in the presence of SH (SH \times casein, $P = 0.05$). These data suggest that increases in small intestinal SH decrease pancreatic α -amylase expression largely by post-transcriptional events. Increases in small intestinal protein increase pancreatic weight and total α -amylase activity, whereas small intestinal SH inhibits these increases.

Key Words: calves, α -amylase, post-ruminal nutrients

335 Abomasal infusion of casein enhances abundance and activity of Na⁺/glucose cotransporter along the small intestine of lambs. S. J. Mabweesh*, D. Guy, and D. Sklan, *The Hebrew University.*

The purpose of this study was to determine the effect of abomasal casein infusion on glucose uptake and abundance and activity of the Na⁺/glucose cotransporter (SGLT1) in brush border membrane vesicles (BBMV) prepared from mucosa in different regions of ovine small

intestine. Lambs (body weight 35 ± 1.0 kg) were surgically fitted with abomasal infusion catheters and were fed diets containing equal portions of wheat hay and cracked corn. Lambs were infused with either 500 g/d water or with 500 g/d water containing 35 g casein. The infusion period lasted 10 d, after which lambs were slaughtered, exsanguinated, and eviscerated. Intake and total tract digestibility of nutrients were similar between treatments and averaged 1134, 1142 and 486 g/d, and 67, 70, 94% for dry matter, organic matter, and non-structural carbohydrates. Crude protein digestibility was higher by 15% in the casein-infused lambs. Glucose uptake to BBMV ranged from 101 to 337 pmol.mg protein⁻¹.sec⁻¹ along the small intestine and was highest in the mid section of the small intestine. In the mid jejunum glucose uptake was higher ($P < 0.07$) in lambs infused with casein and averaged 120 compared to 68 pmol.mg protein⁻¹.sec⁻¹ in the control group. SGLT1 affinity was similar in the different segments of the small intestine of lambs infused with casein and averaged 106 mM. In contrast in the control group a scattered range of values was found in the control group with lowest values in the duodenum. SGLT1 protein abundance correlated positively with glucose uptake in the BBMV in the casein treated lambs, but not in the control group. These data suggest that glucose uptake along the small intestine of lambs is directly influenced by casein or its derivatives in the small intestine via SGLT1 affinity at the brush border membrane. SGLT1 activity may be regulated by post-translational events affected by amino acids and peptides.

Key Words: Sheep, Starch digestion, Glucose transporter (SGLT1)

ASAS/ADSA Ruminant Nutrition: Transition Cow

336 An overview of dietary factors influencing dry matter intake and milk protein yield in early lactation dairy cows. A. N. Hristov*¹, W. J. Price², and B. Shafiq², ¹Department of Animal and Veterinary Sci., ²Statistical Programs, College of Agriculture, University of Idaho, Moscow, ID 83844.

The objective of this meta-analysis was to determine the factors mostly responsible for the variation in DMI and milk protein yield (MPY) in lactating dairy cows. Diets (467) from feeding trials conducted in the U.S. and Canada involving Holstein cows less than 100 DIM published in *J. Dairy Sci.* (volumes 73 through 82) were analyzed for nutrient composition (CPMDairy program). The average DMI of the cows involved in this study was 22.1 kg/d (varying from 16.0 to 29.9 kg) and the average milk yield was 33.0 kg/d (varying from 20.1 to 46.0 kg). The relationships between DMI and MPY with variables representing the chemical composition of the diet and ruminal fermentability of carbohydrate (CHO) and nitrogen fractions were investigated. Principle component analysis (PCA) was used to reduce the dimension of the underlying data and identify specific sources of variability. More than 80% of the data variability was accounted for by the first three components representing starch, fiber and protein intakes. Dominant variables contributing to these axes were non-structural CHO, CHO fraction B1 and fermentable CHO fraction B1 for starch, NDF, CHO fractions B2+C and fermentable CHO fractions B2+C for fiber, and soluble and degradable protein intakes for protein. A subsequent regression analysis was carried out to investigate the relationships between these dietary attributes and the response variables DMI and MPY. A three-parameter model involving CHO fraction B1, NDF, and soluble protein intakes was deemed appropriate for DMI, accounting for 91% of the response variability. Whereas, CHO fraction B1, degradable protein, and NDF intakes were the best explanatory variables for MPY, accounting for 41% of the response variability. In conclusion, during the first 100 days of lactation, starch and NDF intakes were the most important variables in determining DMI, while starch intake was the important variable in determining MPY.

Key Words: Dairy Cows, Dry Matter Intake, Milk Protein Yield

337 Dry period protein nutrition and glucose and protein metabolism in transition cows. W.S. Burhans*¹, R.M. Slepatis¹, P.J. Reeds², and A.W. Bell¹, ¹Cornell University, Ithaca, NY, ²USDA-ARS CNRC, Houston, TX.

The effect of protein nutrition during the dry period on periparturient glucose flux and protein metabolism was assessed in multiparous Holstein cows. Cows (n=12) were dried off at -67 days from expected calving date and fed a common diet (HIGH) containing 157g/kg CP,

40.9% NDF, 34.8% NFC, and 1.59 Mcal/kg NEI. At -60 d and -20 d before expected calving and +3 d after calving cows were infused with a complete mix of ¹⁵N labeled amino acids (AA) and [6-²H] glucose for 8 h (AA) and 4 h (glucose) respectively. Hourly blood samples were taken to determine plasma isotopic enrichment. After infusion for 8h a liver biopsy was taken for determination of protein fractional synthesis rate (FSR) from hepatic incorporation of ¹⁵N AA. After the infusion 6 cows were assigned to a diet (LOW) containing 7.9 g/kg crude protein, 40.9% NDF, 46.2% NFC, and 1.56 Mcal/kg. Cows remained on HIGH or LOW diets until calving, when a common lactating diet was fed containing 175 g/kg CP, 31.1% NDF, 38.9% NFC, and 1.74 Mcal/kg. Tabulated results suggest minimal effects of dry period dietary protein concentration on periparturient glucose or AA metabolism. High dry period DMI and inclusion of additional corn starch to the LOW diet may have ameliorated potential negative effects of low dietary protein concentration. Increased glucose flux postcalving is consistent with increased glucose demand immediately postpartum. Additional work is needed to assess the significance of low dry period protein concentration when intake is low or restricted or when periods are less glucogenic.

338 Production responses of dairy cows to dietary supplementation with conjugated linoleic acid (CLA) during the transition period and early lactation. G. Bernal-Santos*, J. W. Perfield II, T. R. Overton, and D. E. Bauman, *Cornell University, Ithaca NY*.

Thirty Holstein cows entering second or later lactation were utilized to determine whether feeding rumen-protected CLA from 21 d prepartum through 56 d (8 weeks) postpartum would affect dry matter intake (DMI), milk production, or milk composition. Cows were fed common diets as TMR both before and after parturition, and diets were top-dressed with either 116 g/d of a commercial rumen-protected fat supplement (EnerGII; Bioproducts Inc., Fairlawn, OH) as a control or 126 g/d of a rumen-protected CLA supplement (Agribands Purina Canada, Inc., Woodstock, ON). Treatment amounts were calculated to provide the same total amount of fatty acids. The CLA supplement provided 42.8 g/d of CLA. Predominant CLA isomers (wt. %) were: trans-8 cis-10 (9.2%), cis-9 trans-11 (25.1%), trans-10 cis-12 (28.9%), and cis-11 trans-13 (16.1%). Differences in prepartum (12.1 vs. 13.1 kg/d) and postpartum (20.5 vs. 21.6 kg/d) DMI for control and CLA treatments were not significant ($P > 0.20$). Feeding CLA during the transition period and early lactation tended ($P < 0.14$) to increase overall milk yield (42.6 vs. 45.2 kg/d), and a trend ($P < 0.07$) occurred for an interaction of treatment and week because differences increased as week of lactation increased. Feeding CLA decreased ($P < 0.01$) milk fat percentage (3.87 vs. 3.46%). As a result of these offsetting changes in milk yield and milk fat percentage, differences in yields of fat (1.62 vs. 1.52 kg/d) and 3.5% fat-corrected milk (44.9 vs. 44.2 kg/d) were not significant ($P > 0.20$). Differences in the percentage (2.87 vs. 2.89%) and yield (1.20 vs. 1.27 kg/d) of true protein in milk, and the concentration milk urea nitrogen (12.8 vs. 12.7 mg/dl), were not significant ($P > 0.20$). Results suggest that feeding CLA to dairy cows during the transition period and early lactation causes a moderate decrease in milk fat content, tends to increase milk yield, and does not affect DMI.

Key Words: transition period, conjugated linoleic acid, milk fat

339 Changes in Rumen Capacity during the Periparturient Period in Dairy Cows. A.F. Park*, J.E. Shirley, J.M. DeFrain, E.C. Titgemeyer, E.E. Ferdinand, R.C. Cochran, D.G. Schmidt, S.E. Ives, and T.G. Nagaraja, *Kansas State University, Manhattan*.

Four ruminally fistulated, multiparous, pregnant Holstein cows were utilized in a randomized design to delineate ruminal adaptations as the cow transitions from gestation into lactation. Ruminal measurements were obtained 72 (late lactation), 51 (far-off dry), 23, and 9 d (close-up dry) prepartum and 6, 20, and 34 d postpartum. Net energy of lactation (Mcal/kg) and crude protein percentage of the diets were 1.57, 15.6; 1.55, 10.9; 1.57, 15.0; 1.61, 17.0 for late lactation, far-off dry, close-up dry, and early lactation, respectively. On each sampling day, rumens were evacuated prior to feeding; contents were weighed and sampled to determine fill, and then the rumen was filled with water with the cannula cap intact to prevent water from exiting via the cannula. Ruminal water holding capacity (RWC) was determined as the amount of water subsequently removed from the rumen. Dry matter intake expressed as a percent of body weight (quadratic, $P < 0.001$) declined as stage of gestation advanced but increased following parturition. Body weight and condition were highest just prior to parturition (quadratic, $P < 0.001$). RWC gradually increased from the far-off period into early lactation (linear, $P < 0.01$). Total and liquid fill were lowest during the close-up dry period (quadratic response, $P < 0.01$). Dry matter fill (quadratic response, $P < 0.001$) and dry matter fill as a percentage of RWC (quadratic response, $P < 0.01$) were lowest during the early close-up dry period. Total fill as a percentage of RWC was highest during the far-off period (quartic response; $P < 0.05$). Liquid fill as a percentage of RWC was highest during the far-off dry period and decreased as cows approached parturition (quartic response, $P < 0.05$). These data demonstrate that physical capacity of the rumen is not the causative factor of prepartum intake depression.

340 Effects of Fermentable Carbohydrate Sources on Dry Matter Intake, Milk Production, and Blood Metabolites of Transition Dairy Cows. R.S. Ordway*, V.A. Ishler, and G.A. Varga, *The Pennsylvania State University, University Park, PA*.

Thirty-four multiparous Holstein cows (780 17.2 kg BW; 3.39 0.08 BCS) were used in a completely randomized design to evaluate the effects of fermentable carbohydrate sources on dry matter intake, milk production, and blood metabolites of transition cows. Treatments were initiated 30 d prior to expected calving date and continued through calving. After parturition, animals received 50% of their respective prepartum diets and 50% of a typical lactating cow TMR until intake reached 14.5 kg DM at which time they received only the lactating cow ration until 56 d postpartum. The prepartum diet was formulated to contain 1.5 Mcal/kg NEL, 41.3% NDF, and 14.8% CP. The control diet (% DM) consisted of 42% corn silage, 10.6% SBM, 5.5% corn cobs, 10.9% cottonseed hulls, 6.4% soyhulls, 4.3% liquid molasses, 3.8% alfalfa dehydrate, 4.9% vitamin and mineral mix, 0.4% urea, 0.5% Pro Base, and 10.3% ground corn. The treatment diet consisted of replacing 2.4% of the corn with sucrose on a DM basis. Significance was declared at $P \leq .10$ using the MIXED procedure of SAS[®]. Prepartum glucose levels were higher (66.3 ± 1.2 vs. 69.3 ± 1.1 mg/dl) ($P < .08$) for cows fed the diet containing sucrose but were not different postpartum. Neither prepartum or postpartum NEFA, BUN, or insulin differed between treatments. DMI averaged 16.3 ± 0.61 kg/d for the last 4 weeks prepartum and 21.9 ± 0.76 kg/d for the first 8 wk postpartum. Milk yield averaged 45.7 ± 1.6 kg/d, fat averaged $3.7 \pm 0.09\%$ and protein averaged $2.7 \pm 0.05\%$ for the first 8 wk postpartum and were not different among treatments. Prepartum DMI in the current study was 20% higher compared to our last 2 trials in which diets were formulated to contain approximately a 70:30 forage to concentrate ratio. Based on our current study, replacing ground corn with sucrose did not enhance prepartum or postpartum intake or performance.

Key Words: Fermentable Carbohydrate, Nonforage Fiber, Transition Cow

341 Effect of liquid flavor supplementation on performance of dairy cows in the transition period. M. A. Shah*, E. J. Friedman, B. A. Fadl-alla, and M. R. Murphy, *University of Illinois at Urbana-Champaign*.

A nine-week trial was conducted to study the performance of twenty-four Holstein cows during the transition period (3-wk prepartum and 4-wk postpartum). Cows were assigned to either a control or liquid-flavored (0.52 ml/kg of feed) TMR in a randomized complete block design. The TMR contained corn silage, alfalfa haylage, cottonseed and a grain mix based on ground corn and soybean meal. Cows were fed to ensure 10%orts and the diet provided (on a DM basis) 13% CP, 32% ADF, 44% NDF and 1.54 Mcal/kg prepartum and 17.5% CP, 30% ADF, 40% NDF and 1.54 Mcal/kg postpartum. An additional 2.3kg of alfalfa hay was fed the first 5 d postpartum. Weekly means of DMI, milk yield, milk protein, milk fat, SNF, SCC and BW were analyzed using a repeated measures procedure. There was no effect of treatment on these variables ($P > 0.10$), and least-squares means were 16.9 and 15.7 kg/d, 38 and 35.3 kg/d, 3.10 and 3.11%, 3.69 and 3.74%, 8.37 and 8.16%, 1.99×10^5 and 4.33×10^5 , and 631 and 651 kg for cows on control and flavored diets, respectively. Individual cow postpartum DMI data were fitted with an exponential model $[DMI = a + b * e^{(-c * DIM)}]$, where DMI in kg, 'a' asymptotic DMI, 'b' potential for increase in DMI, 'c' rate of increase in DMI]. Rates of increase in DMI were similar, 0.139 and 0.123 for control and flavored diets, respectively. Data for both groups were separately analyzed using multiple regression with FCM as the dependent variable, and BW and DMI as independent variables. More BW was mobilized per unit increase in FCM in cows fed the control than in cows fed the flavor diet. Cows fed control diet were in more negative energy balance during early lactation (especially during wk 1 and 2 postpartum) than cows fed flavored diets ($P < 0.10$). It was concluded that, feeding flavor improved energy balance of cows in early lactation and may reduce the risk of health or reproductive problems.

Key Words: feed flavor, early lactation, prediction model

342 Effects of day relative to parturition and dietary crude protein levels on rumen fermentation in pre-fresh transition cows. M. E. Dorshorst*, S. J. Bertics, and R. R. Grummer, *University of Wisconsin, Madison.*

Eight nulliparous and 12 first parity or greater Holstein cows were used in a randomized block design to examine changes in rumen fermentation as cows fed 10 or 12% CP diets approach parturition. Cows were blocked according to expected calving date and parity. Diets were isocaloric (1.56 Mcal/kg DM) and the difference in CP was achieved by the addition of urea. Diets were fed as a TMR for ad libitum intake. All cows were fed the 10% CP diet starting at d -35 prior to expected parturition. At d -28, one-half of the cows were randomly assigned to the 12% CP diet until parturition. Dry matter intake was measured daily. Rumen fluid samples and estimates of ruminal fiber degradation via in situ dacron bags were obtained at 7 d intervals until d -7 when they were obtained every other day until parturition. There was no effect of treatment or day on rumen pH and total VFA. As cows approached calving, DMI decreased. Rumen NH₃ concentration was significantly increased by feeding the 12% CP diet. Disappearance of NDF after 8 h from dacron bags was affected by day, but not by dietary CP level. Disappearance of NDF after 24 h of incubation tended to be affected by day and was significantly increased by feeding 12% CP. It appears that feeding less than 12% CP to pre-fresh transition cows may limit fiber degradation in the rumen.

343 Metabolic measures around parturition for late gestation cows supplemented with moderate and high dietary calcium during hot weather. P. S. Chan*, J. W. West, and J. K. Bernard, *University of Georgia, Tifton, GA/USA.*

Nine multiparous and 12 primiparous Holstein cows were fed diets containing moderate Ca (100g/d) or high Ca (170g/d) for 21d prepartum to determine the effects of dietary Ca fed with diets containing anionic salts. Cows were monitored on day 21 to 1 prepartum (PRE), day 0, 1 and 2 (CALVING) and day 3 to 21 postpartum (POST). Dietary cation-anion difference (DCAD) for prepartum diets was - 6.43 meq/100g DM (Na + K - Cl - S). Cows were fed positive DCAD diets with 0.88% Ca postpartum. The study was conducted from August 10 to November 16 and mean maximum and minimum ambient temperature and relative humidity were 27.3 and 17.4°C, and 91.7 and 50.7% respectively. There was a 28% decrease in DMI the final week prepartum. No treatment effects on DMI were noted. Mean serum Ca for PRE, CALVING and POST were 9.72, 8.43 and 9.40 mg/dl and there were no treatment effects. Mean serum Ca was higher (P<0.06) for primiparous than multiparous cows (9.47 vs 9.19 mg/dl) for the trial. Mean urine Ca (mg/dl) during PRE, CALVING and POST were 43.07, 4.14 and 2.21 (moderate Ca) and 53.70, 6.19 and 2.33 (high Ca) with no treatment effects. Mean HCO₃⁻ (mmol/L) for PRE, CALVING and POST were 20.10, 25.86 and 26.01 (serum) and 0.36, 45.25 and 109.20 (urine). Mean urine pH for PRE, CALVING and POST were 5.66, 7.45 and 8.24. No dietary treatment effects were noted for all HCO₃⁻ and pH measures. The correlation coefficient for urine pH and urine HCO₃⁻ was 0.85 (P<0.0001). Milk yield was 15.9, 23.8 and 26.2 kg/d for 1, 2 and 3wk postpartum, and there was no difference in mean milk yield for moderate and high Ca treatments (22.3 and 20.1 kg/d). Cows maintained adequate serum Ca levels during the periparturient period for both treatments. Primiparous cows had higher serum Ca compared with multiparous cows.

Results suggest 100g/d Ca is adequate to maintain acceptable blood Ca around parturition during warm weather.

Key Words: Hypocalcemia, DCAD, Heat stress

344 Peripartum responses of Holstein cows and heifers fed graded concentrations of calcium (calcium carbonate) and anion (chloride) 3 weeks before calving. D. K. Beede*, T. E. Pilbeam, S. M. Puffenberger, and R. J. Tempelman, *Michigan State University, East Lansing, Michigan, USA.*

Objective was to determine the effects on peripartum metabolic and health responses, and lactation performance of feeding graded concentrations of Ca without or with supplemental chloride for 3 wk before calving. Pregnant animals (n=420) in two research farms were blocked by parity and assigned randomly to one of five dietary treatments (trt). Postpartum parities were: 164 1st; 82 2nd; and, 174 3rd and greater. Prepartum basal diet fed once daily was 18% alfalfa haylage: 42% corn silage: 40% concentrate. A mixture (16.7% of dietary DM) of HCl-treated, heat-extruded soybean meal (HCl-HESBM) and non-HCl-treated-HESBM was used to vary cation-anion difference (CAD; meq[(Na + K) - (Cl + S)]/100 g of dietary DM). Graded amounts of calcium carbonate were used to vary dietary Ca content. For the entire experiment, average analyzed Ca (%) and CAD of each trt were: (A) 0.47, +18; (B) 0.47, -4; (C) 0.98, -4; (D) 1.52, -4; and (E) 1.95, -4. Weekly urine pH measurements were used to adjust proportions of HCl-HESBM and non-HCl-treated-HESBM to maintain pH between 6.0 and 6.7 for B, C, D, and E. Urine pH the week before calving was 8.1 vs. 6.4, 6.6, 6.6, and 6.6 for A vs. B, C, D, and E (P<0.01). Prepartum DMI was greater for A, B, and C than for D and E (P=0.01). Caudal vein blood was collected within 24 h after parturition. Plasma ionized Ca (iCa) was: 4.29 vs. 4.39, 4.43, 4.53, and 4.52 mg/dl for A vs. B, C, D, and E (P=0.02). Plasma Cl was higher for cows fed B, C, D, and E compared with A throughout the prepartum period (P<0.01). Pre- or postpartum body condition and udder edema scores, cow BW, calf birth weight, and colostrum score were not affected by trt. Overall incidence rates (all parturitions) of ketosis (16.7%), retained placenta (12.2%), milk fever (7.7%), hypocalcemia (16.8%), abomasal displacement (10.3%), and mastitis (7.2%) were not affected by trt. Incidences of clinical milk fever and hypocalcemia (plasma iCa <4 mg/dl) were greater in 3rd and greater parity cows in A vs. B, C, D, and E (P<0.03). Average postpartum DMI (19.8 kg/d) and milk yield (35.7 kg/d) through 70 DIM were not affected by trt. Overall, peripartum health and performance responses were optimum when the anion-supplemented diet (CAD = -4 meq/100 g of dietary DM) contained 0.98% Ca when supplemental Ca was from calcium carbonate.

Key Words: Calcium, Anion, Dietary cation-anion difference

345 Subacute Ruminal Acidosis in Dairy Cows, an Experimental Model. S.E. Ives*, T.G. Nagaraja, A.F. Park, and J.E. Shirley, *Kansas State University.*

Five ruminally fistulated lactating Holsteins, 492 days in milk, producing 32.6 kg/d were used to compare ruminal acidosis induced with a challenge diet deficient in effective neutral detergent fiber (eNDF) or with greater starch availability. The experiment was a crossover design with 15 d periods. Cows were fed a basal diet containing (% DM) chopped alfalfa hay (50), ground corn (35), whole cottonseed (11), Soybest (1), molasses (1), and vitamins and minerals (2). The basal diet was fed ad libitum twice daily. On d 8 to 11, cows were fed on a % of BW equal to the lowest intake for the period. Diets were provided at 2.5% of BW for period 1 and 2.8% for period 2. On d 12, ruminal samples were taken prior to feeding and p.m. feeding was skipped. On d 13 to 15, cows were challenged with dietary treatments of AP (alfalfa pellets replaced chopped alfalfa 1:1 DM basis, reduced eNDF) and SFC (steam-flaked corn replaced ground corn 1:1 DM basis, increased starch availability) to induce subacute ruminal acidosis. Cows were offered the entire daily allotment in the a.m. and feed not consumed in 2 h was placed in the rumen via the cannula. Ruminal samples were taken 3, 6, 9, 12, and 24 h relative to feeding each day and analyzed for pH, total volatile fatty acids (TVFA), and lactate. Cows were considered acidotic when ruminal pH was below 5.6 after feeding and maintained until the next feeding. Acidosis was not evident until d 15 and only AP induced acidosis (pH; diet x h, P < 0.01). On d 14, cows receiving AP had ruminal pH below 5.6 from h 6 to 12. By h 3 of d 15, cows challenged with AP had ruminal pH below 5.6 and it remained below 5.6 through the end of the

d. Cows receiving SFC experienced a ruminal pH below 5.6 on h 6 to 12 on d 14 and h 6 to 9 of d 15. Overall, reducing the effective NDF of a lactation diet appeared to provide a model for induction of subacute ruminal acidosis in dairy cows.

Key Words: Acidosis, Dairy Cows

346 The effect of Tasco™ inclusion in the prepartum diet on the proportion among bovine leukocyte populations in blood and mammary gland secretions. T. J. Wistuba*, E. B. Kegley, T. K. Bersi, and G. F. Erf, *University of Arkansas, Fayetteville AR/USA.*

The effects of Tasco™ inclusion in the diet during the last 21 d of gestation on the proportion among bovine leukocyte populations in blood (WBC) and mammary gland secretions (MGS) was investigated using flow cytometric analysis. Thirty Holstein cows were stratified by parity and randomly assigned to the Tasco™ (170 g/d) supplemented group or control diet. Tasco™ is a product derived from *Ascophyllum nodosum*, a brown seaweed that grows along the coast of Nova Scotia. Treatments were initiated 21 d prior to expected parturition and fed until calving. Blood samples from cows and calves, as well as MGS samples were obtained at parturition and at d 1 post partum. In cows, supplementation of Tasco™ increased the proportion of granulocytes (P = 0.03) in the WBC suspension. Tasco™ did not affect the percentage of lymphocytes, but tended to increase the proportions of B cells (P = 0.08) and decrease the proportions of TCR1+ T cells (P = 0.10) within the lymphocyte population. Supplementation of Tasco™ also tended to decrease the T:B lymphocyte ratio (P = 0.11). Proportions of bovine leukocyte populations in the MGS were affected by time of sampling, but not dietary treatment. The proportion of granulocytes and macrophages/monocytes increased from parturition to d 1 (P < 0.05). The percentage of total (P = 0.03) and B (P = 0.04) lymphocytes increased from parturition to d 1. Proportions of granulocytes and monocytes/macrophages in the WBC suspension from calves tended to increase (P = 0.13 and P = 0.08, respectively) due to Tasco™ supplementation. Proportion of granulocytes in the WBC suspensions of calves increased from parturition to d 1 (P = 0.03). The proportions of CD8+ lymphocytes and B lymphocytes tended to increase in the blood of calves from birth to d 1 (P = 0.15 and P = 0.07, respectively). Dietary supplementation with Tasco™ altered proportions of bovine leukocyte populations. The impact of Tasco™ supplementation on cow and calf health requires further investigation.

347 Forage alone pre-calving is sufficient for foraged cows post-calving. J.R. Roche, M.J. de Veth, and E.S. Kolver, *Dexcel (formerly Dairying Research Corporation), Hamilton, New Zealand.*

This study investigated the effect of diet and genotype on metabolic indicators of energy status in the periparturient cow. Fifty-six Holstein-Friesian dairy cows of two different genotypes (Northern-Hemisphere (NH) and New Zealand (NZ)) were compared. Half of each genotype group received a diet of pasture/pasture silage pre-calving and pasture post-calving (Grass). The other half received a pre- and post-calving TMR of corn silage, grass silage and concentrates. Treatments were balanced for age and genetic merit. Blood samples were collected by coccygeal venipuncture on d -14, -7, -4, -3, -2, -1, 0, 1, 2, 3, 4, 14 and 30 relative to calving. Body weight was measured weekly. NH cows were heavier at calving and lost more body weight in the first 4 weeks of lactation. This greater loss is mirrored in greater plasma non-esterified fatty acid (NEFA) concentrations 30 d post-calving. Although, Grass cows had greater (P<0.05) B-hydroxybutyrate (BHBA) concentrations pre-calving, diet did not affect the concentration of NEFA in plasma. This increased BHBA is probably due to a greater hepatic demand for gluconeogenesis as a result of poor glucose absorption in Grass cows. Plasma BHBA and glucose concentrations were unaffected by genotype. NZ cows had greater plasma cholesterol concentrations. In summary, a pre-calving TMR did not improve the energy status of the cow pre-calving. An all-forage diet pre-calving is sufficient for dairy cows fed forage post-calving.

348 All forage diet pre-calving improves calcium status. J.R. Roche* and E.S. Kolver, *Dexcel Ltd. (formerly Dairying Research Corporation), Hamilton, New Zealand.*

This study investigated the effect of diet and genotype on the calcium status of periparturient cows. Fifty-six Holstein-Friesian (HF) dairy cows of two different genotypes (Northern-Hemisphere (NH) and New Zealand (NZ)) were compared. Half of each genotype group received a diet of pasture/pasture silage pre-calving and pasture post-calving (Grass). The other half received a pre- and post-calving TMR of corn silage, grass silage and concentrates. Treatments were balanced for age and genetic merit. Blood samples for calcium (Ca) analysis were collected by coccygeal venipuncture on d -14, -7, -4, -3, -2, -1, 0, 1, 2, 3, 4, 14 and 30 relative to calving. Milk yields were recorded daily for 30 d post-calving. Multiparous cows fed TMR produced more milk and colostrum than Grass cows. However, colostrum yields of primiparous cows were not affected by pre-calving diet, and milk yields were greater (P=0.06) for grazing cows. This suggests that it is not the transition feeding of TMR per se that increased milk production but rather the effect of TMR during previous lactations on mammary development. NHHF had lower (P<0.05) plasma Ca concentrations post-calving than NZHF. It is possible that the lower plasma calcium concentration in TMR cows was due to a greater demand placed on the plasma pool of Ca by greater milk yields. However, plasma Ca concentration at calving also tended (P=0.08) to be lower in heifers fed TMR pre-calving, even though milk yields were lower. In summary, herds with a high proportion of NH genetics are at an increased risk of hypocalcaemia, as are cows receiving TMR pre-calving.

ASAS/ADSA Ruminant Nutrition: Water Quality and Minerals

349 The effect of water quality on the performance of feedlot cattle. J. J. Wagner^{*1}, G. H. Loneragan², and D. H. Gould², ¹Continental Beef Research, Lamar, CO/USA, ²Colorado State University, Ft. Collins, CO/USA.

Water is an essential nutrient for feedlot cattle. Drinking water may contain a variety of compounds. The important question is to what degree these substances impact water palatability and cattle health. The NRC in 1974 published limits for some potential problem causing substances in drinking water. Recommended safe upper limits for nitrate, sulfate, and total dissolved solids (TDS) were 440, 300, and 3000 mg/L, respectively. In 1999, the National Animal Health Monitoring System conducted a study monitoring water quality in feedlots with 1000 hd or more capacity in the 12 leading cattle feeding states. A total of 263 feedlots from 10 states supplied a water sample for analyses. Average nitrate, sulfate, and TDS content was 33.6±3.5, 204.9±23.5, and 800±100 mg/L, respectively. No samples exceeded the recommended limit for nitrate. Approximately 23% of the samples had sulfate concentration greater than 300 mg/L. Less than 3% of the samples had more than the recommended level of TDS. In a study conducted at Continental Beef Research, water sulfate concentrations greater than 1000 mg/L caused increases in ruminal gas cap hydrogen sulfide (H₂S) concentration and reductions in water intake and feedlot performance. Elevated ruminal H₂S was associated with increased incidence of polioencephalomalacia in a Colorado feedlot using well water containing 2500 mg sulfate per liter. Molybdenum appeared to reduce the rate of H₂S production in vitro. Molybdenum fed at the rate of 100 mg/kg dry matter intake reduced H₂S concentration in the rumen gas cap by 21% (P=0.0337) and reduced the frequency of cattle with greater than 1000 mg/L H₂S by 40% (P=0.0019). No effect on feedlot performance was observed. Cattle fed 57g clinoptilolite daily exhibited a 14.5% and a 36.3% reduction in ruminal H₂S from d0-10 and from d11-20, respectively. Feeding clinoptilolite reduced performance by feedlot cattle. Efforts to alleviate water quality problems through dietary manipulation have not been successful.

Key Words: Cattle, Water quality, Sulfate

350 Impact of variations in chemical composition of water on potential palatability and mineral intake of dairy cattle. M. T. Socha^{*1}, J. G. Linn², D. J. Tomlinson¹, and A. B. Johnson¹, ¹Zinpro Corporation, Eden Prairie, MN, USA, ²University of Minnesota, St. Paul, MN, USA.

Water is the most important nutrient for dairy cattle. However, it is probably the most overlooked nutrient. In addition to assessing adequacy and cleanliness of waterers as well as water supply, nutrition advisors need to assess chemical composition of water. This paper will summarize composition of water from samples collected throughout North America. Issues of significance with variations in chemical composition of water include the effect potential variations have on mineral intake and acceptability of water by the animal. Averages and ranges in chemical composition of 32 water samples collected were as follows: Ca, 167 ppm, 0.05 - 507 ppm; Cl, 121 ppm, 0 - 692 ppm; Cu, 0.07 ppm, 0 - 0.41 ppm; Fe, 0.23 ppm, 0.01 - 0.91 ppm; Mg, 55 ppm, 0.93 - 250 ppm; Mn, 0.091 ppm, 0.003 - 0.29 ppm; Mo, 0.08 ppm, 0.01 - 0.18 ppm; P, 0.71 ppm, 0.03 - 2.12 ppm; K, 3 ppm, 0.7 - 9 ppm; Na, 138 ppm, 7.6 - 811 ppm; S, 556 ppm, 1.2 - 1020 ppm; and Zn, 0.20 ppm, 0.01 - 0.77 ppm. For some minerals, the amount supplied by water is not insignificant. Based upon a water intake of 103.9 liters (Murphy et al., 1983 equation corrected for DM content of diet and assuming 34.0 kg milk, 22.7 kg DMI, 0.5% Na, 15.6°C and 55% DM) and the average mineral content of water given above, the following amount of minerals from water would be consumed daily: Ca, 17 g; Cl, 13 g; Cu, 7 mg; Fe, 24 mg; Mn, 9 mg; Mg, 6 g; Mo, 8 mg; P, 0 mg; K, 0 g; Na, 14 g; S, 58 g; and Zn, 21 mg. Nutrition advisors need to evaluate not only the availability of clean water on farms, but the minerals potentially supplied to animals from water. Research on mineral availability from water and how the chemical composition of water affects palatability, total water intake, animal health and performance, other than for sulfates and salinity, is very limited or nonexistent.

Key Words: Water, Dairy cattle, Chemical composition

351 Dairy manure quantification and characterization in grazing systems. J.J. Rediske^{*}, W.J. Powers, D.R. Thoreson, and M.A. Faust, Iowa State University, Ames, IA.

A 2-yr field study was conducted using two dairy herds to evaluate feeding strategy effects on nutrient excretion and volume of excretions. Holstein cows were grazed during the growing season and fed corn silage-based diets during the remainder of the year. Jersey cows were offered a corn silage-based TMR year-round but were allowed access to pasture in the growing season. Fecal excretions (24-h) were quantified using four of the ten cows with either fecal collection bags (grazing season) or fecal collection pans. Cows representing parity and stage of lactation within the herd were selected for urine and fecal sampling twice monthly. Collected samples were analyzed for solids (TS, VS), N, P and COD content. Feed and pasture samples were collected and analyzed for nutrient content. During the grazing months cows excreted significantly more feces (43.4 vs. 30.5 kg; P<.001). Fecal excretion per kg BW did not differ between herds (P>.10). Fecal TS was greater in the grazing season (16.59% vs. 15.65%; P<.001) and slightly greater in the Jersey herd (16.36% vs. 15.87%; P=.07). Fecal VS was greater in the grazing months (14.36% vs. 12.30%; P<.001) but did not differ between herds (P>.10). Urine COD was greater in the Holstein herd (35.09 g/L vs. 26.54 g/L; P<.001) but less in the grazing season (26.83 g/L vs. 34.81 g/L; P<.001). Fecal COD was greater in the Holstein herd (17.01 g/L vs. 15.44 g/L; P=.02). No seasonal differences were observed. Fecal P was slightly greater in the Jersey herd (1.69% vs. 1.27%; P=.06) and greater in the grazing season (1.72% vs. 1.24%; P=.01). Urine P was greater in the Jersey herd (252.6 mg/L vs. 169.5 mg/L; P<.001) and in the grazing season (228.0 mg/L vs. 194.2 mg/L; P=.02). Urinary N did not differ between herds; however, urine N was less in the grazing season (0.78% vs. 1.00%; P<.001). Fecal N was greater in the grazing season (2.45% vs. 2.33%; P=.04) but not different between herds. A significant herd × season effect was found for urine and fecal N and P and fecal VS, likely due to management differences. Results indicate feeding and management practices have a significant impact on nutrient and volume excretions and should serve as the basis of the nutrient planning process.

Key Words: Dairy, Manure, Grazing

352 Effect of calcium intake on phosphorus excretion in feces of lactating cows. Z. Wu^{*1}, A.G. Rius², and L.D. Satter^{1,2}, ¹University of Wisconsin, ²U.S. Dairy Forage Research Center, USDA-ARS, Madison.

The effect of dietary Ca concentration on P excretion in feces of lactating cows was determined by feeding diets containing 0.36% P and either 0.70 or 1.10% Ca, varied by calcium carbonate. The two diets were fed to 17 late-lactation Holsteins (DIM 233, SD 49) in a crossover design involving 3-wk periods. Fecal samples were collected at 3-h intervals on the last day and lactation performance was measured during the last 2 wk of each period. Increasing dietary Ca concentration from 0.70 to 1.10% increased fecal Ca concentration (P < 0.01), but did not affect fecal P concentration (P = 0.19). Milk yield (29.4 and 28.8 kg/d, SEM 0.5) and DMI (21.0 and 20.8 kg/d, SEM 0.3) were not affected (P > 0.10) by treatment. The lack of treatment effect on performance is consistent with other studies using lactating cows and growing steers that suggest a tolerance of wide Ca:P ratios by ruminants. Many dairy diets are formulated to contain Ca in excess of NRC (2001) recommendations. Reducing dietary P from the current high levels normally fed, as suggested by recent research, does not require a concomitant decrease in dietary Ca to maintain a Ca to P ratio of 2:1 for normal P absorption. This conclusion applies when normal to moderately high amounts of Ca (0.70 to 1.10%) are fed.

Item	— Dietary Ca —		SEM	P
	0.70%	1.10%		
Dietary P	— % of	DM —		
Fecal concentration	0.36	0.36		
Ca	1.68	2.43	0.13	0.01
P	0.89	0.94	0.03	0.19

Key Words: Calcium, Phosphorus, Dairy Cow

353 Effect of supplemental vitamin D on phosphorus excretion in dairy cattle. K.M. Dooley*, J.A. Bertrand, R.J. Thurston, A.B. Bodine, and T. Gimenez, *Clemson University, Clemson, SC.*

Phosphorus (P) excretion in manure is recognized as an environmental concern in the United States. The objective of this study is to reduce P excretion via increased intestinal absorption with the utilization of supplementary vitamin D (D). Repeated measures were taken in a Randomized Complete Block design experiment. Three treatments were assigned randomly to 24 Holstein cows of similar milk yield, lactation, and days in milk. A control group of 8 cows was fed both P and D at National Research Council (NRC) values of .41% DMI of P and 18,000 IU/d of vitamin D. A Low P diet for 8 cows included P at .31% DMI with no additional dietary D above NRC. The remaining 8 cows were given a treatment ration consisting of Low P (.31%) with supplemental vitamin D at 135,000 IU/d. The rations were fed for a total of 84 days. A 48-hour pre-trial collection was taken of total feces and milk along with a blood sample each 24-hour period. An additional 48-hour collection period was run at days 83 and 84. Feces and milk were weighed, sampled, and assayed for P. Serum was harvested and assayed for P and vitamin D. Fecal phosphorus (dry matter basis) in grams per day averaged 99.8g (.74%) for the control group, 83.8g (.60%) for the Low P treatment, and 86.1g (.63%) for the Low P-High D diet. Level of dietary P had a significant effect ($p < .05$) on fecal P excretion but vitamin D did not ($p > .05$). Neither P or D altered secretory P in milk ($p > .05$) or serum P levels ($p > .05$). Excess vitamin D does not appear to alter P absorption in dairy cattle.

Key Words: Phosphorus, Vitamin D, Dairy cattle

354 Effects of zinc source and dietary level on zinc metabolism in Holstein bull calves. C. L. Wright* and J. W. Spears, *North Carolina State University.*

The objective of this experiment was to evaluate the effects of zinc (Zn) source and level on Zn metabolism in cattle. Forty-eight Holstein bull calves were stratified by origin and weight, and randomly assigned to one of four treatment groups. Dietary treatments were administered in two phases. In Phase 1 (98 d), treatment groups received no supplemental zinc (Con), 20 mg Zn/kg DM as ZnSO₄ (ZnS) or ZnProt (ZnP) or 20 mg Zn/kg DM with 50% of the Zn supplied from each source (ZnM). In Phase 2 (14 d), calves continued to receive the same Zn source fed in Phase 1; however, half of the calves in each treatment group were randomly selected to receive 500 mg Zn/kg DM (HiZnS, HiZnP, HiZnM). Average daily feed intake, ADG and feed efficiency were not affected by treatment in either phase of the experiment. Treatment had no effect on plasma Zn concentration or Alp activity in Phase 1, but liver Zn concentration was greater ($P < 0.05$) in bulls fed ZnS than those fed ZnP. In Phase 2, plasma Zn was greater ($P < 0.01$) in bulls fed HiZnP and HiZnM than in those fed HiZnS, and liver Zn was greater ($P < 0.05$) in bulls fed HiZnP than in those fed HiZnS. Duodenal Zn concentrations were greater ($P < 0.01$) in bulls fed HiZnP and HiZnM than those fed HiZnS. Bulls that received ZnP and ZnM tended ($P < 0.10$) to have greater ruminal and omasal metallothionein (MT) concentrations, respectively, than bulls that received ZnS. Liver and duodenal MT concentrations were unaffected by Zn source or concentration. Bulls fed HiZnP and HiZnM had higher ($P < 0.05$) kidney Zn concentrations than those fed HiZnS. Heart, spleen, testicular, and bone Zn concentrations were unaffected by Zn source. Bulls fed ZnS had greater ($P < 0.05$) Zn concentration in hoof wall than bulls fed ZnM; however, hoof sole Zn concentration was not affected by Zn source or concentration. When Zn was supplemented at 20 mg Zn/kg DM, Zn source had minimal impact on plasma or tissue Zn concentrations. However, when Zn was supplemented at 500 mg Zn/kg DM, plasma and tissue Zn concentrations were greater in bulls that received ZnProt than in those that received ZnSO₄.

355 Uptake and transport of zinc from zinc sulfate and zinc proteinate by Caco-2 cells. C. L. Wright*¹, M. L. Failla², and J. W. Spears¹, ¹North Carolina State University, ²University of North Carolina at Greensboro.

Experiments were conducted to evaluate effects of time, Zn concentration, inositol hexaphosphate (IP₆), and simulated ruminal and intestinal

digestion on the uptake and transport of Zn by Caco-2 cells, from inorganic and organic sources, using ⁶⁵Zn-labelled ZnSO₄ and Zn proteinate (ZnProt). Experiments were conducted with cells grown on plastic (uptake only) or on membrane inserts (uptake and transport). In the absence of antagonists, solubilities of Zn from both Zn sources were nearly 100%. Increasing incubation time up to 120 min and Zn concentration up to 200 μM increased ($P < 0.01$) Zn uptake and transport; however, uptake and transport were not affected by Zn source. Zinc solubility in the presence of 200 μM IP₆ and 200 μM Ca was influenced by a concentration × IP₆ interaction ($P < 0.01$), but was not affected by Zn source. In the absence of IP₆ and Ca, solubility was unaffected by Zn concentration; however, when the antagonists were added, solubility declined as Zn concentration increased. Uptake and transport of Zn in the presence of IP₆ and Ca was not affected by Zn source. Solubility of Zn following simulated ruminal and(or) intestinal digestion was not affected by Zn source. Following simulated intestinal digestion alone, uptake by monolayers grown on plastic was affected by a concentration × source interaction ($P < 0.04$). Following simulated ruminal and intestinal digestion, uptake of Zn by cells grown on inserts was affected by a source × concentration interaction ($P < 0.03$). In both interactions, uptake from the aqueous fractions of digestions containing 10 μM added Zn was not affected by Zn source; however, uptake from the aqueous fractions of digestions containing 200 μM added Zn was greater from ZnProt than from ZnSO₄. In the absence of antagonists, or in the presence of IP₆ and Ca, uptake and transport of Zn from ZnSO₄ and ZnProt was similar. Following simulated digestion, Zn uptake from ZnProt was greater than from ZnSO₄ when added at 200, but not 10 μM.

Key Words: Zinc proteinate, Caco-2, Bioavailability

356 Insulin responsiveness of adipose tissue metabolism from steers supplemented with varying concentrations of zinc sulfate. S. L. Archibeque*, G. S. Martin, G. E. Carstens, D. K. Lunt, and S. B. Smith, *Texas A&M University, College Station, TX.*

This investigation documented the interaction of supplemental dietary zinc and insulin responsiveness of acetate incorporation into fatty acids and in bovine adipocytes *in vitro*. Sixty Angus steers were backgrounded on pasture with a free-choice mineral supplement that was designed to be zinc deficient, and then were allotted to one of five different supplementation concentrations (30, 60, 120, 240, and 480 ppm) of zinc in the finishing rations. Steers were fed the treatment finishing rations for approximately 100 d (to a targeted quality grade of Select) or 140 d (Choice). Lipogenesis from 10 mM acetate was measured in flasks that contained 0, 10, 100, or 1,000 mU bovine insulin/mL incubation medium. Lipogenesis (nmol/h per 10⁵ cells) was greater in Select steers (21.3 vs 8.9, $P < 0.01$) which also had a lesser ($P < 0.01$) cell volume (300.1 vs 394.9 pL) and greater ($P < 0.01$) number of cells/g of adipose tissue (23.6 vs 17.4) than adipose tissue from Choice steers. Lipogenesis from acetate declined as zinc supplementation level increased in adipose from Select cattle, whereas the response was opposite in Choice cattle (interaction, $P < 0.03$). There was no interaction between quality grade and insulin concentration on lipogenesis. However, there tended to be an interaction ($P < 0.11$) between zinc intake and the responsiveness of lipogenesis to insulin concentration. At the 60 and 120 ppm supplemental zinc concentrations, increased concentrations of insulin in the incubation medium increased lipogenesis, whereas there was no discernible change in lipogenesis with increased insulin concentrations with tissue from cattle fed 30, 240, or 480 ppm supplemental zinc.

Key Words: Beef Steers, Zinc Sulfate, Adipose Tissue

357 Summary of eight trials evaluating the effect of feeding a combination of complexed zinc methionine, manganese methionine, copper lysine and cobalt glucoheptonate on lactation and reproductive performance of dairy cattle. D. J. Tomlinson*, M. T. Socha, and A. B. Johnson, *ZINPRO Corporation, Eden Prairie, MN.*

The objective of this review was to summarize eight trials (nine comparisons) evaluating the effect of feeding a combination of complexed zinc methionine, manganese methionine, copper lysine and cobalt glucoheptonate (4-PLEX[®], ZINPRO Corporation, Eden Prairie, Minnesota) on lactation and reproductive performance of dairy cattle. In all eight trials, cows consumed daily, 360 mg of zinc from zinc methionine complex, 200 mg of manganese from manganese methionine complex, 125 mg of

copper from copper lysine complex and 25 mg of cobalt from cobalt glucoheptonate. Cows also received additional zinc, manganese, copper and cobalt from inorganic sources. In three studies, the control and treatment diets contained an equivalent amount of zinc, manganese, copper and cobalt. In three studies, the control and treatment diets contained an equivalent amount of zinc from zinc methionine complex. In one study, two comparisons were made, complexes vs. control and complexes vs. sulfates. Six trials were conducted in conjunction with University personnel and two studies were conducted with private consultants. Each trial was a block and each treatment is mean within a trial was treated as an observation. Cows fed a combination of complexed zinc, manganese, copper and cobalt produced more ($P \leq 0.05$) milk (36.8 vs. 35.7 kg/d), energy-corrected milk (37.5 vs. 36.2 kg/d), 3.5% fat-corrected milk (37.5 vs. 36.2 kg/d), milk fat (1.33 vs. 1.27 kg/d) and milk protein (1.15 vs. 1.11 kg/d) than control cows. Cows fed the combination of complexed zinc, manganese, copper and cobalt also had fewer ($P \leq 0.05$) days to first service (74 vs. 81 d) and days open (115 vs. 133 d). This summary of eight dairy trials indicates that feeding a combination of complexed zinc methionine, manganese methionine, copper lysine and cobalt glucoheptonate increases lactation and reproductive performance of dairy cattle.

358 Source of dietary selenium on tissue retention and mobilization of selenium in growing heifers. R. L. Kincaid* and J. D. Cronrath, *Washington State University*.

Diets of newborn Holstein heifers ($n = 26$) were supplemented with sodium selenite, selenized yeast (SeY, Alltech, Inc.), or no Se for 24 wk to compare efficacy of tissue retention of dietary Se. Calves were fed whole milk and starter for 5 wk, starter only for 7 wk, and starter plus hay for 12 wk. The control diet for wk 5 to 12 had 0.22 ppm Se; wk 13 to 16, 0.16 ppm Se; and wk 17 to 24, 0.12 ppm Se. Supplemented diets for wk 5 to 12 had 0.68 ppm Se; wk 13 to 16, 0.46 ppm Se; and wk 17 to 24, 0.36 ppm Se. At 16 wk of age, half of the heifers from each supplemented group were switched to the control diet to determine tissue mobilization of Se. Blood was sampled monthly and samples of liver and muscle were taken by biopsy at 16 and 24 wk. All heifers received a vaccination with a modified live virus at 20 wk. Growth rates of the heifers were not affected ($P > 0.05$) by Se supplementation. At 24 wk, concentrations of Se in blood were highest ($P < 0.05$) for heifers fed SeY (0.197 ppm), intermediate for heifers fed selenite (0.132 ppm) and least for nonsupplemented heifers (0.107 ppm Se). Likewise, muscle of heifers fed SeY had the highest Se concentrations at 16 wk (0.31 ppm for SeY vs. 0.13 ppm for selenite and controls), however, at 24 wk all Se supplemented heifers had higher concentrations of Se in muscle than the control group (0.15 vs. 0.07 ppm Se, respectively). Concentrations of Se in liver were greater ($P < 0.05$) in all heifers given Se supplements than in nonsupplemented controls. Activity of glutathione peroxidase in blood also was higher for Se supplemented heifers at wk 16 than nonsupplemented heifers. After vaccination, there were no significant differences in serum IgM and IgG among treatments. Thus, the chemical form of supplemental Se affected tissue retention of Se. By 8 wk after the Se supplements were removed from the diets, the previously supplemented heifers still had greater concentrations of Se in blood and liver than nonsupplemented controls.

Key Words: Selenium, Heifers, Tissues

359 Influence of supplemental cobalt source and concentration on performance, and ruminal plasma metabolites in growing and finishing steers. M. E. Tiffany*¹, J. W. Spears¹, and J. Horton², ¹*North Carolina State University, Raleigh*, ²*Kemin Industries, Des Moines, IA*.

An experiment was conducted to evaluate the effects of cobalt (Co) source and concentration on performance, ruminal VFA, plasma vitamin B₁₂ and glucose concentration, and carcass characteristics of finishing steers. Sixty Angus steers were stratified by weight and randomly assigned to treatment. Treatments consisted of 0 (control, analyzed 0.04 mg Co/kg), 0.05, 0.10 and 1.0 mg of supplemental Co (as carbonate)/kg DM of diet or 0.05 and 0.10 mg of supplemental Co (as propionate, KemTRACE[®] Co)/kg DM of diet. A cottonseed hull-corn-soybean meal based growing diet was fed for 56 d followed by a high concentrate finishing diet. Steers were fed individually using electronic

Calan gate feeders. Performance was not affected by Co supplementation during the growing phase. During the finishing phase ADFI was higher ($P < 0.08$), and ADG, and gain:feed were higher ($P < 0.06$) over the first 56 d for Co supplemented steers. Steers supplemented with 0.10 mg Co/kg as propionate had higher ($P < 0.01$) ruminal propionate and lower ($P < 0.02$) acetate percentages than those receiving 0.10 mg Co/kg as carbonate during the growing phase. Supplemental Co increased ($P < 0.07$) the percentage of propionate during the finishing phase. Plasma vitamin B₁₂ was higher ($P < 0.05$) in Co supplemented steers by d 56 of the growing phase and remained higher ($P < 0.06$) throughout the entire finishing phase. Steers supplemented with Co had higher plasma glucose ($P < 0.08$) at d 56 to 112 of the finishing phase and steers supplemented with 0.10 mg Co/kg as propionate had higher ($P < 0.07$) plasma glucose than those receiving 0.10 mg Co/kg as carbonate at d 28 of the growing and d 28 of the finishing phase. Hot carcass weight was lower ($P < 0.07$) in steers receiving the control diet while other carcass characteristics were not greatly affected by dietary treatment. These results indicate that diets marginally deficient in Co adversely affect performance, and vitamin B₁₂ status of finished steers.

Key Words: Cattle, Cobalt, Vitamin B₁₂

360 Lactational and reproductive responses of early lactation Holstein cows to varied levels of dietary supplementation of organic cobalt, copper, manganese and zinc. S. L. Sneed*¹, J. E. Tomlinson¹, B. L. Clark¹, E. J. Murphy, III¹, M. E. Boyd¹, and D. J. Tomlinson², ¹*Mississippi State University, Mississippi State*, ²*Eden Prairie, MN*.

Holstein cows ($n=120$) were assigned to four groups of 30 cows each based on lactation number, previous lactation ECM yield and SCC. Treatments were Control (0), 14, 28 and 56g/cow/d of supplemental organic Co, Cu, Mn and Zn provided by ZINPRO 4-PLEX[®]. 4-Plex (14g/d) provided 360 mg complexed zinc, 200 mg complexed manganese, 125 mg complexed copper and 25 mg organic cobalt. All diets were formulated to be nutritionally identical with the exception of the level of complexed Co, Cu, Mn and Zn. The control diet was formulated using inorganic sulfate forms of Cu, Mn, Zn and Co carbonate at 150 percent above NRC (1989) recommendations. Animals were placed on trial 21d prior to expected parturition ($d = 0$) and remained through 150d of lactation. Cows were housed in freestall barn with free access to TMR and water at all times. Cows were group fed 2x daily in amounts to allow for 10-15 percent refusals. Cows were milked 2x daily and milk weights recorded. Pooled milk samples (AM and PM) were taken bi-weekly for fat, protein, lactose and SCC analyses. Liver biopsy samples were taken on d -21, 7, 50 and 120 and analyzed for Cu, Mn and Zn. All liver trace mineral concentrations fell within normal ranges and showed no significant ($p > .10$) differences. Milk yield was similar across treatments; 34.0, 33.8, 35.5, 35.6 kg/cow/d for 0, 14, 28 and 56g, respectively ($p > .10$). However, milk fat percent and fat yield showed significant increases ($p < .05$). Both ECM and FCM were higher ($p < .05$) at the 56g level than both control and 14g. Milk SCC was numerically lower in cows receiving 14g/cow/d than other treatments. Supplementation of ZINPRO 4-PLEX indicated a mean decrease in days open of 12.5d and a mean decrease of 6.5d for days to first service for 14, 28 and 56g compared to 0g. In summary ZINPRO 4-PLEX increased kg of fat, percent fat, FCM and ECM, as well as decreasing days open and days to first service in lactating Holstein cows.

361 Microwave toe trimming Leghorn pullets and its effect on rearing performance. P.H. Patterson*, E.S. Lorenz, and R.M. Hulet, *Penn State University, University Park, PA.*

Previous research toe clipping day old Leghorn pullets reduced bird hysteria with no impact on feed consumption or BW to 16wk (Ruszler, 1974). Egg production was greater and mortality was reduced compared to control birds. Recently, toe trimming turkeys and broilers with a microwave technology has demonstrated reduced carcass tears and downgrading. Therefore, three Leghorn strains at 1d of age were banded and half the chicks/strain (n=75) were treated for 0.6 s with 2.45 ghz of microwave energy (NovaTech Engineering, Wilmer, MN) at the toenail cuticle of three toes/foot. The chicks were caged at 142 cm²/bird to 6wk of age. At 7d all birds were beak trimmed. At 6wk half the birds/cage were moved to a new cage increasing space to 284 cm²/bird to 18wk of age. Feed intake, BW, and mortality were recorded during the study. Within 24h after microwave treatment the chicks toenails turned white, and by 3d had sloughed off. BW at 1d, 6 and 18wk was significantly influenced by pullet strain. Microwave toe-trimmed pullets (TT) at 6 and 18wk weighed significantly less than control birds (437 vs 454g, and 1289 vs 1332g, respectively). Both strain, and treatment significantly influenced feed intake from 1d to 3wk of age. Control birds consumed 17.1^a g/bd/d compared to 14.8^b g for the TT during the same period. No significant strain, or treatment effect was observed for feed intake from 3 to 6wk of age. Initial mortality was high due to brooding challenges, but not significantly influenced by treatment or strain. Total mortality averaged 3.8% from 3 to 18wk. Body scratching was scored at 18wk of age with no scratching = 0 to severe = 4. Strain scores were significant, but low, ranging from 0.07 to 0.56. TT pullets had significantly more body scratches (0.39^a) than controls (0.24^b) although scores were low. Overall, microwave toe trimming of Leghorn pullets was associated with reduced feed intake, reduced body weight and greater body scratches than control birds. The impact on hen house performance is yet to be determined.

Key Words: Microwave, Toe, Trim

362 Drinking water treatment and dietary treatment effects on *Salmonella enteritidis* in Leghorn hens during forced molt. L.F. Kubena*¹, Y.M. Kwon¹, J.A. Byrd¹, C.L. Woodward², R.W. Moore¹, R.L. Ziprin¹, R.C. Anderson¹, D.J. Nisbet¹, and S.C. Ricke², ¹USDA-ARS, SPARC, *College Station, Texas/USA*, ²Texas A&M University, *College Station, Texas/USA*.

The layer industry uses feed deprivation to induce molting and stimulate multiple egg-laying cycles in laying hens. Unfortunately, the stress involved with this method of molting causes an increased susceptibility to *Salmonella enteritidis* (SE) under laboratory conditions and increases the risk of SE positive eggs and internal organs. There is the need for methods to stimulate multiple egg-laying cycles without the increased risk of SE. Studies were conducted utilizing Leghorn hens over 50 wk of age. The hens were divided into treatment groups of 12 hens each and placed in individual laying hen cages. One wk before water and feed changes, hens were exposed to an 8-h light and 16 h-dark photoperiod that was continued throughout the 9-day experiment. Individual hens in all treatments were challenged orally with 10⁴ cfu of SE on the fourth day. Treatments consisted of full-fed hens (non-molted, NM), non-fed hens (molted, M), M hens administered 0.25% lactic acid (LA) in the water, or hens fed a diet containing 10,000 mg zinc/kg (HZ). When compared with the NM treatment, weight losses were higher in the M, M + LA, and HZ treatments and water consumption was reduced. Crop pH and ovary weights were lower in the NM and HZ treatments, when compared to the M treatment. Cecal propionic acid and total volatile fatty acids were decreased in the M treatment when compared to the NM and HZ treatments. The number of crop and ceca culture positive hens and the numbers of SE per crop and per gram of cecal contents were higher in the M treatment, when compared to the NM and HZ treatments. This regimen or other dietary regimens may prove to be useful tools for reducing the incidence of SE in eggs and internal organs during and following molting of laying hens.

Key Words: *Salmonella enteritidis*, Laying hens-molting, Diets-zinc

363 Effect of dietary chitosan on production characteristics and egg proportions and quality from commercial white egg laying strains. K. E. Anderson*, G. S. Davis, and S. Hudson, *North Carolina State University.*

Chitin is considered the second most abundant organic resource on the earth next to cellulose, and it is derived from harvesting the waste of shellfish. Chitosan, a component of chitin, has been shown to exhibit hypocholesterolemic action and reduce cholesterol levels in rats, humans, and broiler chickens. A study was conducted to determine the effects of feeding Chitosan to egg laying hens on the egg production characteristics, quality, and proportions. The study was a randomized complete block design consisting of 4 dietary regimens. The regimens consist of the brood/grow (BG) and Layer phase (L): (1) no Chitosan fed during the BG and L (C); (2) 0.5% Chitosan fed during the BG but not in the L (TC); (3) no Chitosan fed during the BG but fed 0.5% in L (CT); (4) 0.5% Chitosan fed in BG and L (TT). The hens were placed in a layer house which contained 4 banks of tri-deck stair-step cages. Each bank of cages was designated as a block for a total of 4 blocks with 9 replicates per treatment, for a total of 882 hens per treatment. In the initial production period TT reduced yolk proportions and egg weight in contrast to the C by .89 and 3.2 g, respectively. The yolk cholesterol content was not different between any of the treatment groups. However, the cholesterol content (mg/g) of the yolk decreased from 15.2 to 12.3 mg/g as the hens aged. Feed consumption was lower (P<.05) by 0.4 kg in the birds fed Chitosan during the laying cycle. Production parameters were not effected by the feeding of 0.5% Chitosan in the diet. Egg size was shifted (P<.05) from X-Large to mediums. It was concluded that dietary Chitosan does not reduce cholesterol content on an equivalent basis but, can result in altered egg proportions and size distribution.

Key Words: Layers, Chitosan, Cholesterol

364 Effect of Termin-8[®] anti-microbial preservative on the growth of commercial white and brown egg type pullets and environmental microbial population. K. E. Anderson*¹, B. W. Sheldon¹, and K. E. Richardson², ¹North Carolina State University, ²Anitox Corp., *Lawrenceville, GA 30043.*

Farm to Table HACCP programs recommend that feed supplied to the layer industry must be free of microbial pathogens. Microbial pathogens in feed have the potential to be passed to the pullets resulting in the pullets becoming carriers of these organisms and subsequently passing the organisms onto their eggs during the production cycle. The objective of this experiment was to evaluate the feed treatment, Termin-8[®] to eliminate or reduce the microbial contamination of feed. This could benefit the layer by reducing competition in the digestive tract between indigenous and feed borne microorganisms attempting to colonize the small intestine, lowering the microbiological populations in the environment, and enhancing the pullet growth performance. The study utilized 14,976 pullets during the brood/grow period from 0 to 16 wks of age. Pullets were housed in a brood/grow facility with quad-deck cages divided into 4 rooms containing 72 replicates containing 52 birds each at a density of 310 cm² per pullet. Pullets in 2 rooms received rearing diets formulated with 2.72 kg/ton of Termin-8[®]. The pullets in the remaining 2 rooms received the same diets without Termin-8[®]. Each load of feed delivered to the farm was sampled and assayed for mold, total aerobic bacteria, enterobacteriaceae, coliform, *Salmonella* and Termin-8[®] concentration. Body weights and feed consumption data were collected from each replicate on a bi-weekly basis through 16 wks of age and environmental microbial sampling conducted every 4 wks. Treatment of the feed with Termin-8[®] resulted in a reduction (P<.05) of pullet body weight and lower overall feed consumption compared to the control. Mortality was also lower in the brown egg pullets receiving Termin-8[®]. Bacterial counts in the control and treated feeds averaged 3261 cfu/g and 413 cfu./g respectively over the course of the trial. The environmental microbial counts were altered in the rooms containing pullets on the Termin-8[®] supplemented feed. These results suggest that treating the feed with Termin-8[®] reduced microbial contaminants, which was associated with a subsequent positive impact on the pullets growth and feed consumption.

Key Words: Layers, Microorganisms, Termin-8[®]

365 Effect of a feed additive or manure treatment application on the mass generation rate of ammonia produced from laying hen manure. K.W. Koelkebeck*, P.C. Harrison, and G.L. Riskowski, *University of Illinois, Urbana, IL USA.*

An experiment compared the ammonia generation rate from laying hen manure that received an ammonia production inhibitor which worked systemically (through the feed) to a topically applied compound. Eighty-one mature laying hens (56 wk of age) housed in a cage layer facility were divided into three treatments with three replicates each. The treatments were: 1) control, 2) systemic (Micro-Aid[®] in the feed), and 3) topical (Al⁺ Clear[®] sprayed on the manure daily). The application rate of the topical ammonia inhibiting compound was evenly applied as a liquid spray (161.3 g/m²) daily. Hens in the systemic treatment had received the feed treatment for three months prior to the start of the experiment. These treatments were applied for two weeks and ammonia generation rate was measured at Day 1, 7, and 14 following the start of the experiment. The mean overall mass generation rate of ammonia for the two week period of manure collection was 67, 60, and 36 mg NH₃/hr/kg manure for the control, systemic, and topical treatments, respectively. Ammonia generation rate from manure on Day 1, 7, and 14 was the lowest for the topical treatment. Treatments had no effect on manure weight or moisture; however, when ammonia generation rate was compared on a dry weight basis for the 14-d evaluation, the systemic and topical treatments were 17 and 26% lower, respectively, than the control. Thus, these data indicate that the mass generation rate of ammonia production from laying hen manure may be depressed by using a topical manure treatment.

Key Words: Ammonia Generation Rate, Manure Treatment Application, Ammonia Production Inhibitor

366 Interaction of increased Ca and P regimens on commercial strains of layers housed at various densities. M.H. Fosnaught* and K.E. Anderson, *North Carolina State University.*

It is established that nutrient recommendations of layers vary with strain. As layers are being housed at lower density due to animal welfare concerns, nutrient requirements will also vary. Hens housed at lower density generally consume more feed and have greater egg production. Ca and P levels, critical for optimal layer health and production, should be considered in light of not only strain but stocking density. Therefore, two strains of hens were fed two levels of Ca and P while kept at two densities from 18-66 wks of age and evaluated for performance. This 2X2X2 factorial utilized 5,824 hens (14 reps/trt) which were housed in environmentally controlled, stair step cages. The two strains (Hy-Line W-36 (H) and Babcock 300 (B)) were fed two levels of Ca and P (constant Ca and P or control (C) and increasing Ca and P (CaP+)) while housed at two densities (low density (LD or 413 cm²/hen) and high density (HD or 310 cm²/hen) both at 4 birds/cage). Feed cons was measured every 4 wks and egg production daily. Strain and density affected ($p < .05$) most production parameters measured. The H strain compared to B had lower feed cons/100 hens (9.7 vs. 10.3 kg, $p < .01$) and lower hen day production (80.1 vs. 81.3 %, $p < .01$). The LD vs. HD showed lower feed cons/100 hens (10.4 vs. 9.5 kg, $p < .0001$) and higher hen day production (82.9 vs. 78.5 %, $p < .0001$). The finding of particular interest was a significant three-way interaction between strain, Ca and P, and density ($p < .05$). Hens responded similarly to the CaP+ regimen when kept at HD regardless of strain. However, if these hens were housed at LD then the H strain responded favorably to the CaP+ regimen while the reverse response was observed for the B strain. At LD, the H vs. B strain when fed CaP+ consumed less feed/100 hens (9.98 vs. 10.91 kg, $p = .05$), improved FE (.47 vs. .45 g egg/ g feed, $p = .05$), elevated eggs/hen housed (272 vs. 265 eggs, $p = .02$) and increased egg income (\$16.10 vs. \$15.64, $p = .04$). Reevaluating the need of layers for Ca and P when housed at lower stocking densities may be more strain dependent than previously realized. Therefore, as shifts are being made to lower density such as in many European production systems, further research may be necessary to determine optimal nutritional requirements of different strains.

Key Words: Layers, Calcium, Density

367 The effects of dietary protein and available phosphorus on production measures and nutrient excretion by egg-type hens from 21 to 36 weeks of age. R Reed*, J. Nixon, and M. Lilburn, *The Ohio State University/OARDC.*

From 21 to 36 weeks of age, commercial egg-type hens (Hyline W-36) were fed diets containing two levels of calculated available phosphorus (AvP; .25%, .42%) and two levels of dietary crude protein (CP; 14.9%, 16.5%). There were also two combinations of phytase supplementation (0, 300) for a total of 6 possible dietary treatment combinations. The experiment was broken down into four, 28-day production periods and all data was analyzed within each period. During the last week of each production period, feed intake was determined and excreta was collected for nutrient analysis. Egg production was recorded daily and all eggs were collected and weighed during the last week of each production period. These eggs were used for shell weight determination. There were no consistent treatment main effects (AvP, CP, Phytase) on feed intake but the low AvP treatment did result in significant increases in BW over the last 3 experimental periods. The low AvP level resulted in increased egg production over all 4 experimental periods whereas the high CP diets resulted in consistent increases in egg wt over all production periods. There were no other consistent main effects or significant two-way interactions. There were no consistent main effects on shell weight although supplemental phytase did significantly reduce shell wt during periods 2 and 3. Excreta P was significantly increased in all production periods with increased dietary AvP and there were no significant effects due to phytase supplementation. During the last production period, there was an AvP by phytase interaction resulting from less excreta P in the low AvP treatment supplemented with phytase. The high CP diets resulted in increased excreta N but there were no other main effects or interactions. It is important to note that while not significant ($P \leq .063 - .192$), there was a consistent increase in excreta P associated with the high CP diets, most likely due to the increased soybean meal necessary to achieve the higher levels of CP.

Key Words: Phytase, Phosphorus, Manure

368 The effect of claw and beak reduction on growth parameters and fearfulness of two Leghorn strains. C. N. Ferst*¹ and P. L. Ruzsler¹, ¹*Virginia Tech.*

Commercial equipment being used by the turkey industry reduces claw growth and trims the beak without physical invasion of body tissue. To test the effects of this technique on chickens, one-half of two strains of 1250 Leghorn chicks each were subjected to the claw reduction technique (CR) using microwave energy that kills the germinal cells at hatch. The other half retained normal claws (NC). The beaks of 1/3 of the chicks were reduced at hatch using an infra-red energy technique; one-third were precision beak trimmed at 7 days and one-third were not trimmed. Body weight, feed intake, mortality and fearfulness were measured weekly and biweekly until housing at 20 weeks in laying cages. Rearing followed standard commercial feeding and husbandry procedures using 10-20 lumens of light and fed *ad libitum* a 20% starter with 2926 kcal; 17% grower, and 15% developer with 2860 kcal/kg. Body weights were equal to or greater than breeder standards throughout the trial, being 2 weeks advanced at 16 weeks of age. There were no statistically significant differences between treatments in body weight. However, the chicks with beak reduction at 1 day of age experienced consistently lower body weight numerically from 3 to 14 weeks of age and also ate less total feed at the 0.08 level of significance by 14 weeks of age and thereafter. Mortality was less than 1.3% throughout the trial. Fearfulness was being expressed in the NC treatment by 5 days of age, continuing to a peak of 8-10 points at 6-8 weeks of age on a subjective scale of 1 (calm) to 10 (total fear). The CR treatment expressed a fearfulness level of only 3-4 points at 6-8 weeks. Expressed fearfulness later subsided to levels of 2-3 for CR and 6-8 for NC birds by 16-18 weeks. The larger body size of older birds filling the cage space appears to reduce the expression of fear. Reducing the claw growth and beak development during the growing period showed that pullets can be raised on less total feed and without the usual level of fearfulness by improving the environmental climate in the cage.

Key Words: Claw & Beak, Fearfulness, Body weight

369 Growth Response of a *Salmonella typhimurium* Poultry Isolate to Zinc Addition. S. Y. Park*¹, C. L. Woodward¹, S. G. Birkhold¹, L. F. Kubena², D. J. Nisbet², and S. C. Ricke¹, ¹Texas A & M University, College Station, Texas, USA, ²USDA-ARS, Food and Food Safety Research Unit, College Station, Texas, USA.

It has been shown that induced molting by complete feed withdrawal increases *Salmonella* horizontal transfer in laying hens and contamination in eggs. Zinc-containing diets have been used as an alternative means to induce molt in laying as a management while avoiding feed withdrawal. It is not known if the zinc in these molt diets would inhibit *Salmonella* spp. growth and therefore potentially minimize the *Salmonella* spp. infection in individual hens. The objective of this study was to examine the effects of zinc concentration on a primary poultry isolate of *Salmonella typhimurium* growth from either nutrient rich or minimal media after inoculation. zinc sulfate (ZnSO₄) concentrations (0.67%, 2.01%, 3.35%, 4.69%, and 6.03%) were added to either 5ml of tryptic soy broth (TSB) or M9 broth after inoculation of overnight fresh culture. The growth of *S. typhimurium* poultry isolate in individual tubes at 37 °C was measured by as optical density (A₆₀₀) on a spectronic 20D spectrometer. Growth rate was determined by linear regression of change in natural logarithm of A₆₀₀ during exponential growth. Growth rate of *S. typhimurium* poultry isolate was significantly (P<0.05) decreased by the presence of zinc sulfate in M9 at concentrations greater than 2.01%. Zinc added to M9 broth at the same concentrations was much less inhibitory to *S. typhimurium* poultry isolate growth rates. The results indicate that the higher concentrations of zinc addition may be effective by inhibiting *Salmonella* spp. growth.

Key Words: *S. typhimurium*, Molting, Zinc

371 Minimal available phosphorus requirement of molted laying hens. J.L. Snow*, M.W. Douglas, A.B. Batal, M.E. Persia, P.E. Biggs, and C.M. Parsons, *University of Illinois, Urbana, IL USA.*

In an effort to diminish excessive feeding of phosphorus, our objective was to determine the minimal available phosphorus (AP) requirement for hens being molted and kept for two egg production cycles. Six replications of Dekalb Delta hens were fed diets (17% CP, 3.8% Ca) containing 0.10, 0.12, 0.14, 0.16, 0.18, 0.20 or 0.45% AP starting at 21 wk of age. Diets containing 0.10, 0.12, and 0.14% AP were terminated at 35, 39, and 50 wk, respectively, due to low egg production and increased mortality. The remaining hens were then induced molted at 64 wk of age by 10 d feed removal. Following feed removal, three replications from each previous AP level were fed either a 100% corn (C) diet or a nutritionally complete (NC) molt diet (16% CP) for 16 d. The hens were then returned to the same AP layer diet they had been fed from 21 to 64 wk. Egg production performance will be measured from 68 to 110 wk of age, with data for only the 68 to 87 wk period being reported here. During the molt period, mean body weight loss at the end of the 10 d feed removal was 22%. As expected, hens fed the NC molt diet returned to egg production faster and had significantly higher body weight gains than birds fed the C molt diet. For the 68 to 87 wk postmolt period, hens fed the 0.16% AP (163 mg/d) diet had significantly lower egg production and egg mass yield compared to hens fed 0.45% AP (P<.05). Although there were no significant (P>.05) differences in egg production among the other treatments, egg production and egg mass yield were numerically lower (P≤.1) and mortality was higher for hens fed 0.18% AP (185 mg/d) versus those fed 0.45% AP. There were no significant differences in body weight or egg weight among any treatments. Our results suggest that molted hens in their second lay cycle require approximately 0.20% AP or 210 mg AP/d. This requirement is higher than what we determined in several previous experiments for first cycle, nonmolted hens.

Key Words: Available Phosphorous, Requirement, Molting

370 Use of an alfalfa diet for molting in Leghorn hens to reduce *Salmonella enteritidis* colonization and invasion. Y.M. Kwon*¹, L.F. Kubena¹, C.L. Woodward², J.A. Byrd¹, R.W. Moore¹, D.J. Nisbet¹, and S.C. Ricke², ¹USDA-ARS, SPARC, College Station, Texas/USA, ²Texas A&M University, College Station, Texas/USA.

The standard method for molting to stimulate multiple egg-laying cycles in laying hens is feed deprivation. However, the environmental changes within hens caused by feed deprivation are known to increase susceptibility of the hens to *Salmonella enteritidis* (SE) infection. In an effort to develop an alternative method to induce molting without increasing susceptibility to SE, an alfalfa diet was compared with the standard molting method for the level of molting and SE colonization. Hens over 50 wk of age were divided into three treatment groups (12 hens/group); non-molting by normal feeding (NM), molting by feed deprivation (MO), and molting by alfalfa diet (AD). The individual hens in all treatments were challenged orally with 10⁴ cfu of SE on the fourth day after feed changes, and analyzed for ovary weight and SE colonization or invasion in crop contents, cecal contents, liver, spleen, and ovary on the ninth day. In ovary weight, AD (4.8 g) was not different from MO (6.9 g) but was significantly lower (P = < 0.05) than NM (27.5 g), indicating the molting was possibly as successfully induced in AD as in MO. However, the total number of SE positive organs for all of the organs determined by enrichment technique was decreased in AD (10/60) as compared to MO (46/60), while no colonization was detected in NM (0/60). The trends of SE reduction in AD as compared to MO were consistent with all of the organs analyzed. Therefore, the results of this study suggest that an alfalfa diet has the potential to be used as an alternative method for forced molting, without increasing the incidence of SE in eggs and internal organs.

Key Words: *Salmonella enteritidis*, Laying hens-molting, Alfalfa diet

PSA Nutrition: Feed Regimens

372 The effect of various levels of vitamin E supplementation in the diets of laying hens on egg yolk alpha-tocopherol content and hen performance. R. C. Johnson*¹, J. C. Hermes¹, R. Kampen², and A. M. Craig¹, ¹Oregon State University, Corvallis, OR, ²BASF, Abbotsfort, BC, Canada.

Two experiments were conducted to determine the effect of high levels of vitamin E in the diet of laying hens on egg yolk alpha-tocopherol content and hen performance. In experiment 1, 192, 50+ week old hens were fed one of 12 experimental diets formulated to contain 5, 10, 15, 20, 25, 100, 200, 250, 350, 400, 550, or 700 IU/kg of alpha-tocopherol for 4 weeks. Hens were selected at random, housed in individual cages and separated into four replicate treatment groups with four hens per treatment (n = 16). Daily egg production was determined along with weekly analysis of body weight, egg weight, albumen height, yolk color and yolk alpha-tocopherol content. Only egg weight and yolk alpha-tocopherol showed significant differences between dietary treatments. In experiment 2, 96 laying hens, 33 wks of age, were allocated into groups and housed as in experiment 1. The diets were formulated to contain either 15, 250, 1000, 2000, or 3000 IU/kg of vitamin E. Data collected was similar to experiment 1. After consuming the diets during the four weeks of the trial, the hens produced average egg yolk alpha-tocopherol levels of 153, 356, 607, 684, 1549, and 1394 µg/g, respectively. Results with significant differences include egg weight (P<.002), albumen height (P<.002), yolk color (P<.0001), yolk weight (P<.01), and the number of eggs produced per diet (P<.021). In both experiments, the vitamin E level in the feed significantly increased the alpha-tocopherol content in the yolk (P<.05). No signs of alpha-tocopherol toxicity were noticed at necropsy following the experiment.

Key Words: Vitamin E, Egg vitamin content, Layers

373 Nutrient requirements of Hy Line W-36, Bovans White and a new strain of Bovans White hens for optimum profits during phase I. A. Bateman*¹, M. Bryant, and D. A. Roland, Sr., ¹Auburn University.

A study was conducted to compare performance and nutrient requirements of a new strain of Bovans White hen with the previous strain of Bovans White hen as well as Hy Line W-36 hens (weeks 21-36). Three

diets were used in each of the three strains for a 3 x 3 factorial arrangement. One diet was formulated based on protein (P-20) and contained 1.02% lysine and 18.70% protein, while two diets were formulated based on lysine which contained either 0.83% lysine and 16.19% protein (L-20) or 0.92% lysine and 17.34% protein (L-18). The criteria used were egg production, feed consumption, egg weight and egg specific gravity. Diet and strain of bird significantly effected ($p < 0.05$) egg production and egg weight. Both strains of Bovans had higher egg weight and production compared to the Hy Line W-36. Diet also had a significant effect on egg production and egg weight. Hens fed the P-20 diet had the highest egg weight and production, followed by the L-18 and the L-20. Feed consumption, egg specific gravity and feed conversion were significantly effected by strain. The old strain of Bovans had the highest feed consumption, followed by the new Bovans and the Hy Line W-36. The new strain of Bovans had the highest egg specific gravity and best feed conversion, followed by the old Bovans and the Hy Line W-36. Among the three strains, the most profits were obtained with the new strain of Bovans White. For optimum profits during phase I, the new Bovans required 998 mg lysine, 714 mg TSAA and 18.30 g protein per hen per day. These values are higher than the 690 mg lysine, 580 mg TSAA and 15 g protein per hen per day recommended by the National Research Council (NRC).

Key Words: Feed formulation, Bovans White, Profits

374 Feeding and management of Bovans White hens for optimum egg size and profits during phase I using warm temperatures. A. Bateman^{*1}, S. Yadalam, M. Bryant, and D. A. Roland, ¹Auburn University.

A study was conducted to determine the most economical nutrient (protein and lysine) level to feed during phase I (weeks 21-36) to optimize egg weight and profits when hens were exposed to warm temperatures (25.56°C average). Nine hundred and sixty 21-week old hens were randomly divided into six groups of 160 hens per group. Diets were formulated based on protein as well as lysine. The three diets formulated based on protein (0.90%, 1.02% and 1.17% lysine; 17.00%, 18.70% and 20.80% protein) each contained 2871 kcal ME/kg. The three diets formulated based on lysine (0.75%, 0.83% and 0.92% lysine; 14.98%, 16.19% and 17.34% protein) each contained 2834 kcal ME/kg. The criteria used were egg production, feed consumption and egg weight. Neither the diet or the method of formulation had a significant ($p > 0.05$) effect on any of the criteria other than egg weight. As the lysine (or protein) content of the diets increased, egg weight was significantly ($p < 0.05$) increased. Egg weight was also significantly ($p < 0.005$) higher in the diets formulated based on protein versus the diets formulated based on lysine. Egg production peaked at greater than ninety-five percent in birds in all treatments at 33 weeks of age, and remained over eighty-eight percent for the remainder of the study. Using an economic analysis, it was shown that for optimum profits Bovans White hens required 1,076 mg lysine, 750 mg TSAA and 19.1 g protein per hen per day during phase I. These values are higher than the 690 mg lysine, 580 mg TSAA and 15 g protein per hen per day recommended by the National Research Council (NRC).

Key Words: Feed formulation, Bovans White, Profits

375 Evaluation of non-feed removal versus feed removal methods for molting programs. P.E. Biggs^{*}, M.W. Douglas, K.W. Koelbeck, and C.M. Parsons, *University of Illinois, Urbana, IL USA.*

The objective of this study was to determine the effects of feed removal versus feeding high corn or wheat middlings diets as induced molting techniques. An experiment was conducted using 336 White Leghorn hens (60 wks of age) randomly assigned to one of four treatments that consisted of feed removal for 4 or 10 d or no feed removal with *ad libitum* access to 95% corn or 95% wheat middlings molt diets containing supplemental vitamins and minerals. At the end of the 4 or 10 d feed removal period, hens on these treatments were provided with the corn molt diet for 24 or 18 d, respectively. Hens on the corn or wheat middlings treatments were fed the diets for 28 d. At 28 d, hens on all treatments were fed a corn-soybean meal layer diet (16% CP). Both feed removal and the wheat middlings treatments resulted in total cessation of egg production within 8 d. Egg production of hens fed the corn molt diet had decreased to 3% by 28 d. Body weight loss for hens fed the corn or wheat middlings diets was approximately 9% at 28 d. Hens fed the

wheat middlings diet returned to production slightly faster than hens on the other treatments. Post-molt egg production (6 to 28 wks after initiation of the molt treatments) was generally higher for the wheat middlings and 10-d feed removal treatments than for the corn and 4-d feed removal treatments. Average feed intake for Weeks 2 to 4 during the molt period and Weeks 5 to 8 on the layer diet was highest ($P < 0.05$) for the wheat middlings treatment, with all other treatments being similar during these periods. No differences in feed intakes were observed among treatments after Week 8. There were no consistent differences in mortality, post-molt egg weight, egg specific gravity, and Haugh units among treatments. This research indicates that feeding high corn or wheat middlings diets, particularly wheat middlings, are effective non-feed removal methods for molting hens.

Key Words: Induced Molting, Feed Withdrawal, Laying Hens

376 The effect of midnight feeding on feed consumption and eggshell quality in commercial laying hens. A. Petruk^{*1}, D.R. Korver¹, R.A. Renema¹, and M.J. Zuidhof², ¹University of Alberta, ²Alberta Agriculture, Food, and Rural Development, Edmonton, AB, Canada.

The effect of allowing laying hens access to feed for 1 hour at midnight to prevent perturbations in eggshell quality and calcium status was investigated. Two trials were performed using 60 wk old SCWL Shaver 2000 hens (48 hens/experiment). Experiment 1: The hens were exposed to midnight feeding for 27 weeks prior to the study. Half of the hens ($n=24$) were allowed continued midnight feeding (MF treatment) while the other half ($n=24$) had their feeder removed at 2000h and replaced at 0500h to prevent overnight feed intake (CONT treatment). Experiment 2: Experimental conditions and treatments were as described in Experiment 1, except the hens had no prior exposure to midnight feeding. Daytime (0500h to 2000h), night (2000h to 0500h) and total daily feed consumption were recorded daily for each hen; BW was recorded weekly. All eggs were collected and shell quality assessed. Egg specific gravity, yolk weight, and dry shell weight were measured 3 times/wk. The MF hens in Experiment 1 gained more weight than CONT birds (MF, 49.30g; CONT, -15.52g) and relative gain was also higher (MF, 2.51%; CONT, -0.77%) with no differences in Experiment 2. Egg production did not differ in either study, although differences in total (MF, 26.87; CONT, 23.70) ($P = 0.0573$) and settable (MF, 26.61; CONT, 23.39) ($P = 0.0600$) egg production rates approached significance in Experiment 1. Egg weight, shell weight, specific gravity, and yolk weight showed no differences in either experiment. In Experiment 1 (prior exposure to midnight feeding) there were no treatment differences in daytime or total weekly feed consumption. In Experiment 2 (no prior exposure to midnight feeding) daytime consumption of the CONT hens was higher for every week of the study, demonstrating that MF hens had shifted their feeding patterns. Specific advantages of a midnight feeding program on shell quality or egg production were not demonstrated under the experimental conditions of this study.

Key Words: Midnight feeding, Feed consumption, Eggshell quality

377 Effects of commercial strain, dietary sodium bicarbonate level, or animal fat versus vegetable oil addition to feed on performance of caged White Leghorn laying hens from 36 to 48 weeks old in summer. L. R. Minear^{*1}, D. M. Hooe², and K. R. Cummings, ¹Southern States Cooperative, Richmond, VA, ²Hooe Consulting Service, Inc., Eagle Mountain, UT, ³Church & Dwight Company, Inc., Princeton, NJ.

About 6,336 caged White Leghorn hens, 36 wk of age, were used in a 12-wk trial to evaluate effects of strain (Hy-Line W-98, HYL; Bovans, BOV) and dietary treatments in a 2 x 5 factorial arrangement. Phase II diets were: 2.5% animal fat (AF) control basal (CON); CON basal with 0.3, 0.4, or 0.5% level of sodium bicarbonate (SB) in place of an equal amount of brewers grains, with corn and soy adjustment; or 2.5% vegetable oil (VO) feed. The practical corn-soy, brewers grains based diets contained BASF phytase, limestone, and oyster shell. All feeds were formulated to contain calculated potassium (K) and chloride (Cl) levels of 0.71% and 0.21%, respectively, whereas calculated sodium (Na) varied from 0.174% in CON to 0.261, 0.349, and 0.436% in the respective sodium bicarbonate diets. Dietary electrolyte balances, Na+K-Cl in mEq/100 g, were about 19.7 (animal fat or vegetable oil basal diets), 23.2, 24.4, and 25.6, respectively. There were 160 experimental (replicate) units with around 40 hens each (4 or less/conventional cage).

Stocking density was about 0.039 m²/hen. The study was conducted in Virginia from July through September. Significance was by LSD (T method) at P<0.05. The HYL layers had higher livability, feed/dozen eggs, egg weight, albumen weight, and wet shell weight, but lower hen-day egg production and yolk weight than BOV laying hens, with no differences in daily feed intake or egg mass output. The VO supplement tended to increase egg weight (P=0.18) and albumen weight (P=0.11) compared to AF addition. Increasing levels of SB increased feed intake, feed/dozen eggs, feed/kg egg, and yolk weight compared to CON. This increase in feed intake in summer with SB may be due to partial replacement of Cl by HCO₃ in blood lowering dietary "effective Cl" level (as increasing Cl depresses feed consumption based on previous research) or to additional Na increasing water intake and bird cooling, or both. Yolk weight increased from 16.8 to 17.1 g with 0 vs 0.3% SB when feed intake correspondingly increased from 97.2 to 98.7 g/hen/day, associated with +0.018 kg feed/dozen eggs and +0.010 kg feed/kg eggs. Dietary SB at 0.3 to 0.5% increased feed intake and yolk weight, with slight increases in feed per dozen or per kg of eggs in summer.

Key Words: Animal fat, Sodium bicarbonate, Vegetable oil

378 Evaluation of phytase release factors in broiler diets containing different levels of amino acids. W. Pan*, F. Yan, C. A. Fritts, and P. W. Waldroup, *University of Arkansas.*

In addition to its effects on release of phytate-bound P in poultry diets, phytase may release additional nutrients such as amino acids and carbohydrates making more energy available to the chick. However, the research supporting this additional nutrient release is inconsistent and controversial. A study was conducted in which a series of diets with minimum amino acid (AA) levels ranging from 85 to 115% of NRC (1994) recommendations were formulated 1) without consideration of the nutrients released by phytase; and 2) considering the nutrients released by 600 units/kg of phytase (Natuphos[®] BASF). Calcium and nonphytate P were at levels suggested by the NRC, also taking into consideration the release of these nutrients by phytase. Therefore performance should be equal on diets with and without phytase supplementation if the nutrients are released. Each diet was fed to six replicate pens of 25 male chicks maintained in litter pens. Body weight and feed conversion (FCR) were determined at 21 and 42 d. At 42 d tibia were taken from 5 birds per pen. The left tibia was ashed and the right tibia scored for incidence and severity of tibial dyschondroplasia (TD). Overall, performance of chicks fed diets with or without phytase did not differ significantly for any measurement. Performance was influenced by dietary AA level, and there was a significant interaction of AA level x phytase supplementation for BW and FCR with addition of phytase improving performance at some AA levels, depressing performance at other levels, and being equal at some levels. The AA levels significantly influenced the incidence and severity of TD. Tibia ash was not significantly influenced by AA levels or by phytase supplementation. These data suggest that the nutrient release factors might be used when supplementing diets with phytase but results may be highly variable.

Key Words: Phytase, Nutrient release, Amino acids

379 Effects of glycine and threonine supplementation on performance of broiler chicks fed diets low in crude protein. Qi Jiang*, C. A. Fritts, and P. W. Waldroup, *University of Arkansas, Fayetteville, AR.*

Reduction of crude protein by use of crystalline amino acids has been successful to a point but performance eventually declines. Previous work from our laboratory indicates that reducing CP in broiler starter diets below 20% adversely affects performance even though essential amino acids were more than 110% of NRC (1994) recommendations. In recent studies we determined that additional Gly but not Pro, Arg, or Glu improved performance on diets low in CP. The present study investigated the use of both Gly and Thr at levels in excess of NRC recommendations. Diets based on corn and soybean meal were formulated to contain from 16 to 24% in 2% increments. All essential amino acids were at 100% of NRC recommendations with lysine at 110%. Crystalline amino acids were added as needed. The treatments consisted of the five levels of CP, three additional levels of Gly (0, 0.2, 0.4%) and three levels of Thr (0, 0.2, and 0.4%) in all possible combinations. Each diet was fed to six pens of 6 male broiler chicks in battery brooders. Diets with 20% or less CP resulted in significant reduction in BW and feed conversion even though meeting all known amino acid requirements. Addition of Gly but

not Thr significantly improved BW, especially at the lower CP levels. However performance was still less than obtained on diets with 22 and 24% CP. These data suggest that other amino acids may be deficient in diets low in CP.

Key Words: Glycine, Threonine, Broilers

380 Efficacy of Ronozyme PTM liquid phytase and Natuphos[®] liquid phytase in broiler starter diets. J. Broz¹, A. Klunter¹, N.E. Ward*², and J.W. Wilson², ¹*Roche Vitamins, Basel, Switzerland,* ²*Roche Vitamins Inc., Parsippany NJ.*

Two similarly-designed experiments compared Ronozyme PTM Liquid (RL) and Natuphos[®] Liquid (NL) for broilers taken to 22 days of age. Day-old Ross chicks were fed a low phosphorus (P), mash, corn/SBM diet through day 8, after which the birds were allocated by weight to one of three diets: negative control (NEG; 0.51% total P, 0.76% Ca); RL, 500 FYT/kg in NEG; NL, 500 FTU/kg in NEG. Eight (8) replications/treatment (4 groups of males, 4 groups of females) were fed through day 22. Excreta was collected from days 14-17 to determine apparent P and calcium (Ca) retention.

There were no treatment x sex interactions (P>.05), thus data were pooled across sexes. Results for the second experiment mirrored those of experiment 1. Body weight and F/G (adjusted for mortality) were improved (P<.05) with both phytase sources, whereas mortality was unaffected (P>.05) by trt. P and Ca retention were increased (P<.05) by phytase treatments. P and Ca in excreta were decreased (P<.05) equally (P>.05) by the addition of either phytase source to the diet. For both experiments, 500 units phytase/kg diet from either source were found to be equivalent for all variables tested.

Variable	NEG	RL	NL
Phytase, analyzed units/kg	-	618	665
Body wt. gain g/bird	477 ^b	501 ^a	512 ^a
F/G	1.564 ^a	1.526 ^b	1.509 ^b
P-retention g/bird/day	0.157 ^b	0.183 ^a	0.194 ^a
Ca-retention g/bird/day	0.231 ^b	0.279 ^a	0.294 ^a

381 An evaluation of Ronozyme PTM CT in broiler diets in a 36-day floorpen study. J. Broz¹, A. Klunter¹, N.E. Ward*², and J.W. Wilson², ¹*Roche Vitamins, Basel, Switzerland,* ²*Roche Vitamins Inc., Parsippany NJ.*

This 36-day floorpen study was designed to compare two commercial sources of dry phytase in a corn/SBM diet. Ronozyme PTM CT (RCT) was added to provide 500, 750 and 1,000 FYT/kg feed, while Natuphos[®] G (NG) was added at 500 FTU/kg diet. All treatments were cold-pelleted to minimize destruction of NG. Each treatment was replicated 8 times with 20 birds/replication (4 groups of each sex). The negative control (NEG) diet, to which each phytase treatment was added, contained 0.51% total P and 0.83% Ca. A positive control contained 0.61% total P and 0.91% Ca.

There were no (P>.05) treatment x sex interactions, thus all groups were pooled for data evaluation. Analyzed phytase values post-pelleting were in agreement with target values, excepting RCT 1,000 FYT/kg, which appeared erroneous based on actual addition rate. Supplementation of phytase increased (P<.05) body weights and feed intake over that of NEG, but no difference (P<.05) was noted across phytase source. F/G of RCT (750 FYT/kg) was improved (P<.05) over that of NG (500 FTU/kg), while no difference existed within RCT levels. Mortality was unaffected (P>.05) by treatment. Day 36 tibia ash did not differ (P>.05) across phytase level or source, but the addition of phytase increased (P<.05) bone ash over NEG. Over a 36-day period, the two sources of phytase at 500 units/kg were not different (P<.05) for any variable tested, although there was a tendency for RCT to more favorably influence F/G.

Variable	NEG	RCT-500	RCT-750	RCT-1000	NG-500	POS
Analyzed phytase, units/kg	140	479	734	787	516	111

382 Reassessment of Trypsin Inhibitor Activity in Guar Meal. S.R. Conner*, A.L. Cartwright, and C.A. Bailey, Texas Agricultural Experiment Station.

Guar (*Cyamopsis tetragonoloba*) is a drought resistant annual summer legume grown primarily for its galatomannan polysaccharide gum. In the separation of the gum containing endosperm, two distinct fractions are obtained. The first fraction from the splitting of the guar bean has higher germ content and the second fraction removes the hull from the remaining gum containing endosperm. A third fraction results from a combination of the two fractions. Although guar meal can be used as a source of vegetable proteins in animal feeds, a major impediment to protein digestibility is commonly attributed to a trypsin inhibitor. Defatted raw soybeans, dehulled soybean meal and three guar fractions evolved from various stages of guar gum production were assayed for trypsin inhibitor activity using the American Oil Chemists' Society official method Ba 12-75. Results indicated that the trypsin inhibitor

activity of the raw guar beans, guar splits (gum), and the three guar meal fractions were substantially less than the trypsin inhibitor activity of heat treated dehulled soybean meal. Trypsin inhibitor activity is likely not the significant impediment to protein utilization in guar meal.

Key Words: Guar, Guar meal, Trypsin inhibitor

383 Immobilization of Keratinase-Streptavidin Fusion Protein for Keratinolysis. J.C.H. Shih* and J.-J. Wang, North Carolina State University, Raleigh, NC USA.

Keratinase, produced from *Bacillus licheniformis* PWD-1, is capable of hydrolyzing chicken feather keratin. Immobilized keratinase has many potential applications, including the conversion of ground feathers to soluble protein, peptides and amino acids. A biotechnology for keratinase immobilization has been developed. Fusion genes of keratinase (KER) and streptavidin (STP) were genetically constructed. Transformed *B. subtilis* and *E. coli* expressed and produced the bifunctional fusion protein, KER-STP. Isolation and immobilization were achieved by mixing a biotinylated solid matrix with the *B. subtilis* medium or the *E. coli* lysate. Since the fusion protein was produced intracellularly in the inclusion body of *E. coli*, the extraction and renaturation from the cell lysate were laborious and consequently caused a low yield. *B. subtilis* produced and secreted the fusion protein that can be readily immobilized from the medium. The properties of immobilized keratinase-streptavidin fusion protein were characterized. Heat stability, durability, and pH tolerance were found greatly improved. Kinetic parameters of immobilized keratinase, including V_{max}, K_m, and k_{cat} toward the peptide substrate were also determined and compared with the free enzyme. Hydrolysis of three different substrates, insoluble feather keratin, soluble α-casein and bovine serum albumin (BSA) were carried out and analyzed by HPLC. It is interesting to note that keratinolysis by both immobilized and free keratinase produces a characteristic soluble protein with a molecular weight of 18 kDa. (Patent application pending)

Key Words: feather keratin, keratinase, enzyme immobilization

PSA Physiology

384 Performance and Thermo Tolerance of Broilers as Affected by Genotype and Ambient Temperature. H. A. Al-Batshan* and E. O. Hussein, King Saud University, Riyadh, Saudi Arabia.

This experiment was conducted to evaluate the effects of genotype (GT) and ambient temperature (AT) on subsequent performance and body core temperature (CT) of broiler chicks. A factorial arrangement of two GT (Hubbard and ISA) and two rearing AT (either under 33 C and then AT was reduced to 23 C by wk 4, or under constant AT of 33 C throughout the trial) was used in this study. Diurnal CT was monitored continually (2 min intervals) for 4 days using a biotelemetric system at six weeks of age. Results showed that weight gain and feed intake were significantly increased but feed:gain ratio was significantly decreased for Hubbard chicks compared to those of ISA chicks. High AT significantly reduced weight gain and feed intake. There was significant GT by AT interaction for weight gain, revealing that Hubbard chicks were more affected by high AT. Ambient temperature and GT significantly affected CT. Moreover, core body temperature of ISA chicks was significantly higher at the moderate ambient temperature but was significantly lower at the high ambient temperature than those of Hubbard chicks, which resulted in significant GT by AT interaction. The results of this study indicated that chicks with higher growth potential are more susceptible to heat stress.

Key Words: Broilers genotype, Ambient temperature, Diurnal body temperature

385 Changes in Growth and Function of Chick Small Intestine Epithelium Due to Heat Exposure Conditioning. Zehava Uni*¹, Orit Gal-Garber¹, Assaf Geyra¹, David Sklan¹, and Shlomo Yahav², ¹Faculty of Agriculture, Department of Animal Science, The Hebrew University of Jerusalem, Israel, ²Institute of Animal Sciences, ARO, The Volcani Center, Bet-Dagan, Israel.

The effect of exposure to heat at 3 d of age on small intestine functionality and development was assayed by measuring villus size, proliferating enterocytes, and brush-border membrane enzyme expression and activity. Results showed that thermal conditioning caused an immediate effect characterized by lowered triiodothyron (T3) level, reduced feed intake, and depressed enterocyte proliferation and BBM enzyme activity. A second series of effects, observed 48 h posttreatment, was characterized by elevated T3, increased feed intake, increased enterocyte proliferation, and higher expression and activity of BBM enzymes. The association between ambient temperature, feed intake, growth rate, and plasma T3 levels was reflected in the structure and function of the intestinal tract. The results suggest that thermal conditioning at an early age influences T3 concentrations, which in turn alters the intestinal capacity to proliferate, grow and digest. However, these experiments were not able to separate between the effects due to feed intake from those due to thermal conditioning. These changes modulate the intestinal tract for compensatory growth commencing 48 h postthermal treatment.

Key Words: Heat, Small intestine, Chicks

386 Origin of thermal-load induced adaptations in intestinal hexose absorption: heat stress or reduced food intake? M.A. Mitchell*¹, R.R. Hunter¹, M. Moreto², C. Garriga², M. Mitjans², C. Amat², and J.M. Planas², ¹Roslin Institute, Roslin, Midlothian, UK, ²University of Barcelona, Barcelona, Spain.

Previous studies demonstrated increased expression of SGLT-1 transporters in the brush border membranes of enterocytes from chronically

heat stressed chickens. This adaptation may be attributable to the prolonged heat stress per se and/or to the reduced food intake associated with chronic exposure to elevated thermal loads. The present study attempts to dissociate the effects on intestinal function and structure of heat stress and inanition by means of paired feeding. Groups of 8, four week old, female broiler chickens were exposed to thermoneutral (TN; 20C, 50% Relative Humidity) or heat stress (HS; 30C, 70% R. H.) conditions or TN with paired feeding (PF) for 14 days. Food intake was determined daily. Pair fed birds received the amount of food consumed by the heat stress group on the previous day. Body weights and deep body temperatures were monitored throughout the experimental period. Blood samples were taken for hormone analysis (T4, T3, and glucagon). At the end of exposure birds were killed and jejunal segments removed for tissue morphology and assessment of the abundance of the glucose transporters SGLT-1 (brush border membrane - phloridzin binding) and GLUT-2 (basolateral membrane - cytochalasin B binding) and characterization of the transport kinetics of alpha-methyl-D-glucoside in brush border or basolateral membrane vesicles. HS increased phloridzin binding by 54% ($p < 0.05$) and V_{max} for the hexose transport by 55% ($p < 0.05$) in the brush border preparation with no effect upon K_m for active transport or diffusive uptake (K_d). PF had no effect upon binding or transport kinetics. No influence of either treatment (HS or PF) upon cytochalasin binding or hexose transport kinetics was observed at the basolateral membrane. Plasma T3 was reduced in heat stress but T4 and glucagon were unaffected by the treatments. The adaptations in intestinal absorptive function observed during prolonged exposure to elevated thermal loads result directly from the heat stress and not from reduced food intake. The physiological signals mediating this response may include alterations in endocrine and paracrine activity.

Key Words: intestinal absorption, heat stress, chicken

387 Assessment of densitometry to measure bone mineral content and density in live birds as a tool for monitoring osteoporosis in laying hens. M.A. Schreiweis*¹, J.I. Orban², M.C. Ledur³, and P.Y. Hester¹, ¹Purdue University, W. Lafayette, IN, ²Southern University, Shreveport, LA, ³Embrapa Swine and Poultry Research Center, Concordia, SC, Brazil.

Osteoporosis, or loss of structural bone, may be induced by a high rate of lay, demand for calcium during eggshell formation, and limited exercise of birds in caged system. The objective of the current study was to determine the accuracy of bone densitometry as a non-invasive tool for monitoring bone integrity in an egg-laying strain of birds. Bone mineral content (BMC) and bone mineral density (BMD) of the right leg (tibia and fibula) and wing (humerus) bones were determined in 10 adult White Leghorn hens, 75 wk of age, using a Norland pDexa X-ray bone densitometer (Model # 476D014). The scans of respective bones were conducted in live, unanesthetized birds. Following live scans, birds were euthanized, and the humerus and tibia/fibula bones were excised and scanned in the same orientation as the previous live bird scan. The medullary tibia from live bone scans had significantly greater BMD ($0.249 \pm 0.022 \text{ g/cm}^2$) than the pneumatic humerus ($0.166 \pm 0.025 \text{ g/cm}^2$, $P < 0.0001$). The BMD and BMC of excised bones were strongly correlated with live scans ($r = 0.97$ and 0.99 , respectively). Variation in BMD among live scans of the 10 hens occurred as indicated by CV of 9% for the tibia and 15% for the humerus. In a subsequent experiment, live scans of 35 pedigree Hy-Line White Leghorn pullets, 15 wk of age, showed CV among birds of 7% for BMD in both the humerus and tibia. The BMD for tibia and humerus were 0.132 ± 0.010 and $0.110 \pm 0.008 \text{ g/cm}^2$, respectively ($P < 0.0001$). In Hy-Line birds 17 wk of age, the BMD and BMC of 10 excised bones did not differ from respective bones of live scans performed in situ ($r = 0.91$ and 0.99 , respectively). These preliminary data suggest that variation derived from densitometric scans of live birds may serve as a non-invasive tool for genetically selecting against osteoporosis.

Key Words: Bone density, Laying hen, Osteoporosis

388 Matrix metalloproteinases in turkey bile. N. C. Rath*, G. R. Huff, W. E. Huff, and J. M. Balog, PPSR/ARS/USDA, Fayetteville, AR.

Matrix-metalloproteinases (MMPs), gelatinases, interstitial collagenases, stromelysins, and membrane-type MMPs, are endopeptidases

which breakdown extracellular matrix (ECM) components such as collagens and proteoglycans. The MMPs are involved in a variety of physiological functions such as tissue remodeling, angiogenesis, wound healing, and immune regulation. We found that turkey bile contains substantial gelatinase, collagenase, and stromelysin-like activities using gelatin, collagen, and casein zymography, and ³H labeled collagen degradation assays. The intact bile showed at least five major gelatinolytic bands corresponding to approximate MW 64 kDa, 60 kDa, 46 kDa, 40 kDa, and 36 kDa. Organomercurial compounds, p-aminophenylmercuric acetate and thimerosal, which facilitate transformation of proMMP to MMP, caused conversion of the 64 kDa band to the 60 kDa and the 46 kDa to the 40 kDa forms, respectively. The 64 kDa and the 60 kDa bands showed collagenolytic activities whereas the caseinolytic (stromelysin) activities appeared as diffuse bands corresponding to MW of approximately 60 kDa, 40 kDa, and 36 kDa. The bile enzymes showed both a time and a concentration dependent increase in the degradation of ³H-collagen which could be inhibited by EDTA, phenanthroline, and GM 6001 (the MMP inhibitors) but not by serine and cysteine protease inhibitors like phenylmethylsulfonyl fluoride and leupeptin. The 60 kDa and the 40 kDa gelatinase showed affinity adsorption to a gelatin-agarose matrix. The physiological functions of biliary MMPs are not clear. However, in most carnivorous and omnivorous birds there is a need to digest animal tissue proteins consisting of fair amounts of collagens and other ECM proteins in their native forms, therefore, MMPs may be involved in the digestion and denaturation of these proteins which may otherwise be resistant to conventional proteinases such as pepsin, trypsin, and chymotrypsin. These data provide evidence which suggests that biliary MMPs may be involved in the digestive process of birds.

389 Development of the indicator amino acid oxidation technique for measuring amino acid requirements in chickens. H. Y. Tabiri*, R. O. Ball, R. Bertolo, and D. R. Korver, University Of Alberta, Edmonton, AB, Canada.

The indicator amino acid oxidation (IAAO) technique is being adapted for use in chickens as a rapid and sensitive method to determine amino acid (AA) requirements. During IAAO, Phe oxidation decreases, inversely to the change in protein synthesis, as limiting AA intake increases from deficient to adequate. In IAAO, the plateau in breath ¹⁴CO₂ during continuous infusion of labeled phenylalanine (Phe) is used to measure Phe oxidation. Plateau is reached when the ¹⁴CO₂ recovered from breath becomes constant as verified by linear regression. Bicarbonate retention factor (BRF) must be determined to correct for ¹⁴CO₂ that is not recovered in the breath. Metabolic chambers were constructed and calibrated to ensure 100% recovery of ¹⁴CO₂ liberated from NaH¹⁴CO₃. A surgical procedure was established to ensure long-term patency of jugular catheters. Male broiler breeders were surgically implanted with venous catheters, placed in the chambers and infused with NaH¹⁴CO₃. Breath ¹⁴CO₂ was recovered; BRF was 13.12% of infused dose. For the determination of Phe oxidation a bolus of ¹⁴C-Phe ranging from 4.5 to 7 $\mu\text{Ci/kg}$ was used to determine the correct priming dose for the Phe pool. A constant infusion dose was maintained at $3.5 \mu\text{Ci/kg}^{-1}$ for ratios of continuous infusion to priming doses of 1.29, 1.57 and 2.00. At a ratio of 1.57, breath ¹⁴CO₂ attained a plateau between 30 and 60 min after initiation of continuous infusion and remained constant for the next 3 hours. Phe oxidation at plateau was found to be 4.66% (uncorrected for BRF) and 5.27 % (corrected for BRF) of the infused dose. The % Phe dose oxidized is sufficient to be sensitive to changes in AA intake, making it suitable for the determination of AA requirements in chickens using the IAAO technique. This is the first study to our knowledge to determine BRF and Phe oxidation, from primed, constant infusion rate methodology, in chickens. The methods established in the present study will be used to estimate AA requirements in poultry.

Key Words: Indicator Amino Acid Oxidation Technique, Amino Acid Requirements, Bicarbonate Retention Factor

390 Dietary protein regulates in vitro lipogenesis and lipogenic gene expression in broilers. R. W. Rosebrough*, S. M. Poch, B. A. Russell, and M. P. Richards, ARS, Beltsville, MD.

The purpose of this experiment was to determine the possible relationship between certain indices of lipid metabolism and gene expression in chickens fed graded levels of dietary crude protein. Male, broiler chickens growing from 7 to 28 days of age were fed diets containing 12, 21 or

30% protein ad libitum. In addition, another group of birds was feed on a regimen consisting of a daily change in the dietary protein level (12 or 30%). This latter group was further subdivided such that one-half of the birds received each level of protein on a particular day. Birds were sampled from 28 to 30 days of age. Measurements taken included *in vitro* lipogenesis (IVL), hepatic enzyme activities and gene expression of these enzymes and thyroid hormones. *In vitro* lipogenesis was determined by incubating liver explants for 2 h at 37 C in Hanks salts containing 25 mM HEPES and 10 mM [2-¹⁴C]acetate. *In vitro* lipogenesis and ME activity were inversely related ($P < 0.01$) to dietary crude protein levels (12 to 30%) and by acute changes from 12 to 30%. In contrast, ME, FAS and AcCBX message expressions were constant over a dietary protein range of 12 to 21%, but were decreased ($P < 0.01$) by a 30% protein diet (acute or chronic feeding). Increasing dietary crude protein increased ($P < 0.01$) the activities of both AAT and ICD. Results of the present study demonstrate a continued role for protein in the regulation of metabolism in the broiler chicken. It should be pointed out, however, that metabolic regulation at the gene level only occurs with very high levels of dietary protein.

Key Words: Lipogenesis, Gene expression, Metabolism

391 Metformin decreases feed intake and induces hypoglycemia in broiler chicken. C.M. Ashwell^{*1} and J.P. McMurtry¹, ¹Growth Biology Laboratory, USDA-ARS, Beltsville, MD.

The bi-guanide metformin is used to treat non-insulin dependent diabetes in obese patients. In addition to having anti hyperglycemic effects, metformin is also anorectic and reduces body weight. These studies were performed to determine if metformin possesses similar properties in chickens. Metformin HCL was administered to 14-day old broiler chickens at either 300 or 600 mg/kg/day in the drinking water for 10 days while monitoring body weight and feed intake. No changes in water intake were observed, while feed intake and daily gains were only significantly reduced by the 600 mg/kg dose. After oral administration of a single dose of 300 mg/kg metformin HCL, feed intake was significantly reduced ($p = 0.011$) by 4 hours and remained suppressed for greater than 24 hours relative to controls. Plasma hormones and metabolites (glucose, lactate, insulin, glucagon, IGF-I, IGF-II, uric acid, NEFA, triglycerides, and cholesterol) were monitored at 1, 2, 3, 6, and 24 hours post treatment. Significant and acute decreases in blood glucose, insulin, and triglycerides were observed at 3 hours post treatment as compared to controls. Opposing acute increases in glucagon, IGF-II, and NEFA levels were also observed at 3 hours, followed by an increase in uric acid 6 hours post treatment. These observations suggest that metformin induces metabolic changes in birds, similar to that observed in mammals. Metformin may be useful in glucose metabolism studies by inducing hypoglycemia, a condition rarely observed in birds

Key Words: Feed Intake , Hypoglycemia, Broiler

392 *In ovo* and post-hatch administration of peptide YY (PYY) does not affect growth and feed conversion in Cobb X Cobb broiler chickens. B.A. Coles, J. Croom*, J. Brake, and L.R. Daniel, North Carolina State University, Raleigh, NC USA.

In ovo PYY administration at e18 increased 7 d but not 21 d or 42 d BW and adjusted feed conversion ratios (AFCR) in Ross male x Cobb female broilers (Coles et al., 1999). The present study was conducted to investigate whether post-hatch administration of PYY prolonged the positive effects of *in ovo* PYY administration on growth and feed conversion. On e18, Cobb x Cobb eggs were randomly divided into two treatment groups and 100ml of either 1.025% saline (control) or 1.025% saline plus 600 µg PYY/kg egg weight was injected into the air space. At hatch, birds (n = 1280) were sexed, wing-banded and randomly placed in 64 pens within a grower house (16 pens/house quarter, 4 reps/quarter, 20 birds/pen). Water and feed was offered *ad libitum*. Birds and feed were weighed on a pen basis at placement and 1, 2, 3, and 6 wk. At 1 wk, birds were weighed and administered either saline (control) or saline plus 600 µg PYY/kg BW s.c. No further injections were given beyond week 1. Growth data were statistically analyzed with treatment, sex and pen position (house block quadrant) as main effects using the GLM procedure of PC-SAS. At the completion of the study, 8 males per treatment were euthanized and intestinal length, weight and jejunal glucose uptake measured. There was a significant PYY x sex interaction in BW at hatch. Control females were heavier than females from PYY treated

eggs at hatch ($p = .04$, 39.65 g vs 39.05 g, respectively). This difference was not present at 1, 2, 3, and 6 wk. Both total intestinal length and intestinal length adjusted for BW were greater in PYY treated males at 6 wk as compared to controls ($p = .004$, .446 vs .380 per g BW, respectively). These data support previous observations of PYY's hypertrophic effect on the intestines. They do not confirm earlier reports of PYY's ability to enhance intestinal glucose absorption or post-hatch growth in poultry. These data suggest major genotypic effects on PYY's biological activity in broilers.

393 Mitochondrial Function and Feed Efficiency in Broilers. W. Bottje^{*1}, Z. Tang², M. Iqbal¹, D. Cawthon¹, T. Wing³, and M. Cooper³, ¹Dept. of Poultry Science, University of Arkansas, Fayetteville, AR 72701, ²Dept. of Veterinary Pathophysiology, South China Agricultural University, Guangzhou 510642, PRC, ³Cobb-Vantress Inc., Siloam Springs AR 72761..

The objective of this study was to determine relationships of mitochondrial function with feed efficiency (FE) in broiler males. Between 5 and 6 wk, FE was determined in 100 broiler breeder males. Birds with high (0.83 0.01, n = 7) and low (0.64 0.01, n = 7) FE were selected for mitochondrial studies. As feed intake did not differ ($P > 0.50$) between groups ($P > 0.50$), differences in FE were due to greater body weight gain ($P < 0.05$) in the high FE broilers. Mitochondria were isolated from individual birds by differential centrifugation. The respiratory control ratio (RCR, an index of respiratory chain coupling) was higher in breast and leg muscle mitochondria in the high FE group; due primarily to a lower state 4 (resting) respiration. Additionally, breast muscle mitochondrial hydrogen peroxide generation (an index of electron leak) was; a) higher in low FE breast muscle mitochondria, and b) magnified in low FE mitochondria by inhibition of electron transport by rotenone and antimycin A (at Complex I and III, respectively) indicating sites of electron leak from the respiratory chain. Complex I and II activities were higher in high FE than in low FE mitochondria. High FE mitochondria exhibited a much smaller ratio of Complex I to Complex II activities than did low FE mitochondria. Positive correlations were observed between feed efficiency and RCR and Complex activities. The results indicate that low FE was associated with a) lower RCR, b) higher electron leakage, and c) lower activities of respiratory chain Complex I and II activities compared to high FE mitochondria. The findings provide insight into cellular mechanisms associated with feed efficiency in broilers.

Key Words: Mitochondria, Feed Efficiency, Broilers

394 Cardiac energy metabolism slow and fast growing chickens. A.A. Olkowski* and H.L. Classen, University of Saskatchewan, Saskatoon, SK, Canada.

The present study compares the activity of cytosolic enzymes involved in energy synthesis, Creatine Kinase (CK) and Lactate Dehydrogenase (LDH), in left (LV) and right (RV) ventricular myocardium of fast growing broilers (susceptible to heart failure), and slow growing leghorns (resistant to heart disease). Within the category of broilers, comparisons are made between feed restricted, slow growing birds (low incidence of heart failure and ascites), fast growing birds fed ad libitum (high incidence of heart failure and ascites), and broilers with ascites. Overall, the activity profile of CK was lower ($P < 0.01$) in broilers in comparison to leghorns in both LV and RV, but the differences in the activity of the CK system among slow growing, fast growing, and ascitic broilers were only marginal. Total LDH activity was lower ($P < 0.01$) in slow growing broilers in comparison to leghorns. The total activity of LDH was 21, 15, and 9% higher in LV than in RV in leghorns, slow growing broilers, and fast growing broilers respectively, but not in ascitic broilers. There were no differences in total LDH activity in RV in fast growing and ascitic chickens in comparison to leghorns, but relative to leghorns the total LDH activity in LV was approximately 28% lower in slow growing broilers, and 20% lower in fast growing and ascitic broilers (both $P < 0.01$). This indicates that the metabolic demand for catalytic activity of LDH is higher in LV than in RV, and that broilers, in particular, may have insufficiency of LDH activity in LV. Considering that CK and LDH activities are generally lower in broilers in comparison to leghorns, it appears that the energy metabolism capacity may be insufficient in broilers. Inadequate activity of these enzymes may limit the ability of the cardiac muscle to increase its contractile performance during rapid

growth or in response to cold stress. From the present results it appears that, in comparison to leghorns (resistant to heart failure), fast growing broilers (susceptible to heart failure) in general have lower cardiac energy reserve.

Key Words: broiler, energy metabolism, heart failure and ascites

395 Investigation of Proton Conductance in Liver Mitochondria of Broilers with Pulmonary Hypertension Syndrome (PHS). D. Cawthon*, M. Iqbal, J. Brand, and W. Bottje, *Department of Poultry Science, Univ. of Arkansas, Fayetteville AR 72701.*

We have observed mitochondrial dysfunction associated with PHS in broilers that includes increased oxygen radical production. Proton leak or conductance (the futile cycling of protons across the inner mitochondrial membrane) can account for at least 20% of mitochondrial O₂ consumption. The objective of this study was to determine if proton conductance differs in Control and PHS liver mitochondria. Liver mitochondria were isolated from broilers with PHS and from healthy Controls. PHS mitochondria had a lower respiratory control ratio than did Controls. Membrane potential and O₂ consumption were determined simultaneously by monitoring the distribution of the lipophilic cation (triphenylmethylphosphonium [TPMP]) with an ion-sensitive electrode and a Clark electrode, respectively (see Brand, 1995. Ch. 3 Bioenergetics IRL Press, Oxford). Mitochondria were treated with nigericin to dissipate the H⁺ gradient to enable membrane potential to be determined without concomitant changes in H⁺ concentration across the membrane. Proton conductance was assessed by following changes in TPMP⁺ as state 4 respiration was slowed with sequential additions of malonate. The results indicated that at any particular high membrane potential, the PHS mitochondria respired more slowly than Controls. This is the classic demonstration of a lower proton conductance in PHS mitochondria. The lower proton conductance may account for the increased oxygen radical production we have previously observed in PHS mitochondria. These findings help define the nature of mitochondrial dysfunction in broilers with PHS. (Supported by USDA-NRI #99-02123 to W. Bottje.)

Key Words: Pulmonary Hypertension Syndrome, Liver Mitochondria, Proton Conductance

396 Tissue and Mitochondrial Antioxidant Enzyme Activities in Broilers with Pulmonary Hypertension Syndrome (PHS). M. Iqbal*, D. Cawthon, R. Wideman, Jr., and W. Bottje, *Department of Poultry Science, Univ. of Arkansas, Fayetteville, AR 72701.*

Oxidative stress plays a role in the etiology of PHS in broilers. The objectives of this study were to determine if antioxidant enzyme activities a) are altered by PHS and/or high dietary vitamin E (VE), and b) differ in broilers genetically selected (S) or not selected (NS) for PHS resistance. In these studies, broilers were raised in cold temperatures to induce PHS. In Exp. 1, broilers were fed diets with 15 and 100 IU α -tocopherol (VE) per kg. Enzyme activities were determined spectrophotometrically using established procedures that were adapted for microtiter plate analyses. In Exp. 1, PHS lung mitochondria exhibited oxidative stress (lower α -tocopherol, reduced glutathione [GSH] and higher oxidized [GSSG] to reduced GSH ratio) that was associated with higher GSH peroxidase (GSHPx) and lower GSH reductase (GSHRed) activities compared to Controls. Liver γ -glutamyl cysteine synthetase (gGCS), the rate limiting enzyme in GSH synthesis was unaffected by

PHS or high VE. In liver, high dietary VE lowered GSHPx but had no effect on GSHRed or gGCS activities. In Exp. 2, GSHPx activity was higher and GSHRed lower in lung mitochondria obtained from NS compared to S broilers. The lower GSHRed activity corresponded to a higher GSSG/GSH ratio. Whereas there was no differences in liver GSHPx and GSHRed activities, liver gGCS activity was lower in livers obtained from NS compared to S broilers. The results indicate that activities of antioxidant enzymes are altered by PHS, presumably in response to the oxidative stress present in these birds. Modulation of antioxidant activities by high VE was observed in liver tissue. Higher gGCS in the liver birds genetically resistant to PHS could be important in overall antioxidant status of these birds. (Supported by USDA-NRI #99-02123 to W. Bottje.)

Key Words: Pulmonary Hypertension Syndrome, Antioxidant Enzymes, Broilers

397 Effects of dietary sodium chloride, sodium sesquicarbonate, or ammonium chloride, in various combinations and levels, on ascites susceptibility of young broiler chickens in a cool environment at simulated high altitude (17% oxygen). R. G. Teeter*¹, J. H. Swartzlander¹, A. Beker¹, D. M. Hooge², and K. R. Cummings, ¹Oklahoma State University, Stillwater, OK, ²Hooge Consulting Service, Inc., Eagle Mountain, UT, ³Church & Dwight Company, Inc., Princeton, NJ.

Day old, vaccinated Cobb 500 chicks were evaluated in two metabolic chamber studies, 240 chicks per trial (24 chambers of 10 birds each), to 21 days old under moderate cool stress and 17% oxygen atmosphere (nitrogen administration). Ten practical corn-soy-meal blend diets were formulated to contain various levels of sodium chloride (NaCl) or sodium sesquicarbonate (SS; 30.4% Na) singly, or in combination, or ammonium chloride (AC; 66% Cl) and SS in place of NaCl. The SS has equimolar Na bicarbonate and Na carbonate. Analyzed Na levels were 0.19, 0.28, and 0.37% in combinations with Cl levels of 0.11, 0.25, and 0.39% (from previous regular pen trial, using same basal diet, in which 0.23% NaCl + 0.3% SS gave best broiler results with ionophore, coccidial challenge, and built-up litter; see Hooge *et al.*, 2001, IPF abstract 14, Atlanta). Dietary electrolyte balances, Na+K-Cl in mEq/100 g, ranged from 20.8 to 36.5. Significance was at P<0.05 using a completely randomized design. Body weights overall were below industry norms due to oxygen deficiency. The SS treatments without NaCl appeared deficient in Cl; for example, the 0.3% SS diet with 0.19% Na and 0.11% Cl was lower in body weight at wk 1 and 2 than all or most other treatments, but adapted somewhat by wk 3. Heaviest 3 wk body weight was with 0.46% NaCl and lightest was with 0.23% NaCl + 0.3% SS. No differences in feed conversion ratio were detected. Right ventricle weight and ascites heart index (right ventricle/total heart) were not affected, but ascites score (0=least to 3=most severe; P=0.054) at wk 1 was highest for 0.3% SS + 0.42% AC, with 0.23% NaCl intermediate, and 0.3% SS lowest. The 0.23% NaCl control had lowest oxygen consumption, heat production, and carbon dioxide exhaled, but third highest 3 wk weight. Hematocrit was negatively correlated (r²=-0.53) with oxygen consumption or heat production. This confirmed a relationship previously found between lower oxygen consumption, lower heat production, higher hematocrit, and higher ascites score. Under simulated high altitude and moderate cool stress, young broilers had best 3 wk weight (541.7 g) and worst ascites score (0.74) with 0.28% Na and 0.39% Cl from 0.46% NaCl, which could be moderated to good weight (488.7 g) and ascites score (0.52) with 0.37% Na and 0.39% Cl from 0.46% NaCl + 0.3% SS.

Key Words: Ascites, Salt, Sodium sesquicarbonate

Nitrogen, Phosphorus, and Sulfur Interfaces Between Beef Cattle Production and the Environment

398 Federal environmental policy directions for animal agriculture. J.S. Jonker*, *AAAS Environmental Fellow - US EPA, Washington, DC USA.*

The animal agriculture industry has undergone dramatic changes in the past 20 years. The trend toward fewer but larger operations, coupled with greater emphasis on more intensive production methods and specialization, has concentrated more animal manure within some geographic areas. This increase in geographic concentration has led to an increasing concern over environmental impacts of animal agriculture. According to the 1998 *National Water Quality Inventory* which re-

ported on assessments for 32 percent of the U.S. waters, 27,751 river and stream miles and 99,936 lake acres were impacted by animal feeding operations. A recent USDA analysis of 1997 county-level manure production relative to crop uptake in the United States estimated 73 counties had excess manure N and 160 counties had excess manure P. The number of counties with excess manure nutrients has significantly increased since 1982. Some manure could be exported to cropland in other nearby counties, but manure bulk will limit the distance manure can be transported economically. For many of these counties with excess manure nutrients, alternative uses for excess manure will need to be ex-

plored. The role of Federal regulation is to meet an endpoint goal, such as drinking water quality standards. Current and proposed Federal regulations do not dictate specific technologies or alternative uses for excess manure production. However, to meet endpoint goals for water quality, Federal regulations compel animal agriculture to find solutions to excess manure. Because regulatory approaches only impact 5 to 10% of all animal farms, voluntary and incentive based programs are also a vital part of the Federal environmental policy for animal agriculture.

Key Words: Environment, Federal Government, Water Quality

399 Phosphorus recommendations for beef cattle and factors related to their development and use. J.F. KARN*¹, ¹USDA-ARS, Northern Great Plains Research Lab, Mandan, ND, USA.

Current phosphorus recommendations for beef cattle will be discussed and research supporting these recommendations will be explored. Although recommendations have generally decreased in recent years, they must still contain some margin of safety, due to the many variables which affect beef cattle phosphorus requirements, especially under grazing conditions. There are many factors which make it very difficult to assess the true supplemental phosphorus needs of grazing cattle. Soil phosphorus levels are a reflection of soil parent materials and vary widely in the United States and around the world. Forage phosphorus levels reflect not only soil phosphorus levels and availability, but also forage species and stage of maturity. Animal affects include rumen microbial requirements; variation in absorption coefficients; interaction of phosphorus with nitrogen and other minerals; bioavailability differences among supplemental phosphorus sources; the availability of body stores of phosphorus and breed differences. Responses of grazing cattle to phosphorus supplementation have been inconsistent among and within geographical locations. Forage tissue phosphorus concentrations, as well as phosphorus concentrations in many animal tissues, have been considered as status indicators; but none have been consistently reliable. The impact of the above factors on phosphorus requirements, and phosphorus status indicators, as well as responses to phosphorus supplementation will be discussed. Additional knowledge is needed on many factors affecting phosphorus recommendations, and their practical application, to minimize production costs and to reduce phosphorus levels in effluent from pastures and feedlots which may affect the ecosystem of adjacent streams, ponds and lakes.

Key Words: Beef cattle, Phosphorus requirements, Supplementation

400 Effects of manipulating protein and phosphorus nutrition of feedlot cattle on nutrient management and the environment. T. J. Klopfenstein* and G. E. Erickson, University of Nebraska, Lincoln, NE.

Feedlot nutrition will play a role in meeting challenges such as nutrient management. Nitrogen and phosphorus are two nutrients that are currently studied in this context. One nutritional method is formulating diets to not exceed requirements for nitrogen and phosphorus. Requirements are different for calves versus yearlings. The requirements also change during the finishing period. Phosphorus requirements have not been extensively studied for feedlot cattle between 270 and 600 kg. Therefore, P requirement studies were conducted to determine the P requirement of calves (265 kg) and yearlings (385 kg). The requirement was not detected with P levels as low as .14 (yearlings) and .16% (calves) of diet DM based on performance and bone ash. Compared

to NRC-predicted P requirements, P intakes ranged from 76 to 190% (calves) and 71 to 162% (yearlings). In separate nutrient balance experiments, decreasing dietary P to NRC-predicted requirements (.22 to .28%) did not influence gain but decreased P input by 33 to 45% and excretion by 40 to 50% when compared to industry average (.35% P). The metabolizable protein (MP) system was recently adopted and may allow more accurate diet formulation for protein, thereby decreasing N excretion. Compared to industry average (13.5% CP) and formulation with the CP system, using the NRC model and phase-feeding to not exceed MP requirements over the feeding period decreased N inputs by 10 to 20% for calves and yearlings without affecting ADG. Decreasing N inputs led to a concomitant decrease in N excretion (12-21%) and volatilization (15 to 33%) in open-dirt feedlot pens. Nitrogen losses are variable with time of year, with averages of 60 to 70% of excreted N lost during the summer months and 40% lost from November to May feeding periods. Protein requirements are continually being refined as more research data are collected. However, formulation to meet and not exceed protein requirements and removal of P supplements are important nutritional management options to help feedlots become more environmentally sustainable.

Key Words: Nitrogen, Phosphorus, Cattle feedlots

401 Livestock odor abatement with plant-derived oils and urease inhibitors. Vince Varel*, USDA/ARS, U.S. Meat Animal Research Center, Clay Center, NE.

Confined animal feeding operations are under environmental scrutiny for production of large quantities of waste in a small area. The waste can result in odor, global warming gases and the transfer of nutrients and pathogens to water and food sources. An incomplete anaerobic degradation of the carbohydrate, protein, and lipid components in waste is the primary cause of odor emissions. This incomplete degradation results in the formation of short-chain volatile fatty acids (VFA), amines and other nitrogenous compounds, and sulfur-containing compounds. Our objectives are to provide simple, cost effective, and environmentally sound solutions to control odor and pathogens in livestock waste, with nutrient management a top priority. A urease inhibitor, N-(n-butyl) thiophosphoric triamide, was used to reduce urea hydrolysis in beef cattle feedlot pens, conserve nitrogen, and inhibit ammonia emissions which contribute to odor. Laboratory studies with antimicrobial plant-derived oils, thymol and carvacrol, at 2 g kg⁻¹ of feedlot waste completely inhibited the production of VFA in flasks over 42 days. Fecal coliforms were reduced from 4.6 x 10⁶ to 2.0 x 10³ cells ml⁻¹ 2 days after treatment, and were nondetectable within 4 days. Total anaerobic bacteria were reduced from 8.4 x 10¹⁰ to 1.5 x 10⁷ cells per ml after 2 days and continued to be suppressed to that level after 28 days. These plant oils are not degraded under anaerobic conditions. However, our feedlot studies and the literature indicate these oils are degraded under aerobic conditions. This suggests that these generally recognized as safe (GRAS) chemicals, which are routinely used as preservatives in food and personal care products, should not accumulate in soils to which this waste is applied. It is concluded that chemical additives can be added to animal waste to prevent degradation, which in turn controls odor emissions, reduces pathogens, and conserves nutrients until the waste can be recycled as fertilizer. The economics and environmental effects of using thymol and carvacrol in livestock production facilities need to be determined.

Key Words: Livestock Waste, Odor, Essential Oils

Companion Animal Biology as a Focal Point in the Animal Sciences

402 Issues surrounding the teaching of companion animal biology in an animal science department. Neal R. Merchen* and Linda P. Case, University of Illinois, Urbana, IL.

Animal Sciences departments are increasingly faced with decisions about inclusion of courses and training programs related to companion animals in their curricula. Companion animals are economically important through sales of pet food and other accessories and payment for veterinary services. The pet food manufacturing industry uses large quantities of agricultural commodities. Demographics of students have changed such that the majority of students in many Animal Sciences departments are now women, come from urban backgrounds, and tar-

get advanced study (veterinary medicine, other professional curricula, graduate study) as goals following completion of their undergraduate programs. These characteristics often reflect students whose primary animal-related experiences and interests are with companion animals. Thus, Animal Sciences departments need to consider curricula additions that include more training in companion animal biology. A curriculum in companion animal biology has been developed at the University of Illinois. Courses are taught in Companion Animal Biology (general survey of all disciplines related to companion animals) and Human-Companion Animal Interactions. A course in Companion Animal Nutrition has been developed and is offered to junior-senior and graduate students. In ad-

dition to traditional course work, opportunities have been established for student internships with pet food companies, animal shelters, and dog training centers. An annual field trip offers students direct exposure to career opportunities in companion animal management, training, and nutrition. Animal Sciences students that have training with companion animals have enjoyed enhanced experiences in veterinary medicine and opportunities for careers in occupations related to companion animals.

403 Research in companion animal biology: Topics of importance, current controversies, and opportunities. Gail Czarnecki-Maulden¹ and John Bauer*², ¹*Friskies*, ²*Texas A&M University*.

Both fundamental and applied research initiatives in companion animal biology are available in university environments. Where Colleges of Agriculture and Veterinary Medicine co-exist on a single campus, interdisciplinary collaborations using clinical case materials provide unique opportunities for creative investigation. In the absence of such combined resources, opportunities for basic research also exist. Initiatives for companion animal research are generally more similar to those of human health rather than animal production and areas ranging from digestive physiology to genomics are of interest to several funding agency sources. Examples of funding sources, key meetings for interaction and development of mutual interests, and examples of several existing programs in companion animal biology focusing on nutrition will be described. Opportunities for developing key programs in other aspects of companion animal health are also ripe for exploration. As for industry, there is a considerable basic research effort in companion animal nutrition. This research is aimed at providing a point of difference vs competitor products and is often targeting visible differences rather than the more traditional indicators of nutritional adequacy used in the livestock industry. The non-invasive policies of most pet food companies also provide unique challenges to the researcher within industry. Career opportunities for animal scientists in the pet food industry and current research topics will be discussed.

404 Outreach efforts in companion animal science: Issues, controversies, and opportunities. Steven Zawistowski¹ and Tim Phillips*², ¹*American Society for Prevention of Cruelty to Animals*, ²*Watt Publishing Co.*

Well over half of all American homes have a companion animal, and the purchase and care of these animals is a multi-billion dollar business. In addition to direct expenditures associated with companion animals are the additional monies associated with enhanced health care when animals are employed as therapeutic partners or, conversely, the billion dollars in insurance claims made each year due to dog bites. Surveys of pet owners consistently show that a majority celebrate their pet's birthday and buy gifts at holiday time. At the same time, millions of abandoned animals die in animal shelters each year. These contrasts are linked by a common theme. There is a lack of consistent high quality information

on pet acquisition and care, and this is partly due to limited opportunities for education and training of specialists and professionals to participate in the field. Pet care businesses, animal shelters, and extension efforts all require individuals with a background in animal sciences that incorporate the most up-to-date information on nutrition, behavior and management skills. Opportunities in companion animal biology include positions at biomedical facilities, petfood companies, petfood industry suppliers, diagnostic laboratories, colleges, humane societies, animal control facilities, veterinary practices, drug companies, and the military. According to the American Veterinary Medical Association, the areas of greatest potential are molecular biology, toxicology, laboratory animal medicine, immunology, diagnostic pathology, environmental medicine and other specialties, including nutrition. Evidence of a strong interest in companion animal education can be found in the growth of Petfood Forum, an international symposium for those involved with the petfood industry. Since 1993, attendance has grown from 319 to over 1,000 people.

405 Role of animal science departments and the American Society of Animal Science (ASAS) in fostering companion animal programs. Maynard Hogberg*¹ and Ellen Bergfeld², ¹*Michigan State University*, ²*American Society of Animal Science*.

Companion animal programs appear to be on the increase in animal sciences departments in the United States. The changing structure of animal agriculture has caused the traditional student pipeline from livestock farms to diminish greatly. As a result, departments are struggling to maintain enrollments and retain resources. It is critical that departments study and understand the implications that companion animal programs can have upon the following: departmental mission, student enrollment and student credit hours generated, type of students enrolled, departmental resources, fundamental research programs, relationship with Colleges of Veterinary Medicine and placement opportunities in the companion animal field. Companion animal programs can have a very positive impact on traditional animal science programs if properly planned and administered. As for ASAS, the companion animal area represents a vast opportunity for increasing membership and providing information to the public at large regarding animal science. The ASAS mission is "to discover, disseminate and apply knowledge for the sustainable use of animals for food and other human needs". Companionship of animals is a perceived need by many in today's society. ASAS membership and clientele demographics continue to change. A look forward suggests greater numbers of members with non-food animal interests and a shift from "food animal" to "animal". ASAS needs to recognize and embrace companion animal research and education as a legitimate component of animal science; foster greater collaboration with AVMA, veterinary medical colleges, and other related companion animal interest groups; develop educational materials for K-12 (K-life) distribution; and plan symposia, workshops, and other educational events that will be valued by both our members and the general public.

Future U.S. Swine Industry

406 The U. S. Swine Industry: Where we are & how we got here. R. L. Plain*, *University of Missouri-Columbia*.

Hog prices fell below the cost of production in November of 1997 and stayed there until February 2000. During this unprecedented period, hog producers lost over \$4 billion. Producers responded to the record red ink as they always have, by reducing hog numbers. Only this time, the liquidation was less than history would have predicted. Structural change has given us a hog industry that is geared for growth and reluctant to downsize itself. Ten trends are shaping the U.S. swine industry: 1. Improved herd performance: Over the last 20 years, the nation's hog farms have produced 3% more pork per breeding animal per year. 2. Fewer & Bigger Hog Farms: The number of U.S. hog farms has declined from over 1 million farms in 1967 to only 85,760 in 2000 with 235 operations owning 52% of the hogs. 3. Specialization: In 1920, 75% of all U.S. farms raised hogs. Today, only 5% have hogs. 4. Fewer & Bigger Packing Plants: Just as hog farms have become fewer and bigger, so have hog slaughter plants. The concentration ratio for the top four firms increased from 33% in 1980 to 56.2% in 1999. 5. Geographic Shift in Production: Unlike the past, recent growth in production has been in grain deficit regions. 6. Integration of Production & Packing: Four major packers are on the list of the nation's 6 largest hog producers.

Packers currently own 25% of the nation's hogs. 7. Integration of Packing & Processing: Packers are rapidly expanding their ability to further process and brand their pork. 8. Contracting: Over 32% of hogs were finished under production contracts in 1999. In January 2001, only 17% of hogs were purchased on the spot market. 9. Globalization: World trade in pork is increasing by about 8% per year. Last year, we exported over 6% of U.S. pork production. 10. Not In My Back Yard: There is growing community aversion to hog production and packing.

Key Words: Swine, Economics

407 The view from an integrated system. J.D. Lehenbauer*, *America's Best Pork*[®], *Farmland Foods, Inc., Kansas City, MO*.

Three key factors will be the primary drivers of future change in the pork industry: 1) customer demands for specific pork quality characteristics; 2) reduction of food safety risks; and 3) the ability to coordinate and trace the identity of market hog deliveries that satisfy pork quality and food safety requirements. To address these changing dynamics in the pork industry, Farmland Foods developed America's Best Pork[®]

("ABP"), a vertically coordinated pork production system. ABP consists of three primary components: 1) proprietary Triumph genetics; 2) a USDA-approved process verification program; and 3) market hog purchase agreements. Within two years, producer participation in ABP has grown to more than 230,000 sows, which represents more than 55% of Farmland Foods' total processing capacity. From an industry per-

spective, independent producers will have less and less control in the future over major production decisions such as genetics, nutrition, and production practices as pork processors compete to satisfy customers' demands for quality, food safety, and price.

Key Words: Integrated system, Pork, Process verification

Genetics of Carcass Merit and Meat Quality

408 Genetic prediction for time to finish end points in beef cattle. B. L. Golden*¹, ¹Colorado State University.

In national beef cattle genetic evaluation programs recent attention has been given to the development of genetic predictions that are more useful for determining the effects on profit and risk of alternative selection and mating decisions. This is in part due to the fact that many current national beef cattle evaluation programs contain EPD for indicator traits. It has been shown that considering EPD for indicator traits, especially when EPD for the economically relevant traits are available, will actually decrease the accuracy of prediction associated with a selection decision. Because properly formed EPD for economically relevant traits should consider the contribution of the indicator trait, using indicator trait EPD results in a redundancy that increases prediction error and confusion among cattle breeders. A precept has resulted from this renewed understanding that has been termed the principle of economically relevant traits. Using this principle it is possible to identify appropriate traits for inclusion in national beef cattle evaluation programs. The principle has led to an especially interesting set of recommendations for traits of carcass quality and yield. This is in part because of dogma and in part because carcasses are often valued based on traits that indicate a different desirable characteristic (e.g., marbling score versus tenderness, or subcutaneous fat thickness versus yield). Other livestock industries such as the swine industry have overcome these problems by using genetic predictions for amount of time to achieve finish endpoints. Work has begun to develop genetic predictions using random regression models for time to finish endpoints in beef cattle for weight, subcutaneous fat thickness, and quality grade. Having these three finish endpoint EPD will allow producers to not only predict the relative values of alternative selection decisions, but will also allow producers to predict appropriate finishing management programs for groups of slaughter cattle.

Key Words: Beef Cattle, Genetics, Prediction

409 Genetic influences on carcass merit of sheep. N. E. Cockett*¹ and G. D. Snowder², ¹Utah State University, Logan, UT, ²USDA, ARS U.S. Sheep Experiment Station, Dubois, ID.

Sheep numbers have decreased from nearly 30 million head in the early 1960s to 7 million head in 2000. Total production of lamb and mutton has not declined as sharply because of an increase in lamb carcass weight. From 1960 to 2000, the average lamb carcass increased from 22 kg to 31 kg. This change in carcass size is in part the result of improved feed management and an increase in mature size due to direct genetic selection and the use of large terminal sire breeds. Also, lambs are now frequently over-finished because the profit margin often favors larger animals and packers discount only extremely heavy lambs. Heavier carcasses have resulted in increased fat thickness, with the average carcass now exceeding recommendations by the American Sheep Producer Council's Consumer Acceptability Task Force for fat depth. It is possible to produce heavier carcasses with lean lamb characteristics using later maturing breeds, but current production systems have not capitalized on this opportunity. The proportion of lean meat cuts has remained constant in heavier carcasses, except in callipyge and Carwell animals. Lambs expressing these phenotypes have 30 and 8% increases in lean meat, respectively, with associated decreases in fat of 8 and 0%, respectively. However, almost all studies have found decreased tenderness of the callipyge loin. A similar effect on tenderness has not been reported for Carwell carcasses. Consumer consumption of lamb continues to fall, with annual per capita consumption of lamb and mutton dropping from 2.3 to 0.5 kg over the 1960 to 1997 time period. Studies of consumer preference indicate a lamb product with reduced fat and less intense flavor would be more appealing. These changes can be achieved through genetic selection and the choice of breeds. Identification of QTL for carcass merit will also aid in these improvements.

Key Words: Ovine, Carcass, Genetics

410 First generation of QTL searches for carcass traits in beef cattle. R. T. Stone*, USDA, ARS, U.S. Meat Animal Research Center, Clay Center, NE.

Microsatellite-based linkage maps were developed with the expectation of being able to identify quantitative trait loci (QTL) emphasizing those traits for which phenotypic data were sex limited, expensive, or difficult to obtain. Currently, the publically available results for QTL searches for carcass traits are based on a few large half-sib families; five sires and approximately 1,000 offspring. Seven of these QTL are genome-wide significant (one false positive per 20 scans) while more than 20 are considered suggestive (one false positive per scan). Significant QTL affecting rib bone, carcass weight, dressing percentage (BTA5), predicted retail product yield (BTA2), marbling (BTA3), hot carcass weight (BTA4), and fat thickness (BTA8) have been reported. Of those QTL at the suggestive level of significance, some are for correlated traits at the same position or present in multiple families, indirectly suggesting that they are real. The first generation of QTL searches have demonstrated: 1) QTL with modest effects (0.5 standard deviations) can be detected, 2) the need for a much broader sampling of genetic variance, and 3) the need for sampling and statistical methods to detect interacting alleles. The second generation of QTL searches will likely be based on single nucleotide polymorphism (SNP) haplotypes because of their power in determining identity-by-decent and their suitability for high-throughput genotyping technology. The most logical resource populations will be half-sib families, many of which are small or have a limited number of offspring with phenotypic data. Thus, the power to determine identity-by-decent is critical for both QTL and candidate gene analysis. Recently, 120,000 bovine expressed sequence tags (EST) have been assembled into about 20,000 clusters. Thus, an emerging EST or gene-based genetic map will coalesce into the functional and comparative genomics of humans and model organisms. Undoubtedly, developments in genomics and genotyping technology will greatly impact future QTL studies in livestock and their utility in breeding programs.

411 Dissecting the genetic control of carcass merit and meat quality in the pig. Max Rothschild*, Iowa State University.

Modern molecular biology and the science of genomics have opened up new and exciting possibilities to dissect complex phenotypic traits such as meat quality. To date over 4000 genes and markers have been added to the gene map of the pig. In addition to identifying and mapping genes and markers, animal geneticists have begun to search for the individual genes that affect meat and muscle quality in the pig. Meat and muscle quality traits are complex traits and some are often measured in a subjective manner. Measurement of these traits usually includes assessing backfat, intramuscular fat (marbling), loin eye area, pH, color, tenderness, juiciness, water holding capacity and flavor. For many of these traits heritabilities are moderate to high. While it is clear that these traits are likely to be controlled by many genes some individual genes may have large effects. To find these genes three approaches have been employed. The first has been to find or observe that "major" genes such HAL and RN are segregating in a population. The second approach is the "genomic scan" method which uses specialized crossbred resource families and random genetic markers to scan regions of the genome which are associated with meat quality traits. This approach has yielded many regions of the porcine genome associated with traits of carcass merit and meat quality. The final approach is the candidate gene approach and uses genes that by their very nature are expected to be associated with certain physiological functions. The purpose of this paper is to review

the remarkable progress made in identifying genes and genomic regions affecting meat quality traits in the pig.

412 Validation of carcass merit quantitative trait loci (QTL's) and integration of QTL information into genetic programs for improvement of carcass merit. E. J. Pollak¹, M. E. Dikeman², C. Gill³, and D. W. Moser², ¹Cornell University, ²Kansas State University, ³Texas A&M University.

Genetic evaluations for traditional carcass characteristics have been published for limited numbers of sires by various beef breed associations. Collection of carcass information is difficult, which limits the amount of information generated for these traits. The routine carcass field data collected do not include observations for measures of tenderness or any information on sensory panel assessment of meat quality, prohibitive due to costs and logistics. An objective of the National Cattlemen's Beef Association's Carcass Merit Project (CMP) was to collect data on tenderness and sensory panel assessments along with the traditional carcass characteristics from a set of legacy bulls from all breeds participating in the project. These data are being used to provide information for the calculation of expected progeny differences (EPD's) and to validate the segregation of quantitative trait loci (QTL's), discovered in the Texas A&M Angleton Project, in these breeds. Eleven QTL's are being validated, six for Warner-Bratzler shear force, three for marbling, and one each for sensory panel tenderness scores and rib eye area.

Estimates of heritability for shear force measures on Simmental and Angus cattle in the project were 0.22 and 0.25, respectively. Genetic evaluations, ignoring QTL information, for Simmental bulls in the CMP result in a spread of sire EPD's of 0.45 kg of shear force. To date, nine bulls representing four breeds have completed the progeny test required and the DNA analysis in the CMP. Five of the six tested shear force QTL's have been found to be heterozygous ($p \leq 0.05$) in at least one bull. One of the nine bulls has been found to be heterozygous for the QTL for the sensory panel score of tenderness. The difference in progeny group performance, groups defined by which marker allele was inherited for the tenderness QTL, in one Simmental bull was almost as large as the spread in sire EPD's for that breed. A pleiotropic effect of one QTL (tested as a shear force QTL) with marbling has been found. Evidence

for segregation of the three marbling QTL and the rib eye area QTL has not been found in the nine tested bulls.

413 Impact of breeding and genetics on poultry carcass and meat quality. D. L. Fletcher*, *University of Georgia, Athens, GA USA.*

The role of poultry breeding and genetics on carcass and meat quality issues has undergone constant change over the past 150 years. Early poultry breeding efforts were focused on such characteristics as fighting ability, egg production, and improving and maintaining the characteristics of pure bred stock. Poultry meat quality was not a major emphasis. After World War II, the poultry meat industry began to vertically integrate and with dramatic developments in nutrition, disease control, and management, the economics of production were so improved that poultry consumption skyrocketed. During this period, selection programs for commercial strains were also concerned primarily with economy of production including such factors, as growth rate, feed conversion, health, and uniformity. Quality issues included white feathering and fast feathering traits, as well as traditional livestock selection criteria for live animal and carcass conformation, fleshing, meat yield, and avoidance of skeletal defects. By the late 1970's through the 1990's, although most selection criteria were still related to economy of production, programs relative to market demands for increased breast meat yield and reduced carcass fat were given some attention. Other than for breast meat yield (both an economic and quality issue) and fat content, the only other area of selection interest relative to quality has been in attempting to reduce the PSE-like condition common in turkeys. With the dramatic changes in the marketing of broilers from a predominantly whole carcass market to further processed meat products, the issues relative to traditional quality attributes have almost completely disappeared. Current and future selection programs are likely to continue to focus on economy of production but may also begin to incorporate quality issues such as PSE-like conditions, meat and parts proportions (weights, thickness, "bun coverage", and trim waste), functional properties, possible composition modification (nutrient and health-based designer foods), and welfare.

Meat Thermoprocessing: Products and Processes

414 Thermoprocessing, products and processes: Introduction. S. M. Lonergan*, *Iowa State University.*

Development of new meat products continues to be a priority of meat processors interested in capturing and improving the inherent value of muscle foods. Pre-cooked products such as fully cooked bacon, beef crumbles and beef patties have been very successful in food service markets. Recently these products have gained a portion of the retail market. Growth of retail opportunities for these products is dependent on continued development of ingredient, processing, cooking and packaging technologies to ensure safety, consistency, quality and cost efficiency.

415 Thermodynamic cooking methods. J Gaydos*, *Stein Inc.*

The thermodynamic merits of various available cooking methods used for a variety of prepared meat products will be discussed.

Key Words: Thermodynamic, cooking, methods

416 Thermal processing and microbial stability. B.P. Marks*, *Michigan State University.*

Growth in the fully-cooked market sector and evolving federal regulations are creating a need for better information related to thermal inactivation of pathogens. In particular, federal regulations governing the safety of fully-cooked meat products are shifting from a command-and-control basis to performance standards. This shift increases the burden on processors to ensure that a new or modified process achieves target lethality levels. Although product characteristics (e.g., fat content

and pH) and process parameters are known to affect thermal resistance of bacteria, most reported information is from laboratory studies that encompass a limited range of conditions. The validity of using this information in evaluating process lethality is uncertain. Consequently, there is a significant need for validated technical tools that can be used to evaluate the lethality of dynamic cooking processes. This presentation will (1) summarize the current state-of-knowledge related to thermal inactivation of pathogens in meat products, (2) highlight limitations of available inactivation models, and (3) outline current research aimed at developing tools that are directly applicable to evaluating the lethality of commercial cooking processes.

Key Words: Pathogens, Cooking, Models

417 Enhancement of cooked meat quality and safety via packaging. Tom Rourke*, *Emmpak Foods, Milwaukee, WI.*

The standard packaging methods used to improve cooked meat quality and safety are vacuum and modified atmosphere. The efficacy of these systems is well documented when the residual oxygen level is 0.5% or less. Common modified atmosphere packaging (MAP) gas mixtures are 70-80% nitrogen and 20-30% carbon dioxide. Some success has been attained incorporating antimicrobial agents (fungicides, antibiotics, organic acids) directly into packaging films. Oxygen scavengers in the form of polymer additives of film-adhering packets have been extremely successful in preventing aerobic microorganisms, especially molds, on cooked meat products. Edible coatings and films as a final processed meat package is a promising area of research. They are commonly produced from lipids, polysaccharides or proteins and have several distinct advantages such as: biodegradability, edibility, excellent appearance and

oxygen barrier. In addition, these coatings and films can serve as a carrier for a variety of edible antimicrobial agents. Technologies designed to pasteurize processed meats after final packaging have received copious attention. Post pasteurization of vacuum packaged cooked products consists of hot water or steam immersion followed by immediate chilling. Irradiation (gamma, electron beam or X-ray) of cooked vacuum or MAP packaged products can produce very acceptable product at the correct

dose. High pressure processing involves submerging the packaged meat product in water increasing the pressure to 87,000 psi. The process has no effect on product color, texture, flavor, or package purge. Post pasteurization, irradiation and high pressure all increase product shelf life and significantly reduce pathogens.

Molecular Manipulation to Influence Mammary Development and Function

418 Physiological phenotypes of estrogen receptor knock-out mice. K.S. Korach*¹, ¹NIEHS/NIH, Research Triangle Park, NC..

Estrogen receptors (ER) play a crucial role in development and reproduction. Gene targeting allowed generation of mice homozygous for either the disrupted ER α (α ERKO) or ER β genes (β ERKO). α ERKO mice were unresponsive to uterotrophic assays with estradiol, hydroxy TAM, or DES. Estrogen, EGF or IGF-1 treatment to induce DNA synthesis in α ERKO uteri, even though EGF and IGF-1 signaling was shown to be intact by stimulation of c-fos also failed. Progesterone receptor mRNA was detected in α ERKO mice, but was not stimulated by estrogen in the uterus, mammary gland or ovary, indicating an estrogen dependent and independent gene regulation. α ERKO females are infertile and have hypoplastic uteri and hyperemic ovaries. The α ERKO ovarian phenotype occurs developmentally and can be reversed by a GnRH antagonist. Serum estrogen and LH are elevated compared to WT or β ERKO females. Analysis of the mammary glands of adult α ERKO females showed a primitive ductal rudiment rather than the fully developed ductal tree seen in WT or β ERKO mice. α ERKO males are also infertile, with atrophy of the testes and seminiferous tubule dysmorphogenesis resulting in decreased spermatogenesis and inactive sperm. Bone length is decreased in α ERKO of both sexes, but not in β ERKO mice. α ERKO males have reduced bone density and some alterations in cardiovascular function. Phenotypic differences were seen in sex and aggressive behavior in both α ERKO males and females compared to the patterns in WT or β ERKO mice. In contrast to the α ERKO, the β ERKO males are fertile with normal sexual behavior. Recent development of a viable double ER α/β -knock out shows a unique ovarian phenotype of transdifferentiation of granulosa to sertoli cells. Further characterization of the mice and comparison of the individual and double ER gene KO phenotypes will be required to more fully understand the physiological consequences of ER mediated actions and the specific roles of the two different forms of ER in estrogen hormone responsiveness.

Key Words: estrogen knockout, mammary , reproduction

419 Genetic manipulation of the IGF-I axis to regulate mammary development and function. D.L. Hadsell*, S.G. Bonnette, and A.V. Lee, *Baylor College of Medicine, Houston, TX.*

Insulin-like growth factor I is believed to regulate several processes within mammary epithelial cells during mammary gland development. Firstly, IGF-I stimulates cell cycle progression, in both normal mammary epithelial cells and in breast cancer cells. Secondly, IGF-I can stimulate milk protein gene expression and/or milk synthesis in a number of model systems. Lastly, IGF-I inhibits apoptosis in both normal mammary epithelial cells and breast cancer cells. Our laboratory has studied the IGF-I-dependent regulation of these processes by using transgenic and knockout mouse models that exhibit alterations in the IGF-I axis. Our studies on transgenic mice that overexpress IGF-I during pregnancy and lactation have demonstrated that this growth factor slows the apoptotic loss of mammary epithelial cells during the declining phase of lactation while having minimal effects during early lactation on milk composition or lactational capacity. In contrast, our analysis of early developmental processes in mammary tissue from mice which carry a targeted mutation in the IGF-I receptor gene suggests that IGF-dependent stimulation of cell cycle progression is more important to early mammary gland development than potential anti-apoptotic effects. With both models, the effects of perturbing the IGF-I axis are dependent on the physiological state of the animal. The diminished ductal development that occurs in response to loss of the IGF-I receptor is dramatically restored during pregnancy while the ability of overexpressed IGF-I to protect mammary cells from apoptosis does not occur if the mammary gland is induced to undergo forced involution. Data from our laboratory on the expression of IGF-signaling molecules in the mammary gland suggests that this effect of physiological context may

be related to the expression of members of the IRS, or insulin receptor substrate, family.

Key Words: Transgenic mice, Mammary, Apoptosis

420 Regulation of IGF signaling by IGF binding protein-3 in the mammary gland. Wendie Cohick* and Constance Grill, *Rutgers, The State University of NJ, New Brunswick, NJ/USA.*

The insulin-like growth factors (IGF) mediate mammary epithelial cell (MEC) growth and thus play a critical role in mammary gland growth and development. The biological activity of IGF is modulated by IGF binding proteins, a family of six structurally related yet distinct proteins. The immortalized bovine MEC line MAC-T synthesizes four forms of IGFBP. Under basal serum-free conditions, minimal IGFBP-3 protein is secreted. However, IGF-I specifically upregulates the synthesis of IGFBP-3, while having no effect on other IGFBP forms. Stable cell lines genetically engineered to constitutively express IGFBP-3 exhibit enhanced responsiveness to IGF-I in terms of DNA synthesis relative to mock-transfected cells (controls), suggesting that IGF-I regulation of IGFBP-3 acts as a regulatory loop that functions to increase IGF bioactivity. DNA synthesis is also increased relative to controls by factors that activate the IGF receptor but do not bind IGFBP, hence the mechanism does not require a physical interaction between IGF and IGFBP-3. IGF-I receptor number and affinity are similar between IGFBP-3 transfected and control cells. Therefore IGFBP-3 may enhance IGF action by directly influencing intracellular signaling events downstream of the IGF-I receptor. To investigate this, the signaling molecules that mediate IGF action in bovine MEC were first determined. IGF-I does not activate ERK 1/2, suggesting that IGF-I does not stimulate DNA synthesis via this MAP kinase pathway. In contrast, the p85 regulatory subunit of PI3 kinase co-precipitates with IRS-1 following stimulation with IGF-I, indicating involvement of the PI3 kinase signaling pathway. Activation of the downstream effector Akt is observed by 1 min and maximal by 15 min following exposure to IGF-I. Akt phosphorylation is greater at 1 min in MAC-T cells expressing IGFBP-3, relative to controls, and this enhanced activation is maintained through 10 h. In vitro kinase assays confirm that Akt activity is 1.4- to 1.9-fold higher in IGFBP-3 transfected cells. Therefore, IGFBP-3 may potentiate IGF-I activity by enhancing the activation of the PI3 kinase signaling pathway via Akt. Studies are in progress to further define the signaling molecules responsible for this effect.

Key Words: Mammary gland, Insulin-like growth factor binding protein-3, Signaling

421 Regulation of apoptosis during mammary involution by the p53 tumor suppressor gene. D. Joseph Jerry*¹, Ellen S. Dickinson¹, and Amy L. Roberts¹, ¹University of Massachusetts.

Regulation and functions of the p53 tumor suppressor gene have been studied extensively with respect to its critical role in maintaining the stability of genomic DNA following genotoxic insults. However, p53 is also induced by physiologic stimuli resulting in cell cycle arrest and apoptosis. In other situations, the activity of p53 must be repressed to prevent inappropriate removal of cells. The mammary gland provides a valuable system in which to study the mechanisms by which the expression and biological responses to p53 can be regulated under a variety of physiological circumstances. The proapoptotic role of p53 during involution of the post-lactating mammary epithelium is especially relevant to animal agriculture. We have utilized p53-deficient mice to establish the molecular targets of p53 in the mammary gland and biological consequences when it is absent. We have demonstrated that induction of the p21/WAF1 gene (Cdkn1a) is p53-dependent in the involuting mammary epithelium. Abrogation of p53 resulted in delayed involution of

the mammary epithelium demonstrating the physiological role of p53 in this process. Stromal proteases were induced in the mammary gland by 5 days post-weaning providing a p53-independent mechanism that resulted in removal of the residual secretory epithelium. These processes can be interrupted by treatment with hydrocortisone. These data establish p53 as a physiological regulator of involution that acts to rapidly initiate apoptosis in the secretory epithelium in response to stress signals. Therefore, p53 activity may be used as a physiological indicator to select treatments or animals with increased persistency of lactation.

422 The Production and Regulation of Leptin in Bovine Mammary Epithelial Cells. J.L. Smith* and L.G. Sheffield, *University of Wisconsin-Madison, Madison, WI, USA.*

Western blot analysis indicated the presence of leptin in bovine milk, while reverse-transcription polymerase chain reaction (RT-PCR) indicated the presence of leptin mRNA in mammary tissue. Leptin was found to be produced by cultured bovine mammary epithelial cells (MAC-T cell line) by western blot and RT-PCR analysis. A real time RT-PCR method was developed that allowed quantitative assessment of bovine leptin mRNA over approximately 3 orders of magnitude. Time course studies indicated a rapid increase in leptin mRNA in response to insulin or IGF-I. When normalized against bovine GAPDH as an endogenous control, 30 minute or 1hr treatment with 10 ng/ml insulin gave 39±4 and 64±2 fold increase in leptin mRNA compared with 0hr control. Leptin mRNA was increased 257±9 and 75±23 fold by 30 minute or 1hr treatment with 10 ng/ml IGF-I. Dose response studies indicated significant increases in leptin mRNA in response to as little as 1 ng/ml insulin or 0.1 ng/ml IGF-I. Maximum increase in leptin mRNA was observed in response to 10 ng/ml insulin and 10 ng/ml IGF-1. These results indicate that production of leptin by bovine mammary epithelial cells can be regulated by factors known to alter mammary function and nutrient partitioning. This suggests that leptin may be an autocrine/paracrine signal in the bovine mammary gland.

Key Words: Leptin, Mammary epithelial cells, IGF-I

423 Mammogenic effects of estrogen and growth hormone are mediated by local changes in mammary IGF-1 and IGFBP-3. S. D. Berry*^{1,2}, T. B. McFadden^{1,3}, R. E. Pearson², and R. M. Akers², *¹AgResearch, Hamilton, New Zealand, ²Virginia Polytechnic and State University, Blacksburg, VA, ³University of Vermont, Burlington, VT.*

An epithelium-free mammary fat pad was surgically prepared in twenty-five one-month-old, Friesian heifers. At 18 months of age, the heifers were randomly assigned to one of four treatment groups. Treatments were: control (C), growth hormone (GH), estrogen (E) or growth hormone + estrogen (GE). Hormones were administered for 40 hours before the animals were sacrificed to provide mammary samples of parenchyma (PAR), intact fat pad (MFP), and epithelium-free or "cleared" fat pad (CFP). IGF-1 and IGF binding protein-3 (IGFBP-3) mRNA was higher in CFP and MFP than PAR ($P < 0.001$) whereas the protein products were higher in PAR ($P < 0.001$). IGFBP-2, a 28-kDa IGFBP and a 24-kDa IGFBP were more abundant in CFP and MFP. E ($P < 0.01$) and GH ($P < 0.05$) increased incorporation of ³H-thymidine into DNA of PAR by an average of 350% and 125% respectively. Incorporation of ³H-thymidine into DNA of MFP or CFP was minimal. Coincident with the changes observed in mammary epithelial proliferation, the overall effect of E was to increase IGF-1 protein content by 190%, 40% and 60% in MFP ($P < 0.01$), PAR ($P < 0.01$), and CFP ($P < 0.05$), respectively. E increased IGF-1 mRNA levels in MFP ($P < 0.08$), but not CFP, indicating that the regulation of IGF-1 expression is modulated by adjacent epithelium. GH and E reduced IGFBP-3 content in PAR to less than 40% of IGFBP-3 protein content in controls, whereas the 24-kDa IGFBP in CFP and MFP was increased to between 40% and 150% of controls. Increased proliferation of mammary parenchymal cells was associated with increased IGF-1 and reduced IGFBP-3 protein in mammary tissue. An increased ratio of local mammary IGF-1:IGFBP-3 likely mediates the stimulatory effects of GH and E in heifer mammary glands.

Key Words: Estrogen, Growth Hormone, Mammary

424 Influence of feeding level and bovine somatotropin (bST) on transforming growth factor-beta (TGF-β) and its receptor in mammary tissue of growing heifers. K. Plaut*¹, R. Maple¹, X. Cui¹, and S. Purup², *¹University of Vermont, Burlington, VT/USA, ²Danish Institute of Agricultural Sciences, Foulum/DK.*

Transforming growth factor-β is a potent inhibitor of mammary epithelial cell growth. The objective of this study was to determine whether TGF-β or its receptors were altered in heifers when mammary growth was altered. Twenty-four heifers weighing 195 kg were fed to gain at approximately 550 or 1100 gm/day for low or high feeding level, respectively. They were then treated for 35 days with bST injections (0 or 15 mg/day) at either high or low feeding level. Therefore, the treatments (n=6 per treatment) were low feeding level, placebo (LC), low feeding level, bST treated (LST), high feeding level, placebo (HC) and high feeding level, bST treated (HST). The heifers were slaughtered at approximately 230 kg live weight and mammary tissues were removed. TGF-β mRNA expression was analyzed using RNase protection assay and quantified by densitometric scanning. The type II TGF-β receptor was analyzed by competitive binding assay, immunohistochemistry and western blot analysis. TGF-β mRNA was normalized to 100 for HC and compared to all other treatments. The least squares mean for TGF-β mRNA expression was 112 for LC, 86 for LST, 222 for HST ± SEM of 80. Binding was expressed as cpm/100 micrograms of protein and was 8338 for LC, 7590 for LST, 9310 for HC, 4978 for HST ± 1396. Even though mRNA expression was approximately two-fold greater and receptor binding was one-half in animals fed to gain 1200 gm/day and treated with bST compared to all other treatments, differences were not significant due to large variability. Western blot analysis was used to determine that all tissue expressed both the Type I and II receptors. Immunohistochemistry revealed that receptors were localized in ductal and myoepithelial cells consistent with a role for TGF-β in regulating ductal morphogenesis. While TGF-β may play a role in mammary development, it does not seem to be regulated by somatotropin or plane of nutrition during early development.

Key Words: Mammary, Transforming Growth Factor-beta, Bovine Somatotropin and Feed Intake

425 The role of insulin in the modulation of milk fatty acid composition. B. A. Corl*¹, S. T. Butler¹, W. R. Butler¹, and D. E. Bauman¹, *¹Cornell University, Ithaca, NY.*

Milk fat fluidity is regulated by controlling the pattern of fatty acids that comprise the triglycerides. Specifically, shorter chain fatty acids and unsaturated fatty acids lower the melting point of the triglycerides. Δ⁹-desaturase plays an important role in regulating milk fat melting point by adding a *cis*-9 double bond to several medium and long chain saturated fatty acids. In several species, insulin regulates Δ⁹-desaturase gene expression. We utilized a hyperinsulinemic-euglycemic clamp to examine the role of insulin in regulating milk fatty acid composition and Δ⁹-desaturase in lactating cows. This involved continuous infusion of insulin to elevate circulating concentrations and maintenance of euglycemia by variable rates of glucose infusion. The treatment period was 4 days and commenced when cows were 10 DIM. Five cows received intravenous saline infusion (control) and four cows received the insulin clamp. Milk samples were collected two days prior to and during the treatment period. Plasma insulin concentrations were increased 8-fold during the insulin clamp as compared to cows infused with saline. Over the course of the experiment, milk fat yield and milk yield were reduced in cows receiving the insulin clamp. Milk fatty acid composition of cows during saline infusion did not change when compared to pre-treatment values. In contrast, cows receiving the insulin clamp had a decrease in milk fat content of long chain fatty acids as compared to pre-treatment values. Consequently, milk fat content of *de novo* fatty acids increased considerably during the insulin clamp. This effect was most obvious for C_{14:0} and C_{16:0} which increased 68% and 48%, respectively. The ratio of Δ⁹-desaturase fatty acid products to substrates serves as a proxy for Δ⁹-desaturase activity. Insulin infusion increased activity of Δ⁹-desaturase. Although milk fat content of C_{18:0} and *cis*-9 C_{18:1} was reduced 56% and 38%, respectively, the ratio of *cis*-9 C_{18:1} to C_{18:0} was increased 42%. Similar increases were observed for the ratio of *cis*-9 C_{14:1} and C_{14:0} (86%) and the ratio of *cis*-9, *trans*-11 CLA and *trans*-11 C_{18:1} (96%). These data indicate that insulin directly or indirectly regulates Δ⁹-desaturase and also milk fat content of long chain fatty acids presumably via effects on rates of lipolysis.

Key Words: insulin, desaturase

Packaging Food and Dairy Products for Extended Shelf-Life

426 Active packaging: Films and coatings for extended shelf life. Paul Dawson*, *Clemson University*.

Shelf life encompasses both safety and quality of food. Safety and spoilage-related changes in food occur by three modes of action; biological (bacterial/enzymatic), chemical (autoxidation/pigments), and physical. Active packaging may intervene in the deteriorative reactions by; altering the package film permeability, selectively absorbing food components or releasing compounds to the food. The focus of this report will consider research covering impregnated packaging films that release compounds to extend shelf life. The addition of shelf life extending compounds to packaging films rather than directly to food can be used to provide continued inhibition for product stabilization. For further-processed foods with greater than one week shelf life, active packaging can provide an added level of protection downstream in the distribution cycle. Direct addition of antimicrobials for instance, will have a strong initial effect but will have little effect later in the distribution cycle since the antimicrobial will react with food components or be absorbed into the food bulk. For non-fluid foods, the deteriorative reactions occur primarily at the food surface. Thus, less antimicrobial will be needed when used in the package since the compound will be released at the location of need, the food surface. Some research results will be highlighted that focus on using compounds that are either approved for food use or are food components. Antimicrobials used include nisin, lauric acid, and EDTA while antioxidants added to films include BHT, BHA, and rosemary extract. Film and coating materials include soy, wheat, corn, and polyethylene. Pathogens including Salmonella and Listeria have been inhibited by several combinations of antimicrobials and film or coating types. Fresh beef color has been extended by over-wrapping meat with BHA-impregnated polyethylene film and inoculated milk exposed to films containing nisin have had multiple log reduction of Listeria monocytogenes. Positive results for food shelf life extension have been shown by the application of active packaging.

Key Words: antimicrobial packaging, shelf life, active packaging

427 Mold migration in paperboard materials for extended shelf-life milk. J. E. Marcy*¹, L.D. Sammons², S.S. Sumner¹, and C.R. Hackney³, ¹*Virginia Tech*, ²*International Dairy Foods Assoc.*, ³*West Virginia University*.

Research was conducted to elucidate the cause of past fungal contamination experienced by a local dairy in extended shelf-life fluid dairy products. Migration of *Penicillium spinulosum* from paperboard to milk during an extended shelf-life was investigated through inoculation of conidia into paperboard test-squares. These 57.2 cm by 57.2 cm test-squares were sealed on three sides with melted paraffin wax, inserted with a steel pin at 3.2, 6.4, 9.5 and 12.7 mm from the uncoated edge and sterilized by gamma irradiation. A stock solution of *P. spinulosum* was injected at these four distances and the injection site sealed with melted paraffin wax. The squares were incubated at 7 C. in ultra-pasteurized skim milk for 60 days, allowing wicking of the milk to occur. An inverse relationship was seen between distance from the uncoated edge and presence of the test organism in the surrounding milk. The percentage of *P. spinulosum* was 84% at 3.2mm, 72% at 6.4mm, 50% at 9.5mm and 28% at 12.7mm. Survival of *P. spinulosum* was in paperboard test materials was studied.

428 The use of polymeric materials for extended shelf life products. Susan Nielsen*¹, ¹*Eastman Chemical Company*.

The consolidation of dairies, centralization of meat packing operations, and expansion of distribution areas has led to an increase in the need for products with an extended shelf life. The challenge to the food industry is to meet this need while maintaining product quality and not compromising flavor or consumer acceptance. Plastics play an important role in meeting the challenge of extended shelf life. They offer unique advantages in food packaging to both producers and consumers. This talk will look at some of the common polymers used in food packaging, their properties, and how these properties can be used to meet food quality, processing, and storage requirements. The use of plastics in the packaging will be highlighted in a discussion of two products with extended

shelf life, ESL milk and case-ready meat. In the last two years, there has been substantial growth in extended shelf life milk packaged in single serve PET or HDPE containers. The combination of ESL processing and a plastic container results in an extended shelf life of 60 to 90 days, and at the same time provides consumers with the attributes they are demanding from the package: convenience, portability, and resealability. The second example of how polymers are part of the solution to extend shelf life is focused on case-ready beef. Here, a combination of a polymer with the appropriate gas barrier and a modified atmosphere allows beef to retain its bright red color longer, extending its shelf life. Plastics are increasingly used in food packaging and will be part of the future of extended shelf life products.

Key Words: Shelf life, Polymer, Plastic

429 Exploring Product-Package Research in an Interactive Session . J. C. Acton*, *Clemson University*.

Three differing research areas (presented from invited posters) which address current product-package developments will be critiqued with audience participation. After an overview of the research areas, challenging questions will be provided, and those in attendance will actively engage in a brainstorming discussion. The objective is to foster thoughts on what if, why not, spin-offs, the future, and does it matter.

430 Potential of biobased materials for food and dairy packaging. Grete Bertelsen*¹, V.K. Haugaard¹, and T.H. Hansen¹, ¹*Department of Dairy and Food Science, The Royal Veterinary and Agricultural University*.

Biobased food packaging materials are defined as packaging materials derived from renewable sources. Generally, biobased materials are potentially biodegradable, i.e. composting is a potential technique for waste management. Biobased packaging materials include both edible coatings and edible films along with primary and secondary packaging materials. This presentation will focus on biobased primary packaging.

Biobased materials can be classified according to the method of production, resulting in the following three main categories: 1) Polymers directly extracted/removed from natural materials (mainly plants) as, for example, starch, cellulose, casein and wheat gluten, 2) polymers produced by "classical" chemical synthesis from renewable bio-derived monomers as, for example, polylactate, a biopolyester polymerised from lactic acids monomers and 3) polymers produced by microorganism as, for example, the polyhydroxyalkanoates. This presentation will review the wide range of biobased materials and their properties in relation to food packaging.

Prior to commercial use of biobased primary packaging materials several concerns must be addressed. First of all the biobased material must remain stable during storage of the food products, maintaining the mechanical and/or barrier properties. Ideally, the materials should biodegrade efficiently on disposal. Thus, environmental conditions conducive to biodegradation must be avoided during storage, whereas optimal conditions for biodegradation must exist after discarding. In order to reduce deterioration of the food products it is also important that the biobased packaging material meets the requirements of the individual food products. In this presentation the suitability of biobased materials as food packaging will be evaluated. In addition the challenges involved in using biobased packaging materials for different food and dairy products will be identified.

Key Words: Biobased materials, Packaging, Food and dairy product

431 Quality attributes of strawberry swiss style yogurt in the North Carolina marketplace. A. Hansen* and M. Keziah, *North Carolina State University Raleigh, N.C. USA.*

Approximately 300 samples of strawberry swiss style yogurt were obtained from various local dairies and grocery stores across North Carolina. The samples were collected over a two year period and analyzed for appearance, body, texture and flavor. The evaluation was conducted with 15 trained dairy judges according to ADSA protocol. The variation in quality and uniformity was quite extensive across brands. The color went from white to pink to purple for strawberry yogurt. The body and texture was from a runny liquid to a firm gel. The flavors were from slight strawberry, strawberry, chocolate and banana for swiss style strawberry yogurt. The major appearance defects were most to least color leaching, lacks fruit, lumpy, shrunken, free whey and atypical color. The body and texture defects from most to least were gel-like, weak, ropy and grainy. The flavor defects from most to least were acetaldehyde, high acid, lacks flavoring, unnatural flavoring and too sweet. In most cases the national brands had fairly good strawberry flavor but poor color and gel-like body. The store brands had appearance and colors from white or pink to purple. In many of the store brands we observed color leaching, no fruit and lacks fruit. The body and texture in most cases were gel-like with less samples grainy, weak and ropy. The flavoring of the store brands we identified were acetaldehyde, high acid, lacks flavoring, too sweet, banana and chocolate. It is evident that more quality assurance is needed to improve the quality of strawberry swiss style yogurt

Key Words: Swiss Style Yogurt, Marketplace, Quality

432 Consumer acceptability of lucuma and cherimoya ice cream. A. Hansen*¹, M. Keziah¹, and T. Salas², ¹*North Carolina State University Raleigh, N.C. USA,* ²*Gen Peru Lima, Peru.*

Raw milk and cream were obtained from the NCSU dairy plant to produce a 14% fat ice cream. Powdered skim milk was used to raise the milk solids to 9%. Granulated cane sugar was used at the rate of 15% and ice cream stabilizer was at 0.3%. The ingredients were blended and batch pasteurized at 165° F for 30 minutes and then homogenized at 2000 psi on first stage and 500 psi on second stage. The mix was then cooled to 35° F with chill water. The mix was aged for 48 hours and then flavored with frozen lucuma and cherimoya puree. The mix was frozen in a Cherry Burrell Vogt Freezer at 85% overrun, packaged in half-gallon containers and placed in a -30° F hardening freezer. Approximately three weeks later ice cream was removed from the hardening box and tempered at 0° F for sensory testing. Twenty-eight consumers screened for ice cream use participated in a consumer hedonic panel to measure degree of liking of lucuma and cherimoya ice creams. Panelists used a nine-point hedonic scale ballot to rate overall impression, flavor and mouthfeel. Statistical analysis of the sample results reveals that consumers scored the lucuma ice cream overall impression and flavor significantly higher than that of the cherimoya ice cream. The overall impression and flavor scores for the lucuma sample averaged in the "like moderately" to "like very much" range while the cherimoya sample averaged in the "neither like nor dislike" range. Consumers failed to reject the null hypothesis of no difference in mouthfeel. A preference for the lucuma ice cream overall impression and flavor can be inferred from these hedonic scores.

Key Words: Lucuma, Cherimoya, Ice Cream

433 Effect of CO₂ Addition to Raw Milk on Protein and Fat Degradation at 4°C. Y Ma* and David Barbano, *Northeast Dairy Foods Research Center, Department of Food Science, Cornell University.*

Fresh raw milks, with low (3.1x10⁴ cell/ml) and high (1.1x10⁶ cells/ml) somatic cell count (SCC), were standardized to 3.25% fat and from each a preserved (with 0.02% potassium dichromate) and an unpreserved portion were prepared. Subsamples of each portion were carbonated to contain 0 (control, pH 6.9), and 1,500 (pH 6.2) ppm CO₂, or HCl acidified to pH 6.2. Results of HCl acidified milk helped explain if there was a direct CO₂ effect or simply a pH reduction effect. Samples were stored in gas-tight glass jars at 4°C and analyzed on d 0, 7, 14, and 21

for proteolysis (decrease of CN as a percentage of true protein), lipolysis (increase in free fatty acid), and microbial count. As expected, more proteolysis and lipolysis occurred in high SCC milk. For unpreserved milks at d 21, psychrotrophic bacteria count reached 10⁸ cfu/ml for both control and HCl acidified samples; in CO₂ added sample, the count was ca. 10⁶ cfu/ml. At d 21, for control and HCl acidified unpreserved milks, average CN as a percentage of true protein decreased from 81 to 68% and average free fatty acid increased from 0.18 to 0.28 meq/kg milk primarily due to microbial growth; average changes were 81 to 80% and 0.18 to 0.19 meq/kg, respectively, for CO₂ added milk. Microbial growth was effectively inhibited in all preserved milks. Data for preserved milk gave information regarding the direct impact of CO₂ on protein and fat degradation by native milk enzymes separated from degradation brought about by enzymes of microbial origin. Compared with control, both carbonated and acidified preserved milks showed less proteolysis, suggesting that the inhibitory effect of CO₂ on proteolysis was due to pH reduction. No effect of CO₂ or acidification on lipolysis in preserved samples was observed. Carbonation reduced microbial growth in raw milk at 4°C and slowed down proteolysis as a consequence of milk pH reduction. High quality raw milk (low initial bacteria count, low SCC) with 1,500 ppm CO₂ can be stored at 4°C for at least 21 d with minimal protein and fat degradation, i.e., with < 1% decrease in CN as a percentage of true protein and < 0.01 meq/kg increase in free fatty acid.

Key Words: Carbon Dioxide, Prolonged Storage of Raw Milk, Protein and Fat Degradation

434 Effect of storage time and temperature on the serum phase of cultured cream cheese. L Acosta and P.S. Kindstedt*, *University of Vermont, Burlington, VT/USA.*

Syneresis is a problem in Cream cheese that is characterized by whey separation at the cheese surface and general wheying-off during heating. Previous studies demonstrated that the water-holding capacity of cultured Cream cheese decreased during storage at 4° and 25° C, and that changes occurred much more rapidly at 25° C. The objective of this study was to evaluate time and temperature dependent changes in the composition and viscosity of the serum phase of Cream cheese. Four 13.6-kg blocks of cultured Cream cheese made with locust bean gum stabilizer were obtained from a commercial source within 10 d after manufacture. Blocks were sectioned into samples that were vacuum packaged and randomly assigned to one of two storage temperatures: 4° and 25° C. Samples were randomly chosen for analysis after 1, 4, 7, 10, 14, 21 and 28 d of storage at 25° C, and after 0, 14, 27, 41, 55, 69, 83, 96 and 111 d of storage at 4° C. Samples were centrifuged at 12,500 x g for 75 min at 25° C to obtain expressible serum (ES). The ES was analyzed for crude protein, Ca, P, K, Mg, Na, Zn, and viscosity. For each storage temperature, RCB ANOVA was used to determine the significance of changes during storage. Linear regression was used to compare rates of change at 4° and 25° C. The amount of ES increased significantly during storage at 4° and 25° C; the rate of increase was substantially greater at 25° C. Crude protein in the ES increased significantly but only slightly during storage at 25° C, and did not change significantly at 4° C. Mineral contents did not change significantly at either storage temperature. In contrast, the viscosity of ES decreased significantly during storage at 4 and 25° C; the rate of decrease was much greater at 25° C. The amount and viscosity of the ES showed an inverse exponential relationship (R = .85). The results suggest that decreased water-holding capacity of Cream cheese during storage is caused by changes in the stabilizer function and not by changes in the distribution of protein and minerals between the protein-fat matrix and serum phases.

Key Words: Cream cheese, Syneresis, Expressible serum

435 Effect of storage time, storage temperature and pH on the viscosity of aqueous solutions of locust bean gum. M.L. Gigante*¹, M. Almendra-Aliste², and P.S. Kindstedt², ¹*State University of Campinas, Campinas, SP/Brazil,* ²*University of Vermont, Burlington, VT/USA.*

Previous studies demonstrated that the viscosity of the serum phase of cultured cream cheese (made with locust bean gum stabilizer) decreased in a temperature-dependent manner during storage at 4 and 25°C. The

objectives of this study were to determine whether aqueous solutions of locust bean gum (LBG) undergo similar temperature-dependent changes in viscosity during storage, and whether pH influences those changes. LBG solutions (.15, .30, .45, and .60%) were prepared in distilled water. Finely powdered LBG was sifted slowly into the vortex of rapidly stirred (9000 - 1,200 rpm) water at 84 °C. The solutions were then stirred at room temperature for 4 h and then held undisturbed for 16-18 h at 4°C. The solutions were then divided into three treatments and lactic acid was added to adjust the pH to 5.3, 4.8 and 4.3 ($\pm .05$). The acidified solutions were dispensed into sterile culture tubes and stored at 4 or 20°C for up to 28 d. Samples were randomly chosen after 1, 4, 8, 12, 16, 20, 24 and 28 d and analyzed for viscosity at 25°C (Brookfield) and turbidity (absorbance, 420 nm). The entire experiment was replicated three times. For each LBG concentration, the effects of pH, storage time and storage temperature were evaluated by ANOVA according to a split split-plot design. The viscosity of LBG solutions decreased and turbidity increased significantly during storage. These changes were greater at 20°C than at 4°C. Also, viscosity decreased more rapidly at higher pH. The observed changes in turbidity and viscosity indicate that the state of the LBG stabilizer changed during storage, possibly due to self-association. It is possible that similar changes may occur in LBG contained within the serum phase of cream cheese. Thus, changes in stabilizer function may account for the previously observed changes in the serum phase of cultured cream cheese during storage. Finally, results of the present study suggest that the pH of cream cheese may influence the rates at which the serum viscosity and water-holding capacity of the cheese decrease during storage.

Key Words: Cream cheese, Stabilizer, Locust bean gum

436 Application of a model system to study the effect of pH on the serum phase of cultured cream cheese during storage. M.L. Gigante^{*1}, M. Almena-Aliste², and P.S. Kindstedt², ¹State University of Campinas, Campinas, SP/Brazil, ²University of Vermont, Burlington, VT/USA.

Previous studies demonstrated that the viscosity of locust bean gum (LBG) in aqueous solution decreased during storage and was affected by storage temperature and pH of the solution. The present objective was to determine whether the pH of cream cheese influences temperature-dependent changes in the serum phase during storage. Three 13.6-kg blocks of cultured Cream cheese made with LBG were obtained from a commercial source within 15 d of manufacture. Blocks were sectioned into samples that were randomly assigned to three treatments. A model system was used to change cheese pH. One group of samples was exposed to volatile ammonia to increase the pH to ca. 5.2. A second group was exposed to volatile acetic acid to decrease the pH to ca. 4.5. A third group served as a control (pH ca. 4.8). Samples from each pH treatment were vacuum packaged and randomly assigned to one of two storage temperatures: 4 and 20°C. Samples were randomly chosen for analysis after 4, 8, 12, 16, 20, 24 and 28 d of storage. Samples were centrifuged at 12,500 x g for 75 min at 25°C to obtain expressible serum (ES). The ES was analyzed for viscosity at 25°C (Brookfield) and turbidity (absorbance, 420 nm). Effects of pH, storage time and storage temperature were evaluated by ANOVA according to a split split-plot design. Amount of ES increased significantly during storage, and was affected by storage temperature and cheese pH. Significantly more ES was obtained at higher temperature and higher pH. Viscosity of ES decreased significantly during storage and was affected by storage temperature and cheese pH. Viscosity decreased more rapidly at higher temperature and higher pH. Turbidity of ES was not affected by storage temperature or cheese pH. The observed changes in amount and viscosity of ES during storage suggest that the state of LBG within the serum phase of the cheese changed in a temperature and pH-dependent manner. However, in contrast to LBG in aqueous solution, these changes could not be detected by measuring the turbidity of ES, possibly due to the centrifugation conditions used to obtain ES.

Key Words: Cream cheese, Stabilizer, Locust bean gum

437 Effect of centrifugation conditions on expressible serum obtained from cultured cream cheese. M. Almena-Aliste^{*1}, M.L. Gigante², and P.S. Kindstedt¹, ¹University of Vermont, Burlington, VT/USA, ²State University of Campinas, Campinas, SP/Brazil.

Previous studies showed that the amount and viscosity of expressible serum obtained from cream cheese varied significantly from batch to batch and with temperature and time of storage. The objective of this study was to evaluate the effect of centrifugation conditions on expressible serum in an attempt to gain insight into the causes of variation in serum viscosity and cheese water-holding capacity. Cream cheese was obtained from a commercial source and centrifuged at 3 different forces (13,000, 16,000, and 20,000 x g) and 2 different temperatures (cheese pretempered to 25 °C, centrifuged at 25 °C; cheese pretempered to 60 °C, centrifuged at 25 °C). Three replications were performed at each force x temperature combination. Expressible serum was analyzed for viscosity at 25 °C (Brookfield), turbidity (absorbance, 420 nm) and total solids. Data were analyzed by ANOVA according to a 3x2 factorial design. Six different batches of cheese that varied widely in properties were evaluated using this experimental design. Centrifugation force significantly affected the amount of ES obtained from all six cheeses, but significant interactions of force x temperature occurred with three of the cheeses. In general, higher g-force resulted in greater ES. Total solids decreased slightly (< 0.2%) but significantly with higher centrifugation force. In contrast, viscosity was not affected by centrifugation force in 5 of 6 trials. Turbidity results varied widely among cheeses and were inconclusive. The data suggest that functioning stabilizer in the serum is not sedimentable at up to 20,000 x g. Centrifugation temperature significantly affected viscosity and turbidity in 5 of the 6 trials. Higher centrifugation temperature resulted in higher viscosity and higher turbidity. In contrast, total solids varied only slightly (< 0.3%) between temperatures, and the effect was not consistent from trial to trial. The data suggest that the higher cheese temperature before and during centrifugation altered the state of the stabilizer and enhanced its water-binding capacity and ability to increase the viscosity of the serum phase of the cheese.

Key Words: Cream cheese, Expressible serum, Stabilizer

438 Isolation and characterization of gritty particles in cream cheese. Mihir R. Sainani^{*}, Harit K. Vyas, and Phillip S. Tong, California Polytechnic State University, San Luis Obispo, CA.

A gritty/grainy mouthfeel is an undesirable textural defect in cream cheese. Grittiness develops when the coagulated curd (pH 4.55 - 4.6) is heat-treated during cheese making. The objectives of this study were 1) to isolate and characterize gritty particles from cream cheese and 2) to study the effect of gritty particles on texture of the cheese. Gritty particles were isolated from cream cheese by washing with water at 25°C and then 50°C. The mixture was then cooled and held overnight at 10°C and the top fat layer was decanted. These steps were repeated 4-5 times to get a good isolation of the particles. The particulate suspensions were used for estimating particle size using Coulter LS230 particle size analyzer. The suspensions were subsequently vacuum filtered through 2.5 µm filter. The filtered particles as well as cheese were analyzed for moisture, fat, protein and ash using standard AOAC methods and lactose was estimated by the difference. To study the effect on the cheese texture, gritty particles were added at 5, 15 and 25% (w/w) levels to smooth cream cheese and a sensory ranking test was done on the samples (15 panelists). In another experiment, the isolated particles were further separated into two size classes of 8 to 130µm and $\geq 130\mu\text{m}$ using filters. These particles were then mixed with smooth cream cheese at 16 and 29 % (w/w) and a sensory test was conducted on these samples. It was found that the particles were 26% (dry matter basis) higher in protein content and 66 and 63% (dry matter basis) lower in ash and lactose, respectively, as compared to the cheese. The particle size was in the range of 0.42µm to 1500µm. Sensory results suggested that the cream cheese added with particles even at 5% level was perceived as more gritty than the control sample. It also revealed that the perceived grittiness increased with increase in the amount and size of particles. It was concluded that particles were higher in protein content than the cheese and that the size and number of particles affected the grittiness of cream cheese.

Key Words: Grittiness, Cream Cheese

439 Fortification of fluid skim milk with conjugated linoleic acid (CLA). W.S. Campbell*, J. Parker, M.A. Drake, and D.K. Larick, ¹North Carolina State University.

Nutraceutical products make up the fastest growing segment of the U.S. food industry. Conjugated linoleic acid (CLA) occurs naturally in milk at low levels and is an anticarcinogen. Research indicates that concentrations of 1 to 3 g CLA/day would provide protective anticarcinogenic benefits. Increased levels of CLA in fluid milk would produce a nutraceutical dairy beverage. The objectives of this study were to develop a CLA fortified milk with improved nutritional properties. CLA (1 g, 2g, or 3 g /240g) and derivatized whey protein concentrate (DWPC) (0%, 0.25%, 0.5%) were added to raw skim milk prior to homogenization, HTST pasteurization and aseptic packaging. Headspace volatiles

were evaluated by purge and trap gas chromatography. Viscosity was determined using a controlled stress rheometer and visual properties (L^* , a^* , b^*) were evaluated with a colorimeter. CLA fortified skim milk had minimal levels of hexanal and sensory data did not indicate substantial flavor deterioration as compared to control. The addition of CLA increased the whiteness of the milk, but did not significantly affect viscosity. Addition of DWPC at .25% in skim milk mimicked the viscosity of reduced fat milk, however, visual properties were not affected. These results indicate that skim milk may provide a vehicle for CLA consumption and that DWPC enhances the viscosity of skim milk such that it is more similar to reduced fat milk.

Key Words: Conjugated linoleic acid, Milk

ASAS Nonruminant Nutrition: Alternative Ingredients (Nursery & Specialty Grain)

440 Supplementation of α -1,6-galactosidase and β -1,4-mannanase to improve soybean meal utilization by nursery pig. S. W. Kim*¹, I. Mavromchalis², and R. A. Easter², ¹Texas Tech University, ²University of Illinois.

Soybean meal contains 5.6% α -galactoside and 1.2% β -galactomannans that pigs can not utilize because of they lack appropriate enzymes, resulting in gas production and flatulence. Two experiments were conducted to test a hypothesis that dietary supplementation of an enzyme mixture (carbohydrase, mainly composed of α -1,6-galactosidase and β -1,4-mannanase) improves nutrient utilization of soybean meal in nursery pigs. In the first experiment, 108 weaned pigs (21 d; Camborough-15 x line 326, PIC, Franklin, KY) were offered three diets containing either 0% (control), 0.025%, or 0.050% of the carbohydrase for a 5-wk period in six replicates with 6 pigs per pen. Overall, growth response of pigs fed diets containing enzyme was greater ($P < 0.05$) than control group (11% improvement compared to control). Average daily gain was greater ($P < 0.07$) only in pigs fed a diet with 0.025% carbohydrase during the fourth wk post-weaning. There was no improvement in average daily gain in pigs fed a diet with 0.050% of carbohydrase. However, gain/feed ratio was greater ($P < 0.05$) in pigs fed a diet with 0.025% of enzyme during the last 4 wk of the experiment. In the second experiment, ten cannulated female pigs (Camborough-15 x line 326, Pig Improvement Company) were used to measure the effect of the carbohydrase supplementation (0.025%) on the apparent ileal digestibility of energy and amino acids with five pigs assigned to each treatment. Ileal samples were collected for 2-d following by 5-d adjustment period during the fifth wk post-weaning. Apparent ileal digestibility of gross energy was greater (7% improvement, $P < 0.05$) in the carbohydrase-supplemented diet. Also, apparent ileal digestibility of lysine, threonine, and tryptophan was greater (3% improvement, $P < 0.05$) in the carbohydrase-supplemented diet. In conclusion, a carbohydrase composed of α -1,6-galactosidase and β -1,4-mannanase can increase growth performance in nursery pigs by improving the digestibility of energy and amino acids in corn-soybean meal-based diet.

Key Words: Nursery pigs, Soybean meal, Carbohydrase

441 Performance of weaned piglets fed insect-protected (MON 810) or near isogenic corn. G. Piva*¹, M. Morlacchini², A. Pietri¹, A. Piva³, and G. Casadei¹, ¹Istituto di Scienze degli Alimenti e della Nutrizione, U.C.S.C., Facolt di Agraria, Italy, ²CERZOO, ³DIMORFIPA, Facolt Medicina Veterinaria, Bologna, Italy.

The aim of the experiment was to compare the nutritive value for piglets of insect-protected corn (Bt) containing the Cry1A(b) protein (MON 810) with non-modified near isogenic control corn (IC), both produced on two Italian farms located in Lodi and Venezia provinces. The trial utilised 128 weaned Large White piglets weighing 8.8 (1.27) kg. Animals were divided into 4 treatments of 32 animals each (4 pens each of females and castrated males each with 4 pigs/pen). Five climate controlled rooms each containing 6 pens except the fifth room containing 8 pens were used. Treatments were blocked by sex and treatment within each room. Nutritional analytes were not different ($P < 0.05$) between IC and Bt corn. Animals were fed test diets containing 33% corn for 35 days. Feed intake of pigs did not differ ($P < 0.05$) among experimental diets. Feed:gain was not different ($P < 0.05$) among treatments during any period on study (0-14 d, 15-35 d and 0-35 d). Overall ADG was 5.6%

higher ($P < 0.05$) for Bt corn fed pigs (396 g/d) compared with IC pigs (375 g/d). Pigs fed the B.t corn had 2.8% heavier final live weights (22.6 kg) compared to the IC corn fed pigs (22.0 kg) ($P < 0.05$). Differences in performance may be attributed to Bt corn having a 69% lower level of fumonisin B₁ than IC corn and 14.4% lower deoxynivalenol (DON). We conclude that performance of piglets fed Bt corn is at least as good as those fed IC corn.

Key Words: Pigs, Transgenic corn, Mycotoxins

442 Effects of feeding blends of grains naturally-contaminated with *Fusarium* mycotoxins on growth and brain regional neurochemistry of starter pigs and the efficacy of supplemental yeast cell wall polymer in detoxification. H.V.L.N. Swamy¹, T.K. Smith¹, E.J. MacDonald², and A.E. Sefton³, ¹University of Guelph, Guelph, Ontario, Canada, ²University of Kuopio, Kuopio, Finland, ³Alltech Biotechnology Center, Nicholasville, Kentucky, USA.

Naturally-contaminated grains have been reported to be more toxic than equivalent amounts of purified mycotoxin based on chemical analysis. An experiment was conducted, therefore, to determine the effect of feeding a blend of grains naturally-contaminated with *Fusarium* mycotoxins to starter pigs and to test the efficacy of a polymer extracted from yeast cell wall as a dietary treatment for *Fusarium* mycotoxins. A total of 175 starter pigs (initial weight of 10 kg) were fed 5 diets (7 pens of 5 pigs per diet) for 21 days. Diets included a control, a blend of contaminated grains and contaminated grains + 0.05, 0.10 and 0.20% yeast cell wall polymer (MTB-100, Alltech Inc.). Diets containing contaminated grains averaged 3.85 ppm deoxynivalenol, 26.88 ppm fusaric acid and 0.4 ppm zearalenone. Weight gain of all pigs fed contaminated grains was significantly reduced compared to control especially in the first week of feeding. The feeding of contaminated grains significantly reduced concentrations of dopamine in the hypothalamus and concentrations of norepinephrine in the pons. The ratio of 5-hydroxyindoleacetic acid to serotonin was also elevated in pons. The feeding of 0.2% yeast cell wall polymer largely prevented these neurochemical changes. It was concluded that the feeding of grains naturally-contaminated with *Fusarium* mycotoxins can alter brain neurochemistry in starter pigs and that the changes can largely be prevented by the feeding of yeast cell wall polymer at the appropriate concentrations although this may not be reflected in increased growth rate.

Key Words: Pigs, *Fusarium*, Deoxynivalenol

443 Influence of type of cereal and level of fiber on performance of early-weaned piglets. G. G. Mateos*¹, A. Alcantarilla¹, M. A. Latorre¹, R. Lazaro¹, E. Gomez², and N. Laso², ¹Universidad Politecnica de Madrid. Spain, ²Centro de Pruebas de Porcino. Junta Castilla y Leon. Spain.

A trial was conducted to investigate the influence of type of cereal and level of crude fiber used in the diet on performance of early weaned piglets. There were eight treatments and eight replicates per treatment with 5 piglets (blocks 1 and 2) or 12 piglets (blocks 3 and 4) per replicate. The control diet included 8% fish meal, 15% dried whey, and 12% fullfat soy bean, and contained 52% of cooked and expanded corn. Treatments B, C, D, and E substituted 30% of the corn for 30% of cooked decorticated oats, cooked oats, cooked rice, and raw oats, respectively.

In addition, other three extra diets (F, G, and H) were formulated in which approximately 2.6% of cooked and expanded oat hulls were added to diets A, B, and D. Convenient non-orthogonal comparisons were conducted to test the effects of supplemental fiber (ABD vs FGH), source of cooked cereal (AF vs BG vs DH), heat processing of oats (E vs C), and dehulling of oats (B vs C) on piglet performance. At the end of the trial (42 d of age), fiber inclusion did not affect feed intake, daily gains or feed conversion ($P > 0.05$). Piglets fed cooked rice outperformed piglets fed any other cereal and showed the best gains and feed conversion (347, 317, 311 g/d; $P < 0.05$ for growth, and 1.51, 1.57, and 1.63 g/g; $P < 0.05$ for feed conversion for rice, corn, and decorticated oats, respectively). Cooking and expanding the oats improved both daily gains (303 vs 295 g/d) and feed conversion (1.55 vs 1.64 g/g) but the differences were not significant ($P > 0.05$). Dehulling the cooked oats had no impact on piglet performance. It is concluded that rice is a cereal of choice in diets for early-weaned piglets. Increasing the level of fiber of the diet by adding cooked and expanded oat hulls did not impair piglet performance. Data on cost and on productive performance should be taken into account when deciding type of cereal to use in diets for early weaned piglets.

Key Words: Heat processing, Oat hulls, Piglets

444 Singular and combined efficacy of two new microbial phytases in corn-soy or corn-soy-wheat diets for young pigs. C.H. Stahl*, J.M. Porres, K.R. Roneker, and X.G. Lei, Cornell University, Ithaca, NY.

We have expressed a heat-stable phytase from *Aspergillus fumigatus* (AP) and a catalytically-efficient phytase with low pH optimum from *Escherichia coli* (EP) in a yeast system. Two experiments were conducted to compare the efficacies of EP and AP in improving the bioavailability of phytate-P to weaning pigs in singular form and in combination with each other or with cereal phytase. In Exp. 1, 21 pigs (5-wk old, 8.11 ± .87 kg BW) were fed a corn-soybean meal basal diet containing no inorganic P (CS) supplemented with 500 U of phytase/kg of diet from AP, EP, and AP:EP (1:1) for 4 wk. In Exp.2, 36 pigs (5-wk old, 8.25 ± .79 kg BW) were used to compare the efficacy of 200 and 400 U of EP/kg of corn-soy diet containing 7.5% wheat middlings (WM, 151 U of phytase/kg of diet) with that of WM + Pi (.1%), and CS + Pi (.2%). In Exp. 1, pigs receiving CS + EP or CS + AP:EP had higher ADG (576 and 553 g, $P \leq .05$ and .08, respectively) than the pigs receiving CS + AP (463 g) during the last week of the study. Plasma alkaline phosphatase activity (AKP) was 13% higher ($P \leq .03$) in pigs fed CS + AP than those fed CS + EP diet at wk 1, and the difference became marginal at wk 4 (8%, $P \leq .07$). However, there was no difference in AKP between pigs fed CS + AP:EP and the other diets. In Exp. 2., pigs fed the CS + Pi had higher ($P \leq .05$) ADG than the other treatment groups. Increasing EP from 200 to 400 U/kg of diet resulted in 9% higher ($P \leq .05$) plasma inorganic P concentrations at wk 2 and 3. Pigs fed the higher level of EP had plasma inorganic P concentrations similar to those of pigs fed inorganic P-supplemented diets at wk 4. In conclusion, both new phytases were effective in improving phytate-P bioavailability to young pigs, but no significantly synergistic effect was seen with the combination of AP and EP, or with EP + cereal phytase under the current dietary conditions.

Key Words: Phytase, *Aspergillus fumigatus*, *Escherichia coli*

445 Effect of photoperiod on performance and energy metabolism of weanling pigs. E.M.A.M. Bruininx¹, C.M.C. van der Peet¹, W.J.J. Gerrits*², and J.W. Schrama², ¹Research Institute for Animal Husbandry, ²Wageningen Institute of Animal Sciences.

Feed intake is an important determinant of performance that may also reflect the health status of weanling pigs. Previous studies have suggested that illumination stimulates the early development of post weaning feed intake. In a 2-wk experiment the effect of photoperiod on performance and energy metabolism of newly weaned pigs was studied. Forty 4-wk-old crossbred weanling barrows weighing 8.0 kg (SEM = 0.13) were assigned to 8 groups of 5 pigs each based on BW and litter. Groups were allotted to one of two lighting schedules: 8 h light:16 h darkness or 23 h light:1 h darkness. Each group was housed in a climate respiration chamber. Piglets had ad libitum access to feed and water. Energy and nitrogen balances, heat production, ADFI and ADG were measured weekly. Heat production, energy metabolism and performance were unaffected ($P > 0.1$) by photoperiod during wk 1. However, in the second week ADFI (420 vs. 304 g/d) and ADG (381 vs. 240 g/d) were

higher ($P < 0.05$) for pigs at the 23:1 h lighting schedule than at the 8:16 h schedule. Furthermore, total energy retention, energy retained as protein and as fat were higher ($P < 0.05$) during week 2 in pigs at the 23:1 h lighting schedule (+131, +41, and +414% respectively) than at the 8:16 h schedule. Moreover, during wk 2 metabolizability of energy tended to be higher ($P < 0.1$) and energy requirements for maintenance were lower ($P < 0.05$) for pigs at the 23:1 h schedule compared with the 8:16 h schedule ($P < 0.1$). Heat production was unaffected by photoperiod during wk 2. In conclusion, exposing pigs to a longer period of light post-weaning stimulated ADFI and ADG. In addition to the feed intake, the high ADG is due to an improved metabolizability of energy and a reduced energy requirement for maintenance. The results from this study suggest that lighting schedule can be used as a tool to stimulate feed intake post weaning.

Key Words: Photoperiod, Metabolism, Pigs

446 Diets containing high quality animal proteins increase growth of early-weaned pigs. F. R. Dunshea*, P. J. Eason, D. J. Kerton, and T. Moyes, Agriculture Victoria, Victorian Institute of Animal Science, Werribee, Australia.

This study was conducted to compare the performance of early weaned pigs fed diets containing freeze dried bovine colostrum and porcine plasma with that of pigs fed diets containing conventional protein sources. Four male pigs per sow were weaned at 14 d of age from 24 sows and randomly allocated to one of four diets formulated to contain 15.5 MJ DE/kg, 0.95 g available lysine/MJ DE and 23.8% CP. All diets contained fishmeal (10%) and bloodmeal (3%) with the remaining supplemental protein being provided as skim milk (animal protein (A)), skim milk and soyabean meal (7%) (vegetable protein (V)), skim milk and plasma meal (plasma (P)) and skim milk and colostrum (colostrum (C)) The inclusion level of colostrum and plasma were reduced from 6 to 2.5% after 1 wk. Pigs fed P and C diets grew more quickly than pigs fed diets containing more conventional ingredients. However, the performance of pigs fed the A diet was only marginally less than the performance of pigs fed the diets containing immunoglobulins (Ig, C and P). Pigs fed the V diet ate less and grew more slowly than pigs fed any of the other diets, particularly over the first 2 wks after weaning. These data demonstrate that pigs fed bovine colostrum perform similarly to pigs fed freeze dried porcine plasma. While there was little benefit of feeding complex protein sources over feeding a predominantly animal protein diet, inclusion of even a moderate level of soyabean meal in the diet of early weaned pigs reduced performance over the first 2 wks post-weaning. Supported by the Pig Research and Development Corporation.

Age	Dietary A	Treatment V	Within C	IG vs P	Within sed	IG vs non-Ig	Within non-Ig	V vs non-V	
Daily Gain (g/day)

447 Potential for egg protein as a protein source for phase 1 nursery diets. J. F. Jaen*¹, C. V. Maxwell¹, Z. B. Johnson¹, D. C. Brown¹, S. Singh¹, M. E. Davis¹, K. J. Touchette², J. A. Coalson², and R. E. Musser³, ¹University of Arkansas, Fayetteville, ²Merrick's, Inc., Middleton, WI, ³The Pork Group, Inc., Rogers, AR.

An off-site trial using 216 weanling barrows was conducted to determine the efficacy of pasteurized (60°C for 1 hr) or non-pasteurized egg product to replace spray dried plasma (SDP) in the phase 1 (d 0 to 10) diet of nursery pigs. Pigs (The Pork Group, Inc.; 20 ± 2 d of age; 5.6 kg BW) were assigned by initial weight to one of six treatments in a randomized complete block designed experiment. There were six blocks with six pigs/pen. Six diets were fed during phase 1: 1) a negative control diet devoid of egg product and SDP, 2) a positive control diet containing 5% SDP added at expense of soybean meal 48%, 3) as 2 with pasteurized egg product replacing 50% of the SDP, 4) as 2 with pasteurized

egg product replacing 100% of SDP, 5) as 2 with non-pasteurized egg product replacing 50% of SDP, 6) as 2 with non-pasteurized egg product replacing 100% of SDP. All diets were formulated to contain 1.5% lysine. Upon completion of the phase 1 diet, a common phase 2 diet (1.35% lysine) was fed from d 10 to 24 after weaning, and upon completion of phase 2, a common phase 3 diet (1.20% lysine) was fed from d 24 to 38 after weaning. In phase 1, source of egg product (pasteurized or non-pasteurized) had no effect on ADG ($P > 0.1$). However, egg product added at the 50% inclusion level resulted in greater ADG and ADFI than when supplemented at the 100% inclusion level (158 and 241 vs. 134 and 189 g/d, respectively; $P < 0.05$). Pigs fed non-pasteurized egg product had greater G:F than pigs fed pasteurized egg product (0.763 vs. 0.637, respectively; $P < 0.05$). The results of this experiment indicate that non-pasteurized egg product can successfully replace 50% of SDP in nursery diets when SDP was included at 5%.

Key Words: Egg product, Diet, Nursery pigs

448 Performance of growing pigs fed wheat-based diets added with low levels of inorganic phosphorus. M. Cervantes*, A.B. Araiza, N. Torrentera, S. Espinoza, and M. Cervantes, *Universidad Autnoma de Baja California, Mexicali, Mxico.*

An experiment was conducted to evaluate the performance of growing pigs fed wheat-based diets, added with low levels of inorganic phosphorus (P). Thirty crossbred (Landrace x Yorkshire x Duroc) pigs (27.2 kg initial body weight) were assigned to 5 dietary treatments according to a randomized complete block design. Treatments T1, T2, T3, and T4 were wheat-based diets added with .20, .50, .70, and .90% dicalcium phosphate (DP), respectively; T5 was a wheat-soybean meal, control diet, formulated to meet the requirement of total P for the 20-50 kg pigs. Wheat was the sole source of dietary protein, energy, and organic P in the test diets. Inorganic P in the test diets was provided as dicalcium phosphate. Organic (wheat and soybean meal) and inorganic P were assumed to be 50, 23, and 100% available, respectively. Diets were formulated to contain .22, .28, .31, .35, and .43% available P. Feed and water were provided ad libitum. Regression analysis including treatments T1 to T4 were performed; also, the positive control was contrasted against the average of treatments T1 to T4. Daily weight gain, feed intake, feed/gain ratio, and intakes of lysine, threonine, total P, and available P were: 842, 884, 836, 878, 856 g/d; 1.93, 1.94, 1.87, 1.94, 1.76 kg/d; 2.68, 2.66, 2.6, 2.57, 2.31; 16.0, 16.1, 15.5, 16.1, 15.2 g/d; 9.7, 9.7, 9.3, 9.7, 10.9 g/d; 7.9, 9.1, 9.3, 10.5, 8.6 g/d; 4.2, 5.4, 5.8, 8.8, 7.6 g/d. Intake of both total and available P increased ($P < .01$) as the supplementation level of inorganic P increased. However, none of the performance variables (daily gain, feed intake, feed/gain ratio) was affected ($P > .10$) by the supplementation level of inorganic P. The supplementation level of inorganic P did not affect either lysine or threonine intakes. These data indicate that organic P from wheat can replace significant amounts of P from inorganic sources, reducing the cost of the diet and the P pollution. These results also show that formulating diets on the basis of available P reduce the need for inorganic P without affecting pig performance.

Key Words: Pigs, Wheat, Available phosphorus

449 Growth performance and carcass characteristics of grow-finish pigs fed increasing levels of distiller's dried grains with solubles. M. H. Whitney*¹, G. C. Shurson¹, L. J. Johnston², D. Wulf³, and B. Shanks³, ¹University of Minnesota, St. Paul, MN, ²University of Minnesota, Morris, MN, ³South Dakota State University, Brookings, SD.

Currently, the recommended maximum inclusion rate of distiller's dried grains with solubles (DDGS) in grow-finish swine diets is 10%. However, previous studies conducted at the University of Minnesota have shown that DDGS produced from new ethanol plants in the MN-SD region has higher nutrient levels and digestibility than reported in NRC (1998). Therefore, we conducted a growth performance and carcass evaluation study to re-evaluate the recommended maximum inclusion rate of DDGS in grow-finish diets when formulated on a total amino acid basis. A total of 240 (28.4 ± .8 kg) crossbred pigs were randomly assigned to one of 4 dietary treatment sequences in a 5-phase grow-finish feeding program (24 pens, 10 pigs/pen, 6 reps/trt). Dietary treatments consisted of corn-soybean meal diets containing 0, 10, 20, or 30% DDGS. All diets were formulated to contain equivalent total lysine, ME, Ca, and P levels

within each phase. Pigs were weighed and feed disappearance was determined bi-weekly. Time of changing to the subsequent diet phase was based on average pen weight within dietary treatment sequence. Pigs were slaughtered and carcass data collected when average pen weight reached 115 kg. Pigs fed the 20 or 30% DDGS diets had reduced ADG ($P < .10$) compared to 0 or 10% DDGS, but ADFI was unaffected by dietary treatment ($P > .10$). Feed/gain increased when pigs were fed 30% DDGS ($P < .10$) compared to 0, 10, and 20% DDGS inclusion levels. Dressing % decreased linearly ($P < .03$) with increasing dietary DDGS level, but slaughter weight was also lower for pigs fed 20 or 30% DDGS ($P < .05$). Loin depth was lower in pigs fed the 30% DDGS diets ($P < .10$), but backfat depth and % lean did not differ between treatments ($P > .10$). Results from this study suggest that when grow-finish diets are formulated on a total amino acid basis, less than 20% DDGS should be included in the diet for optimal performance and carcass composition. Dietary inclusion levels of 20% or greater may provide satisfactory performance and carcass composition if diets are formulated on a digestible amino acid basis.

Key Words: Pigs, Distiller's Dried Grains with Solubles, Growth

450 Availability of phosphorus in distiller's dried grains with solubles for growing swine. M. H. Whitney* and G. C. Shurson, *University of Minnesota, St. Paul, MN.*

A total of 42 growing barrows (20.1 ± 1.3 kg initial BW) were used in a slope-ratio assay to determine the availability of P in distiller's dried grains with solubles (DDGS) produced from ethanol plants in the MN-SD region. Barrows were randomly allotted by weight and ancestry to one of seven dietary treatments. Pigs were housed in individual metabolism cages and fed either a corn starch-soybean meal control diet (.29% total P) or one of six diets containing increasing levels of total P from either dicalcium phosphate (DCP) or DDGS (.34, .39, and .44% total P). Pigs were fed at a level equivalent to 2% of their initial body wt twice daily, and were allowed a 7 d adjustment period prior to a 5 day collection period. Total feces and urine were collected for each pig and analyzed for total P. Phosphorus retention was calculated as the difference between P intake and excretion. Actual P intake ranged from 2.33 g/d (control diet) to 3.91 g/d (DDGS diet with .44% total P). Urinary and fecal P excreted and total P retained increased linearly ($P < .01$) with increasing P intake, regardless of P source. However, P retention (% of intake) was not different between dietary treatments ($P > .10$). A linear regression analysis was conducted for P excreted and P retained relative to P intake for each dietary treatment separately. The slope ratios of the regression lines from each P source were used to determine P availability. Availability of P in DCP was assumed to be 100%. Slopes for P excreted and retained were .354 and .646 (DCP, $R^2 = .42$ and $.72$) and .405 and .595 (DDGS, $R^2 = .55$ and $.73$), respectively. Availability of P was 87.5 % and 92.2 %, based on P excretion and P retention, respectively. These results suggest that DDGS from the MN-SD region is an excellent source of available P for growing swine, and that P availability is higher than listed in NRC (1998).

Key Words: Pigs, Distiller's Dried Grains with Solubles, Available Phosphorus

451 Feeding value of hullless and hulled barley in grower pig diets. A.N. Fenton*, J.S. Radcliffe, A.F. Harper, M.J. Estienne, D.E. Brann, and C.A. Griffey, *Virginia Polytechnic Institute and State University.*

Ninety-six crossbred pigs (initial BW=38kg) were used in a 6-wk experiment to investigate the feeding value of hulled or hullless barley in pelleted grower pig diets. Pigs were randomly allotted to four dietary treatments, with six replicate pens of each. Diets 1, 2 and 3 were formulated to contain 0.95% Lys, 0.23% available P, 0.60% Ca and 3,446 kcal/kg DE. Diet 1 was corn-soybean meal (SBM) based. Diets 2 and 3 contained 25% corn and a combination of SBM and 46% hullless barley (Diet 2) or 42% hulled barley (Diet 3). Diet 4 was identical to Diet 2 except hulled barley replaced hullless barley on an equal weight basis. Therefore, this diet was lower in CP, energy and mineral content. Pigs had ad libitum access to feed and water. Individual BW and pen feed consumption were recorded weekly. During wk-6, fresh fecal samples were collected six times from at least three out of the four pigs in each pen. Fecal and feed samples were analyzed for Ca, P, Cr, N, DM and energy. The Duncan procedure of SAS (1994) was used to compare treatment means, with pen serving as the experimental unit. Diet type

had no effect ($P>0.10$) on ADG or feed intake over the 6-wk experiment. However, due to numerical differences in feed intake and ADG, feed efficiency was improved ($P<0.05$) for pigs fed Diet 3. There was no effect ($P>0.10$) of diet type on Ca digestibility. Phosphorus, DM, CP and energy digestibilities were lowest ($P<0.05$) for pigs fed Diet 4. The digestibility of P was similar for pigs fed Diets 1, 2 and 3. Pigs fed Diet 2 had a higher DM digestibility compared to pigs fed Diet 1 ($P<0.05$), but were similar to those fed Diet 3. Pigs fed Diet 3 had a higher CP digestibility than those fed Diets 1 or 2 ($P<0.05$). However, pigs fed Diet 3 had a slightly lower energy digestibility than pigs fed Diets 1 or 2 ($P<0.05$). The results of this study indicate that hullless or hulled barley can be incorporated into swine diets at levels of at least 40% and yield performance similar to corn-SBM based diets, if diets are formulated to the same nutrient specifications.

Key Words: Pig, Barley, Digestibility

452 Energy and nitrogen balance of pigs fed four corn grains. R.W. Fent*, S.D. Carter, M.J. Rincker, and B.W. Senne, *Oklahoma State University, Stillwater.*

Six sets of four littermate barrows (27.5 kg) were used to evaluate four corn grains (A, B, C, and D) in an energy and nitrogen balance experiment. Corns A and B were nearly isogenic with A being normal corn, while B was a high-oil variety. Corns C and D were also normal varieties. Pigs were housed individually and allotted to four dietary treatments based on weight and litter. Experimental diets (1.0% Lys) consisted of corns A, B, C, or D (90.48%) with casein (5.04%), crystalline amino acids, and a vitamin/mineral source. Pigs had ad libitum access to water and an effort was made to equalize feed intake within replicate. A 7-d adjustment period to the diets was followed by a 5-d collection of feces and urine. Data are reported on a DM basis unless otherwise noted. GE concentration and CP content of corns A, B, C, and D were: 4,462, 4,761, 4,594, and 4,601 kcal/kg and 8.73, 9.14, 9.47, and 9.02%, respectively. GE intakes for pigs fed diets containing A, B, C, and D were 5,452, 5,291, 5,387, and 4,965 kcal/d. However, fecal and urine GE excretions (kcal/d) were similar ($P>0.10$) across all treatments. The DE for the diets containing A, B, C, and D were 3,924, 4,186, 4,061, and 3,990 kcal/kg while ME were 3,868, 4,127, 4,006, and 3,935 kcal/kg, both varying ($P<0.04$) depending on source of corn. However, no differences ($P>0.10$) were seen in DE:GE (.886, .887, .894, and .885) or ME:GE (.874, .875, .882, and .873). Nitrogen absorption and retention were not affected by corn source. Previously, we determined the ME

of casein to be 4,560 kcal/kg and, thus, the casein in the diet (5.04%) supplied 230 kcal/kg. Subtraction of the ME provided by casein from the ME of the diets resulted in ME concentrations of 3,600, 3,842, 3,660, and 3,625 kcal/kg (as-fed basis) for corns A, B, C, and D. This correction resulted in slight differences ($P<0.10$) in ME:GE (.901, .905, .909, and .890) for the corn grains. These results indicate that although ME concentrations varied for the four corn grains, the differences observed were attributed to initial variation in GE concentration.

Key Words: Corn, Metabolizable energy, Pigs

453 Swine digestible energy evaluations of Bt (MON810) and Roundup Ready® corn compared with commercial varieties. A.M. Gaines*, G.L. Allee, and B.W. Ratliff, *University of Missouri-Columbia.*

Two digestible energy experiments were conducted to compare nutritional value of insect protected (containing CryIA (b) protein, Bt) corn, glyphosate-tolerant (Roundup Ready, RR) corn (containing maize EP-SPS protein), their near-isogenic parents (BtC and RRC) and three commercial corn hybrids (C1, C2, and C3). Twenty crossbred barrows (26.4±2.8 kg) were placed in metabolism crates allowing for separate collection of feces in two collection periods. Pigs were assigned to one of the five dietary treatments in a complete randomized design. Fecal matter was collected and feed disappearance recorded for the five-day periods. Both fecal material and feed were analyzed for dry matter and gross energy values to determine digestible energy coefficients for each of the experimental hybrids. There were significant differences ($P<0.05$) in digestibility coefficients (88.1%, 87.7%, 86.2%, 87.3%, and 87.6% for Bt, BtC, C1, C2, and C3, respectively). However, Bt was not different than its near-isogenic parent (BtC). Twenty additional crossbred barrows (25.5±2.9 kg) were placed in metabolism crates in two collection periods and assigned to one of the five dietary treatments in a complete randomized design. Fecal matter was collected and feed disappearance recorded for the five-day periods. There were significant differences ($P<0.05$) in digestible energy coefficients (87.3%, 88.4%, 86.0%, 88.6%, and 88.0% for RR, RRC, C1, C2, and C3, respectively). However, RR was not different from its near-isogenic parent (RRC). In conclusion, Bt and RR corn digestible energy coefficients values are not different from their near isogenic parents; however, there were differences among the other three commercial corn hybrids tested.

454 Use of matrix exponentials to enforce the positive definite constraint of covariance matrices. S.D. Kachman*, *University of Nebraska.*

Restricted maximum likelihood estimates of covariance matrices must be positive definite. Enforcing the positive definite constraint for unstructured covariance matrices is a challenge. Matrix exponentials provide a means of reducing the positive definite constraint to a symmetry constraint. An unstructured covariance matrix \mathbf{V} can be written as the exponential of a matrix \mathbf{A} . A matrix exponential is defined as $\mathbf{V}=\exp(\mathbf{A})=\sum_{i=1}^{\infty} \frac{\mathbf{A}^i}{i!}$. Provided that \mathbf{A} is symmetric and finite the covariance matrix $\mathbf{V}=\exp(\mathbf{A})$ is positive definite. By taking a spectral decomposition of $\mathbf{A}=\mathbf{P}\mathbf{D}\mathbf{P}'$ and iterating on \mathbf{D} as opposed to \mathbf{A} , the required derivatives are dramatically simplified. The partial derivative of \mathbf{V} with respect to δ_{ij} , element ij of \mathbf{D} , is $\mathbf{P}\Delta_{ij}\mathbf{P}'$ where Δ_{ij} is matrix of zeros except for elements ij and ji which are equal to $[\exp(\delta_{ii})-\exp(\delta_{jj})]/[\delta_{ii}-\delta_{jj}]$. The derivative reduces to $\exp(\delta)$ when $\delta_{ii}=\delta_{jj}=\delta$.

455 Use of partial augmentation to improve the Monte Carlo sampling of variance components. R.A.A. Torres Jr and Richard L. Quaas, *Animal Science Department - Cornell University.*

The use of Gibbs Sampling (GS) to estimate variance components (Σ) for some highly parameterized mixed linear models (animal models) results in chains with very slow mixing. Sampling all location parameters (θ) together may not be enough to overcome the slow mixing. Procedures to sample from the marginal distribution of dispersion parameters have

been suggested but they can be too computationally burdensome for certain applications. Sampling from the marginal distribution of variance components involves evaluating the likelihood as in derivative-free REML estimation, where the determinant of the mixed model equations is obtained using factorization techniques for sparse matrices. This factorization involves reordering the system of equations and results in an arrow shaped system (\mathbf{C}). This shape is the useful feature exploited here. The upper left-hand block (\mathbf{C}_{11}), corresponding to the tail of the arrow, is usually very large and very sparse and its determinant can be computed at a much lower cost than that for the entire system. Our approach is to sample Σ from its distribution marginal with respect to location parameters at the tail of the arrow (θ_1), but conditional to those at the head of the arrow (θ_2). To do so, we compute $\pi(\Sigma-\theta_2, \mathbf{y})$ which is proportional to the target distribution and requires the Cholesky factor of \mathbf{C}_{11} only and use it in a Metropolis-Hastings (MH) algorithm to obtain a sample of Σ . For a system of 255,325 equations, 75,699 were avoided by combining additive and cow effects for non-parents, what is possible as we use MH for sampling Σ . \mathbf{C}_{11} was assigned 168,000 equations as a high increase in computation resulted if more equations were included. This resulted in augmenting only with 11,626 parameters, which is about 4.5% of the number of augmented parameters in the usual implementation of the GS. Such approach is a compromise between marginal sampling and full conditional sampling of dispersion parameters. It is capitalizes on the shorter chain needed with full conditional sampling (lower autocorrelations) and the computational ease of marginalization.

456 Least Squares Lehmann-Scheffe superior to other methods for estimating variance components and heritability. W.D. Slinger* and J.W. Carlson, *North Dakota State University*.

Least Squares Lehmann-Scheffe (LSLS) estimators (Slinger, 1996) of two variance components and heritability were compared with those of ANOVA (=Henderson's Method 3 (H3)), MINQUE, ML, and REML. Model was fixed herd by random sire with interaction. Thirty-nine progeny were distributed over 3 herds and 4 sires. There were 15,000 computer simulation replications per each of 96 combinations of designs ($n=6$), heritabilities (.05, .20, .50, .70), ratios of sire variance to interaction variance (3:1, 1:3), and distributions (normal and chi-square with 3 df). The designs ranged from almost balanced to very unbalanced. Nonzero estimates of variance components and heritability were used in the comparisons presented here. Results for the normal distribution are presented here since normal and chi-square results were approximately the same for all 96 combinations. LSLS was superior to the other four methods, and the more unbalanced the design the more superior was LSLS. For instance, the relative mean square errors for heritability estimators averaged over the 48 combinations were 1.0, 2.7, 2.4, 2.2, and 2.8 for LSLS, H3, MINQUE, ML, and REML, respectively. The analogous percentages of nonzero estimates of heritability were 44, 29, 28, 17, and 28%. For the most unbalanced design, the relative mean square errors for sire variance estimators averaged over the eight combinations were 1.0, 7.6, 9.5, 4.3, and 7.3, for LSLS, H3, MINQUE, ML, and REML, respectively. The analogous percentages of nonzero estimates of sire variance were 67, 64, 61, 40, and 51%. Distributions of all LSLS estimators were superior in that the percentages of estimates within plus and minus 50% of the value of the parameter were almost always greater for LSLS than all other methods. Estimator performances were approximately the same whether the variance ratio was 3:1 or 1:3. Results are substantive evidence that LSLS is superior to the compared methods for estimating variance components and heritability and justify efforts to make the procedure computationally efficient.

457 Correlations between clinical mastitis at different stages of lactation in Norwegian Cattle using a multivariate threshold model. Y. M. Chang*¹, R. Rekaya², D. Gianola¹, B. Heringstad³, and G. Klemetsdal³, ¹*Department of Animal Sciences, University of Wisconsin, Madison*, ²*Department of Dairy Science, University of Wisconsin, Madison*, ³*Department of Animal Science, Agricultural University of Norway*.

Clinical mastitis records on 13,070 first-lactation cows from 1,868 herds, progeny of 250 sires, were analyzed. The interval ranging from 30 days pre-calving to 150 days post-partum was divided into 6 periods of equal length. Within period, it was checked whether mastitis occurred or not. Mastitis incidence was 4.3% and 10.6% in the first two periods, and ranged between 1.9% and 2.1% subsequently. The objective was to infer genetic and residual correlations between mastitis in the 6 periods. An hexivariate analysis was carried out with a Bayesian threshold model, assuming that mastitis (presence vs. absence) was a different trait in each period. Using a multivariate normal link, unobserved mean liabilities were modeled as a linear function of year, age-season of calving, herd, and sire effects. All residual variances were set equal to one. For cows culled before 150 days, missing liabilities were included in an augmented posterior distribution. Gibbs sampling was used to draw from posterior distributions of interest, and an algorithm was devised to collect samples from the residual correlation (covariance) matrix. Heritability of clinical mastitis was 0.12, 0.09, 0.11, 0.09, 0.08 and 0.09 for the 6 periods. Genetic correlations were positive and small (0.03 ± 0.27), except between periods 1 and 3 (-0.07) and periods 1 and 6 (-0.18). Most posterior coefficient of variations were larger than 100%, and zero was included in 95% credibility sets for all genetic correlations, illustrating lack of precision of inferences. Results may suggest that different genes are involved in the expression of clinical mastitis in different periods. Residual correlations ranged between -0.11 and 0.44, and were smaller for non-adjacent intervals.

Key Words: Clinical mastitis, Heritability, Threshold model

458 An assessment of threshold models with Student *t* distributed liabilities for the analysis of calving ease. K. Kizilkaya*¹, P. Carnier², G. Bittante², A. Albera³, and R. Tempelman¹, ¹*Michigan State University, East Lansing, MI, USA*, ²*University of Padova, Legnaro, Italy*, ³*Associazione Nazionale Allevatori Bovini di Razza Piemontese, Carru, Italy*.

A heavy-tailed Student *t* residual distribution may be specified as an alternative to the Gaussian distribution for the conceptual underlying liability variables in a regular threshold model. This threshold-*t* model specification is an attempt to confer outlier-robustness properties for the analysis of ordered categorical data, e.g. calving ease. However, it is not known how well various Bayesian model choice criteria would be able to correctly discern between a threshold-*t* and a regular threshold model specification in animal breeding and what implications model choice might have on breeding value inference. We assess these issues using MCMC methods in a simulation study and in an application to calving ease data. For each of three populations, underlying liabilities were generated for 1000 progeny from 50 sires, with each sire mated to 5 dams. Each population was characterized by a residual scale (variance) parameter of 1.00 and a genetic variance of 0.50 for normally distributed genetic effects. The residual effects were Student *t* distributed with degrees of freedom being 4, 20, or infinity (i.e. Gaussian) for the three populations, respectively. Underlying liabilities were converted to ordinal data with four categories based on the same threshold parameter values (relative to the overall mean) of -0.25, 0.25 and 1.25 for all populations. The data was analyzed using threshold animal models with either normal or Student *t* distributed residual specifications on the liability scale. Model choice, as based on various pseudo-Bayes factor criteria, was correctly assigned in all three cases. The regular threshold and threshold-*t* sire maternal-grandsire models were also applied to data on calving ease scores in Italian Piedmontese cattle. The Bayes factor criteria (>100) appeared to heavily favor a threshold-*t* specification; nevertheless, the rank correlation on posterior means of breeding values between a threshold-*t* and regular threshold model analyses exceeded 0.98.

459 Bayesian inference in linear mixed model using Dirichlet process prior. Romdhane Rekaya*, *Dept. of Dairy Science, University of Wisconsin*.

Practice of hierarchical modeling has exploded in the last decade both in applied statistics and in animal breeding. Such explosion is a result of 1) the great capacity of hierarchical modeling in solving complex problems by breaking them into submodels (parts) that can be solved more easily and then assembled in a natural way and 2) the development of Markov Chain Monte Carlo methods (MCMC) to overcome the computational complexity. In hierarchical models, as with all parametric models, specification of distributions for parameters and often hyperparameters is required. Usually a considerable uncertainty is associated with those distributions leading to inevitable concerns about the sensitivity of the resulting inferences to the assumed forms of component distributions. Hence, a nonparametric or semi-parametric modeling that avoids the prior specification of distribution forms is a logical choice to assess such uncertainty. A nonparametric model using Dirichlet process prior was implemented for a small data set to assess the sensibility of assuming normality for the distribution of the additive breeding values. 5621 first lactation milk yield records and 7094 animals in the pedigree were used to compare a nonparametric hierarchical model with a standard mixed linear model. Posterior mean of heritability was 0.32 and 0.31 using standard mixed linear model and nonparametric hierarchical model, respectively. No significant differences were observed on the posterior means of the genetic and residual variances using both models. The posterior mean of the "degree of belief" or precision parameter on the baseline prior of the distribution of additive breeding values was 13 strongly supporting the normality of such distribution. In animal breeding applications using mixed linear model, it looks more reasonable to assume uncertainty over the distribution of the error terms given the possibility of outlying observations.

460 Bayesian analysis of skewed Gaussian models: an application to reproductive traits in dairy cattle. G. J. M. Rosa^{*1,2}, R. Sartori², M. C. Wiltbank², and D. Gianola², ¹UNESP - Botucatu, SP/Brazil, ²UW - Madison, WI.

A normal distribution is assumed often in statistical analysis. If the assumption does not hold, e.g., when data are skewed, Gaussian-based methods may lead to erroneous inference. Alternatives include data transformations, non-parametric methods or assumptions meeting the skewness requirement. Here, the approach of Fernández and Steel (*JASA* **93**: 359-371, 1998) was adopted for modeling skewed Gaussian distributions. An extra parameter, controlling allocation of mass to both sides of the mode, is required. Data were from an experiment with Holstein cows aimed to study whether or not high milk yield affects embryo quality. Twenty-seven dry and 28 lactating cows (40-100 days post-partum) were synchronized and bred by AI. Five days after insemination, embryos were evaluated for embryonic cell nuclei cycles (ECC, estimated from embryonic cell counts) and number of accessory sperm (NAS). A Bayesian framework (with diffuse priors) was adopted; a Gibbs sampler with Metropolis-Hastings steps was used to carry out the analyses. Gaussian and skewed models with different assumptions about homogeneity of scale and skewness parameters were compared using Bayes factors. Single chains were run for each model, with 300,000 iterations for posterior inferences, after burn-in. There was skewness to the left and to the right, respectively, of the distributions of ECC and of NAS. Bayes factors gave stronger support to models having a homogeneous scale parameter, but different skewness parameters for the two groups, for both traits. No differences were found for NAS between groups of cows. ECC was more skewed in lactating cows, as some embryos had very few cycles. The skewed Gaussian methodology offers a flexible alternative for analysis of biological data.

461 Bayesian inference on uncertain paternity for prediction of genetic merit. F. F. Cardoso^{*} and R. J. Tempelman, *Michigan State University, East Lansing, MI/US.*

A simulation study was used to compare the performance of three different genetic evaluation methods when 30% of non-parent animals (i.e. without progeny) have uncertain paternity due to the use of multiple sires in mating groups. One method was best linear unbiased prediction based on Henderson's average numerator relationship matrix (ANRM). The other two methods were Bayesian and used the data to infer upon the probability of an individual with uncertain paternity being sired by any one of a number (2, 3, or 4) of candidate sires. One of these methods was an empirical Bayes (EBAYES) procedure and the other was a fully Bayesian procedure based on the use of Gibbs sampling (GIBBS). Ten simulated populations were generated at each of three different levels of heritability (h^2): .10, .30 and .50. Each population consisted of four generations of phenotypic selection and included 20 sires, 100 dams and 500 non-parent animals in total. The methods were compared by mean squared error of prediction (MSEP), mean bias (MBIAS) and rank correlation (RANK) between estimated and true breeding values. Mean posterior probabilities of true sires (MPPTS) for individuals with uncertain paternity were generally of similar magnitude under EBAYES and GIBBS. For either Bayesian method, the MPPTS were significantly greater ($P < .05$) than the corresponding prior probabilities (inverse of number of candidate sires) at h^2 equal to .30 and .50; however, these differences were not very large (+3.1 to +7.1%). At h^2 equal to .10, the MPPTS were generally not different from the prior probabilities ($P > .05$). There were no significant differences in genetic evaluations between the three methods in terms of MSEP, MBIAS and RANK ($P > .05$) for all three heritabilities. These results indicate that there may be little power in field data to infer upon candidate sire assignments for individuals with uncertain paternity. Under these and similar situations, ANRM may be satisfactorily used for genetic evaluations, particularly in light of the savings in computing resources compared to EBAYES and GIBBS methods.

Key Words: Multiple sires, Genetic evaluation, Gibbs sampling

462 Two-step and random regression analyses of weight gain of Canadian beef bulls. Flavio Schenkel^{*}, Stephen Miller, Janusz Jamrozik, and James Wilton, *University of Guelph, Guelph, ON, Canada.*

Objective was to compare a two-step (TS) model and a joint procedure via random regression model (RR) for evaluating weight gain of 25,315 bulls, weighed every 28 days on 140 day test. TS analysis consisted of fitting fixed linear regressions to weights of each bull on days of measurement to determine gain on test. In the second step, mixed model analyses of gain estimated variance components and breeding values (EBV), including fixed effects of breed, test group and starting age, and random effects of weaning herd-year group (WHY) and of animal (additive genetic). The RR model included the same effects as the TS mixed model analyses, with additional random animal permanent environment (PE) effect. Fourth order Legendre polynomials of days on test were fitted for all fixed and random effects in the model, except for breed. Breed effects and residual variances were estimated for each measurement period. Variance components and EBV's for gain were obtained from the estimated covariance function and random regression coefficients for weight. RR heritability (h^2) estimates for gain on test increased over time, being maximum at end of test (0.377) and similar to TS procedure (0.376). PE variance ratio estimates also increased over time and were higher than h^2 . WHY variance ratio estimates kept constant over time, being slightly higher at end of test (0.076) than TS (0.069). Genetic correlations between gain up to different days on test given by RR were high (from 0.81, between 28 and 140 day gain on test, to 0.99, between 112 and 140 day gain on test). Genetic correlations between gain on discrete 28 day intervals were moderate to high (e.g., 0.53 and 0.86 between the last 28 days on test and the first and fourth 28 days, respectively). Rank correlation between EBV's for 140 day gain by the two procedures was 0.97, 0.83, and 0.67 for all bulls, the 5% best (highest RR EBV's), and the 1% best bulls, respectively. Results indicate that, despite similar h^2 estimates, the two procedures rank top bulls quite differently for 140 day gain on test. RR model accounted for changes over time of genetic and environmental effects on the test weight gain curve of the bulls.

Key Words: Weight Gain, Beef Cattle, Random Regression

463 Predictions of 305-day lactation yields in cows by ARMA models. N.P.P. Macciotta^{*1}, D. Vicario², G. Pulina¹, and a. Cappio-Borlino¹, ¹Universit di Sassari, Italia, ²Italian association of Simmental cows breeders .

This study deals with ARMA models, a family of stochastic models originally developed in the context of time series analysis, used to predict Test Day (TD) yields of milk production traits in dairy cows. The main feature of ARMA models is their ability to take account both of the average lactation curve of a homogeneous group of animals and of the residual individual variability that may be explained in terms of probability models, such as Autoregressive (AR) and Moving Average (MA) processes. Furthermore, the standard method of ARMA estimation includes several diagnostic tools such as Fourier transform, autocorrelation and partial autocorrelation functions, that are helpful in identifying the most appropriate model structure. Data were TD of milk production traits (milk, fat and protein yields) of 6,000 Italian Simmental cows, with 8 TD records per lactation. Homogeneous groups were formed according to parity (1st, 2nd and 3rd calving) and data were fitted to a Box-Jenkins ARMA model. Different situations of missing data were simulated and cumulated 305-d yields were calculated by TIM using all actual (actual yields) or actual plus forecasted (estimated yields) TD yields. Accuracy of predictions is remarkable also when a few actual TD records are available. As an example, in third parity cows the correlations between actual and estimated yields are 0.88 for milk and protein and 0.84 for fat when 6 out of 8 TD records are predicted. Accuracy rapidly increases with the number of actual TD available: correlations are about 0.96 for milk and protein and 0.93 for fat when 4 out of 8 TD records are predicted. In comparison with the standard method of projecting lactations in progress by extension factors, ARMA modelling do not compress the variance of predictions. Furthermore, ARMA models can be easily implemented in data recording softwares also at farm level.

Key Words: Milk Production Traits, ARMA Models, Test Day

464 Establish confidence intervals for daily milk yield measures by robust bootstrap. P. M. Saama*¹ and I. L. Mao², ¹Michigan State University, East Lansing, MI, ²National Institute of Agricultural Science, Denmark.

Prior to statistical analyses of daily milk yield data, outliers due to equipment malfunction or confirmed milk recording errors should be removed. However, those outliers that are caused by health status, body condition, stress, energy balance, or BST would be valid data. Hence, using the central limit theorem (CLT) to establish confidence intervals (CI) for yield measures could be misleading. The "ordinary" bootstrap performs poorly in these situations. This study demonstrates the use of a robust bootstrap resampling algorithm to construct CI for daily milk yield. The double bootstrap algorithm advances the notion that CI can be constructed from a function of the sample and the mean whose distribution is independent of the mean, the sample, or any other unknown parameter using pivotal quantities. In the algorithm, the mean of the data is computed. Then the first stage bootstrap sample (F) of size n is obtained from the observed data, with replacement (WR). The difference between the mean of F and the mean of the observed data is divided by the SE of the mean (SEM) of F, is a pivotal quantity that provides a robust bootstrap-t distribution of the mean daily yield. Then, the second stage bootstrap sample (G) of size n is randomly drawn WR from F. The difference between the mean of this bootstrap sample and the mean of F is now divided by the SEM of G. The first and second stage bootstraps are repeated B and K times, respectively. The CI for the mean can be obtained from the percentiles of the bootstrap distributions. Daily milk records for 89 first lactation cows from a Michigan herd were used for demonstration with B=500 and K=500. The distribution was skewed to the right at peak and in late lactation. The 95% CI given by the CLT were widest. The ordinary bootstrap gave narrow CI while the bootstrap-t and double bootstrap methods gave relatively stable CIs. After computing 99% confidence intervals using this approach, data that do not fall within the limits of that interval could be removed prior to statistical analysis.

Key Words: Milk yield, Variation, Bootstrap

465 Determination of covariance functions for lactation traits on dairy cattle using random-coefficient regressions on B-splines. R.A.A. Torres Jr and Richard L. Quaas, *Animal Science Department - Cornell University*.

Covariance functions for dairy cattle have been specified either by a multi-trait analysis of records within an interval of the lactation followed by extrapolation or by direct modeling of observations throughout the lactation using random-coefficient regressions. Here we present an approach using regressions on B-splines that is an extension of the within interval multi-trait analysis where the intervals are specified by the knots. It allows local fitting behavior and simultaneous modeling of every day of the lactation. The approach was applied to 296,601 test day records from 36,520 cows for milk yield, 180,474 records from 27,320 cows for fat and protein yield and 135,336 records from 26,628 cow for somatic cell score coming from 13 large dairy herds from New York State during 1989 through 1997. A longitudinal model with cows as subjects was used together with other effects to adjust for environmental effects and a heteroskedastic independent residual. Inferences about the dispersion parameters were made from the samples of a Markov Chain Monte

Carlo procedure. For milk yield the 3 largest eigenvalues of the covariance function for the cow specific effect accounted for at least 85%, 11% and 2.5% of the total variance and the respective eigenfunctions were close to constant, linear and quadratic functions, with slight discrepancy at the extremes causing variance reduction. For fat and protein yield the first eigenvalue accounted for at least 94.88% and 96.20% of the total variance, respectively. This shows that a repeatability model with heterogeneous variance to account for smaller variation, mostly at the beginning of the lactation, should suffice for these traits. Somatic cell score had at least 5 eigenvalues accounting for more than 1% of the total variance. For this trait too, the first 3 eigenfunctions closely followed the constant, linear and quadratic functions.

466 Comparison of random regression test-day models using Bayes factors. Pedro Lopez-Romero*¹, Romdhane Rekaya², Yu-Mei Chang², Daniel Gianola², and Maria J. Carabao¹, ¹Departamento de Mejora Genética y Biotecnología. INIA. Madrid-Spain, ²Department of Animal Sciences. University of Wisconsin. Madison, WI- USA.

Test-day milk yields (TD) from Spanish Holstein cows were analysed with a set of random regression models (RR), including Wilmlink (W) and Ali-Schaeffer (A) functions, and Legendre polynomials (L) of varying order on additive (3 and 5) and permanent (3,5 and 6) effects. Data were 47,982 completed first lactations. L were selected from a previous study, where a wider range of L models was evaluated using REML, assuming constant residual variance (CRV). Model performance had been assessed via goodness of fit, predictive ability, and behaviour of estimated daily variance and of correlations involving yields at different parts of lactation. These RR were revisited from a Bayesian perspective, allowing for heterogeneous residual variance (HRV) between 3 intervals. Gibbs Sampling was used to draw from marginal posterior distributions. The log-marginal likelihood (LML) was estimated for each model using the harmonic mean of likelihood values. Estimated LMLs can be used to compute the Bayes Factors (LBF). LBFs were greater than 150 in all cases, showing a very strong evidence in the Jeffreys's scale. The A model did not reach the convergence after 460,000 iterations. L models reached the convergence very fast since orthogonal polynomials lower the correlation between samples. The most plausible specification was an L model of 3rd order for additive effects, and of 6th order for permanent effects. Further analysis was done for 3 L models of order 3 for additive 3,5 and 6 for permanent effects, assuming CRV. A better performance than for its corresponding HRV counterpart was noted for the 5th and 6th order models for permanent effect.

ASAS/ADSA Food Safety: Microflora Surveillance

467 Effect of Shipping Stress in Beef Cattle on Prevalence Levels of Enterohemorrhagic E. coli and Salmonella spp. from the Feedlot to the Packing Plant. A.R. Barham¹, B.L. Barham*¹, A.K. Johnson¹, D.M. Allen², J.R. Blanton, Jr.¹, and M.F. Miller¹, ¹Texas Tech University, ²Excel Corporation.

Two hundred steers and heifers, from ten pens were used to determine prevalence of Enterohemorrhagic E. coli (EHEC) and Salmonella spp. (SAL) prior to and after shipping to a packing plant. Two samples were collected per animal: ventral midline hide swab and fecal sample, two weeks prior to transportation and at the packing plant. Samples were collected from all trucks before loading animals. EHEC and SAL tests were conducted following USDA & FSIS approved protocols.

Prevalence levels were generated using the frequency procedure in SAS (1995). Changes in prevalence levels were analyzed using the T-test procedure in SAS (1995). Overall prevalence of EHEC on hides and in feces at the feedlot were 18% and 9.5% respectively and 4.5% and 5.5% at the packing plant. Results indicated a numerical decrease in EHEC prevalence from feedlot to packing plant for hides and feces (P>.05). Overall prevalence of SAL on hides and in feces at the feedlot were 6% and 18% respectively, while prevalence at the packing plant was 87% and 43%. Data indicated an increase in SAL prevalence from feedlot to packing plant with the only significant increase seen on hides (P<.0001). Twenty percent of pens at the feedlot had positive EHEC feed samples while no feed samples were positive for SAL. Water samples taken at the feedlot indicated 10% of the pens were positive for both EHEC and SAL.

Seven percent of trucks were EHEC positive and 74.5% were SAL positive. Sex significantly affected EHEC status of fecal samples ($P < .05$). Moreover, there was a relationship between sex and SAL status of fecal samples ($P < .10$). Date slaughtered impacted the change of SAL status on hides ($P < .05$). Data indicate a relationship between date slaughtered and change of SAL status in fecal samples ($P < .06$). Available pen space per animal altered the EHEC and SAL in fecal samples ($P < .05$). Truck did not significantly impact EHEC or SAL status.

Key Words: Beef Cattle, *E. coli*, Salmonella

468 Prevalence, incidence, and duration of fecal shedding of *Escherichia coli* O157:H7 by feedlot cattle throughout the feeding period. S Younts^{*1}, D Smith¹, R Moxley¹, J Folmer¹, J Gray², S Hinkley¹, L Hungerford¹, M Khaitsa¹, and T Klopfenstein¹, ¹University of Nebraska-Lincoln, Lincoln, NE, ²USDA, ARS, ARRU, Athens, GA.

The objective of this study was to describe patterns of fecal shedding of *E. coli* O157:H7 in cattle during the feeding period. One hundred steers were randomly assigned to 10 pens (10 animals each) upon arrival. Steers were fed a high concentrate finishing diet for 136 days starting in June. Once a week, fecal samples were collected from the rectum of each animal and cultured for *E. coli* O157:H7. New cases were those animals shedding the organism that had been culture negative the week before. Animals culture negative the prior week were considered the at-risk population. Duration of shedding was the number of consecutive weeks an individual was culture positive. *E. coli* O157:H7 was recovered from each animal at least once during the study. The percentage of pens with at least 1 steer shedding *E. coli* O157:H7 ranged from 10% (week 1) to 100% (weeks 10, 11, 13, 14, 15, 16, 18). The point-prevalence of cattle shedding the pathogen ranged from 1% (week 1) to 80% (week 10). The first 7 weeks of the feeding period were characterized by low incidence (≤ 0.1 new cases/animal-week) of shedding with short mean duration (≤ 2.5 weeks). Incidence increased dramatically in week 9 (0.5 new cases/animal-week), reached a maximum in week 14 (0.7 new cases/animal-week) and then gradually decreased. Mean duration of fecal shedding was longest mid-feeding, lasting 4.7 and 4.8 weeks for weeks 8 and 9 respectively. On the last sampling date, 30% of animals were culture positive, those positive had been shedding the organism a mean of 3.4 weeks, and at least one animal was shedding *E. coli* O157:H7 in 9 of the 10 pens. We concluded that prevalence of *E. coli* O157:H7 shedding within a group of feedlot cattle varied widely by time and space and that variability in prevalence was due to changes in both incidence and duration.

Key Words: Food safety, *E. coli* O157:H7, Feedlot cattle

469 Occurrence of verotoxin-producing *Escherichia coli* in beef and dairy heifers grazing the same pasture. B. H. Thran^{*} and H. S. Hussein, University of Nevada - Reno.

Verotoxin-producing *Escherichia coli* (VTEC) are foodborne pathogens that have been associated with human illness outbreaks due to consumption of contaminated beef or milk. Although there are over 60 VTEC serogroups that have been implicated in human illnesses, research in the U.S. has focused mainly on *E. coli* O157:H7. Therefore, the objective of this study was to assess the occurrence of VTEC in beef and dairy cattle under the same environment during a 1-year period. A herd of 23 yearling Angus heifers and another of 24 yearling Holstein heifers were allowed to graze an irrigated grass pasture with supplementation of alfalfa (*Medicago sativa*) hay only during winter. Each herd was sampled during four periods (spring [April], summer [July], fall [October], and winter [December]) of 1999 resulting in a total of 86 and 91 fecal samples (directly removed from the rectum) for the beef and dairy heifers, respectively. Using classic microbiological methods (based on sorbitol fermentation and 4-methylumbelliferyl- β -D-glucuronide [MUG] metabolism), 290 and 530 potential VTEC isolates were obtained from the beef and dairy heifer samples, respectively. Potential VTEC isolates were tested for verotoxicity and screened by the polymerase chain reaction for the presence or absence of the verotoxin genes (VT1, VT2, or both). The sequence and expression of the verotoxin genes were confirmed. A total of 22 VTEC isolates were detected in both herds. Serotyping of the VTEC isolates identified five isolates from the beef fecal samples as O26. Members of serogroups O6 ($n = 2$), O39 ($n = 1$), O157 ($n = 4$), O113 ($n = 1$) were isolated from dairy fecal samples. In

addition, nine VTEC isolates (one from beef and eight from dairy fecal samples) were unreactive with the 181 "O" and 52 "H" monovalent antisera used for serotyping. Based on detection of both O157 and non-O157 VTEC in our herds, it is clear that screening of cattle for VTEC should not be limited to O157. It is worth noting that members of the serogroups O6 and O26 were previously associated with human illness outbreaks in the U.S. and worldwide. Identification of VTEC-positive cattle prior to slaughter should help in reducing the risk of human foodborne illnesses and can be a critical step in any on-farm strategy to minimize the risk of food contamination with such pathogens.

Key Words: Cattle, Foodborne pathogens, *Escherichia coli*

470 Salmonella isolation on 12 Midwest and Northeast dairy farms. L.D. Warnick^{*1}, J.B. Kaneene², P.L. Ruegg³, S.J. Wells⁴, M. Saeed², C. Fossler⁴, and L. Halbert², ¹Cornell University, Ithaca, NY, ²Michigan State University, East Lansing, MI, ³University of Wisconsin, Madison, WI, ⁴University of Minnesota, St. Paul, MN.

An on-going 3-year longitudinal study is investigating the occurrence, risk factors and antimicrobial resistance patterns of *Campylobacter jejuni* and *Salmonella* on 130 dairy farms. The objective of this part of the project was to compare salmonella isolation among sample sources on 12 dairy farms sampled weekly for 7-8 weeks. Three herds per state were enrolled from MI, MN, NY and WI based upon predefined herd-size criteria. Samples were obtained from target animal populations, bulk tank milk, milk filters, water and feed sources and environmental sites during weekly herd visits and were submitted to a central laboratory for isolation of *Salmonella* using standard laboratory procedures. All herds had *Salmonella* isolated from at least 1 sample. *Salmonella* was isolated from 372 (9.3%) of 4005 fecal samples collected from cattle. The percentage of positive cultures varied significantly among categories of cattle (chi-squared test $P < 0.0001$) and for different environmental sample sources (chi-squared test $P = 0.03$). *Salmonella* was isolated from 8.8% of preweaned calves, 8.0% of healthy lactating cows, 7.1% of designated cull cows, 19.8% of dry cows due to calve within 2 weeks, 13.5% of lactating cows within 2 weeks of calving and from 13.7% of sick cows. The age of preweaned calves and days in milk of healthy lactating cows were not different for cattle with positive cultures compared with those that were culture negative (Wilcoxon rank sum test $P \geq 0.2$). *Salmonella* was isolated from 92 (11.4%) of 807 samples collected from other sources. Samples with *Salmonella* (percent positive) were bulk tank milk (2.2%), milk filters (10.1%), water tanks or drinking cups (13.8%), feed bunks (13.2%), hide swabs from cows designated to be culled (12.1%), calf pens (9.0%), calving pens (13.5%), sick cow pens (24.0%), lagoon or manure piles (14.0%), and bird feces (8.7%). Sample source had a significant effect on detecting *Salmonella* in these infected dairy herds.

Key Words: Dairy Food Safety, Salmonella

471 Isolation of *Mycobacterium paratuberculosis* (*M.ptb*) from thin market cows at slaughter. C.A. Rossiter^{*1} and W.R. Henning², ¹Cornell University, Ithaca, NY, ²Pennsylvania State University, State College.

The study had two objectives: 1. assess the prevalence of Johne's disease in sound, thin (low body condition score, < 2.5 on dairy score 1-5, < 4 on beef score 1-9) dairy and beef cows at slaughter, at high risk of clinical infection; and 2. assess *M.ptb* dissemination to liver (L) and two lymph nodes, the superficial cervical (SC) and the popliteal (P), associated with muscle used in ground product. Cows ($n = 539$) were sampled at 3 large slaughter plants: 189 dairy (primarily one No. East plant) and 350 beef (plants in So. and No. Central U.S.). The study population represented 30-50% of dairy and 10-15% of beef cows processed at the respective plants. On all 539 cows ileocecal lymph nodes (IC) and feces (FC) were cultured for *M.ptb* (Cornell Double Incubation) to diagnose infection. Culture result categories are Maximum (> 299), Moderate (31-299) and Few (1-30) colony forming units (CFU)/0.1 gm. Liver, SC and P were frozen at -70C and later cultured from 135 cows: 25/25 with Maximum/moderate CFUs, 24/49 with Few CFUs, and 86/465 negatives. *M.ptb* was isolated from IC or FC from 65/189 (34%) dairy and 9/350 (3%) beef cows. Relative diagnostic sensitivity based on + IC or FC was twice + FC alone (14% vs. 8%). Culture of L, SC and P isolated *M.ptb* from 16/135 cows (15 dairy, 1 beef) and only from those with Maximum CFUs on both IC and FC indicating disseminated late-stage infection. All 16 were positive on L; 7/16 on SC or P (6 dairy, 1 beef). CFUs were higher in L (9 Moderate, 7 Few) than SC and P

(1 Maximum, 9 Few). All cows with disseminated infection were likely identified, thus *M.ptb* was cultured from L of 16/539 (3%) of sound, thin market cows: 15/189 dairy, 1/350 beef, and only from cows with disseminated infection. *M.ptb* was cultured from SC and P from 7/539 (1.3%) cows, 6 /189 dairy and 1/350 beef. This work suggests occurrence of *M.ptb* in SC and P in the total market cow population is very low. Prevalence and risk associated with disseminated *M.ptb* should be further characterized.

Key Words: Johne's, paratuberculosis, food safety

472 Weekly shedding of *Campylobacter jejuni* on 12 Midwest and Northeast dairy farms. P.L. Ruegg^{*1}, J.B. Kaneene², L.D. Warnick³, S.J. Wells⁴, A.M. Saeed², C. Fossler⁴, and L. Halbert², ¹University of Wisconsin, ²Michigan State University, ³Cornell University, ⁴University of Minnesota.

Campylobacter jejuni has become the most common foodborne cause of diarrhea in humans. An on-going 3-year longitudinal study of 130 dairy herds is studying the occurrence, risk factors and antimicrobial resistance patterns of *C. jejuni* and *Salmonella* spp. obtained from cattle and environmental samples. The objective of this part of the study was to compare shedding of *C. jejuni* from animals located on 12 dairy farms that were sampled weekly for 4 weeks. Three herds per state were enrolled from MI, MN, NY and WI based upon predefined herd-size criteria. Fecal samples were obtained from target animal populations during weekly herd visits and were submitted to a central laboratory for *C. jejuni* isolation using standard laboratory procedures. *C. jejuni* was isolated from 154 of 2106 fecal samples (7.3%, .26 SD) and the prevalence of isolation was significantly different between farms ($F=2.25$, $p=.01$) ranging from 3.7 to 12.0%. *C. jejuni* was isolated from 6.25% (95% CI, 4.0-8.5) of preweaned calves, 7.13% (5.7-8.5) of healthy lactating cows, 12.8% (2.9-22.7) of designated cull cows, 8.4% (3.1-13.8) of close-up dry cows, 12.4% (6.6-18.2) of recently calved cows and 2.7% (.01-6.6) of sick cows. Calves that were culture positive for *C. jejuni* were 13.1 days older than calves that were culture negative ($p=.0002$). Week of sampling was not associated with prevalence of *C. jejuni* (chi-square = 4.4, $p = .22$) during the 4-week period.

Key Words: *Campylobacter jejuni*, Food Safety, Epidemiology

473 Multiple *Campylobacter coli* genotypes from sows and piglets in a commercial swine operation. M. E. Hume^{*}, R. E. Droleskey, and R. B. Harvey, USDA, ARS, SPARC, FFSRU.

Genotypes of *Campylobacter coli* isolates obtained from the feces of three sows, and rectal swabs from seventeen piglets from a farrow-to-finish swine operation were examined by pulsed field gel electrophoresis (PFGE). Five *C. coli* colonies were picked from a single culture plate for each sample following differential broth enrichment and growth on Campy-Cefex agar. Isolate genotypes were examined by PFGE following genomic DNA restriction endonuclease digestion with *SmaI* and *SacII*. Twenty-three *SmaI* and thirteen *SacII* genotypes were detected among ninety-nine *C. coli* isolates. One *SmaI* genotype was detected among isolates from each of two sows and each of seven piglets, two different genotypes were among isolates from one sow and each of seven piglets, and three different genotypes were detected in each of three piglets. Digestion with *SacII* revealed one genotype among isolates from each of two sows and eight piglets, two genotypes among isolates from each of eight piglets, and three genotypes among isolates from each of two piglets. Although some piglets were related to sows in the study and some were littermates, there was no discernable pattern of shared genotypes among piglets and their respective sows or between related piglets. Data indicate that the pigs had been exposed to multiple *C. coli* genotypes, and that detection of co-colonizing genotypes is possible by PFGE.

Key Words: *Campylobacter*, Swine, Pulsed Field Gel Electrophoresis

474 Chlorate supplementation in drinking water reduces *E. coli* O157:H7 populations in cattle prior to harvest. T. R. Callaway^{*1}, R. C. Anderson¹, T. J. Anderson¹, T. L. Poole¹, and D. J. Nisbet¹, ¹Agricultural Research Service/USDA-Southern Plains Agricultural Research Center.

Cattle are a natural reservoir of *E. coli* O157:H7. Therefore, strategies that reduce *E. coli* O157:H7 in cattle will reduce human exposures to this pathogen. Nitrate reductase converts nitrate to nitrite, but also co-metabolically reduces chlorate to chlorite, which is cytotoxic to bacteria. Nitrate reductase-positive bacteria (e.g., *E. coli*) exposed to chlorate die. As a result of this bactericidal effect, it was suggested that chlorate be used as a strategy to reduce *E. coli* O157:H7 in cattle prior to harvest. This study was designed to determine the effect of chlorate treatment on experimentally inoculated *E. coli* O157:H7 populations in cattle. Cattle ($n=8$) were fed a feedlot-style high grain ration, and were experimentally infected with 3 strains of *E. coli* O157:H7 identified via different antibiotic resistance markers. Fecal and ruminal counts of each O157:H7 strain, as well as generic *E. coli* and total coliforms were determined prior to chlorate treatment. Cattle were given access to drinking water supplemented with 2.5 mM KNO_3 and 100 mM NaCl (Controls) or 2.5 mM KNO_3 and 100 mM $NaClO_3$ (Treatment). Sodium chlorate treatment reduced the population of each O157:H7 strain approximately 2 logs (from 10^4 to 10^2) in the rumen and from 10^6 to 10^3 in the feces. Chlorate treatment reduced total coliforms and generic *E. coli* from 10^6 to 10^4 in the rumen and by 3 logs throughout the rest of the gastrointestinal tract (ileum, cecum, colon and rectum). Strains of *E. coli* O157:H7 were reduced throughout the intestinal tract. Chlorate treatment did not alter total culturable anaerobic bacterial counts. Therefore, it appears that chlorate supplementation is a potential strategy to reduce *E. coli* O157:H7 populations in cattle prior to harvest.

Key Words: *E. coli* O157:H8, Pre-harvest intervention, Sodium chlorate supplementation

475 Integron gene sequences within poultry farms and processing plants. M.T. Roe^{*1}, A. Byrd², D. Smith³, and S. D. Pillai¹, ¹Texas A&M University, College Station, TX, ²United States Dept. of Agriculture, College Station, TX, ³Gainesville College, Gainesville, GA.

The dissemination of multiple antibiotic resistant bacteria is a major issue in the poultry industry. It has been shown that the integron gene sequence plays an important role in the transfer of antibiotic resistance cassettes between pathogens. The objective of this study was to examine the occurrence of integron gene sequences within poultry production and processing. Microbial community DNA from chicken carcass wash samples at key points within poultry farm and processing plants were PCR analyzed utilizing primers specific for the 5# and 3# conserved segments of the integron gene sequence to determine the presence of integrons in sample DNA. Out of 96 total samples, 51% of the samples were positive for the integron sequence. Seventy-one % of on farm samples were integron positive, while, 66%, 46%, and 42% were positive at the post-feather removal, pre-chiller tank immersion, and post-chiller tank immersion location of a processing plant respectively. When two independent chiller immersion tanks were sampled at four discrete points over a 48-hour period, integron sequences were repeatedly detectable. These results indicate that integron sequences are widely distributed within poultry production and processing. Thus, there are multiple locations at which lateral gene transfer of antibiotic resistance gene cassettes can potentially occur.

Key Words: Antibiotic Resistance, Integron Gene Sequence, Poultry Processing

476 Detection of transgenic DNA in bovine milk: Results for cows receiving a TMR containing maize grain modified for insect protection (MON810). R.H. Phipps^{*1}, D.E. Beaver¹, and A.P. Tingey², ¹The University of Reading, Reading, UK., ²Reading Scientific Services Ltd, Reading, UK. .

The aim of the study was to determine the presence or absence in bovine milk of transgenic DNA as a result of animals consuming maize grain genetically modified (GM) for insect resistance by the Bt gene (event MON810). Ten Holstein/Friesian cows (mean days in milk 207, milk yield 25.3 kg/d, DM intake 20.8 kg/d and live-weight 639 kg) received a

TMR, in which the forage component was grass and maize silage (non-GM) in a 1:3 DM ratio and formed 55% of the TMR DM. In study weeks 1-3 the TMR DM also contained non-GM supplements of 18.5% cracked wheat, 26.1% rapeseed meal and 0.4% minerals. In weeks 4-12 ground maize grain (MON810) replaced cracked wheat. Milk and TMR samples were taken weekly prior to and after the introduction of the GM diet. In milk samples spiked with Bt DNA, PCR analyses established a minimum detection level (MDL) of transgenic DNA, of 7.5 g/l of milk. Subsequent semi quantitative PCR analyses were carried out in duplicate on TMR and milk samples using three primer sets to establish the presence of GM DNA. Two of the maize primer sets recognise different regions of the Cauliflower Mosaic Virus (CaMV) 35S promoter and the third covers the integration site of the MON810 inserted DNA. The PCR analysis was capable of detecting GM DNA fragments greater than or equal to 200 base pairs (bp) in length. The feed and milk samples analysed at week 3 when cows received a TMR containing no GM feed ingredients were negative. The TMR feed samples at weeks 4 and 12 were positive for MON810 maize DNA, but all milk samples were negative. In conclusion the results show that GM DNA could not be detected in milk (MDL 7.5 g/l of milk) from cows receiving 18.5% of their diet DM as insect protected (MON810) maize grain. The study was funded by the Milk Development Council and the Dairy Industry Federation.

Key Words: Dairy cows, GM feed ingredients, Transgenic DNA

477 Assessment of novel feeds in animal nutrition. Karen Aulrich* and Gerhard Flachowsky, *Institute of Animal Nutrition, Federal Agricultural Research Centre.*

Apart from feed safety assessment including safety for consumers, animals and environment, nutritional assessment of feeds produced using recombinant DNA techniques (Genetically Modified Organism, GMO) is necessary. In 1997 we started a program to assess GMO's of the so-called first generation (feed plants with changed tolerance or resistance and with minor changes in content of valuable and desirable ingredients) including Bt-corn, Pat-corn, Pat-sugar beets and Gt-soybeans. Apart from main nutrients (crude protein, ether extract, crude fiber, crude ash), amino acids, fatty acids, minerals, fiber components and some mycotoxins were determined in seeds of corn and soybeans, sugar beets and silages from corn and sugar beet leaves. Digestion and feeding experiments were carried out with broilers (Bt-corn), layers (Bt-corn, Pat-corn), pigs (Bt-corn, Pat-corn, Pat-sugar beets, soybeans), sheep (Bt-corn silage, Pat-corn silage, Pat-sugar beet silage), growing bulls (Bt-corn silage) and fistulated cows (Bt-corn silage). Digestibility of nutrients, performance of animals and fate of DNA were investigated. Up to now, we did not find significant differences in nutritional assessment and food quality between feeds from isogenic and transgenic plants of the first generation, except a lower mycotoxin-content (deoxynivalenol and zearalenon) in Bt-corn. The so-called substantial equivalence could be demonstrated. Fragments of plant DNA could be detected in some animal tissues (e.g. muscle from chicken), but fragments of transgenic

ASAS/ADSA Physiology: General Physiology

479 Lutalyse alters the immune response in sows after intrauterine inoculation with bacteria. M. C. Wulster-Radcliffe*¹, R. C. Seals², and G. S. Lewis¹, ¹USDA-ARS United States Sheep Experiment Station, ²University of Virginia.

During luteolysis, increases in PGF_{2α} and decreases in progesterone lead to clearance of uterine infections. Thus, we conducted an experiment to determine whether Lutalyse, a PGF_{2α} analogue, alters the uterine immune response to bacterial challenge in the absence of luteolysis and the concomitant decrease in progesterone. Sows (n = 6/group) were assigned to treatments in a 2 × 2 factorial array; bacterial challenge and Lutalyse were main effects. Vena caval blood was collected daily on d 7 through 11 of the estrous cycle. On d 7, uteri were inoculated with either PBS or 70 × 10⁷ cfu of *Escherichia coli* and 150 × 10⁷ cfu of *Arcanobacterium pyogenes* in PBS (10 mL). On d 9, saline (2 mL) or Lutalyse (10 mg) was injected i.m. On d 11, uteri were collected. Sediment (packed-cell volume; PCV) and ability to culture *E. coli* and *A. pyogenes* from uterine flushings were used to diagnose infections. Differential white blood cell counts and basal and mitogen-stimulated lymphocyte proliferation were used to evaluate immune function. All bacteria-treated sows developed uterine infections. Sows treated with bacteria and Lu-

talyse had less severe infections than sows treated with bacteria and saline (PCV = 25 vs 67%; P < 0.01). No PBS-treated sows developed infections (PCV < 5%). Neither Lutalyse nor bacteria affected progesterone (64 ng/mL) or estradiol-17β (< 1 ng/mL), indicating that luteolysis did not occur. Basal (10.2 vs 2.3 pmol) and lipopolysaccharide-stimulated incorporation (6.8 vs 2.9 pmol) of [³H]thymidine into newly formed lymphocytes was greater (P < 0.01) for Lutalyse-treated than for saline-treated sows. Lutalyse, compared with saline, increased vena caval PGF_{2α} (0.44 vs 0.28 ng/mL; P < 0.05), and Lutalyse increased neutrophils (65 vs 84/100 WBC; P < 0.01) and decreased lymphocytes (28 vs 16/100 WBC; P < 0.01). Thus, exogenous PGF_{2α} can initiate clearance of uterine infections without inducing luteolysis and decreasing progesterone and (or) increasing estradiol-17β concentrations; effects of PGF_{2α} seem somewhat independent of changes in progesterone and estradiol-17β.

Key Words: Novel feeds, Animal nutrition, Genetically modified organism

478 Differences in Transfer of Nicarbazine, Meticlorpindol and Ivermectin from Feed to Milk. C.A. Kan*¹, C.A.J. Hajee², J.A. van Rhijn², A. Klop¹, T. Zuidema², B.J.A. Berendsen², and H.J. Keukens², ¹ID TNO Animal Nutrition, P.O. Box 65, 8200 AB Lelystad, The Netherlands, ²RIKILT, P.O. Box 230, 6700 AE Wageningen, The Netherlands.

Cross contamination during feed production may result in contamination of feeds with feed additives or veterinary drugs. This may lead to contamination of milk, but the extent to which residues might occur was not known. We carried out carry-over experiments with nicarbazine, meticlorpindol and ivermectin. 6 Groups of 4 cows each (both high [> 35 kg/day] and low [<20 kg/day] producing ones) received concentrate artificially contaminated at three different levels. The high-producing cows received 12 kg and the low producing ones 2 kg concentrate per cow per day. The contaminated feed was fed for three weeks. During exposure and at least 7 days post-exposure, milk samples were collected and mixed samples per group were analysed. Two cows (one high and one low producing one) served as controls. Milk samples were analysed by validated HPLC methods with UV or fluorescence detection. The LOQ in milk for nicarbazine and meticlorpindol was 25 ng/g and for ivermectin 0.1 ng/ml. Feed levels were in the 1-12.5 mg/kg range for nicarbazine, in the 2.5-25 mg/kg range for meticlorpindol and in the 0.3-3 mg/kg range for ivermectin. Nicarbazine (measured as DNC) could not be detected in any of the milk samples. Very low levels could be detected in body fat samples of some animals slaughtered after about 8 days withdrawal. Meticlorpindol was found in milk at levels between 5 and 50 ng/g during feeding the contaminated feed only. The levels scattered, but generally a dose-response relationship between levels in feed and in milk could be established. Ivermectin was found in milk throughout the whole exposure period and up to 10 days post-exposure. Levels up to 7 ng/g were found and good dose-response relationships between feed and milk level could be established. These data show that absorption from feed and excretion into milk of these three compounds in dairy cows differed considerably. No general pattern could be deduced from these data and no general conclusion on risks of residues in milk due to cross contamination in feed mills could be drawn.

Key Words: Nicarbazine in milk, Meticlorpindol in milk, Ivermectin in milk

talyse had less severe infections than sows treated with bacteria and saline (PCV = 25 vs 67%; P < 0.01). No PBS-treated sows developed infections (PCV < 5%). Neither Lutalyse nor bacteria affected progesterone (64 ng/mL) or estradiol-17β (< 1 ng/mL), indicating that luteolysis did not occur. Basal (10.2 vs 2.3 pmol) and lipopolysaccharide-stimulated incorporation (6.8 vs 2.9 pmol) of [³H]thymidine into newly formed lymphocytes was greater (P < 0.01) for Lutalyse-treated than for saline-treated sows. Lutalyse, compared with saline, increased vena caval PGF_{2α} (0.44 vs 0.28 ng/mL; P < 0.05), and Lutalyse increased neutrophils (65 vs 84/100 WBC; P < 0.01) and decreased lymphocytes (28 vs 16/100 WBC; P < 0.01). Thus, exogenous PGF_{2α} can initiate clearance of uterine infections without inducing luteolysis and decreasing progesterone and (or) increasing estradiol-17β concentrations; effects of PGF_{2α} seem somewhat independent of changes in progesterone and estradiol-17β.

Key Words: Infection, Sow, Lutalyse

480 Lutalyse can up-regulate the uterine immune system in the presence of progesterone. G. S. Lewis* and M. C. Wulster-Radcliffe, *USDA-ARS United States Sheep Experiment Station.*

In luteal-phase ewes with uterine infections, Lutalyse, a PGF_{2α} analogue, treatment induces luteolysis and clearance of the infections. However, the direct effects of Lutalyse on uterine infections and its effects through luteolysis (i.e., decreased progesterone [P4]) are completely confounded. Thus, this experiment was conducted to determine whether Lutalyse alters the uterine immune response if P4 is maintained. Ewes (n = 8/group) were assigned to treatments in a 2 × 2 × 2 factorial array; ovariectomy, P4 treatment, and Lutalyse were main effects. On d 0 of the estrous cycle, ewes were either sham ovariectomized or ovariectomized. After ovariectomy, either sesame oil (2.5 mL) or P4 (5 mg) in oil was injected i.m. twice daily. On d 6, uteri were inoculated with 70 × 10⁷ cfu of *Escherichia coli* and 150 × 10⁷ cfu of *Arcanobacterium pyogenes* in PBS (5mL). On d 9, saline (2 mL) or Lutalyse (15 mg) was injected i.m. Vena caval blood was collected daily on d 9 through 11, and uteri were collected on d 12. Sediment (packed-cell volume; PCV) and ability to culture *E. coli* and *A. pyogenes* from uterine flushings were used to diagnose infections. Basal and mitogen-stimulated lymphocyte proliferation were used to evaluate immune function. All ewes developed infections. However, compared with controls, infections were less severe (P < 0.01) in the absence of ovarian or supplemental P4 (PCV = 7 vs 15%) or after Lutalyse (PCV = 8 vs 15%). Basal and concanavalin A (Con A)- and lipopolysaccharide (LPS)-stimulated lymphocyte proliferation increased over time (P < 0.01). Basal (1.356 vs 1.710 optical density units [OD]) and Con A- (2.18 vs 2.47 OD) and LPS-stimulated proliferation (1.75 vs 2.12 OD) were greater (P < 0.01) for Lutalyse than for saline-treated ewes. Basal proliferation was less (P < 0.01) for P4- than for oil-treated ewes. After ovariectomy, Con A-stimulated proliferation increased (2.23 vs 2.41 OD; P < 0.05). We conclude that exogenous PGF_{2α} can initiate clearance of uterine infections, independent of inducing luteolysis and decreasing P4 concentrations.

Key Words: Lutalyse, Sheep, Infection

481 Incidence of anestrus in suckled beef and milked dairy cattle. J.S. Stevenson*, *Kansas State University.*

Early conception of suckled cows is limited by the proportion of cows that are cycling at the beginning of the breeding season. Although prolonged anestrus generally is not limiting in milked cattle, negative energy balances are associated with prolonged anestrus. In more than 2,200 beef cows studied, body condition (BC), parity, and days in milk (DIM) influenced the proportion of cows cycling (cyclicality; determined by measuring blood progesterone) before the onset of the breeding season. As BC increased from <4 to >5.5 (1 = thin and 9 = fat), cyclicality increased (P<0.05) by 18.2% for each unit increase in BC. Cyclicality increased linearly from 25% (<50 d) to a peak after 70 DIM (60%). For every 10-d interval from <50 to >80 d, cyclicality increased (P<0.05) by 7.5.07%. Compared to older cows (53%), fewer (P<0.01) 2-yr-old cows with their first calves were cycling (44%), despite calving up to 3 wk earlier. Dairy cows on three farms were studied (milk yields ≥10,000 kg). In one study of 678 cows (milked 2× daily), the average cyclicality was 82% by 40 to 68 DIM. In first-lactation cows, cyclicality was lower (P<0.05) in one herd (72%) than in the second herd (87%), whereas no differences were detected for older cows (88 vs. 86%). Body condition (1 = thin and 5 = fat) assessed at time of blood sampling averaged 2.3.05. For each 0.5-unit increase in BC, cyclicality increased (P<0.01) by 4.6.22%. For each 10-d increase in DIM, cyclicality increased (P<0.01) by 6.1.17%. In a second study of 251 cows in one herd (milked 3× daily), cyclicality was only 44% by 47 to 67 d. First vs. later lactating cows (40 vs. 55%) were less (P < 0.05) likely to be cycling. Again, BC averaged about 2.3.05. As BC increased by 0.5 units, cyclicality increased (P<0.05) by 24.3.49%. Milk yield had no influence on cyclicality. In the last study of 367 cows in three herds (milked 2× daily) during the summer, cyclicality was 84% by 56 to 83 d. In this study, lactation number did not affect cyclicality, but BC (average of 2.4.05) increased (P<0.05) cyclicality by 8.5.23% for every 0.5-unit increase in BC. Further, suckled and milked cows not cycling by the beginning of the breeding period conceived at lesser rates and took longer to eventually conceive.

Key Words: Anestrus, Suckled cows, Milked cows

482 Plasma and luteal progesterone influence *in vivo* embryo development in day 5 post-estrus Holstein Friesian cows. MP Green*¹, MG Hunter¹, and GE Mann¹, ¹*University of Nottingham, Loughborough, Leicestershire, UK.*

Previous studies have demonstrated a close relationship between maternal progesterone and degree of embryo development on day 16 in dairy cows. The aim of the present study was to relate stage of embryo development on day 5 post-estrus to maternal progesterone secretion. Twenty Holstein Friesian cows (parity 1-9) were inseminated at synchronised estrus. Animals were slaughtered on day 5 post-oestrus, (estrus=Day 0) blood samples taken, CL removed and oviducts and uteri flushed. In total, 11 animals (55%) had 15 potentially viable embryos (4 double ovulations). A potentially viable embryo was defined as being intact; non-viable embryos were those with broken or empty zones. Viable embryos collected (n=15) were found to be at a range of development stages; 8-cell (n=7), 9-16 cell (n=4) and morula (n=4). Up to the morula stage all embryos were in the oviduct. Morulae were recovered from the uterus from two of the three animals. Mean plasma progesterone, luteal weight and progesterone concentrations (n=11) were 1.2ng/ml ±0.6ng/ml, 1.8g ±0.9g and 30.2µg/CL ±15.8µg/CL respectively. Plasma progesterone concentrations and progesterone:oestradiol ratio within animals increased significantly (p<0.001) over and between (p<0.05) the three developmental stages recovered. CL weight (p<0.05) and progesterone content µg/CL (p<0.01) increased significantly with stage of embryo development. Moreover, linear regression analysis demonstrated day 5 plasma progesterone increased significantly with CL weight (p<0.01) and luteal progesterone content (µg/CL) (p<0.01). The results demonstrate a close relationship between the degree of embryo development and both plasma and luteal progesterone as early as day 5. This provides further evidence that progesterone is fundamental to early embryo development and survival in the dairy cow. (Funded by Ministry of Agriculture Fisheries and Food, UK)

Key Words: Progesterone, Corpus luteum, Embryo

483 Effects of high plasma urea nitrogen levels on bovine embryo quality and development. M. L. Bode*, R. O. Gilbert, and W. R. Butler, *Cornell University, Ithaca, NY.*

Lactating dairy cows (n = 23) were fed diets designed to result in plasma urea nitrogen (PUN) levels either <19 mg/dL (LD; n = 12) or >19 mg/dL (HD; n = 11). After 30 days on diets, the cows were synchronized for estrus and superovulated in preparation for embryo flushing. Concentrations of PUN were 16.1 and 24.1 mg/dL for LD and HD cows, respectively. Embryos were recovered non-surgically on day 7 after estrus and evaluated for quality and stage of development. Embryos graded as 1 or 2 (n = 96) were frozen for direct transfer to heifer recipients. Virgin heifers (n = 122; 12 to 20 months of age) were fed diets designed to result in either low or high PUN levels (LR, HR; PUN of 8.1 and 25.1 mg/dL for LR and HR, respectively). After 30 days on diets, the estrous cycles of the heifers were synchronized. Embryos were transferred on day 7 after estrus to heifers that exhibited a palpable corpus luteum, forming four experimental groups (HD/HR, HD/LR, LD/HR, LD/LR). There were no differences in the quantity, visual quality, or stage of development of embryos collected from LD cows or HD cows. However, the embryos from the LD cows resulted in a higher pregnancy rate than the embryos from HD cows (35.1% versus 11.1% for low and high PUN, respectively; P < 0.02). Neither the diet of the heifer receiving the embryo or the combination of the donor and recipient diets had a significant effect on pregnancy rate (P > 0.05). In a second experiment, heifers (n = 39) continuing on the same low and high PUN diets as the embryo recipient heifers were synchronized for estrus and artificially inseminated. The circulating level of PUN did not affect the pregnancy rate (P > 0.95). The results of this study indicate that high PUN levels in lactating dairy cows on or before day 7 of pregnancy is deleterious to the viability of the embryo. High PUN in heifers did not affect pregnancy rate, suggesting interaction of high PUN with other conditions in cows *eg.* negative energy balance. However, further research is necessary to determine the mechanism(s) for this detrimental effect.

Key Words: cows, embryo, urea

484 Early gestational modification of conceptus development in sheep. M. E. Wilson*, B. A. Costine, and E. K. Inskip, *West Virginia University*.

The importance of the early uterine environment in determining conceptus growth and survival in livestock species is becoming more evident. These studies were conducted to determine if early gestational treatment with growth hormone could influence lamb birth weights and if treatment with estradiol would influence IGF-I content in the uterine lumen. In experiment I, estrus was synchronized with CIDR devices, inserted for 14 d, and ewes were assigned at random to receive either no treatment (n = 20) or 154 mg of recombinant bovine growth hormone (Posilac; n = 20) at the withdrawal of progesterone. Ewes were housed with fertile rams at a ewe:ram ratio of 12:1 and mating was recorded. Blood samples were collected on d 6 after estrus for quantification of progesterone and both free and total IGF-I. Each ewe was examined by transrectal ultrasonography 40 d after estrus for determination of pregnancy and enumeration of the fetuses present. At lambing, type of birth, birth weight and sex of each lamb were recorded. In experiment II, 16 ewes (n = 4 per treatment) were assigned to receive 0, 125, 250 or 500 g of estradiol on d 5 and 6 after mating (d 0 is estrus). Uterine luminal contents were collected on d 7 after mating for determination of IGF-I content. Treatment with growth hormone did not alter circulating concentrations of progesterone 6 d after estrus (2.6 ± 0.2 ng/ml, $P > 0.10$). However, growth hormone increased ($P < 0.001$) both free (0.70 ± 0.04 vs 4.37 ± 0.68 ng/ml) and total (177 ± 13 vs 490 ± 5 ng/ml) circulating IGF-I 6 d after estrus. Treatment of ewes with bovine growth hormone prior to breeding tended to increase ($P < 0.07$) birth weight of lambs (5.1 ± 0.2 kg vs 4.5 ± 0.2). Treatment of ewes on d 5 and 6 of gestation with 125 and 250 g of estradiol did not increase uterine luminal IGF-I content (5.5 ± 2.2 and 6.1 ± 1.7 ng) when compared to controls (8.4 ± 1.5 ng). However, 500 g of estradiol resulted in an increase ($P < 0.05$; 14.4 ± 2.5 ng) in uterine luminal IGF-I content when compared to controls. These data support our suggestion that modulation of early uterine environment with growth hormone, and potentially estradiol, may modify conceptus development.

Key Words: Ewe, Pregnancy, Conceptus development

485 Use of recombinant GnRH antigens for immunosterilization of beef heifers. T. W. Geary*¹, E. E. Grings¹, M. D. MacNeil¹, S. E. Bellows¹, K. P. Bertrand², D. M. de Avila², and J. J. Reeves², ¹USDA-ARS, Fort Keogh LARRL, Miles City, MT, ²Washington State University, Pullman.

Beef heifers (n = 47) were allotted by age (mean = 8.5 mo) and weight (mean = 238 kg) to evaluate immunosterilization with one of three different GnRH antigens or control. Each heifer received a primary immunization at wk 0 and booster immunizations at wk 6 and 12 containing 1 mg of protein in 1 mL of adjuvant administered in the mammary gland. Heifers were immunized against either a fusion protein consisting of thioredoxin with seven GnRH peptides (tGnRH), a fusion protein consisting of ovalbumin with seven GnRH peptides (oGnRH), a cocktail of tGnRH/oGnRH, or a cocktail containing thioredoxin and ovalbumin (control). Six heifers within each treatment received Synovex H implants at wk #2. Weekly blood samples were collected from wk #2 to 26 to determine serum progesterone concentrations and GnRH antibody titers. GnRH antibody titers increased after the first booster injection, peaked after the second, and remained elevated through the end of the study for GnRH immunized heifers ($P < 0.01$). Heifers that were immunized against oGnRH had greater ($P < 0.05$) GnRH antibody titers than tGnRH heifers but did not differ ($P = 0.20$) from tGnRH/oGnRH heifers. Estrous cycles were suppressed ($P < 0.05$) in 10/12, 12/12, 11/12 and 0/11 tGnRH, oGnRH, tGnRH/oGnRH, and control heifers, respectively. At slaughter, uterovarian weights were lighter ($P < 0.01$) for GnRH immunized heifers than controls. Synovex H implanted heifers had greater ADG from wk 6 to 26 and wk #2 to 26, greater REA, and lower %KPH, yield grade, and quality grade than non-implanted heifers. We conclude that immunization against the tGnRH, oGnRH and tGnRH/oGnRH fusion proteins produced anti-GnRH antibodies that suppressed estrous cycles in 83, 100 and 92% of heifers, respectively, without affecting feedlot or carcass performance. Implanting heifers with Synovex H improved ADG, REA, and yield grade. Protocols that yield greater than 95% estrous suppression may someday replace surgical spaying of heifers.

Key Words: GnRH, Heifers, Sterilization

486 Induction of the "ram-effect" and response to estrus induction procedures in Fall born ewe lambs. M. Knights*¹, Q. S. Baptiste¹, and P. E. Lewis¹, *West Virginia University, Morgantown, WV*.

The ability of ram introduction (RI) to induce the "ram-effect" and the ability of progesterone (P4) pre-treatment and RI to induce estrus and ovulation in Fall born lambs during the anestrus season was investigated. In early July lambs of mixed breeds (41.8 ± 0.6 kg and 250.7 ± 1.3 d) were assigned to be untreated (C, n=7), introduced to rams (7:1 ewe:ram ratio; R, n=7), treated with a CIDR device for 5 d (P, n=5), treated with a CIDR device and introduced to rams at CIDR removal (PR, n=11), or given estradiol (25 mg, E2b i.m.) 24 h after CIDR withdrawal/RI (PER, n=11). Blood samples were collected from lambs in groups R, P and C every 4 h for 60 h from RI/CIDR withdrawal (0 h), to characterize the LH surge profile and in groups R and C every 15 minutes from 12 to 20 h for determination of LH pulse frequencies. Ultrasonographic examinations of the ovaries were conducted at 0, 36 and 60 h. Observations for estrus was done every 4 h from 0 to 60 h. Lambs in group R had a higher LH pulse frequency than C lambs ($P < 0.01$; 7.7 ± 0.5 and 2.7 ± 0.8 pulses/8h for group R and C, respectively). More lambs in the R group than in P or C groups showed an LH surge and ovulated ($P < 0.05$; 7/7 vs 0/5 and 0/7, and 6/7 vs 0/5 and 0/6 for groups R, P and C, respectively). Diameter of the largest follicle at 0 h (3.2 ± 0.1 mm) was not different among groups. Growth rate of the largest follicle between 0 and 36 h was greater in RI groups than group C ($P < 0.05$; 1.5 ± 0.2 , 1.3 ± 0.3 , 0.86 ± 0.3 , -0.11 ± 0.6 mm/d for lambs in R, PR, PER, and C groups). Diameter of the largest follicle at 36 h was 5.6 ± 0.2 , 5.1 ± 0.5 , 4.3 ± 0.4 , and 4.0 ± 0.6 for lambs in R, PR, PER, P and C groups, respectively and was larger ($P < 0.05$) in R than PER, P and C, and in PR than P groups. Number of follicles 3 mm was not different among groups at 0 (1.6 ± 0.1) or 36h (1.3 ± 0.5), but was greater at 60 h in C (1.7 ± 0.4) than in R (0.7 ± 0.2), PR (0.6 ± 0.2) and PER (0.3 ± 0.2) groups. Estrus was observed in 73, 45 and 0 % of lambs in PER, PR and R groups, respectively, and was greater ($P < 0.05$) in P4 pre-treated lambs (PER and PR) than R lambs. During seasonal anestrus, fall born ewe lambs show a typical "ram-effect" response to RI further, P4 pre-treatment and RI when combined with E2 results in a high estrus response.

Key Words: Fall born ewe lambs, Ram-effect, Anestrus

487 Uterine responses to a graded dose of genistein in postpubertal gilts. J.A. Ford, Jr.* and W.L. Hurley, *University of Illinois, Urbana, Illinois*.

Phytoestrogens can affect the reproductive tract in some mammalian species. The objectives were to characterize the change in uterine wet and dry weights in gilts following administration of a graded dose of the soybean phytoestrogen, genistein. Twenty postpubertal gilts were ovariectomized in order to remove endogenous estrogen. The gilts were randomly assigned to one of five treatment groups 15 d post ovariectomy. Genistein was solubilized in DMSO prior to mixing with peanut oil vehicle. Treatment groups received either no hormone (G0) or genistein at 50 mg / d (G50), 100 mg / d (G100), 200 mg / d (G200), or 400 mg / d (G400). Treatments were administered by IM injection at 12-h intervals for 10 d. Gilts were slaughtered after the 10 d of injections. Uteri were collected at the time of slaughter, trimmed of all extraneous tissue, and weighed. Dry weights were determined by freeze-drying a portion of the sample. Uterine wet weight increased as the dosage of genistein increased ($p < .01$; 103.1 ± 43.8 g for G0, 108.7 ± 33.6 g for G50, 108.5 ± 23.8 g for G100, 174.0 ± 34.7 g for G200 and 249.5 ± 70.7 g for G400). Uterine wet weight standardized for body weight increased as the dosage of genistein increased ($p < .01$; 71.3 ± 28.1 g / 100 kg BW for G0, 78.1 ± 21.2 g / 100 kg BW for G50, 78.8 ± 14.6 g / 100 kg BW for G100, 126.4 ± 19.9 g / 100 kg BW for G200 and 171.2 ± 48.1 g / 100 kg BW for G400). Uterine dry weight increased as the dosage of genistein increased ($p < .03$; 17.3 ± 7.6 g for G0, 19.5 ± 3.5 g for G50, 20.7 ± 5.9 g for G100, 27.9 ± 6.6 g for G200 and 35.6 ± 8.2 g for G400). Uterine dry weight standardized for body weight increased as the dosage of genistein increased ($p < .02$; 11.9 ± 4.9 g / 100 kg BW for G0, 13.5 ± 2.1 g / 100 kg BW for G50, 14.4 ± 3.8 g / 100 kg BW for G100, 20.0 ± 3.8 g / 100 kg BW for G200 and 24.5 ± 5.5 g / 100 kg BW for G400). Hydration percentage was unchanged in the uterine samples ($p > .26$; 83.5 ± 1.4 % for G0, 84.4 ± 1.9 % for G50, 82.1 ± 2.2 % for G100, 84.2 ± 1.2 % for G200 and 85.1 ± 1.8 % for G400). A graded dose of genistein causes a significant

increase in uterine wet and dry weights, but does not change the proportion of water in uterine tissue in ovariectomized postpubertal gilts. Administration of high doses of the soybean phytoestrogen, genistein, may affect reproductive tract development and function.

Key Words: gilt, phytoestrogen, uterus

488 Pancreatic insulin response and tissue responsiveness to insulin in dry cows, lactating cows and cows suffering from fatty liver: results of hyperglycemic and hyperinsulinemic euglycemic clamp experiments. M. Kaske*, K. Herzog, S. Kraeft, and J. Rehage, *Clinic for Cattle, School of Veterinary Medicine, D - 30173 Hannover, Germany.*

First objective was to study the pancreatic insulin response to glucose in 5 dry cows (mean \pm SEM: 38 \pm 11 d ap), 5 lactating cows (47 \pm 11 d pp; 28 \pm 2 kg milk/d) and 5 early-lactating cows suffering from fatty liver (increased liver enzymes, liver triglycerides > 50 mg/g; 20 \pm 2 d pp). During the euglycemic clamp, blood glucose was clamped at 4 mM for 2 h by adapting glucose infusion rate according to the blood glucose concentration measured every 5 min. Plasma insulin and non-esterified fatty acids (NEFA) were analyzed repeatedly. The amount of glucose necessary to clamp blood glucose was higher for lactating cows than for dry cows and fatty liver cows (15.5 \pm 1.6, 9.8 \pm 1.4, 10.1 \pm 2.5 μ mol/kg/min, respectively). The pancreatic insulin response to glucose infusion was twice as high in dry cows (steady-state plasma insulin during glucose infusion about 30 μ U/ml) than in lactating cows and fatty liver cows which reached comparable steady-state insulin concentrations during glucose infusion (about 15 μ U/ml). In all groups, irrespectively of marked differences in the basal NEFA concentrations, NEFA dropped during glucose infusion by about 40 %. Second objective was to compare the responsiveness of peripheral tissues to insulin. Each 5 or 6 dry cows (22 \pm 2 d ap), lactating cows (42 \pm 7 d pp), early-lactating fatty liver cows (21 \pm 3 d pp) and early-lactating ketotic fatty liver cows (plasma hydroxybutyrate > 1.5 mM; 18 \pm 5 d pp) received bovine insulin intravenously in amounts of 0.1, 0.5, 2.0, 5.0 and 10.0 mU/kg/min consecutively for 2 h each. Blood glucose was clamped at the basal level by infusing varying rates of glucose. The maximal insulin response defined as the mean steady-state glucose infusion rate during infusion of 10 mU insulin/kg/min was higher in lactating cows than in dry cows; the response was further reduced in fatty liver cows and lowest in ketotic fatty liver cows (35.8 \pm 3.0, 28.2 \pm 0.7, 22.4 \pm 1.3, 14.5 \pm 1.4 μ mol/kg/min, respectively). It is suggested that the insulin resistance of fatty liver cows could be due to post-binding defects in insulin action and/or a depletion of GLUT-4. Results further emphasize that basal plasma concentrations of insulin do not reflect the extent of insulin resistance in cows.

Key Words: Insulin, Clamp, Fatty liver

489 Effect of feeding level on rumen papillae is mediated by IGF-1. Zan-Ming Shen^{1,2}, Berthold Lhrke¹, Falk Schneider¹, Hartmut Franz¹, Arthur Chudy¹, Siegfried Kuhla¹, Rudolf Zitnan^{1,4}, Holger Martens³, and Hans Hagemeister¹, ¹Research Institute for Biology of Farm Animals Dummerstorf, Germany, ²Nanjing Agriculture University, China, ³Berlin Free University, Germany, ⁴Research Institute of Animal production Nitra, Slovakia.

Eight male goats (4-month) were individually fed with grass hay (ad lib.) and concentrate 1.1 kg/d (HL) or 0.3 kg/d (LL) for 41-d to study the effect of feed intake on the rumen papillae development and function as well as IGF-1 profile *in vivo* and to test the effect of IGF-1 on rumen epithelial cell proliferation *in vitro*. The plasma IGF-1 (RIA), ruminal VFA and weight gain were measured before and weekly during experiment. On d 42 of experiment, the papillae size and ion transport (Ussing-chamber) was determined. The isolated epithelial cells were incubated with (25 ng/ml and 50 ng/ml) or without IGF-1 to measure the cell cycle *in vitro*. The HL treatment significantly increased daily weight gain ($P < .05$) and plasma IGF-1 concentration. Compared with LL treatment, the papillae size and surface of rumen epithelium was larger (717, 476 and 110 vs 1626, 1089 and 242 mm²/cm², $P < .05$) in the atrium, ventral rumen sac and ventral blind sac and, the rumen transport of Na⁺ across the epithelium (ventral rumen) was significantly increased by HL treatment. The total VFA concentration was almost identical, but the mole percentage of ruminal butyric and propionic acid was higher in HL ($P < .05$). *In vitro*, 25 ng/ml of IGF-1 increased S and S+G₂ phase cells in LL ($P < .05$ and $P < .10$) and S phase cell in HL ($P <$

.10) treatment, but 50 ng/ml administration did not. The cell number of S phase ($P < .05$) and S+G₂ phase ($P < .05$) were enhanced in HL by 25 ng/ml of IGF-1. The results *in vivo* show a correlation between concentrate feeding, plasma IGF-1 and rumen papillae development. The *in vitro* results suggest that IGF-1 promotes rumen epithelial cell proliferation and that the response of epithelial cell to IGF-1 was regulated by feeding level. In conclusion, the results support the assumption that the effect of feeding level on rumen papillae development is mediated by IGF-1.

Key Words: Feeding level, IGF-1, Rumen papillae

490 Influence of solar radiation and feeding level on feed and water intake, digestibility, thermo-respiratory response and some blood constituents in sheep. Mostafa Kobeisy^{*1}, Faisal Elhommosi¹, Galal Abdel-Hafiz¹, and Hassanain Badawy^{2, 1} *Animal Prod. Dept., Fac. of Agric., Assiut University, Assiut-Egypt., ²Desert Research Center, Cairo-Egypt.*

This study was carried out to investigate the effect of exposure to the direct solar radiation on both feed and water intakes, digestibility of nutrients, thermo-respiratory response, some blood constituents, thyroid (T3&T4) and cortisol hormone. Six clinically healthy saidi rams over one year old and had an average body weight of 40 kg were used in this study. Animals were subjected to solar radiation from 9.00 to 16.00 h and maintained outdoors all over the days of trial throughout July. Feed and water intake were recorded. Blood samples were taken for Hb, PCV %, and serum total protein, albumin, globulin, triglycerides, cholesterol, AST, ALT, T3,T4 and cortisol determination. Respiration and rectal temperature were recorded. Digestibility coefficient were determined. The digestibility coefficients of DM, OM, CP, NFE, ADF and ADF were higher ($P < 0.01$) in animals exposed to direct sun rays than those non-exposed. Respiration rate and rectal, skin and wool temperatures revealed higher ($P < 0.01$) values after exposure to direct sun light than that before exposure. Solar radiation decreased ($P < 0.01$) serum glucose, cholesterol and cortisol hormones concentrations. Animals fed ad libitum level of nutrition had higher ($P < 0.01$) PCV, % than those fed restricted level, particularly after sun exposure. Animals exposed to solar radiation had lower concentrations of glucose and cholesterol.

Key Words: Sheep, solar radiation, digestibility, blood, thermo-respiratory response

491 Cortisol, insulin, triiodothyronine and weight gain in Hereford and Senepol steers on endophyte-infected tall fescue or orchardgrass. R. Browning, Jr.*¹, N. Whittingham, and T. Payton, *Tennessee State University, Nashville.*

Heat-sensitive Hereford (278 kg; n = 30; H) and heat-tolerant Senepol (261 kg; n = 28; S) steers were fed endophyte-infected tall fescue (TF) or orchardgrass (OG) to assess the effect of heat tolerance in cattle on physiological responses to endophytic fescue. Following a pretreatment diet of OG hay, 15 H and 14 S steers were fed TF hay and seed, while the remaining 29 steers were fed OG hay and seed. The study was from mid-June to mid-October of 2000 with experimental diets starting in mid-July. Steers were weighed and bled at 2-wk intervals for 4 mo. Cumulative weight gain was similar for the groups during the 1-mo pretreatment period (21, 20, 26, and 25 \pm 3 kg for HOG, HTF, SOG, and STF, respectively). Weight gain was affected ($P < 0.03$) by a breed \times diet interaction after 1 mo of treatment. Weight loss in HTF (-19 \pm 3 kg) differed ($P < 0.01$) from weight maintenance in STF (1 \pm 3 kg), which in turn differed ($P < 0.01$) from weight gain by HOG and SOG (11 and 17 \pm 3 kg, respectively). After 3 mo on the experimental diets, breed \times diet affected ($P < 0.001$) cumulative weight gain with HTF exhibiting lower ($P < 0.01$) total weight gain (28 \pm 3 kg) compared to STF, SOG, and HOG (48, 50, and 56 \pm 3 kg, respectively). Plasma insulin and triiodothyronine concentrations were affected by a breed \times diet \times time interaction ($P < 0.05$). During the first 2 mo of dietary treatment, mean triiodothyronine concentrations were higher ($P < 0.01$) for STF (126 \pm 3 ng/mL) compared to HTF, HOG, and SOG (104, 107, and 107 \pm 3 ng/mL, respectively). During the first month on experimental diets, HTF had lower ($P < 0.001$) insulin concentrations (3.7 \pm 0.3 μ IU/mL) compared to SOG, STF, and HOG (5.4, 6.0, and 6.2 \pm 0.3 μ IU/mL, respectively). Plasma cortisol concentrations

were not affected by a 3-way or diet \times time interaction. Results suggest that heat tolerance in steers can modify physiological responses to endophyte-infected tall fescue.

Key Words: Fescue Toxicosis, Cattle Breeds, Heat Tolerance

492 The effect of supplemental feed at parturition in the rainy season on hair sheep ewe performance in the tropics. R.W. Godfrey*, W. Gonzales, and R.E. Dodson, *University of the Virgin Islands, Agricultural Experiment Station, St. Croix.*

St. Croix White and Barbados Blackbelly hair sheep ewes were used to evaluate the effect of supplemental nutrition around lambing on ewe and lamb performance during the wet season on St. Croix. Beginning 14 d prior to expected day of lambing (day 0) and for 21 d postpartum, 11 ewes were fed a pelleted complete ration (17% crude protein) at a level to provide 150% of the nutrient requirements, in addition to grazing guinea grass pasture (FEED). Twelve ewes grazed pasture only (CONTROL). This study was conducted during October through January. Total rainfall during this time was 212 mm and forage dry matter ranged from .77 to 2.49 MG/ha. The 24-hr milk production of all ewes was measured on days 7, 21, 35, 49 and 63. Ewes were given 1 IU of oxytocin (i.v.) and

milked by hand and separated from their lambs. Four hours later ewes were hand milked again, using oxytocin, and the milk from the second milking was weighed to determine 24-hr milk production. Ewes were exposed to sterile rams equipped with marking harnesses to detect estrus during the postpartum period. Lambs were weaned at 63 d of age. Data were analyzed by SAS using treatment and days postpartum as main effects. The CONTROL ewes lost a higher percentage ($P < .05$) of their pre-lambing weight during lactation than FEED ewes. There was no difference ($P > .10$) in milk production between FEED and CONTROL ewes. The time to first postpartum estrus was less ($P < .03$) in FEED than in CONTROL ewes (33.0 ± 2.5 vs 41.1 ± 2.4 d, respectively). Litter birth weight was similar ($P > .10$) for FEED and CONTROL ewes ($4.2 \pm .5$ vs $4.9 \pm .4$ kg, respectively). Lamb weaning weight was not different ($P > .10$) for lambs raised by FEED or CONTROL ewes ($17.3 \pm .9$ vs $15.8 \pm .8$ kg, respectively). There was no difference ($P > .10$) in ADG of lambs in the FEED or CONTROL groups (222.1 ± 13.6 vs 200.4 ± 11.9 g/d, respectively). Supplementation of hair sheep ewes around parturition during the rainy season in the tropics does not appear to enhance ewe or lamb production traits.

Key Words: Sheep, Lamb, Milk Production

ASAS/ADSA Ruminant Nutrition: Fat Nutrition/Feed Intake

493 Effect of feeding different sources of supplemental fat on the performance of lactating buffaloes. H. Nawaz, M. Abdullah*, and G. Mohiuddin, *University of Agriculture, Faisalabad, PAKISTAN.*

Four early lactating Nili-Ravi buffaloes were fed four experimental diets either containing no added fat (control) or tallow, poultry fat or mustard oil at 3 per cent of diet dry matter in a 4 \times 4 Latin Square Design. The intakes of DM, and CP decreased ($p < 0.05$) in buffaloes fed diet supplemented with tallow or poultry fat compared to either control or diet containing mustard oil. Intake of NEL were significantly higher in buffaloes consuming mustard oil versus those fed the control diet or diets containing tallow or poultry fat (21.4 vs. 19.6 19.0 19.4 Mcal/d, respectively). Average daily production of milk and 4 percent FCM, was significantly higher in buffaloes fed diets containing supplemental fat (13.0, 20.6, kg/d) vs. in those fed the control diet (10.6, 16.0, kg/d), respectively. Milk fat percentage was significantly higher (8.38 %) in buffaloes consuming diet supplemented with tallow than in those fed diet supplemented with poultry fat (7.90 %), mustard oil (7.45 %) or control diet (7.41 %). The concentrations of C8:0 to C16:1 fatty acids were lower (39.16 vs. 59.13 %) while those of C18:0 to C20:0 were higher (59.69 vs. 40.04 %) in milk fat of buffaloes fed diets containing supplemental fat than in those fed the control diet. Total solids contents were higher for buffaloes consuming tallow-supplemented diet (17.75 %) versus those fed the control (16.47 %), poultry fat (17.27 %) or mustard oil (16.56 %) supplemented diets. The GE of milk (Kcal/kg) and total GE of milk (Mcal/d) were higher for buffaloes consuming the tallow-supplemented diet (1221 and 15.7) compared with the control (1063 and 11.2) or diet containing mustard oil 1074 and 13.7). Digestibility of DM was significantly higher in animals fed diet-containing tallow (71.3 %) than in those fed the control diet (69.9 %). The digestion coefficient of EE increased significantly in buffaloes fed diets containing tallow (75.9 %) and poultry fat (73.8 %) versus the control (70.2 %) or the diet containing mustard oil (69.4 %). Significantly lower ratios of acetate to propionate were observed in buffaloes fed different fat sources (2.6) than the control diet (3.18).

Key Words: Supplemental fat, Buffaloes, Milk production, Digestibility

494 Effect of feeding different levels of supplemental tallow on the performance of lactating buffaloes. M. Abdullah*, H. Nawaz, and G. Mohiuddin, *University of Agriculture, Faisalabad, PAKISTAN.*

Four early lactating Nili-Ravi buffaloes were fed four experimental diets containing 0, 2, 4 or 6 % tallow in a 4 \times 4 Latin Square Design. The intakes of DM, OM, CP, ADF and NDF decreased ($p < 0.01$) but intake of EE ($p < 0.01$) and DE ($p < 0.05$) increased with increasing levels of tallow in the diets. Intake of NEL did not differ significantly with varying levels of supplemental tallow. Daily milk yield increased (from 11.0 to

13.2 kg/d, $p < 0.01$), production of 4 percent FCM, SCM, and ECM increased quadratically ($p < 0.05$) with the increasing level of tallow in the diets. Milk fat content and total milk fat increased respectively with increasing levels of tallow. The proportion of C8:0 to C16:1 fatty acids decreased (53.66 to 35.52 %), whereas, concentration of C18:0 to C20:0 increased (44.93 to 62.84 %) in milk fat of buffaloes fed diets containing different levels of tallow. No differences were observed in concentration of milk protein and lactose among control and those fed different levels of tallow. Total solids contents increased (16.45 to 17.67 %, $p < 0.05$) but SNF percentages did not vary with varying levels of tallow. The GE of milk (Kcal/kg) increased (1096 to 1160, $p < 0.01$) with increasing levels of tallow in the diets. Energetic efficiency of milk production improved in a quadratic ($p < 0.05$) manner with 2, 4 and 6 percent tallow, highest (47.6 %) with 4 % supplemental tallow. The digestibility of DM and OM was 66.4 & 63.4, 67.9 & 64.9, 70.6 & 67.2 and 67.4 & 62.7 %, ($p < 0.05$) with 0, 2, 4 and 6 % supplemental tallow in the experimental diets, respectively. The digestibility of CP did not differ, while that of EE improved (68.2 to 74.5 %, $p < 0.01$). The blood pH and concentration of glucose did not vary significantly due to varying levels of tallow in the diets. The concentrations of cholesterol, triglycerides and blood lipids increased ($p < 0.01$) with increasing levels of tallow. A linear ($p < 0.01$) decrease in acetate to propionate ratio was observed with increasing levels of tallow in the diets (3.24 to 2.66, $p < 0.01$).

Key Words: Supplemental tallow, Buffaloes, Milk production, Digestibility

495 A two-year study measuring the reproductive performance of dairy cows fed soybeans. A. Mowrey*, J. N. Spain, M. C. Lucy, M. R. Ellersieck, and K. L. Fritsche, *University of Missouri - Columbia.*

Two studies were conducted during two consecutive years to evaluate the effects of fat supplementation on milk production and reproduction in dairy cows. Year 1 (Y1) utilized a randomized complete block design with 84 early lactation dairy cows fed a control diet or a diet with either raw cracked soybeans or a rumen inert fat product added. In Year 2 (Y2), 68 early lactation dairy cows were fed a control diet or one of three diets containing increasing amounts of soybeans. Cows received treatments beginning two weeks post-calving and were fed assigned treatment until animals were inseminated (Y1) or until 70-d post calving (Y2). Milk yield, milk components, intake, body weight and plasma progesterone were measured. During Y1, pretreatment and experimental milk yield was significantly higher for control and soybean-fed cows ($P \leq 0.05$). Fat-corrected milk yield was not different among diets. Dry matter intake followed the same trend as milk yield, averaging less for cows fed inert fat; as a percent of body weight these changes were not significant. Plasma stearic acid increased following feeding of the diets containing supplemental fat. Progesterone concentrations changed little due to dietary treatments. Ultrasonographic measures of follicular

and corpus luteum growth during Y1 were similar for cows fed different diets. During Y2, production parameters of milk yield and DMI were unchanged. Milk protein percentage decreased significantly as level of soybeans increased, although yield of milk protein was similar. Plasma cholesterol increased from day one until the end of the study and increased as fat was added to the diets. Plasma stearic and linoleic acid was highest in cows fed the diets containing soybeans. Percentage of cows in estrus after estrous synchronization was 87.2% (Y1) and 71% (Y2) and conception rate to the synchronized estrus was 41.2% (Y1) and 38% (Y2), both were similar across diets. In summary, raw soybeans were fed to lactating dairy cows without significant decreases in production, ovarian activity, or conception rate.

Key Words: Dairy cows, Reproduction, Plasma fatty acids

496 Interactions of Rumensin premix and diet on milk fat percentage in lactating dairy cattle. T Duffield^{*1}, R Bagg², D Kelton¹, and P Dick², ¹Department of Population Medicine, University of Guelph, ²Elanco Division of Eli Lilly Canada Inc.

A total of 91 Ontario Holstein dairy herds were surveyed in the spring of 1999 for general lactating cow ration information and the use of Rumensin[®] premix in their lactating cow diets. In addition, herds were asked to submit wet forage and TMR samples to the Ontario Veterinary College for evaluation of particle size. All herds were enrolled in Ontario Dairy Herd Improvement (DHI) milk recording. Four DHI tests near the time of the feed sampling (March to June) were selected and pooled to calculate the herd mean milk fat percentage. To avoid the confounding effects of stage of lactation, the herd mean milk fat test was calculated for only those cows that were between 100 and 200 days in milk at the time of each DHI test.

Of the 91 herds in the study, 80 fed haylage, 79 fed corn silage, and 58 herds fed a TMR. There were 15% of haylage samples, 14% of corn silage samples and 42% of TMR samples that were below the lower guidelines for the top screen of the Penn State particle separator. These were classified as low fiber samples. In total there were 33 herds that were not using Rumensin in the lactating cow diet and 58 herds that were. Concentrations of Rumensin in feed ranged from 8 to 23 ppm, with a median of 14 ppm. Significant interactions of diet and Rumensin with milk fat are illustrated in the table below.

There appears to be important dietary factors that may allow the prediction of milk fat response to Rumensin in dairy herds. Rations that are deficient in effective fiber appear more susceptible to milk fat depression with Rumensin. In addition, low NSC (< 40.2) diets were more susceptible to milk fat depression with Rumensin than those diets high in NSC (≥ 40.2). Further research is required to fully assess and test these ration interactions with Rumensin.

Ration Parameter	Rumensin in the Ration		p-value
	No	Yes	
TMR	3.61	3.39	0.007
Component	3.62	3.58	0.580
Low Fiber TMR	3.68	3.36	0.001
Normal Fiber TMR	3.60	3.44	0.060
High NSC	3.59	3.58	0.920
Normal NSC	3.75	3.40	0.001

Key Words: Monensin, Milk fat, Effective fiber

497 Effect of supplemental fat and monensin on ruminal fermentation in dual-flow continuous cultures. M. Croucher, S. J. McLeod, and V. Fellner*, North Carolina State University, Raleigh, NC.

Approximately 700 ml of rumen inoculum was obtained from a mature lactating Holstein and incubated in fermentors with a fractional liquid dilution rate of 6.3%/h. Basal diet comprised of alfalfa pellets (7.5g) offered twice daily. Two treatments were assigned to four fermentors (n=2) for a total period of 8 d including 2 d of adaptation to diet and fermentor. Treatments consisted of: 1) Monensin (30 ppm; 450 µg/d) administered for 2 d followed by 4 d of the addition of both monensin and fat (linoleic acid; .450g/d), and 2) Linoleic acid (.450 g/d) added for 2 d followed by 4 d of the addition of both fat and monensin (450 µg/d). Data were analyzed as repeated measures. Both treatments resulted in a lower proportion of acetate and a higher proportion of propionate in ruminal cultures. However the change in VFA pattern was greater when

monensin was added prior to the fat (treatment 1). During the control period C18:0 comprised more than 60% of the long chain fatty acids in ruminal cultures. Treatment 1 resulted in a lower (P <.01) C18:0 content (25.8%) and a higher (P <.05) C18:1 content (28.4%) compared with 55.4% and 17.9%, respectively for treatment 2. The concentration of C18:2 in cultures during the control period averaged 1.4%. Treatment 1 increased (P <.01) C18:2 content which averaged 19.3% compared to the 5.5% observed in cultures receiving treatment 2. The presence of linoleic acid prior to the addition of monensin minimized the effect of the ionophore on ruminal biohydrogenation.

Key Words: Fat, Ionophore, Rumen fatty acid

498 Formulating high fat rations for lactating dairy cattle according to a ratio of metabolizable protein to net energy. V. Pattarajinda*, M. A. Froetschel, H. E. Amos, D. Kumar, and A.A. Gautreaux, The University of Georgia, Athens.

Four Holstein cows in mid lactation were used in a 4x4 Latin square designed experiment with a 2x2 factorial arrangement of treatments to determine if higher levels of fat could be more effectively utilized when a ratio of metabolizable protein (MP) to NE_L was maintained. Four diets were formulated to contain : 1) 45% RUP and 7.6% fat (HRHF), 2) 45% RUP and 3.2% fat (HRLF), 3) 35%RUP and 7.6% fat (LRHF), and 4) 35% RUP and 3.2% fat (LRLF). Whole cottonseed supplied a basal level of dietary fat (5%) and calcium soaps of fatty acids were used as additional fat. Soybean meal was used as the main protein supplement for the 35 % RUP diets and a blend of heat- processed soybean meal, fish meal, blood meal and dried distillers grains were used as sources of RUP for the 45% RUP diets. Feed was offered as a TMR and contained approximately 50% sorghum silage. The metabolizable protein (MP) / NE_L ratio was estimated as 75.7, 83.8, 67.6, and 75.6 g of MP/ Mcal of NE_L in HRHF, HRLF, LRHF, and LRLF, respectively. Intake (% BW) of cattle fed the HRHF diet was depressed 4.7 to 10.4% as compared to the other diets. Milk production was increased by 2.8% by feeding RUP and decreased 2.4% by feeding additional fat. Milk fat (%) was increased 5.5 % by feeding additional fat. Feeding RUP tended to decrease the digestion of DM (DMD) and NDF (NDFD) by 4.6 and 5.7%, respectively. Diet NE_L, predicted from apparent digestible energy, was 9.1% greater in diets with added fat. Efficiency of NE_L used for milk (EE milk) was decreased 11.9 to 13.9% when cattle were fed the lowest ratio of MP/ NE_L. Blood urea N (BUN) was increased 45.9% higher when cattle were fed diets higher in fat. There appears to be some advantages to maintaining a proper MP/ NE_L ratio when feeding high fat diets and encourages the use of this parameter when formulating rations.

499 Effects of feeding different sources of neutral detergent-soluble carbohydrates supplemented with fat and propionate to heat stressed dairy cows. A. M. Akinyode*, M. B. Hall, J. P. Jennings, C. R. Staples, and C. J. Wilcox, *Univ. of Florida, Gainesville.*

The effects of different forms of energy supplementation on the lactation performance of heat stressed cows was evaluated. Thirty-two Holstein cows in mid-lactation were assigned to eight treatments in a 2 x 2 x 2 factorial, partially balanced incomplete Latin square design with three 21-d periods in which the last 7 days were used for sampling. The treatments consisted of citrus pulp- or hominy-based diets (C and H, respectively), with or without propionate supplementation from 0.73% of diet DM as Nutrocal® (P), and with or without fat supplementation from 0.6% of diet DM as Megalac® (F). Cows were fed individually in a freestall barn, with shade, but without additional cooling. Rectal temperatures (RT) and respiration rates (RR) were taken twice daily, and blood samples once daily on days 1, 3, 5, and 7. Values reported are least squares means. Significance was declared at $P < 0.05$. Main effects did not differ for body weight (BW), or morning and afternoon RR (MRR and ARR). Significant factors affecting ARR were milk yield and BW ($R^2 = 0.39$), and BW alone for MRR ($R^2 = 0.23$). P reduced morning RT (MRT), but not afternoon RT (ART). RT and RR were correlated ($r = 0.45$). Decreased intake with P may have been due to dustiness of the product used and decreased palatability. In this study, the effects of treatments on animal performance were limited.

500 An alternative approach to determine the efficiency of energy utilization for milk production in lactating dairy cows. E. Kebreab*¹, J. France¹, R.E. Agnew², and T. Yan², ¹The University of Reading, Reading, United Kingdom, ²Agricultural Research Institute of Northern Ireland, Hillsborough, United Kingdom.

The current energy requirements system used in the UK for lactating dairy cows utilizes key parameters such as metabolizable energy intake (MEI) at maintenance (MEIm), the efficiency of utilization of MEI for (i) maintenance, (ii) milk production (k_l) (iii) growth (k_g), and the efficiency of utilization of body stores for milk production (k_b). Traditionally, these have been determined using linear regression methods to analyze energy balance data from calorimetry experiments. Many studies have highlighted a number of concerns over current energy feeding systems particularly in relation to these key parameters. Underlying these concerns could be the rigid acceptance of linear methods in analyzing energy balance data from dairy cows. Therefore, a database containing 456 individual cow records was created from centers with calorimetry facilities in the UK. Five functions were considered: the conventional 'broken-stick', two diminishing returns functions - the Mitscherlich and the rectangular hyperbola and two sigmoidal functions - the logistic and the Gompertz. Based on the definition of k_l as the ratio of milk energy derived from MEI to MEI directed towards milk production, zero energy balance (± 5 MJ) were used to estimate regression parameters to determine MEIm, and k_l . Positive and negative energy balance data were used to estimate k_g and k_b , respectively. Values of 0.8 and 0.65 were obtained using all the functions for k_g and k_b , respectively, which were significantly different from previous reports of 0.6 for k_g and 0.84 for k_b . When all the data were pooled, the average k_l was 0.61. Non-linear analysis showed a decreasing value of k_l as feeding level above maintenance increases. Various factors affecting k_l were also analyzed. Lower k_l was obtained in experiments conducted after 1991, perhaps due to differences in the genetic merit of the cows. It also showed k_l to be

influenced by forage type, forage:concentrate ratio, ADF content, and stage of lactation.

Key Words: Energy utilization, Dairy cows

501 Effects of dietary supplementation of rumen-protected CLA in dairy cows during established lactation. J. W. Perfield II*, G. Bernal-Santos, T. R. Overton, and D. E. Bauman, *Cornell University, Ithaca, NY.*

Specific isomers of conjugated linoleic acids (CLA) have anticarcinogenic properties (*cis-9, trans-11* CLA), and reduce milk fat synthesis (*trans-10, cis-12* CLA). Short-term studies have shown that abomasal infusion of CLA or dietary supplements of rumen-protected CLA can enhance CLA content and/or reduce fat content of milk. Our objective was to assess effects of CLA supplementation during established lactation. Thirty Holstein cows were blocked by parity and received either a supplement of 116 g of EnerG II (Bioproducts, Inc) (control) or 126 g/d of CLA supplement. Supplements were topdressed on the TMR. The CLA supplement provided 42.8 g/d of CLA in the form of rumen-protected calcium salts (donated by Agribrands Purina Canada Inc.). Predominant CLA isomers were: *trans-8, cis-10* (9.2%), *cis-9, trans-11* (25.1%), *trans-10, cis-12* (28.9%), and *cis-11, trans-13* (16.1%). All cows were pregnant; treatments began 200 d prepartum and continued for 140 d until dry off. This report presents preliminary data covering the first 8 wk of treatment. The greatest treatment effect was on milk fat. Cows receiving CLA had a lower milk fat test (2.82 vs. 3.72%; $P < 0.001$) and a 20% reduction in milk fat yield (1048 vs. 1310 g/d; $P < 0.001$). CLA supplemented cows had a trend for increased milk yield (36.9 vs. 35.2 kg/d; $P < 0.09$) while milk protein yield was unchanged (1118 vs. 1088). The CLA group produced less 3.5% FCM (33.1 vs. 36.8 kg/d; $P < 0.01$), but DMI was similar between groups (23.7 vs. 24.3 kg/d). Milk fatty acid analysis indicated CLA supplemented cows had a reduced content of short and medium chain fatty acids, whereas concentration of longer chain fatty acids was increased. Changes in specific fatty acids indicated that Δ^9 -desaturase was reduced for the CLA treatment group. CLA fed animals also had an increased milk fat content of *cis-9, trans-11* CLA (0.53 vs. 0.47%) and *trans-10, cis-12* CLA (0.04 vs. <0.01%). Overall, feeding rumen-protected CLA resulted in a marked reduction in milk fat, a shift in milk fatty acid composition, a small increase in milk yield, and no change in milk protein.

Key Words: CLA, Milk Fat

502 Effect of pretrial milk yield on feed intake, digestion, and production responses to high- and low-fiber diets by dairy cows. J.A. Voelker*¹, G.M. Burato², and M.S. Allen¹, ¹Michigan State University, ²University of Padova, Italy.

Effect of dietary concentration of NDF on DMI, DM digestibility, and milk yield was evaluated using 32 Holstein cows in a crossover design with two 16 d periods. Cows were 193 ± 55 (mean \pm SD) DIM at the beginning of the experiment. Milk yield averaged 36.3 kg/d and ranged from 20.7 to 58.2 kg/d for the 14 d before initiation of treatments. Treatments were diets with forage to concentrate ratios of 67:33 and 44:56. Forages were alfalfa silage and corn silage, each at 50% of forage DM. Diets were formulated to 17.5% crude protein, and the NDF concentration of the high-NDF (H) and low-NDF (L) diets were 30.7% and 24.3% of DM, respectively. Greater digestibility of dietary DM was expected for L compared to H because grain is more digestible than forage. However, treatment did not affect DM digestibility, because digestibility of NDF and starch were greater ($P < 0.01$ for both) for H (33.2% and 89.7%, respectively) compared to L (26.9% and 86.0%, respectively). A greater increase in body condition score was observed for L compared to H ($P < 0.05$). No effects of treatment were observed for DMI, yield of milk or 3.5% fat-corrected milk (FCM), or percentage of milk components. However, individual DMI response to treatment (L-H) was positively correlated to pre-trial milk yield ($r = 0.43$, $P = 0.02$). DMI response (L-H) increased 0.127 kg/d per kg of pre-trial 3.5% FCM. Responses for yields of milk and fat-corrected milk to the low-fiber diet (L-H) showed a positive, quadratic relationship to pretrial milk yield ($P < 0.01$ for both). No relationship existed between milk composition response (L-H) and pretrial milk yield. The positive linear relationship observed between DMI response to the less filling, low NDF diet (L-H)

and pre-trial milk yield is consistent with the hypothesis that physical fill becomes a greater limitation on DMI as milk yield increases.

Key Words: Dietary NDF, Physical fill, Feed intake regulation

503 Dose-response effects of intra-ruminal infusion of propionate on feeding behavior of lactating dairy cows. M. Oba* and M. Allen, *Michigan State University, East Lansing, MI.*

Dose-response effects of intra-ruminal infusion of propionate on feeding behavior of lactating dairy cows were evaluated. Eight ruminally cannulated Holstein cows (159 ± 26 DIM; mean ± SD) were used in a duplicated 4 x 4 Latin square design. Treatments were mixtures of sodium propionate and sodium acetate infused into the rumen continuously for 14 h at a rate of 25 mmol/min. Treatment solutions contained 0, 33, 67, or 100% sodium propionate (treatment A, B, C, or D, respectively) and sodium acetate was added to keep the osmolarity of infusates constant across the treatments. The experimental diet was formulated to contain 29% NDF, and dry cracked corn (mean particle size = 3.6 mm) was the major source of starch. Infusion started 2 h before feeding and ended 12 h after feeding. Feeding behavior was monitored for 12 h after feeding using a computerized data acquisition system. As infusion of propionate increased, dry matter intake decreased linearly ($P < 0.0001$; 15.0, 13.3, 11.5, and 8.3 kg/12 h, respectively for treatment A, B, C, and D), meal size decreased linearly ($P = 0.02$; 2.5, 2.0, 2.1, and 1.5 kg of DM, respectively for treatment A, B, C, and D), and inter-meal interval tended to increase linearly ($P = 0.08$; 75.4, 76.3, 87.7, and 90.1 min, respectively for treatment A, B, C, and D). Total energy intake was calculated by adding the energy of infusates to dietary energy intake. Total energy intake also decreased linearly ($P < 0.0001$; 30.0, 28.2, 25.9, and 21.5 Mcal NE_L/12h, respectively for treatment A, B, C, and D) as infusion of propionate increased. This indicates that the reduction in dietary energy intake due to propionate infusion was greater than the energy supplied from propionate infusions. Our results demonstrate that propionate plays an important role in feed intake regulation by affecting both satiety and hunger, and can explain depressed energy intake of lactating dairy cows consuming highly fermentable diets.

Key Words: propionate, feed intake regulation

504 Effects of intra-ruminal infusion of propionate salts on feeding behavior of lactating dairy cows. M. Oba* and M. Allen, *Michigan State University, East Lansing, MI.*

Two experiments were conducted to evaluate effects of intra-ruminal infusion of propionate salts on feeding behavior of lactating dairy cows. Our working hypothesis is that hepatic metabolism of propionate causes satiety by increasing hepatic ATP concentration. We speculate that enhanced ATP concentration drives the Na/K pump, hyperpolarizes the hepatic vagus, decreasing its discharge rate, causing satiety. For both experiments, eight ruminally cannulated Holstein cows in mid-lactation were used in a duplicated 4 x 4 Latin square design, and intra-ruminal infusion started 2 h before feeding and ended 12 h after feeding. Treatments in the first experiment were mixtures of propionic acid and bicarbonate salt (none, ammonium, sodium, or potassium). Bicarbonate salts were infused at a rate of 11.9 mmol/min, and propionic acid was infused at a rate of 16.7 mmol/min for all treatments. We speculated that infusion of ammonium reduces the hypophagic effects of propionate because of utilization of ATP for urea synthesis and that infusion of sodium or potassium affects DMI by altering the discharge rate of the hepatic vagus. However, infusion of ammonium propionate tended to decrease DMI compared to sodium propionate and potassium propionate ($P < 0.08$; 11.2 vs. 13.6 and 13.7 kg/12 h), and DMI was not different between sodium propionate and potassium propionate infusions. In the second experiment, effects of VFA (propionate vs. acetate) and salt type (sodium vs. ammonium) on DMI were evaluated using a 2 x 2 factorial arrangement of treatments. The VFA salts were infused at a rate of 16.7 mmol/min. Ammonium treatment decreased DMI compared to sodium treatments ($P < 0.001$), and the effect of ammonium was significantly greater for cows infused with propionate (11.6 vs. 4.7 kg/12 h) compared to acetate (14.7 vs. 13.8 kg/12 h; interaction $P < 0.0001$). Contrary to our pre-trial hypothesis, ammonium has hypophagic effects,

which might be because the urea cycle generates substrate for oxidation in the liver, increasing hepatic ATP concentration and decreasing DMI.

Key Words: feed intake regulation, propionate, ammonium

505 Characteristics of forages and TMR fed to dairy cows in Washington state dairy herds producing in excess of 12,730 kg of milk annually. L. M. Johnson*¹, J. H. Harrison¹, W. Schager¹, D. Davidson¹, S. Chen², C. Stockle², F. Hoisington³, and C. A. Rotz⁴, ¹Washington State University, Puyallup, WA, ²Washington State University, Pullman, WA, ³Dari-Tech Services, Kent, WA, ⁴USDA-ARS, University Park, PA.

The chemical composition of forages and TMR from seven Holstein dairy herds producing greater than 12,730 kg of milk annually were characterized to identify factors that contributed to high milk production. Forages and TMR for the high producing mature cow string in each herd were analyzed for CP, acid detergent insoluble CP (ADICP), starch, NDF, fat, Ca, P, Mg, K, and dietary cation-anion difference (DCAD). The concentration of CP and NDF in the TMR were above recommended ranges according to NRC (2001) for high producing mature cows in early lactation, except for NDF concentrations at Farm 1. The concentration of ADICP was under 2% indicating minimal bound protein in the diets. Calcium concentrations ranged from 23 to 78% greater and P concentrations ranged from 13 to 32% greater than NRC (2001) recommended levels for a sample diet that had similar animal and feed characteristics to this study. Magnesium concentrations were 33 to 129% greater and K concentrations were 42 to 87% greater than NRC (2001) recommended levels for a sample diet. The DCAD concentration in the TMR was between 26 and 39 meq/100 g DM. These levels for DCAD in early lactation postpartum diets have been shown to maximize milk production in other studies. The corn silages ranged from 47 to 57% NDF and from 13 to 26% starch. The alfalfa hay samples ranged from 19 to 28% CP and from 38 to 46% NDF.

Farm	TMR									
	CP %	ADICP %	Fat %	Starch %	NDF %	Ca %	P %	Mg %	K %	DCAD meq/100 g DM
1	18.5	1.7	6.0	17.9	30.6	1.07	0.50	0.45	1.71	27.6
2	17.8	2.0	7.0	17.1	34.5	1.00	0.49	0.41	1.65	33.3
3	18.7	1.7	6.1	21.4	35.6	0.97	0.47	0.40	1.53	29.2

7	19.7	1.5	5.0	18.5	33.6	0.98	0.43	0.51	1.58	26.4

Key Words: TMR, Forages, Chemical Composition

506 Nutrient intake and body characteristics of dairy cows in Washington state dairy herds producing in excess of 12,730 kg of milk annually. L. M. Johnson*¹, J. H. Harrison¹, W. Schager¹, D. Davidson¹, S. Chen², C. Stockle², F. Hoisington³, and C. A. Rotz⁴, ¹Washington State University, Puyallup, WA, ²Washington State University, Pullman, WA, ³Dari-Tech Services, Kent, WA, ⁴USDA-ARS, University Park, PA.

Seven Holstein dairy herds producing greater than 12,730 kg of milk annually were selected to characterize animal factors related to high milk production. Six herds used BST, one herd milked 2x, five herds milked 3x, and one herd milked 4x per day. In each herd the top mature cow string was measured for body characteristics and intake of nutrients. Other parameters that were measured included the number of cows in a string, DIM, milk production, and physical effectiveness of the diet (DM on two sieves of NASCO's® Particle Separator). Body weight was within 20 kg between herds, except for Farm 3, where the cows were giving more milk and weighed 50 to 70 kg less than the other herds in this study. The majority of the herds had DMI greater than 25 kg/day. Starch intake ranged from 4.1 to 6.8 kg/day, NDF intake ranged from 7.7 to 9.3 kg/day, and CP intake ranged from 4.6 to 5.3 kg/day. These results indicate that the level of starch and NDF in the diet can vary, and high levels of milk production can still be achieved. Physical effective fiber ranged from 44 to 76%, and physical effective NDF ranged from 15 to 27%. A minimum physical effective NDF intake of 20% of ration DM was recommended for lactating dairy cows.

Farm	No. Cows	DIM	Milk kg	Body Wt. kg	Wither Ht. cm	Length to Pins cm	DMI kg	Physi- cal Effect Fiber %	Physi- cal Effect NDF, %
1	58	100	49.5	652	25.7
2	80	266	46.4	657	25.5	76.1	26.9
3	119	125	50.5	604	143	95	26.5	67.9	24.2

ASAS/ADSA Teaching Undergraduate and Graduate Education and PSA Extension and Instruction: Teaching I

507 Poultry science student recruitment through teacher and counselor education. R.J. Lien, J.B. Hess*, R.A. Voitle, J.P. Blake, D.E. Conner, and W.D. Berry, *Auburn University, Auburn, AL 36849-5416.*

University poultry science student recruitment is vital to the long-term success of the poultry industry and the survival of university poultry science programs. Conservative estimates indicate that universities in the Southern U.S. are only able to fill 20-30% of the annual regional need for poultry science graduates in the poultry industry. Efforts by the U.S. Poultry and Egg Association and university poultry science programs are attempting to spread the message of job opportunities to potential high school and junior college students. Auburn University's Poultry Science Department instituted a Teacher/Counselor Education Program in 1995 in an attempt to reach more prospective students. Initial efforts were targeted at teachers and guidance counselors that had placed students with Poultry Science in the past. Subsequent efforts have drawn participants from state-wide mailings to all high school science and agribusiness teachers and counselors, and advertisements in counselor and science teacher association newsletters. Enrollment for the 1.5-day course (all expenses paid on campus) has averaged 20/year, with the majority of participants attending from schools in areas of poultry concentration. Continuing education credits are offered. Topics covered include Alabama and U.S. poultry industries, educational opportunities, departmental and college scholarships, job opportunities and veterinary school options. Average enrollments in the department have been 40% higher since the inception of this program.

Key Words: Student Recruitment, Undergraduate Teaching, Continuing Education

508 A paradigm to increase student enrollment in animal science courses and fulfill educational expectations. Darrel J. Kesler*¹, ¹*Department of Animal Sciences, University of Illinois.*

Projections that intensification of animal production is decreasing the need for animal scientists that could lead to the demise of the animal science profession (Cheeke, J. Anim. Sci. 77:2031; Letters to the Editor, J. Anim. Sci. 78:1691) have either generated concern, with little action, or are rejected. In an attempt to avoid the projection, I have developed and implemented a paradigm to increase student enrollment in animal science courses and the fulfill educational expectations of our new generation of animal science students. The first step was to reinvent an existing course, now titled Biology of Reproduction (AnSci/Biol 231). This involved changing a more traditional farm animal reproduction course to be more inclusive of all species, including humans (Kesler, NACTA J. 44[3]:11). The course was designed to fulfill general education requirements in natural sciences and was cross-listed in Biology. The second phase was the creation of a discovery course (AnSci 110), Life with Animals and Biotechnology, that approached the discipline in a non-traditional manner (Kesler, J. Anim. Sci. 75:273). It began as a 1-credit hour course but has been revised to a 3-credit hour course that fulfills general education requirements in natural sciences. The third phase involved instruction on nontraditional animal careers. Although this phase is incomplete, a traditional spring trip course was modified the past two spring semesters where students were introduced to biomedical industries with animal related careers. Student enrollment in AnSci 110 and 231 increased ($r=.99$; $P<.01$) from 66 in year 1 to 212 in year 7. Course quality evaluation ratings also increased ($r=.94$; $P<.01$) and

paralleled ($r=.95$; $P<.01$) the increase in enrollment. Although the average class size (department enrollment 4 classes) also increased, course enrollment in AnSci 110 and 231 increased at a greater rate (3.5 times greater) increasing instructional units credited to animal science. The major reason for the increase was non-majors (41% of the students were non-majors this past year; $r=.98$ [$P<.01$]; non-majors were primarily from outside the college) enrolling in the course. Therefore, animal science can remain as a viable discipline; however, revision may be appropriate even if the pessimistic projection is wrong.

509 A model for choosing instructional strategies to support distance education students. A.M. Shorridge and J.L. Emmert*, *University of Arkansas.*

The Department of Poultry Science at the University of Arkansas has developed web-based distance education courses in poultry science that include Broiler and Turkey Production and Breeder and Layer Management. Although the use of the Internet to teach university curricula is commonplace, few guidelines have been published to support course authors as they attempt to move their teaching out of the traditional classroom and into cyberspace. In an effort assure the quality of the courseware produced for this project we conducted an examination of current instructional design models, distance education and learning theories, the use of media in education, and available web-based distance education courses. The results indicated that most university level courses currently offered are limited in that they are not grounded upon an appropriate learning theory that is able to provide interactive instructional strategies. Results also indicated that the interactive component of web-based distance courseware could be increased substantially by the use of concept mapping within a human constructivist framework. Our next objective was to evaluate the integration of concept mapping into web-based distance education courseware as a tool to increase interactivity and learning outcomes. Students in traditional poultry production courses were provided with videotaped concept mapping instructions similar to what would be available on the Internet. Concept mapping assignments were then given before and after course modules were presented to allow comparison of pre- and post-maps. A blend of qualitative methods, including document analysis, observation, concept mapping and interviewing were used to probe a real-life context within a unique case orientation. This study also made use of data triangulation and investigator triangulation to establish credibility of the findings. Data indicate that concept mapping may be utilized successfully within web-based distance education courseware as a tool to enhance interactivity and establish effective pedagogy.

510 Technology enhanced instruction: Incorporating Internet activities into a poultry products course. T. J. Buttles*¹ and B. S. Walters², ¹*University of Minnesota, St. Paul, MN,* ²*University of Wisconsin - River Falls, River Falls, WI.*

The Internet is changing many aspects of our culture, including classroom instruction. Internet tools and resources have been added to the list of instructional methods available to teachers. Several different types of Internet based activities have been incorporated into the poultry products technology course offered as part of the Midwest Poultry

Consortium sponsored Undergraduate Poultry Science Center of Excellence summer program. Students were required to find and critique poultry products related articles on the Internet as well as in print media. Students also used the Internet to submit selected assignments. WebCT, a package of web based course tools, was also utilized as part of the instruction in this course. Computer based instruction modules were developed for a small portion of the course content. These modules supplemented classroom and lab instruction, allowing students to control the speed and direction of instruction. Links to Internet resources were embedded into the lessons, with several lessons requiring students to visit specific websites to complete the activities. Several quizzes were also given with WebCT. This form of delivery allowed students to take the quiz when they felt ready for it and also provided immediate feedback on the answers to objective type questions. WebCT was also used to provide electronic backup copies of the syllabus and assignment sheets that students could access at any time. Finally, WebCT was used to provide students with access their individual grades. The instructors were able to put the grades into the WebCT system immediately following the completion of the course, as compared to the several weeks it took for official grades to make it into the campus system. Overall, these Internet activities provided an additional way for students to learn course material, be assessed on their learning, and interact with course instructors. While they will never replace even a majority of the classroom and laboratory instruction in this course, Internet activities did provide one more tool for instructors to try and provide appropriate learning activities for a diverse range of students.

Key Words: Instruction, Teaching, Internet, Midwest Poultry Consortium

511 Assessment of students' access of world wide web course material posting in small class size. M. A. Wattiaux* and K. Kanwar, *University of Wisconsin, Madison*.

Our objective was to use the student-tracking feature of an electronic course delivery package (Webct) to monitor students' access of course-related material posted on the world wide web and to correlate web usage with final grade. The study was conducted in a two-credit ruminant nutrition course including 19 juniors or seniors and four graduate students. At the beginning of the semester, the posted material included a 700-word glossary and three modules. Each module included 15-20 slides with instructor/s notes, a study guide and assignments. Weekly additions to the site included primarily lecture slides (without instructor/s notes or study guide) and assignments. Students' access to the web was recommended, but optional because course modules were covered in lectures and discussion sessions. Number of HTML pages accessed by each student was recorded weekly. Seventy-eight percent of the students accessed the site for the first time within two days of its announcement, but one student did not access the site until 20 days into the semester. The first three modules were covered by the end of the first two weeks of class, and the average number of hits per student (HPS) was then 96 (range 0 to 243). Henceforth, HPS declined sharply and averaged 6.8 (range 0 to 13) per week over the remaining part of the semester. Discrete events associated with a rise in weekly HPS included taking time in class to show the web (week 5; HPS = 12) and posting of the previous year/s mid-term exam (week 10; HPS = 13). Posting of lecture slides alone did not attract students' attention. At the end of the semester, total HPS averaged 177 (range 30 to 658). Non-parametric, Spearman correlation indicated that HPS after the first week of class was a good predictor of HPS at the end of class ($r = .88, P < .001$). There was no correlation ($r = .27, P > .05$) between total HPS and final grade. In small class size, students' intrinsic motivation for the course may be a major determinant of web usage.

Key Words: Instructional technology, Undergraduate learning, Internet

512 Use of Trans Texas Video Network for graduate education between Texas A&M University System and Texas Tech University. L. W. Greene*¹ and C. R. Richardson², ¹Texas A&M University System, Amarillo, ²Texas Tech University, Lubbock.

A minerals and vitamins animal nutrition lecture class was developed and taught to students in the Texas A&M University (TAMU) System and Texas Tech University (TTU) for three consecutive yr via Trans Texas Videoconference Network (TTVN). The TTVN is an interactive media for lecture delivery. TTVN is a statewide videoconferencing system at TAMUS locations, TTU and other state agency offices. The

system provides a two-way multipoint digital video conferencing and data transmission service. Universities, extension services, public service agencies and research organizations fund the system. The class has been taught at TAMU-College Station (yr 1, 2), WTAMU-Canyon (yr 1, 2, 3), TTU-Lubbock (yr 1, 2, 3), TAMU-AREC-Amarillo (yr 1, 2, 3) and TAMU-Kingsville (yr 2). Student enrollment for yr 1, 2 and 3 was 26, 20 and 9, respectively. Students enroll and obtain credit for the class at their home institution. The mineral section originates from TAMU, Agricultural Research and Extension Center, Amarillo (Greene) and the vitamin section originates from TTU at Lubbock (Richardson). Each section of the class consists of 12 to 13, 80 to 90 min lectures. Lecture notes and related course information were developed with the same style and form, and published on the internet. Students are graded based upon their performance on written test and term papers. Grades from each section are weighted equally for calculation of final grades. Open-book exams and papers are e-mailed by the students to the instructor for grading. A proctor (local faculty member) is assigned at each location to supervise closed-book exams, and mailing exams to the instructor. Outside of class, students communicate with instructors, and turn in term papers and open-book exams via e-mail. Questions and answers are also handled during interactive class time on TTVN. This class provides students at several locations the opportunity of taking a minerals and vitamins animal nutrition class.

Key Words: mineral/vitamin nutrition, classroom instruction, distance education

513 Teaching Animal Nutrition online. P.A. Schoknecht*¹ and H.D. Hafs², ¹University of Richmond, ²Rutgers, The State University of New Jersey.

Web-based distance education has the potential to expand course offerings and/or conserve teaching resources. During the Fall of 2000, the lecture (3 credits) of Rutgers Animal Nutrition was offered online (instructor in VA) to 94 students in NJ. Students also attended a resident laboratory section (1 credit). The distribution of grades was comparable to the previous 3 years when the same instructor taught the course in residence, suggesting that student learning was not impaired. A survey completed by 85 students provided the following data. Online learning was entirely new for 98% of the students and the course was required for 92%. 93% of the students felt they had sufficient access to both a computer and an Internet connection, with 39% of those living in networked university housing, 26% using a modem, 21% using both a modem and university computer labs and 14% using only the computer labs. While 70% of the students felt they had too little interaction with the instructor, only 52% of the students ever emailed the instructor outside of the required homework assignments and only 24% of those emails pertained to course material. When given the opportunity to post questions to a website, students posted none. Instructor postings were read by only about 10 students unless the posting had to do with an exam. The aspects of the online course that students liked the most were that they were able to work at their own pace (36%), did not have to attend lecture (22%), had detailed notes (16%), and the studying was interactive (16%). On the other hand, they missed interactions with the instructor (50%), felt they had problems learning (28%), and had computer problems (22%). The majority of students were not prepared for the self-discipline and initiative required for an online course. In overview, despite the difficulties, students not only learned animal nutrition effectively they also learned about self-directed studying and time management. While many students were uncomfortable, they may have been well-served by being forced to learn these skills, as 75% reported they are now better prepared to take future online courses.

Key Words: Distance Education, Undergraduate Education, Web-based Teaching

514 Development of a capstone course in dairy herd management. D. K. Combs*, G. E. Shook, and M. C. Wiltbank, *University of Wisconsin-Madison*.

During the last 8 years we have developed a three credit course that is designed around troubleshooting nutrition, genetics, reproduction, and milk quality on commercial dairy farms. Early in the semester, class-room activities center on discussion and case studies that utilize principles of Total Quality Management (TQM) to assess processes and critical control points on dairy farms. In the first month, pairs of students are teamed with a nutrition consultant who identifies a farm for

the students. Farms are selected by the consultant and faculty based on availability of records, interest of the dairy producer, and nature of the management issues likely to be encountered. The students and consultant form a working team, and make the initial farm visit together. Students arrange subsequent farm visits directly with the producer. By mid semester, students present a written report and an oral presentation to the class that gives an in-depth evaluation of each of the four disciplines for the farm they are working on. The consultant, fellow students, and faculty critique the student's farm evaluation. Discussion after the mid-term presentation helps students select a key issue that appears to be most limiting on their farm. Issues addressed by students have included: nutritional metabolic disorders, forage quality, business plans for anticipated expansions, reducing somatic cell counts, and reducing calving intervals. At the end of the semester, the students generate a letter to the producer and give a final oral presentation to the class, producer, and faculty that analyzes critical data on the current situation, possible new strategies, and estimated economic consequences. The consultant, producer, fellow students, and faculty evaluate the presentation and plan. Consultants involved with the course have been enthusiastic about participating again. Detailed student evaluations of the course have been very positive. The TQM approach has helped to focus students on actual data and production processes rather than stereotyped solutions. The use of a team of students, consultants, and farmers to bring current farm cases back to the class has allowed more in-depth analysis of multiple farms than visits to farms by the entire class.

Key Words: Teaching, Dairy management, Total quality management

515 Practical Broiler Production - A hands-on approach to student learning. J. C. Hermes*¹, ¹Oregon State University, Corvallis, OR.

Classroom teaching in a lecture format has been the traditional method of teaching of undergraduate students. This method is used for most of an undergraduate's credit load for courses as diverse as American History, English Literature, Biochemistry, Genetics, and Poultry production. To enhance student learning, some courses have a laboratory section which may or may not be required. In some instances, laboratories may or may not give students a sense of the "real world" with real questions to investigate or they may be simply show and tell. We know that students learn best by doing, and many students prefer a hands-on approach to learning compared to the traditional lecture format. To address student interest we have developed "Practical Broiler Production," a completely hands-on course to teach not only the science but also the art of producing poultry meat.

Beginning with a student suggestion, we began a completely hands-on educational experience for our students. Partnering with local industry groups, companies, and individual broiler producers, donations of money and equipment were raised to retrofit an underused poultry research building into a typical broiler house. With the generous support of Foster Farms, our facility is currently a contract producer of about 4600 broilers each term. Students are the growers, making management decisions and learning in the "real world", an experience that can be compared with an industry internship. It is our hope that because of the hands-on nature of this course, our students will be better prepared to move from their academic experience into industry by increasing their credibility with company representatives and producers.

Key Words: Teaching, Broiler production, Hands-on education

516 Oregon State University's Steer-A-Year program: integrating classroom learning and hands on experience. C. J. Ackerman*, D.W. Weber, and R. L. Dickson, Oregon State University, Corvallis, OR.

The Steer-A-Year course is designed to provide classroom and hands-on experience, industry-student interaction, and student group problem-solving opportunities. It is a cooperative agreement between the Department of Animal Sciences and the Oregon Cattlemen and Cattlewomen's Associations. Steers are donated to the program by beef producers, fed a high concentrate ration to a target BW and condition, and marketed as either carcass or retail beef. After feed and management expenses are deducted, the Department of Animal Sciences distributes one-half of the profit towards beef facilities improvements and the other half is distributed to the donor's choice of either the Oregon Cattlemen or Cattlewomen's Association. Approximately 30 steers have been donated to the program annually each of the past eight years. The donor receives

regular updates regarding steer performance during the feeding period and carcass data following harvest of the animal. Students and instructors feed and manage the steers. The instructor uses classroom time to provide information to enable students to make informed management decisions. Officers are elected from within the class each term. Student officers are responsible for ensuring that cattle are managed and fed appropriately and they lead the class in putting together and sending out regular producer updates. A facet of the class that is evolving is in the area of processing and marketing. Steers are sold locally through the Animal Sciences Meats Lab. Students are encouraged to participate in a separate course in which they process the steers into retail product. In this manner, students in the project have the opportunity to be involved in procurement, management, processing, and marketing. The course is challenging for the instructor as it requires management of lecture material, cattle health and feeding, producer and employee rapport, and student participation to ensure annual success of the program in terms of student learning and public relations. The course is very well received by students, most of whom have labeled it as a great learning experience.

Key Words: Cattle, Beef, Finishing

517 Quantification of learning in animal nutrition: An assessment of teaching. R. S. Kensinger*, Penn State University.

Institutions of higher education are in an era of greater scrutiny with regard to the use of public funds. Teaching programs in Universities should be both creative and rigorous in nature. In order to achieve this goal, there is a need to develop methods that better quantify the quality of instruction. A method of evaluation was used to evaluate teaching of an introductory course in animal nutrition. The method used a simple examination that was given, unannounced, on both the first and last day of class. The examination included only 20 questions, required less than 10 minutes to complete, and was used to evaluate acquisition of information. All students were informed that the exam had no bearing on their grade for the class. Over 400 students have participated in use of this evaluation tool. Mean class performance on pre-exams has been 7.1/20 compared to mean of 13.4/20 on the post-exam ($P < .01$) demonstrating significant acquisition of information. Data from this exercise show that previous knowledge is important, as there were significant positive correlations between pre-examination score and final class average ($r = .416$ to $.543$, depending upon the semester, $P < .01$). Furthermore post-examination score was a very good predictor of final class average, as correlations range from $.660$ to $.678$ (all $P < .01$). The few students (about 1%) who did not show significant improvement were characterized by poor attendance, or problems with their attitude about the course; which had been documented prior to completion of the semester. It was concluded that this simple tool could be used to quantify learning in the classroom. It could be useful to evaluate instructional approaches used by the instructor. It places the emphasis on the student rather than the instructor, and it has demonstrated that learning is an incremental process.

Key Words: Teaching, Evaluation, Animal nutrition

518 An integrative approach to teaching advanced undergraduate non-ruminant animal nutrition. N. L. Trottier* and J. Perez-Laspiur, Michigan State University.

With the growing number of undergraduate students in the animal science field, it is becoming increasingly challenging to teach courses that supply both theoretical and applied based knowledge. In addition, it is a concern of both faculty and industry that animal science students graduating with a nutrition emphasis may not possess sufficient applied based knowledge across farm animal species. A non-ruminant animal nutrition course for advanced undergraduate students has been developed at Michigan State University to enhance application in nutritional diversity. While 75% of the students have equine interests, the course covers three major species categories, i.e. swine, poultry, and equine, with equal emphasis. Each laboratory (lab) category utilizes the same lab format. Week one is devoted to teaching and discussing feed ingredients and nutrient requirements for the species in question via the web based National Research Council. The second week focuses on teaching diet formulation using manual techniques, computer based programs and models. The lab practicum (prac) is conducted during the third and fourth week. Students learn to allocate animals to different experimental

diets, collect biological samples, and record data. During the fifth week, a group discussion of the results is conducted. Students are responsible for retrieving the lab information and the compiled data from the web prior to participating in the discussion. The swine lab consists of evaluating the effect of fat supplementation on lactational performance and milk composition in lactating sows. The objective of the poultry lab is to evaluate the effect of feeding diets deficient methionine concentration on egg production in laying hens. The poultry lab prac is conducted over a 10-day period. The equine lab consists of testing the effect of feeding a legume hay versus a grass hay on the nitrogen balance of the horse. Students work in groups of four, and rotate every 6 hours over a 5-day collection period. Students are required to submit a complete report for each lab category. The lab report is written following a guideline provided on the web. Reports must integrate the knowledge gained from diet formulation and lab prac results, and theory learned in class.

519 Utilization of small-group special species projects to facilitate undergraduate applied animal nutrition learning experiences. J.R. Carpenter*, *University of Hawai'i at Manoa, Honolulu, HI USA.*

Over the past five years, the use of a small group "Special Species Project" has been adopted as a major learning component for our undergraduate applied animal nutrition course. This philosophy was adopted to assist students in: 1) addressing the desired CTAHR graduation competencies, 2) fulfilling their writing intensive course requirements, 3)

PSA Environment and Management: Composite Group

520 Interaction of feeding program and space on broiler breeder egg production. J. Brake*, *North Carolina State University, Raleigh, NC USA.*

Broiler breeder pullets (Cobb 500 FS) were placed in 12 pens, each of which contained 12 Kuhl DH-4 38 cm (15-inch) diameter feeders. There were 19 pullets per pan in all pens to 14 weeks of age. Density was 6.9 birds per square meter. Pullets were randomly removed from all pens at 14 weeks of age to achieve either 15 or 18 pullets per pan to 22 weeks of age. This gave densities of 5.4 or 6.4 birds per square meter. During the rearing period pullets were fed on either a Low, Medium, or High program that provided 24,240 kcal ME and 1296 g CP, 26,020 kcal ME and 1391 g CP, or 27,780 kcal ME and 1485 g CP, respectively, at 21 weeks of age. With the exception of space, feeding and management were identical among the treatments following movement to breeding quarters and photostimulation at 22 weeks of age. Early egg production responded positively in a dose-related manner to feeding program but no overall difference was observed due to space. Inspection of the interaction revealed little effect of space on the High or Low programs but an obvious improvement in egg production due to more space on the Medium program. These data suggest that space has little effect when all pullets are nutrient deficient (Low) or nutrient replete (High) but has a measurable effect on egg production when cumulative nutrition is marginal.

Key Words: Feeder Space, Floor Space, Density

521 Early protein intake influences long term egg production by broiler breeder hens. R.J. Lien*, J.B. Hess, and W.D. Berry, *Auburn University, Auburn, AL.*

A total of 800 Cobb 500 strain broiler breeder hens provided either high or low protein intake to 4 wk of age were subsequently provided equal allotments of the same feeds through 65 wk to determine long term effects on egg production. Feeds containing 2860 Kcal ME/kg and either 19(high) or 15%(low) CP were provided *ad libitum* to 2 wk, in limited daily allotments to 3 wk, and in limited allotments on 4 of 7 d/wk during wk 4. Allotments were adjusted so total feed intake to 4 wk was 0.95 kg/bird in both trts. This resulted in total CP intakes to 4 wk of 142g (low) and 180g (high). Equal allotments of a 15% CP developer feed were provided both groups on 4 of 7 d/wk from 4 to 21 wk and daily from 21 to 23 wk. A photoschedule of 8h L:16h D was provided to 21 wk and 15h L:9h D was provided from 21 to 65 wk. Peak feed allotments of 159 g/hen/d were provided from 29 to 32 wk. Allotments were then decreased 4.0 g/hen/wk for 2 wk, and 0.9 g/hen/wk thereafter. At

developing their interpersonal and communication skills by working in small groups of 2 or 3, 4) developing research and problem-solving abilities, 5) applying principles of ration balancing, 6) enhancing computer skills and use of computers in diet formulation, and 7) improving public speaking skills. Because of the intensity of the course and the small class size (only 20 students), it has been very successful during the brief time it has been implemented. The class has encompassed the following species: equine, bovine, ovine, caprine, avian, porcine, canine, feline (both companion and exotic), marine mammals (dolphin and monk seal), and various aquatic species (both carnivorous and herbivorous fish and crustaceans). Since the students are involved in species assignment, there is genuine interest, increased energy, enthusiasm, and the desire to learn. So many undergraduates are raised in urban settings, lacking the practical experiences and exposure to animal production and companion/zoo-related industries, their feeding programs and specialized equipment/facilities. Students contact industry and community representatives and become aware of the diversity of animal nutrition as a career. In the course, students are also exposed to critical review of scientific journal articles and the use of the internet, popular press, and other sources of information as resources. They frequently express appreciation for the practical application of principles and special skills learned in previous lectures/labs. Although much of the effort is guided, there still is flexibility for the students to complete requirements within the semester time constraints. Challenges of the course will also be discussed.

Key Words: Small group active-learning, Applied animal nutrition, Instruction

4 wk, BW of high and low CP trts were 577 and 540 g, respectively. However, BW of the 2 trts did not differ from 9 to 65 wk. At 65 wk, mean BW was 3.87 kg. Feed consumption rate was greater in the high trt at 4, 6 and 8, but not 10 wk. Bone in breast wt, shank and keel length, and carcass moisture, CP and ash were all greater in the high trt at 4 wk. Fat pad wt and carcass fat were greater in the low trt at 4 wk. There were no differences in carcass composition at 21 or 30 wk. Uniformity was greater in the high trt at 4 wk; however, no differences were seen at 21, 25 or 30 wk. Age at onset of lay did not differ between trt. Total egg production/hen at 65 wk were 157 and 141 in the high and low treatments, respectively. Egg production did not differ between trt from 25 to 35 wk. However, from 36 to 45, 46 to 55, and 56 to 65 wk, egg production/hen in the low trt was reduced by approximately 4, 5 and 5 eggs, respectively. Egg wt and specific gravities did not differ between trt. Increased early CP intake had no measureable long term effects on BW or carcass composition, but resulted in greater post-peak and total egg production by breeder hens.

522 Body weight management and performance of broiler breeder males. Wallace Berry*¹, Pingbo Liu¹, Haitao Li¹, and Alex Peterson¹, ¹*Auburn University Department of Poultry Science.*

Complex feeding programs for broiler breeders require intensive management. Underestimation of feed allotments can permanently damaging fertility. To avoid this, males are often allowed to become too large. One possible strategy to reduce these risks is to restrict growth early to keep the birds below the usual body weight targets while still allowing growth. This would provide an increased margin of error between actual growth and the desired growth targets. To test this strategy, male chicks in the Small group were full fed standard 22% broiler starter until they reached 1.2 lbs average body weight. Chicks in the Large group were full fed starter until they reached 1.9 lbs body weight. When the chicks in each group reached target body weight, they were switched to a 12% protein rearing diet and fed to maintain positive growth rates and body weight divergence through week 21. At 21 weeks of age, the male birds were placed with females in pens in a curtain sided, slat/litter breeder house. The ratio of females to males was 10:1. Lighting schedule was arranged to provide 14 hours of light with an increase of 15 minutes of light each week to a maximum of 16 hours light. Body weights were measured every 4 weeks. Weekly fertility was monitored by breakout of eggs following 7 days of incubation. Every fourth week eggs were incubated to

hatch to determine hatchability and embryonic mortality. Small males were 1.25 lbs at week 3, 5.5 lbs at photostimulation, 8.5 lbs at peak, and 9.75 lbs at week 45. Large males were 1.9 lbs at 3 weeks, 7 lbs at photostimulation, 9.75 lbs at peak, and 11.2 lbs at week 45. Weight uniformity at 21 weeks of age was 84% for the small males and 85% for the large males. Small males suffered less culling and mortality than large males (22% vs. 30%). Small males gave an overall mean fertility rate of 97.75 % as compared to 96.6% for the Large males with the greatest differences occurring before and after peak production. Differences in embryonic mortality were slight. The results of this study indicate that heavy breeder males can be maintained at body weights below guideline recommendations, but with continued growth, up to peak production without adversely affecting fertility and hatchability.

Key Words: Breeder, Body weight, Fertility

523 The effects of feeding different levels of protein with and without the DFM, Primalac, on production parameters of bobwhite quail. G. S. Davis^{*1} and L. R. Minear², ¹NC State University, Raleigh, NC USA, ²Southern States Cooperative, Providence Forge, VA USA.

The Bobwhite quail (BQ) is an upland wild gamebird in the USA, and its numbers have declined approximately 80% in the wild during the past 40 years. Consequently, 20,000,000 BQ are produced each year with the majority of these birds being raised and released on commercial hunting preserves. Producers of BQ typically experience high mortality during the rearing period. However, previous research has shown that adding PrimaLac (P), a Direct-Fed Microbial (DFM), to the diet significantly reduced BQ mortality and improved body weight (BW) gain and feed efficiency (FE). There is very little information regarding the dietary protein requirements of BQ. Therefore, a study was conducted to examine production parameters of BQ provided different levels of dietary protein (DP) with and without P from 1 d to 10 wk of age. 720 BQ were divided into 8 Trt groups and randomly placed into 6 replications each. A 2 X 2 factorial arrangement of Trts with 4 DP levels and 2 P levels (0 and 2 lbs/ton feed) consisted of the following dietary regimens: Trt 1=28% DP starter for 5 wk and 24% developer for 5 wk; Trt 2=26% DP starter for 5 wk and 20% DP developer for 5 wk; Trt 3=28% DP starter for 10 wk; Trt 4=30% DP starter for 2 wk and 26% DP developer for 8 wk; Trt 5=Trt 1+P; Trt 6=Trt 2+P; Trt 7=Trt 3+P; Trt 8=Trt 4+P). Livability was enhanced by the DFM during the first 2 wk. BQ fed 28% and 30% DP with P exhibited consistently heavier BW from 6 to 10 wk. Cumulative FE at 10 wk was improved in the DFM Trts (5.28) compared to BQ with 0 DFM (5.30). BQ feather score at 10 wk in the DFM Trts (6.75) was greater than that of the 0 DFM Trts (4.6). It was concluded that dietary P can enhance livability, BW, and feather score in BQ.

Key Words: Bobwhite quail, DFM

524 Effect of Acute Heat Stress on Some Productive and Physiological Traits of Bronze Turkey. Talat, M. El-Sheikh^{*1} and Mordy, A. Kalamah², ¹South Valley University, Faculty of Agriculture, Sohag, Egypt, ²Menofia University, Faculty of Agriculture, Menofia, Egypt.

The objective of this study was to investigate the effect of acute heat stress on physiological and productive traits of the Bronze turkey. One hundred and two Bronze turkey at 10 weeks of age were divided into three treatments and placed in climate chambers at 45C and 40% RH (heat stress) for two hours, the first and second groups were exposed for two and three times weekly and the third group reserved as control. Birds were given feed and water ad libitum and weighed biweekly from 10 to 32 weeks of age. Body temperature, respiration rate were measured weekly per bird before and after heat stress. Semen quality and blood constituents were measured at 12, 20 and 28 weeks of age after exposure of heat stress. The results revealed that the high temperature caused significant reduction in body weight and growth rate. Respiration rate and body temperature were significantly ($P<0.01$) higher in birds exposed to heat stress than those in control. The toms exposed to heat stress had significantly lower sperm motility, concentration ($P<0.01$), and live and abnormal sperm ($P<0.05$) than control toms. However, ejaculate volume and semen pH were not significant. Heat stress caused significant reduction in plasma total protein, albumin globulin, total lipids, calcium and inorganic phosphorus, creatinine, T4, growth hormone ($P<0.01$), and T3 ($P<0.05$) of birds. However plasma cholesterol

and alkaline phosphatase did not differ between birds exposed to heat stress and control.

Key Words: Bronze turkey, Heat stress, Productive traits, Physiological parameters

525 Effect of dietary diacetoxyscirpenol and fusaric acid on turkey poult performance. A.S. Fairchild^{*1}, J.L. Grimes¹, J.K. Porter², W.J. Croom¹, L.R. Daniel¹, and W.M. Haggler, Jr.¹, ¹North Carolina State University, Raleigh, NC USA, ²R.B. Russell Agricultural Research Center, USDA/ARS, Athens, GA USA.

Effects of dietary diacetoxyscirpenol and fusaric acid were determined on day-old turkey poults by randomly placing poults in batteries and feeding them one of four dietary treatments: control (C); control plus 4ppm diacetoxyscirpenol (DAS); control plus 300ppm fusaric acid (FA); and control plus 4ppm DAS and 300ppm FA (DF). There were 10 poults per pen with 6 replicate pens per treatment. Individual BW, BW gains (BWG) and pen feed consumption were determined at d6, 12, and 18. Period and cumulative feed gain was calculated. Relative liver, spleen, bursa, intestine, and jejunum weights were measured at d18. Mouth lesions were scored for treatments at d18. Performance parameters were regressed on treatment means using the GLM Procedure of SAS[®]. Means were separated using LSMEANS with significance level set at $P\leq 0.05$. FA had no effect on BW or BWG at any period compared to C. Poults fed DF had reduced BW and BWG compared to C, while poults fed DAS had lower BW than all treatments at every period. Final BW were: C (451.7g), FA (464.9g), DF (389.0g), and DAS (351.4g). Poults fed FA or C had better feed to gain than poults fed DAS or DF (1.05 and 1.04 vs. 1.19 and 1.15, respectively) at d6. However, the effect of FA was transient: there were no differences among the treatments at d12 or d18. Poults fed FA had significantly lower relative intestine wt than poults fed other diets, and had significantly higher relative bursa wt at d18 when compared to poults fed DAS or DF. Poults fed DAS or DF had higher mouth lesion scores than poults fed FA or C, but mouth lesion scores in DAS and DF poults were not different from each other (4.48 vs. 4.64). In conclusion, dietary DAS resulted in decreased poult performance, while dietary FA had little or no effect. However, FA fed in combination with DAS resulted in some protective effect towards DAS.

Key Words: Diacetoxyscirpenol, Fusaric acid, Turkey

526 The effect of a biological litter treatment on microbiological litter quality in turkey breeder flocks. T. Wiard^{*1}, M. Gockley¹, G. Troyer², and T. Rehberger¹, ¹Agtech Products, Inc., Waukesha, WI, ²Willmar Poultry Co., Willmar, MN.

A study was conducted to determine the effects of a biological litter treatment on the quality of litter in turkey breeder flocks. A flock of breeder hens were moved from a brooder barn at five weeks of age and divided into two grower barns. One barn was used as a control barn with no biological litter treatment applied, while the second barn was treated with a biological litter treatment. At twenty-eight weeks of age hens from the control grower barn were moved into two layer control barns, and hens from the treated grower were moved into two treated layer barns. In both facilities, the litter treatment was reapplied to the treated barns every ten weeks. Biweekly litter samples were taken and serial dilutions were used to enumerate total gram-negatives, coliforms, and *E. coli* found in the litter. Additionally, monthly drag swabs were collected and used to determine the presence of *Salmonella* in each barn. In the grower phase, total gram-negative bacteria in the litter were reduced by 65%, coliforms by 69.5%, and *E. coli* by 6.3% in the treated barn compared to the control barn. In the grower barn, the initial *Salmonella* drag swab samples for both the treated and control barns were negative. In the control barns, the number of positive *Salmonella* samples rose to 60% by the second sampling, and to 80% by the third sampling, where they remained until the birds were moved out of the grower barns. During the same time period, *Salmonella* remained at an undetectable level in the treated barn. In the initial drag swab samples from the layer barns, only one sample was positive for *Salmonella* in the treated barns compared with three positive samples from the control barns. By the eleventh week in the layer barns, 40% of the samples tested positive for *Salmonella* in the control barns, while *Salmonella* was at an undetectable level in the treated barns. The biological litter treatment was effective in controlling the number of total

gram-negatives, coliforms, *E. coli*, and *Salmonella* present in litter from turkey breeder flocks.

527 Sex differences in some hatching parameters. Akrum Hamdy*, *Animal Prod., Dept., Fac., of Agric., Minia Univ., Egypt.*

One thousand and hundred fertile eggs of Hisex Brown layers were used in this study. Variations in hatching time as affected by egg size and their subsequent effect on hatch weight, placement weight and sex ratio were evaluated. Egg weight had a positive correlation coefficient with hatch weight and placement weight (0.664 and 0.656, respectively). While it has a negative value with hatching time (-0.602). Female chicks tend to hatch earlier than males. About 71% of females had hatched by 506 hrs. whereas 55% of the males had hatched at a comparable time. Greater weight loss in females than males may be due to evaporation, which occurred in the hatcher. From these results, it may be advantageous to develop procedures for harvesting female chicks more than one time during the hatching period.

Key Words: Sex Differences, Hatching Time, Egg Size

528 Real time incubation temperature control and heat production of broiler eggs. R. M. Hulet*¹ and R. Meijerhof², ¹*Pennsylvania State University, University Park, PA,* ²*Hybro BV, Boxmeer, NL.*

Previous research has shown the value of controlling heat production during incubation for high-meat yielding broiler eggs. The purpose of this study was to evaluate the effect of maximizing heat production from five to eighteen days of incubation on hatchability and embryonic mortality. Two trials were conducted using 115,200 eggs from broiler breeders between 42 and 45 weeks of age (Lagerwey BV, NL) in two Hatchtech™ incubators. After five days of age, temperature of the setter was adjusted to maximize heat production of the egg mass. Temperature, humidity, and carbon dioxide measurements were recorded every fifteen minutes during the incubation period. Weight loss, fertility, stage of embryonic death, chick weight, and hatchability were recorded for each incubator. Test incubators were compared to control incubators that contained eggs from the same flocks. Results showed a two percent increase in hatchability (90.3 and 89.3 versus 88.2 and 86.8 percent) for the test incubators when compared to the control setters that resulted, primarily, from decreased late dead embryos. Heat production was found to be .20 and .19 watt/egg, respectively for trial I and II which was similar to previously reported for high yielding broilers. In summary, real time monitoring of incubation can result in gains in hatchability by controlling embryonic heat production during critical periods of incubation.

Key Words: Incubation, Embryonic Heat Production, Temperature

529 Reduction of turkey hatching egg shell contamination with ultraviolet irradiation. R. A. Russo*, C. Chavez, T. P. Niemeyer, P. L. Reynolds, and J. B. Carey, *Texas A&M University, College Station, TX.*

The germicidal effects of 254nm ultraviolet light (UV) have been well documented in other sanitation applications. Field trials were conducted to test the impact of UV exposure on turkey hatching egg shell microbial contamination. An egg washing unit (with a motorized finger-type conveyor belt) was modified to be utilized as a UV chamber. Nine 40 watt lamps (three on top and three on each side) were placed in the UV chamber. The lamps operated at an intensity of $\geq 10.84\text{mW/cm}^2$ and egg exposure time was 45 seconds. The conveyor belt allows for the eggs to pass through individually and rotate on the longitudinal axis as they pass through the chamber, allowing full exposure of the shell to the UV radiation. Five trials were conducted with eggs from commercial turkey breeder flocks. Sixteen eggs were used in each trial (8 controls, 8 treated). After treatment, eggs were placed in 50mL of sterile phosphate buffer solution (PBS) and massaged for 4 s. Serial dilutions of the PBS were plated in duplicate on plate count agar (PCA), eosin methylene blue agar (EMB) and brilliant green agar (BGA). All plates were incubated at 37C for 48h before enumeration. In all trials, PCA counts of treated eggs were significantly lower than those of controls. *Salmonella* colonies detected on EMB was significantly lower on treated eggs in 4 of the 5 trials, and not significantly different in the other 1. *E. coli*

colonies enumerated on EMB were significantly lower in 2 of the trials, and not significantly different in the other 3. *Salmonella* colonies enumerated on BGA were significantly lower on treated eggs in 2 trials, and not significantly different in the other 3. *E. coli* colonies detected on BGA were significantly lower in 2 of the trials, and not significantly different in the other 3. These data indicate a potential for reduction of egg shell microbial contamination of turkey hatching eggs with UV irradiation.

Key Words: UV irradiation, Turkey hatching eggs, Egg shell contamination

530 The effects of age at photostimulation on reproductive efficiency in three strains of broiler breeders varying in breast yield. N. S. Joseph*¹, F. E. Robinson¹, R. A. Renema¹, and M. J. Zuidhof², ¹*University of Alberta, Edmonton, AB, Canada,* ²*Alberta Agriculture, Food and Rural Development, Edmonton, AB, Canada.*

The effects of photostimulating at 20 versus 23 wk of age were examined in three strains of female broiler breeders (Arbor Acres Farms Inc.; Classic, Feather Sexable Yield [FSY], and an experimental line [EXP]). The EXP line had been selected for more breast muscle yield than the other two strains. One objective was to determine if genetic selection for meat yield has changed the age at onset of lay. A second objective was to examine varying ages at photostimulation. At 19 wk of age, 48 pullets from each strain were housed in individual laying cages. The photoperiod during rearing and at the time of placement was 8 h of light/d. A solid black curtain was placed down the center of the room, dividing it into two halves. At 20 wk of age, one-half of the birds were photostimulated by increasing the photoperiod to 15 h of light/d. The other half remained on 8 h of light/d until 23 wk of age when they received the same increase in photoperiod as the 20-wk treatment. Strain of bird had no effect on age at sexual maturity. Birds that were photostimulated at 23 wk of age weighed more and were older at sexual maturity than birds photostimulated at 20 wk of age (185.6 and 180.0 \pm 1.1 d of age, respectively). However, once photostimulated, the pullets in the 23-wk treatment took less time to reach peak production than those in the 20-wk treatment. The later-photostimulated group had a higher mean egg weight throughout lay. There was no strain or treatment difference in hen-day egg production or settable egg number. Breast weight was heavier for EXP than Classic and FSY hens at 53 wk of age. The later-photostimulated group had more large yellow follicles than the early-photostimulated group. Although there were strain differences in breast muscle weight, strain did not affect the number of eggs produced. Delaying photostimulation by 3 wk was effective as hens began production faster and had an increased egg weight throughout lay without a decrease in egg production.

Key Words: Broiler breeder, Photostimulation age, Reproductive parameters

531 The effect of administering Oasis™ hatching supplement prior to chick placement on growth and body weight uniformity of female broiler breeders. S. I. Boersma*, F. E. Robinson, G. M. Fasenko, and R. A. Renema, *University of Alberta, Edmonton, AB, Canada.*

Transportation of broiler breeder chicks may cause energy loss and dehydration during the time period between hatch and placement. Arbor Acre Classic broiler breeder pullets were used to examine the effects of chick hatch condition on flock BW uniformity. Chick hatch condition assessment included eggshell quality, moisture loss, chick weight at hatch and chick weight 36 h post-hatch. A total of 2500 broiler breeder parent eggs were incubated and 856 female broiler breeders were successfully pedigree hatched in order to match egg and chick weights. An equal number of chicks received one of two treatments as follows; Assisted (AST), received Oasis (Novus International Inc., St. Louis, MO) for 36 h; Control (CON), received no hatching supplement. Chicks were placed in 8 floor pens (107 birds/pen) in a light-tight facility from 36 h post-hatch to 18 wk of age. Individual BW were recorded at 1, 2, 3, 4, 8, 12, 16, and 18 wk of age. Feed allocation was determined according to group BW following breeder guidelines. Eggshell quality, egg set weight and chick hatch weight were similar between AST and CON treatment groups. The AST post-hatch weights were lower than CON (37.24 g compared to 37.86 g, P = 0.0058). However, BW for AST treatment were higher than CON for 1, 2, 3 and 4

wk, as well as the BW gains for 0-1, 2-3 and 16- 18 wk. The AST treatment showed more variation in BW uniformity at wk 1 (CV of 10.21%) than CON treatment (CV of 9.16%). Overall, AST and CON birds had similar BW uniformity throughout the rearing period. Whereas Oasis treatment did not affect pullet BW uniformity beyond 1 wk of age, it may contribute to enhanced BW and BW gains during the first 4 wk of the rearing period.

Key Words: Broiler breeders , Body weight uniformity, Chick quality

532 Physical traits and reproductive success in male primary broiler breeders. S. McGary*¹, I. Estevez¹, M. R. Bakst², and D. L. Pollock³, ¹Univ of MD, College Park, MD 20742, ²USDA-ARS, Beltsville, MD 20705, ³Perdue Inc, Salisbury, MD 21802.

Genetic selection for high yield in primary broiler breeder males may result in skeletal modifications that impede sperm transfer upon mating. In addition, fluctuating asymmetry (FA) in bilateral traits has been shown to reliably indicate male reproductive potential in some avian species. The goal of this study was to determine if physical variation due to genetic selection and FA could explain and predict differential fertility and semen quality in male broiler breeders. Sixty males from two primary broiler breeder strains (A and B) were individually housed with an average of 10 females. Fertility was estimated by examining the germinal disc (GD), and semen quality by counting sperm penetration (SP) through the perivitelline layer. At 50 wks, body weight (BW) was taken and males euthanized. Posterior pelvic length and width (PPL and PPW), dorsal pelvic length and width (DPL and DPW), tarsometatarsal length and width (TL and TW), and wattle length and width (WL and WW) were measured with digital calipers. Strain differences included BW ($P < 0.01$), WL ($P < 0.0001$), WW ($P < 0.0001$), PPL ($P < 0.01$) and DPW ($P < 0.001$). The degree of FA in TL ($P < 0.05$) and WL ($P < 0.05$) was greater in Strain A, however FA did not correlate with fertility or SP in either strain. Strain A WL correlated with SP ($r = 0.295$; $P < 0.05$). There was a negative relationship between Strain A fertility and DPW ($r = -0.298$; $P < 0.05$). Strain A DPW alteration may affect sperm transfer upon copulation, however, this correlation was weak and should be further investigated to validate the relationship between pelvic structure and copulatory success. Fertility and SP did not correlate with physical traits in Strain B. Strain differences demonstrate potential impact of selection on physical traits. A significant relationship between comb

size and Strain A fertility has been previously shown, and the present study provides further evidence supporting evaluation of sexual traits as fertility indicators for Strain A.

Key Words: Broiler breeder, Fertility, Genetic selection

533 Effects of rearing feed intake on carcass characteristics of male broiler Breeders to 26 wk of age. R. H. McGovern*¹, J. L. Wilson¹, F. E. Robinson², and L. F. Bouvier², ¹The University of Georgia, ²University of Alberta.

Male broiler breeders require adequate fleshing to attain sexual maturity, while at the same time must remain lean enough to prevent them from becoming too large to mate naturally during the breeding period. Knowledge of the skeletal and carcass characteristics of male broiler breeders has been proposed as a management technique. Four hundred and eighty commercial male broiler breeders were reared in 12 floor pens. Birds were assigned to one of four rearing feed level treatments: standard (SF) (recommended BW profile), plus 15% (P15) (BW approximately 15% heavier than the SF), plus 30% (P30), and full fed (FF) at 1 d of age. Starting at 21 wk of age, male BW was restricted to attain the recommended breeder BW at 24 wk of age. Shank length, keel length, chest width, head width, and comb height were recorded for all birds. Forty birds (10 birds per treatment) were dissected at 6, 12, 18, 20, 22, 23, 24, 25, and 26 wk of age. Shank color and a visual shank color score of all males were assessed from 12 wk of age. The FF treatment males had the greatest gain from 5 to 6 wk of age (334 g) and maintained the greatest BW at 18 and 20 wk of age (3395g and 3747g, respectively). At 6 wk, the FF and P30 treatment males had the greatest fatpad weight compared to the SF bird (17.3g and 18.2g, respectively compared to 7.5g). The FF males had a greater BW and greater breast muscle development than the other BW treatments at 12, 18, and 20 wk. There were no differences in testes weight among the treatments prior to photostimulation at 22 wk. Head width, comb height, chest width, keel length, and shank length were increased in early rearing with feeding level. From 22 to 24 weeks of age, the FF males are in a period of BW weight loss. Testes of birds in the FF treatment were smaller compared to the P30, P15, and SF treatment males at 24 wk (11.7 g, 26.6 g, 29.2 g, and 25.5 g respectively).

534 Major histocompatibility (B) complex gene dose effects on Rous sarcoma virus tumor growth. T. A. Tupick¹ and R. L. Taylor, Jr.*¹, ¹Dept. of Animal and Nutritional Sciences, University of New Hampshire, Durham, NH 03824.

This study's objective was to examine major histocompatibility (B) complex (MHC) gene dosage effects on the outcome of Rous sarcomas. Matings between Line UNH 193 ($B^{19}B^{19}B^{19}$) trisomic sires and dams produced progeny having $B^{19}B^{19}$ (disomic), $B^{19}B^{19}B^{19}$ (trisomic) or $B^{19}B^{19}B^{19}B^{19}$ (tetrasomic) MHC chromosome doses. The MHC and the nucleolus organizer region (NOR) are both located on a medium size microchromosome, designated 16. Nucleoli from feather pulp cells were enumerated using phase-contrast microscopy to determine chromosome dose. Six-week-old chickens were inoculated in the wing-web with 30 pock forming units (pfu) of subgroup A Rous sarcoma virus (RSV). Tumors were scored for size six times over a 10-wk period. The six tumor size scores were used to assign a tumor profile index (TPI), which indicates the degree of tumor growth. The TPI values, based on the general regressive nature of the B^{19} haplotype in these chickens, were 1 = complete regression by 28 days, or earlier; 2 = complete regression by 42 or 56 days; 3 = complete regression by 70 days, or a decreasing slope, or complete regression by 56 days followed by recurrence; 4 = general upward trend, or plateau or slight regression after 56 days; 5 = terminal tumor prior to 70 days. Mean tumor size scores were evaluated by repeated measures analysis of variance. The TPI values were rank transformed and analyzed by ANOVA. Fisher's Protected LSD at $P < 0.05$ separated significant means. The 88 chickens that developed tumors were 28 disomic, 47 trisomic and 13 tetrasomic types. No difference in tumor growth over time was detected among the three MHC gene doses with most chickens regressing their tumors. Disomic chickens had a significantly lower TPI than trisomic but not tetrasomic chickens. The TPI of trisomic and tetrasomic chickens did not differ significantly.

These data indicated that MHC dose alterations, at least to the trisomic level, have a negative impact on Rous sarcomas tumor outcome.

Key Words: Oncogene, Tumor, Aneuploid

535 Wattle swelling and antibody titers in BSA hypersensitive and naive hens. Paul Cotter*¹ and Swami Halidi², ¹Framingham State College, ²Department of Animal and Poultry Sciences, University of Guelph, Canada.

Wattle swelling was measured at 4, 24, 48, and 72 h in hens challenged with BSA. The swelling responses in those hens previously sensitized to BSA were greater at measurements up to 48 h compared to naive hens. Extraordinary swelling was observed in 10, 6 and 3 of 13 sensitized hens and in none of the naive hens at 4, 24 and 48 h respectively. Thus 19 of 39 (49%) of the presensitized group responses were not considered salutary versus none in the naive group. There was a slight tendency for the sensitized hens to show weight loss at one wk after the challenge but some loss occurred in certain naive hens as well. The log₂ antibody titers to BSA were detected by passive hemagglutination. These were 2.8 in naive hens and 8.0 in the sensitized hens at the time of the wattle challenge. Titers rose to 8.0 in naive hens but fell slightly to 7.2 in sensitized hens one wk after the wattle challenge. Natural antibodies to mouse and rabbit erythrocytes were also affected by the wattle challenge. Anti-mouse titers rose from a prechallenge average log₂ of 1.9 to 3.4. Anti-rabbit titers also rose from 4.8 to 6.7 during the same period. The net change in both types of natural antibody was about the same (1.7) for the two groups. Overall it appears as if total antibody output is balanced so that increasing one type is offset by decreasing or not changing another type. Thus changes in humoral immune output (natural and acquired antibody levels) accompanied the

cell mediated wattle reaction. Based on the combined observations a theory called "immunologic homeostasis" is advanced. Accordingly net immunologic work does not change in a well-balanced system. Temporary immunologic needs are met by drawing from available reserves so that momentary perturbations in this system may be accommodated. Implications of this theory may extend to both infectious diseases and vaccination.

Key Words: wattle swelling, antibody, immunologic homeostasis

536 High-Throughput Gene Expression Profiling To Study Host-Parasite Interactions In Avian Coccidiosis. H Lillehoj^{*1}, W Min¹, J Zhu¹, C Ashwell², C Van Tassel³, T Sonstegard³, J Burnside⁴, and B Matthew⁵, ^{1,2,3}*U.S. Department of Agriculture-ARS, Beltsville, MD*, ⁵*U.S. Department of Agriculture-ARS, Beltsville, MD*, ⁴*University of Delaware, Newark, DE*.

Coccidiosis is an intestinal infection caused by intracellular protozoan parasites, *Eimeria*. Understanding the interaction between host and parasites is crucial in designing new approaches. Documented evidence that T cells are the primary effectors of immunity to *Eimeria* has led to further interest in understanding the role of T cells in coccidiosis. *Coccidia* induces local and systemic changes in many cytokines including IL-2, IL-15, IFN-gamma and TGF-beta4. To better characterize host-parasite interactions, high-throughput gene profiling DNA arrays were used to identify genes with altered expression following infection with *E. acervulina*. Over 1000 expressed sequence tag (EST) genes from an activated T cell library, including those for several cytokines, were arrayed on DNA chips and hybridized with mRNAs from *E. acervulina* infected intestinal cells. Over 200 genes showed significant changes following infection. The success of this DNA microarray approach prompted us to construct a normalized cDNA library from intestinal cells after infection *Eimeria* to identify specific genes regulating protective immunity. This library contains 1.87 times 10⁷ transformants/ml with an average insert size of 1.56 kb. Presently, single pass sequence was obtained on over 6000 EST clones of which 80% contain high quality inserts and 50% are unique based on a BLAST search. DNA microarray analysis of this library will allow better characterization of chicken genes involved in local host-parasite interactions in avian coccidiosis (Supported by Fund for Rural America, Grant No 9704985 and partially by ARS CRIS).

Key Words: DNA microarray, intestinal genes, coccidiosis

537 Seroepidemiology of Newcastle disease virus in wild pigeons in Shahre-Kord in Iran. Majid Bouzari^{*1} and Khodarahm Argang², ¹*Department of Biological Sciences, Faculty of Sciences, Isfahan University, Isfahan, Iran*, ²*Private Veterinary Practitioner, Shahre-Kord*.

Newcastle disease is one of the most important viral diseases of poultry in Iran. It is an enzootic disease and sometimes epizootic. It causes a great loss in poultry industry. Wild birds may act as reservoirs and play an important role in the spread of the virus among poultry flocks. Among wild birds pigeons which have easy access to poultry houses and food stores may play a critical role in the spread of the disease. For determining their role, 390 wild pigeons from three different areas in Shahre-Kord province (Shahre-Kord, Saman and Kiar) were captured and their blood serums were examined for the presence of antibodies against Newcastle disease virus by hemagglutination inhibition (HI) test in autumn and winter of 1998 and spring and summer of 1999. HI antibody titers of 1, 2 and 3 and above were categorized as negative, suspected and positive respectively. Chi-square test was used for statistical analysis. HI titers of up to 7 (log base 2) were recorded. The percentage of the negative, suspected and positive HI antibodies in the whole area were 32.88, 19.18 and 47.94 in autumn, 9.62, 17.30 and 73.08 in winter, 50.45, 18.02 and 31.53 in spring and 63.64, 13.64 and 22.73 in summer respectively. Significant differences were observed between winter and other seasons ($P < 0.05$). The differences between spring and summer, and spring and autumn were not significant ($P < 0.05$). No significant differences were observed among different areas ($P < 0.05$). The rate of contamination in wild pigeons in areas studied was 31.88-41.45 percent with 95% confidence interval. The higher level of positive birds in winter could be correlated to overcrowding of the pigeons in places which is called Ghanat and the higher possibility of feeding in food stores of poultry farms due to lack of enough seeds during this season. The lower rate of positive birds in spring could be correlated to the introduction of new young birds to the whole population and more availability of food in nature and as a results less crowding and less contact with poultry

farms. It was concluded that wild pigeons might act as reservoirs and play an important role in the spread of the Newcastle disease virus.

Key Words: Newcastle disease virus, Seroepidemiology, Wild pigeon

538 Comparison of PEMS-associated and classical astroviruses-mediated effects on performance and immune functions of turkey poults. M. A. Qureshi^{*1}, Y. M. Saif², R. A. Ali¹, F. W. Edens¹, C. L. Heggen-Peay¹, and G. B. Havenstein¹, ¹*NC State University, Raleigh, NC*, ²*The Ohio State University, Wooster, OH*.

Poult enteritis and mortality syndrome (PEMS) is an acute, infectious, transmissible intestinal disease of young turkeys. A turkey astrovirus (TAst-OSU) of 30-32 nm size was isolated from intestinal contents of poults exhibiting clinical signs of PEMS. While involvement of astroviruses in enteric disease is not new, they have achieved a renewed importance due to their involvement in PEMS. Experimental inoculation of turkey poults with purified TAst-OSU resulted in growth suppression, diarrhea, 100% morbidity with variable mortality, significant atrophy of thymus and bursa, and reduced lymphoblastogenesis. We have, therefore, compared the recent PEMS TAst-OSU isolate with the "Classic turkey astrovirus" (C-TAst) which was isolated and reported in 1986 (Avian Dis. 30:728). Specific-pathogen-free poults were housed in HEPA-filtered bubble-type isolation units and exposed to 10³EID₅₀ TAst-OSU or C-TAst in 1 mL/poult at 7 d of age. Control poults received 1 mL of sterile PBS. Poults in both virus-challenge groups exhibited reduced ($P = 0.01$) wt gain (123 - 129 g) as compared with the control (141 g) poults at 7 dpi. While bursal development was not affected, poults in both TAst-OSU and C-TAst groups had significant reduction in thymic growth ($P = 0.0006$) and enlarged spleen ($P = 0.044$) vs. control poults at 7 dpi. Lymphoblastogenic response stimulation index against concanavalin-A was lowest in TAst-OSU (0.304), as compared with the C-TAst (0.542) and control (1.182) poults ($P < 0.05$). Poults in C-TAst group exhibited over a 1 log reduction ($P = 0.044$) in total and IgM anti-SRBC antibodies whereas TAst-OSU poults exhibited antibody levels comparable to the control poults. Therefore, this study indicates that the PEMS-associated (TAst-OSU) and the classic turkey astroviruses (C-TAst) are capable of inducing performance and immune function defects. However, these two astroviruses appear to differ in their effects on immune endpoints in young turkey poults.

Key Words: PEMS, astroviruses, immune functions

539 PEMS-associated reovirus: viral replication, effects on avian cell livability, and cytokine expression. M. A. Qureshi^{*1}, C. L. Heggen-Peay¹, K. A. Schat², B. Sherry¹, M. A. Cheema¹, R. A. Ali¹, and P. H. O'Connell², ¹*NC State University, Raleigh, NC*, ²*Cornell University, Ithaca, NY*.

We have recently isolated a reovirus from intestinal contents of poults suffering from poult enteritis and mortality syndrome (PEMS). This PEMS-reovirus (CU-98) is approximately 80 nm in size and consists of 10 dsRNA segments clustered in three size classes, designated large, medium and small, based on electrophoretic mobility. Experimental challenge of poults with CU-98 resulted in decreased liver and bursal weights suggesting contributory role of reovirus in PEMS. In the current study we examined the interaction of CU-98 with LMH, a liver hepatocyte cell line; MQ-NCSU, a macrophage cell line; and RP-9 and DT-40 (B lymphocyte cell lines) by exposing the cells to 10-fold dilutions of the CU-98 stock. CU-98 produced CPEs (e.g., syncytia, rounding, sloughing) only in LMH cells with 10⁶TCID₅₀. CU-98 was found in abundance in cytoplasm of LMH cells via TEM. In contrast, CU-98 particles were detected bound to the MQ-NCSU cell surface but not within the cytoplasm. When CU-98 infected and noninfected LMH and MQ-NCSU cells were examined electrophoretically after metabolic labeling with ³⁵S-methionine, viral protein bands of 145 and 43 kD were found in infected LMH cell lysates but not in MQ-NCSU lysates. Single oral challenge of poults with CU-98 resulted in low-titer (1:4) neutralization antibodies at 10 dpi. CU-98 was plaque-purified and exposed to MQ-NCSU. IL-1 mRNA was examined at 2 h time points by RT-PCR. While no IL-1 mRNA was detected in sham-exposed macrophages, IL-1 was upregulated in macrophages after 2 h of virus exposure and seemed to decrease in a time-dependent manner up to 10 h of exposure. In contrast, IL-1 mRNA was present in both sham and virus exposed LMH cells and appeared to decrease after 8-10 h suggesting a possible down-regulation of IL-1 by CU-98 in liver cells and signaling the beginning of

CPE. These findings imply that PEMS-reovirus may be a key contributory agent in the overall PEMS etiology. Furthermore, some immunological and metabolic alterations observed in PEMS poultts may also be attributable to exposure to reovirus.

Key Words: PEMS-Reovirus, CPE, Cytokines

540 Non-covalent modification of protein antigens can direct them to scavenger receptors and induce inflammatory immune responses. S.S. Vandaveer*, G.F. Erf, and J.M. Durdik, *University of Arkansas.*

After pathogen invasion, an organism's survival depends on choices the immune system makes. For intracellular infections, the body can choose one of two pathways mediated by T helper type 1 (Th1) or 2 (Th2) cells. Th1 cells produce inflammation, and Th2 cells, antibody-production. Choosing Th1 over Th2 can prevent host mortality and promote recovery. One way to induce a Th1 response in chickens is to target antigens to scavenger receptors (SR), expressed on B cells and macrophages. Conjugating maleic anhydride to an antigen confers a negative charge to it, allowing it to effectively bind to SR. This binding can be specifically reduced by preincubation with other known SR ligands, evidenced by flow cytometry and immunohistochemistry. We have shown that Th1 responses can be induced by direct covalent modification of protein antigens with maleic anhydride as evidenced by functional biological tests (wattle swelling vs. antibody titers) and confirmed with molecular tests for interferon (IFN) γ production. Our hypothesis is that maleyl-pLL will serve as a general linker to deliver protein antigens to SR. We show that the protein need not be directly modified with maleyl to generate Th1 responses. Instead, we covalently modify poly-L-lysine (pLL) with maleyl and then take advantage of protein binding to pLL to deliver the pLL:maleyl-protein complex to SR. The advantage with pathogenic proteins is that linkers may be a benefit because of the practical difficulty in obtaining large amounts of protein antigen needed for direct chemical modification. The pLL was tested as a linker for a model protein antigen, bovine serum albumin (BSA). Chickens were injected with pLL:BSA and maleyl-pLL:BSA to test for Th1 responses. As a result, maleyl-pLL:BSA produced significant wattle swelling and IFN γ production, indicative of a Th1 response. This was in contrast to antibody titers produced against pLL:BSA immunization, indicative of a Th2 response. The data establish the likelihood that maleyl-pLL can be used as a linker to deliver many protein antigens to SR to induce Th1 responses in birds.

Key Words: Macrophages, T cell subsets, Scavenger receptors

541 Hypo and Hyper responsiveness to bacterial LPS may be due to differential expression of Toll-like receptor-4 in chicken macrophages from different genetic backgrounds. N. Dil* and M. A. Qureshi, *NC State University, Raleigh, NC.*

Macrophages respond to external stimuli by inducing the expression of various cytokines, adhesion molecules, and enzymes, that modulate various immune functions. Inducible nitric oxide synthase (iNOS) is one such enzyme that catalyses the biosynthesis of nitric oxide which in turn mediates several immunological and physiological functions. We have shown previously that macrophages from Cornell K-strain (B¹⁵B¹⁵) exhibit higher iNOS activity in terms of nitrite production as compared with GB1 (B¹³B¹³) and GB2 (B⁶B⁶) chicken macrophages regardless of the LPS bacterial source. In the current study we exposed macrophages (1 x 10⁶) to 5 μ g/mL LPS from *Escherichia coli*, *Shigella flexneri*, *Serratia marcescens*, and *Salmonella typhimurium*. Northern-blot analysis revealed that K-strain macrophages expressed higher intensity of iNOS mRNA (iNOS/ β -actin ratio) than macrophages from GB2 (which was hardly detectable even in 20 μ g total RNA) regardless of the LPS source. We further investigated if any differences exist in possible molecular mechanism(s) involved in iNOS gene expression in these two strains of chickens. The constitutive expression of LPS-related macrophage cell surface receptors CD14 and Toll-like receptor-4 (TLR4) was examined via flow cytometry using anti-human CD14 and TLR4 antibodies. CD14 surface expression and intensity was not different between macrophages from K and GB2 chickens. In contrast, while the overall percentage of TLR4-positive macrophages was the same (K-strain, trial 1 = 92%, trial 2 = 62%; GB2, trial 1 = 91%, trial 2=64%), the receptor intensity (i.e. receptor numbers) was significantly higher ($P=0.05$) in K-strain macrophages (mean fluorescence intensity trial 1 = 145; trial 2 = 131) than in GB2 (trial 1 = 101; trial 2 = 98) macrophages. Furthermore, TLR2 (a previously thought candidate as LPS signaling molecule)-positive cell numbers were higher in K-strain than the GB2 macrophages

in one of the two trials with no difference in the intensity of TLR2 cell surface expression in either trial. These findings suggest that the observed differences in iNOS expression and activity among the K-strain (hyper responder) and GB2 (hypo responder) chickens are, at least in part, due to differential expression of LPS signaling molecule, namely Toll-like receptor-4, leading to relatively stronger LPS-mediated activation of K-macrophages.

Key Words: iNOS, CD14/TLR4, macrophage

542 Effect of a *Lactobacillus*-based dietary probiotic on oocyst shedding and interferon- γ production following *Eimeria acervulina* infection in broilers. R. A. Dalloul*¹, H. S. Lillehoj², and J. A. Doerr¹, ¹Dept. of Animal & Avian Sciences, Univ. of Maryland, College Park, MD/USA, ²Parasite Biology, Epidemiology and Systematics Laboratory, USDA-ARS, Beltsville, MD/USA.

Previously we reported increased resistance (reduced fecal oocysts) in *Lactobacillus*-treated broilers to *Eimeria acervulina* (EA). The present study was designed to examine IFN- γ (interferon-gamma) and oocyst production under similar conditions. Day-old male broiler chicks were fed control (CON) or probiotic-supplemented (PRO)(Primalac[®]) diets. In Exp. 1 (24 chicks/diet) chicks were orally challenged with 10⁴ oocysts of EA on day 20. Sera and intestinal secretions were sampled at 3, 6, 9, and 12 days post-infection (d PI). In Exp. 2 (8 chicks/diet), the chickens were challenged with 2x10⁴ oocysts/bird and oocysts were enumerated at 10 d PI.

Intestinal IFN- γ in CON chicks was constant through the sampling period except at 6 d PI when a significant ($P < 0.05$) increase occurred. In contrast, PRO chicks had a significantly higher IFN- γ at 3 d PI, which then declined until 12 d PI. No differences in serum IFN- γ were observed. No significant differences in anti-coccidial antibodies were found. Fecal oocyst shedding was slightly but significantly lower for PRO than for CON chicks; however, the reduction in shedding was not as great as in a previous study when half the inoculum rate was used. These results suggest an immunoregulatory effect of PRO diets on the local immune system in poultry and provide a rationale for further study to investigate the beneficial effects of *Lactobacillus*-based probiotics in food animals.

Key Words: Mucosal immunity, *Lactobacillus*, *Eimeria acervulina*

543 Antigen-Induced Ion Secretion in the Chicken Intestine Following Oral or Intraperitoneal Immunization Against Bovine Serum Albumin (BSA). J.L. McReynolds*¹, A.P. McElroy², H.D. Danforth³, and D.J. Caldwell¹, ¹Texas A&M University, College Station, TX, ²Virginia Tech, Blacksburg, VA, ³USDA/ARS/LPSI/PBEL, Beltsville, MD.

Our laboratories are investigating epithelial ion secretion, as mediated by Type I hypersensitivity, as a determinant and potential component of functional immunity in the chicken intestine. The present study evaluated antigen-elicited changes in ion secretion following immunization of SCWL chicks against BSA by oral or intraperitoneal (IP) routes. Oral immunization consisted of administering a daily *per os* bolus of 1 ml of 25 mg BSA/ml to chicks between 10 and 16 days of age. IP immunization consisted of administering 1 ml injections of 10 μ g/ml BSA-10mg alum (AlK(SO₄)₂) to chicks on either 1,7, and 14 or 10 and 16 days of age. IP control groups received 1 ml injections of 10 mg alum only. Distal ileal segments from BSA-immunized or control chickens were evaluated for *in vitro* responsiveness to antigen in Ussing chambers on days 20-22 of age in three replicate experiments. Ileal segments from oral BSA-immunized chickens responded to antigen in a significantly ($P < .05$) greater degree than other experimental groups. This response, a change in transmural short circuit current (Δ Isc), occurred within 1 minute of antigen exposure and reached a maximum level (Δ Isc=40.54) within 3 minutes. Response of negative control tissues was significantly lower (Δ Isc=12.47). When tissues from chickens receiving IP BSA or alum on days 1,7, and 14 were compared, significant differences were not observed (Δ Isc=12.78 and Δ Isc=7.87, respectively). Similarly, when ileal segments from chickens receiving IP BSA or alum on days 10 and 16 were compared, significant differences were not observed (Δ Isc=32.3 and Δ Isc=10.03, respectively). The present data confirm and extend previous findings from our laboratories suggesting epithelial ion secretion is a component of mucosal immunity in chickens. Further, these data may have important implications for vaccinating poultry against enteric pathogens.

Key Words: mucosal immunity, intestinal anaphylaxis, chicken

544 Utilizing solanum glaucophyllum and phytase to improve phosphorus utilization in broilers. Y-H Cheng^{*1}, J.P. Goff², J.L. Sell³, S Gill⁴, E. Pawlak⁴, M. Elena⁴, and R.L. Horst², ¹Iowa State University/Biomedical Science, ²National Animal Disease Center, ³Iowa State University/Animal Science, ⁴CAE, Buenos Aires, Argentina.

Both 1,25-dihydroxyvitamin D3 and phytase are known to improve phosphorus utilization in broilers (Biehl and Baker, J Nutr 1997). Solanum glaucophyllum (Sg) is a plant containing high amounts of 1,25-dihydroxyvitamin D bound to a glycoside. It may be an economical source of 1,25-dihydroxyvitamin D for animal feeds. We examined the effect of Sg, with and without phytase, on phosphorus utilization in broilers fed corn-soybean meal diets. The basal diet was 0.6% Ca, 0.45% total P (0.15% available P) with adequate vitamin D3 (3000 IU/kg). The six treatments included basal diet, basal with 7.5 g Sg/kg, basal with 10 g Sg/kg, basal with 1200 FTU phytase/kg, basal with phytase (1200 FTU/kg) and Sg (7.5 g/kg), and "normal" diet (0.7% total phosphorus, 1% calcium). Each treatment was given to six pens of 8 chicks. When compared with the basal diet, addition of 7.5 g Sg/kg or phytase improved growth and bone mineralization. Increasing Sg to 10 g/kg diet did not significantly improve weight gain or bone density over the 7.5 g Sg/kg dose. Phytase and Sg supplementation increased plasma and bone Ca and P concentration similarly, however the greatest weight gain and tibia ash was observed in the phytase (1200 FTU/kg) group. Adding 7.5 g Sg to the phytase supplementation did not significantly improve P utilization over phytase alone.

Diet	Blood P	Bone ash	Bone density	Weight gain
	mg/dl	g/tibiae	g/cm ³	gw
Basal(B)	4.56a	1.022a	1.117a	984a

Key Words: Solanum Glaucophyllum, Phytase, Phosphorus

545 Effect of wheat bran phytase subjected to different conditioning temperatures on phosphorus utilization by broiler chicks based on body weight and toe ash measurements. W. B. Cavalcanti^{*}, K. C. Behnke, R. S. Beyer, and M. Okot-Kotber, Kansas State University, Manhattan, KS.

Cereal grains and oilseed byproducts are among the major components of diets fed to poultry. Although phosphorus levels are high in these ingredients, most of it is presented in phytate form and thus, unavailable. Wheat bran is known for having high phytase enzyme activity. A study was conducted with the objective of evaluating the efficacy of wheat bran in improving utilization of phytate phosphorus by broiler chicks. Four diets with increasing calculated levels of available phosphorus (Pav) (0.35, 0.40, 0.45, 0.50%) were used as references. Four test diets were formulated to contain 0.35% Pav. Three diets had a 5% inclusion of wheat bran subjected to different treatments: unconditioned, conditioned at 60°C and 80°C. The fourth diet had no wheat bran, but a commercial source of phytase. All treatments were isocaloric, isonitrogenous and formulated to meet or exceed NRC recommendations. Diets in the mash form were used in a (0-3) weeks battery study. Regression equations were used to estimate levels of Pav in the test diets. Increasing levels of Pav in reference diets resulted in improved live weight gain (LWG) and percent toe ash (PTA) on a dry matter basis. When utilized in the unconditioned form, wheat bran provided similar results for LWG and PTA to those obtained with the commercial phytase diet. Although some additional phosphorus was estimated to be available in those diets, due to phytase activity, the levels of the mineral were still below those recommended by the NRC. Increasing conditioning temperature (60°C and 80°C) lowered LWG and PTA of birds fed those diets. The results lead to the conclusion that wheat bran can be utilized in low Pav diets for broilers without any negative effects in LWG and PTA measurements when compared with diets containing proper levels of phosphorus. It may also be suggested that wheat bran cannot be conditioned or pelleted without losing most of its enzyme activity.

Key Words: Wheat bran, Phytase, Broiler

546 Evaluation of the available phosphorus requirement & optimal phytase level of 21-42 day old male broilers. J. R. Timmons^{*1}, J. M. Harter-Dennis¹, and A. E. Sefton², ¹University of Maryland Eastern Shore, Princess Anne, MD, ²Alltech, Inc., Guelph, Ontario, Canada.

Two trials were conducted to determine the available phosphorus (AP) requirement of 21-42 day old male broilers fed a corn & soybean meal diet. Also, the optimal dose & the phosphorus-sparing effect (PSE) of added phytase (Allzyme[®], Alltech, Inc.) was evaluated. A RCB design was used in both trials. Weight gain (WG), feed efficiency (G/F), tibia breaking strength (TBS) & % tibia ash (TA) were used as dependent variables. Trial 1 was conducted to determine the AP requirement of 21-42 day old male broilers. Treatments included 5 levels of AP (0.15, 0.20, 0.25, 0.30, & 0.35%). WG results were 829.1^b, 910.7^{ab}, 886.4^{ab}, 949.1^{ab} & 1026.7^a, respectively. There was no effect (P>0.05) of treatments on G/F. TBS & TA values were 24.2^d, 33.3^c, 35.7^{bc}, 38.9^{ab}, 40.5^a kg, & 45.5^c, 47.9^b, 51.4^a, 53.5^a, 53.5^a% for diets containing 0.15, 0.20, 0.25, 0.30 & 0.35% AP, respectively. Using TA the AP requirement was determined to be 0.29%. Trial 2 was designed to confirm the AP requirement from trial 1 & determine the optimum phytase level & PSE of added phytase. Treatments included 4 levels of AP (0.15, 0.20, 0.25, & 0.30%) & 4 levels of phytase (2875, 5750, 8625, & 11500 PTU/kg). All phytase diets contained 0.15% AP. WG & G/F values were 925.8^b, 947.7^b, 1011.8^{ab}, 1198.1^a g, & 0.283^b, 0.338^{ab}, 0.322^{ab}, 0.421^a in birds fed 0.15, 0.20, 0.25, & 0.30% AP, respectively. There were no differences (P>0.05) in WG & G/F between any of the phytase treatments. Both TBS & TA increased as the level of AP or phytase increased in the diet. TBS results were 13.2^e, 18.2^{bc}, 20.2^b, 23.5^a, 14.7^{de}, 17.0^{cd}, 18.3^{bc}, & 18.0^{bc} kg (AP & phytase levels, respectively). Using TA the AP requirement was determined to be 0.22%. The phytase level that maximized TA was determined to be 6769 PTU/kg. Also, the PSE of added phytase was estimated to be 0.04%. These results suggest that the AP level recommended by NRC may be high for 21-42 day old broilers.

Key Words: Phytase, Available phosphorus, Allzyme[®]

547 Reduction in dietary phosphorus concentration does not change brush border phytase activity along the small intestinal axis in broiler chicks. E. M. Onyango^{*1}, E. K. Asem², and O. Adeola¹, ¹Department of Animal Sciences, ²Department of Basic Medical Sciences, Purdue University.

A study was conducted to determine if intestinal brush border phytase activity in chicks could be altered by decreasing the phosphorus (P) content in the diet. A deficiency in P could lead to upregulation of enzyme systems involved in the digestion of its compounds. Two groups, each of six 7-day-old male broiler chicks, were fed either a P-adequate diet or a low-P diet for 2 wk. The corn-soybean meal based diet contained 10.1 g Ca and 7.4 g total P or 10.6 g Ca and 3.4 g total P per kg for P-adequate or low-P diet, respectively. The low-P diet had no inorganic P added. The broiler chicks were killed on day 21, the small intestine was removed, cleaned and divided into the duodenum, jejunum and ileum. Mucosa was scrapped and used to prepare intestinal brush border vesicles by the magnesium chloride precipitation method. Phytase activity (nanomoles Pi/mg protein/min) in the vesicles was measured at pH 6.0 using sodium phytate as substrate. Released Pi was reacted with ammonium molybdate to form a blue complex and quantified spectrophotometrically at 620 nm. Phytase activity (Mean SEM) in chicks fed P-adequate diet was 36.695 8.163, 21.087 4.486 and 4.706 0.125 in the duodenum, jejunum and ileum, respectively. Activity in chicks fed low-P diet was 29.732 2.610, 18.821 3.672 and 8.781 0.613 in the duodenum, jejunum and ileum, respectively. There was no significant difference in phytase activity in the duodenum, jejunum and ileum of chicks fed P-adequate diet and those fed low-P diet. Phytase activity was highest in the duodenum followed by the jejunum and lowest in the ileum in chicks fed either diet. It is concluded that, at the level of P used, P content in the chick diet does not seem to affect brush border phytase activity. Regardless of dietary P concentration, there was a proximal to distal decrease in phytase activity along the small intestinal axis.

Key Words: Broiler chick, Phytase, Phosphorus, Brush border membrane vesicle

548 Power of two methods for the estimation of bone ash of broilers. L. E. Hall*, R. B. Shirley, R. I. Bakalli, S. E. Aggrey, G. M. Pesti, and H. M. Edwards, Jr., *University of Georgia*.

An experiment was conducted to compare two common methods of estimating bone ash from growing broiler chicks (A = autoclaving; B = boiling/extracting). Ross x Ross day-old-broiler chicks were fed a corn-soy, phosphorus deficient diet (22.7% CP; 1% Ca; 0.2219% AP), with either 0, 750, 1500, 3000, or 6000 units of phytase. Method A was compared to method B at 7, 14 and 21 days of age by sacrificing chicks from each treatment and removing one leg from each bird for analysis by each method. Using method A, bones were autoclaved, cleaned of flesh and cartilage ends, oven dried (105°C for 24 hr), weighed and ashed at 600°C overnight, allowed to cool, and weighed. Using method B, bones were boiled, cooled, cleaned of flesh (not cartilage), extracted for 24 h with ethanol and 24 h with anhydrous ether, dried, and weighed and ashed as above. At d-7, bone ash ranged from 33.5±0.59 to 46.1±0.14% for method A, and 25.8±0.58 to 38.2±0.24% for method B. At d-14, bone ash ranged from 39.6±0.06 to 49.0±0.9% for method A, and 33.3±0.7 to 42.60.3% for method B. At d-21, bone ash ranged from 39.6±0.6 to 49.0±0.9% for method A, and 33.3±0.7 to 42.6±0.3% for method B. To detect a 2% difference in bone ash for any two treatments at a 5 and 90% power, it would require a sample size (n) of 52 and 51 for methods A and B, respectively at d-7; an n of 63 and 44 for methods A and B, respectively at d-14; and an n of 114 and 40 for methods A and B, respectively at d-21. The variability in method A increased with age, while the reverse was observed using method B. In conclusion, both methods can be used to determine bone ash, however, more numbers are required for the autoclaving method compared to the boiling/extracting method, at the same power of estimation.

Key Words: Broiler chicks, Phytase, Bone ash

549 Effect of dietary iron overload on plasma total antioxidant capacity and hepatic lipid peroxides in chickens. Jennifer Cosgrove*, Deniz Maurice, and Stephen Lightsey, *Clemson University, Clemson, SC 29634*.

We previously reported that dietary iron overload increased ascorbic acid (AA) synthesis and hepatic lipid peroxides and decreased storage of AA. These experiments involved sacrificing the animal; thus, it was desirable to find a method to estimate hepatic iron concentration (HIC) and oxidative/antioxidant status without killing the animal. Therefore, this experiment examined a possible correlation between HIC and plasma total antioxidant capacity (PTAC). Plasma antioxidant capacity can be easily measured from fresh plasma. Forty-eight 1-day-old Ross x Arbor Acre were separated into 4 groups of 16 birds and placed on one of 4 diets. The diets were a corn-soy starter diet containing a basal concentration of 250 mg/kg Fe, supplemental iron was provided as ground FeSO₄·7H₂O. Diet analysis showed the control diet contained an average of 250 mg/kg Fe, and diets 2, 3 and 4 contained 1233, 5123, and 10633 mg/kg respectively. The birds were maintained on these diets for 4 weeks before blood, kidney, and liver were collected. Response variables measured included: PTAC, plasma and liver AA, AA synthesis, hepatic and renal Fe, Cu, & Zn, and hepatic lipid and protein oxidation. The mortality rate was 50% in the birds fed diets 3 and 4. Those that survived exhibited a 500% depression in body weight and 500% increase in HIC compared to treatment 1 & 2. As expected, there was a significant decrease in stored AA (p<0.001) and increase in hepatic lipid peroxide values (p<0.01) in the highly overloaded animals. Results of the measurement of PTAC showed a similar trend in that levels from treatments 3 & 4 were significantly higher than levels from treatments 1 & 2 (p<0.001). These results show that measuring PTAC by this method can be useful when there is severe iron overload. From the pattern of iron overload seen in these birds, we cannot say with certainty that PTAC is effective or ineffective in detecting smaller differences in HIC.

Key Words: Hepatic Iron, Plasma Antioxidant Capacity, Ascorbic Acid Metabolism

550 Cloning and sequence analysis of manganese-containing superoxide dismutase(MnSOD) cDNA in chickens. X. G. Luo*¹, Y. Q. Bu¹, S. F. Li¹, C. Lu², Y. W. Li², T. D. Crenshaw³, X. Kuang¹, B. Liu¹, J. F. Li¹, and S. X. Yu¹, ¹*Institute of Animal Science, Chinese Academy of Agricultural Sciences, Beijing, P. R. China*, ²*Southwest Agricultural University, Chongqing, P. R. China*, ³*University of Wisconsin, Madison, U. S. A.*

The objective of this study was to identify the entire nucleotide sequence of MnSOD cDNA in chickens. Manganese is of particular importance for chickens. Previous studies by our laboratory demonstrate that MnSOD activity was significantly higher in heart than liver and other tissues for both broilers and laying hens. Only heart MnSOD was affected by dietary Mn levels in practical corn-soybean meal basal diets. The entire sequence of MnSOD cDNA in these chickens has not been cloned and defined. The sequence would aid future investigations of heart MnSOD gene expression as affected by dietary Mn. Therefore, in this study, a 990bp cDNA fragment encoding MnSOD from broiler chicken heart was amplified by 3'RACE (Rapid Amplification of cDNA Ends) with degenerate primers designed on the N-terminal amino acid sequence of chicken MnSOD. The amplified fragment was cloned and sequenced. The 5'terminal region of the MnSOD transcript was also determined by using 5'RACE procedure. The 5'RACE fragment is 521bp in length, including 352bp of the overlapped region with the 3'RACE fragment. The MnSOD cDNA in chicken heart is 1108bp in length, including 25bp of the 5'untranslated region, 675bp of the coding region, and 408bp of the 3'untranslated region. The coding region encodes a peptide of 224 amino acid residues, in which there is a signal peptide of 26 amino acids and a mature peptide of 198 amino acids. The molecular weight of the mature MnSOD protein is 22KD. Comparisons of the deduced amino acid sequence with those of human, rat, *C. elegans*, and *D. melanogaster* show the amino acid homology of 82.4%, 84.7%, 62.4%, and 59.3%, respectively. Supported by the National Foundation (Premier Foundation) of Outstanding Young Scientists of China in NSFC (Project No: 39925028).

Key Words: Cloning and sequence analysis, MnSOD cDNA, Chickens

551 Comparative bioefficacy of Natuphos phytase versus peniophora lysii phytase. M.B. Coelho, B.W. Cousins*, J Braun, and W.F. McKnight, *BASF Corporation, New Jersey*.

Two hundred fifty two day old broilers were utilized in a 3X3 factorial design (10 replications/treatment) to determine the bioefficacy of Natuphos[®] phytase compared with peniophora lysii phytase using a monocalcium phosphate standard. A phosphorus deficient corn/soybean diet was used as the control. This phosphorus deficient diet was supplemented with monocalcium phosphate (0.2, 0.4 and 0.6 g P/kg) or phytase (100, 200 and 300 U/kg). Bioefficacy was compared based on weight gain regression analysis. Regression equations of phytase effect on weight gain were $y=0.3247x + 761$, $R^2=0.8122$ and $y=0.147x + 761$, $R^2=0.0658$ for Natuphos and peniophora lysii phytase, respectively. Weight gain increased by 0.325 and 0.147 g per phytase unit for Natuphos and peniophora lysii phytase. Natuphos required fewer (p<.05) phytase units than peniophora lysii to reach 902 g bw (434 and 959 U, respectively). The bioefficacy of Natuphos and peniophora lysii phytase based on weight gain regression analysis were 100% and 45%, respectively.

Key Words: Phytase, Bioefficacy, Broilers

552 Phosphorus sparing effect of phytase, 25-hydroxycholecalciferol, and citric acid when fed to broiler chicks. R. Angel*¹, A. S. Dhandu¹, T. J. Applegate², and M. Christman¹, ¹*University of Maryland*, ²*Purdue University*.

An experiment was done to determine the non-phytate phosphorus (nPP) sparing effect of three feed additives (phytase (PHY), 25-hydroxycholecalciferol (25OHD3) and citric acid (CA)). Day-old, male Ross 308 chicks were placed in floor pens and fed a starter diet that met all NRC (1994) recommendations until 14 d of age. On d 14, 120 battery pens (eight birds per pen, eight pens per treatment) were assigned to fifteen treatments. The experiment was designed as a complete factorial arrangement of three PHY (0, 200 and 500 FTU/kg), two 25OHD3 (0 and 70 µg/kg) and two CA (0 and 3%) levels added to a low nPP (0.16%) and 0.80% calcium diet. Three additional diets that contained graded levels of nPP (0.24, 0.32 and 0.40%) were used to determine

a regression curve against which improvements in P utilization, based on tibia ash, were measured. Performance measures were determined from 14 to 24 d of age. All birds were sampled at 24 d and the right tibia removed for dry-defatted ash determination. Body weight gain was not affected ($P>0.05$) by any of the feed additives but feed consumption was lower ($P<0.05$) when CA was added. Feed-to-gain was positively affected ($P<0.05$) by the addition of PHY and CA. There was a main effect ($P<0.05$) of PHY, 25OHD3 and CA on tibia ash. No interactions were seen on any of the variables measured. When tibia ash was regressed on diet nPP a linear regression was obtained ($35.01 + 41.19 \cdot \text{nPP}$, $r^2=0.83$, $P<0.05$). Using this equation for tibia ash, the nPP sparing effect for the different feed additives was calculated. All three feed additives had a positive impact ($P<0.05$) on sparing effect but no interactions were seen. The sparing effects of the feed additives alone were 0.014, 0.048, 0.035 and 0.030% nPP when 200, 500 FTU PHY/kg, 3% CA, 70 μg 25OHD3/kg, respectively were added to the diet. The sparing effect when the highest levels of all three feed additives were used together was 0.116% nPP.

Key Words: Broilers, Citric acid, Phytase, 25-hydroxycholecalciferol, Non-phytate phosphorus

553 Non-phytate phosphorus sparing effect of phytase and citric acid when fed to poults. R. Angel^{*1}, T. J. Applegate², M. Christman¹, and A. S. Dhandu¹, ¹University of Maryland, College Park, ²Purdue University.

An experiment was done to determine the non-phytate phosphorus (nPP) sparing effect due to phytase (PHY) and citric acid (CA). Day-old, male Nicholas poults were placed in floor pens and fed a starter diet that met all NRC (1994) recommendations until 8 d of age. On d 8, 120 battery pens (nine birds per pen, eight pens per treatment) were assigned to fifteen treatments. The experiment was designed as a complete factorial arrangement of three PHY (0, 300 and 600 FTU/kg) and four CA (0, 1, 2 and 3%) levels added to a low nPP (0.44%) diet containing 1.20% calcium. Three additional diets were added that contained graded levels of nPP (0.53, 0.59, and 0.74%) and were used to determine a regression curve against which improvements in phosphorus utilization, based on tibia and/or toe ash, were measured. Performance measures were determined from 8 to 15 d of age. All birds were sampled at 16 d and the middle toe from both feet and the right tibia removed for dry-defatted ash determination. PHY and CA affected ($P<0.05$) gain, feed consumption, feed-to-gain ratio, toe and tibia ash but no interactions were seen. When tibia and toe ash were regressed on diet nPP, linear regressions were obtained ($29.11 + 44.28 \cdot \text{nPP}$, $r^2=0.90$, $P<0.05$; $0.45 + 34.38 \cdot \text{nPP}$, $r^2=0.88$, $P<0.05$; respectively). Using these equations the sparing effect of nPP for the two feed additives was calculated. A main effect ($P<0.05$) of PHY and CA on nPP sparing effect was observed but no interactions were seen. The sparing effect, based on tibia ash, was 0.0280 and 0.0898% nPP for 300 and 600 FTU PHY/kg, respectively. CA had an effect ($P<0.05$) only when added to the diet at a 3% (0.031% nPP) level. A similar sparing effect was found for 3% CA and for 600 PHY when toe ash was used (0.031 and 0.0875% nPP, respectively). When 600 FTU PHY/kg and 3% CA were used together the sparing effect was 0.130 and 0.125% nPP for tibia and toe ash, respectively.

Key Words: Broilers, Citric acid, Phytase, Non-phytate phosphorus

554 The effects of supplemental phytase on egg shell quality in broiler breeder hens. M. Lilburn* and J. Nixon, *The Ohio State University/OARDC.*

Environmental concerns coupled with legislative efforts aimed at minimizing nutrient excesses in animal manures have resulted in an array of dietary strategies to help achieve these goals. The enzyme phytase and its incorporation into commercial type diets has become one of these aforementioned tools. Phytase liberates phytate-bound phosphorus from plant source feedstuffs, ultimately resulting in greater dietary utilization of plant phosphorus and lower levels in the excreta. While there has been considerable literature on the phosphorus requirement of various classes of poultry and the role that phytase plays in meeting these requirements, there is still considerable confusion with respect to optimizing phosphorus nutrition and minimizing excretion. There has been considerable phytase research with commercial egg-type hens, but to date there is a paucity of research with broiler breeder hens. The objectives of the research reported herein was to study, in broiler breeder hens, the effects of different levels of available phosphorus (.12%, .22%, .32%)

in diets with and without supplemental phytase (0,300 units). Mature broiler breeder hens were fed these diets (154 g/hen/d) beginning at 36 wk of age and the experimental periods were 36 to 40, 40 to 44, and 44 to 48 wk. Egg production was recorded daily. During the last wk of each production period, all eggs were individually weighed and broken out for shell wt determination. There was an increase in egg wt with age and an increase in shell wt with age and level of available P. The best results were observed with 0.22% AvP. At the end of the study, all eggs were divided into 5 classes with mean egg wts of 54.5 g, 58.9 g, 63.7 g, 67.8 g, and 72.6 g. Within each egg wt class, the 0.22% AvP treatment resulted in the highest shell wt and this would have allowed for 334 mg AvP per day. The effects of supplemental phytase were inconsistent.

Key Words: Phytase, Phosphorus, Broiler breeder

555 Effect of dietary calcium and phosphorus levels on response of broiler chicks to phytase supplementation. F. Yan, J. H. Kersey, C. A. Fritts, and P. W. Waldroup*, *University of Arkansas.*

It has been frequently demonstrated that addition of phytase to corn-soybean meal diets will improve the utilization of the phytate-bound P for broiler chickens. The effect of the phytase on release of other nutrients is less clear-cut. One phytase producer suggests that Ca is also released by phytase and that consequently the dietary Ca level might be reduced. A study was conducted to examine the effects of phytase supplementation on diets with varying levels of Ca with different levels of nonphytate P. A diet was formulated that provided nutrients in excess of NRC (1994) with 1.0% Ca and 0.5% nonphytate P. By varying the amounts of dicalcium phosphate and limestone in aliquots of a common basal diet, diets were prepared with 1) Low-P and Low-Ca; 2) Low-P and High-Ca; 3) High-P and Low-Ca; 4) High-P and High-Ca. The diets were analyzed to determine Ca and P content and blended as needed to provide test diets in a factorial arrangement of three Ca levels (0.5%, 0.7%, 0.9%) with eight levels of nonphytate P (0.15% to 0.5% in increments of 0.05%). These 24 diets were then divided and half supplemented with 1000 units/kg of phytase (Natuphos#, BASF). Each treatment was fed to six pens of six male broilers from one to 21 d of age. When diets received no phytase, both BW and tibia ash (TA) were depressed at the lowest level of P as Ca increased. Adding phytase to these diets improved both BW and TA, as a result of increased availability of P. At both 0.5% and 0.7% Ca, the dietary Ca level was a limiting factor in maximizing both BW and TA regardless of level of nonphytate P or phytase supplementation. Diets containing 0.9% Ca supported greater BW and TA than diets with lower Ca levels regardless of P level or phytase supplementation. These data indicate that minimal Ca appears to be released by phytase and that no reduction in Ca should be implemented when diets are supplemented with phytase.

Key Words: Phytase, Calcium release, Phosphorus

556 Evaluation of dietary chlorine for turkey poults. K.D. Roberson^{*1}, ¹Michigan State University.

Dietary salt level has been linked to roundheart disease in turkey poults with dispute. Past research has focused on either added salt or specifically on sodium due to hypertensive effects associated with high dietary sodium. Problems with roundheart mortality have been common after 6 days of age in the turkey growout facility at Michigan State University when crumbles are fed. No roundheart mortality was observed in one trial when part of the sodium requirement was provided by sodium bicarbonate in place of sodium chloride in mash feed. A 14-day trial was conducted in a battery brooder to determine the effects of varying dietary chlorine levels on growth performance and roundheart mortality when dietary sodium was held constant at 0.17%. A corn-soybean meal-fish meal based diet was fed in a mash form to 6 pens of 8 toms per treatment. The calculated dietary chlorine levels were 0.17, 0.21, 0.25 or 0.29%. There was a quadratic ($p=0.010$) response of 14-d body weight to dietary chlorine as poults were lighter when 0.17% chlorine was fed (347 g) compared to poults fed 0.21 or 0.25% chlorine (370 or 374 g, respectively). There was no effect on feed efficiency. Mortality was low in the trial and not due to roundheart. Heart weight, as a percentage of body weight, ranged from 2.92 to 3.25% as dietary chlorine increased and resulted in a linear response at $p=0.080$. The results of this study suggest that altering the dietary electrolyte balance by feeding chlorine as high as 0.29% does not induce roundheart mortality in turkey poults.

The NRC requirement for chlorine (0.15%) appears to be too low for 0 to 4-week-old poult.

Key Words: Chlorine, Poult, Roundheart

557 Influence of supplemental citric acid and sodium and potassium citrate on phytate-phosphorus utilization in broiler chicks fed phosphorus-deficient diets from one to 42 days of age. Ahmed Metwally*, *Animal Prod. Dept., Fac. of Agric., Assiut University, Assiut-Egypt.*

Experiments were conducted to determine if the addition of citric acid to a phosphorus (P) deficient corn-soybean meal (SBM) diet would enhance phytate P utilization in broilers. Citric acid (C), Citric acid and

Sodium citrate(1:1 mixture,CS) and Citric acid and Sodium citrate and Potassium citrate (1:1:1 mixture, CSP) were added at levels of 0, 4.5 and 6% to a P-deficient diet containing 0.91 Ca and 0.22% available phosphorus. Each of three dietary treatments was fed to replicate groups of eight chicks from one to 42 days of age. Increasing levels of dietary citrate to 4.5% increases performance traits. Carcass quality and tibia weight and ash improved for chicks fed 4.5% mixture of CSP. The bone ash response to the mixture of CSP was much greater than the bone ash response to the mixture of CS. The results of this study indicate that the mixture of CSP at level of 4.5% enhances phytate P utilization in broiler diets from one to 42 days of age.

Key Words: Citrate, Performance, Phytate-phosphorus utilization, chicks

PSA Pathology Session I

558 Influence of IBDV on the immune system and incidence of proventriculitis in SPF leghorns. T.V. Dormitorio*¹, J.J. Giambrone¹, and K. Cookson², ¹*Auburn University, Auburn, Alabama*, ²*Ft. Dodge Animal Health, Lawrenceville, Georgia.*

Infectious bursal disease virus (IBDV) isolates have been linked to cases of proventriculitis in commercial broilers. These isolates appear to be variant in nature as they do not cause much edema, but mostly atrophy of the bursae. Some are very pathogenic and associated with immune suppressed flocks.

Fourteen-day old Specific Pathogen Free (SPF) white leghorns received four different IBDV vaccines. At 28 days, chicks were challenged with 707B IBDV isolate by eye and nose routes. At 34 days of age, pullets were tested for cell-mediated immune (CMI) response using a skin test. At 36 days of age all birds were killed and weighed, and the bursa were weighed and examined post mortem for gross lesions. Bursa weight to body weight ratios were also determined and the means of all groups analyzed for differences using SAS system.

SPF white leghorns were susceptible to the 707B IBDV field isolate at 26 days of age. Nearly 100% of these birds had severe gross lesions in bursa (atrophy) and proventriculus (glandular enlargement and edema), and numerically reduced final body weight. All commercial live intermediate IBDV vaccines produced excellent protection against proventricular lesions induced by this isolate. This IBDV isolate also cause a reduced CMI response. These data provide more evidence that this IBDV isolate had a major role in causing immunosuppression and proventriculitis in chickens.

Key Words: IBDV, Proventriculitis, CMI

559 In ovo administration of experimental reovirus vaccines^b. Z.Y. Guo* and J.J. Giambrone, *Auburn University, Auburn AL*.

Avian reoviruses are an important cause of poultry diseases worldwide and can induce various diseases in chickens. *In ovo* administration of viral vaccines is a new technique used in preventing diseases. It is commonly used for the administration of Marek's Disease and infectious bursal disease viruses (IBDV) vaccines in commercial broilers. According to our preliminary experiments, the current reovirus vaccine, Enterovax, complexed (combined) with specific antibody against reovirus was too pathogenic for *in ovo* use. Therefore, a milder reovirus vaccine, Chick Syno-vac, was employed. This vaccine, complexed with antibody, was able to induce immunity against reovirus challenge and was less pathogenic than Enterovax. We are currently examining an even milder vaccine (VA Chick Vac) combined with antibody to determine its pathogenicity and immunogenicity, when given by *in ovo* route.

Key Words: Reovirus, *In ovo*, Vaccination

560 Changes in serum levels of ovotransferrin during experimental inflammation and diseases in chickens. H. Xie*^{1,2}, N. Rath¹, F. Clark², L. Newberry², W. Huff¹, G. Huff¹, and J. Balog¹, ¹*PPPSRU, ARS, USDA*, ²*Department of Poultry Science, University of Arkansas.*

We have identified serum ovotransferrin as an avian acute phase protein. To measure the changes in serum levels of ovotransferrin during inflammation and poultry diseases, we developed a solid phase competitive

enzyme immunoassay using rabbit anti-chicken serum transferrin antibody and biotinylated ovotransferrin. Serum ovotransferrin competes with biotinylated ovotransferrin to bind to anti-chicken transferrin antibody. The residual biotinylated ovotransferrin bound to anti-chicken transferrin is then detected using streptavidin-horse radish peroxidase followed by a colorimetric detection step. Serum levels of ovotransferrin are then determined according to a standard curve generated using known concentrations of ovotransferrin. Inflammation was experimentally induced in 4-wk-old male broiler chickens by subcutaneous injection of croton oil, and specific pathogen free (SPF) chickens were challenged with various bacteria or viruses to induce specific disease. In the experimental inflammation model with croton oil, the serum levels of ovotransferrin increased by 16 h post-injection, reached a peak by 72 h, remained high through 5 days, and returned to the basal level of olive oil-injected sham-controls by 10 days. Similarly, compared to the control birds, SPF chickens challenged with *E.coli*, pox virus, reovirus, infectious bursal disease virus, or laryngotracheitis virus had significantly higher levels of ovotransferrin in serum ($P<0.05$). Our results demonstrate that ovotransferrin can be utilized as a clinical marker for inflammation associated with certain infectious avian diseases.

Key Words: Ovotransferrin, Inflammation, Enzyme immunoassay

561 Differential intestinal response to *Eimeria acervulina* challenge in broiler chickens. B.C. Morris*¹, H.D. Danforth², D.J. Caldwell³, and A.P. McElroy¹, ¹*Virginia Tech, Blacksburg, VA*, ²*USDA/ARS/LPSI/PBEL, Beltsville, MD*, ³*Texas A&M University, College Station, TX.*

Immunovariability between coccidial species in vaccines and those found in poultry rearing facilities has emerged as a potential complication associated with vaccination. The host pathogen interaction and immune response in the intestine must be further investigated to understand immunity and pathophysiology to *Eimeria* in chickens. Experiments were conducted comparing two isolates of *Eimeria acervulina* (EA), EA1 and EA2. In three experiments, commercial broilers chicks were divided into control (non-challenged) and EA1 or EA2 challenged (14 days of age) groups. In all 3 experiments, EA1 resulted in significantly ($P<0.05$) higher lesion scores than EA2, however, weight gain of EA1 challenged birds was not significantly different from controls. EA2 challenged birds had significantly higher lesion scores than control birds in Expts 1 and 3, with no lesions characteristic of classical EA infection in Expt 2. EA2 resulted in significantly decreased weight gain as compared to EA1 or control in Expt 3. While EA1 resulted in classical EA lesions with no significant difference in weight gain, EA2 resulted in few classical lesions with significant depression of weight gain. Subjective observation of intestines from EA2 challenged birds was suggestive of a severe secretory intestinal response and weakened intestinal strength. In Expt 4, EA2 oocysts were cleaned with 5.25% sodium hypochlorite to evaluate the possibility of an external bacterial factor contributing to the observed detrimental affects in the presence of few lesions. Birds were challenged with bleached or non-bleached EA2. Although there was no significant difference in lesion scores between EA2 challenged groups, non-bleached EA2 resulted in significantly decreased weight gain

as compared to bleached. These data are indicative of immunovariability between different isolates of the same coccidial species and are suggestive of differences in the host response that may contribute to the pathogenicity.

Key Words: *Eimeria*, Immunovariability, Broilers

562 Digestive and Reproductive Organ Characteristics in Commercial Laying Hens as affected by F-Strain *Mycoplasma gallisepticum*. M. R. Burnham^{*2}, S. L. Branton¹, E. D. Peebles², M. S. Jones², B. D. Lott¹, J. B. Yeatman², S. K. Whitmarsh², and P. D. Gerard³, ¹USDA, ARS, South Central Poultry Research Laboratory, ²Department of Poultry Science, Mississippi State University, Mississippi State, MS 39762, ³Agricultural Information Science, Mississippi State University, Mississippi State, MS 39762.

The effects of F-strain *Mycoplasma gallisepticum* (FMG) on digestive and reproductive organ characteristics in commercial laying hens were investigated. Ten hens were assigned to each of sixteen negative pressure fiberglass biological isolation units. Birds in eight units served as uninoculated controls and those in eight other units were inoculated (treated) with FMG at 12 wk of age. At 20, 36, 44, 46, and 48 wk of age, two birds from each of two units and at 60 wk of age, four birds from each of six units designated as either control or treated were euthanized by cervical dislocation and their organs removed. Variables examined included liver, duodenum, jejunum, ileum, infundibulum, magnum, isthmus, uterus, vagina, and ovarian weights, percentage liver moisture and lipid contents, and ovarian follicular hierarchical numbers. Organ weights were expressed as percentages of bird weight. Main effects due to bird age were observed for all parameters. Hierarchical follicle number decreased in FMG-treated hens relative to controls. Relative vagina weight was decreased at 20, 36, 44, and 48 wk by FMG; whereas, the effects of FMG on percentage liver moisture and lipid contents were inconsistent throughout the 20 to 60 wk period. These data suggest that changes in egg production in response to FMG infection in commercial layers, as noted in previous reports, may be associated with changes in liver and reproductive organ characteristics in commercial layer hens.

Key Words: *Mycoplasma gallisepticum*, necropsy, liver, intestine, ovary, oviduct, layer hen

563 Virulence Response of a *Salmonella* Typhimurium *hilA:lacZY* Fusion Strain to Spent Media From a *Salmonella* Typhimurium Poultry Isolate and Non-*Salmonella* Bacteria. J. D. Nutt^{*1}, L. F. Kubena², D. J. Nisbet², and S. C. Ricke¹, ¹Texas A&M University, College Station, TX USA, ²USDA-ARS Food and Feed Safety Research Unit, College Station, TX USA.

Salmonella invasion into host epithelial cells requires genes located on *Salmonella* pathogenicity island 1 (SPI). *HilA*, a transcriptional activator encoded on SPI1, is necessary for maximum expression of SPI1 genes and invasion into epithelial cells. Certain environmental factors stimulate the expression of SPI1 genes, specifically *hilA*, which can be used as an indicator of overall level virulence expression. Influential factors may include changes in the gastrointestinal environment of birds during different dietary regimes. The objective of this study was to determine if growth of specific microorganisms alters the environmental conditions sufficiently to signal *S. Typhimurium* virulence response. Spent media was obtained from a *hilA:lacZY S. Typhimurium* strain, a poultry *S. Typhimurium* strain and *Escherichia coli* K12 after 2 and 23 hrs incubation in brain heart infusion broth (BHI). Cells were removed by centrifugation and the supernatant was filter sterilized. Spent media samples (1.5ml) were each inoculated with 0.120ml of a *hilA:lacZY* fusion strain of *S. Typhimurium* inoculum and incubated for two hours. After incubation, β -galactosidase assays were performed on the samples to determine virulence expression. Although no significant differences were seen among the virulence responses of the three separate bacteria strains, in general responses were 5 to 10-fold higher ($p < 0.05$) than uninoculated BHI controls (40 to 50 Miller units) and more than doubled when exposed to 23 h spent media versus 2 h spent media for *S. Typhimurium* (481 to 507 versus 217 to 221 average Miller units). Based on these results, it appears that growth of similar bacterial species may alter the composition of rich media sufficiently to influence virulence.

Key Words: *Salmonella*, spent media, virulence

564 Viral disinfectant efficacy assay for duck hepatitis B virus using PCR. Chi-Young Wang^{*1} and Joseph Giambrone¹, ¹Auburn University.

The risk of transmission of human hepatitis B virus (HBV) by plasma concentrates has been reduced by use of virus inactivation procedures. However, serious concern persists over nosocomial infections that could be acquired through the use of inadequately disinfected equipment or accidental exposure to blood or other infectious body fluids from HBV-positive individuals. Duck hepatitis B virus (DHBV) is closely related to HBV and shares its general biological and structural properties. With the duck embryonic hepatocyte culture system and PCR, the evaluation of efficacy of disinfectants for DHBV was made more plausible and accurate. Nested PCR was also developed and could increase the limits of detection one hundred fold. In our study, when the concentrations of disinfectants (Quat-stat) were below 600ppm, they caused only a one log₁₀ reduction in titer (titer = 5×10^4 to 3.5×10^5 TCID₅₀/ml). If we increased the concentrations above 2400 ppm, it caused a reduction in titer ≥ 4 log₁₀. No cytotoxicity due to the disinfectants was observed on uninfected indicator cells. The U.S. EPA requires that a specific virucidal claim for a disinfectant intended for use on hard surfaces be supported by efficacy test. According to this, the optimal concentration of a compound is virucidal reduces the viral titer by 3 logarithm units. Therefore, the optimal concentration of "Quat-Stat" for DHBV was 2400ppm.

Key Words: Duck hepatitis B virus, nested polymerase chain reaction (nested PCR), viral disinfectant efficacy assay

565 Water-soluble tylosin tartrate (Tylan Soluble Powder) for treatment of necrotic enteritis in broiler chickens. J.J. Brennan^{*1}, R.B. Bagg², G. Vessie², J. Wilson³, D.A. Barnum³, G. Moore⁴, A. Zimmermann⁴, P. Dick², and S. Poe⁴, ¹Shur-Gain Agresearch, RR#3, Burford, ON N0E 1A0, ²Elanco Animal Health, Eli Lilly Canada Inc., Research Park Centre, 150 Research Lane, Guelph, ON N1G, ³Ontario Veterinary College, University of Guelph, Guelph, ON N1G 2W1, ⁴Elanco Animal Health, 2001 West Main Street, POB 708, Greenfield, Indiana 46140.

The effects of tylosin tartrate (Tylan[®] Soluble Powder) on mortality, intestinal lesion scores and growth performance of *Clostridium perfringens*-challenged broiler chickens were evaluated in a floor pen study. A randomized complete block design was used to study the effects of administration of 0, 50, 100 or 150 ppm tylosin tartrate in drinking water following confirmation of a necrotic enteritis (NE) outbreak. Each floor pen contained 25 male and 25 female birds on day of placement (Day 0). The pen was considered the experimental unit. There were ten replicate location blocks in the study. Challenge was administered via feed on days 14 and 15. An NE outbreak was confirmed based on NE mortality on Day 16. Medicated drinking water was introduced on Day 16 and provided for five consecutive days. On Day 17, three birds per pen were randomly selected, sacrificed and scored for necrotic enteritis lesions on a scale of 0 (normal) to 4 (extensive necrosis). Necrotic enteritis (NE) mortality (%) for the four respective treatments was 2.4a, 1.6ab, 1.4ab and 0.4b ($P < 0.05$) during Day 16 to 28. Mean small intestinal lesion scores of sacrificed birds were 1.27a, 0.20b, 0.17b and 0.20b on Day 17 for 0, 50, 100 and 150 ppm treatments, respectively ($P < 0.05$). Final (Day 28) bodyweight was 1.001a, 1.124b, 1.129b and 1.128b ($P < 0.05$) kg for the four respective treatments. The results of this study indicate that tylosin tartrate is effective for treatment of necrotic enteritis when administered in drinking water at a concentration of 50 to 150 ppm.

Key Words: Broiler chicken, Tylosin phosphate, Necrotic enteritis

PSA Processing and Products: Poultry Meat Quality

566 The effect of stunning and decapitation on broiler activity during bleeding, blood loss and carcass quality. W. D. McNeal* and D. L. Fletcher, *University of Georgia, Athens, GA USA*.

Four experimental trials were conducted to determine the effects of stunning (14 volts, 500 Hz) and decapitation on bird activity during bleeding, blood loss, and carcass quality. Birds were subjected to modified Kosher killing (no stun, unilateral neck-cut), conventional killing (stun, unilateral neck-cut), decapitation without stunning, and decapitation following stunning. During bleeding, the birds were subjectively scored for severity of immediate reaction (0 to 10 s), intermediate activity (10 to 60 s), and late activity (greater than 60 s). Reactions and unconscious activity were scored as none (no visible reaction or only minor muscle quivering), mild to moderate (mild wing flapping and moderate spasmodic motion), or severe (violent wing flapping sufficient to cause major carcass movement or result in possible carcass damage). Birds were weighed before and after killing to determine blood loss. Carcasses were scored for completeness of picking, red wing tips, and red tails. Results showed dramatic differences in the severity of initial response and degree of unconscious activity during bleeding. Traditional Kosher killing resulted in little to mild initial response to the neck cut, followed by rather strong unconscious reactions at about 30 seconds post cut. Conventional stunning and killing showed almost no initial reactions and only mild intermediate or late reactions. Decapitation without stunning resulted in very strong immediate wing flapping and violent activity which steadily diminished in severity and which was almost completely ended by 45 to 60 seconds post-kill. Decapitation following stunning was similar to conventional stunning and killing with the exception of almost no late reactions at any level of severity. Compared to conventional slaughter, decapitation resulted complete cessation of movement after 60 s, a 0.2 % less blood loss (as measured by both the loss of blood and head), and no difference in carcass scores for feather retention, or red wings or tails. These results indicate that decapitation may be an effective means of slaughter following adequate stunning.

Key Words: Broiler stunning, Decapitation, Slaughter technology

567 Different attributes of breast meat quality in broiler great-grandparent lines. N. A. Gonet*, D. A. Sandercock, R. R. Hunter, and M. A. Mitchell, *Roslin Institute, Roslin, Midlothian, UK*.

Previous studies in our laboratory have shown that broiler great-grandparent lines (GGP) exhibit differences in muscle membrane integrity and stress sensitivity. It is not known if these differences influence meat quality (MQ). This study examined 3 commercial GGP lines in terms of both appearance and physical properties of their breast meat. The 3 lines (A, B and C) which differed according to their genetic origins and recent selection history were compared. Birds were reared under standard commercial conditions. At six weeks of age, all birds were killed in a commercial processing plant, chilled for 24 h at 4°C after which both breast fillets were cut from the carcass, weighed and frozen. Fillets were thawed at 4°C and estimates of water loss (thaw loss) were obtained. Meat color (lightness, redness and yellowness), extent of hemorrhaging and shear strength were also determined. Statistical analyses included (ANOVA and t-tests). Line B had highest body and fillet weights ($p < 0.01$) though C had highest %breast meat yield ($p < 0.01$). Fillets from lines B and C were the most red in color and exhibited a greater incidence of hemorrhaging ($p < 0.001$ vs. A). There were significant differences in meat lightness across the 3 lines ($p < 0.001$), line C being the lightest ($p < 0.001$) and most yellow in color ($p < 0.001$). Line C exhibited greatest water loss on thawing ($p < 0.001$). Shear force values were higher in lines A and C compared to line B ($p < 0.001$). The results show that differences in MQ attributes can be detected between commercial GGP lines which maybe indicative of genetic differences. Birds with higher %breast meat yields (line C) produced lighter colored, firmer meat with greater water losses. The heaviest line had more tender, redder meat with more extensive hemorrhaging. Understanding cellular mechanisms that lead to these differences in meat characteristics of broiler GGP lines may provide insights into the genetic origins of MQ which can lead to novel methods for genetic selection for improved muscle and meat quality.

Key Words: broiler, meat quality, genetic selection

568 Effect of Dietary Sorghum Cultivars on the Storage Stability of Cooked Broiler Breast and Thigh Meats. D. U. Ahn*¹, M. Du¹, K. C. Nam¹, and G. Cherian², ¹*Iowa State University*, ²*Oregon State University*.

A total of 150 day-old male broiler chicks (50 birds/pen, 3 pen/treatment) were fed corn-soy- flax meal-based diet (Control) with added sorghum at 10%. Two cultivars of sorghum (Ruby Red and Dekalb) were used for the study. Birds were slaughtered at the end of 42-day feeding trial. Twelve birds from each treatment (4 per pen) were randomly selected, and boneless, skinless breast and thigh muscles were collected. Breast or thigh meats were ground twice through a 3-mm plate, and patties were prepared. Patties were individually put in zipper bags, irradiated at 0 or 2.5 kGy, and cooked in a 90C-water bath to an internal temperature of 75C. At day 0 and 5 of storage, the TBARS of cooked patties were analyzed. Vacuum-packaged cooked patties were used to determine time- dependent volatile production during 12-h holding time. Meat from birds fed Dekalb had higher storage stability than those fed the control or Ruby Red diet. Irradiation had significant effect on the TBARS of cooked breast and thigh meats from Dekalb at Day 0. The aldehydes and sulfur compounds of cooked breast meat were lower in Dekalb compared with Control or Ruby Red. The content of total volatiles in thigh meat was not influenced by the dietary treatments. The results indicated that feeding Dekalb sorghum to broiler diet can improve the storage stability of cooked meat.

Key Words: Dietary Sorghum, Cooked Broiler Meat, Storage Stability

569 Antemortem holding temperature effects on broiler processing shrink, yield and breast meat quality. M. Petracci², D. L. Fletcher*¹, and J. K. Northcutt¹, ¹*University of Georgia, Athens, GA USA*, ²*University of Bologna, Bologna, ITALY*.

The influences of antemortem holding temperatures on broiler live shrink, processing yields, and breast meat quality were evaluated. In each of three independent trials, approximately 210 broilers were grown to 45 days using standard production practices. Prior to slaughter, the birds were individually weighed, placed in coops, and held for 12 h without access to feed and water. The coops were randomly divided into one of three groups and held at either 25, 29.5, or 34 C. For processing, the birds were first weighed live just prior to shackling, and the carcasses weighed following picking, evisceration, and chilling to determine live shrink and processing yields. Breast meat was removed at 2 or 24 h post-mortem for pH, R-value, sarcomere length, meat color, cooked yield, and shear value determinations. Birds held at 34 C had the greatest live shrink, 5.7%, compared to 3.9 and 3.2 % for those held at 29.5 or 25 C, respectively. Birds held at 34 C had lower processed carcass yields based on initial catch weight, but when calculated using post-shrink weights, there were no significant differences. For breast meat harvested at 2 h post-mortem, birds held at 25 C had higher R-values, redness, and yellowness values and lower cooked meat yield and shear values. For breast meat harvested at 24 h post-mortem, birds held at 25 C birds had higher pH, R-values, and redness. These results indicate that holding conditions may dramatically effect live bird shrink and yields, but have little effect on subsequent breast meat quality.

Key Words: Live bird holding, Processing yields, Breast meat quality

570 Marination of PSE broiler meat using non-meat binders. L. C. Cavitt* and C. M. Owens, *University of Arkansas, Fayetteville, AR, USA*.

In recent years, the poultry industry has seen a significant increase in the incidence of pale, soft, and exudative (PSE) meat exhibiting characteristics unsuitable for further processing due to excessive variation in meat color, poor meat binding, and decreased water holding capacity. Incorporating different non-meat binders into whole muscle products may be an effective way to improve water holding capacity of PSE meat. In this study, soy protein, whey protein, and modified food starch non-meat binders were vacuum tumbled with PSE and non-PSE meat. A total of 150 fillets (75 pale and 75 normal) were collected from a local processing plant. Meat color (L*value) and muscle pH were measured on each fillet at 24h postmortem. The fillets were then tumbled with a marinade using water only or water plus NaCl (0.6%), sodium tripolyphosphate

(STP) (0.3%) and either a soy protein isolate (SPI), whey protein isolate (WPI), or modified food starch (MFS) at 2%. Fillets were vacuum tumbled with a 20% marinade (based on meat weight) for 45 min in a 4 C cooler, stored at 4 C overnight, and then cooked. Marination retention and cook loss were determined. As expected, the pale fillets had significantly higher L^* values and lower pH values compared to the normal fillets. Marinades containing the SPI, WPI, or MFS improved water holding capacity compared to either the STP-control or water-only control as indicated by significantly lower cook losses. Furthermore, fillets marinated with MFS had significantly lower cook losses compared to all other treatments. Marinating with the MFS further improved water holding capacity of the pale fillets to the level of the normal colored fillets as indicated by no significant difference in cook loss. These results suggest that using modified food starch in commercial marinade solutions can enhance water holding capacity in broiler breast fillets including those that are PSE.

Key Words: PSE broiler meat, Marinade, Water holding capacity

571 Tenderness of chicken breast fillets processed in a commercial air-chill facility. L. J. Bauermeister*, S. J. Lewis, A. Velsquez, M. Tamayo, A. Aguilar, and S. R. McKee, ¹University of Nebraska-Lincoln Lincoln, NE..

The goal of this study was to determine the optimal deboning time for commercially air-chilled (AC) poultry. Deboning breast fillets from carcasses early post-mortem (PM) has been shown to cause meat toughening. However air chilling may alter rigor development thereby altering the PM aging period needed to prevent meat toughness. Birds from a commercial air-chilled facility were deboned at 2, 4, 6, 8, 10, 12, 14, 16 and 24 hrs PM (n=6 x 2 replications) and stored on ice at 4 C. Immersion-chilled (IC) fillets were purchased at a local grocery store (n=20 x 2 replications) and used as a comparative measure. Samples for pH and shear values were taken at each deboning period and cook loss was also determined. Results indicated pH reached 6.00 by 2 hrs PM, and by 4 hrs PM an ultimate pH of 5.85 was reached. This pH was maintained through 24 hrs PM. The average shear value of AC breast fillets decreased from 2 to 4 hrs PM with shear values of 7.40 kg/g and 4.10 kg/g respectively. Aging prior to deboning past 4 hrs PM did not result in any further improvements in meat tenderness for AC breast fillets. Store bought IC breast fillets had shear values of 10.15 kg/g. Commercial processing facilities often debone at 2 to 4 hours PM. Cook loss was determined after fillets were cooked in cook-in bags to an internal temperature of 76 C and cooled to room temperature before weighing. In general, the average cook loss for AC breast fillets decreased the longer the muscle stayed on the carcass and was lower than the cook loss of the IC fillets. The results of this study suggest that AC breast fillets could be deboned as early as 2 hrs PM without compromising meat tenderness.

Key Words: Air-chilling, Poultry meat quality, Aging on carcass

572 Rigor development and meat quality of large and small broilers and the use of Allo Kramer shear, needle puncture, and razor blade shear to measure texture. L. C. Cavitt*, C. M. Owens, J. F. Meullenet, R. K. Gandhapuneni, and G. W. Youm, University of Arkansas, Fayetteville, AR, USA.

In two trials, 150 female and male broilers of different sizes in each sex (large or small) were obtained from a commercial grower and were commercially processed to evaluate rigor development and texture. Breast fillets were excised at 0.25, 1.5, 3, 6, and 24h postmortem (PM). Muscle pH and L^* value was determined for each deboning time. Breast fillets were aged on ice until 24h PM, cooked to 76C, cooled, and then analyzed for texture using either Allo-Kramer (10 blade), needle puncture (2 mm), or razor blade shear (8 mm width) methods. Allo-Kramer tests were performed on intact muscles. Body size or sex had no effect on rigor development or color as indicated by no significant difference in breast muscle pH or L^* value through 6h PM. All three instrumental methods evaluated showed significant shear value differences between samples deboned at 0.25 or 1.5h PM and 3, 6, and 24h PM. A three way analysis of variance using sex, body size, and deboning time as main effects explained a small percentage of variation of the Allo-Kramer shear values ($R^2=0.46$), needle puncture energy ($R^2=0.26$) and razor blade energy ($R^2=0.46$). From these results, it would seem that both Allo-Kramer shear and razor blade tests performed similarly for differentiating breast meat toughness though Kramer shear force and razor blade energy were

weakly correlated ($r=0.65$). While both instrumental tests were performed in the same vicinity on each breast, it is possible that variation within the breast would have caused this marginal correlation. Although further studies would be necessary to compare the performance of both tests for assessing poultry meat toughness, the proposed razor blade test has the advantage of requiring no sample preparation (i.e. cutting of a strip of constant dimensions) other than cooking.

Key Words: Poultry meat, Texture analysis, Rigor development

573 The Effects of Raw Broiler Breast Meat Color Variation on Marination and Cooked Meat Quality. M. Qiao¹, J. K. Northcutt*¹, D. L. Fletcher¹, and D. P. Smith², ¹The University of Georgia, ²USDA-ARS, Russell Research Center.

Experiments were conducted to determine the effect of raw broiler breast meat color variation on marinated and cooked meat quality. In each of three independent trials, fillets were collected from a commercial deboning line based on breast meat lightness as follows: 30 fillets lighter-than-normal (lightness, $L^* > 53$), 30 normal fillets ($48 < L^* < 53$), and 30 darker-than-normal ($L^* < 46$) fillets. Within each color division (light, normal, and dark), 3 replicate groups of 10 fillets were individually weighed and marinated (20% marinate, wt:wt). Following marination, fillets were weighed to determine marinate uptake, held for 24 h at 2 C and re-weighed to determine marinate retention, cooked, and weighed again to determine cooked meat yield. The pH was determined on raw, marinated, and cooked samples. Color, moisture, and shear were measured on cooked meat. Results showed that breast meat identified by color differences affected meat pH, marination, marination retention, cooked yield, and texture but had no effect on cooked meat moisture content. Raw meat color differences were retained even after marination and cooking. There were significant negative correlations between meat lightness and pH; however, raw muscle pH did not correlate with final product moisture and shear. A positive correlation was observed between raw muscle pH and meat yield, but a negative correlation was found between pH and marination pickup. These results indicate that the pH variation associated with raw breast meat of different color can affect marination and cooked meat quality.

Key Words: Broiler, Breast meat color, Marination

574 The relationship of chilling time and temperature on quality of turkey pectoralis. C. Z. Alvarado*¹ and A. R. Sams², ¹Virginia Tech, ²Texas A&M University.

Pale, soft and exudative meat is a growing problem in the turkey industry. The objectives of this study were to determine the relationship between chilling rates and development of PSE-like conditions. At 22.5 wk of age, 96 Nicholas toms were conventionally processed in two trials, chilled for 45 min or 90 min in 0, 10, 20, or 30 C chill water, and deboned at 60 min or 105 min PM. Temperature and pH of fillets were recorded at 15 min PM, deboning, and 24 h PM. At deboning, L^* value, cook loss, gel strength, total protein solubility and bound phosphorylase were determined. At 24 h PM, cook loss, gel strength, and L^* values were determined. At 15 min PM, there were no differences in pH among treatments. At 60 and 105 min PM, the 30 C chilled carcasses had significantly lower pH compared to 0 C. All carcasses chilled at 30 C had the lowest pH at 24 h PM. In fillets deboned at 60 min PM, L^* value and cook loss were significantly higher and gel strength significantly lower in 30 C chilled carcasses compared to 0 C. At 24 h PM, there were no differences in L^* value and cook loss in fillets deboned at 60 min PM; however, gel strength was lower at 20 C as compared to 0 C chilled carcasses. Fillets deboned at 105 min PM had significantly lower L^* values when chilled at 0 C compared to 10, 20, and 30 C. The 20 C chilled carcasses had softer gels compared to 0 C chilled carcasses, and the 10 C chilled carcasses had higher cook loss compared to those chilled at 0 and 20 C but were not different from 30 C. At 24 h PM, cook loss was significantly lower in carcasses chilled at 0 C compared to the remaining treatments, however there were no differences in L^* value and gel strength. There were no differences in total protein solubility among treatments. However, there was a higher amount of bound phosphorylase present at 60 min and 105 min PM in 30 C chilled carcasses compared to the remaining treatments. Therefore, chilling carcasses at higher temperature for longer periods can result in poor meat quality.

Key Words: PSE, Chilling, Turkey

575 Skin Color Evaluation in Broilers Fed Natural and Synthetic Pigments. S. M. P. Castaeda*, E. M. Hirschler, and A. R. Sams, *Texas A&M University, College Station, TX.*

Broiler carcass skin color is important in the USA and Mexico. Because pigments are expensive, this study evaluated the use of natural and synthetic pigments in broiler diets at commercial levels. In two trials, 280 chicks were randomly distributed (20 birds each) into seven treatments according to the pigment class (natural or synthetic) and the inclusion level (ppm of pigments) of yellow (apoester) and red (canthaxanthin) pigments. Two treatments were designed to mimic current commercial practices in the USA and Mexico. The treatments were: control (no pigment); natural-low level, natural-high level, synthetic-low level, synthetic-high level, a common USA level, and a natural-synthetic blend used in Mexico. Diets were started at week 3 and feed consumption, body weight, skin color, and blood pigment level were evaluated weekly from weeks 3 to 7. At 49 d of age the birds were processed and skin color was measured after picking and chilling. The natural pigments had consistently greater skin b^* values (yellowness) than the synthetic pigments. The high levels produced greater skin b^* values than the low levels, regardless of source. The synthetic pigments had a slower increase in skin b^* but reached the same level as the natural-low by 7 wks. There was no difference in skin a^* values (redness) due to pigment source or level or the age of the bird. By 7 wks, all pigment sources approached plateau levels in the blood but the synthetic pigment diet had higher blood levels of both yellow and red pigments than the natural pigment diets. Processing intensified skin yellowness and reduced skin redness. These data suggest that natural pigments were more efficient at increasing skin yellowness and that there were only small differences between high and low levels for each pigment source. This may allow a reduction in pigment use and feed cost to achieve the same skin acceptance by the consumer. color, pigment, carotenoid, skin, broiler

576 Mechanisms of pink color formation in irradiated precooked turkey breast. K. C. Nam*, M. Du, H. Ahmed, S. J. Hur, Y. H. Kim, and D. U. Ahn, *Iowa State University.*

Irradiation produces pink color defect in precooked poultry breast meat. The chemical pigment form of the pink color in irradiated, precooked poultry meat has not been identified. According to our preliminary study, irradiation decreased oxidation-reduction potential (ORP) and produced gas compounds that can act as a sixth ligand of heme pigments. Therefore, we hypothesize that production of certain gas compounds and increased reducing conditions induced by irradiation may be responsible for the red/pink color formation in precooked irradiated turkey breast. The objectives of our study were to characterize color compounds generated by irradiation, and to determine the effects of packaging and storage on color production in precooked turkey

breast. Precooked turkey breast muscles were aerobically or vacuum-packaged and then irradiated at 0, 2.5, or 5.0 kGy using a Linear Accelerator. The CIE color, reflectance, ORP, gas production, and lipid oxidation of samples were determined at 0, 7, and 14 days of storage. Irradiation dose-dependent increase of pink color was found in mainly vacuum-packaged samples, and the increased pink color did not decrease during vacuum-packaged storage. Irradiation decreased ORP and produced carbon monoxide (CO) indicating that the pink color of irradiated precooked turkey breast was caused by the decreased ORP and heme pigment-CO complex formation. The reflectance of meat and the absorption spectra of myoglobin solution derivatives supported that denatured CO-myoglobin would be the pigment responsible for the pink color in irradiated precooked turkey breast. Lipid oxidation was not directly related to the pink color intensity of precooked irradiated turkey breast.

Key Words: Irradiated color, Carbon monoxide, ORP, Precooked turkey breast

577 Effects of selected chemicals on red discoloration in fully cooked broiler breast meat . D. P. Smith*¹, J. K. Northcutt², and J. R. Claus³, ¹*USDA Agricultural Research Service, Athens, GA 30604*, ²*University of Georgia Department of Poultry Science, Athens, GA 30602*, ³*University of Wisconsin-Madison, Madison, WI 53706.*

Two replicate experiments were conducted to determine effects of selected chemicals on red discoloration in uncured, fully cooked broiler breast meat. Breast fillets and femurs were removed from commercial broilers after chilling. Fillets were finely chopped and the meat was divided into five portions for treatment additives: No additive (Control); 0.3% ascorbic acid; 0.3% citric acid; 200 ppm ethylenediaminetetraacetic acid (EDTA); and, 3% nonfat dry milk (NFDM). One g of bone marrow, prepared by chopping and grinding primary spongiosa from the femurs, was added to the middle of ten g portions of meat, which were then placed into each of five replicate tubes. Tubes were cooked to an internal temperature of 76.6 C, immediately cooled, and meat was removed. Color values (CIE L^* , a^* , and b^*) were measured in triplicate on the meat surface adjoining the marrow. Lightness (L^*) ranged from 45.5 to 51.3, redness (a^*) ranged from 23.4 to 28.9, and yellowness (b^*) ranged from 14.4 to 16.8. Citric acid ($a^* = 23.4$) and EDTA ($a^* = 23.8$) significantly ($P < 0.05$) reduced redness compared to Control values ($a^* = 27.4$). Neither ascorbic acid ($a^* = 24.8$) nor NFDM ($a^* = 28.9$) reduced redness values when compared to Control values, although ascorbic acid redness values were significantly lower than NFDM. These data show citric acid and EDTA significantly reduced redness in this experiment, whereas ascorbic acid and NFDM did not reduce redness values.

Key Words: Cooked breast meat, Red discoloration, Bone marrow

Animal Products in Today's Diet

578 The nutritional contributions of animal products to the US diet - The USDA Food Pyramid and Dietary Guidelines. Donald. J. McNamara, Ph.D.*¹, ¹*Egg Nutrition Center.*

Seems all one ever hears about dietary recommendations is "eat more whole grains, more fruits, more vegetables" and nary a good word about milk, beef, pork, chicken, eggs or the other animal products in the diet. Too many so called nutrition experts put animal products in the "bad food" group based on fat and cholesterol without recognizing the wealth of contributions these products make to a healthy and nutritious diet. There are good reasons why animal products hold important places in the USDA Food Guide Pyramid and in the Dietary Guidelines for Americans, and no matter what the fat/cholesterol-phobic and animal rights activists say, the evidence is clear that the diet is more nutritious, and more enjoyable, with the inclusion of animal products in a balanced diet.

Key Words: Animal products, Nutrition, Dietary guidelines

579 Modified protein diets. E. Hentges*, *National Pork Producers Council.*

Diets higher in protein have gained popularity in the U.S. and other developed countries for several reasons. Hentges will discuss the protein diet effects on insulin resistance, serum lipids, and weight control. He will also discuss the effects this diet has had on the industry and the response from national health organizations.

Key Words: Protein, Diets

580 Designer foods. D.C. Beitz* and T.J. Knight, *Iowa State University.*

Governmental agencies and human health associations have made specific and general recommendations for consumers to improve their health by changing their diet. Animal scientists have responded with a variety of nutritional, genetic, and management tools that can be used to redesign meat, milk, and eggs compared with previously produced products. But, to continue to meet consumer demands and to make animal-derived foods even more appealing, animal scientists must continually strive to modify animal food composition and quality to meet

the evolving recommendations being offered. Although, most modifications address a specific recommendation, other characteristics of the products may also be negatively altered. For example, should production systems be modified to increase the polyunsaturated fatty acids, conjugated linoleic acids (CLA), and omega-3 fatty acids and how will these changes affect shelf-life of the products? Should we attempt to decrease cholesterol content of animal foods? How can animal-derived foods be modified to contain greater concentrations of endogenous and of exogenous compounds to improve healthfulness of the resulting foods? Experiments that result in greater concentrations of polyunsaturated fatty acids including CLA and omega-3 acids and lesser total fat content in animal foods will be described. The influence of dietary fats and vitamin D on food quality, specific breeding programs, and molecular biological procedures that can be used to make specific changes in composition of animal foods will be described and specific examples will be given.

Key Words: Designer foods, Food quality, Fat composition

581 Designer foods: egg products. Hilary Shallo*, *Egg Nutrition Center.*

Last year, 158 million American - 85% - used a dietary supplement. Whether to simply maintain health or manage/treat a condition, nine out of ten shoppers prefer naturally nutritious foods to supplements (FMI/Prevention, 1999; HealthFocus 1999). In its efficient ovoid container, eggs are naturally a functional food providing valuable nutrients, from their high-quality protein to significant levels of beneficial vitamins, antioxidants, and other healthful compounds. In addition to the eggs being a natural functional food, the egg's nutrient content can be altered by the feed given to chickens. Consumers can now find eggs with even less cholesterol and saturated fat than typical and with an added bonus of increased vitamin E and DHA. And processors are beginning to make similar products available on an industrial level. Dr. Hilary Shallo will discuss the new nutrient-enhanced egg products that are available in the marketplace.

Key Words: eggs, designer eggs

582 Dairy Foods and Ingredients - Nutritious and Functional Products for the Food Industry and the Consumer. P. Tong*¹ and C. Podgurski¹, *¹Dairy Products Technology Center, California Polytechnic State University.*

Milk and the products made from milk are known to offer consumers good nutrition and good taste. Technologies continue to improve for the

processing of milk into highly functional dairy ingredients for the food industry. In addition, consumer interest in health promoting foods is increasing. As a result dairy ingredients are widely used in formulating baked goods, nutritional beverages, confections, sauces and other foods for today's consumers. As our understanding of the biological function of individual milk components improves, a whole new line of bio-active, functional dairy foods and ingredients are emerging. These specialized dairy ingredients are being used in foods which are thought to improve overall health (e.g., immune function, intestinal health, blood pressure regulation, etc.).

Key Words: dairy foods, milk, nutrition

583 Product Overview: Meat Products. D. H. Beermann*, *University of Nebraska, Lincoln.*

Linkages between nutrients in foods and human health have long been used as a basis for dietary recommendations. The Dietary Guidelines and the Food Guide Pyramid provide guidance through identity of basic food groups and suggested relative daily intakes. Concerns about total fat, saturated fat, and cholesterol content of meat and meat products spurned suggestions in the 1980s and 1990s that intake of meat and meat products be reduced. Although these recommendations lacked credence because daily contributions to the diet relative to dietary guidelines were not described for meat and other foods, consumers responded to these suggestions. This prompted research investigations directed at discovering strategies or technologies that improve fat-to-lean ratio, fatty acid composition, and altered concentrations of other nutrients. Success in altering carcass and retail cut composition was achieved through genetic selection, genomic analysis, administration of metabolism modifiers (somatotropin, beta-adrenergic agonists, conjugated linoleic acid (CLA)) and improving diet formulations to more closely match nutrient requirements of livestock. Technologies were developed for reducing fat content and altering nutrient composition of manufactured meat products. Examples of these are discussed. The discovery of the anti-carcinogenic, anti-tumorogenic, anti-diabetic effects of the cis-9, trans-11 isomer of CLA led to investigations of strategies for elevation of CLA concentrations in lipid depots of meat animals, primarily through dietary manipulation strategies. Feeding full-fat extruded soybeans at a level of 25% of the diet increased CLA cis-9, trans-11 15 to 20% in steers, but in other studies, feeding 6% yellow grease doubled concentration of the isomer. Comparison of results of several unpublished studies is presented.

Key Words: Designer Meat, Fat, CLA

Contemporary Issues in Sheep Production and Research

584 Outlook for wool markets in the 21st century. C. J. Lupton*, *Texas Agricultural Experiment Station, San Angelo.*

Wool's current market share of world fiber production is 3% with man-made fibers having 59% and cotton 38%. Raw material prices, processing costs, fashion trends, and fiber characteristics are all major factors in the global fiber competition for market share. In the past 15 yr, world production of wool has declined by 662 thousand tonnes from 3002 during the 1985/1986 season to 2340 in 1999/2000. During this time, production actually peaked at 3358 thousand tonnes in the 1990/1991 season. This high level of production, historically high prices, political and economic turmoil in the USSR and some eastern European countries, war in the Middle East, a drastic reduction in purchases by China, and the onset of recession in several major market countries combined to force suspension of the Australian Reserve Price Scheme in February, 1991, (a stabilizing factor on wool prices for the previous 17 yr). The concurrent accrual of a large wool stockpile (4.7 million bales in Australia alone) without price support resulted in an immediate downward adjustment in wool prices (35%). The effects of these events are still being felt. Slowly, the balance between supply and demand is being restored at price levels that will permit profitable production. Low prices have caused many producers to leave the sheep business. On the other hand, low prices have made wool more attractive to textile processors, and have helped wool retain some of its market share. Raw wool prices are now forecast to increase moderately over the next 10 yr because of lower supply, modest improvements in demand, and increasing numbers and affluence of consumers. In future, production and manufacturing

is expected to be concentrated in those countries that can produce and process it at the lowest cost. The high standard and cost of living in the US, high labor costs, increasing land values, greater public concern for the environment and the well-being of wildlife including predators, the expectation of younger generations for more comfortable lives, and sheep's inability to adapt well to large-scale, indoor factory operations all lead me to believe a decreasing proportion of wool and lamb will be produced domestically. Imports will supply the predicted moderate increases in demand by U.S. consumers for wool and lamb.

Key Words: Wool, Wool Markets, Sheep

585 Current status of genomic tools for genetic improvement in sheep. B. A. Freking*, *USDA, ARS, U.S. Meat Animal Research Center, Clay Center, NE.*

Rapid accumulation of genomic sequence data from a variety of mammalian species has led to increased knowledge of the structural organization and function of genes which impact production traits in livestock species. Tremendous genetic variation exists within and between sheep breeds for many economically important traits. Identification of the specific allelic variation would allow efficient use of DNA-based technologies to enhance information used to predict breeding values. The existing genetic map based on microsatellites is useful for initial scans of the sheep genome, but lacks comparative information on positional candidate genes. Current efforts in gene discovery have generated substantial

numbers of expressed sequence tags (EST) for cattle and swine. Over 150,000 bovine and 50,000 porcine EST sequences are publicly available. The cDNA clones used to produce the EST sequences are also useful resources for the production of microarrays used to profile gene expression patterns. At MARC, primers designed to amplify genomic samples for mapping bovine and porcine EST sequences have also been successful in amplifying sheep DNA. To date, 276 bovine-derived and 128 porcine-derived EST primer pairs have generated sheep amplification products. Sequence variation between different animals in the form of single nucleotide polymorphisms (SNP) will be the future platform for high-throughput automated genotyping technologies and evaluation of marker associations of phenotypes and important genes. The sheep industry must focus on the relevant traits which improve the viability and efficiency of lean lamb production. Genomic tools are rapidly changing our ability to efficiently identify and utilize genetic variation.

586 Nutrient recommendations for sheep: gaps in information and future approaches. H.C. Freetly*, *USDA, ARS, Roman L. Hruska U.S. Meat Animal Research Center, Clay Center, NE.*

Developing nutrient recommendations is an iterative process that involves taking available information, making a set of recommendations, testing the recommendations, and using the new information to refine the recommendations. The National Research Council last published its recommendations of sheep nutrient requirements in 1985. Given the

elapsed time, the question has been raised, do those recommendations need to be refined? Changes in the demographics of the sheep industry have resulted in changes in the types of sheep raised and management used. These changes have resulted in some deficiencies in the previous recommendations. Recommendations for the growing lamb do not take into consideration 1) decreases in maintenance energy with increased age, 2) the effect of previous nutrition on subsequent performance, 3) breed type differences, or 4) defined amino acid utilization. Recommendations for the ewe do not take into account 1) dynamic changes in body weight, 2) dynamic adjustments for gestation and lactation, 3) large litter sizes, and 4) defined amino acid utilization. Using the existing equations to predict nutrient recommendations for large lambs and ewes results in extending the input data beyond that used to parameterize the equations. Recommendations for mature rams are absent. Since the last recommendations were developed, a sparse amount of research has been conducted that addresses these deficiencies. This paucity of available research suggests that major changes in the system would be difficult to make. The mathematical structure of the system will determine what research needs to be conducted. The current recommendations are mathematically based on a net energy system. Alternative model structures can be used to develop the future nutrient recommendations. A consensus on the structure of the next mathematical model will provide guidance to investigators in their experimental designs that will allow them to focus their resources on collecting the information required to parameterize the system.

Key Words: Sheep, Nutrition

Animal Production and the Environment: Challenges and Solutions

587 CNMPs, TMDLs, CAFOs/AFOs, effluent guidelines, and other issues. T. Hebert*¹, ¹*Capitolink, LLC.*

Livestock agriculture faces enormous challenges and opportunities that are driven by events and programs at both the federal and state levels. Most of these are directly related to proposed and coming changes in key water quality regulatory policies. These include proposed rules for permitting of Concentrated Animal Feeding Operations (CAFOs) and their related Effluent Limitation Guidelines, Comprehensive Nutrient Management Plans (CNMP's), the final rulemaking on Total Maximum Daily Loads (TMDL's). In addition, the farm bill is also in the process of being re-authorized, and a key item for consideration is potential funding to help livestock producers manage manures more effectively and to protect water quality. The status of these matters, the outlook for their final disposition, and some key implications for the livestock sector will be discussed.

Key Words: CAFO, CNMP, TMDL

588 Challenges and opportunities facing animal agriculture: Optimizing nutrient management in the atmosphere and biosphere of the earth. E. B. Cowling*¹, ¹*North Carolina State University.*

Humans need food. Humans use energy. Production of food and combustion of fossil fuels increase concentrations of biologically active N in the atmosphere, soils, and surface and ground waters of the earth. These increases are caused in part by demand for animal protein in human diets, increased use of synthetic N fertilizers, and widespread planting of N-fixing legumes. The world's crops, forests, and fisheries respond to N enrichment with some positive benefits (e.g., increased food, feed, timber, and fish production) and some negative consequences (e.g., acidification and eutrophication of aquatic and terrestrial ecosystems, decreased biodiversity, increased regional haze, global warming, and such human health impacts as nitrate contamination of drinking water and increased pulmonary and cardiac disease caused by exposure to toxic ozone and fine particulate matter).

So far, most pollution abatement strategies have aimed at resolving one or another pollution problem in which oxidized or reduced forms of N play an important part. The time has come to consider more fully integrated strategies by which N management practices can be optimized to increase agricultural, forest, and fish production while decreasing N-induced soil-, air-, and water pollution.

The challenges and opportunities facing animal agriculture include joining with EPA, university, and other stakeholders in: 1) making realistic assessments of actual positive and negative impacts of N and particulate

matter emissions from animal agriculture, and 2) developing practical (economic) guidelines and strategies for: a) minimizing use of fossil fuels in agriculture, b) improving feed conversion efficiency in poultry, egg, swine, cattle, and dairy production, c) conserving and reusing valuable nutrients in animal wastes, d) minimizing N and P losses from manures, e) developing horizontally and vertically integrated systems of meat production and manure management through production and marketing of high-return value-added products.

Key Words: Atmosphere, Biosphere, Nutrient Management

589 Animal production impacts on nitrogen emissions to air and ground water: a Dutch case with a European perspective. Wim de Vries*¹, Hans Kros¹, Oene Oenema¹, Gert Jan Reinds¹, and Max Posch², ¹*Alterra Green World Research, Wageningen, the Netherlands.* ²*National Institute of Public Health and the Environment, Bilthoven, the Nether.*

In the Netherlands, intensive animal husbandry has led to very high N emissions into the environment. The estimated total annual N input flux per hectare on agricultural land for the year 1997 is 485 kg for the Netherlands compared to 146 kg for the European Community. The animal manure production in the Netherlands is approximately 5 times the average European value (265 kg compared to 56 kg) and the same holds for the N surplus (256 kg compared to 52 kg).

To gain insight in the fate of N input in the Netherlands, a study was carried out analysing the nitrogen fluxes for 250 × 250 m² grid cells with a simple N balance model representing all crucial processes in the N chain. Results of average annual fluxes (kton N.yr⁻¹) for the year 1997 equalled 1077 for the total N input and 261 for the total N emission to air, ground water and surface water, i.e. 140 for NH₃ emission, 103 for N leaching and 18 for runoff to the sea.

Despite the relative low N leaching and N runoff compared to the N input, it does cause an excess of critical limits for nitrate in ground water (50 mg.l⁻¹) and nitrogen in surface water (2.2 mg.l⁻¹) in large parts of the Netherlands. We calculated the maximum allowable nitrogen application on the basis of the critical limits given above and the acceptable ammonia emission related to the protection of biodiversity of natural areas. Results showed a reduction of 50 to 70% is needed to reach the ceilings necessary to protect the environment against all adverse impacts.

On a European scale NH₃ emissions are the major cause of elevated N deposition. Results of atmospheric deposition measurements at 317 forested plots, mostly concentrated in central Europe, showed that more

than 50% of the investigated plots received a nitrogen input above a deposition level at which the species diversity of the ground vegetation may be at risk.

Key Words: Nitrogen, Critical loads, Animal production

590 The role of nutrition in reducing nutrient output from ruminants. L.D. Satter*¹, T.J. Klopfenstein², and G.E. Erickson², ¹*U.S. Dairy Forage Research Center, Madison, WI*, ²*University of Nebraska, Lincoln*.

Much of the effort expended on nutrient management has focused on the post-excretion product. It is important to keep in mind that management of the diet can have important impacts on quantitative and qualitative aspects of the excreted nutrient. Surveys of nutritionists and extension specialists show that dairy producers are advised to feed .45-.50% phosphorus (P)(DM basis) in their lactating cow diets. This is 20-30% in excess of NRC (2001) requirements. Feeding to requirement would reduce P excretion by 30% or more, and would reduce solubility and potential for runoff of the P that is applied to fields. Nitrogen (N) excretion by dairy cows can also be decreased, but by a lesser amount. Balancing RUP and RDP, and use of protected methionine along with strategic selection of protein supplements that are relatively rich in lysine, may permit a 10-15% reduction in total N excretion, with most of the reduction occurring in urinary N. Urinary urea, following conversion to ammonia, is the N excretion product most vulnerable for loss to the environment. Feedlot cattle routinely consume P in excess of NRC (1996) predicted requirements, and recent research suggests the NRC estimates of the P requirement are high. Decreasing dietary P from the industry average (.35% P) to the NRC predicted requirement (.22-.28%) decreased P input by 33 to 45% and excretion by 40-50% in nutrient balance studies. With grain-based feedlot diets, overfeeding P is inevitable. At minimum, supplemental P sources should be removed from diet formulations. More accurate formulation of feedlot diets for protein provides opportunity for reducing N excretion. Using the NRC model for metabolizable protein, and employing phase-feeding, N inputs may be decreased by 10-20% from the feedlot industry average of 13.5% dietary CP. This translates into a 12-21% reduction in N excretion, and 15-33% reduction in ammonia volatilization in open-dirt feedlot pens. Diet formulation can have important impact on the amount of N and P excreted in both dairy and beef. It is much easier to control potential pollutants by managing their release into the environment than to recover or confine them once they are released.

Key Words: Nitrogen, Phosphorus, Ruminant

591 Nutritional strategies to reduce environmental emissions from non-ruminants. P.R. Ferket*¹, R.C. Angel², E. van Heugten¹, and T.A. van Kempen¹, ¹*College of Agriculture and Life Sciences, North Carolina State University, Raleigh, NC 27695*, ²*Department of Animal Science, University of Maryland, College Park, MD 20742-2311*.

The amount of nutrients (i.e. N, P, Zn and Cu) and associated odors emitted from production animals into the environment can be modulated by several different nutritional strategies, but their practical application is dependent upon costs and other biological limitations. In general, nutrient excretion may be reduced by avoiding the feeding of excessive amounts or using nutritional manipulations to enhance nutrient utilization in the animal. Manufacture and handle feed to minimize wastage and improve feed/gain. Develop feeding programs that are specific for sex and strain of animal, increase the number of feed phases,

and formulate diets according to the minimum nutrients required to satisfy production goals. Use the ideal protein concept to estimate amino acid requirements and use synthetic amino acids supplements to reduce N emission. Use feed ingredients with high digestibility and nutrient bioavailability, and formulate diets based on nutrient availability instead of total nutrient content. Nutrient digestibility of feedstuffs is dependent upon processing conditions, genetic characteristics of the grains and oilseeds, and the presence of nutritional antagonists in the diet. Avoid feed ingredients that lead to odor production (e.g. fishmeal and some easily fermentable feed ingredients). Use feed additives, such as antibiotics, nonstarch polysaccharides, direct-fed microbials, organic acids, microbial enzymes (i.e. phytase, carbohydrases, and proteases) to increase the digestibility and absorption of nutrients or to modulate microflora. Finally, a cost factor for the control or disposal of nutrients or odor should be considered in the feed formulation to optimize the various nutritional strategies discussed above. Regardless of biological and economic limitations, significant reductions in nutrient and odor emission from non-ruminants can be achieved by appropriate nutritional strategies.

Key Words: nutrition, nutrient and odor emission, non-ruminants

592 Development of comprehensive nutrient management plans: Practical aspects of getting nutrient management plans implemented . Mary Combs*¹, ¹*USDA-Natural Resources Conservation Service, Raleigh, NC*.

The 1998 Clean Water Action Plan required the EPA and USDA to jointly develop a unified strategy to minimize the environmental and health impacts of the nation's animal feeding operations (AFOs). This Unified National Strategy for Animal Feeding Operations identified a national expectation that all AFOs develop and implement Comprehensive Nutrient Management Plans (CNMPs) by 2009. Focusing on the smaller, non-regulated (federal) AFOs with limited resources, NRCS and its partners may need to assist with an estimated 262,700 CNMPs across the U.S. to meet this expectation.

Significant CNMP development and implementation issues remain: (1) Substantial resources for staff and training are required to provide this accelerated technical assistance for CNMP development. Developing the CNMP is just the first step; considerable follow-up with producers is required to assist with operation, maintenance, and revision of the Plans as producers' needs change. (2) More research is needed in several critical areas to better understand nutrient movement and validate states' phosphorus indexes and models that assess potential nutrient losses. (3) In areas of concentrated AFOs and limited land for application, nutrient management policy may result in no technically or economically feasible solutions for the producer. (4) Both regulators and technical specialists must recognize the economic situation of producers. The cost of waste management systems is site specific, and is not only a function of operation size. The special challenges to limited resource farmers must be considered. (5) Cost sharing and incentives are inadequate to meet the needs. In North Carolina, USDA's Environmental Quality Incentives Program and the N.C. Agricultural Cost-Share Program fund about 1/3 of the existing demand. (6) Ensuring compatibility with state programs, laws, rules, and certification criteria for technical specialists will continue to a significant coordination effort. (7) NRCS's image by its customers continues to evolve. NRCS practice standards, developed to support voluntary USDA programs, are becoming regulatory instruments, as federal or state regulations reference these standards.

Key Words: AFO, CNMP, NRCS

Novel Genes and Gene Products

593 Differential display as a tool to identify a steroid-induced gene. Robert Kempainen*, *Auburn University, Auburn, Alabama* .

Differential display is one of several methods designed to identify differentially induced or expressed genes and has been used successfully in many studies to identify new genes in various tissues or cells. The basic method involves collection of RNA from target tissues followed by cDNA synthesis using oligo-dT primers designed to make cDNA from subpopulations of the mRNA. These different cDNA's are then used as templates in PCR in conjunction with the original oligo-dT primer and

a set of arbitrary upstream primers. Labeled PCR products are loaded onto sequencing gels so that side-by-side comparisons can be made to identify up- or down-regulated genes. We used the technique to identify dexamethasone-induced genes in a pituitary cell line. Since steroid negative feedback requires gene transcription/translation and the identity of steroid-induced genes is unknown, differential display seemed to be an ideal technique for this purpose. Cells were treated with dexamethasone or its vehicle and RNA was collected and used for differential display. The screen performed used 240 primer combinations, surprisingly; only about 20 induced bands were consistently generated. Of the

20, 19 turned out to be false positives and one dexamethasone-induced gene was identified; its full-length cDNA was cloned from a library and sequenced. The cDNA is a novel member of the Ras-superfamily and was named *Dexas1* due to its ability to be induced by dexamethasone. Experiments are in progress to characterize the role of *Dexas1* in the pituitary and in other steroid-responsive tissues. Overall, differential display was extremely useful in identification of a novel gene, however, it may require considerable effort in terms of testing various PCR primer combinations and the technique may be expected to generate a significant number of false positives.

Key Words: Differential , Display, Dexamethasone

594 Genes, Chips and Animal Biology. Nagappan Mathialagan*¹, Charles Bolten¹, Steven Wagner¹, John Byatt¹, and Frances Buonomo¹, ¹*Monsanto Animal Agricultural Group.*

Genomic technologies have transformed the animal biology research into a new era of discoveries in a similar fashion as the introduction of radioimmunoassay techniques. Genomics has resulted in the identification of thousands of new gene sequences in farm animal species with no real link to functional association. Comparative genomic analysis with completed genomes such as human has been used to discover orthologous genes. However, this approach still leaves out the annotation of genes which are novel to the animal species. Gene expression technologies like Microarrays and Serial Analysis of Gene Expression (SAGE) are used to determine the expression of thousands of genes simultaneously. Species-specific microarrays need to be used to associate a function to these new genes. However, cross-species microarrays may be used in instances where there are no species-specific arrays. We have used Incyte human microarrays for transcript profiling of bovine mammary gland to identify regulated genes associated with milk production. A set of human gene homologues were identified that are regulated during lactation and involution. Genes up-regulated during lactation, identified by heterologous profiling, were selected for confirmation by other methods such as Northern blot analysis, quantitative RT-PCR, subtractive cDNA libraries and nylon arrays. One example of a regulated gene we selected for confirmation was Stearoyl-CoA-Desaturase (SCD), an enzyme involved in the synthesis of conjugated linoleic acid. An increased expression was associated with lactation while a sharp decline in the expression was observed with involution. In addition, our experience with

heterologous arrays showed that genes can be erroneously identified due to sequence identity of bovine genes to unrelated genes in human. This observation emphasizes the preference to use species-specific arrays for gene expression studies.

Key Words: Transcript Profiling, Microarrays, Genomics

595 Proteomics in the animal sciences. Lawrence Dangott*, *Texas A&M University, College Station, TX.*

One of the goals of biologists in the post-genome era will be to characterize all the proteins within an organism, tissue or organelle, in order to describe the pathways and protein interactions that mediate cellular function. Proteomics is the term given to the large-scale analysis of proteins using biochemical, biophysical and chemical techniques of analysis. Although traditionally associated with the two-dimensional display of large numbers of proteins, in the post-genomic era, proteomics is dividing into three main areas; 1) protein identification and micro-characterization; 2) differential expression analysis of proteins in normal and altered tissues; and 3) studying protein-protein interactions. Approaches to achieve these goals require the combination of traditional molecular biological, biochemical and biophysical techniques with the expanding capabilities of high-throughput robotics and high-sensitivity, high-resolution mass spectrometry as well as the development of new technologies. These kinds of approaches are being used in our laboratory and others to explore and explain the functions, interactions and regulation of proteins in animal reproductive biology and environmental toxicology. Proteins involved in embryo implantation are being identified in ovine uteri using 'knock-out' ewes, two-dimensional gels and in gel digestion techniques coupled to automated protein micro-sequencing and MALDI-TOF (matrix-assisted laser desorption ionization time-of-flight) mass spectrometry. Similarly, proteins involved in horse sperm differentiation are being identified by applying these techniques to proteins isolated from in vitro cultures of equine seminal tubules. In related experiments, post-translational modifications are being mapped by ion-trap electrospray mass spectrometry and multi-dimensional chromatography coupled with mass spectrometry is being used to identify components of protein complexes.

Key Words: Proteomics, Mass spectrometry

Preharvest and Postharvest Approaches to Modification of Milkfat

596 The milk fat globule membrane of buttermilk: a unique ingredient. M. Corredig*, *Department of Food Science and Technology, University of Georgia.*

The presence of material derived from the milk fat globule membrane (MFGM) makes buttermilk (the byproduct of buttermaking) distinct from any other dairy product. Studies of MFGM have revealed strong associations of the membrane lipids with various membrane proteins (butyrophilin, xanthine oxidase and some minor proteins). When membrane material is isolated from buttermilk a high ratio of polar lipids is found, in particular phosphatidyl ethanolamine, phosphatidyl choline and sphingomyelin. Phospholipids play an important role in many metabolic processes, and phospholipid-enriched fractions are today marketed as important ingredients in a variety of dietary products. Furthermore, evidence is emerging that sphingomyelin from milk may have anti-cancer properties and other health-related benefits. In addition to

the nutritional quality of MFGM, a more detailed analysis of the composition of buttermilk has suggested the utilization of buttermilk as an ingredient in the manufacture of foods, for example low fat cheese and yogurt. The behavior of buttermilk as a functional ingredient can be attributed to the presence of skim milk proteins and the MFGM, however the role played by the various components and their interactions is not understood. Processing history and compositional differences also seem to affect the functionality of MFGM. Understanding the various components and the functional properties of buttermilk will allow this byproduct to become a source of new and unique ingredients. Our discussion will review the current literature in this area and present some thoughts on the further development of commercial products derived from the MFGM.

Key Words: phospholipids, MFGM, buttermilk

Role of Extracellular Matrix (ECM) in Growth and Development

597 The role of the extracellular matrix in growth and development: An introduction. M.W. Orth*, *Michigan State University.*

Besides providing structural support, the extracellular matrix (ECM) has recently been shown to play a significant role in the regulation of tissue growth and development. As an example, certain ECM molecules can sequester growth factors and release them during tissue remodeling. Also, proteolytic products of ECM molecules can have a unique biological activity via interactions with cell surface receptors. The focus of this symposium will be to examine the role and regulation of the ECM in four tissues of particular interest to the animal scientist. Dr. Sandy

Velleman will describe the architecture of the ECM in skeletal muscle tissue with an emphasis on the function of the proteoglycan component. The predominant focus on myofibrillar proteins traditionally has overshadowed this exciting area of research. Dr. Tom Schmid will discuss the role of the ECM during endochondral bone formation, with an emphasis on ECM proteins found in unique regions of growth plate and articular cartilage that were discovered in his laboratory. He will also discuss the potential of using ECM molecules as biological markers in physiological fluids to monitor the development and health of the skeleton. Dr. Russ Hovey will discuss the development of the mammary gland and its complex architectural structure. Specifically his research interest focuses on understanding the contribution of the mammary stroma dur-

ing mammary epithelial proliferation and function. Finally, Dr. George Smith will elaborate on his research into the role of matrix metalloproteinases and plasminogen activators in ovarian function. His laboratory has found that these two families of ECM proteinases are temporally and spatially regulated during the ovarian cycle and contribute to ECM remodeling associated with growth, differentiation, and resorption of ovarian structures. We hope that through this symposium animal scientists will gain a deeper appreciation for the ECM and how it could play a major role in understanding and solving some of the problems encountered in the animal science industry.

Key Words: growth, development, matrix

598 Role of the extracellular matrix in muscle growth and development. Sandra G. Velleman*¹, ¹The Ohio State University/OARDC.

Studies on the growth and development of skeletal muscle have predominantly focused on the myofibrillar components especially myosin and actin. It has been largely overlooked that skeletal muscle cells secrete a network of extracellular matrix macromolecules which have the potential to regulate the growth and development process. The extracellular matrix is composed of a network of glycoproteins, collagen, and proteoglycans that surround the skeletal muscle fibers. The positioning of the individual extracellular matrix macromolecules is not random, but instead the individual components interact to form a precise structural architecture which becomes the epimysium, perimysium, and endomysium skeletal muscle connective tissue layers. The extracellular matrix then functions by maintaining tissue shape and structure, regulating tissue function, and communicating information back to the cells through the formation of cell-extracellular matrix signal transduction pathways. Information communicated to the cell from the extracellular matrix may influence migration and adhesion, and proliferation and differentiation. As muscle ages, the composition of the extracellular matrix changes. During muscle formation, the embryonic extracellular matrix appears to be involved in the spacing of the developing muscle fibers and later in development changes to a matrix with macromolecular components involved in growth factor regulation. Although basic aspects of skeletal muscle extracellular matrix composition are known, it is not well understood how the extracellular matrix affects skeletal muscle development and function. Focus will be on the proteoglycan component of the extracellular matrix because of its role in regulating collagen fibrillogenesis, cellular growth properties, and cellular growth factor responsiveness.

Key Words: Muscle, Proteoglycans, Extracellular Matrix

599 Role of the extracellular matrix in skeletal growth, development and health. T. M. Schmid*, *Rush Medical College, Chicago, IL.*

The mass and volume occupied by the skeleton is primarily due to its abundant extracellular matrix (ECM). Research over the last 3 decades has characterized many skeletal macromolecules including classes of collagens, proteoglycans and glycoproteins. These molecules fulfill different structural functions, but also can exhibit regulatory roles. The ECM provides a scaffold for skeletal remodeling and acts as a reservoir for growth factors and nutrients. The matrix of cartilage and bone are distinctly different, however their calcified cartilage interface is surprisingly similar. The growth of this organ is orchestrated by a symphony of growth factors. The fine-tuning of this metabolic activity requires an information exchange at the cell-matrix interface. Cell surface receptors bind extracellular matrix ligands and generate intracellular signals, which direct cellular activities. Fragments of matrix macromolecules can modulate these interactions. The remodeling of the extracellular matrix in growth and development is a highly regulated process involving several classes of proteolytic enzymes. A variety of biochemical assays have been developed to study the synthesis and degradation of the extracellular matrix in cartilage and bone. Work in my laboratory has focused on the identification of macromolecules that are unique to specific regions of growth or articular cartilage. Type X collagen is the prototype of these molecules and is found almost exclusively at the interface of cartilage and bone. Another exciting molecule, which protects the articular cartilage surface, is superficial zone protein (SZP). This is a 345-kDa proteoglycan that is synthesized by superficial zone chondrocytes, but not deep zone chondrocytes. We have recently shown this molecule to be an abundant glycoprotein in synovial fluid and has lubrication activity when tested on a cartilage-glass interface. Another protein Dell

appears to be enriched in the superficial layer of articular cartilage and in the hypertrophic zone of the growth plate. Future studies will define if these molecules hold promise as biochemical markers to monitor the growth, development and health of the skeleton.

Key Words: Growth plate, Cartilage, Skeleton

600 Role of the stroma and extracellular matrix during mammary gland growth and development. R.C. Hovey*, ¹National Cancer Institute, NIH.

The normal mammary gland undergoes extensive development prior to assuming the ultimate lactogenic phenotype. Under hormonal regulation the mammary epithelium proliferates within the stromal matrix of the mammary fat pad, giving rise to an architecturally-complex and species-unique ductal network. These species differences reflect an altered abundance and proliferation of various stromal cell types (adipocytes, fibroblasts, endothelial cells) that intimately associate with myoepithelial and epithelial cells. Together these cells contribute the various elements of the extracellular matrix that regulate normal epithelial cell proliferation, differentiation and milk protein gene expression, and tumorigenesis and metastasis during breast disease. Historically, attention has focused on the function of mammary epithelial cells, independent of the stromal matrix. Our research has begun to explore the contribution of the mammary stroma during mammary epithelial proliferation and function. It is increasingly evident that cellular constituents within the mammary fat pad are integral sites of hormone action that mediate systemic signals through altered stromal proliferation and paracrine growth factor expression. Likewise, species differences in stromal function may confer differential morphogenesis to the mammary epithelium. In addition, development of the vasculature system within the mammary gland occurs within the mammary fat pad under hormonal and growth factor influences that converge during epithelial-stromal and extracellular matrix interactions. Although the mechanisms by which epithelial-stromal and epithelial-matrix-stromal interactions regulate mammary gland growth, morphogenesis, function and neoplasia have not been resolved, increasing evidence points to their integral function within the mammary gland.

Key Words: mammary, stroma, epithelial-stromal interaction

601 Regulation of extracellular matrix remodeling during the ovarian cycle: Implications for the control of growth, differentiation and resorption of specific ovarian structures. George W. Smith*^{1,2}, Mark P.D. Dow^{1,2}, Leanne J. Bakke², Will A. Ricke³, Carolyn A. Cassar¹, Michael W. Peters¹, J. Richard Pursley¹, and Michael F. Smith³, ¹Department of Animal Science, Michigan State University, ²Department of Physiology, Michigan State University, ³Department of Animal Science, University of Missouri-Columbia.

For many years, the ovarian extracellular matrix (ECM) was thought to function merely as scaffolding providing architectural support. However, a growing body of evidence indicates the ovarian ECM also plays a key regulatory role. In general, changes in the ECM can influence gene expression and cell migration, proliferation, differentiation and death. Within the ovary, changes in the ECM help regulate specific events during the ovarian cycle. Growth of bovine ovarian follicles from the primordial to preovulatory stage is characterized by an approximately 360,000-fold increase in surface area as follicles expand within the confines of the surrounding ovarian stroma (ECM). Ultimately, most follicles die by atresia and are resorbed. The remaining follicles undergo ovulation, characterized by follicle rupture and release of the egg. Follicle rupture is dependent upon localized degradation of the ECM at the apex of the preovulatory follicle wall. Extensive ECM remodeling is also characteristic of the luteal phase. Following ovulation, transformation of remnants of the preovulatory follicle into a corpus luteum involves mechanisms similar to wound healing and tumor formation. Disruption of cell-ECM contacts, loss of steroidogenic capacity, cell death and tissue resorption characterizes corpus luteum regression at the end of a nonfertile cycle. Two families of proteinases that regulate ovarian ECM remodeling are the matrix metalloproteinases (MMP) and the plasminogen activators (PA). The MMP are a large gene family that digest various ECM components and are noted for their role in ECM remodeling during tissue growth, morphogenesis and repair. The PA are implicated in control of ECM remodeling via their ability to convert the ubiquitous zymogen plasminogen to its active form plasmin, which directly and indirectly mediates ovarian ECM degradation. The fundamental

role of the ECM in the control of growth, differentiation, and resorption of ovarian structures and the regulation of ovarian ECM remodeling by the MMP and PA will be discussed. Our results indicate that the MMP and PA are temporally and spatially regulated during specific stages of the ovarian cycle and control ECM remodeling fundamental to ovarian

function. Supported by USDA 98-35203-6226 (GWS) & 98-35203-6282 (MFS).

ADSA Dairy Foods: Cheese

602 Quality attributes of cheddar cheese in the North Carolina marketplac. A. Hansen* and M. Keziah, *North Carolina State University Raleigh, N.C. USA.*

Approximately 250 samples of cheddar cheese were obtained from various retail markets in North Carolina. Cheddar cheese samples were evaluated over a two year period. The evaluation was conducted with 15 trained dairy judges. Attributes were appearance, body and texture and they were evaluated according ADSA protocol. The major defects in appearance were open and a few samples were gassy. The major body defects were, from most to least, short, crumbly, pasty and curdy. The flavor defects from most to least were high acid, bitter, whey, sulfide, unclean, heated, flat and yeasty. The national brands of cheeses had less appearance and body defects. The main flavor defects were high acid, bitter, sulfide and whey, whereas the store brands tended to be more open and gassy in appearance. The body and texture would be short, curdy, crumbly and pasty depending on the brand. The store brands tended to have more off flavors such as unclean, oxidized, yeasty, flat, whey, sulfide, fermented and fruity. The store brands of sharp cheese tended to be acid, bitter and sulfide as compared to the national brand cheese which were acid and sulfide. The national brands usually had a cleaner flavor and were better quality

603 Salt and calcium distribution in injected cheese. A.J. Pastorino*¹, N.P. Ricks², C.L. Hansen¹, and D.J. McMahon¹, ¹*Utah State University*, ²*Ohio State University*.

Modifying cheese attributes by injecting ionic solutions requires knowledge of the time needed to obtain uniform concentration of ions in the cheese. Therefore, our objective was to determine whether even distribution of sodium chloride (salt) and calcium chloride in cheese, over 1.0 cm distance from injection site could be obtained after 30 to 45 d. Full-fat salted cheese (25% fat, 45% moisture) and reduced-fat unsalted cheeses (22% fat, 42% moisture) were made according to direct-acid, stirred-pressed curd procedures. Cheeses were cut into 0.4 to 0.6-kg blocks, vacuum-packaged, and stored at 4°C. After 3 wk of storage, full-fat cheese blocks were high-pressure injected with a 40% calcium chloride solution, while reduced-fat blocks were injected with a 23% salt solution. Injection was performed in a single, centered row, in the top of the cheese block, with injection sites 1 cm apart. Pressure of injection was set at 1500 psi, and burst duration at 1.5 s. Cheese blocks were then vacuum-packaged and stored at 4°C. After storage, cheeses were sectioned into bands, 0.5 cm thick, parallel to the injection line. Three bands to each side of the injection line were considered for analysis, and the chloride and calcium content determined. Salt-injected cheese was analyzed 6 wk after injection and had increased salt content compared to uninjected cheese, 0.25% versus 0.16% ($P < 0.01$). Also, the injected cheese had an even distribution of salt over 1.5 cm from the injection line. Calcium-injected cheese, analyzed 4 wk after injection, had increased calcium content when compared to uninjected cheese, 0.43% versus 0.33% ($P < 0.01$), and had even distribution of calcium over 1.0 cm from the injection line. Upon injection, increased localized ion concentration generated a concentration gradient in the cheese that operated as a driving force for ions to diffuse. Also, deflection of the injectant as it enters the cheese would provide some initial dispersion of the solution. We concluded that injecting concentrated solutions of sodium and calcium chloride allows for increasing their content in the cheese, and that injecting these solutions using a 1 x 1-cm injection pattern allows for even distribution of ions in 30 d.

Key Words: Cheese, Salt, Calcium

604 Characterization of the melt properties of Cheddar cheese during ageing using dynamic low amplitude oscillatory rheology and melt profile analysis. Achyuth Hassan* and John Lucey, *University of Wisconsin-Madison.*

Melt characteristics are an important functionality of cheese on pizza. The melting properties of Cheddar cheese during ageing were determined by melt profile analysis and two dynamic low amplitude oscillation (DLAO) tests on a Physica UDS 200 rheometer. The newly developed melt profile method measures changes in cheese height during heating from 12 to 60°C and provides information on extent of flow and softening temperature. Extent of flow values (i.e., decrease in original cheese height) for 1, 7, 14, 21, 30, and 90 d samples were 54, 61, 64, 71, 71.5, and 71.5%, respectively. Rheological properties of cheese were evaluated at a strain of 0.2% and frequency of 0.1 Hz. Storage modulus (stiffness) and loss tangent parameters were determined from DLAO tests during heating. Cheeses were given two different types of heating profiles; one profile was the same as that used in the melt profile analysis technique (a non-linear but short heating profile or SHP). In the second heating profile, cheeses were heated from 5 to 80°C at constant rate of 1°C/min (long heating profile or LHP). In both heating profiles the loss tangent remained constant up to 40°C (0.5) and thereafter increased. The temperature when the loss tangent initially increased was similar to the softening temperature determined by melt profile analysis. Loss tangent values (at temperatures >40°C) increased with the age of cheese. In SHP tests, the values of the loss tangent at 55°C were 0.7, 1.3, 1.5, 1.7, 2.0, and 2.3 for 1, 7, 14, 21, 30, and 90 d cheese, respectively. In samples subjected to LHP, a well defined peak was observed in loss tangent and maximum values were 1.2, 2.0, 2.3, 2.5, and 2.1 which occurred at temperatures of 69, 67, 65, 64, 62, and 57°C for 1, 7, 14, 21, 30, and 90 d cheese, respectively. The decrease in height of cheese samples during heating paralleled trends in the increase in loss tangent value from rheological tests. An increased loss tangent indicates a change in character of cheese from solid-like material to viscous or liquid-like and it appears that this increase is involved in melting and flow of cheese at high temperatures. With increasing age and proteolysis the extent of flow increased and this coincided with higher loss tangent values in rheological tests.

Key Words: Rheology, Cheese, Melt profile

605 Reduced fat Cheddar cheese from a mixture of cream and liquid milk protein concentrate. Shakeel Rehman* and Nana Farkye, *Dairy Products Technology Center, Calpoly State University.*

Liquid milk protein concentrate (LMPC) is a high protein and low lactose dairy ingredient manufactured by ultrafiltration of skim milk. The study was undertaken to use LMPC and cream mixture in reduced fat Cheddar cheese (RFC) manufacture in order to increase yields. Control RFC was manufactured from standardized milk casein/fat, C/F 1.7, obtained from mixing whole milk (WM) and skim milk (SM) while experimental RFC was manufactured from standardized milk, C/F 2.0, obtained from mixing LMPC and 35 % fat cream. The % yield, % total solid (TS) and fat recoveries in the experimental RFC were 21.2, 61.4 and 85.4 as compared to 8.0, 45.1 and 77.3 in the control RFC, respectively. The average % moisture, fat, protein, salt and lactose were 40.7, 15.3, 32.8, 1.4 and 0.07, respectively, in the experimental cheese and 39.3, 15.4, 33.0, 1.3 and 0.10, respectively, in the control cheese. No growth of non-starter lactic acid bacteria (NSLAB) was detected in control or the experimental cheeses up to 3 mo ripening but at the end of 6 mo ripening the experimental cheese had 10^7 cfu NSLAB / g as compared to 10^6 cfu / g in the control. The experimental cheese had lower levels of water soluble N (as % of total N) than the control cheese after 6 mo ripening, suggesting lower levels of primary proteolysis in the experimental cheese. The total free amino acids, determined by Cd-ninhydrin method, were significantly lower in the experimental cheese than the control cheese during 6 mo ripening, suggesting lower

secondary proteolysis in the cheese containing LMPC. It can be concluded from the results of this study that LMPC can be used in the manufacture of RFC to improve yield, and fat and TS recovery. However, proteolysis in cheese made with LMPC and cream is slower than that made with WM and SM.

Key Words: Milk protein concentrate, reduced fat Cheddar

606 Effects of standardization of whole milk with milk protein concentrate on the yield and ripening of reduced fat Cheddar cheese. Shakeel Rehman¹, Nana Farkye¹, and Andrew Schaffner², ¹Dairy Products technology Center, Calpoly State University, San Luis Obispo, CA, ²Department of Statistics.

Milk Protein concentrate (MPC), manufactured by spray drying of skim milk retentate, is becoming a popular dairy ingredient. Because of its high protein and low lactose contents, MPC can be used to standardize whole milk to give high yields of reduced fat Cheddar cheese. Four cheesemaking trials were conducted, each involving three cheeses, one control (CC) made from standardized milk (casein to fat ratio, C/F 1.7) obtained by mixing skim milk and whole milk (WM); the other two (MP1 and MP2) made from standardized milk (C/F 1.8) obtained from mixing WM and MPC. Commercial mesophilic starter was added at the rate of 1% to the CC and MP1, and 2% to MP2. The addition of MPC doubled the yield and resulted in significant increases in the recovery of fat (94% in MP1 and MP2 vs 92% in CC) and total solids (43% in CC vs 63% in MP1 and MP2). Although minor differences were noted in the gross composition of the cheeses, both MP1 and MP2 cheeses had lower lactose, 0.25 or 0.32, respectively in MP1 or MP2 than in CC (0.60%). All the three cheeses had 10⁹ cfu/g starter bacteria. The non-starter lactic acid bacteria (NSLAB) grew slowly in MP1 and MP2 cheeses during ripening compared to CC, and at the end of 6 mo, the CC had 1-2 log cycle NSLAB higher than MP1 and MP2. Primary proteolysis, as noted by urea-PAGE or water soluble N contents, was markedly slower in MP1 and MP2 compared to CC. The concentration of total free amino acids, as determined by Cd-ninhydrin method, was highest in the CC cheese followed by MP2 and MP1, respectively, suggesting slower secondary proteolysis in the MPC than in CC cheese. Increasing the amount of starter bacteria improved secondary proteolysis in MPC cheese.

Key Words: Milk protein concentrate, reduced fat Cheddar

607 Controlling the coagulation properties of high solids cheesemilks that are standardized with cold ultrafiltration retentates. S. Govindasamy-Lucey^{*1}, J.J. Jaeggi¹, M.E. Johnson¹, and J.A. Lucey², ¹Wisconsin Center for Dairy Research, University of Wisconsin, Madison, Wisconsin/USA, ²Department of Food Science, University of Wisconsin, Madison, Wisconsin/USA.

The cheese industry is currently using higher solids milks with the objective of increasing yields and processing efficiency. Increasing the solid contents of milk in-vat from 11 to 14.5% results in faster coagulation and firmer setting of the curd but possibly increased fat losses in whey if the cutting process is not carefully controlled. In this study, the coagulation properties of cheesemilks were determined using dynamic low amplitude oscillation in a Physica UDS 200 Rheometer. Milks with elevated solids (14.5%) were made by blending retentates obtained by cold (<7C) UF. Control milks with similar casein:fat ratios and total solids of 11.3% were also analyzed. The effects of cutting on the textural properties of rennet-induced gels were simulated using a low constant shear (0.01 s⁻¹) test of the pre-formed gel made in the rheometer. The shear test was performed at the cutting times that our licensed cheesemakers used in cheese trials with these types of milk. Several trials were performed with gels made in the rheometer under identical conditions (pH, temperature, enzyme concentration) as used in Parmesan and Swiss cheese manufacture. Gels made from higher solids cheesemilks coagulated faster (although the rennet to casein ratio was identical for all samples), with a reduction in clotting time by 25-30%. The shear stress of the gels, that is, the force required to break the gels, during shearing was considerably higher (120-130%) in the high solids cheesemilks compared to control samples, which indicates that the cutting operation may need to be modified to prevent excessive fat losses. The storage modulus (or stiffness) of all gels at cutting were generally similar as our cheesemakers started cutting the coagulum earlier in the higher solids milks. The rate of firming was considerably faster in the higher solids milks. In commercial cheese vats, it is more difficult to monitor coagulation and the cutting cycle is considerably longer than in our pilot-scale

cheesemaking; both problems need to be addressed so as to successfully use higher solids cheesemilk with conventional cheesemaking equipment.

608 Study of the effects of pH, temperature and NaCl on amino acid catabolic enzyme activities using quadratic response surface methodology. A.C. Curtin¹, M. De Angelis², M. Cipriani², M.R. Corbo³, P.L.H. McSweeney^{*1}, and M. Gobbetti⁴, ¹University College, Cork, Ireland, ²University of Perugia, Italy, ³University of Foggia, Italy, ⁴University of Bari, Italy.

The objectives of this study were to screen cystathionine- β -lyase, cystathionine- γ -lyase and L-methionine aminotransferase activities of lactococci, lactobacilli and coryneform bacteria and to determine the individual and interactive effects of temperature, pH and NaCl concentration on these enzyme activities which may have a role in flavour development during cheese ripening. A subcellular fractionation protocol and specific enzyme assays were used, and a quadratic response surface methodology was applied. The majority of the strains (21 of 33) had detectable cystathionine lyase activity the level of which varied between strains. L-Methionine aminotransferase activity was observed in only 3 strains. The cystathionine lyase activities of *Lactobacillus reuteri* DSM20016, *Lactococcus lactis* subsp. *cremoris* MG1363, *Brevibacterium linens* 10 and *Corynebacterium ammoniagenes* 8 and the L-methionine aminotransferase activity of *Lb. reuteri* DSM20016 had temperature and pH optima of 30-45C, and 7.5-8.0, respectively. As shown by quadratic response surface methodology, these enzymes retained activities in the range of temperature, pH and NaCl concentration characteristic of the cheeses from which the bacteria originated. The results of this study contribute to knowledge about the role of amino acid catabolic enzymes in flavour development in cheese during ripening.

609 Headspace analysis of volatile compounds in Monterey Jack goat milk cheese. R. Attaie^{*1}, Prairie View A&M University, Prairie View, TX.

Samples of goat Monterey Jack cheese were used for analyses of volatile compounds on day 1 and at 6 week intervals for 30 weeks during aging. These cheeses were vacuum-packed and stored at 4 to 5C for sampling and aging. Triplicate 0.5 g samples of cheese were placed in 20 ml vials of headspace analyzer (HS 40XL, Perkin Elmer, Norwalk, CT) and heated at 120 C for 60 min while rotating. The needle temperature was kept at 120 C and the transfer line was set at 150 C. Samples were pressurized for 0.5 min prior to injection and the injection time was 0.1 min. Analyses were performed using a bonded polyethylene glycol fused silica capillary column (Supelcowax-10, 60 m x 0.32 mm i.d., 0.25-m coating thickness; Supelco Inc., Bellefonte, PA). Gas chromatography was performed with a model HP 5890 Series II (Hewlett-Packard, Avondale, PA) equipped with a flame ionization detector. Ultra-high purity helium at 1.5 ml/min and 30 ml/min was used as carrier and makeup gas, respectively. Ultra-high purity hydrogen (30 ml/min) and high purity air (400 ml/min) were used for flame ionization detector. Detector temperature was at 250 C, whereas the column oven temperature was increased from 40 to 220 C at 3 C/min after an initial hold at 40 C for 2 min. The peak areas of compounds from gas chromatographic responses were measured quantitatively by a model HP 3396 Series II integrator (Hewlett-Packard). Both the integrator attenuation and threshold were set at 2. The following volatile compounds that contribute to flavor of goat Monterey Jack cheese were identified: propionaldehyde, butanal, methanol, ethanol, pentanal, 2,3-butanedione, propanol, 2-hexanone, 3-ethyl-2-pentanone, butanol, 2-heptanone, pentanol, 3-methyl-2-pentanol, 3-hydroxy-2-butanone, hydroxy acetone, 2-nonanone, acetic acid, 2-decanone, 2,3-butanediol, butanoic acid, 2-methyl butanoic acid, pentanoic acid, hexanoic acid, heptanoic acid, octanoic acid, and nonanoic acid.

Key Words: Goat cheese, Flavoring compounds, Ripening

610 Effect of microbial exopolysaccharide on functionality in high moisture cheese. T. J. Singleton^{*1}, D. J. McMahon¹, J. R. Broadbent¹, and C. J. Oberg², ¹Western Dairy Center, Utah State University, ²Weber State University.

Functional attributes of cheese such as shreddability and melt are dramatically affected by cheese moisture level. Previous work by our group has demonstrated that the addition of *Streptococcus thermophilus* MR1C, a strain that produces a large capsular exopolysaccharide (EPS⁺), to cheese results in a significant increase in the cheese moisture level. The objectives of this study were to determine if the addition of MR1C could be used to improve shreddability in high moisture American style cheese. Stirred curd cheeses were manufactured to contain equivalent moisture levels using either MR1C (41.4 - 43.7% moisture) or a non EPS-producing (EPS⁻) derivative of MR1C (40.5 - 44.4% moisture). The suitability of individual cheeses for shredding was determined by rheometry and texture profile analysis. Cheese firmness was determined after 1, 3, and 6 weeks of aging, then the cheese was shredded, and 3% (wt/wt) powdered cellulose was added to prevent caking. The cheese was packaged with a nitrogen gas flush, and melt properties were measured periodically. When cheeses with the same moisture content (i.e., 41.6 ± 0.2%) were compared over the 6 wks of storage, there was no overall significant affect on hardness although there was a significant week * culture interaction ($P = 0.026$). The (EPS⁺) cheese was softer at wk 1, then became harder at wk 3, but softened by wk 6. There was also a tendency ($P = 0.095$) for the (EPS⁺) cheese to be less adhesive than the (EPS⁻) cheese. There were no overall differences in elasticity or viscosity, and the cheeses melted to the same extent after 6 wks storage from when the cheese was shredded.

Key Words: Exopolysaccharide, Functionality, American style

611 Relationship between chemical, physical and sensory properties for pasta filata and stirred curd LMPS Mozzarella cheeses. C. M. Chen^{*}, A. L. Dikkeboom, M. E. Johnson, and M. G. Zimbric, Wisconsin Center for Dairy Research.

Chemical (pH, TCA sol N) and physical properties (free oil release, melt profile) of LMPS Mozzarella (46.4.9% moisture, 42.8.9% FDM) were correlated to sensory characteristics. Descriptive taste panelists scored the degree of skinning (none to pronounced), chewiness (tough/chewy to tender/fluid), and preference (dislike to like) of cheese on pizza pies cooked in traditional and forced air ovens. Stirred curd Mozzarella tended to exhibit more skinning than pasta filata Mozzarella. In a traditional oven the degree of skinning remained constant (very slight, all ages). In a forced air oven, cheeses had an increased skinning after 10 d (slight to definite). For the stirred curd Mozzarella in a forced air oven there was a high correlation between the skinning and softening temperature (negative, $R^2 = .95$) and proteolysis (positive, $R^2 = .89$). Cheese chewiness was influenced by the age, manufacturing protocol, and to a lesser extent, oven type. Stirred curd Mozzarella was more fluid/tender than the pasta filata Mozzarella, and cheeses baked in a forced air oven tended to be more chewy. For stirred curd Mozzarella, softening temperature in the melt profile most highly correlated with

the chewiness scores ($R^2 = .88$). For pasta filata Mozzarella, chewiness was most highly correlated to free oil release ($R^2 = .85$). Preference was influenced by the cheese age, but not manufacturing style or oven type. Cheeses were most preferred at 10 d, with stirred curd Mozzarella being slightly more liked than the pasta filata Mozzarella. The high preference scores can be attributed to lack of skinning, slightly tender/fluid chew characteristics and more acceptable strand formation. Using the linear relationship between chewiness scores and softening temperature, one can predict that if a stirred curd LMPS Mozzarella cheeses softens between 40.5 and 43.3C it will have acceptable performance on pizza pies. Similarly, pasta filata LMPS Mozzarella with free oil release between 43 and 48% (wt free oil release/wt cheese fat) will have acceptable performance on pizza pies.

Key Words: Mozzarella, physical properties, sensory analysis

612 Reversibility of pH-induced changes in the melting characteristics and calcium distribution of Mozzarella cheese. Q. Ge, M. Almena-Aliste, and P.S. Kindstedt^{*}, University of Vermont, Burlington, VT/USA.

Previously a model system was developed to increase or decrease the pH of Mozzarella cheese through exposure to volatile ammonia or acetic acid, respectively. Changing the cheese pH in this manner caused large changes in the apparent viscosity and calcium distribution. The objective of this study was to evaluate whether these pH-induced changes are reversible. In the first experiment, representative samples of shredded low moisture part-skim Mozzarella cheese were exposed to ammonia to increase the pH by ca. 1.0 pH unit in 3 increments. After equilibration at 4°C for 24 h, the samples were analyzed for apparent viscosity and water soluble calcium. Next, the sample with the highest pH value was divided into representative subsamples and then exposed to acetic acid vapor to decrease the pH by ca. 1.0 pH unit (i.e., to the original cheese pH) in 3 increments. After equilibration at 4°C for 24 h, the subsamples were analyzed for apparent viscosity and water soluble calcium. This experiment was replicated 3 times with different batches of cheese. The second experiment was similar to the first except that the cheese pH was first decreased in 3 increments to ca. pH 4.7 and then increased. In the first experiment, increasing the cheese pH from ca. 5.3 to 6.3 resulted in linear increases in apparent viscosity and linear decreases in water soluble calcium. Upon reversal of cheese pH back to ca. 5.3, apparent viscosity decreased and water soluble calcium increased in linear manners, displaying high degrees of reversibility. In the second experiment, decreasing the cheese pH from ca. 5.3 to 4.7 resulted in nonlinear increases in apparent viscosity and water soluble calcium. Upon reversal of cheese pH back to ca. 5.3, apparent viscosity and water soluble calcium decreased in nonlinear manners, displaying high degrees of reversibility. Results indicate that the melting characteristics of Mozzarella cheese can be altered substantially and then restored by manipulating cheese pH and shifting calcium between the water soluble and casein-associated states.

ASAS Nonruminant Nutrition: Weaning Pig Nutrient Requirements

613 Effect of threonine supply on the true ileal digestibility of amino acids and on performance in weaned piglets†. L. Babinszky^{*}, J. Tossenberger, P. Horn, and R. Kovcs, University of Kaposvar, Kaposvar, Hungary.

Weaned piglets were used in a trial aimed at determining the effect of threonine supply on true ileal digestibility of amino acids and piglet performance. Digestibility studies used a total of 8 animals per treatment, growth studies a total of 96 piglets per treatment, respectively. Initial live weight was 12.4±1.8 kg in the digestibility studies, and 7.8±1.0 kg in the growth study. Nutrient content of the wheat-barley-soybean based diets of different threonine levels complied with the NRC (1998) recommendations. One kg of the basal diet contained 13.4 MJ ME, 188 g CP, 12.2 g Lys, 8.5 g M+C and 6.2 g Thr. Endogenous amino acid excretion was determined in a separate trial group (n=8) by feeding N-free diets. In the digestibility studies we used three treatments (0, 1.3 and 2.1 g crystalline Thr per 1 kg feed), and six treatments in the growth studies (0, 0.42, 0.84, 1.26, 1.67, 2.09 g crystalline Thr per 1 kg feed). The diet chemical composition was determined in accordance with

AOAC. Trial data were subjected to variance and regression analyses. Our results show that 586 mg/kg DM intake threonine was excreted in the endogenous protein. From non-essential amino acids, excretion rate of proline was highest (2321 mg/kg DM intake). The varying threonine supply did not affect the true digestibility of amino acids ($P \geq 0.05$), the digestibility of threonine, however, was improved significantly ($P \leq 0.05$). Based the regression analysis and performance studies data the true ileal digestible threonine content for weaned piglets (8 to 30 kg) can be recommended at 6.6 g per kg of diet, which corresponds to a true ileal digestible threonine to lysine ratio of 62:100.

†Trials were supported by DEGUSSA-HLS AG/Germany

Key Words: Threonine, Piglets, Digestibility

614 The optimum threonine:lysine ratio in nursery diets to maximize growth performance of weanling pigs. B. W. James*, R. D. Goodband, M. D. Tokach, J. L. Nelssen, J. M. DeRouchey, and J. C. Woodworth, *Kansas State University, Manhattan.*

The objective of this 21-d growth assay was to determine the optimal apparent digestible threonine:lysine ratio in nursery pig diets to maximize growth performance. A total of 210 pigs (initially 8.2 kg and approximately 25 d of age, PIC C22 × 327) were blocked by weight and allotted randomly to seven dietary treatments. Each treatment had six replicates and five pigs per pen. Corn, soybean meal, and spray-dried whey were analyzed for amino acid concentrations prior to diet formulation. Crystalline L-threonine was added to the basal diet (14.1% CP; 1.07% apparent digestible lysine) to provide 0.48, 0.54, 0.59, 0.64, 0.70, and 0.75% apparent digestible threonine (45, 50, 55, 60, 65 and 70% of lysine). A negative control diet (Neg) contained less L-lysine-HCl and provided 0.97% apparent digestible lysine and 0.75% apparent digestible threonine to ensure that lysine did not exceed the pigs' requirement. During the 21-d experimental period, ADG increased (linear, $P < 0.02$) as the ratio of apparent digestible threonine:lysine increased and was maximized for pigs fed 65% apparent digestible threonine:lysine. Feed intake tended to decrease (quadratic, $P < 0.09$) with increasing concentrations of apparent digestible threonine. Feed efficiency (G:F) improved (linear, $P < 0.01$) as the ratio of apparent digestible threonine:lysine increased and was maximized at 55% threonine to lysine. Plasma urea N measured on d 14 tended to decrease (linear, $P < 0.08$) with increasing apparent digestible threonine. The two-slope broken-line method predicted an approximate apparent digestible threonine requirement of 65 and 52% of apparent digestible lysine for ADG and G:F, respectively.

Item	% Threonine:Lysine						Neg
	45	50	55	60	65	70	
Days 0 to 21							
ADG, g	442	447	460	448	485	447	479
ADFI, g	804	762	758	732	815	787	829
G:F	0.55	0.59	0.61	0.61	0.60	0.61	0.58

Key Words: Threonine, Lysine, Weanling pigs

615 Effects of diet and crystalline glutamine supplementation on growth performance and small intestine morphology of weanling pigs. S. J. Kitt*, P. S. Miller, A. J. Lewis, and R. L. Fischer, *University of Nebraska, Lincoln.*

The objective of this experiment was to determine whether crystalline glutamine affects weanling pig growth and/or small intestine morphology. A total of 115, 18 (± 2)-d-old, mixed-sex pigs were used in this study. Four pigs were killed on d 0 to determine base-line intestine morphology. The remaining pigs were blocked by initial BW (6.1 \pm 1.1 kg) and randomly allotted to 16 pens and one of four dietary treatments in a 2 × 2 factorial arrangement. Treatments were two diet types (simple or complex) and two supplemental concentrations of crystalline glutamine (0 or 1%). The simple diet consisted primarily of corn and soybean meal. The complex diet consisted primarily of whey, corn, soybean meal, spray-dried plasma, and fish meal. All diets (total dietary lysine = 1.60%) were formulated to exceed all nutrient requirements (NRC, 1998). Average daily gain and ADFI were measured on d 4, 7, 14, and 21. Four pigs from each treatment were killed and duodenal and jejunal samples were collected on d 4. Intestine samples were fixed in 10% formalin and stored in 70% ethanol. Tissues samples were mounted on slides and villus height was analyzed using a commercially available software program. The complex diet improved ($P \leq 0.10$) ADG of pigs during d 0 to 4, 7 to 14, and 14 to 21. The complex diet increased ($P \leq 0.05$) ADFI during d 0 to 4, 4 to 7, 7 to 14, and 14 to 21. The simple diet increased ($P \leq 0.05$) ADG/ADFI during d 7 to 14, and 14 to 21. The addition of glutamine increased ($P \leq 0.05$) ADG/ADFI during d 14 to 21. Villus height was not affected ($P \geq 0.10$) by diet type or glutamine supplementation during d 0 to 4. These data suggest that glutamine improves growth performance in weanling pigs but does not affect villus height during the first four days after weaning.

Key Words: Glutamine, Small intestine morphology, Pigs

616 Responses of pigs and chicks to phosphorus supplementation in casein- vs soybean meal-based diets. E. G. Xavier*, G. L. Cromwell, and M. D. Lindemann, *University of Kentucky, Lexington.*

Previously, we have assessed the bioavailability of P in feedstuffs using a dextrose-dehulled soybean meal (SBM) diet (0.22% total P, 0.15% phytate P) with P sources substituted for dextrose. In some instances, it would be desirable to utilize a low-P basal diet containing no phytate P. This study was conducted to assess the suitability of semipurified diets with casein vs SBM as the protein source without and with added P (as monocalcium phosphate) for young pigs and chicks. In Exp. 1, 20 pigs (4 reps, 10.8 kg BW) were fed 5 diets (1.2% lys, 0.8% Ca) for 35 d: sucrose-dextrose (SD)-casein (15%) with 0, 0.1, and 0.2% added P or SD-SBM (40%) with 0.04 and 0.24% added P. The bioavailable P in both basal diets was 0.11%. AA (lys, thr, trp, met, arg) were added as needed. ADG, feed/gain, and breaking strength of the femurs and metatarsals were: 461, 520, 644, 470, 652 g; 2.04, 1.98, 1.89, 1.91, 1.74; 45, 80, 169, 48, 147 kg; 14.9, 22.7, 38.9, 19.6, 39.8 kg. Performance and bone traits of pigs fed the two basal diets were similar as were the linear ($P < 0.01$) responses to added P in both diets. A 14-d study was conducted with 3-d-old chicks fed casein or SBM-based diets. Chicks (4 reps of 6 chicks/pen) were fed: dextrose-starch (DS)-casein (20%) with 0.10, 0.15, 0.20, 0.25, 0.30, and 0.35% added P or DS-SBM (40%) with 0.16, 0.26, and 0.36% added P. Ca was 1.0% in all diets. The two basal diets contained 0.25 and 0.43% total P, and 0.25% non-phytate P. AA were added as needed. ADG and tibia strength were: 20.6, 23.0, 25.1, 24.4, 23.8, 25.7, 19.6, 28.5, 33.7 g; 4.6, 7.4, 9.9, 10.9, 9.7, 11.2, 2.8, 7.8, 13.9 kg. Performance was similar for chicks fed the two basal diets. Growth and bone responses to added P were linear ($P < 0.01$) for both diet types; however, responses were greater for the SBM vs casein diet, primarily due to greater feed intake (43 vs 35 g/d), thus greater P intake, of chicks fed the high-P, SBM diet. The results indicate that casein-based diets containing no phytate P should be acceptable for future P bioavailability studies with pigs and chicks.

Key Words: Pigs, Chicks, Phosphorus

617 Ideal dietary tryptophan regimen for pigs as influenced by antigen exposure. C. P. Machado*¹, T. S. Stahly¹, and T. J. Stabel², ¹Iowa State University, Ames, ²National Animal Disease Center, Ames, IA.

Pigs from a high lean strain were reared via a SEW procedure and self-fed a basal diet containing 100% of ideal ratio (IR; NRC, 1998) of digestible tryptophan (Trp) to digestible lysine (Lys). At 30 d of age, pigs were allotted within litter to one of four dietary ratios of Trp:Lys: 50, 75, 100 or 125% (day 0). The basal diet consisted of a corn-SBM-gelatin mixture containing a growth limiting amount of digestible Lys (0.95%) and all other essential amino acids, except Trp, at ratios greater than 100% of IR. Tryptophan was added as L-Tryptophan at the expense of cornstarch. Half of the pigs were administered subcutaneously a non-replicating antigen, autoclaved BCG (13 × 10⁶ CFU/mg), at a dose of 0.20 mg/kg BW on d 4, 8 and 12. BCG induces IFN-gamma synthesis and thus indoleamine 2-3 dioxygenase release, which degrades tryptophan in several body tissues. BW gain, gain:feed ratio (GF) and body nitrogen accretion (NA) were determined for three consecutive four-day periods (d 4-16). As dietary Trp:Lys ratios increased, daily BW gain (79, 280, 518, 528 g), GF (.26, .52, .71, .68) and daily NA (3.6, 8.7, 13.9, 14.3 g) increased quadratically ($P < .01$) independent of BCG and period. BCG depressed ($P < .05$) BW gain (316 vs. 386 g), GF (0.51 vs. 0.57) and NA (9.2 vs. 11.1 g) with the magnitude of the depression increasing from d 8 through 16. In conclusion, the IR of Trp:Lys (NRC, 1998) was not altered by exposure to autoclaved BCG, a non-replicating antigen.

Key Words: Pigs, Tryptophan, BCG

618 Pyridoxine (B6) metabolism and requirement in weaned piglets. J. J. Matte*, A. Giguere, and C. L. Girard, *Dairy and Swine R & D Centre, AAC, Lennoxville, QC, Canada.*

Three trials were carried out in order to determine the effects of dietary B6 and its interactions with riboflavin (B2) on metabolic criteria such as blood B6 and B2 status, insulinemic responses to *i.v* and gastric glucose, and on growth performance of piglets weaned at 2 wks of age. In

Trial 1, 36 piglets fed through a permanent gastric tube received 4 combinations of B6 and B2 supplements (ppm), 0-0, 0-25, 50-0 and 50-25. There was a marked effect ($P \leq .01$) of the B6 supplement on B6 in red blood cells (RBC) but no effect ($P \geq .20$) of B2 on B2 metabolites (riboflavin, FMN and FAD) in plasma. C-peptide and insulin responses to *i.v.* glucose decreased ($P \leq .08$ and $.03$, respectively) with B2. This B2 effect disappeared in presence of B6 after gastric glucose (interaction $B6 \times B2$, $P \leq .02$); the response was maximized with both vitamins. It seems that B6 acts via the entero-insular axis of insulin secretion. No treatment effect ($P \geq .30$) was observed on growth rate. In trial 2, treatments used in trial 1 were given to 544 piglets in commercial conditions. No effect ($P \geq .39$) of either B6 and/or B2 supplements, given during the 2 wks after weaning, was observed on growth performance between 2 (weaning) and 10 wks of age. However, the B6 profile in RBC suggested that the lack of effect on growth performance could be due to the short duration of the B6 supplementation. Another trial, under similar conditions to Trial 2, was therefore undertaken to measure the effect of the B6 supplement alone (50 ppm) given between 2 (weaning) and 10 weeks of age. Despite a marked and persistent increase ($P \leq .01$) of B6 in RBC, the effect on growth performance was marginal and even slightly (less than 2 %) detrimental ($P \leq .03$). In conclusion, although a dietary supplement of 50 ppm of B6 was necessary to saturate the RBC pool in B6, the basal provision of dietary B6 (analytical level of 7.6 ppm) in the present diets, already 5 times higher than the NRC (1998) recommendation, appears sufficient for growth performance during the post-weaning period in piglets.

Key Words: Early-weaned piglets, Pyridoxine, Riboflavin

619 Effect of desiccated bile salts on fat digestibility in early-weaned pigs. J. Orban*¹ and B Harmon², ¹*Southern University*, ²*Purdue University*.

Thirty-six early-weaned pigs averaging 13 to 14 days of age were fed diets containing 7% hog fat and desiccated hog bile at 0, 0.15, 0.30, and 0.45 % in a metabolism study to determine the response of the pigs to fat digestibility and nutrient metabolism. The study was conducted in two trials. In Trial 1, a total of 24 barrows were used, placing 2 barrows per pen in a metabolism room with 12 metabolism crate-pens. Dietary treatments were replicated 3 times among pens and pigs in a pen constituted an experimental unit. Trial 2 was conducted similarly to Trial 1, except 12 barrows were used with one barrow per pen. In both trials, pigs were acclimated for 6 days and fasted 24 h prior to providing diets at the rate of 5% of the pigs' body weight. Fecal samples were collected in a 5 to 6-d period for digestibility assay. Results showed that the inclusion of desiccated hog bile in diets of early weaned pigs resulted in a significant ($P < 0.01$) linear increase in fat digestibility (from 93 to 97%) with respect to bile level (from 0 to 0.45%) in the diet. General animal performance (feed intake, weight gain and feed efficiency) was not affected by the presence of bile in the diet. The digestibility of dry matter, nitrogen and gross energy also was not affected by the presence of bile in the diets of early-weaned pigs. Results suggest that the inclusion of desiccated hog bile in the diets of early-weaned pigs improved their ability to digest dietary fat with no adverse effect on general performance and nutrient metabolism.

Key Words: Desiccated hog bile, Fat digestibility, Early-weaned pigs

620 The efficacy of zinc methionine and zinc oxide in promoting nursery pig performance. G. A. Hollis*, D. C. Mahan, S. D. Carter, T. D. Crenshaw, G. L. Cromwell, G. M. Hill, A. J. Lewis, and T. L. Veum, *NCR-42 Swine Nutrition Committee*.

Previous research has suggested that organic Zn sources could be added to pig nursery diets at dietary levels below the pharmacological levels of ZnO commonly used in pig starter diets and still produce similar growth promotion benefits. A regional study was therefore conducted using five treatments to compare the efficacy of supplemental Zn methionine at levels of 125, 250, and 500 ppm Zn, 2,500 ppm Zn from ZnO, and a basal diet that contained a conventional Zn level. A total of 616 pigs was used in a randomized complete block design conducted at seven university research stations in 26 replicates. Pigs were weaned at an average of 21 d of age and 6.3 kg BW, and housed with 4 to 6 pigs/pen (pig number per pen was constant within replicate). Diets fed during d 0 to 14 and 15 to 28 d were formulated to contain 1.40% and 1.25% lysine (total) levels, respectively. Diet analyses demonstrated that the basal diets averaged 124 ppm Zn. Analyzed Zn contents of treatment

diets were close to calculated values when the amount in the basal diet was added to the supplemental level. During the initial 7-d period, there were no treatment differences ($P > 0.15$) in daily gains or feed intakes. Both sources of Zn improved performance responses after 7-d postweaning when compared to pigs fed the basal diet. From 7 to 14 d, 0 to 14 d, 14 to 28 d, and for the overall 28-d period, pigs fed the ZnO source had higher gains ($P < 0.05$) than pigs fed Zn methionine. Feed intakes were unaffected by treatment during the initial 14 d postweaning, but from d 14 to 28 and for the 0 to 28-d period feed intake was higher when ZnO was fed ($P < 0.05$). Overall ADG, ADFI, and G/F ratio for the basal, three levels of Zn methionine, and ZnO treatments were: 371, 391, 389, 396, 415 g/d; 586, 618, 607, 617, 642 g/d; 0.633, 0.633, 0.641, 0.642, 0.642, respectively. These results demonstrated that lower dietary levels of Zn methionine did not achieve the improved performance responses as did 2,500 ppm Zn from ZnO when fed to weaned pigs.

Key Words: Zinc, Weaning, Pigs

621 Effects of iron administration on complete blood counts of nursing pigs. S.D. Carter, S.L. Mandali, and J.S. Park*, *Oklahoma State University, Stillwater*.

Two experiments were conducted to determine the effect of iron administration on body weight and complete blood counts (white blood cells, WBC; red blood cells, RBC; hemoglobin, HGB; hematocrit, HCT; mean cell hemoglobin (MCH) and concentration, MCHC; and platelets, PLT) of nursing pigs. In Exp. 1, 12 pigs from 6 litters (2 pigs/litter) were allotted randomly by BW on the day of birth (d 0) to either a saline or 150-mg injection of Fe as iron dextran. Pigs were bled on d 0, 1, 2, 4, 8, 12, 16 and at weaning. In Exp. 2, 18 pigs from 9 litters (2 pigs/litter) were allotted as in Exp. 1 and bled on d 0, 2, 4, 8, 10, 12, 16, and at weaning. Whole blood samples were analyzed within 2 hr of collection. Injections of saline or Fe were administered on d 2 following blood collections. Average weaning age was 20.5 d in each experiment. Initial (d 0) BW and HGB, averaged across experiments, were 1.60 kg and 9.52 g/dL, respectively. There were no differences ($P > 0.10$) in BW or blood variables on d 0, 2, or 4. Body wt tended to increase at a faster rate in pigs given Fe vs saline-treated pigs from d 4 to weaning (Day x Trt, $P < 0.10$). However, pigs injected with Fe tended to be heavier ($P < 0.12$) only at weaning. HGB, HCT, MCH, and MCHC in saline-treated pigs declined with age, but they increased with age in pigs given Fe (Day x Trt, $P < 0.01$). This divergence occurred by d 4 (Exp. 2) or d 8 (Exp. 1), and pigs given Fe had greater values ($P < 0.01$) each day following d 4. Blood HGB in saline-treated pigs fell below 7 mg/dL by d 8 and 6 mg/dL by d 12 in each experiment. WBC and RBC were reduced ($P < 0.10$) from d 8 to weaning in saline- vs Fe-treated pigs; however, PLT were markedly increased ($P < 0.04$). Even though pigs treated with saline were severely anemic, survival to weaning was 100%. Body weight was not correlated ($P > 0.10$) with any of the blood counts. These results suggest that Fe administration has profound effects on blood counts, in addition to HGB and HCT. However, in these pigs weaned at less than 21 d of age, iron deficiency had minimal impact on performance or survival to weaning.

Key Words: Pigs, Iron, Hemoglobin

622 Effects of L-carnitine and soybean oil on growth performance in weanling pigs. M. J. Rincker*¹, S. D. Carter¹, R. W. Fent¹, B. W. Senne¹, and K. Q. Owen², ¹*Oklahoma State University, Stillwater*, ²*Lonza, Inc., Fairlawn, NJ*.

Two-hundred sixteen weanling pigs were used in a 2 x 2 factorial arrangement of treatments in two separate experiments to evaluate the effects of L-carnitine (0 vs 50 ppm) and soybean oil (SBO; 0 vs 5%) on growth performance. In Exp. 1, 96 weanling pigs (6.0 kg; 18 d) were randomly allotted based on BW, sex, and litter to four dietary treatments (6 pens/trt of 4 pigs/pen). In Exp. 2, 120 pigs (5.6 kg; 18 d) were randomly allotted to the same treatments as in Exp. 1 (6 pens/trt of 5 pigs/pen). The four dietary treatments were: 1) 0% SBO and 0 ppm L-carnitine; 2) 0% SBO and 50 ppm L-carnitine; 3) 5% SBO and 0 ppm L-carnitine; and 4) 5% SBO and 50 ppm L-carnitine. Pigs were fed in three dietary phases (P1: d 0-10; P2: d 11-24; and P3: d 25-38 with 1.6, 1.4, and 1.2% Lys, respectively). Phase 1 and 2 diets were complex corn-soybean meal-dried whey based containing additional protein sources, while diets for P3 were corn-soybean meal based. Pigs and feeders were weighed weekly for the determination of ADG, ADFI,

and G:F. There were no treatment by experiment interactions; therefore, data were pooled across experiments (12 pens/trt). ADG, ADFI, and G:F for the 38-d study were: 394, 398, 370, and 391 g; 566, 567, 536, and 540 g; and .696, .703, .690, and .725, respectively. Pigs fed SBO tended ($P < 0.10$) to grow slower and consume less feed compared to those not fed SBO, but G:F was not affected ($P > 0.10$). The addition of L-carnitine did not affect ($P > 0.10$) ADG or ADFI; however, it did improve ($P < 0.01$) G:F. Also, the increase in G:F associated with L-carnitine was more pronounced in pigs fed SBO than those not fed SBO (carnitine \times SBO, $P < 0.08$). The greatest response to L-carnitine occurred in P2 with an increase in ADG ($P < 0.05$) and G:F ($P < 0.01$). In contrast, the response (G:F) to SBO was greatest during P3. These results suggest that the addition of 50 ppm L-carnitine improved growth performance in weanling pigs; however, supplemental L-carnitine was more effective when SBO was provided in the diet.

Key Words: Carnitine, Fat, Weanling pigs

623 Effects of L-carnitine on carcass composition and tissue accretion in weanling pigs. M. J. Rincker^{*1}, S. D. Carter¹, R. W. Fent¹, B. W. Senne¹, and K. Q. Owen, ¹Oklahoma State University, Stillwater, ²Lonza, Inc., Fairlawn, NJ.

We have previously reported that supplementing L-carnitine to the diet of weanling pigs improved growth performance and nutrient digestibility. Additionally, the effects of L-carnitine on carcass composition and tissue accretion rates in weanling pigs were evaluated. Six sets of four

littermate barrows (4.9 kg; 18 d) were housed individually and randomly allotted to four dietary treatments containing 0, 25, 50, or 100 ppm L-carnitine. Pigs were fed in three dietary phases (P1: d 0-10; P2: d 11-24; and P3: d 25-38 with 1.6, 1.4, and 1.2% Lys, respectively). Phase 1 and 2 diets were complex corn-soybean meal-dried whey based containing additional protein sources, while diets for P3 were corn-soybean meal based. All diets contained 5% soybean oil. At the conclusion of the experiment, each pig was killed and ground for determination of carcass composition. In addition, a fifth littermate from each set of pigs was killed at the beginning of the experiment for initial body composition. Percentages of protein and fat in the carcass were, respectively: 13.42, 14.01, 13.99, and 14.07; and 8.35, 7.42, 7.17, and 6.89. Increasing L-carnitine increased (linear, $P < 0.01$) the percentage of protein and decreased (linear, $P < 0.01$) the percentage of fat. Accretion rates for protein, fat, and energy were, respectively: 33, 42, 48, and 45 g/d; 21, 21, 24, and 21 g/d; and 379, 425, 483, and 426 kcal/d. A quadratic increase ($P < 0.05$) in total (g) and rate (g/d) of protein and energy accretion was observed with increasing L-carnitine. Also, the ratio of protein accretion to fat accretion (1.59, 2.07, 2.08, and 2.23) improved (linear, $P < 0.01$) with added L-carnitine. In general, the response to L-carnitine tended to plateau at 50 ppm. These results suggest that supplementation of L-carnitine improved the rate of protein and energy accretion in weanling pigs. Furthermore, an improvement in carcass composition was observed as the ratio of protein to fat accretion increased with L-carnitine addition.

ASAS/ADSA Animal Health: Dairy

624 Prevalence of bovine mastitis increases with average linear score and has possible implications for genetic selection. David Wilson^{*1}, Ruben Gonzalez¹, George Shook², Linda Garrison-Tikofsky¹, and Ynte Schukken¹, ¹Cornell University, Ithaca, NY, USA, ²University of Wisconsin, Madison, WI, USA.

Bovine genetic selection indices are critical to ranking cows and bulls to be parents of the next generation. This retrospective study was conducted to determine the relationship between average Linear Score (AVELS) of the SCC of the current lactation and the overall prevalence of intramammary infections (IMI) among cows within each one-log interval of AVELS using the standard LS scoring system. The main objective was evaluation of AVELS as a proxy variable for mastitis and therefore a potential tool for genetic selection in favor of bulls and cows whose offspring are less likely to contract IMI. For 65,229 cows with an AVELS for the current lactation recorded at the time that they also had milk culture performed, there was a significant positive association between the log intervals of AVELS and overall prevalence of IMI in cows within each log of AVELS. This relationship was found for the mastitis pathogens *Streptococcus agalactiae*, *Staphylococcus aureus*, streptococci other than *Strep. agalactiae*, *Escherichia coli*, *Klebsiella* spp., *Serratia* spp., yeast, *Prototheca* spp., *Arcanobacterium pyogenes*, and *Mycoplasma* spp. (chi-square, $P < 0.001$). For example, for cows with AVELS < 1.0 , the prevalences of *Streptococcus agalactiae*, *Escherichia coli*, and *Mycoplasma* spp. were 0.6%, 0.2%, and 0.0%, respectively; for cows with AVELS > 9.0 , their prevalence was 7.0%, 1.6%, and 0.8%, respectively. Overall prevalence of IMI was 18% for cows with AVELS < 1.0 , and increased to 74% for cows with AVELS > 9.0 . The heritability of mastitis characteristics range from .10-.17. This together with the demonstrated value of LS as an indirect indicator of mastitis suggests a need for increased weight given to average LS in genetic value estimate equations. Results will be presented and discussed in detail for 13 mastitis agents.

Key Words: Mastitis, Linear Score, Genetics

625 Dairy farmers and veterinarians: partners in profit. A.W. Jalvingh^{*}, CR Delta, Arnhem, The Netherlands.

Modern dairy farming imposes increasing demands on farmers' management skills to maintain profit and guarantee continuity of the farm. The role of the veterinarian on the dairy farm has over time moved from curing diseases to preventing diseases and managing risks. Farmer and veterinarian together form a perfect combination to improve the health status, and thus technical and economic results. To stimulate Dutch

farmers to use the veterinarian more as their advisor in problem analysis the project "Partners in Profit" was initiated. Partners in profit is a collaboration of CR Delta, a farmers' cooperative in cattle improvement, KNMvD, the Dutch society of vets, and Pfizer Animal Health, a pharmaceutical company. The basic idea is that participating vets receive information on participating farms based on data collected by CR Delta through milk recording, AI and other services. In the first year attention is focused on fertility, the second year on udder health and the third year on other health issues. In the first year 300 veterinary practices and 8000 dairy farmers are participating and will receive the first reports on fertility in February 2001. The vet receives a report with all the relevant parameters of the past year. One overview contains the average values for the practice as a whole and for the group participating farmers in the practice, and next to that the country averages are given and the averages of the group of farms with the 25% lowest values and 25% highest values. This report gives an idea of how the farmers in the practice on average are performing related to national averages and the observed variation. Next to that there is an overview which contains the basic farm figures over the past year from participating farms in the practice. Based on this information the vet can contact the farm without any further obligations. Vet and farmer together will decide whether they want to be partners in profit. For this second step, they can order an in-depth report, with figures for the last month, quarter, half year, year as well as target values. These in-depth reports form a good starting point for the analysis of the strong and weak points of the farm and to formulate further actions to improve the farm's health status.

626 Evaluation of early detection of induced *Staphylococcus aureus* mastitis using infrared thermography. M. M. Schutz^{*1}, S. D. Eicher², J. M. Townsend¹, G. Shaw³, and D. M. Kocak³, ¹Purdue University, ²USDA-ARS, ³eMerge Interactive.

Increased blood flow and temperature increases may accompany initial immune response to a mastitic infection. The objective of this study was to determine whether infrared (IR) thermography could aid in early detection of mastitis by identifying these symptoms. Six multiparous, late-lactation Holstein cows were kept in a tie stall barn for nine days. Cows were separated by an empty stall and milked separately from other herdmates at 0600 and 1700. One forequarter of each of four cows was randomly selected and infused on d 5 with 450 cfu of *S. aureus* (Newbould). Infrared thermographs were taken from approximately 1.5 m of

each fore quarter and the rear quarters every .5 h for 2 h before and after each milking on all 9 d. A black body temperature standard was used to calibrate IR temperatures (IRT) before, amid, and after each series of images. Environmental conditions of temperature, humidity, and barometric pressure were recorded prior to collection of images to provide additional IR correction, if necessary. Rectal temperatures (RT) and bacteriological cultures were collected at scheduled days and times for mastitis detection using conventional methods. Challenged quarters were infused with cephalopine sodium for consecutive milkings upon observation of clinical mastitis, or on d 9. Three of four challenged cows developed clinical mastitis ($\chi^2=3$, $p=.08$, $DF=1$) although positive *S. aureus* cultures and elevated RT were noted only in two. Overall, patterns of IRT correlated to RT ($r=.58$, $t=52.5$, $p<.001$), but differences among quarters were apparent. IRT increases accompanied elevated somatic cell scores in challenged quarters ($r=.33$, $t=2.04$, $p<.05$), but not in other quarters ($r=-.33$, $t=-4.13$, $p<.001$). Adjustment of rolling average (12 and 24 h) RT and IRT for ambient temperatures accounted for diurnal variation. Results from this study show IRT can detect elevated temperatures associated with mastitis, but are unlikely to detect mastitis earlier or be more cost effective than existing methods.

Key Words: Mastitis, Infrared, Temperature

627 Effects of acidosis inducing diets on memory responses to viruses in Holstein steers. D. C. Donovan^{*1}, A. R. Hippen¹, and D.J. Hurley¹, ¹South Dakota State University, Brookings.

Cattle are more susceptible to infectious disease when acidotic. Susceptibility to disease is dependent on the level of infectious agent and the immune response to the agent. To evaluate the relationships between acidosis and immune responses, Holstein steers (220 +/- 43 kg) were used in a 4 x 4 Latin square examining the influence that acidosis inducing diets exert on memory responses to bovine viral diarrhea virus (BVDV), bovine respiratory syncytial virus (BRSV), parainfluenza type 3 (PI3), and bovine herpes virus (BHV-1) tested in vitro. Diets were designed to evaluate the effects of the metabolites, lactate and ketone bodies, or mineral salts in decreasing blood pH. Diets were defined as control (45% concentrate, C), high grain (100% concentrate, HG), supplemented with 1,3-butanediol (700 ml/d, BD), or anionic salts (dietary cation anion difference of -30 mEq/100 gm, AS). Data was collected on day 18 and 20 of each period. Blood pH was decreased in treated steers and the decrease was greatest in AS (7.38, 7.37, 7.32, and 7.36 for C, BD, AS, and HG, respectively; $P < 0.009$ for treatments; $P < 0.05$ for AS vs. C). Decreased T cell proliferation in response to *Staphylococcus aureus* exotoxin B was observed in treated steers (54816, 37654, 35226, and 29459 cpm for C, AS, BD, and HG; $P < 0.006$), but was not correlated to blood pH. Increased T cell memory response to BVDV stimulation was observed in treated animals (133, 2428, 1407, and 2429 cpm for C, AS, BD, and HG; $P = 0.11$), and was negatively correlated to blood pH ($r = 0.45$, $P < 0.01$). Increased T cell memory response to BRSV stimulation was observed in steers supplemented with BD (516, 244, 2051, and 336 cpm for C, AS, BD, and HG; $P = 0.06$), but was not correlated to blood pH. Memory response to PI3 tended to be increased in steers supplemented with AS (9, 174, 36, 25 for C, AS, BG, and HG; $P < 0.10$), and was strongly, negatively correlated with blood pH ($r = 0.51$, $P < 0.01$). Diets that induced an acidotic state, decreasing blood pH, had an effect on immunity. Memory of T cells was affected differentially in response to ketoacidosis and mineral acidosis. Therefore, acidosis may increase susceptibility to disease. The effects of acidosis on viral load remain to be evaluated.

Key Words: Acidosis, T Cell Memory, Virus

628 Association between retained placenta and blood interleukin-8 concentration and lack of association of retained placenta with energy and calcium metabolic profiles. Kayoko Kimura^{*1}, Jesse Goff¹, Timothy Reinhardt¹, and Shigeru Sato², ¹National Animal Disease Center, USDA-ARS, ²NOSAI Miyagi, Japan.

We previously reported that neutrophil function (chemotaxis and myeloperoxidase activity) of cows that would develop retained placenta (RP) was significantly decreased compared to neutrophil function of cows that expelled the placenta normally (No RP) (J Dairy Sci 83,Suppl.1:3) using 142 cows (20 RP, 122 No RP cows). Why neutrophil function of cows with RP is impaired remains unknown. We

hypothesized that the metabolic state of the cow prior to calving influences neutrophil function. Using plasma obtained during the cited study, we examined the relationship between energy or calcium status during the periparturient period and the development of RP. In addition an ELISA for interleukin-8 (IL-8), a cytokine critical to neutrophil chemotaxis and activation, was performed on a subset of 8 RP and 8 No RP cows. Plasma calcium and phosphorus concentrations decreased at calving to the same extent in both RP and No RP cows. Energy status at parturition, as assessed by plasma NEFA (0.53 ± 0.14 meq in RP and 0.67 ± 0.07 meq in No RP) and -hydroxybutyrate (8.76 ± 1.74 mg/dl in RP and 12.0 ± 1.90 mg/dl in No RP) concentrations were also essentially the same in both RP and No RP cows. IL-8 concentration at calving in plasma of No RP cows (125 ± 14 pg/ml) was significantly higher than in RP cows (61 ± 15 pg/ml). It remained higher throughout the first 2 weeks of lactation as well. Fetal cotyledons were collected within 4 h of calving in a subset of 3 RP cows and 15 No RP cows for histologic evaluation. Binucleate giant cells, thought to produce placental lactogen, are reported to be present in "retained" placenta and absent in placenta that are expelled normally. Binucleate giant cells comprised 14.7% of the total epithelial cells in retained placenta and 14.2% of epithelial cells in placenta expelled normally. We are unable to confirm previous reports suggesting retention of binucleate giant cells is a cause of RP. We also could not show an association between plasma calcium or energy status at calving and retained placenta. We did find further evidence that the immune system of the cow may be involved in RP as IL-8 concentration at calving was significantly lower in cows developing RP.

Key Words: Retained placenta, Interleukin-8, Binucleate giant cell

629 Impact of leptin on in vitro cytokine production during early and mid lactation. Gina M Pighetti^{*}, University of Tennessee, Knoxville, TN USA.

The ability of leptin to regulate energy stores within the body has allowed it to evolve and help regulate other energy-dense processes such as reproduction and immunity. However, very little if any information exists regarding the consequences of leptin on bovine immune function. Therefore, the objective of the current study is to compare the in vitro responses of peripheral blood mononuclear cells isolated from both mid-to-late (ML) and periparturient (PP; within 3 days after calving) dairy cows to leptin. Increasing doses of concanavalin A (0-2 ug/ml) and/or recombinant human leptin (0-50 ng/ml) were administered to the cells 12 hours prior to collection for RNA. Interferon (IFN)- γ and interleukin (IL)-4 mRNA were measured as indicators of cellular and humoral immunity, respectively. Preliminary evidence indicates that cells isolated from PP and ML cows respond in a similar fashion to leptin, but vary as to which concentrations they respond to. Leptin approximately doubled the relative expression of IFN γ mRNA in cells from ML cows, regardless of dose. In contrast, cells from PP cows only responded to the lowest leptin dose (1 ng/ml). Little, to no IL-4 mRNA was produced in stimulated cells collected from ML lactation cows. However, costimulation with a minimum of 5 ng/ml leptin increased IL-4 mRNA to levels comparable to IFN- γ . In contrast, it required 50 ng/ml to achieve the same effect in cells from PP dairy cows. These preliminary results indicate that immune cell populations are responsive to leptin and that this response can vary with the stage of lactation. Moreover, with the fluctuations in leptin that can occur with body condition and pregnancy, it is imperative to further investigate this link between leptin, energy metabolism/storage, and immune function in order to promote better animal health.

Key Words: Immunity, Leptin, Stage of lactation

630 Serum antibody responses in Holstein cows immunized five times with J5 Bacterin. K. Smith^{*}, C. Phipps, J.L. Burton, and R.J. Erskine, Michigan State University, East Lansing, MI.

In a previous study of J5 bacterin-immunized dairy steers, we observed significantly higher and more sustained serum IgM, IgG1, and IgG2 antibody responses when animals were immunized 5 times than when they were immunized 3 times. We also showed that the hyperimmune steer serum was highly effective at promoting neutrophil phagocytosis of opsonized *E. coli in vitro*. Because of the implications of these results for improved resistance to coliform mastitis in vaccinated dairy cows, we were curious to know if five immunizations with J5 bacterin (Pharmacia

and Upjohn, Kalamazoo, MI) would elicit better antibody responses in lactating cows than the currently recommended 3-immunization protocol. Therefore, our objective was to monitor anti-J5 antibody response profiles in dry and lactating Holstein cows immunized either 3 times ($n = 5$) or 5 times ($n = 5$) with J5 bacterin. All cows received the first 3 immunizations according to manufacturer's recommendation (5 ml of bacterin administered subcutaneously at dry off, at 30 days dry, and within a few days of calving), and the 5-shot group received two additional immunizations (5 ml) at 30 and 60 days in milk. Antibody response profiles were monitored (ELISA) on the 7th day following each immunization. Results showed that 3 immunizations caused modest increases in serum anti-J5 IgM and IgG1 antibodies that persisted until 60 days in milk, but was not effective in eliciting an IgG2 antibody response. Five immunizations caused an approximately 2-fold higher IgG1 antibody response than the 3-shot protocol, and successfully elicited IgG2 isotype switching. Based on these results we conclude that 5 immunizations of J5 bacterin may be more effective than 3 immunizations in eliciting higher, more sustained humoral immunity against coliform bacteria that cause mastitis.

Key Words: Hyperimmunization, J5 Bacterin, Antibody Responses

631 Changes in the Amino Acid Ratio and Ammonia Concentration in Plasma and Cerebrospinal Fluid of Dairy Cows suffering from Hepatosteatorrhea and Liver Failure. J. Rehage*, C. Meier, M. Kaske, and H. Scholz, *Veterinary School of Hannover, Hannover, Germany.*

Cows with liver failure develop clinical signs of a hepatic encephalopathy (HE), such as loss of appetite, general depression, ataxia, recumbency or even coma. The pathogenesis is still unclear. The objective was to study the amino acid ratio and ammonia concentrations in plasma and cerebrospinal fluid (CSF) in German HF cows with fatty liver and HE. The study included healthy controls ($N = 19$; age: 5.8 ± 1.2 years, liver triglyceride: 19.5 ± 3.2 mg/g FW [mean \pm s]; dry), uncomplicated fatty liver cows (group FL; $N = 12$; age: 5.1 ± 1.2 years; 14.3 ± 3.2 days p.p.; liver triglyceride: 57.2 ± 19.7 mg/g FW) and 31 cows with HE (age: 5.3 ± 1.2 years; 12.3 ± 3.9 days p.p.). Mild signs of HE showed 17 cows (group HE1; no appetite, general depression, ataxia; liver triglyceride: 65.3 ± 18.9 mg/g FW) and 14 severe HE (group HE2; recumbency, coma; liver triglyceride: 78.5 ± 23.5 mg/g FW). CSF was obtained lumbally, blood samples were taken from the jugular vein for amino acids (AA) and from the auricular artery for ammonia determinations. The amino acid pattern was measured by HPLC and the amino acid ratio was calculated from the concentrations [μ mol/L] of (VAL + LEU + ILE / (PHE + TYR)), ammonia was determined on an automated analyzing system. Compared to controls and FL cows in HE cows plasma levels of branched chain amino acids (VAL, ILE, LEU) decreased considerably and those of aromatic AA (PHE, TYR) increased slightly, whereas in CSF the increase in aromatic AA levels was most prominent. The mean amino acid ratio in plasma of controls, FL cows, HE1 and in HE2 was 6.4 ± 0.5 , 6.1 ± 0.5 , 3.5 ± 0.3 , 2.9 ± 0.4 ($p < 0.01$), and in CSF 6.2 ± 0.3 , 5.5 ± 0.4 , 2.8 ± 1.0 , 3.3 ± 0.6 ($p < 0.01$), respectively. Mean ammonia concentrations [μ mol/L] in controls, FL, HE1 and HE2 in plasma were 18.9 ± 8.7 , 20.5 ± 9.5 , 50.3 ± 12.8 , 65.8 ± 14.1 ($p < 0.01$), and in CSF 7.4 ± 3.8 , 11.1 ± 6.4 , 26.8 ± 10.7 , 33.5 ± 13.2 ($p < 0.01$), respectively. Results revealed that liver function in dairy cows has as in monogastric species a substantial impact on the plasma and CSF amino acid pattern as shown by the amino acid ratio and that the occurrence of HE is correlated to ammonia concentrations in plasma and CSF.

Key Words: Dairy cows, Ammonia, Amino acids

632 Growth Responses of *Escherichia coli* to Purified Immunoglobulin G from Cows Immunized with Ferric Citrate Receptor FecA. K. Takemura*, J. S. Hogan, and K. L. Smith, *Ohio Agricultural Research and Development Center, The Ohio State University.*

The effect of purified immunoglobulin (Ig) G from cows immunized with FecA on growth of *Escherichia coli* was investigated in an in vitro assay. Twenty-one cows were assigned to one of 3 treatments: 1) FecA immunized cows, 2) *E. coli* J5 immunized cows, and 3) unimmunized control cows. Immunizations were: 1) subcutaneous injection at 14 d prior to drying off, 2) intramammary infusion at 7d after drying off, and

3) subcutaneous injection at 28 d after drying off. FecA used to immunize cows was purified from *E. coli* UT5600/pSV66 by ion exchange chromatography. Protein G affinity chromatography was used to purify IgG from pooled colostrum whey from each treatment group. The whey from FecA immunized cows had significantly higher IgG titers against FecA compared with whey from *E. coli* J5 immunized cows and control cows. Fourteen isolates of *E. coli* from the cases of naturally occurring mastitis were cultured at 37°C for 6 h under iron restricted conditions in a chemically defined medium containing $200 \mu\text{M}$ α - α' -dipyridyl and 1 mM citrate. Bacterial cells were washed and resuspended in PBS to approximately 10^3 cfu/ml. The bacterial cells were mixed with purified IgG at concentrations of 0, 2, and 4 mg/ml and incubated at 37°C . Fifty μM FeCl_3 was added to the assay containing 4 mg/ml IgG to determine the effects of exogenous iron on bacterial growth. At 0, 6, 12, and 24h incubations, samples were taken and serially diluted to culture on MacConkey agar plates. Iron restriction decreased rates of the growth, but did not reduce peak bacterial counts. The presence of IgG decreased the growth of *E. coli* under iron restricted conditions; however, the growth did not differ among IgG sources nor between IgG concentrations. The addition of exogenous iron overrode the inhibitory effects of the iron depletion and the presence of IgG, but did not restore growth of *E. coli* to that comparable in iron replete control medium.

Key Words: Mastitis, FecA, IgG

633 Opsonic activity of serum and whey from cows immunized with the *Escherichia coli* ferric citrate receptor. A.J. Wise*, J.S. Hogan¹, and K.L. Smith¹, ¹*Ohio State University, OARDC-Wooster.*

The effect of immunizing dairy cows with the ferric citrate receptor (FecA) on the opsonic activity of serum and whey was measured in a phagocytosis assay. Fifteen cows were assigned to five blocks of three cows based on date of expected parturition. Cows within a block were randomly assigned to one of three treatments: 1) FecA immunization, 2) immunization with a commercially available *Escherichia coli* J5 bacterin, and 3) unimmunized controls. Immunizations were 1) subcutaneous injections fourteen days prior to the end of lactation, 2) intramammary infusion seven days after the end of lactation, and 3) subcutaneous injection twenty-eight days after the end of lactation. Cows were challenged approximately twenty-one days after parturition by intramammary infusion of *Escherichia coli* 727, a strain previously isolated from bovine mastitis. The phagocytosis assays included opsonizing *E. coli* 727 with either 10% heat-inactivated serum or 50% heat-inactivated whey from each cow. Immunization with FecA and the commercial bacterin increased antibody titers against *E. coli* 727 compared with control cows. Cows immunized with FecA had reduced clinical signs of mastitis following challenge compared with either cows immunized with *E. coli* J5 or unimmunized controls. However, sera and whey collected from cows immunized with FecA did not enhance opsonization of *E. coli* 727 compared with sera and whey from control cows. Immunization with the commercial bacterin increased opsonization of both sera and whey greater than immunization with FecA. Results of the current trial suggest that the protective effects of immunizing cows with FecA against bacterial challenge with *E. coli* 727 does not relate to enhanced opsonization and in vitro phagocytosis.

Key Words: Mastitis, *Escherichia coli*, Ferric Citrate Receptor

634 Opsonization of *Escherichia coli* cultured in iron-replete and iron-deplete media. A.J. Wise*, J.S. Hogan¹, and K.L. Smith¹, ¹*The Ohio State University, OARDC-Wooster.*

The effects of iron availability in culture medium on the opsonization of *Escherichia coli* by bovine sera were tested in an in vitro phagocytosis assay. Fourteen isolates of *E. coli* from bovine intramammary infections were tested. Isolates were cultured 16 h in trypticase soy broth as an iron-replete environment. Isolates were cultured 16 h in trypticase soy broth plus .2 mM dipyridyl and 1 mM citrate as an iron-deplete environment. Cultures were centrifuged and cells opsonized by 5% pooled bovine serum in HBSS. Opsonized bacteria were added to neutrophils at a 2:1 bacteria:neutrophil ratio and incubated 1.5 h at 37°C . Phagocytic indices were measured by direct microscopic count of neutrophils stained with acridine orange and crystal violet. A portion of bacterial cells cultured in both iron-replete and iron-deplete media was suspended separately in 6% dextrose and stained to determine the presence of a

capsule. Phagocytic index, percentage of neutrophils containing intracellular bacteria, and average number of intracellular bacteria per positive neutrophil were each greater for bacterial cells cultured in iron-replete medium compared with bacterial cells cultured in iron-deplete medium. Bacterial isolates positive for capsule were more resistant to phagocytosis than isolates that were capsule-negative. Iron availability in culture did not affect expression of a bacterial capsule. Culturing *E. coli* in iron-deplete medium increased resistance to phagocytosis by bovine neutrophils compared with culture in iron-replete medium.

Key Words: *Escherichia coli*, Opsonization, Iron

635 Oral glycerol as an aid in the treatment of ketosis/fatty liver complex. J.P. Goff^{*} and R.L. Horst, *USDA-ARS, National Animal Disease Center, Ames, IA.*

Glycerol can be converted to glucose in the liver of cattle. Glycerol enters the gluconeogenic pathway at the level of dihydroxyacetone phosphate and 3-phosphoglycerinaldehyde. This is several biochemical steps closer to glucose than the traditional gluconeogenic precursors, propionate and propylene glycol. Use of glycerol as an aid in the treatment of ketosis was suggested during the 1960s but not adopted due to high costs. New sources of glycerol have reduced the cost. We examined the effect of glycerol administration on blood glucose in dry cows and did a dose titration to determine the maximal tolerable dose. Treatment groups consisted of 3 cows (one of which had a rumen fistula) which were given 1, 2 or 3 L of glycerol via esophageal pump. Blood samples were taken hourly for the next 8 hrs and also at 24 hrs. At 0.5 hr after treatment mean blood glucose increased 16, 20, and 25% respectively over pretreatment values. They remained elevated for the next 8 hrs. All cows had returned to baseline glucose values at 24 hrs. Two of three cows given 3 L glycerol exhibited staggering and depression; from which they recovered from within 4 hrs. Rumen pH was unaffected by treatment with glycerol. Two lactating cows with clinical ketosis, which had been previously treated for 2 or 3 d with IV glucose with little response suggesting fatty liver involvement, were treated with 1 L glycerol. In both cases ketone level in urine was reduced to trace amounts by 24 h and milk production increased 4-6 lb. In the first cow blood glucose increased from 48 mg/dl to 75 mg/dl 0.5 hr after treatment and was 109 mg/dl 5 hr after treatment. In the second cow blood glucose did not increase until about 4 hr after treatment when it increased from 48 mg/dl to 74 mg/dl and was just 64 mg/dl 8 hr after treatment. Glycerol offers another means of treating cows for ketosis which may have less toxic effects than propylene glycol.

Key Words: glycerol, ketosis, gluconeogenic

636 Economic consequences of Johne's disease control programs on dairy herds in Pennsylvania. H. Groenendaal^{*} and D.T. Galligan, *University of Pennsylvania, School of Veterinary Medicine, Kennett Square, PA, USA.*

A stochastic simulation model called JohneSSim has been developed to evaluate different Johne's disease control programs on their epidemiological and economic consequences. The model was applied to infected farms in the Pennsylvania dairy industry. Input data were collected from literature or obtained from experts. The results showed that none of the 'test-and-cull' strategies alone are effective in reducing the Johne's disease prevalence. 'Test-and-cull' strategies have an average benefit-costs ratio of around 0.85 (5% and 95% percentiles are respectively 0.00

and 1.30) and are therefore economically not attractive. However, improved management and hygiene for calves until 12 months of age, is much more effective in reducing the prevalence. This reduction will gradually start after 3-5 years because of the long sub-clinical period, but will result in a prevalence close to 0, after 15-20 years. In addition, the 'management improvement' strategies result in significant economic benefits. On average, the benefits increase from none (in year 1) to US dollar 11,000 in year 20 for a 100 cow dairy herd. Furthermore, 'heifer contract rearing' appeared to be an effective, simple, cheap and therefore attractive way of reducing the Johne's disease prevalence under Pennsylvania conditions with economical benefits, similar to 'management improvement strategies'. It was concluded that only a complete improvement of the calf management can reduce the prevalence effectively, and is therefore critical in any Johne's disease control program.

Key Words: Johne's disease, Simulation, Economics

637 Using *Solanum glaucophyllum* as a source of 1,25-dihydroxyvitamin D to prevent hypocalcemia in dairy cows. R.L. Horst^{*1}, J.P. Goff¹, S. Gill², E. Pawlak², and M.E. Dallorso³, ¹*National Animal Disease Center, USDA-ARS, Ames, IA,* ²*CAE, Buenos Aires, Argentina,* ³*Universidad Nacional de Lomas de Zamora, Buenos Aires, Argentina.*

Reducing cation-anion difference of diets (DCAD) fed just before parturition can prevent milk fever. However this dietary regimen does not entirely eliminate hypocalcemia. Milk fever can also be prevented by exogenous administration of the calcium regulating hormone 1,25-dihydroxyvitamin D. Unfortunately 1,25-dihydroxyvitamin D treatment remains expensive and the pre-parturient diets used in most trials would be classified today as high in cations. *Solanum glaucophyllum* (SG) is a plant which contains high levels of a glycoside form of 1,25-dihydroxyvitamin D. Could administration of SG leaves to cows that were already being fed a low DCAD pre-parturient diet further improve calcium status at calving? Nine multiparous Jersey cows were fed a low DCAD diet prior to calving. Urine pH of cows was maintained below 7.0 in all cows the week prior to parturition. Five cows were daily given 2 or 3 g SG leaves in gelatin boluses beginning 6 days (on average) before calving and continuing for the first 14 days of lactation. None of the four cows fed the low DCAD diet developed milk fever. Their blood calcium concentrations were 7.6, 7.0 and 8.0 mg/dl the day of calving and d 1 and 2 after calving respectively. Cows receiving SG in addition to low DCAD diet had significantly higher blood calcium concentration during the periparturient period with blood calcium concentrations of 7.8, 8.8 and 9.3 mg/dl the day of calving and d 1 and 2 after calving respectively. Control cows suffered an average of 3 days of subclinical hypocalcemia (blood calcium < 7.5 mg/dl) and the SG treated cows suffered 0.8 d of subclinical hypocalcemia the first 2 wk of lactation. Thus SG treatment improved calcium status in animals that were also being fed a low DCAD diet. Unfortunately, all cows receiving SG suffered 1-2 days of hypocalcemia (1 cow developed milk fever) between 6 and 8 days after SG treatment was ended. Mean blood calcium on d 22 of lactation of SG cows was 6.9 mg/dl compared with 9.2 mg/dl in untreated cows. It appears that SG treatment supplanted calcium homeostasis mechanisms in cows so that withdrawal of treatment left the cows temporarily unable to control blood calcium concentration.

Key Words: milk fever, *Solanum glaucophyllum*, hypocalcemia

ASAS/ADSA Forages and Pastures: Silages

638 Corn plant and silage nutritive value in different stages of maturity. Jorgelina Ferrero^{*1}, Oscar DiMarco², Enrique Rossi², and Daniel Valle², ¹*Fac. Cs. Agrarias U.N.L.,* ²*Fac. Cs. Agrarias UNMdP-INTA Balcarce.*

The nutritive value of corn "fresh cut" (FC) and ensiled (S) whole plant, stalk and leaf blade was evaluated in three stages of maturity: milking (A), half milk line (B) and physiological maturity (C). Chemical composition, *in vitro* DM digestibility (IVDMD) and *in situ* DM and NDF degradability (48 h) of whole plant, stalk and leaf blade, before and after ensiling, were evaluated. Three silos of each fraction were made in each stage of maturity in plastic containers (5 liters), which were stored for 45 days. In addition, samples of stalk and leaf blade were ensiled

in each container by placing them in nylon mesh bags inside the whole plant silage. Data from each plant fraction were analyzed by a two factorial analysis of variance (stage of maturity and ensiling). Whole plant (FC) chemical composition was: 52.2 % NDF, 3.2 % starch and 17.3 % soluble sugars (CNES) in A, and 43.9 % NDF, 21.6 % starch and 20.9 % CNES in C. The concentration of CNES diminished in stalk with maturity from 27.4 in A to 18.2 % in C. The IVDMD of whole plant did not differ between stages of maturity (average: 66.8 %). IVDMD of stalk diminished between B and C (50.6 to 48.8 %, P<0.01), due to a lower concentration of CNES, and in leaf blade IVDMD decreased between A and B (65.2 to 56.7 %, P<0.01), due to a decrease in NDF quality. The *in situ* NDF degradability decreased (P<0.01) with maturity (A and

B) in stalk (41.8 to 38.2 %) and in leaf blade (70.9 to 57.6 %) without affecting whole plant DM degradability (72.8 %). Ensiling depressed CNES but did not affect NDF concentrations in whole plant, stalk or leaf blade. Significant interactions between maturity and ensiling were found for IVDMD and degradability (MS and NDF) in whole plant, stalk and leaf blade. It was concluded that the increase in starch accumulation with maturity compensated for the decrease in stover quality; and that care should be taken in extrapolation of results between data of fresh cut and ensiled corn.

Key Words: maize, silage, maturity stage

639 Evaluation of the nutritive value of low moisture corn silage stored in Ag Bag® vs bunker silos. J. H. Harrison*, D. Davidson¹, and D. Linder², ¹Washington State University, Puyallup, ²Ag Bag®, Warrenton, OR.

Pioneer® hybrid 39K72 was harvested on 10-22 and 10-23 -1999 as alternating loads in to a 3 meter Ag Bag® or 4.2 x 2.4 x 45 meter bunker silo. Average DM of the whole plant corn was 37% at ensiling. Each silo contained ~ 150 tons of silage. Silage temperatures were monitored at two locations at .3 and 1 meter depths in each silo. After 6 months of storage the two silages were compared in a 2 x 2 Latin square design lactation study with 2 week periods. Each group of cows had 24 cows and was fed diets that contained 26 % corn silage, 13 % alfalfa hay, 13 % whole cottonseed, and 52 % grain mix. The fermentation profile of Ag Bag® and bunker stored corn silages were: pH, 3.9 and 4.2; acetate % DM, 0.9 and 0.9; lactate % DM, 2.9 and 2.8, and ethanol % DM, .2 and .1, respectively. Average silage temp was 0.8 to 2.0°C cooler during storage for Ag Bag® silage. Data shown below support the conclusion that low moisture corn silage stored in an Ag Bag® system had greater nutritive value.

Silo	Milk, kg	Milk fat %	3.5 FCM, kg	Milk protein, %	Milk protein, kg
Ag Bag®	38.1	3.80	39.4	2.89	1.08
Bunker	37.6	3.61	38.2	28.6	1.07
P<	.17	.05	.06	.17	NS

640 Evaluation of the nutritive value of processed corn silage harvested at three chop lengths. J.H. Harrison*, D. Davidson, and L. Johnson, Washington State University, Puyallup, WA/U.S.A..

Pioneer® hybrid 3845 was harvested from 10-20 through 10-22-1999 at three chop lengths (16, 28, and 40 mm) with a John Deere 5830 harvester equipped with kernel processor and ensiled in 3 m Ag Bag® silos. After 3 months of storage the three silages were compared in a continuous design lactation study beginning three weeks pre-partum through 10 weeks postpartum. Each group had 5 cows and were fed diets that contained 26% corn silage, 13% whole cottonseed, and 52% grain mix. Data summarized below indicate a trend for a time x chop length interaction with long chopped corn silage sustaining a greater intake of DM, less loss of BW, and greater 3.5% FCM. Milk protein content was greatest for cows consuming long chopped corn silage.

Silage	3.5 FCM, kg		Milk fat, %	Milk protein, %	BW, kg	BCS
	Milk, kg	DMI, kg				
16 mm	39.3	20.6	42.6	4.01	2.97	599
28 mm	39.6	20.3	42.7	4.07	2.80	617
40 mm	40.3	22.0	44.5	4.27	3.02	609
P ≤ Chop length	NS	NS	NS	.34	.08	NS
P ≤ Chop length x week	.29	.13	.15	NS	.03	.27

Key Words: dairy, nutrition, corn silage

641 Production response of Holstein cows fed diets containing annual ryegrass and corn silage with either ground or steam-flaked corn. J. K. Bernard*, J. W. West, and D. S. Trammell, The University of Georgia, Tifton, GA USA.

Twenty-four lactating Holstein cows were used in a 6-wk randomized design trial with a 2 x 2 factorial arrangement of treatments to determine

the effects of feeding ground (GC) or steam-flaked corn (SFC) in diets based on either annual ryegrass silage (RS) or a 50:50 blend of annual ryegrass and corn silages (BLEND). Cows were fed a basal diet during the first 2-wk of the trial and data were collected for covariate analysis. Experimental diets contained 49.6% forage and were formulated to contain equal concentrations of CP, NDF and energy. There were no interactions of forage and processing of corn. The mean DMI, milk yield, milk fat percentage, milk protein percentage, and energy-corrected milk (ECM) yield was 19.7 kg/d, 30.8 kg/d, 3.28%, 2.85% and 27.6 kg/d for cows fed RS and 22.3 kg/d, 31.5 kg/d, 3.41%, 2.78%, and 31.2 kg/d for cows fed BLEND. Cows fed BLEND consumed more DM (P < 0.001) and tended to produce more ECM (P < 0.09) due to numerically higher milk yield and milk fat percentage than those fed RS. Efficiency of converting DM to milk was greater (P < 0.01) for the diet based on RS compared to BLEND, but no difference was observed for efficiency of converting DM to ECM. There were no differences in BUN and glucose concentrations (P > 0.10) between forages. The mean DMI, milk yield, milk fat percentage, milk protein percentage, and ECM yield was 21.5 kg/d, 29.8 kg/d, 3.59%, 2.84% and 28.8 kg/d for cows fed GC and 20.4 kg/d, 32.5 kg/d, 3.10%, 2.78%, and 30.0 kg/d for cows fed SFC. Cow fed diets containing SFC consumed less DM (P < 0.04), but had higher milk yield (P < 0.004) that tended to have lower concentrations of fat (P < 0.10). Yield of milk protein was higher (P < 0.01) for cows fed SFC (0.90 kg/d) compared with cows fed GC (0.83 kg/d). Efficiency of converting DM to milk was greater (P < 0.005) when cows were fed SFC than GC. No differences were observed in efficiency of converting DM to ECM. Blood glucose concentrations were similar for cows fed either GC or SFC, but BUN was lower (P < 0.03) for cows fed SFC (15.6 mg/dl) than GC (18.2 mg/dl). Results of this trial indicate that feeding a blend of annual ryegrass and corn silage supports greater milk yield than feeding all ryegrass silage and that steam-flaked corn improved milk yield and utilization of DM over ground corn.

Key Words: Ryegrass silage, Corn silage, Steam-flaked corn

642 The effect of Lactobacillus buchneri 40788 and enzymes on the fermentation and aerobic stability of barley silage fed to lactating cows. C. C. Taylor*, J. A. Mills, J. M. Neylon, and L. Kung, Jr., University of Delaware, Newark, DE.

We investigated the effects of adding a heterofermentative lactobacilli, *L. buchneri*, to whole plant barley on the aerobic stability and the nutritive value of silage. Chopped barley (40% DM) was either treated or not treated with a combination of *L. buchneri* (LB, 400,000 cfu/g of fresh forage) and enzymes (Biotal, Inc., Eden Prairie, MN) and ensiled in a bag silo. About 40 t of forage was prepared for each treatment. The average concentration of acetic acid in treated silage was higher (6.68%, P < 0.05) than in untreated silage (2.69%, DMB) during the first 16 wk of ensiling. After 7 mo of storage, both ends of the bag silo were opened simultaneously and untreated and treated silages were fed to sixteen multiparous and eight primiparous Holstein cows producing about 26 kg of milk/d (124 ± 52 DIM; mean ± SD). Cows were fed a TMR comprised of 35% untreated or treated barley silage, 15% corn silage, and 50% (DMB) of a pelleted concentrate. The experiment was a crossover design consisting of two 21-d periods; the last week in each period was used for collection of production data. During feedout, barley silage treated with *L. buchneri* had higher concentrations of acetic acid (5.92 vs. 4.02%, DMB, P < 0.06), fewer yeasts (2.63 vs. 4.89 log₁₀ cfu/g, P < 0.05), and took longer to spoil when exposed to air (>190 vs. 66 h, P < 0.05) when compared to untreated silage. The aerobic stability of the TMR was longer (P < 0.05) when it contained treated (77 h) rather than untreated (46 h) barley silage. Dry matter intake (18.6 kg/d), milk production (25.7 kg/d), and milk composition did not differ between treatments. These findings show that *L. buchneri* can improve the aerobic stability of barley silage in farm-scale silos and high concentrations of acetic acid in treated silage did not reduce DMI. The data also show that mixing silage treated with *L. buchneri* into a TMR, can improve the aerobic stability of that TMR even though it contained corn silage that had not been treated.

Key Words: Lactobacillus buchneri, Silage, Aerobic stability

643 Adding *Lactobacillus buchneri* 40788 to alfalfa silage increases the production of acetic acid in laboratory and farm-scale silos and has no effect on the dry matter intake of high producing dairy cows. C. C. Taylor, M. P. Lynch, J. M. Neylon, T. L. Ebling*, and L. Kung, Jr., *University of Delaware, Newark, DE.*

We applied a heterofermentative lactobacilli, *L. buchneri*, and enzymes (Biotol, Inc., Eden Prairie, MN), to alfalfa silage (38% DM) and studied its effects on silage fermentation in lab and farm silos. Alfalfa was chopped and treated with nothing, or *L. buchneri* to obtain a final application rate of 1×10^5 , 5×10^5 , or 1×10^6 cfu/g of fresh forage. After 56 d of ensiling in lab silos, treated silages had higher ($P < 0.05$) concentrations of acetic acid (6.00 versus 4.24%), propionic acid (0.18 versus 0.06%), and ammonia N (0.346 versus 0.289%) than did untreated silage. Yeasts and molds were less than 2.00 log₁₀ cfu/g in all silages. In a subsequent experiment, alfalfa (43% DM) was not treated or treated with *L. buchneri* (5×10^5 cfu/g) and enzymes and stored in a bag silo for 4 mo before feeding. Twenty four multiparous and six primiparous cows (86 11 DIM) were fed a diet comprised of 32% untreated or treated alfalfa silage, 11% corn silage, 5% chopped alfalfa hay, and 52% of pelleted concentrate (DMB) for a 6-wk treatment period. Dry matter intake (25.2 kg/d), milk production (40.3 kg/d), and milk composition were unaffected by treatment. During feed out, treated silage had a higher pH (4.66 vs. 4.36, $P < 0.05$) and higher concentration of acetic acid (5.69 vs. 3.38%, $P < 0.05$), but lower lactic acid (5.26 vs. 6.58%, $P < 0.05$) than untreated silage. Yeasts and molds were less than 2.00 log₁₀ cfu/g for both alfalfa silages but was 6.11 and 5.72 log₁₀ cfu/g in corn silage, respectively. Alfalfa silages, alone, did not heat but the TMR containing untreated silage heated after 69 h whereas the TMR containing the silage treated with *L. buchneri* did not heat until 100 h ($P < 0.05$). These data show that treating alfalfa silage with *L. buchneri* increases the concentration of acetic acid and when the silage mixed with other feeds, it can improve the aerobic stability of the TMR.

Key Words: *Lactobacillus buchneri*, Silage

644 Evaluation of nutrient composition and IVDMD of alfalfa and/or tropical grasses grown in Hawaii and harvested as round bale silage. D.T. Harauchi*, J.R. Carpenter, R.J. Early, and C.N. Lee, *University of Hawaii-Manoa.*

Currently, much of the nutritional composition data available in Hawaii has come from samples taken from outside the State. Since the current data from most forages have come from temperate climates, the objective of this study was to expand a database of nutrient composition for locally grown forages used for dairy rations. The samples consisted of alfalfa (*Medicago sativa*), guinea grass (*Panicum maximum*), green panic (*P. maximum* var. *trichoglume*), klein grass (*Panicum coloratum*), or a combination of these forages. The silage was grown in Wailua on the northern coast of Oahu and harvested between September 1997 and December 1998 at varying stages of regrowth. The ensiled samples were obtained from Dole Food Co. and CP, NDF, and ADF were determined using NIRs (NIRSystems Model 6500). DM, and ash were determined using AOAC techniques, and 48h IVDMD by Ankom procedures. A fistulated steer fed alfalfa cubes ad libitum was used as the source of rumen inoculum (4 h post-prandial). A total of 289 samples were separated according to forage type and different stages of maturity (<4, 4-5, 5-6, >6 weeks) to determine the effect of species and age of regrowth on digestibility. The mean DM was 47.1, and the % ash, CP, NDF, ADF and IVDMD for the 289 samples (DM basis) was 8.1, 17.4, 52.2, 34.4, and 76.6, respectively. NDF and ADF were lower ($P < .01$) for alfalfa (41.6 and 31.0%, respectively) than alfalfa/guinea (50.6 and 35.6%) and these were all lower than the other grasses (68.3 and 38.9%). 48h IVDMD, DM, and ash showed no significant difference between the grasses. The CP was highest ($P < .01$) for alfalfa (21.8%) followed by alfalfa/guinea mix (17.8%), green panic/guinea (13.6%), klein/guinea (10.9%) and other mixed grasses (9.3%). NDF values were higher ($P < .01$) with each increase in age of regrowth, and IVDMD was higher ($P < .01$) for the alfalfa and alfalfa guinea mix than the other grasses at all ages except for 5-6 wk where no differences were observed.

Key Words: Alfalfa and tropical grass silages, Nutrient composition, IVDMD

645 The effect of inoculation with *Lactobacillus plantarum* MTD1 and packing density on the fermentation of high DM alfalfa silage. M. P. Lynch*, J. A. Lazartic, J. M. Neylon, C. C. Taylor, M. A. Reddish, and L. Kung, Jr., *University of Delaware, Newark, DE.*

We investigated the effect of packing density and microbial inoculation on the fermentation of alfalfa silage with a high DM content. Alfalfa was wilted to 53% DM before chopping. Treatments were: 1) untreated, tightly packed (411 kg/m³, DMB) (UT), 2) inoculated with *Lactobacillus plantarum* MTD1 (Ecosyl Products, Ltd., Stokesley, England; 100,000 cfu/g of fresh forage), tightly packed (LPT), 3) untreated, loosely packed (205 kg/m³) (UL), or 4) inoculated, loosely packed (LPL) in laboratory silos. After 8 d of ensiling, LPT had higher ($P < 0.05$) concentrations of lactic acid, but lower ($P < 0.05$) concentrations of ammonia N and acetic acid than did UT. In contrast, UL had a higher pH (5.60 vs. 5.31, $P < 0.05$), a lower concentration of lactic acid (1.28 vs. 2.49%, $P < 0.05$), and fewer lactic acid bacteria (8.23 vs. 8.67 log₁₀ cfu/g, $P < 0.05$) than did UT. Adding homolactic acid bacteria to loosely packed silage (LPL) increased the concentration of lactic acid and decreased acetic acid ($P < 0.05$) when compared to UL, but the effect was intermediate ($P < 0.05$) to that of LPT. After 42 d of ensiling (see table), untreated, loosely packed silage (UL) had a higher ($P < 0.05$) pH, a lower ($P < 0.05$) concentration of lactic acid, and more ($P < 0.05$) yeasts and molds than did UT. Microbial inoculation overcame the detrimental effects of loose packing (LPL) by causing a more ($P < 0.05$) predominant homolactic acid fermentation. However, inoculation of loosely packed silage could not prevent the accumulation of yeasts and molds that were undetectable in tightly packed silage (UT and LPT).

646 Why digestibility of alfalfa stems declines with maturity. H. G. Jung*¹ and F. M. Engels², ¹USDA-ARS, St. Paul, MN, ²Wageningen University, The Netherlands.

Development of an alfalfa stem internode from three genotypes was examined to determine why digestibility of alfalfa stems declines with maturity. The seventh internode from the stem base was collected from replicated field plots at five stages of development (12, 17, 21, 31, and 87 d of summer regrowth). Internode samples were preserved in alcohol for microscopic analysis and freeze-dried for cell wall (CW) and in vitro digestibility analysis. While minor genotypic differences were noted, the general pattern of development and digestibility was similar for the genotypes so only means are presented. Young, elongating internodes (12 and 17 d) had thin, nonlignified CWs in all tissues except primary xylem vessels which were already lignified. Internode elongation was complete by 21 d of regrowth, at which time there was some deposition of xylem fibers and this tissue was lignified. Further maturation (31 and 87 d) consisted of xylem tissue proliferation by cambial activity, and lignification of primary phloem and pith parenchyma tissues. CW concentration increased with maturity. Pectin (Pec) concentration in the CW declined while cellulose (Cel), hemicellulose (Hemi), and lignin (Lig) all increased with maturation. Major CW changes occurred when internode elongation ceased. All alfalfa stem tissues were completely digested in the two youngest maturity stages, except primary xylem vessels. Xylem fiber remained undigested after 21 d of regrowth and amount of undigested xylem increased with maturity. Some primary phloem and pith parenchyma tissues were undigested in the two oldest samples. CW polysaccharide digestion declined steadily from 17 to 87 d of regrowth. Xylem fiber was lignified as soon as it was formed and was almost completely indigestible. Proliferation of xylem fiber accounts for the increase in stem mass and reduction in alfalfa stem digestibility with maturity.

647 Nutrient composition of several brown midrib and non-brown midrib sorghum varieties. J. B. Banta*, F. T. McCollum, B. Bean, D. Pietsch, and M. Rowland, *Texas A & M University System*.

ABSTRACT: Nutritional constituents were compared in sorghum harvested for silage. The study included 17 brown midrib (BMR) and 48 non-BMR sorghum varieties. Varieties were randomly assigned to plots (four 0.762 m rows by 7.62 m long) in three replications. The varieties were planted on May 24, 2000, at a depth of 3.81 cm and 296,400 plants/ha. Fertilizer N was applied at 202 kg actual N/ha and Bicep II Magnum was applied immediately after planting. The soil type was a Pullman clay loam with a pH of 7.4. The varieties were grown under full irrigation. Harvest occurred on August 30, September 6, or September 27, when each entry was at the soft-dough stage. Forage samples were collected from 1 m of row in each plot, weighed, chopped and subsampled. Supsamples were immediately frozen and sent to the Dairy One Laboratory (Ithaca, New York) for analysis. The samples were analyzed using near infrared spectrometry and in vitro techniques. All varieties were ranked from most desirable (1) to least desirable (65) for each constituent. Mean nutrient values and ranks for BMR were more desirable than for non-BMR. However, based on individual variety data there was overlap between the two forage types. Hence, selection of a sorghum based solely on the BMR trait does not guarantee a more desirable nutrient profile.

648 Performance of lactating dairy cows fed red clover based diets augmented with normal or brown midrib corn silage. P.C. Hoffman*¹ and L.M. Bauman¹, ¹*University of Wisconsin-Madison*.

Red clover (RC), normal corn silage (CS), and brown mid-rib corn silage (BMR) were harvested at recommended stages of maturity and ensiled. Eighteen early lactation (57±37 DIM) primiparous (N=9) and multiparous (N=9) Holstein cows were fed diets with forage bases of 100% RC, a 50:50 ratio of RC and CS, and a 50:50 ratio of RC and BMR. Concentrate mixtures were formulated for RC, CS, and BMR and fed at 56.0, 50.0 and 50.0% of dietary DM to yield isofibrous (NDF) and isonitrogenous diets. Lactation performance, feed intake, and milk protein fractions were evaluated. Numerically, RC contained more CP, NDF, and lignin than CS or BMR. The in vitro (IV) DM and NDF digestibility (D) of BMR was numerically higher than CS and was substantially higher than RC. There were no parity but treatment interactions, therefore data from primiparous and multiparous cows were combined. Cows fed CS and BMR produced more ($P < 0.07$) milk and consumed more ($P < 0.01$) DM than cows fed RC. Cows fed BMR consumed ($P < 0.05$) more DM than cows fed CS. Milk fat%, protein%, or casein% was not different between cows fed RC, CS, or BMR. Data suggested DM intake

and milk yield of lactating dairy cows fed red clover can be enhanced by addition of CS or BMR to the diet.

649 The effect of applying a buffered propionic acid-based preservative (Ki-112) alone or in combination with a mixture of homolactic acid bacteria (HAB) on the fermentation and aerobic stability of high moisture corn. J. M. Neylon*¹, C. L. Myers², C. C. Taylor¹, J. A. Lazartie¹, and L. Kung, Jr.¹, ¹*University of Delaware, Newark, DE*, ²*Kemin Industries, Des Moines, IA*.

The objective of this study was to evaluate the effect of applying Ki-112 alone or in combination with HAB on the fermentation and aerobic stability of ground, high moisture corn (29% DM) ensiled in lab silos. Treatments were: 1) no additive, 2) 0.1% (fresh forage weight) Ki-112 (a propionic acid-based additive, Kemin Industries, Des Moines, IA), 3) 0.2% Ki-112, 4) HAB, which was comprised of *Lactobacillus plantarum*, *L. bulgaricus*, and *L. acidophilus* to obtain 100,000 cfu/g of fresh forage weight (Kemin Industries), 5) 0.1% Ki-112 + HAB, and 6) 0.2% Ki-112 + HAB. The inoculant and chemical additive were applied separately in treatments 5 and 6. The addition of Ki-112 and HAB, alone or in combination, had few effects on the fermentation of high moisture corn during the early stages of ensiling. Similar to concentrations in freshly treated corn, treatments containing Ki-112 had greater concentrations of propionic acid than untreated corn after 120 d of ensiling. Numbers of yeasts were 4.16 log₁₀cfu/g in untreated corn and were less ($P < 0.05$) than 2.00 log₁₀cfu/g in corn that was treated with 0.2% Ki-112. HAB alone, did not affect the numbers of yeasts (3.92 log₁₀cfu/g) in high moisture corn. Corn treated with only 0.1% Ki-112 (161 h, $P < 0.10$) and 0.2% Ki-112 (218 h, $P < 0.05$) was more stable when exposed to air than untreated corn (122 h). Treatment with only HAB or HAB + 0.1% Ki-112 did not affect the aerobic stability of corn. However, treatment with HAB + 0.2% Ki-112 markedly improved the aerobic stability (> 400 h, $P < 0.05$) of corn. Data from this study indicates that application of Ki-112 at 0.2% of fresh weight is required to improve the aerobic stability of high moisture corn. A microbial inoculant, alone, had no effect on aerobic stability, but when combined with the 0.2% Ki-112, stability was markedly improved.

Key Words: Propionic acid, Aerobic stability, Silage

650 Evaluation of the replacement value of HMEC for steam rolled corn grain. J. H. Harrison*¹, D. Davidson¹, D. Linder², and F. Hosington³, ¹*Washington State University, Puyallup*, ²*Ag Bag® Int., Warrenton, OR*, ³*Dari-Tech Services, Kent, WA*.

Pioneer[®] hybrid 3489 was grown in George, WA in 1999 for harvest as high moisture ear corn (HMEC) or dry grain. The planting date was ~ April 23 and harvest date for HMEC (31% moisture) was October 26. The grain corn was harvested ~ 2 weeks later and artificially dried. The HMEC was harvested with a Claas 860 chopper equipped with a kernel processor. The HMEC was ensiled in a 3 meter Ag Bag[®] and treated with Pioneer[®] 1189 inoculant. The dry corn grain was steam rolled prior to feeding. The two forms of corn grain were fed in a 4 x 4 Latin square design trial with 14-day periods. Cows averaged 104 DIM at the onset of the experiment and all cows received rBST on day 4 of each period. The four dietary treatments were ratios of HMEC:steam rolled corn of: 1) 100:0, 2) 75:25, 3) 25:75, and 4) 0:100 to provide 25 % of diet DM. The

12 hr macro in situ digestibility of starch and NDF of HMEC and steam rolled corn grain was: 18, 77, 22, and 69, respectively. The data shown below supports the conclusion that 25 % of steam rolled corn could be replaced with HMEC.

ASAS/ADSA Ruminant Nutrition: Feedlot

651 Effects of supplemental phosphorus concentrations on inorganic phosphorus serum concentrations, growth performance, carcass characteristics, and cost of gain of finishing cattle. Wendy R. Flatt*¹, Tim Stanton¹, Jessica Davis¹, and Dave Schutz², ¹Colorado State University, ²CSU-Eastern Colorado Research Center.

ABSTRACT: The objective of this study was to evaluate the effects of dietary phosphorus (P) concentration on cattle growth, performance, blood serum levels and carcass characteristics. Two hundred and twenty-one beef cattle (119 heifers, 102 steers) with an average initial live weight of 296 ± 70.5 kg were used in a randomized experimental design. Calves were randomized by live weight, stratified by breed, and assigned to one of two treatments (four pens/treatment). Control (C) was fed at 0.34% (DM basis) for 147 days on feed (DOF). Low phosphorus (LP) cattle were fed at 0.34% P (DM basis) until day 85 at which time supplemental P was dropped to 0.24% until finish. Over the 147 d feeding period, feed intake was not affected (P > 0.05) by P level. Feed intake was 9.30 and 9.32 kg DM (± 0.02kg) of feed per day for C and LP, respectively. Average daily gain, although not significant (P > 0.05), was higher for cattle on C compared to cattle on LP (1.64 vs. 1.60 ± 0.04 kg/day). Feed efficiency was not affected by P treatments. No significant differences were determined between serum levels of inorganic P of cattle on C vs. LP. Dressing percent, hot carcass weight, muscling score, percent grading choice, and yield grade were not affected by the level of dietary P in the supplement. However, percent dark cutters for C and LP were significantly different as the percent not grading because they were dark cutters was 4.50% for cattle on C vs. 13.64% for cattle on LP. The calves on LP also had a higher (P < 0.05) incidence of morbidity than those calves on C, 13.51% vs. 4.50%, respectively. Reducing supplemental P from the diet at reimplant time may increase the incidence of morbidity and dark cutters.

Key Words: Phosphorus, Dark cutters, Feed efficiency

652 Effects of wet corn gluten feed and intake level on diet digestibility and rumen passage rate in steers. S. P. Montgomery*, J. S. Drouillard, E. C. Titgemeyer, J. J. Sindt, T. B. Farran, J. N. Pike, C. M. Coetzer, A. M. Trater, and J. J. Higgins, Kansas State University, Manhattan..

Twelve ruminally cannulated Jersey steers (534 ± 52 kg BW) were used in an incomplete Latin square design experiment with a 2 × 2 factorial arrangement of treatments to determine effects of wet corn gluten feed (WCGF) and total DMI level on diet digestibility and rumen passage rate. Treatments consisted of diets formulated to contain 40% WCGF or no WCGF, fed once daily either ad libitum or limited to 1.6% of BW. Two consecutive 24-d periods were used, consisting of 18 d for adaptation, 4 d for collection, and a 2-d in situ period. Chromic oxide (10 g/hd) was fed as a digestibility marker, and steers were pulse dosed with Yb-labeled alfalfa hay and a Co-EDTA solution via rumen cannula to measure solid and liquid passage rates. Dacron bags containing 5 g of either steam-flaked corn, WCGF, or ground (2-mm) alfalfa hay were placed into the rumens of all steers and removed after 3, 6, 12, or 48 h. WCGF increased total tract digestion of OM and NDF (P < 0.01), reduced total VFA concentration (P < 0.01), increased rumen NH₃ concentration (P < 0.01), increased rumen pH (P < 0.01), and tended (P < 0.06) to increase total tract digestion of starch. WCGF also increased rumen passage rate of solid digesta (P < 0.01). Limit feeding reduced (P < 0.01) total tract digestion of both OM and NDF, reduced total VFA concentration (P < 0.01), increased rumen NH₃ concentration (P < 0.01), and increased rumen liquid passage rate (P < 0.02). Total tract

digestion of starch was not affected by DMI level (P > 0.70). A DMI level × h interaction (P < 0.01) occurred for rumen pH. Limit feeding increased rumen pH at 0 and 12 h after feeding, but reduced rumen pH 4 h after feeding. WCGF or DMI level did not affect (P > 0.25) rate of in situ DM disappearance. This study suggests that WCGF increases OM and NDF digestion, and that limit-feeding high-energy diets once daily may depress OM and NDF digestion.

Key Words: Wet corn gluten feed, Limit feeding, Digestibility

653 Performance of beef heifers limit-fed growing diets containing alfalfa hay and wet corn gluten feed. S. P. Montgomery*, J. S. Drouillard, J. J. Sindt, T. B. Farran, J. N. Pike, C. M. Coetzer, H. J. LaBrune, A. M. Trater, and R. D. Hunter, Kansas State University, Manhattan..

Crossbred beef heifers (n = 339, BW = 277 ± 11.4 kg) were used in a randomized complete block design to determine optimum combinations of alfalfa hay (AH) and wet corn gluten feed (CGF) in limit-fed growing diets containing steam-flaked corn. Heifers were fed a common diet ad libitum for 15 d preceding the growing study to minimize differences in gastrointestinal tract fill. Heifers were then blocked by weight and allotted to pens containing four to seven head per pen, with six pens per treatment. Treatments consisted of diets containing 10, 20, or 30% ground AH, and 0, 40, or 68% CGF in a 3 × 3 factorial arrangement. All diets provided 33 mg/kg of monensin and were fed once daily at 1.6% of BW for 84 d. On d 8, 22, 37, 51, 64, and 79, unconsumed feed was removed from feed bunks 2 h after feeding, weighed, and returned to the respective feed bunk in order to measure rate of DMI. Prior to obtaining final weights, cattle were fed a common diet ad libitum for 15 d. An interaction occurred (P < 0.05) between level of AH and CGF level for both ADG and gain efficiency. ADG for the 99-d growing study were 1.03, .96, .90, .90, .88, .84, .85, .90, and .78 ± 0.02 kg/d and gain efficiencies were .196, .185, .175, .171, .172, .160, .163, .180, and .153 ± 0.004 kg gain/kg DM for 10AH/0CGF, 10AH/40CGF, 10AH/68CGF, 20AH/0CGF, 20AH/40CGF, 20AH/68CGF, 30AH/0CGF, 0AH/40CGF, and 30AH/68CGF, respectively. Increasing the levels of AH or CGF reduced cattle performance with the exception of 30AH/40CGF, which supported ADG similar (P > 0.10) to 20AH/0CGF or 30AH/0CGF, and improved gain efficiencies (P < 0.05) compared to 30AH/0CGF. DMI 2 h after feeding increased linearly (P < 0.01) with increasing AH, and decreased linearly (P < 0.01) with increasing CGF. This study suggests that 40% CGF can effectively replace steam-flaked corn in limit-fed growing diets containing 20 or 30% AH.

Key Words: Wet corn gluten feed, Alfalfa hay, Limit feeding

654 Wet corn gluten feed and alfalfa hay combinations in steam-flaked corn finishing diets. J. J. Sindt*¹, J. S. Drouillard¹, S. P. Montgomery¹, J. N. Pike¹, T. B. Farran¹, C. M. Coetzer¹, T. J. Kessen¹, and R. T. Ethington², ¹Kansas State University, Manhattan, ²Minnesota Corn Processors, Marshall, Minnesota.

A 153-d finishing experiment was conducted using 631 heifers (BW = 284 ± 7.9 kg) to determine optimum combinations of wet corn gluten feed (WCGF) and alfalfa hay in steam-flaked corn based diets. Heifers were randomly allocated to pens and stratified by weight to six treatments (2 pens per diet, 48 to 58 heifers per pen). Diets contained 25, 35, or 45% WCGF and 2 or 6% alfalfa hay (25/2, 25/6, 35/2, 35/6,

45/2, and 45/6) on a dry basis in a 2 × 3 factorial arrangement of treatments. Heifers were allowed *ad libitum* access to diets fed once daily. Heifers were implanted with Synovex C on d 1 and were adapted to final finishing diets within 21 d. Final diets provided 300 mg Rumensin, 90 mg Tylosin, and 0.5 mg MGA per heifer daily. On d 56 heifers were re-implanted with Synovex Plus. DMI (7.6, 7.8, 7.9, 8.1, 7.8, and 8.0 kg/d), and ADG (1.15, 1.16, 1.16, 1.17, 1.15, and 1.14 kg) were similar ($P > 0.19$) for cattle fed 25/2, 25/6, 35/2, 35/6, 45/2, and 45/6, respectively. Gain efficiencies (.152, .149, .146, .144, .147, and .143 kg gain/kg DM) decreased ($P < 0.05$) linearly as the level of WCGF increased. Carcass weights and dressing percent were not different ($P > 0.18$) among dietary treatments. A WCGF × alfalfa hay interaction occurred ($P < 0.10$) for ribeye area. For heifers fed 2% alfalfa hay, ribeye area increased with increasing dietary WCGF, however, for heifers fed 6% alfalfa hay ribeye area decreased with additional WCGF. Fat thickness (1.22, 1.22, 1.19, 1.27, 1.09, and 1.14 cm) for cattle fed 25/2, 25/6, 35/2, 35/6, 45/2, and 45/6, respectively, decreased ($P < 0.10$) linearly with increasing dietary WCGF. Incidence of liver abscesses (2.7, 4.7, 1.9, 0.9, 2.8, and 2.9%) for heifers fed 25/2, 25/6, 35/2, 35/6, 45/2, and 45/6, respectively, was lowest ($P < 0.05$) for heifers fed 35% WCGF. Alfalfa hay fed at 2% of diet dry matter is sufficient roughage in steam-flaked corn diets containing 25, 35 or 45% WCGF.

Key Words: Finishing Cattle, Wet Corn Gluten Feed, Roughage Level

655 Wet corn gluten feed and alfalfa hay combinations in steam-flaked corn finishing diets: effects on ruminal characteristics and diet digestibility. J. J. Sindt*, J. S. Drouillard, E. C. Titgemeyer, S. P. Montgomery, J. N. Pike, C. M. Coetzer, and T. B. Farran, *Kansas State University, Manhattan.*

Ruminally cannulated, mature Jersey steers ($n = 12$, BW = 585 ± 48 kg) were fed steam-flaked corn- (SFC) based finishing diets containing combinations of wet corn gluten feed (WCGF) and alfalfa hay (AH) to determine diet digestibility and ruminal characteristics. Dietary treatments consisted of 25 or 45% WCGF and 0, 2, or 6% AH in a 2 × 3 factorial arrangement. An incomplete Latin square design was used with three 14-d periods each containing a 10-d adaptation and a 4-d sampling period. Steers were offered *ad libitum* access to diets fed once daily. Chromic oxide (15 g) was fed as a digestibility marker, and Co-EDTA was pulse dosed to measure rumen liquid passage rate. WCGF, SFC, and AH were ruminally incubated in Dacron bags and removed at 0, 3, 6, 12, and 48 h on d 12 and 13. Feeding 45% WCGF reduced ($P < 0.05$) total tract digestibility of OM and tended to increase ($P < 0.10$) ruminal pH. The undegradable fractions of AH, SFC, and WCGF were decreased ($P < 0.06$) by feeding 45% WCGF. Total VFA concentrations decreased ($P < 0.05$) quadratically, whereas NH₃ and butyrate increased ($P < 0.05$) quadratically with increasing dietary AH. pH, acetate, and acetate: propionate increased ($P < 0.05$) linearly in response to additional AH, whereas propionate decreased ($P < 0.01$) linearly and the undegradable fraction of SFC *in situ* tended ($P < 0.10$) to decrease linearly as the level of AH increased. Rate of liquid passage tended ($P < 0.12$) to increase linearly with increasing dietary AH. A WCGF × AH interaction existed ($P < 0.05$) for turnover time (TT). For steers fed 25% WCGF, TT increased linearly as AH increased, but for steers fed 45% WCGF, TT decreased linearly with increasing amounts of AH. Few interactions existed between WCGF and AH. WCGF fed at 25% diet dry matter may provide sufficient roughage in steam-flaked corn finishing diets.

Key Words: Wet Corn Gluten Feed, Roughage Level, Digestibility

656 Feedlot performance of growing cattle fed four silages with a silage inoculant. M. H. O'Connor*¹, G. M. Hill¹, S. A. Martin², R. N. Gates³, and J. K. Bernard¹, ¹*University of Georgia, Tifton, GA/USA*, ²*University of Georgia, Athens, GA/USA*, ³*USDA-ARS, Tifton, GA/USA*.

Corn (CS), pearl millet (PM), tropical corn (TC), and sorghum (S) silages with (I) or without (NI) SureSorbTM inoculant added at ensiling were compared to determine effects on growing cattle performance. Silages were fed free-choice for 84-d. Dietary energy and CP were adjusted with supplements (SUP) containing rolled corn and soybean meal: SUP-A (27.9% CP, DM basis) fed at 1.25 kg/animal daily with all CS and TC silages; SUP-B (16.2% CP, DM basis) fed at 2.27 kg/animal daily with all PM and S silages. Each SUP delivered Vitamins A, D, and E (24,000, 8,000, and 400 IU/d, respectively), Se (2.0 mg/d) and

lasalocid (150 mg/d). On d 1, steers were implanted with Synovex-S[®], heifers with Synovex-H[®]. Means of consecutive daily full weights were used as initial and final BW. The 10-mo old steers ($n=64$; 282 kg BW) and heifers ($n=64$; 228 kg BW) were ranked by weight and randomly assigned to treatments in a 4 X 2 factorial arrangement. Silage (6 samples/treatment) DM, CP, ADF, NDF, and calculated TDN (%), respectively, were: CS=28.1, 9.3, 25.5, 42.4, 69.8; CSI=29.3, 8.8, 24.3, 41.3, 68.7; PM=21.0, 11.7, 40.0, 59.5, 55.3; PMI=20.8, 12.2, 40.8, 61.2, 56.3; TC=25.9, 8.2, 35.3, 56.8, 66.2; TCI=27.3, 8.2, 35.4, 58.0, 66.0; S=22.2, 7.8, 39.1, 61.4, 56.0; SI=23.6, 7.6, 38.4, 61.3, 55.8. The ADG and DMI (kg), and DM/gain, respectively, by main effects were: Silage=CS, 1.39, 6.97, 5.02; PM, .94, 5.93, 6.37; S=1.16, 6.50, 5.64; TC, 1.07, 6.10, 5.66; SE=ADG, .07, DMI, .05, DM/gain, .14; Inoculant=NI, 1.13, 6.33, 5.71; I, 1.16, 6.41, 5.6; SE=ADG, .05, DMI, .37, DM/gain, .20. Kind of silage affected ADG and DM/gain ($P < 0.01$), and DMI ($P < 0.07$), with highest ADG on CS, lowest on PM, but adding the inoculant did not improve ($P > 0.10$) ADG, DMI or DM/gain in growing cattle.

Key Words: Cattle, Silage, Feedlot

657 Are bacterial direct-fed microbials effective against sub-clinical acidosis in feedlot cattle? G. R. Ghorbani*^{1,2}, D. P. Morgavi¹, K. A. Beauchemin¹, and J. A. Leedle³, ¹*Agriculture and Agri-Food Canada, Lethbridge, AB, T1J 4B1, Canada*, ²*Isfahan University of Technology, Isfahan, Iran*, ³*Chr. Hansen BioSystems, Milwaukee, WI, 53214*.

Sub-clinical acidosis can result in significant economic losses to the feedlot cattle industry. A study was conducted to determine whether bacterial direct-fed microbials (DFM) can be used to minimize the risk of acidosis without compromising the high production levels achieved with high concentrate diets. Six ruminally cannulated steers were used in a double 3 × 3 Latin square to study the effects of DFM on feed intake, ruminal pH, and ruminal and blood characteristics. Steers were provided *ad libitum* access to a diet containing steam-rolled barley, barley silage, and a protein-mineral supplement; 87, 9, and 4% (DM basis), respectively. Treatments were A) *Propionibacterium* P15, B) *Propionibacterium* P15 and *Enterococcus faecium* EF212, and C) control. The bacterial treatments, 10⁹ CFU/g whey powder carrier, or whey powder alone for C, were topdressed once daily at the time of feeding (10g/head/d). Periods consisted of 2 wk of adaptation and 1 wk of measurements, and ruminal pH was measured every 15 min for 6 d using indwelling electrodes. DMI, ruminal pH (mean, minimum, hours pH < 5.8) and blood pH were not affected by treatment ($P > 0.05$). However, treatment A increased ruminal NH₃ concentration ($P < 0.1$) and protozoal numbers ($P < 0.05$) with a concomitant reduction in the number of amylolytic bacteria ($P < 0.05$) compared with the control, while treatment B had no effect. However, it decreased *Streptococcus bovis* enumerated using a selective medium, although this effect was not significant. Although the bacterial DFM used in this study did not induce changes in DMI or ruminal pH, some rumen variables indicated that the propionic acid producing *Propionibacterium* might decrease the risk of acidosis in feedlot cattle.

Key Words: Sub-clinical acidosis, Bacterial direct-fed microbials, Feedlot diet

658 Effect of corn processing on ruminal starch digestion, microbial protein flow, and degradable intake protein requirements of finishing cattle. R. J. Cooper*, C. T. Milton, T. J. Klopfenstein, T. L. Scott, and D. J. Jordon, *University of Nebraska, Lincoln*.

Metabolism and finishing studies were conducted to evaluate the effect of corn processing on ruminal starch digestion, microbial protein flow, and degradable intake protein requirements of finishing cattle. In the metabolism study, six ruminally and duodenally-cannulated steers (523 kg) were used in a replicated 3 × 3 Latin square design experiment. Dietary treatments consisted of 90% concentrate diets that were dry-rolled (DRC), high-moisture (HMC), or steam-flaked corn-based (SFC). True ruminal OM digestibilities were increased ($P < .07$) by approximately 18 and 8% for HMC and SFC, respectively, compared with DRC. Ruminal starch digestibilities were similar between HMC and SFC, but were approximately 19% higher ($P < .05$) compared with DRC. Microbial N flow to the duodenum (g/d) was similar between DRC and SFC; whereas, microbial N flow to the duodenum was approximately 31% higher ($P < .05$) for HMC compared with the average of DRC and

SFC. Microbial N efficiencies were similar among treatments and averaged 25.9 g of microbial N flowing to the duodenum per kg OM truly fermented in the rumen, or 14.4 g of microbial CP per 100 g of total tract OM digestion. In the finishing study, 90 individually-fed steers were fed the same DRC, HMC, and SFC diets as in the metabolism study; however, urea was factored across diets at 0, 0.5, 1.0, or 2.0% of DM. For the dry-rolled corn-based diet, feed efficiency was not improved beyond the first increment of urea, suggesting that the DIP requirement was met at 6.3% of DM. For the high-moisture corn-based diet, nonlinear analysis predicted maximal feed efficiency at 1.14% urea which provided a dietary DIP value of 10.0% of DM. For the steam-flaked corn based diet, nonlinear analysis predicted maximal feed efficiency at 1.64% urea which provided a dietary DIP value of 9.5% of DM. We conclude that degradable intake protein requirements for finishing cattle are increased by corn processing methods that increase ruminal starch digestion compared with dry-rolled corn.

Key Words: Corn Processing, Degradable Intake Protein, Finishing Cattle

659 Factors affecting conjugated linoleic acid production by mixed ruminal bacteria. S. A. Martin^{*1} and T. C. Jenkins², ¹University of Georgia, Athens, GA, ²Clemson University, Clemson, SC.

The objective of this study was to identify environmental factors that influence conjugated linoleic acid (CLA) production by mixed ruminal bacteria. Ruminal contents were collected from a 600-kg ruminally fistulated Hereford steer maintained on pasture. Mixed ruminal bacteria were obtained by differential centrifugation under anaerobic conditions and added to basal medium that contained a commercial emulsified preparation of soybean oil and a mixture of soluble carbohydrates (cellobiose, glucose, maltose, and xylose). Culture samples were collected from batch culture incubations at 0, 2, 4, 6, 8, 12, 24, 26, 28, 30, 32, and 48 h. Continuous culture incubations were conducted at dilution rates of 0.05 and 0.10 per h, extracellular pH values of 5.5 and 6.5, and 0.5 and 1.0 g/L of mixed soluble carbohydrates. Culture samples were obtained from the culture vessel once steady state conditions had been achieved. In batch culture, *trans*-C_{18:1} concentrations increased over time and reached a maximum at 48 h. Little CLA was produced during the first 8 h, but *cis*-9, *trans*-11 CLA concentrations remained high between 24 and 30 h and *trans*-9, *trans*-11 CLA concentrations were high between 24 and 32 h. When mixed ruminal bacteria were maintained in continuous culture on 0.5 g/L of mixed soluble carbohydrates, concentrations of *trans*-C_{18:1}, *cis*-9, *trans*-11 CLA, and *trans*-9, *trans*-11 CLA were reduced ($P < 0.05$) at a dilution rate of 0.05 per h and extracellular pH of 5.5. Similar effects were also observed when 1.0 g/L of mixed soluble carbohydrates was used. When extracellular pH was lowered to 5.0, neither *trans*-C_{18:1} or CLA isomers were detected. In conclusion, our results suggest that culture pH appears to have the greatest influence on the production of *trans*-C_{18:1} and CLA isomers by mixed ruminal bacteria.

Key Words: conjugated linoleic acid, rumen, bacteria

660 Influence of diet on conjugated linoleic acid content of beef. C. S. Poulson^{*}, T. R. Dhiman, D. Cornforth, K. C. Olson, and J. Walters, Department of Animal, Dairy and Veterinary Sciences, Utah State University, Logan, UT 84322-4815.

Conjugated linoleic acid (CLA) has been shown to have health benefits in animal models. Increasing the CLA in beef would enhance its nutritive value. Twenty Angus crossbred steers (235 ± 18.8 kg BW) were used to study the effect of diet on the CLA content of beef. Steers were assigned to one of four treatments in a randomized block design, and were followed from weaning to slaughter. There were two feeding periods (backgrounding and finishing). During backgrounding: Trt 1, 2 and 3 received a diet consisting of a 60:40 forage to grain ratio. Trt 4 received alfalfa hay only. During finishing: Trt 1 and 2 received a diet consisting of a 15:85 forage to grain ratio. In addition to the basal diet Trt 2 received 84 g per head/d of a synthetic mixture of rumen protected CLA isomers. Trt 3 and 4 were finished on pasture containing predominantly Kentucky bluegrass and orchardgrass. Average live BW at slaughter was between 500 to 600 kg. Muscle tissue samples were collected at slaughter from the loin and round of each carcass and analyzed for fatty acid profile. Cattle finished on pasture (Trt 3 and 4) had 275 and 470% more C_{18:1} *trans* fatty acids, respectively, compared with Trt

1 (Table below). C_{18:1} *cis* fatty acids were not different among treatments. Beef from steers raised only on forages (Trt 4) had 550% more CLA (*cis*-9, *trans*-11), whereas steers receiving grain in backgrounding and grazed on pasture during finishing (Trt 3) had 300% more CLA compared with beef from steers fed typical high grain feedlot diet (Trt 1). Supplemental protected CLA (Trt 2) slightly increased CLA in the round, but not the loin. Raising cattle on forages and pasture with no grain supplementation can enhance the CLA content of beef.

Fatty acid*	Muscle	Trt	Trt	Trt	Trt	P <
		1	2	3	4	
C _{18:1} <i>trans</i>	Loin	1.1 ^d	2.6 ^c	3.6 ^b	6.1 ^a	0.03
CLA <i>cis</i> -9, <i>trans</i> -11	Loin	0.19 ^c	0.33 ^c	0.63 ^b	1.06 ^a	0.01

Key Words: Beef, CLA, Pasture

661 Effect of corn silage and soybean oil on *in vitro* production of conjugated linoleic acid (CLA) and 18:1 fatty acids by beef finishing diets. K. E. Griswold^{*}, G. A. Appgar, B. N. Jacobson, E. D. Frantz, R. A. Robinson, and J. S. Ely, Southern Illinois University, Carbondale, IL.

A study was conducted to determine the effect of level of corn silage (CS) and soy oil (SO) on *in vitro* production of CLA with beef finishing diets. The experimental design was a 2x3x5 factorial randomized complete block with CS (20 vs. 40% of diet DM), SO (0, 4, or 8% of diet DM) and time (0, 6, 12, 24, and 48 h) as the factors. There four replicates per treatment, and the experiment was conducted twice. Following standard *in vitro* digestibility procedures, incubated samples were analyzed for NDF digestion and fatty acid composition. Fatty acid analysis was performed on fatty acid methyl esters (FAMES) formed by direct acidic methylation. FAMES were quantified by gas-liquid chromatography. The CLA isomers measured were *cis*-9, *trans*-11 (c9,t11), *trans*-9, *trans*-11 (t9,t11), and *cis*-10,*trans*-12 (c10,t12). Total CLA (TCLA) and total 18:1 fatty acids (18:1FA) were also measured. Fatty acid concentrations are reported as mg per g of DM contents. NDF digestion was significantly less when CS was increased from 20 to 40% of diet DM ($P < .05$), and when 8% SO was added compared with 0 or 4% added SO ($P < .05$). Level of SO significantly increased production of t9,t11, TCLA and 18:1FA ($P < .001$), and there was a trend for level to increase c10,t12 ($P = .0725$). Level of CS tended to increase c9,t11 production ($P = .0759$). There was a significant CS by SO interaction for t9,t11, TCLA and 18:1FA ($P < .02$). Time significantly affected c9,t11, t9,t11 and 18:1FA production ($P < .05$) with the greatest concentrations occurring at 12 h of incubation. There was a trend for TCLA concentrations to be affected by time ($P = .0883$) with the greatest concentrations occurring with the 24 h incubation. Both CS and SO can be used to alter CLA and 18:1 fatty acid production during *in vitro* fermentation.

Key Words: CLA, In Vitro, Rumen Biohydrogenation

662 Effects of flake density of high oil corn and typical corn on performance and carcass characteristics of feedlot steers. T. C. Bramble¹, K. F. Wilson^{*1}, C. R. Richardson¹, C. P. Bridge¹, and F. N. Owens², ¹Texas Tech University, Lubbock, ²Du Pont Specialty Grains, Des Moines, IA.

To determine if density of steam-flaked high oil corn (HO) or typical corn (T) affected feedlot performance and carcass composition of feedlot steers, 16 English x Continental crossbred steers (BW = 363 ± 10.6 kg) were fed diets containing corn steam-flaked at either .31 kg/L (24 lb/bu) or .36 kg/L (28 lb/bu) flake densities for 127 d. Prior to initiation of the study steers were fed T processed at .36 kg/L. On d 0, steers were randomly allotted to four dietary treatments: typical corn, .31 kg/L (T24); typical corn, .36 kg/L (T28); high oil corn, .31 kg/L (HO24); or high oil corn, .36 kg/L (HO28). Diets, designed to meet or exceed NRC (1996) requirements, were formulated to be isocaloric and isonitrogenous by including HO into the diet at 75% of DM while T was included at 72% of diet DM with 2.8% blended vegetable and animal fat added to produce diets equal in ether extract. Daily gain of steers was greater ($P = .07$) d 0 to 28 for steers fed HO24 than for steers fed

HO28 and was greater ($P < .05$) from d 0 to 56 for steers fed HO24 than steers fed T24. Neither corn type nor degree of processing affected ($P > .10$) DMI. Feed efficiency (FE) over the total trial was superior ($P > .05$) for HO24 as compared to T24 and HO28. From d 0 to 56, feeding HO24 produced greater ($P < .01$) FE than feeding T24, T28, or HO28. Carcass characteristics (hot carcass weight, internal fat, external fat, marbling score, longissimus muscle area) were unaffected ($P > .10$) by dietary treatments. Differences in carcass variables were not expected because diets were formulated to be isocaloric and isonitrogenous. High oil corn can effectively replace typical corn plus supplemental fat in feedlot diets, and more extensive processing of high oil corn will enhance its feeding value.

Key Words: High oil corn, Steam-flaked corn, Steers

663 Effect of Dry-Rolled High-Oil Corn or Added Corn Oil on Ruminant and Total Tract Digestibility of Beef Cattle Finishing Diets. L.R. Kennington^{*1}, C.W. Hunt¹, J.G. Andrae¹, G.T. Pritchard¹, and F.N. Owens², ¹University of Idaho, Moscow, ²Dupont Specialty Grains, Des Moines, IA.

Three ruminally and duodenally cannulated Angus steers were used in a replicated 3 x 3 Latin square design to evaluate digestion characteristics of dry-rolled high-oil corn and its isogenic counterpart in finishing diets. Dietary treatments included: 1) isogenic typical corn (TC, 79.2% of diet DM), 2) a high-oil corn hybrid (HOC, 79.2% of diet DM), and 3) TC with 2.4% added corn oil (OIL, 76.9% typical corn). Ruminant OM and GE digestibilities were greater ($P < .05$) for HOC and OIL than for TC (66.2, 70.9 vs. 60.2%; 63.5, 67.2 vs. 54.9%, respectively). In contrast, total tract OM digestibility was greater ($P < .05$) for TC and OIL diets than for the HOC diet (88.4, 89.2 vs. 86.9%). Total tract GE digestibility was greater ($P < .05$) for OIL (88.1%) than HOC (85.8%) with GE digestibility of TYP being intermediate (87.2%). Ruminant starch digestibility was greater ($P < .05$) for OIL than TC or HOC (86.1 vs. 75.5 and 78.9%) while total tract starch digestibility was greater for OIL and TC ($P < .05$) than HOC (97.1, 96.3 vs. 94.8%). Total fatty acid digestibility was greater ($P < .05$) for HOC and OIL than TC (75.7, 75.2 vs. 68.8%). Due to higher fatty acid intake, steers fed HOC and OIL had greater ($P < .05$) daily intake of ME (DE^{*.82}) than steers fed TC (32.1, 32.6 vs/ 30.6 Mcal/d). However, diet ME (Mcal/kg DM) was greater ($P < .05$) for OIL (3.07) than TC (2.95) with diet ME of HOC being intermediate (3.01). Despite the higher oil content of HOC and its 3.6% greater GE concentration, slightly greater fecal starch and fatty acid losses reduced its ME advantage to only 2.2% over the diet containing typical corn. Subtracting DE contributed by other diet components,

ME content was not significantly greater (2.6% higher) for the rolled high-oil corn than typical corn. In contrast, adding 2.4% corn oil to the diet increased diet GE by 3% and diet ME by 4.2%, due to slight decreases in fecal starch and NDF concentrations.

Key Words: High-oil corn, Beef, Energy

664 Effects of high oil corn and shade on performance of Angus and Bonsmara x Beefmaster feedlot steers. T. C. Bramble^{*1}, C. R. Richardson¹, K. F. Wilson¹, G. V. Pollard¹, C. P. Bridge¹, F. N. Owens², and G. R. Chapman³, ¹Texas Tech University, Lubbock, ²Du Pont Specialty Grains, Des Moines, IA, ³Amarillo, TX.

This experiment was designed to determine if corn source [high oil corn (HO) vs typical corn (T)] would alter performance of finishing steers with or without access to shade in partially slotted floor feedlot pens. Steers of Angus (A) (n=59, BW = 322 ± 2.2 kg) and Bonsmara x Beefmaster (B) (n = 56, BW = 294 ± 2.1 kg) heritage, were fed for 150 d (July 17 to December 13, 2000). Breed was nested within pens and steers were blocked into pens by weight. Treatments included: NST (no shade, typical corn), NSHO (no shade, high oil corn), ST (shade, typical corn), and SHO (shade, high oil corn). Finishing diets, formulated to meet or exceed NRC (1996) requirements, consisted of 77.7% steam-flaked (.36 kg/L, 28 lb/bu) corn (either HO or T), 10% roughage, and protein, vitamin, mineral, and feed additive supplements. Shade structures, black, 80% light-occluding polypropylene cloth fixed 3 m above pens, covered 67% of pen area (9.8 m² of shade/steer). Supplemental shade increased DMI by 6.8% ($P = .05$) during the first 28 d, HO improved ($P = .02$) DMI by 3.2% from d 28 to 56, but neither shade nor diet impacted ($P > .10$) DMI for the total trial. Steers fed HO had greater ($P = .07$) ADG (1.62 vs 1.55 kg) than steers fed T for the total study, but shade had no effect on ADG. Daily gain was greater ($P < .01$) for A than B cattle over the total trial. Feed efficiency (FE) was improved ($P = .04$) by shades from d 28 to 56 but was not different ($P > .10$) for any other period during the trial. High oil corn improved ($P < .01$) FE by 5.8% from d 0 to 85 and improved ($P = .06$) overall FE by 3.0% (5.13 vs 5.29 kg feed/gain). Although Angus steers gained faster than Bonsmara x Beefmaster and substituting high oil corn for typical corn improved ADG and FE, shades failed to improve performance when averaged over the total trial. However, early in the trial or when ambient temperature increased, shade may improve DMI and FE of typical corn.

Key Words: High oil corn, Shade, Bonsmara

665 An evaluation of feeding practices associated with milk production and milk composition. C.R. Richardson^{*} and D.A. Christensen, University of Saskatchewan.

The objective of this study was to look for links between feeding management strategies and milk composition on dairy farms near Saskatoon, SK, Canada. Eleven dairy farms that fed a total mixed ration (TMR) and participated in Dairy Herd Improvement (DHI) testing were selected to participate in a 54 d, observational study. Nine farms completed the study. Data collected included dry matter intake (DMI), particle size variation of TMR, times fed per day, bulk tank milk production and weekly milk composition. Milk component production (Kg) and 3.5% fat corrected milk (FCM) were calculated. Analysis was done on TMR for moisture, CP, NDF, ADF, EE, moisture and ash. Herd size ranged from 37 to 197 cows. Milk protein content ranged from 3.10 % to 3.36 %, which differed between farms ($P < 0.05$). Milk fat content ranged from 3.45% to 4.00% ($P < 0.05$). Total milk production and milk per cow was significantly different between farms ($P < 0.05$). DMI ranged from 19.0 to 31.5 Kg per day. Herds with the highest intakes did not always have the highest milk production. Pearson correlations for DMI and milk yield per cow ranged from -0.35 to 0.46. Herds differed in times fed per day and particle size of the TMR. Herds with the highest NDF and ADF were not necessarily the highest fat herds. Small ration particle size was not always highly correlated with milk fat percentage. Strength of correlations for feeding practices varied between farms. Milk production correlated strongly with milk protein yield ($r^2=0.988$) and milk fat yield ($r^2=0.993$). Fluctuations in daily DMI were significant between farms. There are many factors that influence milk production

and composition. It appears that the amount each of these factors contributes varies from farm to farm and includes a combination of feeding management techniques

Key Words: milk composition, feeding management, nutrition

666 Effect of different levels of dietary protein on nitrogen metabolism of heifers. J.C. Marini^{*} and M. E. Van Amburgh, Cornell University, Ithaca NY 14853.

Four Holstein heifers (with an initial weight of 204 kg ± 5 SD) were used in a Youden square design (5 periods and 5 treatments) in order to investigate the effect of dietary protein levels on nitrogen (N) metabolism. Five diets (D) calculated to be isocaloric on a ME basis (30% hay:70% concentrate) varied in CP levels from D1 to D5, 8.9, 12, 15.7, 18.6 and 21.4 %CP respectively, and were fed to the animals at 2x maintenance. Differences in CP were achieved by substituting citrus pulp for soybean meal. Plasma urea nitrogen (PUN) concentration and rumen ammonia concentration (RAN) for D1 and D2 were low and suggested that they were N deficient although only the lowest level of protein intake depressed total tract DM and NDF digestibilities ($P < 0.01$). Nitrogen balance increased with increasing levels of CP although D2 was not statistically different than D3, D4 and D5. Fecal N excretion and the non-urea fraction of urinary N did not differ among treatments. Lucas analysis showed that the true digestibility of the protein was 96% and metabolic fecal N excretion was 0.54 g N/MBW ($R^2=0.99$). Endogenous urinary N was 0.24 g/kg MBW and the N excreted in the urine

accounted for 87% of the N apparently absorbed ($R^2 = 0.97$). The data demonstrate that heifers on a N deficient diet (D2) were able to maintain performance and NDF digestibilities similar to heifers on higher CP diets despite low levels of RAN. It appears the heifers were able to salvage N by reducing urea clearance by the kidney. Creatinine clearance suggests that this was achieved by increasing the tubular reabsorption (TUR) of urea.

667 Effect of increasing level of dietary protein on serum concentrations of metabolic hormones and mammary development in Holstein heifers consuming a moderate-energy diet. R. Lopez^{*1}, C.R. Krehbiel², M.G. Thomas¹, D.M. Hallford¹, D.H. Keisler³, B.S. Obeidat¹, J.A. Hernandez¹, W.D. Bryant¹, M. Garcia¹, and R. Flores¹, ¹New Mexico State University, ²Oklahoma State University, ³University of Missouri.

The dietary level of CP and CP:ME dietary ratio could be used as tools to manipulate physiological processes of growth and mammary development and increase lifetime milk production. Herein, 24 Holstein heifers (initial BW = 143–30 kg) 120 d of age were individually fed a 52:48 concentrate:roughage diet (NEm = 1.61 Mcal/kg; NEg = 1.01 Mcal/kg) with increasing levels of protein (12, 14, 16, and 18% CP from Soybean meal [SBM]; DIP=68.5% of CP; n = 6 heifers/protein level) until they reached puberty. After puberty, heifers were slaughtered during the mid-luteal phase of the estrous cycle. Previously, we reported that maximum growth rate was achieved in heifers consuming 16% CP, but levels of 12 to 18% produced adequate growth rates without altering the weight of viscera, liver, peripheral tissue, mammary gland or the age of puberty [J. Anim. Sci. 78 (Suppl. 1): 294]. Further investigation revealed that corporal fat (P = 0.31), mammary parenchymal tissue weight (P = 0.58), parenchymal RNA and DNA (P = 0.24), and the RNA:DNA ratio (P = 0.50) were not affected by treatments. However, heifers consuming 16% CP tended (P = 0.12) to have more total mammary fat than those consuming 12, 14, or 18% CP. Mammary fat masses for 12, 14, 16, and 18% CP diets were 0.65, 0.65, 1.1, 0.64 kg, respectively. No differences were observed in serum concentrations of leptin, GH, or IGF-1 (P ≥ 0.28) across treatments. However, serum concentrations of insulin (P < 0.02) were greatest in heifers consuming diets of 16% CP whereas serum concentrations of glucose were greatest (P < 0.05) in heifers consuming diets of 18% CP. Concentrations of insulin, glucose, and leptin increased (P < 0.05) in heifers as they aged

from 120 to 291–8 d. Uniquely, partial correlation analyses with the effect of treatment removed, revealed that serum concentrations of leptin were positively correlated with mammary fat (r = 0.21, P < 0.05) but negatively correlated with (r = -0.23, P < 0.05) corporal fat. Data provide evidence to suggest that moderate energy diets containing 16% CP from SBM stimulate enhanced growth and mammary adiposity relative to diets containing 12, 14, and 18% CP. These results could be due to alterations in the milieu of metabolic hormones influenced by the diets.

Key Words: Holstein, Mammary, Leptin

668 Increased crude protein to energy ratios on in situ dry matter disappearance, rumen ammonia, nitrogen balance, and urinary excretion of purine derivatives of prepubertal Holstein heifers. M.T. Gabler^{*}, A.J. Heinrichs, and L.C. Griel, *The Pennsylvania State University.*

Four prepubertal Holstein heifers, 1465.0 d of age and 152.87.6 kg of BW, fitted with ruminal cannulae were used to evaluate dietary crude protein (CP) to metabolizable energy (ME) ratio's (g CP: Mcal ME) influence on in situ DM disappearance (DMD), rumen ammonia (RA), N excretion (NE), and urinary excretion of purine derivatives in a 4X4 Latin square design with 21 d periods. The diet's CP:ME ratios were 45:1, 63:1, 69:1, and 77:1 g of CP per Mcal of ME. The CP:ME ratios were altered by adjusting the concentration of CP (11.9, 16.7, 18.1, and 20.1 % CP) with similar amounts of ME (2.6 Mcal/kg) across all diets. Diets contained corn silage and grass hay as forage sources with a protein pellet and supplemental soybean meal as the protein sources. Diets were formulated to provide a 60:40 forage to concentrate ratio, and were fed once daily at 2.0 % BW DMI. In situ DMD increased quadratically (P<0.01) for the ratio 63:1 CP:ME and was 8 % and 14 % greater than the 77:1 and 45:1 CP:ME ratios respectively. A linear increase (P<0.01) was observed for RA and blood urea nitrogen as CP:ME ratios increased. A linear increase (P<0.01) in urinary N excretion resulted in a linear increase (P<0.01) in total NE as CP:ME ratios increased. Nitrogen utilization tended to improve quadratically (P=0.17) with the ratio 63:1 CP:ME which showed a 41 %, 14 %, and 20 % greater N retained as a % N consumed than the 77:1, 69:1, and 45:1 CP:ME ratios, respectively. Urinary excretion of the purine derivative allantoin increased linearly (P=0.02) with increasing CP:ME ratios. Feeding a CP:ME ratio of 63:1 at 2% BW DMI has comparable performance with higher CP:ME ratios, but results in greater N retained as a % of N intake.

669 Degradation of soluble crude protein in the rumen. M. Melin¹, M. Gierus^{*1}, A.M. van Vuuren¹, and G.A.L. Meijer¹, ¹ID TNO Animal Nutrition.

Although CP in the soluble fraction lost during washing of nylon bags is often assumed to be fully and rapidly degraded in the rumen, its actual fate in the rumen is questioned. We developed a filtration procedure that mimics machine washing of nylon bags and enables a further characterization of this soluble fraction. The filtrate of 1-3 g of DM of ten feeds was collected in 100 ml of rinsing water. Feeds were two grass silages (GS1, 25% of DM, and GS2, 53% of DM), wet brewers grain silage (WBGS) and corn gluten feed silage (CGFS), 3 types of corn gluten feed (CGF1 to 3), soybean meal (SBM), lupine meal (LPM) and rape seed meal (RSM). DM and N losses of the filtration procedure and machine washing were compared in quadruplet samples. DM losses during filtration and from nylon bags ranged from 16% in WBGS to 46% in GS1 and were not different between procedures. N recovered in the filtrate ranged from 11.5% for SBM to 56.1% for GS1. The filtrate was centrifuged at 1500 g for 20 min. The pellet was analyzed for N in non-soluble particles (NS). Soluble true proteins (TP) in the supernatant were precipitated with TCA (10% in the final volume), and the N in the remaining supernatant was defined as non-protein N (NPN). The NS fraction comprised 0% (GS1 and 2) to 87% (WBGS) of N in the filtrate. Significant amounts of TP were found in SBM (53%), LPM (30%) and RSM (27%). NPN ranged from 13% (WBGS) to 100% (GS1 and 2) of N in the filtrate. The degradation of the protein N (NS +TP) in the filtrate of 6 feeds was measured in rumen fluid using a modified Broderick method. After 4h of incubation the percentages of degraded protein were: 0% (WBGS and CGFS), 24% (CGF 2), 55% (RSM), 79% (LPM) and 80% (SBM). These results show that CP in the soluble fraction, as determined in the nylon bag technique, consists of different protein and non-protein fractions, that are not always rapidly and fully degraded

in the rumen. The potential underestimation of the protein value of these feeds, calculated as $((NS + TP) / N_{feed}) \times \% \text{undegraded}^{4h}$, is 2 - 7 % for the concentrates, and 13 % and 26 % for CGFS and WBGS, respectively.

670 Effects of varying dietary protein and fiber levels on the production of lactating dairy cows. G. A. Broderick*, U.S. Dairy Forage Research Center, Madison, WI.

Eighteen primiparous and 45 multiparous Holstein cows were blocked by parity and DIM and randomly assigned to 7 squares in an incomplete Latin square trial with 4, 4-wk periods. Nine TMR, 3 levels of NDF each at 3 levels of CP, were formulated from alfalfa and corn silages, high moisture corn, solvent soybean meal, plus minerals and vitamins. Levels averaged (DM basis) 36, 32 and 28% NDF and 15.1, 16.7 and 18.4% CP. Milk yield and DMI were measured daily in the last 2 wk of each period; yield of milk components was determined one day in each of the last 2 wk of each period. Fecal and urine grab samples were collected in the last wk of each period to estimate N excretion. The statistical model included square, cow(square), period(square), CP and NDF level, and 2-way interactions; the error term was cow(square). No 2-way interactions or quadratic effects were significant ($P \geq 0.21$) (data not shown). There were linear increases in DMI, MUN and urinary N excretion, and linear decreases in milk N/N intake (NI) and fecal N excretion, with increasing dietary CP. There were linear increases in BW gain, yield of milk and milk components and milk/DMI, and linear decreases in MUN, milk N/NI and urinary N excretion, with decreasing dietary NDF. Reducing dietary NDF improved milk yield and efficiency; increasing dietary CP from 15.1 to 18.4% had little effect on yield but reduced N utilization.

671 The effect on milk production of a ruminal nitrogen (N) deficiency in dairy cows: evaluation of the Cornell Net Carbohydrate and Protein System (CNCPS) ruminal N deficiency adjustment. R. Ruiz*, L. O. Tedeschi, and D. G. Fox, Cornell University, Ithaca, NY.

Twenty-four multiparous and fifteen first lactation Holstein cows averaging 263 days in milk and 614 kg of body weight (BW) were fed ruminal N deficient or adequate diets, based on predictions of the CNCPS. After adjustment to a low CP TMR (11% CP) the cows were allocated in 13 blocks based on milk production, body condition score, and BW. Within each block, cows were randomly assigned to one of the 3 treatment (TRT) diets (8, 10 and 13% CP for TRT 1, 2, and 3 respectively). All diets contained the same proportion of high moisture corn, chopped grass hay, and minerals, with urea substituted for corn silage as needed to reach the 3 CP levels. The TRT diets were then fed for 4 wk. Feed samples were composited weekly and analyzed for NDF, lignin, CP, soluble protein, NPN, NDFN, ADFN, fat, and ash. Carbohydrate degradation kinetics were determined on the corn silage and hay samples. The least squares means for ruminal N balance (% of required) predicted by the CNCPS differed ($P < .0001$) among the 3 TRT; values were 92.3, 108.2, and 132.3% for TRT 1, 2, and 3 respectively. Milk production was significantly affected by TRT; milk production increased as ruminal N balance increased. TRT affected DMI; however, no significant differences were found between TRT 2 and 3. Plasma urea nitrogen (PUN) concentration differed among the 3 TRT diets. CNCPS predictions (with

and without the N deficient adjustment) of metabolizable protein (MP) allowable milk production were compared to observed milk production. Using individual weekly cow data from all 3 TRT, the CNCPS accounted for 69 and 72% of the variation in MP allowable milk without and with the N deficient adjustment, respectively.

672 Effect of dietary carbohydrate composition on utilization of ruminal ammonia nitrogen for milk protein synthesis in dairy cows. A. N. Hristov* and J. K. Ropp, Department of Animal and Veterinary Sci., University of Idaho, Moscow, ID 83844-2330.

A trial with four ruminally and duodenally cannulated, late-lactation dairy cows (32319.5 DIM; 26.81.65 FCM) was conducted to investigate the effect of dietary carbohydrate (CHO) composition on ruminal ammonia N utilization and transfer into milk protein. Two diets were fed three times a day, at 8-h intervals in a cross-over design. The diets (RFSS and RFNDF) were formulated to provide similar levels of undegradable and soluble protein and total ruminally fermentable CHO but differed in the composition of the CHO fractions: diet RFSS contained a larger proportion of available CHO in the sugars and starch fractions (barley and molasses) and diet RFNDF contained a larger proportion in the ruminally fermentable NDF fraction (corn, beet pulp, and brewers grains). Nitrogen-15 was used to label ruminal ammonia N and consequently the microbial and milk N pools. Diet RFNDF resulted in a lower (trend at $P < 0.1$) proportion of bacterial N derived from ruminal ammonia N (36.6%) as compared to diet RFSS (61.8%). The proportion of milk protein N originating from ruminal microbial N (based on the areas under the ¹⁵N-enrichment curves) was higher ($P < 0.001$) on the RFNDF diet as compared to the RFSS diet (44.0 and 29.4%, respectively). The proportion of milk protein-N originating from ruminal ammonia-N was not different ($P > 0.05$) between the two diets (18.7 and 16.4%, diets RFSS and RFNDF, respectively). The milk urea N concentration varied greatly with time of sampling and individual cows and was lower ($P < 0.05$) with the RFNDF than with the RFSS diet (13.9 and 16.1 mg/dl, respectively). The results from this study suggested that, compared to diets containing higher levels of ruminally fermentable starch and sugars, diets providing higher concentration of ruminally fermentable NDF can enhance the transfer of ruminal microbial N into milk protein. The overall level of utilization of ruminal ammonia-N for milk protein synthesis was not affected by the CHO composition of the diets.

673 Evaluation of models to predict urinary excretion and milk urea nitrogen. R.A. Kohn*¹, K.F. Kalscheur², and E. Russek-Cohen¹, ¹University of Maryland, College Park, ²South Dakota State University, Brookings.

Milk urea nitrogen (MUN) has been used to estimate urinary nitrogen (N) excretion and identify overfeeding or underfeeding of protein to dairy cows. Urinary N (g/d) was first reported to equal 12.54 times MUN (mg/dl), but recently was reported to equal 17.64 times MUN. In September of 1998, the National Dairy Herd Improvement Association (DHIA) revised the methods for developing calibration standards for MUN analyses. As a result, MUN values reported by DHIA labs decreased from previous values by an undetermined amount. The objectives of this research were 1) to evaluate models that predict urinary N and expected MUN, and 2) to quantify changes that occurred in the fall of 1998 in MUN analyses performed by DHIA. Two data sets were used. The first was from the spring of 1998 (n=92) and the second was from the spring of 1999 (n=12). The lack of fit of the models to the data was represented as the root mean square prediction error (RM-SPE) which includes error due to bias and dispersion. For the older data set, the newer model underestimated ($P < 0.01$) MUN by an average 3.8 mg/dl (RMSPE = 4.9), while the older model was accurate (RMSPE =

4.3). However, for the newer data set, the older model overestimated ($P < 0.01$) MUN by 4.8 mg/dl (RMSPE = 6.2), while the newer model was accurate (RMSPE = 3.0). MUN measurements were compared for the two data sets after adjusting for differences in milk production, feed intake, and body weight. In the period between the two studies, MUN values appeared to decrease by an average of 4.0 mg/dl, thus changing coefficients to predict urinary N and target MUN concentrations. Using the recent data set, urinary N (g/d) was equal to MUN (mg/dl) times 16.2 (SE=0.85) for Holstein cows averaging 623 kg in body weight. Changes in the MUN values reported by DHIA labs have resulted in target MUN concentrations changing from 12 to 16 mg/dl to a current target range of 8 to 12 mg/dl for most Holstein herds.

Key Words: Milk urea nitrogen, Urinary nitrogen

674 Effect of diet and sampling technique on milk allantoin. W.M. Schager*, J.H. Harrison, and D. Davidson, Washington State University, Puyallup, WA USA.

Two experiments were conducted on dairy cows to determine the effect of: 1) a diet change on the temporal change in milk allantoin output, and 2) techniques for collecting milk samples for allantoin determinations. In experiment one, 4 lactating Holstein cows were used in a 2 x 2 Latin square design with 2 treatments and 2 periods. Treatments were the ratio of forage to concentrate (40:60 and 60:40) and periods were 5 days. Milk samples were collected twice daily for 20 consecutive milkings and analyzed for milk allantoin. Milk yield and dry matter intakes were also recorded. In experiment two, milk from 6 Holstein cows was collected at 1030 h by: 1) a strip sample collected immediately before milking, 2) a strip sample collected 3 minutes from start of milking, and 3) a composite sample taken with an autosampler. Milk yield, milking time, and milk allantoin concentration were recorded for each cow. In experiment one, there was a significant ($P < 0.02$) change in the amount of allantoin in milk 12 h (first subsequent milking) after a change in diet. There was no difference in milk yield or dry matter intake between treatments. In experiment two, no difference was detected in milk allantoin concentration among the three sampling methods. In conclusion, a temporal change in milk allantoin amount can be observed within 12 h after a diet change. Strip samples of milk taken immediately before milking may be an alternative to collecting composite milk samples for the analysis of milk allantoin.

675 Protein quantity and quality for dairy cows exposed to hot, humid weather. J. W. West*¹, J. K. Bernard¹, D. S. Trammell¹, P. S. Chan¹, and J. M. Fernandez², ¹University of Georgia, Tifton, GA/USA, ²LSU Agricultural Center, Baton Rouge, LA/USA.

Twenty lactating Holstein cows averaging 103.3 DIM (± 37.5 d) were used in an 11 wk trial to determine the response to dietary CP and RUP concentrations fed during hot weather. The study duration was May 10 through July 25. Mean maximum and minimum temperature, relative humidity, and temperature-humidity index (THI) were 32.6 and 20.6°C; 89 and 42%; and 80.9 and 69.1. Treatments were arranged as a 2 x 2 factorial to provide 17.0 or 18.5% CP and 33.6 or 41.1% RUP using Prolak[®] as the RUP source. Intake of DM, milk yield, 3.5% FCM yield, and FCM per DMI for moderate and high CP and moderate and high RUP diets were: 22.7, 23.7, 23.2, 23.2 kg/d; 28.3, 31.5, 30.3, 29.4 kg/d; 31.3, 35.3, 33.4, 33.2 kg/d, and 1.37, 1.45, 1.41, 1.42 kg/kg. No significant main effects or interaction were detected ($P > .10$). Milk fat and protein percentages, fat and protein yields, and milk urea N for

moderate and high CP and moderate and high RUP diets were: 4.04, 3.91, 4.05, 3.91%; 2.89, 2.82, 2.92, 2.80%, 1.17, 1.28, 1.24, 1.22 kg/d, 0.83, 0.91, 0.88, 0.87 kg/d, 11.1, 13.2, 11.8, 12.5 mg/dl. There was a CP by RUP interaction for fat yield ($P < .07$), and MUN was higher for the high CP diet ($P < .03$). Respiratory rate was not different by treatment, but was elevated (79.1 breaths/min). Concentrations of triiodothyronine (T3), thyroxine, cortisol, insulin, glucose, and serum urea N for moderate and high CP and moderate and high RUP diets were: 117.42, 102.43, 118.64, 101.20 ng/dl, 3.30, 3.40, 3.52, 3.17 μ g/dl, 1.05, 1.02, 1.10, .97 μ g/dl, 9.33, 10.73, 9.86, 10.19 μ IU/ml, 3.03, 3.07, 3.09, 3.01 mmol/L, and 5.10, 6.17, 5.47, 5.80 mmol/L. Significant effects for CP and RUP on T3 concentration ($P < .06$ and $P < .03$, respectively), and for CP on serum urea N content ($P < .001$) were detected. There was a trend for improved milk and FCM yield with high CP, but no effect with RUP supplementation. It appears that the moderate levels of CP and RUP were adequate to maintain production under the hot, humid conditions of the study.

Key Words: Heat stress, Protein, Rumen undegraded protein

676 Effect of condensed tannins on proteolytic bacterial populations in the rumen and on nitrogen flow to the abomasum of sheep. B.R. Min*¹, G.T. Attwood², W.C. McNabb², and T.N. Barry³, ¹E (Kika) de la Garza Institute for Goat Research, Langston, ²AgResearch, Grassland Research Center, Palm/North, NZ, ³Massey university, Palm/North, NZ.

Twelve six month old sheep (33 ± 2.3 kg BW) were fed *Lotus corniculatus* (32g condensed tannins (CT)/kg DM) to examine effects of CT on four proteolytic rumen bacterial populations and nitrogen (N) flux to the abomasum (Ab). In Experiment 1, the populations of rumen bacteria were enumerated directly from rumen samples using a competitive polymerase chain reaction technique. In Experiment 2, ruminal N flux in whole rumen digesta was measured by continuous infusion of ¹⁵N ammonium chloride into the rumen of all sheep. Effects of CT were determined by making measurements in the presence and absence (CT-acting) of polyethylene glycol (PEG), which binds and inactivates CT. When feeding perennial ryegrass/white clover (referred to as pasture), populations of *Clostridium proteoclasticum* B316, *Eubacterium* sp. C12b, *Streptococcus bovis* B315, *Butyrivibrio fibrisolvens* C211a were 1.6×10^8 , 2.7×10^8 , 7.1×10^6 and 1.2×10^6 per ml, respectively. When the diet was changed from pasture to Lotus, the average populations of same strains from the same animals decreased significantly ($P < .001$) to 5.1×10^7 , 1.5×10^8 , 2.6×10^6 and 1.0×10^6 per ml, respectively. When PEG was infused into the rumen of sheep fed Lotus, the populations of proteolytic bacteria increased significantly ($P < .01-.001$) compared with the CT-acting group. The N and DM intake, rumen non-ammonia N (NAN) and microbial NAN (MNAN) pool sizes, and abomasal MNAN flux were similar in both groups. However, CT reduced ruminal N digestibility and ammonia pool size ($P < .05-.01$), and increased the flow of non-MNAN to the Ab ($P < .01$). Lotus CT protected protein against degradation in the rumen, and increased the flow of by-pass protein to the Ab. Therefore, more protein was available for hydrolysis in the small intestine in sheep fed Lotus.

Key Words: Bacterial population, N flux

677 Multiple regression analysis of data collected across many trials: a meta-analytic approach. N.R. St-Pierre*, The Ohio State University.

There are frequent reports of statistical analyses done on data collected across many studies published in scientific literature. Generally, standard multiple regression analysis procedures are used. There are two fundamental reasons why such methods are inappropriate in these instances. First, observations within a study have more in common than observations across studies. Ignoring the study effect in the analysis leads to inflated and biased estimates of the residual variance. Second, levels of the independent variables are not pre-planned and, generally, are very imbalanced. Ignoring the study effect leads to biased estimates of regression coefficients. We illustrate the proper meta-analytic procedure using two regression analyses published in the 2001 Nutrient Requirements of Dairy Cattle publication (table 5-3). The regression involved 206 observation means from 38 studies. Using conventional multiple regression methods, the milk response (M, kg/d) to dry matter intake (I, kg/d), rumen undegradable protein (U, % of DM), and rumen degradable protein (D, % of DM) was: $M = -52.6$ (SE=10.2) + 1.10

(SE=0.11) I + 8.66 (SE=1.74) D + 1.52 (SE=0.24) U + 0.35 (SE=0.08) D² with an estimated residual variance of 22.6. A mixed model with the same fixed effects but also with the random effect of study yielded the following equation: M = -17.2 (SE=7.5) + 1.42 (SE=0.09) I + 2.31 (SE=1.23) D + 0.95 (SE=0.17) U + 0.09 (SE=0.05) D² with an estimated residual variance of 6.59. A more complete mixed model resulted in an estimated residual variance of 5.70. The marginal milk production response to R and D must account for the marginal effect of R and D on I derived by fitting the following mixed model also with the ran-

dom effect of *study*: I = 18.1 (SE=1.26) + 0.16 (SE=0.08) D + 0.14 (SE=0.07) U. In a second example of the response in milk production to I and crude protein level in the diet, mixed models methods again reduced the estimated residual variance and generated better estimates of regression coefficients. Using the proper meta-analytic methods resulted in more accurate and precise estimates of production responses to nutrient concentrations in the diet.

Key Words: Meta-analysis, Multiple regression, Milk production response

ASAS/ADSA Teaching Undergraduate and Graduate Education and PSA Extension and Instruction: Teaching II

678 NASA's Reduced Gravity Student Flight Opportunities Program enhances undergraduate experiences and promotes team-building skills. S.T. Willard*¹, ¹*Department of Animal and Dairy Sciences, Mississippi State University, Mississippi State, MS.*

A proposal was submitted to NASA's Reduced Gravity Student Flight Opportunities Program (RGSFOP) by 9 undergraduate animal science majors and their advisor. The RGSFOP provides a unique academic experience for students to propose, design, fabricate, fly and evaluate a reduced-gravity experiment of their design. The overall experience includes scientific research, traditional and non-traditional classroom experiences and educational/public outreach activities. Of the 87 applications submitted, 47 proposals were accepted (54%) including the proposal from the Mississippi State Team. The aim of the proposed project entitled "Photonic Emission Kinetics of the Firefly Luciferase Enzyme in Microgravity" was to determine whether enzymatic reactions are altered in microgravity. The students met weekly to design the experiments and learn about working in microgravity. The team then traveled to the Johnson Space Center (Houston, TX) where for two weeks they participated in astronaut training, learned about NASA programs and tested their experiments. The students then flew aboard the Boeing KC-135A reduced gravity trainer aircraft to conduct their experiments during the 20 or more 25-second Zero-gravity maneuvers on each of two flights. Results indicated that there was a significant increase (P < .05) in the area under the enzyme reaction curve; illustrating that microgravity altered luciferase kinetics. Upon returning home, students participated in outreach activities including television, radio and newspaper interviews and presentations at departmental, alumni and other university functions. The students also constructed a web-site detailing their activities and continued to meet weekly to discuss their experiences. In addition to learning about scientific research and NASA, the students also learned the foundations of NASA Mission Operations: discipline, competence, confidence, responsibility, toughness and teamwork. In terms of lasting outcomes, the participating students commented that this experience was life-changing for many of them. This was re-enforced by comments from many of their professors indicating a positive change in student attitudes and confidence. In summary, the NASA RGSFOP offers both a unique research and personal growth experience for undergraduate students.

Key Words: Undergraduate education, NASA, Microgravity

679 Engaging students in the learning process in an undergraduate animal breeding course. G. E. Shook* and D. L. Thomas, *University of Wisconsin-Madison.*

An active learning approach that utilized short lectures, in-class discussions, and written feedback from students was applied to an undergraduate animal breeding course. The approach is based on a textbook that meets course goals in breadth and depth of content. The textbook and special readings, not lectures, define the scope of the course. The course is organized into two-period modules. Each module relates to a specific assignment that students are expected to read before class. Students take a 10-min quiz over the reading assignment at the start of the first period of a module before there is any in-class coverage of the material. The quiz tests for broad understanding rather than mastery of the material and rewards students that have read the assignment. The last question on the quiz is, "What is the most difficult or unclear concept in the chapter?" A 25-min lecture on the important points of the reading follows. For the final 15 min, students are given a discussion question that gives application to the material or reinforces concepts. Groups of 2 to 4 students are formed, and the group writes down their response. Several groups are asked to reveal results of their deliberations, and

the instructor comments on the accuracy and applicability of their comments. The second period starts with a 35-min lecture that addresses the concepts that the students indicated on the quiz were most difficult for them and finishes with another 15-min discussion question. Each module has a homework assignment that provides practice with application of concepts presented in the module. With this overall approach, students come to class familiar with the material to be discussed, attend class (something is completed in class and graded every period), have some control in directing the lecture to areas they are less sure about, and learn from the experiences of their classmates during the discussion periods. Students are active participants in their learning, and instructors are well informed by frequent feedback from students. Student comments include: "The organization of the class, homework and quizzes made me keep up with the material." "The discussions are an absolute must." "Discussion took up too much time in class." "This class requires self-teaching."

Key Words: Active learning, Animal breeding, Teaching

680 Research Proposal Writing and Student Peer Panel Evaluation as an Instructional Component for a Microbiology Graduate Course in Poultry Science. I.B. Zabala Diaz*, X. Li, and S.C. Ricke, *Texas A&M University, College Station, Texas/USA .*

Proposal writing is a vital experience for Poultry Science graduate students seeking academic careers, but graduate programs provide minimal opportunities to develop successful proposal writing skills. Proposal writing is emphasized in a graduate microbiology course taught in the Poultry Science Department, Texas A&M University. Based on a survey of enrolled students in the year 2000, only 28.5% of the students had previous experience in class proposal writing, but none possessed experience in proposal writing for funding. In addition, 71 % of the students had some experience at scientific writing but less than 30% had published scientific papers. The proposals for the course were written on a research problem that utilized information and concepts from the course and included a student peer panel evaluation as part of the course grade. The proposals were judged on the clarity of hypothesis presentation, the appropriateness of the experimental approaches and research relevance in basic and applied science. Overall, students found the experience an important one for developing writing skills in scientific style. However, peer panel evaluation received a mixed response as students found it difficult to understand proposals that fell out of their area of study (21%) and had little preparation in order to offer constructive criticism of other proposals (43%). Based on survey responses of students (36%), it is apparent that further improvement in the student peer panel evaluation needs to be made to increase the relevance of this exercise. In conclusion, proposal writing and in-class evaluation as part of a graduate course in Poultry Science provided graduate students with additional writing and communication skills required for future careers in research.

Key Words: Proposal writing, Communication skills, Peer panel evaluation

681 Evaluation of student performance in an introductory animal science course by pre-test and post-test scores. T. L. Perkins* and R. J. Andreasen, *Southwest Missouri State University, Springfield, Missouri.*

AGS 101 is an introductory course emphasizing farm animal industries, breeds, numbers, distribution, nutrition, heredity, reproduction, health, and products. Students enrolling in this introductory course come from a wide range of diverse backgrounds and experiences. In addition, this

course, AGS 101 is a general education requirement for all agriculture majors at Southwest Missouri State University. A pre-test examination containing 29 multiple choice questions was given to all students enrolled in each of six sections over the past three years. The same examination was utilized at the end of the semester to assess the knowledge level of each student. Information was additionally gathered concerning major, class rank, gender, FFA background, GPA, and final course grade. Initial data results point to a significant increase in scores from pre-test ($\mu = 38\%$) to post-test ($\mu = 59\%$) examinations. Highest pre-test scores were found on dairy specific questions (63%) and equine specific questions (48%). Highest post-test scores were found on genetics specific questions (73%) and dairy specific questions (67%). Area specific questions indicated students improved (pre- vs post-test) from highest to lowest as follows: 1) genetics (29%), 2) reproduction (25.7), 3) beef (25.5%), 4) meats (23.6%), 5) nutrition (23%), 6) sheep (19%), 7) horse (11%) and 8) dairy (4%). Generally, students who indicated previous high school FFA experience had a higher mean pre-test score than did students without high school FFA experience. Likewise students indicating animal science or pre-veterinary science as their major scored higher on the initial pre-test examination. While the mean post-test examination score improved in all classes, students without previous high school FFA experience improved their post-test examination scores by a greater percentage. A similar relationship was noted for animal science and pre-veterinary science majors as compared to other departmental majors.

Key Words: Pre-test, FFA, Examination

682 Assessment of student learning in animal science programs: how do we know that they know? R. C. Rhodes III*, *University of Rhode Island.*

Assessment, a key element in accountability and accreditation, is a process that has been widely incorporated into the strategic plans of academic organizations with a goal of improving institutional effectiveness. As education is the primary endeavor of academic institutions, focus of assessment efforts has typically been on the processes of teaching and learning. However, the dilemma faced by many academic units including departments of animal science is the "what" and "how" of assessment. What should our students know when they graduate from our programs? How do we assess what they know? What evidence is available that animal science students have great depth of understanding in their subject area? The key to success of an assessment effort is the clear articulation of what we want students to know. Hence, we must define in broad terms, the objectives of our animal science programs. Equally imperative is the definition of desired, specific academic outcomes. Once objectives and outcomes are established, evidence is then collected to document outcomes. Importantly, a variety of outcome indicators should be used in the assessment of student learning in the animal sciences. Examples of outcome indicators include: capstone experiences (e.g., senior thesis, internships, directed or independent research studies), portfolios (e.g., a compendium of papers written by a student in conjunction with reflections on writing), standardized tests (e.g., GRE), locally developed tests (e.g., a department-generated exit examination), professional licensing or certification (e.g., ARPAS certification), grade point average, graduation rates, job placements, graduate school acceptances, professional school acceptances, employer surveys, etc. For successful completion of the assessment, outcome data is evaluated and, afterward if needed, academic objectives and outcomes are revised. The assessment process should benefit all stakeholders: improved learning by students; shared purpose and focus of faculty and reaccreditation of the institution for administrators are all tangible endpoints. Ultimately, assessment is meant to be a continuous process that leads to improvement of institutional effectiveness.

683 Utilizing a group project to teach principles of reproductive management. G. A. Perry* and M. F. Smith, *University of Missouri, Columbia, MO.*

Reproductive Management (senior level course; ~40 to 50 students/semester) students at the University of Missouri are required to develop a detailed plan for improving reproductive efficiency in a beef herd over a 5 yr period. The objectives of this exercise are to: 1) improve reproductive efficiency through implementation of reproductive management principles, 2) integrate economic principles of reproductive

management, and 3) understand the constraints of different geographical locations on approaches to reproductive management. Groups of 3 to 4 students are provided with the reproductive and economic records of a farm/ranch at different locations within North America. Students create reproductive management plans consisting of 1) detailed discussion of farm/ranch environment (climate, terrain, forage and grain availability, and stocking rate; season for breeding and calving; and justification for choice of breed), 2) assessment of current level of reproductive performance, 3) identification and economic justification of specific (measurable) objectives, 4) discussion of alternatives for accomplishing specific objectives, 5) prediction of reproductive performance (pregnancy rate, pounds of calf weaned per cow exposed, and cost per pound of calf weaned) in response to implementation of specific management practices, and 6) an annual reproductive and economic summary. Students obtain livestock marketing information for their assigned location via the Internet. Excel spreadsheets were developed to calculate the reproductive efficiency of postpartum cows and replacement heifers based on the groups' management decisions as well as a yearly economic summary for each of the 5 yr. Management decisions are justified in a written report, and oral presentations are given to the class upon completion of the project. Greater than 80% of students indicate that this exercise increased their understanding of how management decisions affect the reproductive efficiency and profitability in a beef operation and gave them added confidence as they apply for beef management positions.

Key Words: Reproductive Management, Problem Solving, Group Project

684 Dairy Challenge: A competitive and educational experience in evaluation of dairy herd management. L.E. Davis*¹, F.M. Martsolf², J.J. Domecq¹, and M.S. Weber¹, ¹*Michigan State University, East Lansing,* ²*Cargill Animal Nutrition, Mentone, IN.*

The Dairy Challenge event allows students to apply knowledge gained in the classroom by competitively evaluating the management practices of commercial dairy farms. Michigan State University, with the generous support of Cargill Animal Nutrition, has implemented the annual program in the Department of Animal Science. Participants in the Dairy Challenge will do the following: 1) critically evaluate dairy herd management practices and make recommendations for improvements; 2) visit local farms and gain knowledge of different farms' management practices; 3) interact with company representatives from the industry, and increase their understanding of the role of companies in the dairy industry; 4) evaluate herd records, and gain knowledge in PC-DART and computer presentation tools; and 5) improve speaking, presentation, and problem-solving skills. Teams of three or four undergraduate students consist of second-year Agriculture Technology and/or upper level students in the four-year program in the College of Agriculture and Natural Resources. Students critically evaluate a commercial dairy farm using herd records from the past year, a description of the farm, and a tour of the facilities. The farmer and the herd's nutrition consultant answer questions pertaining to management of the farm. Teams give a 30-minute presentation that is scored on their description and assessment of the management practices and recommendations for improvements in facilities and management. Additionally, scoring is based on apparent level of preparation, speaking, presentation skills, and responses to questions asked by judges. The judges for this event are university and dairy industry specialists, including a dairy extension agent, nutrition consultant, dairy business specialist, technical service specialist, and the farm manager. This event allows students to interact with dairy farmers and representatives from the dairy industry, and challenges the knowledge and skills gained by the students during their academic career.

Key Words: Dairy Management, Teaching, Evaluation

685 Extended supplementation of limiting amino acids to increase effective dietary protein and improve production of heat stressed broilers. A. J. Zarate*¹, E. T. Moran, Jr.¹, and D. J. Burnham², ¹*Poultry Science Department, Auburn University, Auburn, AL 36849*, ²*Heartland Lysine Inc. Chicago, IL 60631*.

Broilers in a hot environment decrease their feed intake and growth. Uric acid formation from amino acids in excess of optimal balance generates heat. Presumably, adding limiting essential amino acids (EAA) beyond requirement levels but proportioned for total balance enables an increase in effective protein which could compensate for reduced feed intake while decreasing heat generation. A total of 400 male and 400 female broilers Ross x Avian 24K was reared sex separate to 7 weeks of age in 32 floor pens. A commercial type feeding regimen was fed either "as is" or supplemented with limiting EAA to assure at least 110% of the requirements that approximated an ideal pattern. Environmental conditions existing from May-June were sufficiently hot to depress performance but not cause related deaths. Increasing the levels of EAA and balance within existing crude protein and ME did alter live performance throughout experimentation. Measurement of abdominal fat after birds were processed indicated a significant increase with the carcasses of both sexes when the 110% level of EAA was employed. Carcass yield without abdominal fat, incidence of grade defects, and recovery of deboned breast meat were similar between treatments, respective of sex. Improved amount and balance of effective protein together with reduced excretion of N likely increased dietary productive energy with its conversion to depot fat, but no advantage to live performance was perceived.

Key Words: Broilers, Carcass Characteristics, Heat Stress, Limiting Essential Amino Acids.

686 Reduced lysine and threonine levels in a phase-feeding regimen can support maximum growth performance during the grower phase. J.A. Townsend*, H.R. Pope, and J.L. Emmert, *University of Arkansas*.

Phase-feeding (PF) has been explored as a means of reducing feed costs without reducing growth performance. Predicted amino acid requirements for PF are generated using linear regression equations derived from estimates of lysine (Lys), sulfur amino acid (SAA) and threonine (Thr) requirements. The objective of this study was to determine if growth performance would be impacted by reduced levels of lysine and threonine in a PF regimen relative to birds fed NRC recommendations. In addition to NRC (Treatment 1) and unmodified PF (Treatment 2) regimens, four modified PF treatments were tested. In two modified PF treatments, predicted Lys (Treatment 3) and Thr (Treatment 5) requirements were reduced by 10%, whereas in the remaining modified PF treatments the slopes of the linear regression equations used to predict Lys (Treatment 4) and Thr (Treatment 6) requirements were increased by 15%. The six dietary treatments were administered from 3-6 weeks of age. The NRC diet was fed throughout the entire experiment, whereas treatments 2, 3, 4, 5 and 6 were tested in a series of 3 diets (21-28, 28-35, and 35-42 d). Despite a reduction in Lys and Thr levels in treatments 3, 4, 5 and 6, no differences ($P > 0.05$) in weight gain, feed intake and feed efficiency were detected among treatments at 42 d. Relative to treatments 1 and 2, digestible Lys intake was reduced ($P < 0.05$) by treatment 3 and digestible Thr intake was reduced ($P < 0.05$) by treatments 5 and 6. Breast yield was not reduced ($P > 0.05$) in treatments 3, 4, 5 and 6 relative to treatments 1 or 2, however abdominal fat percentage was increased ($P < 0.05$) by treatment 3. These data indicate that despite a substantial reduction in Lys and Thr levels, growth performance of birds fed these PF regimens was not different than birds fed NRC recommendations. Because dietary Lys, SAA, and Thr levels are decreased under PF systems, substantial dietary cost savings may be available.

Key Words: Broiler, Phase-feeding, Amino Acids

687 Evaluation of Amino Acid Dose-Response Data and Implications for Commercial Formulation of Broiler Diets. D. Hoehler*, S. Mack, and M. Pack, *Degussa-Huels Corporation, Kennesaw, GA*.

Many of the performance indicators of a modern integrated broiler enterprise, such as feed cost per ton, serve to de-link the operation into

discrete business units. This disintegrative management does not necessarily lead to the best overall profit. In the present study, case scenarios are drafted for two different production goals minimum feed cost per kg live weight gain or minimum feed cost per kg breast meat, which comprise the whole production chain. The amino acids lysine and Met+Cys are used as variable factors, because their dietary concentration has a large effect on several efficiency measures of an integrated operation. Actual performance data of 9 dose-response experiments for Met+Cys and another 5 with lysine were combined with cost figures for feed and supplemented amino acids. Data covered the grower/finisher period of commercial broiler strains. The relative response in performance between the lowest and highest levels of lysine or Met+Cys was similar, which offered the opportunity to pool all dose-response data after transforming them to a relative scale. Data were then subjected to exponential regression analysis. The best performance as described by the maximum of the regression curve was set at 100%. Subsequently, relative performance data were transformed back to absolute values by setting the desired optimum performance at 100%. Under the given conditions, feed cost per kg live weight gain reached a minimum at dietary concentrations of 0.90% Met+Cys and 1.03% lysine. The response in feed cost per kg breast meat to rising amino acid levels is not only affected by the feed to gain ratio, but also by the increasing breast meat yield as percentage of live weight. This extra benefit shifted the optimum dietary Met+Cys and lysine concentration to 0.98% and 1.16%, respectively. Price changes for raw materials or amino acids only slightly shifted the economic optimum level for the respective amino acid. This approach may well be extended to other nutrients and can serve as a general tool to determine dietary specifications in a meaningful way.

Key Words: Broiler, Dose-Response, Economics

688 Growth and carcass response of male broilers to two commercial sources of supplemental L-lysine. ME Jackson*¹, A Lemme¹, JL Emmert², and HR Pope², ¹*Degussa Huls Corporation, Kennesaw GA*, ²*University of Arkansas, Fayetteville, AR*.

Biolys[®] 60 is a new form of lysine containing 47.3% L-lysine (46.8% free plus 0.5% protein-bound L-lysine) plus additional energy and nutrients from the biomass, including 0.2% phosphorus, 0.3% Met+Cys, 0.5% Thr, and 0.15% Trp. Biolys[®] 60 is produced by microbial fermentation of *Corynebacterium glutamicum*, and the lysine substitution value is calculated as 60% of the value of L-lysine-HCl. A 49-d floor pen trial with 1890 male Ross X Cobb broilers, 54 floor pens, and 35 birds/pen was conducted to determine responses to 2 forms of supplemental lysine. Starter and grower series of corn/soybean meal/corn gluten meal-based diets were provided from 0-21 and 22-49d. Nine isonitrogenous dietary treatments (x 6 replicates) included a non-supplemented control and 4 levels of added lysine from the 2 sources. Starter and grower basal diets contained 20.72 and 17.56% CP and 0.83 and 0.62% Lys, respectively. L-lysine was added at 0.08, 0.16, 0.24% and (0.42% starter, 0.30% grower) from each source. Birds responded to both lysine sources with 0-49 d gain ranging from 1466 g (no supplementation) to 2811 g (highest supplementations) ($P < 0.01$), feed:gain ratio (FCR) decreasing from 3.10 to 2.10 ($P < 0.01$), and breast yield increasing from 17 to 27% of carcass weight ($P < 0.01$). Experimental data were subjected to non-linear exponential regression analysis. This permits the evaluation of the complete response curve to graded levels of a limiting amino acid. The data fitted well to predicted values with r-square values ranging from 0.90 to 0.99 for the measured criteria. The calculated relative effectiveness of Biolys[®] 60 compared to L-lysine-HCl was 110 and 104% for weight gain and breast yield, respectively. Both values were not significantly different from 100%. It is concluded that Biolys[®] 60 is at least equal to L-lysine-HCl in eliciting performance responses in broiler chickens.

Key Words: Lysine Sources, Broilers, Breast Yield

689 Interaction of methionine and lysine in broiler diets changed at NRC or industry time intervals. M. B. Cafe*, C. A. Fritts, and P. W. Waldroup, *University of Arkansas*.

The broiler industry changes feed at intervals that differ from those on which NRC requirements are based. A study was conducted to examine the response of broilers to diets formulated to contain different levels of Lys and Met when diets were changed at intervals on which NRC recommendations are made (0 to 21 d for starter; 21 to 42 d for

grower; 42 to 49 d for finisher) as compared to intervals used by the poultry industry (0 to 16 d for starter; 16 to 35 d for grower; 35 to 49 d for finisher). Diets were formulated to provide a minimum of 110% of essential amino acids (NRC) other than Met or Lys; these were formulated to be at 100% of NRC recommendations. Aliquots of a common basal diet were fortified with DL-methionine and lysine HCl to provide a factorial arrangement with three Met levels (100, 115, 130% of NRC) and four Lys levels (100, 110, 120, 130% of NRC). These were fed at either NRC feed change intervals or at industry feed change intervals for a total of 24 treatments. Each treatment was fed to four pens of 60 male broilers in litter floor pens. At 35, 42, and 49 d samples of birds were processed to determine dressing percentage (DP) and breast meat yield (BY). Changing at NRC intervals resulted in significantly higher BW and better FCR at 21 and 42 d but not at 35 or 49 d. Birds fed diets changed at NRC intervals had significantly greater BY at 42 and 49 d. However there were no interactions between time of change and either Met or Lys levels for any factor. Birds fed diets with 110% of Lys were significantly superior to those fed 100% Lys in virtually every category. Increasing levels of Met also improved performance in nearly every category. However, there were few interactions between Lys and Met levels. Results of the study suggest that more attention be paid to needs of these amino acids when dietary feeding programs are altered.

Key Words: Broilers, Diet Change, Amino acids

690 Ileal true digestibility of protein does not increase with age in broiler chicks. E.L. Miller*, Y.X. Huang, O.C. Fabb, B. Rayner, and S. Kasinathan, *Department of Clinical Veterinary Medicine, University of Cambridge.*

Endogenous N (EN) loss and ileal true digestibility of fish meal (FM) and soybean meal (SBM) were determined at 4, 7, 11 and 14 days of age. Six diets contained 144, 185 and 226 g crude protein (CP)/kg supplied by FM or SBM as the sole protein. A further diet (EHC) contained 211g CP/kg from enzyme-hydrolysed casein supplemented with amino acids to determine EN. Chromic oxide was used as marker. From 350 day old male broiler chicks (Ross) 96 chicks weighing (SD) 492.4g were randomised to 24 cages each with 4 chicks. The FM and SBM diets were each randomised to 3 replicate cages while EHC was randomised to 6 cages. The remaining chicks were reared on commercial chick starter crumb until 4, 7 or 11 days of age when 72 chicks of average weight 80.5, 154.14, 18315.3g were allocated at 3 birds per cage to 3 replicates of each test diet and 6 replicates of EHC. Test diets were offered for 3 or 4 days ad libitum, fasted overnight and then killed by intra-peritoneal injection with sodium pentobarbitone 4 h after the re-introduction of food. Ileal digesta was washed from the ileum (vitelline junction to 1 cm from the ileo-caecal junction) freeze-dried, pooled per cage and analysed for N and Cr. Ileal digesta from EHC was centrifuged over a 10,000 dalton membrane before drying. EN (mg N/g diet) determined with EHC and by regression to zero FM or SBM (including EHC as zero FM or SBM) did not change with age (meanSEM, EHC 1.350.146, 1.030.085, 0.960.166, 1.140.103; regression with FM 1.380.255, 1.030.230, 1.050.248, 1.160.178; regression with SBM 1.290.175, 0.94.0.154, 0.970.289, 1.120.160 at 4, 7, 11, 14 d). Ileal true digestibility, calculated from the regression of ileal N/g diet on diet N/g diet including EHC as zero test N, did not differ with age with FM (0.910.011, 0.890.010, 0.900.011, 0.910.008 at 4, 7, 11, 14 d) but with SBM d 4 (0.950.008) was greater than d 7 (0.920.007) or d 11 (0.910.013) (P<0.05) but not d 14 (0.930.007). EN and ileal true digestibility of FM or SBM N did not increase with age.

Key Words: Ileal Digestibility, Endogenous , Age

691 Effects of supplemental antibiotics in a diet containing sub-optimal protein, methionine and lysine on the performance, carcass characteristics and organ measurements of finishing broilers reared under hot-humid climate. A. A. Onifade*¹, A. A. Odunsi², S.G. Ademola^{1,2}, and B.R. Olorede³, ¹Department of Animal Science, University of Ibadan, ²Department of Animal Production and Health, Ladoke Akintola University of Technology, Ogbomoso, ³Department of Animal Production and Health, Usmanu Danfodiyo University, Sokoto, Nigeria.

Protein and amino acid requirements of broilers decrease with age; therefore, finishing broilers may be economically and environmentally friendly raised on lower protein and critical amino acid concentrations. However, maximization of performance and reduction of carcass fat in broiler fed

low-protein diet critically deserve research attention, and we hypothesized that supplemental dietary antibiotics might be useful. 5-week old broilers were fed for 4 weeks on diets containing 16% crude protein (CP) and 80% of the recommended methionine and lysine without or with penicillin, streptomycin, tylosin, and zinc bacitracin added separately at 75 mg kg⁻¹ or control diets containing 18% or 20% CP and adequate amino acids. Antibiotic-fed broilers enhanced (P<0.05) their feed intakes; feed conversion correlated with dietary CP and was similar in all broilers fed 16% CP. The body weights, carcass and breast yields of antibiotic-fed broilers were heavier (P<0.05) than those fed unsupplemented diet, compared with those fed 18% CP, but lower than those fed the 20% CP. Abdominal fat of antibiotic-fed broilers was smaller (P<0.05) than those fed unsupplemented 16 and 20% CP, which were inexplicably similar. Antibiotic-fed broilers had bigger (P<0.05) lymphoid organs: spleen and bursa of fabricious; lengthier (P<0.05) intestines and smaller (P<0.05) gizzards than broilers fed unsupplemented 16% CP though gizzard weights were generally heavier on all the 16% groups irrespective of the supplements. The implication of the comparable productive indices obtained on low-protein antibiotic-fed broilers suggests improved, economical and environmentally friendly feeding program with feasible adoption in finishing broiler nutrition barring no restrictions to antibiotic use in animal feeds.

Key Words: Supplemental Antibiotics, Sub-optimal Dietary Protein and Amino Acids, Finishing Broilers

692 Influence of heat processing of corn and barley and enzyme supplementation on nutrient digestibility of broiler chicks. M. I. Gracia*, M. J. Aranibar, and G. G. Mateos, *Universidad Politecnica de Madrid. Spain.*

A trial was conducted to study the influence of heat processing (HP) of cereals, and enzyme supplementation (ES) on digestibility of nutrients of broilers from 0 to 21d. There were 8 treatments arranged factorially, with two basal cereals (corn vs barley), two processing treatments (raw vs cooked for 1h at 103°C and 19% moisture), and two levels of ES (0 vs 500ppm). The enzyme complex contained 20,000 TLXU of xylanases, 90 BAU of α -amylases, and 19,000 PU of proteases per kg. Each treatment was replicated 5 times (16 Cobb chicks per cage). The apparent fecal digestibility (AFD) of organic matter (OM), crude protein (CP), ether extract (EE), and neutral detergent fiber (NDF) was measured at 4, 8, 15, and 21d of age. Digestibility of nutrients varied with time for all treatments (P<0.05). Heat processing improved AFD of OM, CP, and NDF until 8d of age (58.6 vs 62.1 %, 45.5 vs 47.6 %, and 22.6 vs 27.5 %, respectively; P<0.05), but not thereafter. However, HP increased AFD of EE throughout the trial (58.4 vs 64.3 %; P<0.05). Also, HP increased AFD of NDF in barley but not in corn diets (P<0.01), while the opposite occurred for EE (P<0.01). Birds fed barley had lower digestibility coefficient of OM at 8 and 15d (P<0.05) than broilers fed corn diets, but the differences disappeared thereafter. On the other hand, AFD of EE was greater for barley than for corn diets throughout the trial (P<0.01). Enzyme supplementation improved AFD of OM, CP and EE for all diets throughout the trial (61.3 vs 64.0 %, 46.7 vs 51.1 %, and 58.9 vs 63.7 %, respectively; P<0.05) but the effect was greater for barley than for corn diets (P<0.05). Enzyme supplementation improved AFD of EE more for HP than for raw cereal diets (P=0.05). It is concluded that nutrient digestibility of broiler chicks was modified by both HP and ES though the beneficial effects of HP were only noticed during the first week of age, and the effect of ES was greater for barley than for corn diets.

Key Words: Heat Processing, Digestibility, Broilers

693 Age and dietary influences on size and fermentation patterns in the gastrointestinal tract (GIT) of broilers fed wheat and corn diets. E. N. Fischer*¹, H. L. Classen¹, and M. Choct², ¹University of Saskatchewan, Saskatoon, SK Canada, ²University of New England, Armidale, NSW, Australia.

An experiment was conducted to identify changes in size and bacterial fermentation patterns in broilers (840) fed diets containing corn (C), wheat (W) or wheat supplemented with endoxylanase (E, Avizyme 1300, 0.1%). Birds were sampled for GIT measures and contents were collected weekly for viscosity and volatile fatty acid (VFA) determination. Jejunal viscosity was highest (p≤0.05) for the W treatment (trt) at all ages except 7d. Ileal viscosity was highest in this diet at all ages. Empty jejunal and ileal weights and ileal length were higher (p≤0.05) for W and E trts relative to the C trt at most ages. Jejunal content

weight also trended higher for W and E trts at most ages ($p \leq 0.001$, 35d). Ileal content weights were highest ($p \leq 0.05$, 7d) from birds on the W trt to 21d, after which both W and E trts yielded higher content weights than C ($p \leq 0.05$, 35d). Empty caecal weights were highest ($p \leq 0.05$, 14, 21, 35d; $p \leq 0.10$, 42d) from birds on the E trt, while content weights from this trt trended highest to 21d only. Ileal VFAs were not affected by trt and levels peaked at 14d and declined thereafter. Caecal VFAs from all trts increased steadily to 28d, then declined. Acetate and butyrate accounted for the greatest proportion of total VFAs and were both highest ($p \leq 0.05$) in birds from the W and E trts at 21d, when ileal viscosity peaked. Caecal propionate ($p \leq 0.05$) and isovalerate ($p \leq 0.10$) levels were highest in birds from the C trt at all ages except 7d. The higher NSP content of the wheat diets likely caused the increased GIT size of the W and E trts. While the NSP in W and E trts are broken down by the caecal bacteria to acetate and butyrate, the C trt resulted in the production of propionate and isovalerate. The latter finding suggests that undigested starch and protein from corn enter the caeca and are being fermented by bacteria in this location.

694 Live performance, caloric efficiency, carcass characteristics, and cost/gain of broiler chickens fed corn-soy-poultry byproduct diets with or without the enzyme Rovabio Excel™. M.D. Sims*¹, M. Blair², and D. M. Hooge³, ¹Virginia Scientific Research, Inc., Harrisonburg, VA, ²Aventis Animal Nutrition, Alpharetta, GA, ³Hooge Consulting Service, Inc., Eagle Mountain, UT.

Two floor pen trials were conducted to evaluate and compare the performance, caloric efficiency and carcass characteristics of broilers fed diets with or without Rovabio Excel™ enzyme (RX). Custom starter, grower and finisher corn-soy based diets containing a level of 4% poultry by-product meal were used in each trial. The studies were similar except for dates the tests were conducted and broiler strain crosses used. In trial 1, 2,880 Ross x Ross 308 and in trial 2, 2,880 Ross x Arbor Acres broilers were used. Two series of basal diets, differing by 66 kcal ME/kg within each trial and identified as regular energy (RegME) and lower energy (LowME) diets, were used. Calculated ME levels of RegME feeds ranged from 3030 to 3251 kcal/kg, and LowME feeds ranged from 2964 to 3185 kcal/kg. Crude protein levels were adjusted proportionally with energy. The liquid form of RX was used in these trials and was sprayed on RegME and LowME pelleted feeds at 200 ml/metric ton. Live weights, feed conversion, caloric efficiency, mortality and carcass characteristic data were pooled after no significant treatments x experiment interactions were found. Pooled wk 3 live weight of the LowME + RX group tended to be heavier ($p=0.11$) than the LowME group. Combined wk 7 live weight of the RegME + RX group was significantly heavier ($p=0.02$) than the RegME group. Pooled wk 3 feed conversion ratio was significantly lower ($p=0.03$) for the LowME + RX group than the LowME group. Caloric efficiency (adjusted to a common weight) of the LowME + RX group was significantly better ($p < 0.001$) than its LowME control (6,184 kcal/kg vs. 6,425 kcal/kg, respectively). Deboned breast of the RegME + RX and LowME + RX groups were heavier ($p < 0.01$ and $p=0.06$, respectively) than those of their respective control groups. Feed expense per kg gained was lower ($p \leq 0.05$) for the LowME + RX group than for the LowME group (0.2899 dollars vs. 0.2961 dollars, respectively) but similar ($p \geq 0.05$) between the two RegME groups (0.2961 dollars vs. 0.2959 dollars). Broilers benefited from the addition of RX to diets with either RegME or LowME but most prominently when applied to LowME diets with calculated ME in the range of 2964 to 3185 kcal/kg.

Key Words: Broilers, Rovabio Excel™, Caloric efficiency

695 The effect of barley concentration, Natugrain blend 66%L and Natugrain 33%L on performance of broilers fed wheat-based diets. M.B. Coelho¹, B.W. Cousins¹, W.F. McKnight*¹, P. Blanchard¹, A. Knox², and J. McNab², ¹BASF, ²Roslin Nutrition Ltd.

Three thousand eight hundred and forty, day old broilers were utilized in a 4X3 factorial design (8 reps/treatment) to determine the effect of barley concentration (0, 10, 20 and 30%), and enzyme (0, Natugrain® Blend 66%L at 150 ppm, and Natugrain® 33%L at 300 ppm) on the performance of broilers fed wheat-based diets. The starter phase diets were

fed in crumble form and growing-finishing phase diets were fed in pellet form. Eighteen-day performance of 0% barley diets for enzyme treatments 0 enzyme, Natugrain Blend and Natugrain were: weight gain, g (624^d, 587^{abc} and 585^{abc}), FCR (1.412^{ab}, 1.422^{ab}, 1.456^{ab}), viscosity, cps (2.912^a, 5.242^c, 7.009^d). Eighteen-day performance of 20% barley diets for enzyme treatments 0 enzyme, Natugrain Blend and Natugrain were: weight gain, g (603^{cd}, 592^{abc} and 580^{abc}), FCR (1.454^{ab}, 1.428^{ab}, 1.479^{ab}), viscosity, cps (3.981^b, 6.297^d, 6.584^d). Increasing levels of barley decreased performance. However, NSP enzyme addition compensated for the negative performance effect of barley.

Key Words: Broilers, NSP enzymes, Diet composition

696 Improved utilization of wheat screening by enzyme supplementation. B.A. Slominski*¹, D. Boros¹, W. Guenter¹, L.D. Campbell¹, and O. Jones², ¹University of Manitoba, Winnipeg, MB, Canada, ²Canadian Bio-Systems Inc., Calgary, AB, Canada.

Research conducted in our laboratory has shown positive attributes associated with wheat screenings. In comparison to wheat, wheat screenings were found to contain less starch (44.8 vs 56%, as fed basis), similar amounts of sugars (1.4 vs 1.2%) and NSP (9.9 vs 9.1%) and significantly more protein (15.0 vs 12.6) and fat (6.4 vs 1.2%). The latter two components contributed to good performance of broiler chickens (2 week growth trial) fed wheat-based diets substituted with wheat screenings. A significant improvement in animal performance was also noted with enzyme supplementation. To further substantiate the importance of enzyme supplementation, a long-term production trial with broiler chickens was conducted. Five replicate pens of 60 birds per treatment were used in starter (21 days) and grower (16 days) phases of the experiment consisting of three treatments: positive control (PC)(wheat/soybean meal/fish meal), negative control (NC)(wheat/wheat screenings/barley/soybean/canola meal) and NC+Enzyme. In comparison to PC, the NC diet contained 10% less metabolizable energy, crude protein, amino acids and calcium and 25% less available phosphorus. The enzyme supplement included xylanase, glucanase, cellulase, phytase and a broad spectrum of other enzyme activities. Body weight gain and feed conversion ratio averaged 2.14, 2.10, 2.17 kg/bird and 1.68, 1.76, 1.66 for PC, NC and NC+Enzyme, respectively. A significant ($P < 0.05$) improvement in broiler chicken performance with enzyme supplementation was further substantiated by the same magnitude of difference in dry matter (71.2, 68.7, 75.1%), energy (AME)(2956, 2827, 3066 kcal/kg), starch (92.5, 90.3, 95.6%), NSP (4.8, 15.0, 36.1%) and phytate (44.3, 37.5, 69.5%) digestibilities. It is evident from this study that the use of wheat screenings in concert with an effective enzyme supplement will allow for cost effective formulation of poultry diets.

Key Words: Wheat screenings, Nutritive value, Broiler chicken, Enzyme

697 Apparent metabolizable energy of drought tolerant barley cultivars as affected by enzyme supplementation. G. W. Barbour*¹, A. H. Darwish¹, M. T. Farran², N.N. Usayan³, M. M. Beck⁴, H. H. Machlab¹, M. G. Uwayjan², and V. M. Ashkarian², ¹Agriculture Research Institute, Tel Amara, Beqa'a, Lebanon, ²American University of Beirut, Beirut, Lebanon, ³Lebanese University, Beirut, Lebanon, ⁴University of Nebraska, Lincoln, Nebraska.

A chick assay was conducted to study the effect of enzyme supplementation on AME and AME_n of three drought tolerant barley cultivars 'Litani' (L), 'Pamir-35' (P), and 'Rihane-03' (R). A reference diet containing 55% glucose was prepared. Corn, L, P, and R replaced 50% glucose in the experimental diets with 0 or 0.1% Avizyme 1100®. Each diet was fed to 4-d-old Arbor Acres male broiler chicks in four replicates with four birds per replicate. Total fecal collection was made 48 and 96 h post 7-d adaptation period. Soluble non-starch polysaccharide concentration in L, P, R, and corn grains was 5.83, 2.56, 4.86, and 1.36%, while total β-glucan content was 3.91, 4.32, 3.56, and 0.04% DM, respectively. The AME and AME_n of corn were 4034 and 3944 kcal/kg DM, respectively. There was no significant interaction between barley cultivar and enzyme level. Also no significant cultivar effect was detected and the overall means across enzyme levels of AME were 3226, 3164, and 3191 kcal/kg DM, while those of AME_n were 3094, 3083, and 3088 kcal/kg DM for L, P, and R, respectively. Enzyme addition, however, increased ($P < 0.05$) AME and AME_n means across barley cultivars by

283 and 304 kcal/kg DM, respectively. In conclusion L, P, and R barley cultivars had similar ME values which were improved through enzyme supplementation.

Key Words: Barley cultivars, Enzyme, Apparent metabolizable energy

698 ME-equivalent value of feed enzymes varies with dietary nutrient concentrations for broilers. Keying Zhang*, Shaoqun Zuo, Zhiyong Ni, and Daiwen Chen, *Institute of Animal Nutrition, Sichuan Agricultural University, Yaan, Sichuan 625014, PR. China.*

ME-equivalent value (MEV) of feed enzymes is important for the formulation of diets supplemented with enzymes. Whether MEV of an enzyme product is constant or varies with dietary nutrient concentrations (DNC) is not yet known. In this study, a two-factor D-saturated optimization regression design with six treatments was used to measure MEV of a complex feed enzyme product (CFE) in the diets of various DNC for broilers. CFE consisted of amylase (2400U/g), beta-amylase (20000U/g), beta-glucanase (5800U/g), protease (3800U/g), cellulase (1700U/g), xylanase (4600U/g) and pectinase (55000U/g). Basal diet

699 Effect of fasting versus feeding Oasis[®] after hatching on nutrient utilization in chicks. A.B. Batal* and C.M. Parsons, *University of Illinois, Urbana, IL USA.*

Two experiments were conducted to determine the effects of fasting, feeding OasisTM, or feeding a corn-soybean meal (SBM) diet immediately after hatching on growth performance, and energy and amino acid utilization of chicks. In each experiment, six pens of eight chicks were assigned to four treatments which were feeding a corn-SBM diet for 21 d immediately after hatching, fasting for 48 h (no feed or water) after hatching, or feeding OasisTM for 24 or 48 h after hatching. The fasting and feeding OasisTM treatments were followed by feeding the corn-SBM diet for 21 d. Excreta were collected at 0-2, 3-4, 7, 14, and 21 d on feed for determination of MEn and amino acid digestibility. Fasting chicks for 48 h posthatching significantly depressed weight gains compared to all other treatments at 21 d of age. Although weight gains were not significantly different at 48 h posthatching, chicks fed OasisTM for 48 h had significantly ($P < 0.05$) higher weight gains at 1, 2, and 3 wk of age than did chicks fasted for 48 h. As days on feed increased from three to 21, energy utilization (ME_n) increased for all the experimental treatments. In addition, the ME_n of the corn-SBM diet for chicks fed OasisTM for 24 and 48 h was significantly ($P < 0.05$) higher than for chicks fasted for 48 h at most ages. There were generally no large differences in ME_n values among other dietary treatments within ages. Digestibility of most amino acids increased with increasing age for all experimental treatments, and the digestibility values were similar among treatments. Our results indicated that feeding OasisTM (compared to fasting) had a beneficial effect on subsequent energy utilization of a corn-SBM diet and that OasisTM may be stimulating early gut development even though early growth (0-48 h) is not affected.

Key Words: OasisTM, Age, Chicks

700 The effect of mannanoligosaccharides, bambarmycins, and virginiamycin on the physical and microbial characteristics of the gastrointestinal tract of large white male turkeys. C. W. Parks*, J. L. Grimes, and P. R. Ferket, *NC State University, Raleigh, NC USA.*

The objectives of this experiment were to investigate the effects of a growth-promoting oligosaccharide and two traditional antibiotics on the physical and microbial attributes of the gastrointestinal tract of male turkeys. Day old Hybrid Large White male poult were assigned to four dietary treatments: Control, Bio-Mos[®] (MOS), Bambarmycins (BM), and Virginiamycin (VM). There were eight replicate floor pens per treatment with 20 birds per pen reared from 1 to 140 days of age. All data were analyzed using the GLM procedure of SAS (1994). At 12 wks of age, three birds per pen were randomly sampled to measure the following: intestinal section weights, length, density, and mucosal and muscularis weights. Jejunal and cecal digesta samples were taken for

was formulated with corn, soybean meal and extruded soybean to contain on as-fed basis (DM86.9%) ME 12.55 MJ/kg, CP 20%. Ground rice hull was used to dilute the basal diet to formulate diets with 5.0%, 8.0% and 11.5% lower in ME, CP and amino acid contents than basal diet. The doses of CFE in diets ranged from 0% up to 0.23%. 360 1-d-old Avian male broilers were randomly allotted into the 6 treatments with 4 replicates of 15 birds each, and were fed ad libitum until 42 days old. Then 8 birds per treatment were selected for a 4-d metabolism trial, during which excreta were completely collected for measuring nutrient utilizations. Bodyweight gain and feed efficiency were improved quadratically ($P < 0.01$) as DNC increased, and so did the utilizations of dietary energy, protein and dry matter. Performance and nutrient utilizations responded quadratically ($P < 0.01$) to the doses of CFE, and reached peak when CFE dose was 0.1%. ME-equivalent value (MEV) of CFE was calculated by the difference of measured ME of diets with vs. without CFE supplementation at the same DNC. When CFE was included in diets at 0.1%, its MEV was 173, 343, 451 and 586 MJ/kg respectively for the diets of control, and 5%, 8% and 11.5% lower in DNC compared to control. It is concluded that MEV of feed enzymes varies with dietary nutrient concentrations.

Key Words: ME-Equivalent Value, Feed Enzymes, Broilers

ammonia, pH, lactate, volatile fatty acids, and dietary AME_N measurement. Birds fed MOS exhibited no effects on physical parameters while BM resulted in significantly increased duodenal attributes compared to control ($P \leq 0.05$). In contrast, feeding VM resulted in significantly decreased duodenal, ileal, cecal, colon weights and decreased duodenal, jejunal, and ileal muscularis weights compared to control ($P \leq 0.05$). In comparison to controls, jejunal propionate and total VFA production was decreased in the MOS and BM treatments, respectively. Feeding VM resulted in a significantly increased jejunal pH level and significantly decreased propionate production as compared to control-fed birds ($P \leq 0.05$). Dietary AME_N was not significantly affected by treatment. Results suggest that MOS affects the enteric ecosystem by a different mode than antibiotic (BM and VM) growth promotants.

Key Words: Turkey, Mannanoligosaccharide, Antibiotics

701 Effects of ratios of dietary linoleic to linolenic acid on hen performance, mitogenic response, and antibody production of White Leghorn hens against Newcastle disease vaccine. U. Puthongsiriporn*¹ and S. Scheideler¹, ¹*University of Nebraska-Lincoln.*

The objective of this study was to investigate the effects of ratio of dietary linoleic to linolenic acid on hen performance, mitogenic response, and antibody production against Newcastle disease (NDV) vaccination in the second phase of the laying cycle. A corn-soybean meal diet was supplemented with flaxseed to have ratios of dietary linoleic to linolenic acid (n:6/n:3) of 17:1 (control), 8:1, or 4:1. Each diet was randomly assigned to 6 replicate pens with 5 hens/pen. Hy-Line W-36 hens were fed the diets from 53 to 58 wks of age. At the age of 57 wks, hens were boosted with NDV vaccine (Merial Select[®]; 25-5,000 Pkg/dose). No differences on feed consumption, body weight, egg production, and egg quality were observed throughout the study. The n:6/n:3 ratio did affect mitogenic response and antibody production of hens only after vaccination. Mitogenic response to concanavalin A (Con A) was significantly greater ($P \leq 0.02$) in hens fed n:6/n:3 of 8:1 (0.742), or 4:1 (0.728) as compared to the control (0.577). Mitogenic response to Salmonella typhimurium lipopolysaccharide (LPS) was greater ($P \leq 0.008$) in hens fed n:6/n:3 of 8:1 (1.028), or 4:1 (0.991) as compared to the control (0.899). Dietary decrease in n:6/n:3 induced higher ($P \leq 0.0004$) antibody production against NDV vaccine measured by an ELISA test. Mortality rate of hens in each treatment was 0% during the study. These results indicate that a decrease in the ratios of dietary linoleic to linolenic acid (n:6/n:3) enhanced mitogenic response and antibody production against the Newcastle disease vaccine, but not performance of White leghorn hens in the second phase of the laying cycle.

Key Words: Ratios of Linoleic to Linolenic Acid, Mitogenic Response, Newcastle Disease Vaccine

702 Effect of dietary xanthophylls on carotenoid content of lymphoid tissues of layer chicks. E.A. Koutsos*, C.C. Calvert, and K.C. Klasing, *University of California, Davis; Davis, CA.*

Layer chicks were fed diets ranging from 0 to 48 mg/kg total xanthophyll (xan) to determine the effect of dietary xan on tissue xan concentration. Dietary xan consisted of lutein (lut) and zeaxanthin (zea) (Oroglo Dry) and canthaxanthin (cantha) (Carophyll Red) at a ratio of 1.5:1. After 4 weeks, splenic macrophages, plasma, red blood cells (RBCs), liver, thymus and bursa were analyzed for xan content by HPLC. Neither bursa lut nor zea correlated with dietary xan ($p=0.79$, $p=0.10$, respectively); cantha was undetectable. Thymus lut and cantha correlated with diet levels: thymus lut (ug/g) = $0.06+(0.02*\text{diet lut (ppm)})$ ($r^2=0.93$, $p<0.001$); cantha = $-0.01+(0.06*\text{diet cantha})$ ($r^2=0.83$, $p<0.001$). Thymus zea tended to be correlated with diet zea ($p=0.08$). Plasma xan correlated with diet: plasma lut (ug/ml) = $0.03+(0.05*\text{diet lut})$, ($r^2=0.83$, $p<0.001$); zea = $-0.02+(0.014*\text{diet zea})$, ($r^2=0.69$, $p<0.002$); cantha = $0.02+(0.09*\text{diet cantha})$, ($r^2=0.88$, $p<0.001$). RBC lut and zea were not correlated with diet xan ($p=0.16$, $p=0.26$); cantha was undetectable. Liver lut correlated with diet: lut (ug/g) = $0.24+(0.026*\text{diet lut})$, $r^2=0.78$, $p<0.001$, but liver zea and cantha were not correlated with dietary xan ($p=0.44$, $p=0.56$). Total liver xan related to diet xan by a polynomial relationship: liver xan(ug/g) = $1.56+(0.13*\text{diet xan})-(0.002*\text{diet xan}^2)$ ($r^2=0.77$, $p<0.003$), suggesting that liver xan plateaued at approximately 20 mg xan/kg diet. Splenic macrophages contained very high levels of lut (avg=34.8 ug/g 9.7) and zea (56.7 ug/g 10.4), and there was no correlation with diet lut or zea ($p=0.40$, $p=0.42$). Macrophage cantha was not detected. This suggests that macrophages, unlike other tissues, may sequester xan from egg yolk, and maintain xan levels regardless of diet. Liver, bursa and RBC xan appear to plateau within the tested dietary range. In contrast, plasma and thymus xan appeared to continue to increase in a linear response to diet xan.

Key Words: Xanthophyll, Macrophage, Layer

703 Fluid therapy of poult infected with turkey corona virus (TCV) and *E. coli*. L. El-Hadri*, M. A. Qureshi, J. D. Garlich, P. R. Ferket, and J. S. Guy, *NC State University, Raleigh, NC USA.*

Supplementation of drinking water with electrolytes, glucose, betaine may help sustain poult afflicted with enteric disease. This hypothesis was tested in 2 experiments with poults receiving an oral inoculation containing TCV and *E. coli* at 7 d of age. In trial 1, beginning at 2 d post inoculation (DPI) poults were randomly assigned to one of the 4 treatments: unsupplemented control (C), electrolytes (E), electrolytes + 25 g glucose/l (EHG), electrolytes + 13 g glucose/l (ELG). Mortality was recorded daily and weights of whole body, bursa, and thymus were taken at 7 and 14 DPI. Birds treated with E (99 mOsm), EHG (252 mOsm) and ELG (189 mOsm) gained more weight than controls (0 mOsm) ($P<0.01$). Feed conversion was reduced ($P<0.002$) in all the supplemented water treatments. In comparison to the E and C treatments, EHG and ELG resulted in lower mortality rates (63 and 52% vs 37 and 36%, $P<0.01$), and greater thymus weight (0.106 g and 0.11 g vs 0.195 g and 0.186 g, $P<0.006$) at 7 DPI. Trial 2 tested betaine (B) as an osmotic modulator in therapeutic fluids containing high (HG) and low (LG) glucose concentration, using a 2X3 factorial arrangement of 2 levels of betaine (0 and 300 mg/l) and 3 levels of glucose (0, 13, and 25 g/l). A B X G interaction effect indicated B depressed body weight gain in LG groups (BLG, 231g vs LG, 267 g, $P<0.05$), whereas it had no effect on HG birds (BHG, 187 g vs HG, 162 g, $P>0.05$). Bursa and thymus weights were increased by the G treatments only ($P<0.003$). Fluid consumption at 3 and 4 DPI was increased by G but not B. Although all fluid treatments had some benefit relative to the controls, the greatest reduction in mortality rate was observed when G and B were included in the fluid together (6.5% vs 20%, $P<0.05$). Supplementation of drinking water with electrolytes (99 mOsm) plus glucose (low, 189 mOsm, or high, 251 mOsm) improved survival and immune organ weights of TCV and *E. coli* -infected poults.

Key Words: Electrolytes, Glucose, Betaine

704 Effect of dietary betaine on intestinal leukocyte numbers, osmolality, and morphology during an *Eimeria acervulina* challenge. K. C. Klasing*¹, K. L. Adler¹, C. C. Calvert¹, and J. C. Remus², ¹*University of California, Davis, CA*, ²*Finnfeeds, St. Louis, MO.*

In addition to its methyl-donor activities, betaine is used by cells to defend against hyperosmolality. We examined relationships between betaine, osmolality (OS), and coccidiosis. Broiler chicks were fed corn-soy diets containing either 0.0, 0.05, or 0.10% betaine (8 pens/diet; 7 chicks/pen) and half were challenged at 14 d with 4.6×10^4 oocysts (Cocci). Cocci decreased weight gain and feed efficiency, while betaine did not affect either. Intestinal samples from 1 chick/pen were taken on 4 and 7 later. Cocci increased OS of the duodenal and jejunal mucosa. Betaine decreased OS of the duodenum ($P<0.01$), especially in Cocci challenged birds (interaction $P<0.07$). Cocci increased the thickness ($P=0.04$) and number of leukocytes ($P<0.01$) in the duodenal lamina propria. The increase in leukocyte numbers was greatest at high betaine levels (interaction $P=0.05$). The height of duodenal villi was decreased by Cocci ($P=0.05$) and this effect was ameliorated by 0.10% betaine (interaction $P=0.04$). Intra-epithelia leukocyte numbers were increased by Cocci ($P<0.01$) and this increase was greatest with 0.05 and 0.10% betaine (interaction $P=0.04$). Villi width and crypt depth were unaffected by the treatments. In a second experiment, peritoneal macrophages (Macs) or peripheral blood heterophils (Hets) were incubated in media with an osmolality of either 200, 310, 600, or 900 milli-osmol and either 0.0, 0.1, 0.5 or 1.5 mM betaine (4x4 factorial). *Eimeria* were added to cultures after 6 hrs exposure to media. Phagocytosis by Macs was decreased by hypo-OS (200) and hyper-OS (600, 900) media relative to iso-OS media ($P=0.015$). Phagocytosis by Hets was decreased only by 900 milli-osmol. In Macs, but not Hets, phagocytosis was increased by 0.1 mM betaine compared to 0.0 betaine ($P=0.05$). Macs and Hets incubated in hyper-OS media had decreased chemotaxis and NO release. Betaine increased NO release by Hets ($P=0.039$).

Key Words: Coccidiosis, Betaine, Villi

705 Utilization of metabolizable energy in broilers. J. van Milgen*¹, J. Noblet¹, S. Dubois¹, B. Carr², and H. Juin³, ¹*INRA, St-Gilles, France*, ²*INRA, Nouzilly, France*, ³*INRA, Le Magneraud, France.*

Four groups of broilers (ISA 915) were used to study the effect of body weight on the partitioning of metabolizable energy between protein and lipid deposition, and components of heat production. Broilers were group-housed in a cage measuring 105 x 65 x 45 cm equipped with two feeders of 30 cm each. The cage was mounted on force sensors to measure physical activity of the animals. Temperature was maintained at 21C (60-65% relative humidity) and a 22 h/d lighting schedule was adopted. Animals had ad libitum access to feed (20.5% CP, and 12.7 MJ ME/kg feed) and water. Heat production was measured using indirect open-circuit calorimetry whereas protein and lipid deposition was determined through nitrogen and energy balances. Heat production was measured during two successive weeks. Each week consisted of one day of adaptation, five days of collection of excreta and measuring feed intake and heat production when fed, and one day of measuring the fasting heat production (temperature 24C). In the first week, heat production and nitrogen balance were measured in groups of 11-12 broilers (starting at 21 d of age). At the start of the second week, group size was reduced to 8-9 broilers. The average weight of the broilers was 1.00 and 1.61 kg during the first and second week, respectively. Dry matter feed intake per broiler increased from 120 g/d in week 1 to 161 g/d in week 2. Growth rates (prior to fasting) averaged 89 and 100 g/d for weeks 1 and 2, respectively. To express maintenance energy requirements relative to BW (prior to fasting), the model $Y = aBW^b$ was used. For the fasting heat production, the value of "b" significantly differed from 0.75 but not from 0.60, resulting in an activity-free fasting heat production of 490 kJ/(kg BW^{0.60})/d. Similarly, ME intake and total heat production were not affected by stage of growth when expressed per (kg BW)^{0.60}. On average over the two weeks, broilers consumed 1764 kJ ME/(kg BW)^{0.60}/d, 53.4% of which was lost as heat. The retained energy was partitioned between protein (47.4%) and lipid (52.6%). Heat production was partitioned between fasting heat production (52.1%), physical activity (17.0%) and thermic effect of feeding (30.9%). For the latter two components, this represented 9.1 and 16.5% of ME intake, respectively.

Key Words: Broilers, Energy Metabolism, Heat Production

706 Broiler bone metabolism changes significantly during acute stress. Alfonso Jr Mireles*, Sun Kim, Russell Thompson, and William R. Amundsen, *Foster Farms, Modesto, CA.*

A preliminary study showed acute stress caused by an *E. coli* lipopolysaccharide (LPS) subcutaneous injection significantly decreased weight, breast yield, and bone tibia bone strength. Because weight gain and tibia strength are known to be directly correlated, this study was conducted to determine whether this observed loss of bone quality is also affected by an acute inflammatory response. There were 5 treatment groups of 17 cockerels each. Birds were subcutaneously injected *E. coli* LPS at 0, 33, 66, 100, or 425 micrograms/100 grams body weight. Weight gains after 3 days were 263, 209, 195, 186, and 127 grams/bird respectively. Similarly, tibia strength scores were 43.1, 38.8, 38.5, 34.0, and 32.2 Kgs. Tibia elasticity scores were 3.91, 3.66, 3.51, 3.43, and 3.35 mm. Three day mortality was 5, 0, 10, 15, and 40% respectively. Linear regression equations were calculated for each treatment group, and actual weight vs. predicted bone strength were plotted by treatment group. Results showed that, at the same weight, tibia strength is directly related to LPS dosage. As the level of stress (LPS) increased, the regression lines shifted downwards and away from the non-stressed group line. Results suggested bone catabolism is an essential part of an acute stress, which can be used as a sensitive index for nutritional immunomodulation.

Key Words: Nutritional immunomodulation, Bone strength and metabolism, Acute stress

707 Growth promoters in broiler feed (coccidiostat + antibiotics) may play a crucial role during acute stress. Alfonso Jr Mireles* and Sun Kim, *Foster Farms, Modesto, CA.*

To evaluate the effect of growth promoters in broiler feeds during acute stress conditions, 2 treatments were prepared (Control with 50 gms Salinomycin + 25 gms Bacitracin MD/ton (C) vs. No Feed Additives (NFA)). A field experiment was conducted during summer and lasted 45 days. There were 10 replicate pens of 50 birds per treatment. Twenty males per treatment were sampled at 35 days for tibia and breast quality. At 39 days, 14 birds per treatment were injected 100 micrograms *E. coli* lipopolysaccharide (LPS) subcutaneously per 100 grams body weight and their performance was compared vs. 14 non-injected birds. At 35 days, NFA birds had weaker ($P < 0.05$) tibias (37.3 vs 32.7 Kgs), lower tibia yields (1.1 vs 1.0%) and similar breast yields as C birds. At 45 days, NFA birds had poorer ($P < 0.05$) weight gain (2.4 vs 2.3 Kg), feed/gain (1.72 vs 1.77), and similar mortality as C birds. A LPS challenge decreased ($P < 0.05$) weight (2.23 vs 2.09 Kg), tibia strength (35.8 vs 32.3 Kg), breast yield (14.9 vs 14.3%), and increased mortality (0 vs 12%). C birds, however, handled the stress significantly better ($P < 0.05$) than NFA birds. At 210 minutes post-LPS, body temperature of C birds was lower than that of NFA birds (42.6 vs 43.0 °C). Coccidiostats and/or antibiotics appear to impart a critical protective effect on broilers during acute stress. This stress is detrimental to breast yield and bone strength and quality.

708 Impact of galactose on growth performance, toxicity and metabolizable energy when fed to broiler chicks. M.W. Douglas* and C.M. Parsons, *University of Illinois, Urbana, IL USA.*

A study was conducted to determine the effect of increasing dietary galactose (GAL) on growth performance, toxicity and metabolizable energy when fed to commercial broiler chicks. One-day old Ross x Hi Y male chicks were randomly assigned to one of six treatments. The treatments were a 22% CP corn-soybean meal-dextrose basal diet with the addition of 0, 2, 4, 6, 10 or 15% GAL at the expense of dextrose. The diets were fed from 0 to 21 days of age. Metabolizable energy of the diets was determined from collection of excreta for Days 18 to 21. The 15% GAL treatment resulted in high mortality (26%) by Day 3 and was terminated. The 10% GAL treatment also resulted in increased mortality, most of which occurred during the 7 to 14 d period. However, the 10% GAL diet had no significant negative effect on growth performance compared to the basal diet (0% GAL). There was no difference in mortality for the 0, 2, 4 and 6% GAL treatments. Addition of GAL at the 2, 4, and 6% level resulted in numerically increased weight gain and feed

efficiency over chicks fed 0% GAL, with the increases being 10% and significant ($P < 0.05$) for the 4% inclusion rate. Feed intake for the 21 d period was not significantly ($P > 0.05$) different for any level of GAL fed (0-10%). Metabolizable energy was greatest for chicks fed 0% GAL (3.149 kcal/g DM). Supplementation of 2, 4, 6 and 10% GAL resulted in decreases in ME_N of 4, 6, 7 and 11%, respectively (significant linear response, $r^2 = 0.85$). Our results indicate that low levels of GAL may increase growth performance of commercial broiler chicks even though dietary ME_N may be reduced.

Key Words: Chicks, Galactose, Growth Performance

709 The effect of fasting at different ages on growth and tissue dynamics in the small intestine of the young chick. David Sklan*, Assaf Geyra, and Zehava Uni, *Faculty of Agriculture, Hebrew University of Jerusalem, Israel.*

The small intestines of hatching chicks undergo rapid developmental changes in the immediate posthatch period when the birds are making the transition from endogenous nutrient supply from yolk to dependence on exogenous feed. This transition usually only begins 48 h or more after hatch due to logistical considerations. The effects of fasting for 48 h at different times during this critical period on small intestinal development and enterocyte dynamics were examined by morphometric determinations and use of staining for proliferative cell nuclear antigen and 5-bromo-2-deoxyuridine. The effects of fasting were specific to both time of fasting and to the intestinal segment examined. Decreased development was found in the duodenum and jejunum and less apparent in the ileum. Fasting between 0 and 48 h decreased crypt size in the duodenum and jejunum, the number of crypts per villus, crypt proliferation, villus area and the rate of enterocyte migration. Fasting at later times resulted in smaller effects, although the jejunum appeared to be the most sensitive of the intestinal segments. Growth was correlated with the number of cells in the crypts, the number of cells along the villus and the segment surface area.

Key Words: Small intestine, Fasting, Chicks

710 Influence of source of energy of the pre-starter diet on performance and nutrient digestibility of broiler. M. J. Aranibar, M. I. Gracia, R. Lazaro*, and G. G. Mateos, *Universidad Politecnica de Madrid, Spain.*

A trial was conducted to investigate the influence of different energy sources in the pre-starter diet on performance and nutrient digestibility of broiler chicks. There were five treatments and five replicates of four chicks per treatment. The experimental diets (0 to 10d) were based on corn and soybean meal and included either 6.8% of a fat source (sunflower oil, fish oil or lard) or 15.0% of a carbohydrate source (starch or sucrose). The nutrient content of these diets was approximately 3,150 kcal AMEn/kg and 1.33% Lys for the fat diets and 2,920 kcal AMEn/kg and 1.23% Lys for the carbohydrate diets. From 10 to 21d all the birds received a common diet containing 3,000 kcal AMEn/kg and 1.33% Lys. Productive performance was measured at 10 and 21d and apparent fecal digestibility of crude protein (CPD) and crude fat (CFD), and the AMEn of the diets were determined at 4, 7, and 10d of age. No differences in performance were observed among treatments at 21d of age. As expected, birds fed the fat diets had similar body weight but better feed conversion ($P < 0.01$) than broilers fed the carbohydrate diets at 10d of age. Apparent CPD and AMEn of the diets increased with age (48.3, 55.4, and 58.4%; $P < 0.001$, and 2,637, 2,731, and 2,853 kcal AME/kg; $P < 0.001$ at 4, 7, and 10d of age, respectively). Unexpectedly, apparent CFD decreased at 7d as compared to 4d (67.7 vs 76.4%; $P < 0.01$) and then increased slightly at 10d of age (70.5%). The differences on CFD between 4 and 7d were more pronounced for fish oil (80.8 vs 58.4%; $P < 0.001$) and lard (77.8 vs 62.3%; $P < 0.001$) than for sunflower oil (84.7 vs 80.3%; $P > 0.05$). We conclude that fat digestibility of chicks was lower at 7 than at 4 or 10d and that type and source of energy used from 0 to 10d does not influence broiler performance at 21d.

Key Words: Broilers, Digestibility, Fat

711 Starch digestion rate in the small intestine of broilers differs among feedstuffs. R.E. Weurding^{*1}, A. Veldman¹, W.A.G. Veen¹, M.W.A. Verstegen², and P.J. Van der Aar¹, ¹*Institute for Animal Nutrition 'De Schothorst', Lelystad, The Netherlands*, ²*Wageningen University and Research Center, Wageningen, The Netherlands*.

A digestibility trial with 720 broilers was performed in which starch digestion of twelve diets, varying in starch source, was determined in three different segments of the small intestine as well as total starch digestion. The choice for the starch supplying feedstuffs was made considering known differences in starch accessibility, -structure and -composition. Based on digestibility coefficients and retention times in the different gut segments, in vivo starch digestion rate was calculated. Ileal starch digestion varied from 33% (potato starch) to 99% (tapioca). No starch degradation was observed in the hind gut. Dietary mean retention time in the small intestine varied from 136 min (barley diet) to 182 min (potato diet). Starch digestion rates varied from 0.5 /h (common beans) to 4.3 /h (tapioca). Ranking of feedstuffs according to total starch digestion (in increasing order) was: potato starch, legume seeds, cereal grains, tapioca. An in vitro technique which mimics passage through the gastrointestinal tract (GIT) of humans was adapted to mimic passage through the GIT of broilers. In vitro starch digestion was measured at different incubation times in the same diets as used in the in vivo digestion trial. From the starch digestion coefficients at the different incubation times, starch digestion rate was estimated. Correlations between in vivo and in vitro starch digestion data were calculated. In vitro starch digestion after 2 h incubation correlated well with starch digestion in the posterior jejunum ($r = 0.94$) and in vitro starch digestion after 4 h incubation correlated well with starch digestion in the posterior ileum ($r = 0.96$). In vitro starch digestion rate was lower, but showed a good correlation with in vivo starch digestion rate ($r = 0.87$). It was concluded that starch digestion rate in broilers varies among feedstuffs and can be predicted by the adapted in vitro method.

713 Use of the OptiBreed Sperm Quality Analyzer[®] for evaluating semen quality of turkey breeders. S. L. Neuman^{*1}, C. D. McDaniel², J. Radu³, L. Frank³, and P. Y. Hester¹, ¹*Purdue University*, ²*Mississippi State University*, ³*Alpharma, Inc.*

The OptiBreed Sperm Quality Analyzer[®] (SQA) measures overall sperm quality as a Sperm Quality Index (SQI). The SQI value generated by the SQA is indicative of turkey sperm concentration, motility, and viability (Neuman et al., *Poultry Sci.* 79:suppl.1:49) The objective of the current study was to monitor the quality of semen in a turkey breeder flock throughout its semen production cycle. A commercial secondary breeder flock of BUTA breeder toms was monitored for sperm quality at 4-wk intervals beginning at 32 wk of age. Individual ejaculates were collected from the same 200 male breeders each month for 7 months. The semen was diluted 50-fold in 0.85% saline prior to determining the SQI for each individual bird. The SQI values were measured within 5 to 10 minutes of collecting the ejaculates. Individual semen volume was also determined gravimetrically. A univariate procedure, conducted monthly on individual SQI values and semen volume, indicated that SQI values were not normally distributed with the exception of month 7 in which SQI values were normally distributed (Shapiro-Wilk $W = 0.9939$, $P = 0.65$ for month 7). Semen volume was normally distributed during months 1, 2, 6, and 7 ($P > 0.05$). The CV for SQI was highest during month 1 at 26%, but decreased during subsequent months and averaged 15%. The CV for monthly semen volume averaged 32%. An ANOVA, conducted on semen traits to evaluate time effects, indicated that mean SQI values were lowest during months 1 and 7 of semen production with peak values occurring during months 2 through 6. Semen volume was at its lowest during the first month of production with subsequent increases during months 2 through 7. Correlation for all months between semen volume and SQI values was low ($r = 0.17$, $P < 0.0001$). In conclusion, the SQA can be used as a tool to monitor semen quality of breeder toms as a flock ages.

Key Words: Sperm Quality Analyzer, Sperm Quality Index, Turkey breeder

The practical relevance of starch digestion rate will be studied in growth trials.

Key Words: Starch, Broilers, Digestion rate

712 Effect of colistin and aureomycin on intestinal microorganism and their relationship with the riboflavin metabolism of broilers. H. Y. Cai^{*1}, L. Wang¹, and G. H. Liu¹, ¹*Feed Research Institute, Chinese Academy of Agricultural Sciences, Beijing, P. R. China*.

To investigate the interrelationship between antibiotics, intestinal microorganisms and riboflavin metabolism in broilers, a total of 280 one day of age AA broilers were randomly allotted to 5 dietary treatments. Experimental diets were formulated to contain of two antibiotics at two different dosages (aureomycin: 50, 100 mg/kg; colistin: 10, 20 mg/kg) and the control without adding antibiotics. At 3 wk of age, four birds were taken at random from each of the treatment groups for the riboflavin (B2) analysis of cecal contents and determination of differential microbial counts. All data was statistically analyzed by Statistica 6.0 software and multiple comparisons conducted by DUNCAN. There was a gradual but significant ($P < 0.05$) reduction in *E. coli* numbers with increasing levels of either colistin or aureomycin. Colistin supplementation at 20 mg/kg significantly ($P < 0.05$) increased bifidobacterium numbers. Similarly, aureomycin supplementation at 50 mg/kg and 10 mg colistin/kg numerically increased bifidobacterium counts ($P > 0.05$). The B2 concentrations in the broilers' cecal contents at 21 days of age were significantly higher ($P < 0.05$) in birds receiving 20 mgcolistin/kg. Aureomycin supplementation at 100 mg/kg numerically increased the cecal level of B2 ($P > 0.05$). The B2 concentrations in the colons of 21 day-old birds fed either 100 mg aureomycin/kg or 20 mg colistin/kg were numerically reduced ($P > 0.05$) indicating a possible improvement of B2 absorption in the hindgut.

714 Effects of Feeding Regimen and Strain on Fertility of Broiler Breeder Hens as Indicated by the Perivitelline Layer Sperm Penetration Assay. R. A. Renema^{*}, F. E. Robinson, and G. M. Fasenko, *University of Alberta, Edmonton, AB., Canada*.

The fertility of broiler breeder hens can be reduced by overfeeding. Monitoring fertility is a key step in the early diagnosis of reproductive problems. The Perivitelline Layer (PL) Sperm Penetration Assay has been demonstrated to be an alternative, non-incubation method of fertility assessment. In this study, the PL Sperm Penetration Assay was used to assess fertility in broiler breeder hens of four strains either feed restricted (FR) or ad libitum (AL) fed from photostimulation. Four strains of pullets (Shaver Starbro, Cobb 500, Hubbard Hi-Y, Avian 24k) were reared on a common growth curve. Strains were assigned the anonymous labels W, X, Y, or Z. Forty pullets of mean BW from each strain were individually caged at 20 wk of age. Birds were photostimulated at 22 wk and either maintained under RF conditions, or switched to an AL regimen. At 45 wk of age, 15 hens/tmt were artificially inseminated with pooled semen, and eggs collected 2-9 d after insemination. Eggs were assessed for PL sperm hole number at 40X and 100X magnification and data summarized in 3, 3-d periods (2-4 d, 5-7 d, and 8-10 d). There were no strain differences in the number of PV sperm holes determined at 100X magnification. However, at 40X magnification, 146 PV holes were present in Strain W eggs 2-4 d after insemination compared to 72 and 80 in Strain X and Y eggs, respectively. Although PV hole numbers were low in Strain Y eggs during the 2-4 d period, they did not subsequently decline as rapidly as in other strains. There were 43.1% and 34.8% fewer PV sperm holes in AL eggs than in RF eggs during the 2-4 d post-insemination period when examined under 100X and 40X magnification, respectively. Despite differences in PV sperm holes due to feeding level, actual fertility was affected by AL feeding in a strain-dependent manner. However, as breeder strain influenced the PV hole number independently of actual fertility, the value of the PV hole method for strain comparison was reduced.

Key Words: Broiler breeder, Fertility, Genetic strain

715 Differences in in vitro sperm hydrolysis of the perivitelline layer between two commercial lines of turkeys. B. D. Fairchild* and V. L. Christensen, *North Carolina State University, Raleigh, NC USA.*

Sperm penetration of the ovum inner perivitelline layer (IPVL) is positively correlated with fertility. Higher sperm penetration of the IPVL is indicative of successful insemination and can be positively associated with filling of the sperm storage tubules in the uterovaginal region of the oviduct. The hypothesis tested was that in vitro sperm hydrolysis of the IPVL would differ between two commercial turkey lines at two different periods in production. The objectives were to determine strain, age, male and female influence on sperm hydrolysis of the IPVL. Two experiments were conducted. In Experiment 1 strain and hen age were examined. Two commercial strains (N & H) and two hen ages within the laying period (early period=1-4 weeks of lay and mid period=12-16 weeks of lay) were used as factors in a factorial design. In Experiment 2, Tom (HM and NM) and Hen (HF and NF) were arranged in a factorial design to examine male and female influence on sperm hydrolysis. Eggs were obtained at oviposition from non-fertilized hens. Perivitelline layer (PVL) was isolated from non-germinal disc regions of the egg, sectioned into 1cm² pieces, then incubated with 25x10⁶ viable sperm cells. After incubation, all PVL sections were rinsed, fixed on a microscope slide and stained. Holes from sperm hydrolysis were then counted. In Experiment 1, young hens had significantly more hydrolyzed holes than older hens and H hens had more hydrolyzed holes than N hens. No interaction between age and commercial line was detected indicating that both lines performed similarly at both production periods examined. In Experiment 2, HM and HF had significantly more sperm hydrolyzed holes than NM and NF. The results of these two experiments suggest that strain, hen age, sire and hen have significant effects on sperm hydrolysis of the IPVL and that by crossing sires and hens of different lines no gain in sperm hydrolyzed holes was achieved in vitro.

Key Words: Turkey, Fertility, Sperm hydrolysis

716 Production of germline chimera by transferring gonadal germ cells (GGCs) collected from 7 or 9 day-old chick embryos. A. Tajima*¹, M. Ohara², T. Minematsu¹, T. Kuwana³, and Y. Kanai¹, ¹*Institute of Agriculture and Forestry, University of Tsukuba*, ²*Poultry Division, Takikawa Agricultural Experiment Station*, ³*Pathology Section, National Institute for Minamata Disease.*

Fertilized eggs of the genetically selected White Leghorn line (SH strain) produced at Takikawa Animal Experiment Station (Hokkaido, Japan) were transported to University of Tsukuba (Ibaraki, Japan) by a commercial courier. Eggs were incubated at 37.8 C for 7 or 9 days and the recovered gonads were dissociated mechanically. Dissociated gonadal cells containing 7-day-old or 9-day-old gonadal germ cells (7d-GGCs or 9d-GGCs, respectively) were suspended in freezing medium containing 10 % dimethyl sulphoxide (DMSO). The cell suspension was frozen at 1 C/min. until the temperature reached -80C; this was followed by immersing the cells into liquid nitrogen at -196 C then stored up to 3 months. Between twenty five to one hundred frozen/thawed GGCs were injected into the dorsal aorta of stage 14-15 (H&H) Rhode Island Red (RIR) embryo from which blood was drawn prior to germ cell injection. The injected embryos were incubated until hatched and hatched chicks were raised until sexually mature. Hatchability as well as male:female ratio were 78% (7/9) and 5:2, and 42% (5/12) and 3:2 for embryos transferred with 7d-GGCs and 9d-GGCs, respectively. Upon reaching sexual maturity, a progeny-test was performed for 4-19 weeks by mating recipient chicks with normal RIR of the opposite sex. Out of 5 male 7d-GGC recipient, one male produced chick derived from transferred GGCs and the ratio was 1.7 % (1/58). Out of 3 male 9d-GGC recipient chick, one male produced chick derived from transferred GGCs and the ratio was 3.9 % (8/197). None of the female recipients hens produced chick derived from transferred GGCs. Present results demonstrate that frozen/thawed male 7d-GGCs and male 9d-GGC are still capable of producing germ-line chimeras in chicken when injected into blood stream of 2-day-old recipient embryo.

717 Luteinizing Hormone, Progesterone, and Estradiol-17 β Concentrations, and distribution of Hierarchical Follicles in Normal and Arrested-laying Turkey Hens. H.-K. Liu, D.W. Long, and W.L. Bacon*, ¹*The Ohio State University, Wooster OH.*

Photosensitive turkey hens of a line selected for increased egg production (Egg line) were photostimulated with constant light (24 h light: 0 h dark⁻¹) at 30 wk of age. Egg laying became arrested in 6 of the 12 hens after only 2 to 3 wk of laying. Comparisons of ovarian and oviductal morphology and changes in plasma hormones [luteinizing hormone (LH), progesterone (P₄) and estradiol-17 β (E₂)] over 10 d of hourly serial bleeding between the laying and arrested-laying hens were made. The number of hierarchical follicles (follicles > 1.0 g) was much greater in the arrested-laying hens than in laying hens. Some of the arrested-laying hens presented a poly-cystic ovarian follicle condition, with a large number of follicles slightly heavier or much heavier in weight than F₁ follicles of the laying hens. The oviducts of the arrested-laying hens were fully developed and similar in weight to those of laying hens. The plasma concentration of LH in the arrested-laying hens was relatively low and without preovulatory surges, which were detected in the laying hens. The baseline concentration of LH in the laying hens and the interval between preovulatory surges were similar to previously reported values for laying hens of the Egg line. The concentration of P₄ in most of the arrested-laying hens was maintained at a relatively high level without preovulatory surges. The baseline and surge amplitude concentrations of P₄ in the laying hens and interval between surges were similar to previously reported values for laying hens of the Egg line. The concentrations of E₂ were not different between normal and arrested laying hens. In conclusion, the relatively high and surge-less concentration of P₄ in the plasma of the arrested-laying hens might block ovulations but not block entrance of follicles into the hierarchy nor alter their hierarchical growth, leading to an accumulation of numerous F₁ or larger sized follicles in the ovary. Further, some of the accumulated mature follicles may resume an abnormal growth leading to the formation of cystic ovarian follicles.

Key Words: Turkey hen, arrested-laying, progesterone

718 Profile of Plasma Hydroxyproline in Laying Hens During an Ovulatory Cycle. J. I. Orban*¹ and P. Y. Hester², ¹*Southern University at Shreveport, LA*, ²*Purdue University, IN.*

Hydroxyproline is required for collagen formation and is associated with bone remodeling. In humans, estimation of hydroxyproline level in the blood and urine has become a useful method to assess bone turnover, especially in bone degradation. In laying hens, bone integrity depends on calcium need, which is in part associated with the rate and magnitude of bone remodeling. The objective of this study was to determine the level of free plasma hydroxyproline in laying hens in relation to plasma calcium level during the ovulatory cycle to assess when bone resorption occurs to provide additional calcium for eggshell calcification. Twenty-five laying Leghorn hens (12 hens, 25 wk-old and 13 hens, 60 wk-old) were bled at 0, 5, 10, 15 and 20 h post-oviposition. Blood plasma obtained was analyzed for free hydroxyproline level using a modified method of Dabev and Struck (1971, *Biochem. Med.* 5:17). Calcium was analyzed using a Sigma calcium kit (St. Louis, MO 63178). Data were analyzed using a one-way ANOVA with a split plot in time (h post-oviposition). Both the 25 and 60 wk-old hens showed a significant (P < 0.0001) increase in plasma levels of hydroxyproline at 15 h post-oviposition (8.8 ug/mL for 25 wk hens and 8.0 ug/mL for 60 wk hens) as compared to basal levels at 0, 5, 10, and 20 h post-oviposition (6.2, 6.4, 6.4, and 7.2 ug/mL for 25 wk hens and 6.3, 7.1, 6.6, and 5.7 ug/mL for 60 wk hens, respectively, pooled SEM = 0.4). Mean plasma calcium levels during the time period for both age groups were 36 (0 h), 39 (5 h) 34 (10h) 23 (15h) and 18 mg % (20 h), pooled SEM = 2. The significant (P < 0.001) drop in calcium level from 15 to 20 h during the ovulatory cycle indicated the period of active eggshell calcification during which the spike increase in hydroxyproline was observed. Results indicate that the 15 h post-oviposition spike increase in plasma hydroxyproline level could represent bone turnover or medullary bone resorption to release additional calcium for eggshell calcification.

Key Words: Plasma hydroxyproline, Plasma calcium, Laying hen

719 Development of an ELISPOT assay for monitoring chicken Follicle-Stimulating Hormone (cFSH) release from individual dispersed pituitary cells. N. Puebla-Osorio*¹, J.A. Proudman², H.H.M. Gerets³, F. Vandesande³, and L.R. Berghman¹, ¹Texas A&M University, College Station TX, ²USDA-ARS Beltsville, MD, ³University of Leuven, Belgium.

From a methodological point of view, FSH and thyroid-stimulating hormone (TSH), are among the most difficult pituitary hormones to study in most vertebrate species. The amount of hormone in the pituitary tends to be very small and the glycoprotein hormones themselves are complex molecules consisting of two non-covalently linked glycosylated subunits, only one of which is hormone-specific. The present study describes the development of a new cFSH ELISPOT assay, a hybrid between a sandwich ELISA and an immunodot assay. Pituitary cells from laying White Leghorn hens were gently dispersed using trypsin (1 mg/ml). In the meantime a nitrocellulose (NC) -bottomed 96-well filtration plate (Millipore, Bedford, MA), was coated with 1 mg monoclonal anti-cFSH, and then blocked with 0.5 % of BSA. The single cell suspension was counted and 50 ml of cell suspension, densities ranging from 1000 to 100,000 cells/ml, were seeded onto the NC bottoms. The cells were left to incubate overnight in the presence or absence of 50 mM KCl in DMEM medium containing 1 mg/ml of BSA. After incubation, the cells were removed and the FSH that had been captured in the spots immediately surrounding the cells was further detected using rabbit anti-chicken FSH α . The latter was then identified with a biotinylated secondary antibody and alkaline phosphatase-conjugated streptavidin. Visualization of the spots was attained with a final incubation with the substrate system NBT/BCIP. The NC discs were then air dried for microscopic evaluation of the frequency and diameter of the spots. Dark purple spots were observed with the smallest cell number, the spot frequency being proportional to the cell density. No spots were observed in the absence of cells and detection antibody, respectively. Also, KCl-stimulated cells produced markedly more and bigger spots. As soon as the quantitative analysis of the results has been developed, this tool can be used to evaluate cFSH secretion from individual pituitary cells under different physiological circumstances.

Key Words: chicken, FSH, ELISPOT

720 Dopaminergic neurotransmission controlling PRL/VIP secretion in the turkey. O.M. Youngren¹, Y. Chaiseha², S.E. Whiting¹, and M.E. El Halawani*¹, ¹University of Minnesota, St. Paul, MN, ²School of Biology, Institute of Science, Suranaree University of Technology, Thailand.

Vipergic neurons are the main element regulating avian PRL secretion. Our recent studies have demonstrated the modulation of VIPergic activity by stimulatory (via D₁ DA receptors) and inhibitory (via D₂ DA receptors) DAergic inputs. Dynorphin, serotonin (5-HT), DA, and VIP stimulate PRL secretion via a common hypothalamic pathway expressing κ opioid, 5-HTergic, DAergic, and VIPergic receptors, with the VIPergic system as the final mediator. Electrical stimulation (ES) within the turkey hypothalamus at the level of the medial preoptic nucleus (POM), the anterior hypothalamic nucleus (AM), the ventromedial hypothalamic nucleus (VMN), the infundibular nuclear complex (INF), and the median eminence (ME) results in the release of PRL. When the selective D₁ DA receptor antagonist SCH-23390 HCl was infused intraventricularly (icv) at the rate of 10 nmol/min, ES in POM, AM, and VMN was no longer able to increase PRL levels. Infusion of the D₁ DA antagonist did not prevent ES in ventral INF and ME from increasing PRL to the same level as that of controls. These results are interpreted to suggest that the D₁ DA receptors involved in PRL release lie caudal to VMN and dorsal to ventral INF. Electrical stimulation in POM, AM, or VMN appears to stimulate cells or fibers that release DA and this DA release is stimulatory for PRL secretion, whereas ES in INF and ME stimulates cells or fibers that release VIP directly to the pituitary. Microinjections of D₁ DA receptor agonist (SKF-38393 HCl, 50 ng, bilateral, n=5) into POM and VMN failed to produce any increase in PRL after 40 min, while microinjections in INF increased PRL from a baseline value of 40.8 \pm 4.7 ng/ml to 75.8 \pm 11.4 ng/ml after 15 min, reaching a high of 107.4 \pm 25.5 ng/ml 30 min after injection. This suggests that the only D₁ DA receptors involved in PRL release are located in the INF, the same area where changes in VIP neurons are known to occur throughout the reproductive cycle. USDA Grant No. 00-02127

721 Expression of D₁ and D₂ dopamine receptors in the hypothalamus and pituitary during the turkey reproductive cycle. Y. Chaiseha*¹, O.M. Youngren², S.A. Schnell³, and M.E. El Halawani², ¹School of Biology, Institute of Science, Suranaree University of Technology, Thailand, ²University of Minnesota, St. Paul, MN, ³University of Minnesota, Minneapolis, MN.

The regulation of avian prolactin (PRL) secretion and PRL gene expression is influenced by hypothalamic vasoactive intestinal peptide (VIP), the PRL releasing factor in avian species. Recent evidence indicates that D₁ and D₂ dopamine (DA) receptors play a pivotal role in VIP and PRL secretion. The differential expression of DA receptors on hypothalamic VIP neurons and anterior pituitary cells may affect the degree of prolactinemia observed during the turkey reproductive cycle. The relative expression of D₁ and D₂ DA receptor subtype mRNAs was quantitated using *in situ* hybridization histochemistry (ISH). The expression of D₁ DA receptor mRNA in the hypothalamus was found to be 6.8-fold greater than that of D₂ DA receptor mRNA. Higher D₁ DA receptor mRNA content was found in the anterior hypothalamus (3.6-fold), the ventromedial nucleus (2.0-fold), the infundibular nuclear complex (INF; 1.9-fold), and the medial preoptic nucleus (1.5-fold) of laying hens as compared to that of non-photostimulated hens. The levels seen in laying hens remained essentially the same in incubating hens, except for the INF area where levels increased 52%. During the photorefractory stage, the D₁ DA receptor mRNA was at its lowest level in all areas tested. No differences were observed in hypothalamic D₂ DA receptor mRNA abundance throughout the reproductive cycle. However, a marked reduction in pituitary D₂ DA receptor mRNA was observed in incubating hens. Pituitary D₁ DA receptor mRNA remained unchanged during the incubating phase. These results clearly demonstrate that the expression of stimulatory D₁ DA receptor mRNA in the hypothalamus increases in hyperprolactinemic incubating hens, whereas inhibitory D₂ DA receptor mRNA increases in the pituitary of hypoprolactinemic photorefractory hens. USDA Grant No. 00-02127

722 Regulation of Prolactin Gene Expression by Vasoactive Intestinal Peptide and Dopamine: Role of Ca²⁺ Signaling. A. A. Al-Kahtane*¹, D. Deepak², M Kannan², and M El Halawane¹, ¹University of Minnesota - Department of Animal Sciences, ²University of Minnesota - Department of Veterinary Pathobiology.

It is well documented that vasoactive intestinal peptide (VIP) is the prolactin (PRL) releasing factor in avian species. Our previous study shows that dopamine (DA), through D-2 DA receptors on pituitary cells, inhibits the stimulatory effects of VIP on PRL secretion, PRL-mRNA steady state level, PRL transcription rate and PRL-mRNA half-life. In this study we examined: 1) the effects of VIP and DA D₂ receptor agonist (R(-)-propylnorapomorphine hydrochloride) on intracellular Ca²⁺ [Ca²⁺]_i in turkey primary pituitary cells, and 2) the involvement of extracellular Ca²⁺ in the regulation of PRL gene expression by VIP and DA. Fura-2 (Molecular Probes) was used as the fluorescent calcium indicator to measure [Ca²⁺]_i in turkey pituitary cells. Reverse transcription-polymerase chain reaction (RT-PCR) technique was used to determine PRL-mRNA levels. Measurement of [Ca²⁺]_i by Fura-2 indicated that VIP gradually increased [Ca²⁺]_i with all doses used (10⁻⁹ to 10⁻⁵M). Preincubating the pituitary cells with DA D₂ receptor agonist (10⁻¹⁰M) for 10 min. inhibited the stimulatory effect of VIP on [Ca²⁺]_i. Blocking Ca²⁺ influx by verapamil, an L-type Ca²⁺ channel blocker, diminished the stimulatory effect of VIP on PRL-mRNA level. In contrast, Bay K8644, an L-type Ca²⁺ channel agonist, mimicked the stimulatory effect of VIP on PRL-mRNA content. These results show clearly that: 1) the influx of extracellular Ca²⁺ is required for the stimulatory effect of VIP on PRL gene expression and PRL secretion in avian species, and 2) DA, via D₂ DA receptors, antagonizes the stimulatory effects of VIP on PRL-mRNA and PRL secretion at least by inhibiting the influx of extracellular Ca²⁺ in pituitary cells. This demonstrated the involvement of the Ca²⁺ signaling pathway in the dual regulation of PRL secretion and PRL gene expression by DA (inhibitory) and VIP (stimulatory) at the pituitary level. Supported by USDA grant #00-02127.

723 Characterization of the VIP response element (VRE) in turkey prolactin promoter. S.W. Kang^{*1}, S. You², E.A. Wong³, T. Bakken¹, and M.E. El Halawani¹, ¹Dept. of Animal Science, Univ. of Minnesota, ²Dept. of Animal Science and Technology, Seoul National University, ³Virginia Polytechnic Institute and State University.

We showed previously that vasoactive intestinal peptide (VIP) increases prolactin (PRL) gene expression and secretion in turkey primary pituitary cells. We have now used 5'-flanking deletions and mutations of the turkey PRL promoter fused to the luciferase (Luc) reporter gene in transient transfection assays to further characterize sequences involved in stimulation of PRL gene expression by VIP. Promoter activities were determined by quantitative RT-PCR of Luc mRNA. The deletion analysis of turkey PRL promoter (tPRLP) indicated that the VIP-stimulated tPRLP activity was controlled by three major positive regulatory regions and two negative regions. From the -127 to -14 Luc construct, where the 7-8 fold increase of promoter activity by VIP occurred, we did deletion assay with -92/-14 and -60/-14 Luc constructs for investigating the minimal VRE of the promoter. The 35-base pair (bp) segment (position -127 to -93) deletion induced complete suppression of VIP-stimulated promoter activity, suggesting that the nucleotides between position -127 and -93 in the tPRL promoter are essential for the VIP-stimulated promoter activity. A putative Pit-1 binding site was found in the middle of the 35-bp segment and the significance of this element (12 bp) was tested by Decoy assay, deletion, and mutation analysis. The result of the present study demonstrated that VRE (12bp) in the proximal prolactin promoter is an important cis-element for the VIP-stimulated PRL gene expression in turkey primary pituitary cells. 724 Met-enkephalin directly regulates the GnRH-I system in Japanese quail. MA Ottinger^{*1}, N Thompson¹, and P Micevych², ¹University of Maryland, ²UCLA Center of Health Sciences.

Studies in our laboratory have shown that met-enkephalin (ENK) is a powerful regulator of the GnRH-I system. We have demonstrated a dose dependent, ENK-inhibition of GnRH-I release in vitro (Chen and Ottinger, 1999; Poult Sci abstr. #293). Other studies have suggested that ENK-inhibition of GnRH-I release may be directly on GnRH neurons and indirectly, through interneurons. The current study was conducted to examine the anatomical relationship of ENK immunoreactive to the GnRH-I cell bodies and processes. Double-labeling immunocytochemistry revealed close anatomical proximity of ENK and sexual dimorphism in the GnRH-I system as well as in ENK innervation. Confocal

microscopy was used to determine if the ENK preferring delta opioid receptors occur on GnRH-I neurons, thereby providing a means for direct opiate regulation of the GnRH-I neuron. Fixed brains from adult males and females (n=6/group) were sectioned (20 μ m) and double stained using antibodies specific for GnRH-I (kindly provided by Dr. S. Wray, NIH) or δ -opioid receptor (Diasorin, Inc). Many, but not all, GnRH-I positive cells were also immunoreactive for delta-opioid receptor. Further, the distribution of double labeled cell bodies tended to be in the rostral preoptic-septal region. GnRH-I axonal projections to the median eminence were also double labeled. These data provide evidence for colocalization of opiate receptor in the GnRH-I neuron, indicating a mechanism for direct opioid peptide regulation of the GnRH-I neuron. Supported by NRI #92-37203 (MAO) and NS 39495 (PM).

725 Localization of neurons projecting to the infundibular nuclear complex and the median eminence in the turkey hypothalamus. K Al-Zailaie, O Youngren, and M El Halawani, Dept. of Animal Science, University of Minnesota.

The release of prolactin (PRL) from avian anterior pituitary is under stimulatory control by vasoactive intestinal peptide (VIP), which functions as the PRL-releasing factor. VIP is mobilized from neurons concentrated within the hypothalamic infundibular nuclear complex (INF) that project to the external layer of the median eminence (ME). Dopamine (DA) acts centrally through D1 DA receptors to stimulate turkey PRL secretion and requires an intact VIPergic system in order to do so. The mechanisms of dopaminergic action upon VIP neurons are unclear. We have previously demonstrated the distribution of dopaminergic neurons in the turkey hypothalamus. It is not known if these DA neurons project directly to VIP neurons or if transsynaptic regulation is involved. To address this question, we have used the lipophilic fluorescent tracer Dil to determine the location of neurons which project to INF and ME. Birds were injected in INF and ME with the tracer and allowed to survive for 5 days, after which the brains were perfused, processed, and examined for retrograde transport. Following application of Dil to the INF, labeled neurons were detected in four distinct regions: preoptic area (POA), paraventricular nucleus (PVN), preopticus dorsolateralis (PD) and lateral septum (LS). After injecting Dil into ME, labeled neurons were detected in three distinct regions: INF, PVN, and preoptic medialis. The projections described above could provide anatomical substrates for neuroendocrine regulation of PRL. The identification of these labeled neurons is currently under investigation. USDA Grant No. 00-02127

Key Words: DA regulation of VIP, Turkey PRL, Dil

Reciprocation Sessions on Meat Science

726 The MARC beef carcass image analysis system. S. D. Shackelford^{*}, T. L. Wheeler, and M. Koohmaraie, U.S. Meat Animal Research Center.

At present, beef carcass value is a function of USDA quality grade, a subjective estimate of meat palatability, and USDA yield grade, a subjective estimate of carcass composition. Although "expert" calculated USDA yield grade is a relatively accurate predictor of carcass composition, producers continue to distrust use of yield grade in pricing formulas because application of yield grades is subjective and a high level of error can occur when carcasses are evaluated at rates of 300 to 400 head per hour. In 1997, we developed a system to predict beef carcass cutability based on image analysis of the 12th rib cross-section which was removed from carcasses for tenderness classification. This method provided a more accurate prediction of beef carcass cutability than did "expert" calculated USDA yield grade ($R^2 = 0.89$ vs 0.77). The Agricultural Research Service entered into a cooperative research and development agreement with IBP, Inc. to adopt this technology for application directly to beef carcasses. On-line testing has shown that this system provides a much more accurate ($R^2 = 0.89$ vs 0.61) prediction of boneless closely-trimmed, "user-friendly" beef carcass yields than is currently achieved by on-line USDA graders. In fact, the MARC image analysis system provides a more accurate prediction of beef carcass yields than does expert calculated yield grade ($R^2 = 0.75$). The ability of this system to predict "expert" calculated USDA yield grade was

evaluated using 182 steer and 219 heifer carcasses that encompassed the typical range for carcass weight (227 to 455 kg), adjusted preliminary yield grade (2.2 to 4.7), ribeye area (57 to 132 cm²), and calculated yield grade (-0.3 to 5.1). Combining image analysis variables with hot carcass weight explained 88% of the variation in "expert" calculated USDA yield grade. Implementation of this technology should allow beef packers to more accurately determine differences among carcasses in cut-out value. Thus, this system should be a key component of value-based beef price discovery systems.

Key Words: Beef, Cutability, Prediction

727 Development of Instructional Materials for CD-ROM and the Internet, the Beef Myology and Muscle Profiling project. S.J. Jones^{*} and R.L. Roeber, University of Nebraska-Lincoln.

With the improvement of computers to handle graphic images and search through large databases rapidly, it is now possible to develop a CD-ROM or web page that will serve as a resource for the muscular anatomy of the beef animal. With funding from the National Cattlemen's Beef Association, a CD-ROM was developed on beef myology and muscle profiling. Six different sections were developed to view the muscular and skeletal anatomy of the beef carcass; they included cross-sections, lateral views, sub-primal views, skeletal views and muscle and bone descriptions by

name. Photographs of 1" cross-sections of each wholesale cut was obtained and converted to JPEG format. A second beef side was laterally dissected with the removal of fat and individual muscles removed and photographed along with the carcass. Drawings in GIF format were developed for each picture. Sub-primal cuts were prepared and photographed on a rotating table every 22.5 degrees so all sides of the cut could be viewed. Information about each muscle was obtained and put into a database. The program was rendered using hypertext markup language (HTML). Application logic was written in JAVA so information is presented to a reader using an internet browser as the user interface and allowing the information to be shared. Flash animations were utilized to give the user a three dimensional view of sub-primal cuts. Utilization of computer technology helped to develop a beef myology and muscle profiling manual that can be updated rapidly and accessed world wide through the internet.

Key Words: CD-rom, Beef Myology, Internet

728 Bacon quality evaluation methods. Roger Mandigo*, *University of Nebraska-Lincoln.*

This Reciprocation session will address a variety of techniques and procedures used in the evaluation of sliced bacon. Some of the procedures to evaluate bacon to be discussed include: Camera Visioning and Computer Data Capture for Fat/Lean Quantity, Fat/Lean Color Classification System, Color of Pre-cooked Bacon, Slice Abnormalities, Shattering, Laciness, Length/width of slice, shrinkage during cooking, cooked slice distortion. Other techniques for discussion include: bacon slab firmness, where to measure, how to measure slab parameters, temperature at pressing/slicing and fatty acid profiles.

Key Words: Bacon

729 "Meal Solutions": Value added processing for a changing industry. J.W. Rocke*¹, ¹*RMH Foods, Inc.*

The dramatic growth of the "Meal Solutions" Category at both Retail and Food Services is signaling the shift from a commodity, fresh meat driven industry to a Value Added, consumer driven industry. This shift is requiring new technologies, processes and approaches to products that were once considered out of date or undervalued. Food Safety, Quality Eating Experiences and Variety are a few of the challenges that must

be addressed by processors to meet and exceed the desire of today's consumer.

730 A potential neural tract-tracing method for use in avian species. W.J. Kuenzel*¹, R. Ramesh², J.A. Proudman³, and R.R. Miselis⁴, ¹*University of Arkansas, Fayetteville, AR*, ²*National Institutes of Health, Bethesda, MD*, ³*United States Department of Agriculture, Beltsville, MD*, ⁴*University of Pennsylvania, Philadelphia, PA.*

Turkey hens display broodiness or incubation behavior involving contact of the breast area with eggs. The purpose of the study was to utilize a method found effective in mammals for tracing neural fiber tracts to determine whether it might be applicable for tracing a pathway from the brood patch to the brain in turkey hens. The method employed was the pseudorabies virus (PRV, Becker's strain) procedure. Four turkey hens were utilized: one injected with PRV along the left side of the brood patch near nerve fibers, a second bilaterally injected, a third injected into the left vitreous humor and a fourth served as a control. The concentration of PRV was 4-7 x 10⁸ plaque forming units/ml and the amount injected at each site was 5.0 µl. Brain sections were exposed to a polyclonal antibody to PRV (1:10,000) and subsequently processed using immunocytochemistry. Results of the bilateral injection into the brood patch showed immunostaining in the nucleus tractus solitarius, the dorsal motor nucleus of the vagus, the nucleus vestibularis descendens, the ventrolateral medulla and the nucleus reticularis gigantocellularis. Results of the injection into the vitreous humor included immunostaining of two portions of the proposed suprachiasmatic nucleus (SCN) of birds: the SCN pars medialis and the ventral nucleus of the supraoptic decussation. Other neural structures immunostained included the anterior, medial hypothalamic nucleus (n.), the bed n. of the pallial commissure, the paraventricular n., the lateral hypothalamic area, the inferior hypothalamic n., the n. of I, the archistriatum, the intercollicular n. and the central gray. A caution concerning the use of PRV in birds is that the immunostaining was not robust, particularly when brain sections were compared to those performed in rats following injection of Bartha's K strain of PRV into a peripheral injection site. The reason for the reduced number of neurons that show immunoreactivity following injections of PRV into hens compared to the rat is not known. Supported by USDA grant 97-35206-5087 to JAP and WJK.

Applications of Ultrasound in Livestock Production Systems

731 Scanning the future - Ultrasonography as a reproductive management tool for dairy cattle. P. M. Fricke*, *University of Wisconsin, Madison, Wisconsin.*

Application of transrectal real-time ultrasonography to the study of bovine reproduction represents a technological breakthrough that has revolutionized our knowledge of reproductive biology. New research information generated through ultrasonic imaging has clarified the nature of complex reproductive processes in cattle including ovarian follicular dynamics, corpus luteum function, and fetal development. Widespread adoption and use of ultrasonography for routine reproductive examinations of dairy cattle is the next contribution this technology will make to the dairy industry. Although rectal palpation is the established method for conducting reproductive examinations in dairy cattle, the information-gathering capabilities of ultrasonic imaging far exceed those of rectal palpation. Assessment of pregnancy status and fetal viability early post breeding to identify cows that fail to conceive improves reproductive efficiency by decreasing the interval between AI services and increasing AI service rate. Early identification of cows carrying twin fetuses allows for implementation of differential management strategies to abrogate negative effects of twinning during the periparturient period. Ovarian and uterine pathologies not accurately detected via rectal palpation can easily be visualized and appropriate therapies selected and implemented. Determination of fetal sex in utero is useful when coupled with a management decision that justifies the expense of fetal sexing. Development of integrated reproductive management systems that combine ultrasound with new and existing reproductive technologies will further enhance the practical applications of ultrasonography. Collectively, current and future applications of ultrasonography hold tremendous potential to enhance reproductive management and improve reproductive efficiency in dairy cattle. Development of Extension education

programs to train bovine practitioners to use ultrasound for routine reproductive examinations is a critical step toward rapid implementation of this technology into the dairy industry. As ultrasound equipment becomes increasingly portable and less costly, it is only a matter of time until widespread implementation of this technology occurs in the dairy industry.

Key Words: Ultrasound, Dairy Cattle, Reproduction

732 Ultrasound applications in beef cattle research and management. A.R. Williams*, *Mississippi State University, Starkville, MS.*

The advent of real-time, B-mode ultrasound has greatly facilitated and accelerated research capabilities in the areas of bovine reproductive physiology and live animal carcass evaluation. The incorporation of ultrasound in bovine reproductive research has led to greater understanding of ovarian physiology, early embryonic development, follicular wave dynamics, and reproductive disorders. Ultrasound has been used extensively in the development of controlled breeding programs involving estrus synchronization and ovulation synchronization for effective timed AI. Practical applications of ultrasound in bovine reproduction include imaging of the ovary as a diagnostic aid, examination and confirmation of ovarian cysts, early pregnancy detection, fetal sex determination, and identification of twins. More specialized reproductive applications include follicular oocyte aspiration (ovum pickup) and follicle ablation. Live animal carcass evaluation is another important area of research. Recent advancements in carcass image interpretation software have allowed for highly accurate estimates of ribeye area, backfat, percent intramuscular fat, and rump fat. Ultrasound measurements are

being used to gather data for genetic evaluations in breeding and feedlot cattle. Instead of relying on progeny testing based on the collection of actual carcass data, beef sires are being evaluated at a younger age with a high degree of accuracy. Several breed associations are currently using ultrasound data to estimate carcass EPDs. Research has indicated ultrasound is effective in sorting cattle in the feedlot for more optimum finishing and sorting prior to feeding. The future of carcass ultrasound includes continued update of current software system models and algorithms, development of an automated software package, and potential use in identifying factors determining tenderness. Practical applications of ultrasound in the beef industry will become normal practice in the near future. Data generated will have a positive impact on both reproductive efficiency and carcass quality.

Key Words: Beef Cattle, Ultrasound, Applications

733 Evolution and use of ultrasonic technology in the swine industry. S.J. Moeller*, *The Ohio State University, Columbus OH.*

The use of ultrasound to measure biological tissue dates back to at least 1950 (Wild, 1950), with early ultrasonic work focusing primarily on human medicine. The application in livestock species was somewhat slow due to the cumbersome, fragile machines and high investment costs. Historically, the application of ultrasound to swine has focused upon composition and reproductive status assessment, with most of the research carried out through universities and land-grant institutions. Hazel and Kline (1959), Price et al. (1960), and Stouffer et al. (1961) using various ultrasonic systems were among the first to report results relating ultrasound readings with carcass measures of composition. However, the accuracy of the early amplitude-depth (A-mode), single-crystal devices was often quite variable. The introduction of B-mode (brightness modality) ultrasound, using multiple-crystal transducers and displayed in real-time (RTU) greatly enhanced the accuracy of live animal composition evaluation (Alliston et al., 1982; Forrest et al., 1986; Turlington et al., 1990) and provided an understanding of extraneous effects on accuracy of measurements. In 1993, the U.S. swine industry implemented a national ultrasound training and certification program for composition assessment on live swine. Early research in the reproduction area utilized Doppler ultrasound systems that measured fluid flow within the uterus (Fraser et al., 1968, 1971). A-mode systems were evaluated by

Lindahl et al. (1975) and Hansen and Christensen (1976). Doppler and A-mode devices, while relatively inexpensive and accurate within specified time frames during gestation, are less accurate than RTU. Research indicates RTU is an accurate system of pregnancy detection as early as 22 d after first mating (Inaba et al., 1983; Jackson, 1986; Almond and Dial, 1987). Enhanced technology, increased portability and reduced cost have allowed ultrasound to be a common tool used in swine units, packing plants and research institutes. Future research in the areas of composition, muscle quality, and reproductive biology, along with enhanced imaging capabilities, will lead the way to new, innovative applications.

734 Ultrasound as a tool to assess reproductive status in poultry. J.D. Kirby*, R.W. Rorie, V. Melnychuk, and N.B. Anthony, *University of Arkansas, Fayetteville, AR 72701.*

Ultrasound has been used to evaluate reproductive status in humans and other mammals for many years. In the domestic fowl, the primary reproductive organs of both sexes are completely internalized making visual evaluations of reproductive status difficult. Additionally, due to the low relative value of each individual hen or rooster in an integrated production and management system there has been little effort to evaluate the reproductive performance of individuals, resulting in group management schemes. Over the past few decades, the genetic resources used to develop production parent stock has been consolidated into a limited number of elite lines owned by only a few companies. These companies use intense selection, typically only the top 0.1 to 10% are retained, to produce the elite "pedigreed" breeding stock. These elite breeders are then used to develop multiplier great- and grandparent populations. Due to the potential fecundity of poultry, pedigree males and females can ultimately be responsible for many millions of pounds of product produced. We have been able to use ultrasound to assess reproductive potential, primarily in hens, of broiler breeder and layer type chickens. Our results suggest that ultrasound can be used as a tool for selecting individuals with well formed, normal, follicular hierarchies or, in males, testis development. The potential for application in domestic or threatened bird species is tremendous and merits further evaluation.

Key Words: ultrasound, poultry, reproduction

Bioethics in Animal Science

735 Applied ethics and animal science. W.R. Stricklin*¹ and Lars Vikinge*², ¹*University of Maryland*, ²*Center for Applied Ethics, Linköping University, Linköping, Sweden.*

Animal agriculture is currently confronting many issues that range across a wide spectrum of public opinion. Environmental issues, animal treatment, gene manipulation, food safety, declining farm numbers, changes in rural society, and farm and food worker labor issues are but a few areas where there are valid differences of opinion relative to ethical questions involving animal agriculture. The response to these issues by animal scientists of course varies among individuals. However, we suggest that a somewhat common view by scientists is of the following type, "I only deal with facts. Science tells me everything I need to know. Philosophy is simply words related to opinion where one can not collect data and establish facts." We contend that values are an unavoidable part of all human decision-making, including for instance choices of research focus in science. We further contend that the methods for moral reasoning used by applied ethicists have many similarities to the scientific process. While we acknowledge that not everyone using this process will always reach the same conclusion, we contend that this is also true for the scientific method. Ultimately, if animal scientists are to serve the needs of animal agriculture as they contend is their mission, then they have an obligation to address the issues that are confronting animal agriculture. The challenge then becomes a matter of seeking methods for beginning the establishment of consensus in a pluralistic society. We will argue that the tools used by applied ethicists can be useful in the pursuit of this consensus. Not necessarily each animal scientist should take on this endeavor, but we propose that it should be a supported activity of at least some. These individuals must expand their knowledge base to include some familiarity of philosophy and arm themselves with additional academic tools other than those of science. Specifically, to increase their effectiveness, they must become somewhat conversant in

the methodology of moral philosophy and then work toward the development of collaborative efforts with applied ethicists. And finally, the leadership of the discipline of animal science should work toward facilitating the dissemination of knowledge regarding applied ethics and the process of consensus building.

Key Words: Applied ethics, Animal agriculture, Bioethics

736 Postmodernism for animal scientists. K.K. Schillo*¹ and P.B. Thompson*², ¹*University of Kentucky, Lexington, KY*, ²*Purdue University, West Lafayette, IN.*

Our goal is to explore whether postmodernism, a popular perspective within the humanities and social sciences, is relevant to animal science in the context of addressing contentious policy issues. As a social institution in Western culture, the animal science profession favors a modern ideological perspective. This view, which emerged in the 16th century and developed into the 19th century, is characterized by several pivotal assumptions: 1) humans are essentially rational individuals; 2) science is the paradigm of rationality and is therefore the most legitimate source of knowledge; 3) change brought about by science-based technology is inherently progressive. During the last century, there has been growing criticism of modernism. For example, a number of groups question the claim that science is an objective practice and view technology in terms of creating unnecessary risks rather than serving a social good. Such criticisms have been attributed to postmodernism. In general, postmodern theorists emphasize the role of language as a means to explain reality, and argue that because language is both historically and culturally relative, no one account of reality can be purely objective. In this sense, postmodernism has often been characterized as "anti-scientific." Some varieties of postmodernism embrace a nihilistic perspective and

portray scientific knowledge as nothing more than personal preferences that don't matter. However, other varieties view science as a value-laden social practice, but recognize that scientific methods can provide useful ways for coping with nature; especially when they take into account multiple perspectives. It is this latter view that offers insight into how the animal science profession can address policy issues in morally responsible ways. Currently, the animal science community advocates the modern view that public policy should be based only on sound sci-

ence. This view conceives the animal science community as one that is segregated from and holds authority over a greater human community. A perspective which seems more compatible with addressing the diverse interests of a greater community is one which views animal scientists as part of such a community, and who provide only some of the perspectives that should be considered when addressing policy issues.

Mechanisms of Hormonal Signal Transduction

737 Progesterone regulates reproductive function through two functionally distinct receptor isoforms. OM Conneely*¹, B Mulac-Jericevic¹, and F DeMayo¹, ¹*Baylor College of Medicine.*

Progesterone regulates reproductive function by interaction with two intracellular receptors, PR-A and PR-B, that arise from a single gene. To establish the selective physiological roles of PR isoforms in vivo, we have selectively ablated PR-A (PRAKO) or PR-B (PRBKO) expression in mice. Ablation of PR-A results in severe abnormalities in ovarian and uterine function but does not affect responses of the mammary gland or thymus to progesterone. Analysis of uterine function of PRAKO mice reveals an unexpected progesterone-dependent proliferative activity of PR-B in the epithelium and provides evidence that the tissue specific functions of this isoform are due to specificity of target gene transactivation rather than differences in spatiotemporal expression relative to PR A. Contrary to PRAKO mice, PRBKO mice are fertile and have successful pregnancies that result in normal litter sizes. Histological studies of uteri isolated from PRBKO mice revealed normal sensitivity to estrogen and progesterone. Specifically, progesterone acting through PR-A alone antagonizes estrogen-induced proliferation of the uterine epithelium in PRBKO mice. Progesterone receptors are critical for mammary gland development and morphogenesis. We have analyzed mammary glands response to estrogen and progesterone in PRBKO animals ovariectomized at 6 or 10 weeks of age. Whole mounts analysis of mammary glands obtained from ovariectomized 6 week old PRBKO mice treated with estrogen and progesterone for 3 weeks showed significantly reduced side branching when compared to wild type and PRAKO mice. Interestingly this phenotype is reverted in 10 week old PRBKO mice treated under identical hormonal regime. These results further demonstrate tissue specific functions of progesterone receptor isoforms.

Key Words: progesterone receptor isoforms, female reproduction

738 Role of Neurotrophic Factors in Ovarian Development. S.R. Ojeda*, G.A. Dissen, C. Romero, and A. Paredes, *Oregon Regional Primate Research Center/Oregon Health Sciences University, Beaverton, OR.*

The neurotrophins nerve growth factor (NGF), neurotrophin-4/5 (NT-4/5), and brain derived neurotrophic factor (BDNF), and their high-affinity tyrosine kinase membrane-anchored receptors (trkA for NGF and trkB for NT-4/5 and BDNF) are expressed in the mammalian ovary before the initiation of follicular assembly. Mice carrying a null mutation of the NGF gene had a reduced number of primary follicles and a normal population of primordial follicles, suggesting that NGF is not required for follicular formation, but is necessary for the initiation of follicular growth. The fewer primary follicles seen in NGF KO mice appear to result from a deficiency in somatic ovarian cell proliferation. After formation of primary follicles, NGF facilitates early follicle growth by inducing the synthesis of biologically active FSH receptors. Concomitant

deletion of the NT-4 and BDNF genes, or deletion of the gene encoding their trkB receptor, resulted in reduced granulosa cell proliferation and decreased formation of secondary follicles at the onset of follicular growth. Thus, activation of trkA receptors during early follicle development appears to sustain the conversion of primordial into primary follicles, whereas activation of trkB receptors facilitates the acquisition of additional layers of granulosa cells by the primary follicles. Thecal cells of antral follicles continue to express NGF and respond to the neurotrophin with proliferation and prostaglandin release. While an increase in thecal trkA expression occurs at the time of the preovulatory surge of gonadotropins, blockade of trkA receptors inhibits ovulation, suggesting a role for NGF in ovulatory rupture. Thus, neurotrophins contribute to regulating two key phases of ovarian development: the initiation of follicular growth, and follicular rupture at ovulation. Together, these results identify a novel function for the neurotrophins in the development of a nonneural organ, and demonstrate that they act in the ovary to facilitate the proliferation and differentiation of specific cellular subsets involved in follicular growth. (Supported by NIH grants HD-24870, RR-00163 and U54-HD18185)

Key Words: Ovarian Development, Neurotrophic Factors, Follicular Growth

739 Growth hormone signaling to the nucleus. Jessica Schwartz* and Graciela Pivien-Pilipuk, *Dept. Physiology, University of Michigan.*

Effective use of growth hormone (GH) depends on understanding its mechanism of action. The diverse actions of GH are mediated by multiple signaling mechanisms. When GH binds, the GH receptor associates with the tyrosine kinase JAK2, initiating multiple signaling events. Analysis of GH-regulated gene expression indicates that multiple signaling cascades triggered by GH regulate the function of multiple transcription factors. The proto-oncogene c-fos is a target for several GH-initiated signaling pathways. One pathway, mediated by GH-promoted tyrosine phosphorylation of Signal Transducers and Activators of Transcription (STATs), regulates the *Sis-Inducible Element*. Transcriptional activation mediated by the Serum Response Element in response to GH depends on the phosphorylation and activation of the transcription factor Elk-1 by MAP kinases. The dephosphorylation of the transcription factor C/EBP beta promoted by GH appears to reflect inhibition of Glycogen Synthase Kinase 3 (GSK3) via GH-stimulated PI-3 kinase/Akt, leading to changes in the binding and function of C/EBP beta. It is likely that signaling networks involving multiple pathways initiated by GH-GH receptor-JAK2 interactions contribute to the coordinated regulation of gene expression in response to GH. Such changes in gene expression underlie the physiological actions of GH.

Key Words: Gene expression, GH signal transduction, Transcription factors

Profitable Meat Goat Production: The Interaction of Genotype and Management

740 Rheological characteristics of uncooked goat meat. Eric Risch* and Jackson M. Dzakuma, *Prairie View A&M University, Prairie View, TX. USA.*

After weaning, 48 kids of Spanish (SP) and Tennessee Stiff-Legged (TS) breeds were individually penned and fed an 18% CP and 65% TDN ration for six months during which time their weights were taken on a bi-weekly basis. These breeds represent goats with small (TS) and intermediate (SP) mature sizes. They were slaughtered at six months of age. Four replicates of rectangular slabs (approximately 2.54 cm x 2.54

cm x 1.77 cm) of samples were taken from the fore-quarter, hind-quarter and breast regions of the carcasses. An Instron Universal Testing Machine (Model 4201) was used to apply 80 % compression deformation at a strain rate of 2.54 cm/min to each sample in the axial direction. The strength or ultimate stress (as determined by the ultimate load applied to the sample till failure), the elastic modulus (as determined by the ratio of ultimate stress over strain) and the toughness of the sample (derived from the area under the force-deformation curve and giving an indication of the energy required to propagate failure) were determined

by measurement or calculation. For the three properties measured (*Ultimate Stress (ULTSTRESS), Elastic Modulus and Toughness*) these assumptions were made: Samples were homogeneous and isometric. Results indicated that no differences ($P > .05$) were observed in the three properties measured for main effects of breeds. For sex main effects, statistically significant differences ($P < .01$) were observed in all three properties: ULTSTRESS (67.7 vs 46.5 kg/m²); Modulus (422.7 vs 286.1 kg/m²); Toughness (9.9 vs 7.1 kg-m/m³) for females and males, respectively. Between the two breeds at the same dietary levels, statistically significant differences ($P < .05$) were observed. For example, between SP and TS, respectively: ULTSTRESS at 70% level (72.8 vs 34.7 kg/m²) and at 85% level (40.5 vs 77.2 kg/m²); Modulus at 70% level (429.6 vs 192.1 kg/m²) and at 85% level (274.5 vs 481.9 kg/m²); and for Toughness at 70% level (11.7 vs 5.12 kg-m/m³) and at 85% level (5.2 vs 12.2 kg-m/m³). The results would seem to indicate that the level of the feed intake affects the rheological characteristics of goat meat. This would tend to influence consumer acceptance of goat meat and meat products which depends on perceived textural properties of the product.

Key Words: Goat, Rheological, Modulus, Toughness, Ultimate Stress

741 The impact of breed and management on market and carcass value. Louis Nuti^{*1}, Frank Pinkerton², and Ken McMillin³, ¹*Prairie View A&M University*, ²*The Goat Works*, ³*Louisiana State University Agricultural Center*.

Meat producers are faced with many management decisions and necessarily choose among several options concerning breeding, feeding, health and marketing programs. Historically, Spanish and Angora goats have been the breeds of choice, primarily due to the numbers available. Year round grazing on brush and perennial grasses with minimal protein and energy supplementation have long been the norm. Slaughter goats have usually been marketed via auctions, traders and private treaty, with producers typically having little recourse and even less knowledge of marketing channels, supply and demand. The recent advent of Boer goats from South Africa and other meat goat breed types pose a number of questions for traditional meat goat producers. Such questions as, will Boer and other crosses grow more efficiently, grow faster and be more readily accepted and be more valuable than currently available slaughter animals? The objectives of this project were to: 1) determine production responses of meat goat breeds to different feeding regimes; 2) determine auction barn responses as influenced by breed, grade and management; 3) compare relative 'profitability' of breeds as influenced by management; and, 4) compare carcass qualities. Previous confinement feeding trials have shown that feed conversions (kg feed/kg gain) at current levels of feed cost (\$0.10-\$0.12/pound) and current market prices for goats (\$0.70-\$0.80 per cwt) were not practical. Trials using native or improved pastures, with or without supplementation did show a significant positive growth response ($P < 0.05$) when cross bred Boer wethers were supplemented with 0.45 kg corn/hd/day. This group of wethers also graded higher live and yielded a higher auction barn price per pound. The net effect was to show an improvement in income-over-supplemental feed cost by Boer crosses. This advantage over Spanish wethers was apparently due to: 1) larger A.D.G.; 2) better live grades; 3) increased price/lb of sale weight. The carcass data suggests that the real advantage to breed and supplementation was that the heavier carcasses yielded higher ($P < 0.05$) weights of total cuts for the same age animals.

Key Words: Meat goats, Management, Economics

742 The economic implications of genotype by nutrition interactions in goats raised for meat. Will R. Getz^{*}, *Georgia Small Ruminant Research & Extension Center, Fort Valley State University, GA.*

Resources used for goats in meat production systems are numerous and varied. Among the most costly are nutrient resources. Costs of energy and protein are associated with land value, agronomic practices, and purchased supplements. Animal genotype determines potential growth rate, milk yield, muscle development, and mature size. Growth, milk yield, reproduction and mature size determine nutrient requirements for maintenance and production. As genotype changes so do nutrient requirements. Systems of goat meat production are dynamic and diverse. They are impacted by biological, economic, and social factors. The combination of these factors is best analyzed holistically. Although

some useful and interesting work has occurred with sheep, the literature for goats is relatively thin. With this in mind we have undertaken to give due consideration to the interactions to be factored in optimizing systems when reviewing existing frameworks and testing new configurations. This paper seeks to highlight several of the factors which suggest existing interactions. Product output per unit of nutrient input involves a complex of relationships. Improvements in productivity may not result in improvement in efficiency or profitability. Resources used and production level attained can best be expressed in terms of value added to the final product, and returns to labor, land and capital. Those which are site specific tend to be less diverse but the impact of interactions suggests that what we know about main effects must be tempered by knowledge of the nutritional environment. Recent availability of genotypes with suggested higher production and more desirable product form, require that cost-benefit relationships be revisited. Maintenance requirements, prolificacy and fecundity, weight gain and competition from internal parasites are all factors that enter the productivity equation and impact on profit conscious breeders and meat producers. Where changes in genotype bring about different results under two or more nutrition environments then interactions are real and must be considered in any economic analysis.

Key Words: Goat, Economic implications, Genotype nutrition interactions

743 Goat growth in relation to feed intake. H. Blackburn^{*1}, J. Dzakuma², and A. Goetsch³, ¹*USDA-ARS*, ²*Prairie View A&M University*, ³*Langston University*.

Growth and growth efficiency are complex functions mediated by genetics, nutrient quality, intake level, maturing patterns and environmental factors. Using Tennessee Stiff-legged (TS) and Spanish (SP) breeds growth, body composition, feed intake and feed efficiency were evaluated from weaning to 1 yr of age when fed ad libitum or at 85 or 70% of ad libitum intake. Twenty-four animals of each breed, with equal numbers of different genders, were individually penned and fed a diet consisting of 18% CP and 65% TDN. Feed intake was measured daily and body weight was determined every 14 d. At 6 mo of age, cumulative feed intake for TS and SP breeds, respectively, was 50.5 and 51.3 kg; and growth weights was 18.6 and 19.1 kg. From 10 to 13 mo of age, cumulative feed intake for the same breeds, respectively, was 66.6 and 67.7 kg, and 13-mo growth weight was 25.9 and 26.1 kg. No differences ($P > 0.01$) existed in feed intake and growth weights despite the differences in mature sizes (TS = 36.8 and SP = 47.5 kg), implying that the TS were more efficient ($P < 0.05$) in converting feed into weight gain. The TS gained 0.167 kg per kilogram of feed consumed, compared with 0.122 for SP. The Brody growth equation was fitted to growth data of the TS and SP populations. Analysis yielded the same maturing rate (0.00268) for the two breeds. Maturing rate describes the rate at which an animal achieves its mature size. Animals with different mature sizes (e.g., TS and SP) should have different maturing rates. These results demonstrate TS had the same maturing rate as SP, a larger breed. Such a result implies TS is growing more efficiently than SP, confirmed by feed efficiency and average daily gain calculated on these goats. To more fully evaluate the above data a simulation model was used to compare our understanding of the integration of growth, nutrient partitioning, and feed intake. There were deviations between live animal and simulated data for portions of growth, feed intake, and body composition. These deviations represent an incomplete understanding of the growth process and provide a basis for designing focused experiments to better elucidate our understanding.

Key Words: Goats, Growth, Feed efficiency

744 Isolation and identification of proteolytic psychrotrophic bacteria from raw milk. Ahmed S. Zahran*¹ and Bruce F. Ward², ¹Minia University, ²University of Edinburgh.

A large number of bacteria secrete extracellular proteases, lipases and phospholipases into the external medium. The presence of these enzymes cause problems for the dairy industry. Proteases for example produce bitterness, gelation of UHT milk and decrease in the keeping quality of milk during the manufacture of cheese and other dairy products. Eight genera of protease producing psychrotrophic bacteria were isolated from raw milk. Four genera were found to be Gram-positive and four were Gram-negative. The Gram-positive genera were *Bacillus*, *Micrococcus*, *Corynebacterium* and *Staphylococcus*. The Gram-negative bacteria were *Flavobacterium*, *Pseudomonas*, *Acinetobacter* and *Cytophaga*. *Flavobacterium* spp and *Pseudomonas* spp were the two main genera, they represented 48.8 and 34% respectively. *Pseudomonas* spp were more active in terms of protease production than *Flavobacterium* spp. Five different *Pseudomonas* species were identified, they were *P. fluorescens*, *P. putida*, *P. aeruginosa*, *P. diminuta* and *P. vesicularis*. *P. fluorescens* was the dominant species, it represented 42.9% of the *Pseudomonas* species isolated. All the isolated *Pseudomonas* showed polar flagella when examined by transmission electron microscopy. Strain 8 synthesized the enzyme in basal and complex media. The amount of protease secreted (activity/growth) in complex medium was higher than that produced in basal medium.

Key Words: Proteolytic, Psychrotrophic, raw milk

745 Survival of a five strain cocktail of *E. coli* O157:H7 during the 60 Days Aging Period of Hard Cheese Made from Unpasteurized Milk. Joseph Schlessner*¹, Kevin Madsen², and Robert Gerdes², ¹Food and Drug Administration, NCFST, Summit-Argo, IL, ²Illinois Institute of Technology, NCFST, Summit-Argo, IL.

Hard cheese was made from unpasteurized milk inoculated with 10⁵ cells/ml of a five-strain cocktail of *E. coli* O157:H7 (*E. coli* O157:H7 43895, *E. coli* O157:H7 SEA 13B88, *E. coli* O157:H7 932, *E. coli* O157:H7 C7927, and *E. coli* O157:H7 ENT 9490). Samples of unpasteurized milk, curd and whey were collected during the cheese manufacturing process. After pressing, the blocks of hard cheese were packaged into plastic bags, and sealed with a vacuum-packaging machine, and aged at 7 ° C. After 1 week, the cheese blocks were cut into smaller uniform-sized pieces, and vacuum sealed in clear plastic pouches for ease of sampling at the various aging intervals. Samples were plated and enumerated for *E. coli* O157:H7 using BCM for *E. coli* O157:H7 (+) Plating Medium; and plate count agar for total plate count enumeration. Populations of *E. coli* O157:H7 increased to 10⁶ cells/gm in the drained curd and to 10⁷ cells/gm at milling and pressing. Populations of *E. coli* O157:H7 in cheese aged for 60 and 90 days at 7 ° C were reduced by 1-log and 1 to 2-logs, respectively. Populations of *E. coli* O157:H7 in cheese aged for 180 and 240 days at 7 ° C were reduced by 2-log and 3-logs, respectively. Cheese was also made from unpasteurized milk inoculated with 10³ cells/ml of a five-strain cocktail of *E. coli* O157:H7. Populations of *E. coli* O157:H7 increased to 10⁴ cells/gm in the drained curd and at milling and to 10⁵ cells/gm at pressing. Preliminary results shows no change in population at 60 days of aging at 7 ° C.

Key Words: aging, hard cheese, survival of pathogens

746 Production of an exopolysaccharide-containing whey protein concentrate by fermentation of whey with *L. delbrueckii* ssp. *bulgaricus* RR. E. M. Panko* and R. F. Roberts, Pennsylvania State University.

About 22 million metric tons of whey is produced annually in the U.S. Approximately half is manufactured into whey protein concentrate (WPC); the remainder is considered a waste stream. Using whey as a fermentation media presents the opportunity to create value-added products. Fermentation of whey with exopolysaccharide-producing (EPS⁺) bacteria may result in WPC with unique functional attributes. However, exopolysaccharide-producing lactic acid bacteria are weakly proteolytic, and the amount of low molecular weight nitrogen in whey is limited. Conditions were developed to partially hydrolyze the whey

proteins and then ferment the product with EPS⁺ bacteria. In preliminary experiments, pasteurized Cheddar cheese whey was treated with FlavourzymeTM to partially hydrolyze the protein (%DH 2-12). Fermentation (38°C, pH 5.0) with *L. delbrueckii* ssp. *bulgaricus* RR revealed that hydrolysis increased the amount of EPS produced from <5 to ca. 400 mg/L. Furthermore, low levels of hydrolysis resulted in EPS levels similar to high levels of hydrolysis. In scale up experiments, whey was separated and pasteurized, then hydrolyzed to 2% DH with FlavourzymeTM. Following protease inactivation, 60 L of partially hydrolyzed whey was fermented at 38°C, pH 5.0. After fermentation the broth was pasteurized, bacterial cells were removed using a Sharples centrifuge, then the whey was ultrafiltered and diafiltered (10,000 mwco) to remove lactose and salts, freeze-dried and milled to a powder. Unfermented hydrolyzed and unhydrolyzed whey controls were processed in the same manner. The EPS-WPC ingredients contained approximately 72% protein and 6% EPS. The whey-EPS blends exhibited low protein solubility (70%, pH 7.0) and extensive protein denaturation. The ingredient (2% protein) formed stable gels (G' increased from 0 to 10⁴ Pa) upon heating to 85°C. Fermented whey ingredients exhibited gelation onset at lower temperatures than the control whey (65 vs. 80°C). Partial hydrolysis of whey, followed by fermentation by an EPS-producing bacteria and downstream processing, produced functional whey-based ingredients.

Key Words: exopolysaccharide, whey protein concentrate, *Lactobacillus delbrueckii* ssp. *bulgaricus*

747 Continuous production of antimicrobial compound(s) and organic acids by bifidobacteria cells entrapped in sodium alginate beads. Z. Morrison, S.A. Ibrahim, M.M. Salameh, A. Shahbazi, and C.W. Seo, North Carolina Agricultural and Technical State University.

Whey contains high quantity of lactose and other nutrients, which can be easily utilized by lactic acid bacteria and probiotics to produce organic acids and value added products. Therefore, the objective of this research was to evaluate the technical feasibility of producing antimicrobial compound(s) and organic acids (lactic and acetic acids) from whey and high lactose media using a continuous fermenter inoculated with *Bifidobacterium* sp. (B-1-2) cells entrapped in sodium alginate beads. Immobilized beads were packed in a column for continuous fermentation using 1-liter Lactose MRS broth (4% lactose, 1.5% MRS, 0.005% MnSO₄ and 0.01% Tween 20) or whey-based medium. The broth medium was placed inside a round flask sitting in a water bath (37.5 °C), and fed to the bottom of the bead column using a peristaltic pump. Samples collected at different time intervals during the fermentation period were analyzed for antimicrobial compound(s) using the disk bioassay and for organic acids using high-performance liquid chromatography (HPLC). All experiments were performed in duplicate. Under these fermentation conditions, the lactose conversion rate was 25%, and maximum organic acid produced was 2.3%. Maximum organic acids and antimicrobial compound(s) were achieved after a 24h incubation period. Results of this work showed that immobilization could offer the possibility of a more stable means of producing antimicrobial compound(s) and organic acids using laboratory media, as well as whey-based medium.

Key Words: bifidobacteria, immobilization, antimicrobial compound

ASAS Nonruminant Nutrition: Enzymes, Feed Additives, and Environment Management in Finishing Pigs

748 Effect of xylanase inclusion level on nutrient digestibility of diets containing different corn varieties and wheat middlings in finishing pigs. Young Hyun*¹, Mike Ellis¹, and Howard Simmins², ¹University of Illinois, Urbana, ²Finnfeeds International Ltd., UK.

The objective of this study was to determine the effect of dietary xylanase supplementation (Porzyme #, Finnfeeds International Ltd., UK) on nutrient digestibility in diets based on either waxy or normal corn and containing 20% wheat middlings, in finishing pigs. The study was conducted using a 4 x 4 Latin Square design having 2 x 2 factorial arrangement of treatments. The treatments were 1) type of corn (waxy vs normal) and 2) enzyme level (0.000 vs 0.125 %). Eight pigs fitted with a post-valve T-cecal cannula were used to measure the apparent ileal digestibility of nutrients. The average initial BW was 101.0 ± 7.25 kg and the average final BW was 118.8 ± 6.22 kg at the end of a four-week study period. The normal corn and waxy corn diets were formulated to the same content (3,241 vs 3,246 ME Kcal/kg; 18.3 vs 18.2 % CP and 0.66 vs. 0.66 % true ileal digestible lysine, respectively). Chromic oxide (0.5 % of the diet) was used as a marker for the determination of the ileal digestibilities. For the first period (week) of the study, pigs were fed 2.4 kg of feed per day in two equal meals at 8 am and 3 pm (1.2 kg per meal). Feed intake was increased by 200 g per day (100 g per meal) after each experimental period. Pigs had free access to water. In each period, the pigs were allowed to adapt to the diets for five days (days 1 to 5). Ileal digesta were collected on days 6 and 7, in two 12-hr periods from 0700 h to 1900 h. There were no interactions (P > 0.05) between corn type and enzyme level for nutrient digestibility. The waxy corn had higher (P < 0.05) ileal digestibility for dry matter and energy than the normal corn (65.5 vs 61.7 SE 0.99 % and 66.4 vs 62.6 SE 1.10 %, respectively). However, there was no difference (P < 0.05) in crude protein digestibility between the corn types. Dietary supplementation with the enzyme at 0.125 % of the diet when compared to the control treatment resulted in higher digestibility for dry matter (60.5 vs 66.7 SE 0.99 %, P < 0.01), protein (70.6 vs 74.0 SE 0.93 %, P < 0.05) and energy (61.5 vs 67.5 SE 1.10 %, P < 0.01). Xylanase supplementation improved ileal digestibility of nutrients in diets based on both normal and waxy corn and wheat middlings.

Key Words: Xylanase, Ileal digestibility, Finishing pigs

749 Effects of feed processing technologies and diet formulation strategies on growth performance and carcass characteristics in finishing pigs. D. J. Lee, J. D. Hancock, G. A. Kennedy*, C. L. Jones, and C. W. Starkey, Kansas State University, Manhattan.

A total of 176 crossbred pigs (avg initial BW of 52 kg) were used to determine the effects of feed processing technologies and diet formulation strategies on growth performance and carcass characteristics in finishing pigs. The pigs were blocked by sex and weight and allotted to 16 pens with 11 pigs per pen. Corn (mean particle size of 900 microns)-soybean meal-based diets, formulated to 17% CP, 0.60% Ca, and 0.50% P for d 0 to 39 and 14% CP, 0.54% Ca, and 0.45% P for d 39 to 67, were used as the control. Low-excretion diets were formulated to 15% CP (with added lys, thr, met, and trp), 0.61% Ca, and 0.51% P for d 0 to 39 and 12% CP (with added lys, thr, met, and trp), 0.48% Ca, and 0.40% P for d 39 to 67. Also, these diets had 5% soybean oil, and for d 39 to 67, the vitamin and trace mineral premixes were omitted. To enhance nutrient digestion in these diets, the corn was ground to a mean particle size of 600 microns and the diets were steam conditioned (82°C), expander processed (cone pressure of 14.1 kg/cm²), and pelleted (diameter of 4.8 mm). Finally, phytase (500 FTU/kg) was sprayed onto the cooled pellets. The pigs were slaughtered at a commercial plant and the pars esophagea of the stomachs were collected and scored on a scale of 0 to 3 (0 = none, 1 = slight, 2 = moderate, and 3 = severe) for stomach ulceration. Rate and efficiency of gain were increased by 11 and 13% (P < 0.001) for pigs fed the low-excretion diets. Dressing percentage and FFLI were not affected (P > 0.10), but last rib backfat thickness was increased (P < 0.04) and ulcer scores were greatest (P < 0.001) for pigs fed the low-excretion diets. Our data suggest that growth performance was increased with low-excretion diets, but pigs fed these diets tended to be fatter and have greater scores for stomach ulcers.

Item	Control	Low excretion	SE
ADG, kg	0.82	0.92	0.01
Gain/feed	0.291	0.335	0.005
Dressing %	73.4	73.8	0.3
Backfat, mm	25	27	0.4
FFLI, %	51.6	51.1	0.2
Ulcer score	0.00	2.08	0.09

Key Words: Pig, Growth, Nutrient excretion

750 Improving ileal and total tract digestion of corn and soybean meal-based diets by growing pigs using feed enzymes, steeping, and particle size reduction. M. R. Smiricky*, K. L. Saddoris, D. M. Albin, V. M. Gabert, and G. C. Fahey, Jr., University of Illinois, Urbana.

Limited research has been reported concerning the efficacy of fiber-degrading enzymes (FDE) in conjunction with feed steeping and /or phytase supplementation. These enzymes may assist in the digestion of the incompletely utilized fibrous fraction of corn and soybean meal. Twelve barrows were surgically fitted with a simple T-cannula at the distal ileum to evaluate the efficacy of the addition of the FDE, α -galactosidase (0.3%), cellulase (0.1%), hemicellulase (0.2%), pectinase/arabinase (0.1%), and xylanase (0.05%) with or without feed steeping, and with or without 0.5% phytase on large (731 micron) and small (555 micron) particle size diets. The barrows were separated into two 6 x 6 Latin squares. Square 1 utilized 731-micron particle size diets and square 2 utilized 555-micron particle size diets to test the efficacy of enzymes and steeping. The corn-soybean meal-based diets were formulated to contain 17% CP and chromic oxide for determination of nutrient digestibilities. Water for feed steeping was added in a 1.45:1 ratio on a weight basis. The pigs were fed 1.40, 1.52, 1.68, 1.84, 2.00, and 2.12 kg/d, respectively, for periods 1-6 in 2 equal feedings at 0800 and 2000 h. The experimental period lasted 7 d, with 5 d diet adaptation, fecal collection on d 6, and ileal digesta collection on d 7. Diets, feces, and digesta samples were analyzed for DM, OM, N, AA, and chromic oxide concentrations. Diets were analyzed for particle size. Lower particle size improved (P < 0.05) ileal digestibilities of OM, Asp, Pro, Ala, Leu, Tyr, and Phe. Lower particle size improved (P < 0.05) total tract digestibilities of N and all AA measured. Ileal and total tract digestibilities of DM, N, and AA were improved (P < 0.05) by FDE and phytase addition in combination or by feed steeping. In conclusion, decreasing particle size, the addition of phytase, as well as feed steeping improved digestibilities of most of the nutrients measured.

Key Words: Pigs, Digestibility, Enzymes

751 Use of toe ash regression analysis to compare bioefficacy of phytase enzymes. M Coelho*, B Cousins, and W McKnight, BASF Corporation.

Two hundred fifty two day old broilers were utilized in a 3X3 factorial design (10 replications/treatment) to determine the bioefficacy of Natuphos[®] compared with peniophora lysii phytase using a monocalcium phosphate standard. A phosphorus deficient corn/soybean diet was used as the control. This phosphorus deficient diet was supplemented with monocalcium phosphate (0.2, 0.4 and 0.6 g P/kg) or phytase (100, 200 and 300 U/kg). Bioefficacy was compared based on toe ash regression analysis. Regression equations of phytase on toe ash were $y = 0.0122x + 19.7$, $R^2 = 0.9715$ and $y = 0.0066x + 19.7$, $R^2 = 0.4022$ for Natuphos and peniophora lysii phytase, respectively. Toe ash increased by 0.0122 and 0.0066 mg per phytase unit for Natuphos and peniophora lysii phytase, respectively. Natuphos phytase required fewer (p.05) phytase units than peniophora lysii to reach 26.88 mg toe ash (588 and 1087 U, respectively). The bioefficacy of Natuphos phytase and peniophora lysii based on toe ash regression analysis were 100% and 54%, respectively.

Key Words: Enzymes, Phytase, Bioefficacy

752 In vitro and in vivo hydrolysis of phytate in feed ingredients and complete feeds by phytase. J. S. Sands*¹, P. H. Simmins², and O. Adeola¹, ¹Purdue University, West Lafayette, IN USA, ²Finnfeeds International Ltd., Marlborough, UK.

The hydrolysis of phytate in a variety of feed ingredients and complete feed (CF) by phytase was investigated both *in vitro* and *in vivo*. For the *in vitro* release of P in feed ingredients and CF (73% corn, 23% soybean meal; 17% CP; 0.33% P - not supplemented with inorganic P), 6 replicates of each feed ingredient or CF were used with phytase stock solution added to give: 0, 125, 250, 500, 750, 1000, 2000, or 4000 units/kg sample. The response in P release to phytase concentration was curvilinear. Under conditions used in this study, maximal P release were 0.9, 1.8, and 1.12 mg P/g sample for corn, soybean meal and CF, respectively. For wheat, barley, canola, and sunflower meals, maximal P release were 2.97, 2.97, 3.27, and 3.17 mg P/g sample, respectively. For the *in vivo* study, 36 barrows with an average initial weight of 19 kg were assigned to six diets and housed in stainless-steel metabolism crates. The CF was supplemented with 0, 250, 500, 750, or 1000 phytase units/kg diet. Pigs were fed in two equal feedings daily in a study consisting of a 5-d adjustment period followed by a 5-d period of total but separate collection of feces and urine. Fecal phosphorus output was higher ($P < 0.05$) in pigs fed CF than in those fed the phytase-supplemented diets. This led to both lower ($P < 0.05$) daily absorbed P and percent P digestibility in CF than the phytase-supplemented diets. Phytase supplementation of corn-soybean meal diet significantly improved the digestibility of phytate. Nonlinear broken-line regression analysis revealed that the optimum level of phytase in the corn-soybean meal diet used in the current experiment was 298 units/kg for daily absorbed P and 326 units/kg for percent P digestibility. The digestibilities of nitrogen and energy were not affected by phytase supplementation. The results of these studies show that the phytase preparation is efficacious in hydrolyzing phytate.

Key Words: Pigs, Phytase, Phosphorus

753 Enhanced phosphorus digestion and reduced pollution potential by transgenic pigs with salivary phytase. Serguei Golovan, Roy Meidinger, Ayodele Ajakaiye, Michael Cottrill, Claire Plante, Ming Fan, Anthony Hayes, Roger Hacker, John Phillips, and Cecil Forsberg*, University of Guelph, Guelph, Ontario, Canada.

To address the problem of manure-based environmental phosphorus pollution in the pork industry, we have developed phytase transgenic pigs. The transgene introduced into pigs by pronuclear microinjection is composed of the mouse parotid secretory protein promoter and the *Escherichia coli appA* phytase gene. The transgenic pigs secrete the enzyme phytase in their saliva that hydrolyzes dietary phytate releasing phosphorus which is readily absorbed in the small intestine. Without this enzyme, phytate phosphorus passes undigested into the manure. These pigs offer a unique biological approach to management of phosphorus nutrition and environmental pollution in the pork industry.

Key Words: Transgenic pigs, Phytase, Phosphorus digestibility

754 The effects of phytase on calcium, phosphorus, and dry matter digestibility in pigs fitted with steered ileocecal valve cannulas. J.P. Rice*, J.S. Radcliffe, and R.S. Pleasant, Virginia Polytechnic Institute and State University.

Twelve crossbred barrows fitted with steered ileo-cecal valve cannulas were used in a replicated 6 x 6 Latin square design to investigate the effects of phytase on Ca, P and DM digestibilities. Each 2-wk period consisted of a 7-d adjustment, a 3-d total collection, a 12-h ileal digesta collection, a 3-d adjustment to the enzymatically hydrolyzed casein (EHC) diet and a second 12-h ileal digesta collection. The EHC diet was fed to supply readily available amino acids so that true amino acid digestibilities could be determined. All diets, except for the EHC diet, were corn-soybean meal based and contained 0.15% available P, 0.44% Ca, and 0.05% Cr₂O₃ as an indigestible marker. Water was supplied ad libitum and feed was supplied at a level of 9% of metabolic BW (BW^{0.75})/d. Pigs were weighed prior to the start of each period and feeding levels were adjusted. Diets 1, 2 and 3 contained 13.0, 12.0 and 11.0% CP, respectively. Diets 4, 5 and 6 were Diet 3 plus 250, 500 or 750 U of phytase per kilogram of diet, respectively. Digesta and fecal samples were pooled by pig for each collection day/period and analyzed for P, Ca, Cr and DM. As the level of dietary CP decreased, ADG ($P < 0.001$)

and feed efficiency ($P < 0.01$) decreased linearly. The addition of phytase to the low CP diet did not affect ($P < 0.10$) ADG or feed efficiency. The addition of phytase to the diet resulted in a linear increase ($P < 0.001$) in P apparent ileal digestibility (AID) and Ca apparent total tract digestibility (ATTD), a quadratic increase ($P < 0.01$) in P ATTD, and a tendency ($P < 0.10$) towards an increased Ca AID and DM ATTD. As the level of dietary CP was decreased a quadratic response ($P < 0.05$) was observed for P and DM AID and ATTD. Calcium AID and ATTD were unaffected by dietary CP level. Pigs fed the 12.0% CP diet had a higher P and DM AID and ATTD compared to pigs fed the 13.0 and 11.0% CP diets. Phytase addition to the diet improved P and Ca AID and ATTD and tended to improve DM ATTD.

Key Words: Pig, Phytase, Digestibility

755 Xylanase improves the ileal energy and nitrogen digestibility of high wheat finisher diets containing increasing levels of wheat shorts in swine. S. C. Wolford¹, P. H. Simmins², and T.A.T.G. van Kempen*¹, ¹North Carolina State University, ²Finnfeeds International.

Wheat and wheat byproducts contain non-starch polysaccharides, predominantly arabinoxylans, which negatively affect nutrient digestibility. In-feed xylanases reduce the anti-nutritional effects of the arabinoxylans on digestibility, although responses have been variable in pigs. The efficacy of three levels of xylanase (0, 4000, and 7000 IU/kg, Porzyme[®] 9300) in diets containing 77% wheat + 10% wheat shorts, 67% wheat + 20% wheat shorts, and 57% wheat + 30% wheat shorts was evaluated in an ileal digestibility experiment. Diets were evaluated in nine ileally cannulated grower pigs using a Youden square design with eight periods. Ileal digesta were collected over a 2-d period following a 5-d adaptation period. The model that best described the results used wheat shorts level as a discrete variable and enzyme level as a continuous variable. No significant interactions occurred between wheat shorts level and enzyme level. Increasing wheat shorts from 10 to 20% numerically reduced energy digestibility with $0.99 \pm 0.65\%$ ($P = 0.13$) without affecting nitrogen digestibility ($P = 0.48$), and when increased from 20 to 30%, energy digestibility was reduced with $3.23 \pm 0.65\%$ and nitrogen digestibility was decreased $1.29\% \pm 0.55$ ($P < 0.05$). Xylanase linearly increased nitrogen and energy digestibility of the diets within the range tested, with an increase in digestibility for energy of $0.37 \pm 0.09\%$ and for nitrogen of $0.22 \pm 0.08\%$ for each IU enzyme per g of feed ($P < 0.05$). Interestingly, xylanase decreased both the indigestible nitrogen and energy with approximately 1.2% for each IU enzyme per g of feed. Results from this experiment indicate that increasing wheat shorts inclusion from 20 to 30% has a negative effect on digestibility of energy and nitrogen. Xylanase improved the digestibility of both nitrogen and energy in a linear fashion. In conclusion, the in-feed xylanase improves the digestibility of both nitrogen and energy in high wheat swine diets containing between 10 to 30% inclusion of wheat shorts.

Key Words: Swine, Digestibility, Xylanase

756 Use of feed processing technologies and diet formulation strategies to maximize digestibility and minimize excretion of nutrients in finishing pigs. D. J. Lee*, J. D. Hancock, J. M. DeRouchey, C. A. Maloney, and D. W. Dean, Kansas State University, Manhattan.

Six crossbred barrows (70 kg average BW) were used in a repeated 2 x 2 Latin square design to determine the effects of feed processing technologies and diet formulation strategies on nutrient utilization. A corn (ground to a mean particle size of 900 microns)-soybean meal-based diet, formulated to 16.5% CP, 0.55% Ca, and 0.50% P, was used as the control. A low-excretion diet was formulated to 13.4% CP (with added lys, thr, met, and trp), 0.45% Ca, and 0.40% P. Also, this diet had 5% soybean oil and the vitamin and trace mineral premixes were omitted. To enhance nutrient digestion in this diet, the corn was ground to a mean particle size of 600 microns and the diet was steam conditioned (82°C), expander processed (cone pressure of 14.1 kg/cm²), and pelleted (diameter of 4.8 mm). Finally, phytase (500 FTU/kg) was sprayed onto the cooled pellets. In this 14-d experiment, initial and final BW were not different for pigs fed the control vs the low-excretion diet ($P > 0.27$). Dry matter intake was similar for pigs fed the two diets ($P > 0.07$) but DM excretion was decreased by 35% for pigs fed the low-excretion diet ($P < 0.001$). Nitrogen intake and excretion were decreased ($P < 0.003$) by 22 and 39% and P intake and excretion by 27 and 51% ($P < 0.002$)

for pigs fed the low-excretion diet. Apparent ileal digestibilities of lysine and threonine were increased by 11 and 18% ($P < 0.02$) and DE and ME were increased by 11 and 12% ($P < 0.004$) for pigs fed the low-excretion vs the control diet. Our data indicate markedly desirable effects on digestibility and excretion of nutrients from currently available processing technologies and diet formulation strategies.

Item	Control	Low excretion	SE
DM intake, g/d	2,064	2,128	18
DM excreted, g/d	477	311	5
N intake, g/d	73.1	56.9	0.6
N excreted, g/d	43.1	26.2	1.8
P intake, g/d	12.4	9.1	0.1
P excreted, g/d	10.5	5.1	0.3
Ileal lys dig, %	79.0	88.3	1.7
Ileal thr dig, %	64.4	78.5	2.2
DE of the diet, kcal/kg	3,657	4,117	17
ME of the diet, kcal/kg	3,181	3,617	51

757 Dietary factors are additive in reducing in vitro ammonia emission from pig manure. G.C.M. Bakker*¹ and M.C.J. Smits², ¹*ID TNO Animal Nutrition, Lelystad*, ²*IMAG, Wageningen*.

In the past the effects of dietary factors on ammonia emission from pig manure have been studied separately and not in combination. Therefore, in the present study it was hypothesized that the effects of the tested dietary factors on ammonia emission are additive. Of each of the four dietary factors three levels were studied: crude protein (142, 161 and 180 g/kg), calcium sulfate (0, 9 and 18 g/kg), dietary fiber (129, 189 and 245 g/kg) and fermentable fiber (62, 83 and 104 g/kg). The number of $3^4=81$ potential dietary combinations was reduced to 26 by using a fractional design for the study, the Box-Benken design. This design allowed quantifying linear and quadratic main effects and two-way interactions, whereas from the more complex interactions only qualitative information could be obtained. The 26 diets contained similar amounts of ileal digestible amino acids, minerals and net energy. In total 39 individually housed pigs were used; two diets were tested more than once for determining standard deviation. All pigs were allowed a 3-week adaptation period and received similar amounts of water and energy. Their mean weight during the test period was 70 kg. In a 5-day period feces and urine were collected and mixed as slurry. A sample from this slurry was placed in an in vitro system to determine the cumulative ammonia emission for 7 days. Results on ammonia emission showed only linear main effects of the dietary factors; there was no evidence for quadratic or interaction effects. Of the four feed components, only dietary fiber had no effect on ammonia emission. The equation was: cumulative ammonia emission (g per 7 d) = $-5.67^{***}(0.678) + 0.058^{***}(0.0035) \times \text{protein content} - 0.052^{***}(0.0073) \times \text{calcium sulfate} - 0.011^{**}(0.0037) \times \text{fermentable fiber}$; R-square = 93.2; all feed factors in g/kg. We concluded that the effects of the dietary factors on ammonia emission are additive. However, these in vitro results need to be validated under pig house conditions, where excretion patterns, floor pollution and climate, especially air flow dynamics are included.

Key Words: Ammonia emission, Dietary factors, Pig manure

758 Effect of dietary crude protein level and fiber sources on nitrogen excretion patterns of grower pigs. S. Zervas^{1,2} and R.T. Zijlstra*¹, ¹*Prairie Swine Centre Inc.*, ²*University of Saskatchewan, Saskatoon, Canada*.

Successful nitrogen (N) management is important for sustainable pork production. Effects of dietary CP (high, 18.5%; low, 15.6%) and fiber sources (control, soybean hulls (SH; 15%), and sugar beet pulp (SBP; 20%) on N-excretion patterns were studied in a 2x3 factorial arrangement. Diets were formulated to 3.3 Mcal DE/kg and 2.4 g dLys/Mcal, supplemented with Lys, Met, Trp, Thr, Ile, and Val to maintain a similar content of digestible AA. Pigs (30.5 \pm 3 kg; n = 30) were housed in confinement-type metabolism crates, with restricted access to feed (3 x maintenance DE) from d 1 to 18, and free access to feed from d 19 to 26. Feces and urine were collected from d 15 to 18 and d 23 to 26, and blood on d 25. With restricted access to feed, feces N (as % of N intake) was increased 3% for low vs high CP, and increased 5% for SH and 7%

for SBP compared to control ($P < 0.05$); urine N was reduced 5% for low vs high CP, and reduced 4% for SH and 8% for SBP compared to control ($P < 0.05$). Retention of N (in g/d) was reduced 12% for low vs high CP (17 vs 19 g/d; $P < 0.05$), and similar among fiber treatments ($P > 0.10$). With free access to feed, feces N (as % of N intake) was increased 3% for low vs high CP, and increased 6% for SH and 9% for SBP compared to control ($P < 0.05$); urine N was reduced 6% for low vs high CP, and reduced 8% for SH and 10% for SBP compared to control ($P < 0.05$). Retention of N (in g/d) was similar for CP levels (29 g/d; $P > 0.10$), and reduced for SH (27 g/d; $P < 0.05$) compared to control (31 g/d), and intermediate for SBP (29 g/d). Plasma urea was correlated to urine N ($R^2 = 0.69$; $P < 0.001$). Reduction of dietary CP reduced urine N, and fiber sources high in fermentable fiber shifted N excretion from urine N to feces N. Level of feed intake is an important consideration when effectiveness of a nutrient management strategy is studied. Diets with a low CP and containing synthetic AA should be studied using pigs with free access to feed to verify that nitrogen retention is maintained.

Key Words: Pig, Nitrogen excretion, Fiber

759 Efficacy of betaine as a carcass modifier in finishing pigs fed normal and low protein diets supplemented with amino acids. L. A. Pettey*, G. L. Cromwell, M. D. Lindemann, J. H. Randolph, H. J. Monegue, K. M. Laurent, G. R. Parker, and R. D. Coffey, *University of Kentucky, Lexington*.

Three experiments were conducted to determine if betaine would overcome the reduced carcass leanness often associated with feeding low protein, AA supplemented diets to pigs. Exp. 1 and 2 involved 192 pigs (10 reps of five pigs/pen) from 53 to 113 kg BW. Diets 1 and 3 were fortified corn-soy with adequate CP (16% to 85 kg, then 14.5%) or low CP (12%, 10.5%) with added lys (0.30%), thr (0.08%), and trp (0.03%). Diets 2 and 4 were the same as 1 and 3 except betaine was included at 1.14 g/kg (0.125% Betafin[®] [Finnfeeds Intl., Ltd, Marlborough, U.K.]). Lys levels in all diets during the two phases were 0.80 and 0.70%. All pigs were scanned by real-time ultrasound at 110 kg. ADG, feed/gain (F/G), 10th rib backfat (BF), and estimated carcass lean for pigs fed diets 1-4 were: 916, 918, 857, 882 g; 3.48, 3.53, 3.66, 3.50; 23.2, 22.1, 23.7, 23.4 mm; 52.9, 53.6, 52.6, 52.9%. Low CP resulted in slower gains, more BF, and reduced carcass lean ($P < 0.05$). Betaine improved F/G in pigs fed low CP ($P < 0.05$) and improved leanness in pigs fed adequate CP ($P < 0.05$). In Exp. 3, 180 pigs (six reps of five pigs/pen; 37 to 117 kg) were fed diets with (1) adequate CP during three phases (17.5/15.5/13.5%), (3) reduced CP (16/14/12%) with added lysine (0.15%), or (5) low CP (14.5/12.5/10.5%) with lys (0.30%), thr (0.08%), and trp (0.03%). CP levels were changed at 56 and 84 kg BW. Three other diets (2, 4, and 6) were as 1, 3, and 5 but with betaine. Lys levels during the three phases were 0.90, 0.80, and 0.70%. All pigs were scanned at 114 kg. ADG, F/G, BF, and carcass lean for pigs fed diets 1-6 were: 943, 955, 948, 934, 950, 930 g; 2.86, 2.94, 2.93, 2.96, 2.87; 20.9, 21.2, 21.1, 21.5, 22.4, 21.6 mm; 53.9, 53.6, 53.9, 53.4, 53.0, 53.7%. Performance was unaffected by diet. Carcasses tended to be fatter with less lean in pigs fed low CP, and this appeared (ns, $P=0.10$) to be alleviated with betaine. In this study, the effects of betaine on performance and carcass leanness in pigs were inconsistent.

Key Words: Pigs, Betaine, Amino acids

760 Descriptive flavor analysis of bacon and pork loin from lean-genotype gilts fed conjugated linoleic acid. L. Averette Gatlin*, D.K. Larick, M.T. See, and J. Odle, *North Carolina State University Raleigh*.

Conjugated linoleic acid (CLA) supplementation has previously been demonstrated to increase firmness of pork bellies. However, effects of CLA on flavor of pork have not been described. This study evaluated the combined effects of dietary CLA and supplemental fat (SF) on organoleptic characteristics of bacon and pork loin samples. Lean-genotype gilts (49.3 kg; n=48) were randomly assigned to a 2 x 3 factorial arrangement of supplemental fat level and linoleic acid supplementation for the final 47d of finishing. Supplemental fat treatments included 0%, 4% yellow grease (YG), and 4% tallow (T). Linoleic acid (LA) treatments included 1% corn oil (CO) or 1% CLA (CLA-60, Natural Lipids, Norway). Lysine:calorie ratio was constant in all diets. A trained six-member sensory panel developed a flavor profile on commercially cured bacon samples (12 descriptors) and center-cut boneless pork loin chops (19 descriptors) using a 14-point universal intensity scale. Samples were

vacuum packaged and stored at -7 C, then thawed in a refrigerator 20 to 24 h and cooked immediately prior to analysis. Bacon samples from pigs fed 4% SF were considered to have a sweeter flavor (4.07 .07) than those fed 0% SF (3.89 .07; $P < .04$). The intensity of salty flavor was higher in bacon samples from pigs fed CO (6.18 .09) compared to those fed CLA (5.86 .10; $P < .02$). The intensity of salty aftertaste was greater when CO was combined with YG (5.21 .14; $P < .07$) or T (5.44 .14; $P < .01$) than CO alone (4.85 .14) but SF combined with CLA was not different from CLA alone (SF * LA; $P < .02$). Sour flavor intensity tended to be lower in loin samples from pigs fed CLA than from those fed CO (1.60 vs 1.73 .06; $P < .09$). Samples from animals fed 4% T tended to have slightly lower ($P < .09$) notes of astringent aftertaste (1.42 .08) compared to those fed 0% SF (1.62 .09) or 4% YG (1.66 .09). In summary, minimal differences in flavor descriptors determined by the sensory panel were detected. Panel results indicate consumer acceptance of bacon and pork products from pigs fed CLA will not differ from commodity pork products.

Key Words: Conjugated Linoleic Acid, Pork flavor, Bacon

761 Effect of dietary betaine supplementation on energy partitioning in pigs. J.W. Schrama¹, P.H. Simmins², and W.J.J. Gerrits^{*1}, ¹Wageningen Institute of Animal Science, Wageningen University, Wageningen, The Netherlands, ²Finnfeeds International Ltd, Malborough, UK.

The effect of dietary betaine supplementation on energy partitioning in pigs was studied. Six groups of 14 group-housed barrows were assigned

to one of two dietary treatments: control or betaine supplemented (1.25 g Betafin[®] per kg of feed). The experimental diets were maize and soybean meal-based. Diets were aimed to be limiting in energy content and sufficient in protein. The experiment consisted of a 3-wk adaptation and a 3-wk experimental period. Initial BW was 46 kg during the experimental period, when each group of pigs was housed in a climate respiration chamber. During the experimental period, pigs were offered changed diets, which were diluted with 10% oat hulls. Pigs were fed at 2.5 times the energy requirements for maintenance. During the experimental period, heat production, energy and nitrogen balances were measured weekly. The metabolizable energy intake was unaffected by dietary betaine supplementation ($P > 0.10$). Averaged over the experimental period, betaine supplementation reduced heat production ($5 \text{ kJ} \cdot \text{kg}^{-0.75} \cdot \text{d}^{-1}$, $P < 0.05$). Moreover, this difference between diets increased with time within the experimental period ($P < 0.05$). Averaged over the 3-wk period, energy retention was increased ($P < 0.10$) and energy requirements for maintenance were decreased ($P < 0.10$) in pigs fed the betaine supplemented diet. However, the effect of betaine on the energy requirements for maintenance changed with time ($P < 0.05$). Maintenance requirements were similar in Week 1 and were reduced by betaine supplementation by 5.5% during Week 3 (477 vs. 452 $\text{kJ} \cdot \text{kg}^{-0.75} \cdot \text{d}^{-1}$). The current results showed that betaine supplementation affected energy partitioning of growing pigs. This effect was not due to a methionine sparing effect of betaine, because diets were formulated to be sufficient in amino acid as well as choline.

ASAS Swine Species

762 ECG-gated dynamic MR examination of pig heart. Robert Romvari¹, Imre Repa¹, Zsolt Petras¹, Gabor Bajzik¹, Bela Fenyves², and Peter Horn^{*1}, ¹Kaposvar University, Faculty of Animal Science, Diagnostic Institute, ²Szent Istvan University, Faculty of Veterinary Science, Department and Clinic of Surgery.

The selection of pigs for high lean meat production plays an important role in the disadvantageous changes of the circulatory system. In pork production cardiovascular disorders mean serious problems during fattening, namely 14 to 18 % of the total deaths have a circulatory background.

For in vivo examination of the porcine heart, dynamic MR imaging methodology was developed. Measurements were carried out on 15 meat type pigs (22 or 106 kg) using a Siemens Magnetom Vision Plus type equipment of 1.5 T magnetic-field strength.

Regarding the motion sensitiveness, inhalation anaesthesia was applied, then ECG-gating synchronised the data acquisition with the pulsation of the heart. At first quick images were made to locate the heart according to the co-ordinate system of the body. Following in the sagittal, coronal and transversal planes localisation images were taken to allocate the longitudinal axis of the heart. Finally, depending on the heart frequency and on the size of the heart, in each case 8 to 10 slices and in each slice 8 to 14 cine images were acquired prospectively according to one heart cycle.

The means of traits measured in ml at 22 and 106 kg liveweight, respectively were; left ventricular end-diastolic volume: 51.4 vs. 125.7, left ventricular end-systolic volume: 24.4 vs. 60.1, left ventricular stroke volume: 27.0 vs. 65.6, right ventricular end-diastolic volume: 55.7 vs. 118.4, right ventricular end-systolic volume: 28.6 vs. 52.5, right ventricular stroke volume: 27.1 vs. 65.9. The left ventricular ejection fraction: 52.5 vs. 52.2 and the right ventricular ejection fraction: 48.7 vs. 55.7 were given in percentage. The cardiac output values were 3.5 l (22 kg, 132 beat/min.), and 6.0 l (106 kg, 91 beat/min.), respectively. The contraction values were also determined by the septum (70%), and by the anterior (61%), posterior (41%) and lateral (54%) walls.

Based on the investigation, the preconditioning, the narcotic procedure, the specific details of ECG measuring (i.e. proper signal transmission) and the correct MR imaging were worked out. After our results we declare this methodology as a well applicable one in the quantitative measurement of the heart, where each investigation takes 30 to 40 minutes.

Key Words: pig, heart, magnetic resonance imaging

763 A comparison of methods of editing and adjusting feed intake data from electronic swine feeders. D.S. Casey^{*} and J.C.M. Dekkers, Iowa State University, Ames, Iowa.

Data from electronic swine feeders contain errors that must be identified, edited, and replaced. The objective of this study was to compare the accuracy of six methods of editing and replacing missing data to estimate daily (DFI) and average daily feed intake (ADFI) in short and long test periods. Data from FIRETM feeders on 591 pigs from the National Pork Producers Council's Maternal Line Genetic Evaluation Program were used. Errors in each visit were identified using 16 criteria. To create an error-free data set as a basis for comparison, data from 124 pigs with few errors were selected and visits with errors were replaced by error-free visits from the same pig. Resulting DFI and ADFI were assumed to be the true trait values. Error visits were then introduced to create long test period data (average 12 weeks), representative of real data. The last 4 weeks per pig were used to create short test period data. Data were edited using 6 methods (EM1-6). For EM1, a DFI record was deleted if $\text{DFI} < 1000\text{g}$ or $> 4500\text{g}$. For EM2-6, the 16 criteria were used to identify errors in each visit. For EM2 and 3, all DFI records with ≥ 1 and ≥ 2 error visits were deleted. For EM4-6, DFI was obtained by summing feed intake over error-free visits. For EM5 and 6, DFI records were then adjusted for the effects of presence of error visits on unadjusted DFI, which were estimated from a linear model analysis of the complete data set (591 pigs) for EM5 or from the data sets being edited (124 pigs) for EM6. For EM1-4, missing DFI records were replaced by linear or quadratic regression estimates of DFI on test day for each pig. DFI and ADFI from the edited data sets were correlated to true values. Correlations were high (.89 to .99) for both traits for all editing methods except EM1. EM6 had the highest correlations for DFI in both test periods ($\geq .96$). EM2 and EM6 had the highest correlations for ADFI (.98 to .99). EM1 had the lowest correlations for both traits and test periods (.76 to .94). Results indicate that editing methods affect the accuracy of data from electronic feeders. EM6 is recommended for maximum accuracy.

Key Words: Swine, Feed Intake, Editing Methods

764 Effects of piglet birth weight and liquid milk replacer feeding during lactation on pig performance to slaughter weight. B. F. Wolter^{*}, M. Ellis, B. P. Corrigan, and J. M. DeDecker, University of Illinois, Urbana, IL.

The effects of piglet birth weight and liquid milk replacer feeding during lactation on growth performance to slaughter was evaluated in a study

carried out with thirty-two sows (PIC C-22) and their piglets (n=384, PIC Line 337 sires). A randomized block design with a 2 × 2 factorial arrangement of treatments was used. Treatments were birth weight (Heavy and Light) and liquid milk replacer (Supplemented or Unsupplemented). The study was divided into 2 periods. In period 1 (birth to weaning), pigs were assigned at birth to either a heavy or light (1.83 vs 1.32, SE = 0.01 kg; P < 0.001) litter of 12 pigs and one-half the litters were given ad libitum access to supplemental milk replacer (Land O'Lakes, Inc., Fort Dodge, IA) from d 3 of lactation to weaning. In period 2 (from weaning at 21 d of age to slaughter at 110 kg), a total of 308 randomly selected pigs were allocated at weaning within previous treatment group and sex to pens of 4 pigs. Pigs were given ad libitum access to feed, and diets were formulated to meet or exceeded NRC recommendations. Heavy litters were heavier at weaning (6.58 vs. 5.72, SE = 0.14 kg; P < 0.001), tended to have more pigs weaned (11.4 vs. 10.9, SE = 0.21 pigs; P = 0.10), had greater post-weaning ADG (850 vs. 800, SE = 6.7 g; P < 0.001) and ADFI (1866 vs. 1783, SE = 17.6 g; P < 0.001), similar G:F (0.46 vs. 0.45, SE = 0.003; P > 0.10), and required 7 fewer d (P < 0.001) to reach slaughter. Feeding supplemental milk replacer during lactation produced heavier pigs at weaning (6.60 vs. 5.69, SE = 0.14 kg; P < 0.001), tended to increase pigs weaned (11.4 vs. 10.9, SE = 0.21 pigs; P = 0.10), but had no effect (P > 0.10) on growth performance from weaning to slaughter; however, milk replacer fed pigs required 3 fewer d (P < 0.01) to reach slaughter weight. Sow feed intake and BW loss during lactation was not affected (P > 0.10) by either birth weight or milk replacer treatment. In conclusion, pigs with heavier weaning weights resulting from increased birth weight or from feeding of milk replacer required less time to reach market weight.

Key Words: Pigs, Weaning Weight, Milk Replacer

765 Effect of initial stocking rate and weighing frequency on pig performance in wean-to-finish pens. B.F. Wolter*¹, M. Ellis¹, S.E. Curtis¹, G.R. Hollis¹, R.D. Shanks¹, E.N. Parr², and D.M. Webel², ¹University of Illinois, Urbana, IL/USA, ²United Feeds, Inc., Sheridan, IN/USA.

Crossbred pigs (n = 1,560) were used in a randomized-block design with a 2 × 2 factorial arrangement of treatments to determine the effects of initial stocking rate (Single [52 pigs/pen] vs. Double [104 pigs/pen]) and weighing frequency (High [every 2 wk during the study] vs. Low [3 times during the study]) on pig performance from weaning (5.8 ± 0.43 kg BW; 17 d of age) to slaughter (114 kg BW). Floor and feeder space allowances per pig were 0.650 m² and 4 cm and 0.325 m² and 2 cm for Single- and Double-stocked pens, respectively. Drinker allocation (13 pigs/drinker) was the same for all treatments. At the end of wk 10 post-weaning, Double-stocked pens were divided into 2 equal-sized groups with similar mean BW and CV of BW, and pigs in one of the groups were moved to a different location in the same house. Pigs had free access to feed and water throughout. In the first 10 wk post-weaning, Double compared to Single stocking resulted in lighter pigs (39.7 vs. 42.6 kg; P < 0.001) and lower ADG (8%; P < 0.001) and ADFI (7%; P < 0.001), but similar G:F (P > 0.10). From wk 10 to slaughter, pigs that previously had been on the Double- compared to the Single-stocking-rate treatment had similar ADG and ADFI (P > 0.10), but greater G:F (4%, P < 0.01). Double-stocked pigs required 2 additional days to reach slaughter BW (P < 0.05), but had similar (P > 0.10) carcass backfat and loin depths. Double-stocked pigs moved at the end of 10 wk had similar (P > 0.10) growth performance to those that stayed in the original pen. Growth rate was not affected (P > 0.10) by frequency of weighing. Mortality and morbidity were similar (P > 0.10) for all treatments. In summary, Double stocking reduced growth rate to 10 wk post-weaning and increased days to reach slaughter BW, but increased subsequent feed efficiency.

Key Words: Pigs, Stocking Rate, Wean-to-Finish

766 Effect of feeder-trough space on pig growth performance in double-stocked wean-to-finish pens. B.F. Wolter*¹, M. Ellis¹, S.E. Curtis¹, E.N. Parr², and D.M. Webel², ¹University of Illinois, Urbana, IL/USA, ²United Feeds, Inc., Sheridan, IN/USA.

Previous research has shown that double-stocking compared to single-stocking pigs in wean-to-finish pens reduced growth performance from weaning to 10 wk post-weaning. The objective of the current experiment was to evaluate the effect of doubling feeder-trough space (4 cm/pig

[Double] vs. 2 cm/pig [Control/Standard]) on pig performance from weaning to 8 wk after weaning. In a randomized-block design, crossbred pigs (n = 1,728) were randomly allocated at weaning (5.4 ± 0.23 kg BW; 16 d of age) to mixed-sex pens of 108 pigs/pen on the basis of weight and sex. Floor-space allowance (0.30 m²/pig) and drinker allocation (14 pigs/drinker) were the same for both treatments. Two six-place (35 cm/place) feeders (Jumbo Wean-to-Finish, Farmweld, Teutopolis, IL) positioned together in the center of each pen were accessible from both sides. However, only one feeder contained feed in pens on the Control trough-space treatment. Pigs had free access to feed and water. Pigs were weighed and feed disappearance was recorded every 2 wk throughout. Doubling feeder-trough space did not affect (P > 0.10) pig growth rate from weaning to the end of wk 6 after weaning. Pigs on the Double compared to those on the Control trough-space treatment had higher ADG (669 vs. 633 g; P < 0.05) from wk 6 to 8 and were heavier (31.7 vs 30.9 kg; P < 0.05) at the end of wk 8, although, ADFI and G:F did not differ (P > 0.10). These results suggest that pigs double-stocked in wean-to-finish pens for longer than 6 wk post-weaning need additional feeder-trough space to maintain growth performance.

Key Words: Pigs, Feeder Space, Wean-to-Finish

767 Carcass and meat quality of halothane gene carriers and negative pigs. Jorge Galindo-Garcia*, Daniel A. Villagomez, and David R. Sanchez-Chipres, *Centro Universitario de Ciencias Biológicas y Agropecuarias, Universidad de Guadalajara, Mexico.*

Among the major genes identified in swine, the halothane gene, perhaps, is the most economically relevant due to its detrimental effects on technological meat quality parameters (Enfalt, 1997). Because differences in gene penetrance are expected when the same genotypes are exposed to different environments, (Falconer, 1989) we carried out this investigation to evaluate the halothane gene effects on carcass quality and technological traits of pork from commercial hybrids pigs (F₁ York/Landrace X synthetic hybrids), which were carriers (Nn) or negative (NN) for the Hal mutation. A total of forty three (22 females and 21 castrates) pigs, fattened in conventional housing and management, were slaughtered at 100 Kg of live weight. PCR and restriction enzyme analysis allowed Hal genotyping of pigs. For statistical analysis, the animals were grouped according to sex and halothane genotype in a 2X2 factorial array, the size of each group being nearly equal (11 animals). Carriers had shorter carcass length (P ≤ 0.05) than negative pigs. However, % carcass yield, as primary cuts, was higher for pigs carrying the major gene (P ≤ 0.05). There were no differences between groups for back fat, nor for rib eye area. Muscle pH at 45 min (*longissimus dorsi*) was significantly lower (P ≤ 0.05) in carriers than negative pigs, 6.02 vs. 6.32, respectively. Water-holding capacity was similar between groups. Nevertheless, the occurrence of pale, soft and exudative pork was higher (P ≤ 0.05) in pigs carrying the Hal gene.

Key Words: Carcass and meat quality, Halothane gene, Pig

768 Test performance of halothane gene homozygous and heterozygous pigs under no controlled climate. D. R. Sanchez-Chipres, D.A.F. Villagomez*, and J. Galindo-Garcia, *Centro Universitario de Ciencias Biológicas y Agropecuarias, Universidad de Guadalajara.*

Porcine Stress Syndrome (PSS) is a genetic disorder that mainly affects fast growing. Sudden death or pale, soft, and exudative (PSE) pork at slaughter may occur. At present, it is well known that PSS, PSE and Malignant Hyperthermia (MH) are associated with the same mutation of a ryanodine receptor gene (O'Brien, et. al.,1990; Fujii, et. al.,1991). The halothane gene (after challenging to halothane anesthesia; Archibald and Imlah, 1985) genotype of an animal is identifiable by PCR and restriction enzyme analysis. The present investigation was conducted to evaluate the productive performance of halothane negative (NN) and carrier (Nn) pigs reared individually at a test station without climate manipulation. Forty four pigs (22 females; 22 males) from commercial genetic lines (F₁ York/Landrace X synthetic hybrids) were evaluated. The test started when the animals weighted an average of 25 Kg and finished when they reached 100 Kg. The feed consumption, body weight, back fat and loin area (ultrasound) was measured during the time of the test. A frequency of 61.4 % (27 animals) and 38.6 % (17 animals) of the pigs were either NN or Nn, respectively. Better daily live weight gain was shown (P ≤ 0.05) by homozygous (NN) pigs than

heterozygous (Nn), 1.06 vs. 1.01 Kg, respectively. However, there were not statistical differences between groups on days to 100 Kg, back fat and loin area. Nevertheless, contrary to the current literature, a tendency of best performance for homozygous (NN) pigs was observed in our experimental conditions. There was no genotype X sex interaction, both sexes having similar performance.

Key Words: Test performance, Halothane gene, Pig

769 Performance Levels, Genetic Parameters and Genotype-Health Interactions for Production Traits in Pigs. R. Bergsma^{*1}, E.F. Knol¹, J.W.M. Merks¹, and G.J. Van Groenland², ¹IPG, Institute for Pig Genetics, Beuningen, ²TOPIGS, Vught, The Netherlands.

Replacement boars and gilts are potential carriers of infectious agents for pig production farms. Demand for healthy breeding stock is increasing. Consequently, production facilities of these animals should be of high health. However, from a genetic point of view questions should be raised whether 1) genetic trend realized under high health conditions (SPF) will be expressed in the same magnitude under conventional conditions, and 2) selection under SPF will, in the long term, decrease genetic disease resistance. SPF in the current analysis was defined as controlled free of Pseudorabies, PRRS, TGE, *Mycoplasma hyopneumoniae*, *Actinobacillus pleuropneumoniae*, *Brachispira hyodysenteriae*, *Pasteurella multocida* (DNT), *Streptococcus suis* (Type II), endoparasites and ectoparasites. On the conventional farms used, some, but not all, of the pathogens were present. Data analysis of a genetically linked structure of 2 SPF farms and 3 conventional farms for fertility traits, and 3 SPF- and 2 conventional farms for finishing traits yielded different performance levels under SPF for: Total Number Born (TNB, +0.7), Gestation Length (GL, -0.5 d), Nurse sow PreWeaning Mortality (PWM, -1.4 %), Test Growth (25-80 kg; TG, +143 g/d), and Ultrasonic Backfat (USB, +0.58 mm). Heritability tended to be higher only for TNB (0.13 vs. 0.10) under SPF. Genetic correlations between traits measured under SPF and under conventional conditions were positive and high ($r_g > 0.8$) for Stillborn, TNB, and TG and moderate ($0.5 < r_g < 0.8$) for GL, PWM, and USB. It is concluded that selection under the defined SPF conditions will not markedly reduce genetic trend on farms with a conventional health status. A genetic decrease in resistance is difficult to detect. Using health and performance data of SPF sired offspring in a conventional environment will help to control this potential risk.

Key Words: Pigs, Genotype Health Interaction, SPF

770 Sustainable Outdoor Pork Production. W. P. Tynan^{*}, J. G. Gentry, A. K. Johnson, H. A. Rachuonyo, J. F. Smith, and J. J. McGlone, Texas Tech University, Lubbock, Texas/USA.

A Sustainable Pork (SP) Research and Demonstration Farm was developed based on past research and the following conditions. The objectives of the SP Farm were to develop a precisely defined production technology. Acceptable criteria include that the farm does not use waste lagoons; uses no more land than a conventional indoor production system and should have no negative impact on the land. The farm may use no more labor than a conventional system and must be economically competitive. Neither may the farm have an offensive odor. It must be viewed as a positive member of the rural community. Plants used as groundcover must uptake the nutrients the animals add to the soil and

ASAS/ADSA Animal Health: Dairy, Beef Cattle, and Other Species

772 Parenteral vitamin E for prevention of retained placenta in dairy cows. S. LeBlanc, K. Leslie^{*}, T. Duffield, K. Bateman, J. Ten Hag, and J. Wallace, University of Guelph, Guelph, Ontario, Canada.

Immune function is suppressed, and the risk of infectious and metabolic disease is increased in periparturient dairy cows. Several studies have shown improved immune function and decreased risk of RP or mastitis in transition cows supplemented with vitamin E in feed and/or parenterally. However, these benefits are not universally reproducible and may depend on baseline vitamin E and selenium status of animals, and other factors. Additionally, a fraction of animals will demonstrate hypersensitive reactions to parenterally administered vitamin E. The objective

recycle them by retaining carbon, nitrogen and other nutrients in a solid form. Finally, the farm should contribute healthy meat to the segment of consumers who wish to protect the environment, the animals and the workers. This niche market may be available in the United States now. Started "from scratch" on grassland that was in the Conservation Reserve Program for ten years, the farm shows the feasibility of successfully operating a 300-sow farrow-to-finish pig production outdoor sustainable farm. The farm has completed two years of operation. Production of piglets began in January 1999 and approximately 15,000 piglets have been weaned and finished outdoors. There were no health problems in the herd of 300 sows that received no sub-therapeutic antibiotics. Meat is sold to the public under the trademarked Sustainable Pork[®] label at the Texas Tech University Meats Laboratory. Visitors to the farm are impressed by the absence of odor due to the maintenance of ground cover and the manner in which the sows and piglets live a healthy, active life style. Consumers may consider their meat to be of better quality and taste panel results confirm the consumer perception of better taste in some trials. Soil analyses indicate that the farm's program of maintaining groundcover, which is being fertilized by the animals, has prevented a buildup of some nutrients in the soil. This production system works well in a dry, warm climate.

Key Words: Outdoors, Pigs, Environment

771 Evaluation of three genetic populations of pigs for response to four levels of ractopamine. A. P. Schinckel^{*1}, C. T. Herr¹, B. T. Richert¹, and M. E. Einstein¹, Purdue University.

Gilts (n = 300; BW = 83.5 kg) were allotted to pens (n = 60) by weight in a 3 x 4 factorial arrangement of treatments in a randomized complete block (n = 5) with three genotypes (G) and four ractopamine levels (RL): 1) control, 0 ppm; 2) 5 ppm; 3) 10 ppm; and 4) 20 ppm RAC to evaluate the effects of ractopamine (RAC) on growth performance in a four week trial. All pigs were fed an 18.6% CP, 1.1% lysine diet. The weekly pen data were fitted to numerous linear, nonlinear and biphasic equations of ractopamine level (RL), and either duration of time (DRAC, midweek days on RAC), or weight gain (WTGRAC, kg) on RAC. The values of DRAC and WTGRAC were set to zero for the control treatment. The RAC response was also divided into two phases: (1) RL1, 0 for control and 5 for all other RAC treatments, and (2) RL2, (RL-RL1) for RAC treatments 2, 3, and 4. For ADG (kg/d), the equations included the fixed effects of block, G and week on test ($p < .01$) and either a biphasic $[0.0186 \text{ RL} + .0272 (\text{RL}2)^{.007}]$ or nonlinear function $\{.113 [1 - \exp (-.713 \text{ RL})]\}$ of RL level. For gain:feed (G:F), the models included the fixed effects of week ($p < .01$) and either a biphasic linear $(.0084 \text{ RL}1 + .0013 \text{ RL}2)$ or nonlinear function $\{.0513 [1 - \exp (-.717 \text{ RL})]\}$. The partial sums of squares accounted for by the biphasic functions were 4.4 and 8.9% greater than the nonlinear functions for ADG and G:F, respectively. For daily feed intake (ADFI, kg/d), the equation with the lowest RSD included the fixed effects of block, G, week, and $-.0068 \text{ RL}2$ ($p < .01$). The change in the RAC response with WTGRAC were not significant ($p > .50$) for any variable. The predicted linear change in RAC response to DRAC were small for ADG $(-.0035, p = .19)$, G:F $(-.0008, p = .49)$, and ADFI $(-.0026, p = .31)$. The regression analyses indicated that the three variables respond differently to increasing RL. The biphasic and nonlinear functions of RL resulted in different predicted RAC responses. The RAC response did not significantly change over the duration of the 28-day feeding trial.

Key Words: Ractopamine, Genetic, Finishing

of this study was to investigate the effect of vitamin E administered subcutaneously to prepartum cows on the incidence of periparturient health problems. A total of 1184 cows in 20 herds were randomly allocated to receive either a single SC injection of 3000 IU vitamin E (d- α -tocopherol) or placebo approximately one week prior to expected calving date. Incidence of peripartum disease (retained placenta, milk fever, metritis, ketosis, displaced abomasum, clinical mastitis, and lameness) was recorded. Data were analyzed in SAS using the GENMOD procedure including herd as a random effect. The risk factors for RP and the effect of vitamin E on RP were different between primiparous and multiparous cows. Therefore, these parity groups were modeled separately. Occurrence of dystocia was offered to the models but was not a signifi-

cant effect. There were no hypersensitive reactions following treatment. Overall, there was no association between vitamin E injection and any disease except RP. Among primiparous animals, treatment reduced the probability of RP by 40% ($P = .06$), with no interactions with season or time of administration relative to calving. Among multiparous cows, occurrence of milk fever or twins were significantly associated with increased risk of RP. Even excluding affected cows, there was no significant effect of vitamin E on the risk of RP in parity 2 or greater. Analysis of the pharmacokinetics of vitamin E in 18 animals suggests that after a single SC injection of 3000 IU, peak circulating vitamin E level is reached in 1 week, and returns to baseline level after 2 weeks.

Key Words: Retained Placenta, Vitamin E, Transition Cow

773 The incidence and impact of clinical endometritis in dairy cows. S. LeBlanc¹, K. Leslie^{*1}, T. Duffield¹, K. Bateman¹, and G. Keefe², ¹University of Guelph, Ontario Veterinary College, ²University of Prince Edward Island, Atlantic Veterinary College.

Endometritis is a localized inflammation and/or infection of the uterus characterized by delayed involution of the uterus, and associated with chronic bacterial uterine infection and purulent uterine discharge. Diagnosis and treatment of endometritis are a source of controversy among veterinarians, fuelled by a lack of large-scale clinical trials with an objective case definition and economically meaningful outcomes. The objectives of this study were to assess diagnostic criteria for endometritis, and to quantify the impact of endometritis on reproductive performance. A total of 1910 cows on 26 farms were studied. The occurrence of dystocia, twins, retained placenta and metritis were recorded. Every cow was examined once between 20-33 DIM, with an external inspection and vaginoscopic examination, followed by rectal palpation of the genital tract for collection of objective data (cervical diameter, location, size, texture and symmetry of the uterus, and ovarian structures). The character of the discharge was scored. Subsequent reproductive performance and culling were monitored for all cows. Multivariate survival analysis was used to identify the factors that predicted longer time to pregnancy (days open), accounting for cows that failed to become pregnant. Adjustment was made for clustering of cows within herds. There were 606 animals (32%) that had visible purulent discharge, but only cows with muco-purulent or worse discharge, or cervical diameter > 7.5 cm after 26 DIM, had significantly reduced pregnancy rate. Using this case definition, the prevalence of endometritis was 21%, and affected cows had an increase of 17 median days open compared to normal cows (140 vs. 123 median days open, respectively). Among cows with endometritis, 69% were diagnosed by vaginoscopy. Given vaginoscopy, only cervical diameter was associated with reduced pregnancy rate; all uterine palpation findings had no predictive value for time to pregnancy. Herd level prevalence of endometritis ranged from 7% to 31%. Endometritis significantly impairs reproductive performance, but identification of affected individuals depends on objective assessment and consideration of the interval from calving to diagnosis.

Key Words: Endometritis, Reproduction, Vaginoscopy

774 The influence of negative energy balance on udder health. K. Leslie, T. Duffield, S. LeBlanc, and J. Ten Hag, University of Guelph, Ontario Veterinary College.

There is growing evidence that the mechanisms of udder defence are impaired in periods of negative energy balance and hyperketonemia. Two recent experiments, involving approximately 1000 periparturient dairy cows in Ontario, were utilized to investigate the association between subclinical ketosis and subsequent mastitis. In the first study, 951 cows were blood sampled at 1, 2, 3, 6, and 9 weeks after calving. Overall, 15.1% of cows (39 of 258) with subclinical ketosis had clinical mastitis, as compared to 10.1% (70 of 693) non-ketotic cows ($p < 0.05$). In cows with ketosis during the first week postpartum, 18.1% had clinical mastitis. In multi-variable regression analysis, it was found that parity, calving in summer and fall seasons, and being ketonemic at a threshold of greater than or equal to 1400mol/L BHB were all significantly associated with an increased risk of clinical mastitis. The associations between subclinical ketosis and elevated SCC were also studied. Of cows with ketonemia for two or more weeks in the postpartum period, 21.6% had an elevated SCC, as compared to 13.6% of cows without chronic ketonemia. In the second study, 1142 cows in 20 herds had blood samples collected during the week before calving and in the first week postpartum. Mastitis

was monitored as a producer diagnosis of clinical signs in the first 30 days in milk. Using this definition, there was 9.7% lactational incidence rate of clinical mastitis (111 cases). Of cows with serum BHB greater than or equal to 1400 mol/L in the week before calving, 28.6% subsequently had clinical mastitis, as compared with 8.7% of cows that were non-ketonemic prepartum. The results of these two studies add to the growing evidence that negative energy balance and subclinical ketosis is associated with increased rates of mastitis.

Key Words: Negative Energy Balance, Subclinical Ketosis, Mastitis

775 The effects of metaphylactic treatment with tilmicosin on the incidence of bovine respiratory disease in growing dairy replacement heifers. D.G. Schmidt^{*1}, J.E. Shirley¹, E.C. Titgemeyer¹, M.V. Scheffel¹, and D.G. McClary², ¹Kansas State University, Manhattan, ²Elanco Animal Health, Greenfield, IN.

One hundred forty four Holstein heifers were used to evaluate the efficacy of a metaphylactic tilmicosin treatment on the incidence of bovine respiratory disease (BRD). Heifers were moved from individual calf facilities at 56 d of age to an off-site (5 h transport) facility, weighed on arrival, ranked by weight, and alternately assigned to pens (6 heifers/pen). Pens with similar weight heifers were paired and randomly assigned to control or tilmicosin treatment. Pens (12/treatment) served as the experimental unit in a randomized block design. Tilmicosin (10 mg/kg of body weight) was administered immediately after pen assignments were completed (day of arrival) to calves in the treatment group. Individuals unaware of treatments conducted health observations twice daily. Incidence of clinical BRD was observed in 2.8 and 4.2 percent of control and tilmicosin treated heifers, respectively. One relapse (clinical signs of BRD within 21 d after treatment) occurred in a tilmicosin treated heifer, and one new episode (clinical signs of BRD after 21 d from first treatment) was observed in a control heifer. Heifers treated with tilmicosin gained more weight ($P < 0.05$), consumed more feed ($P < 0.05$), and were more efficient ($P < 0.05$) during the first 28 d after treatment. Improved performance during the first 28 d in the tilmicosin treated group is presumed to be due to a reduced incidence of sub-clinical BRD.

Key Words: Dairy heifer, Tilmicosin, Bovine respiratory disease

776 On-farm batch pasteurization destroys Mycobacterium paratuberculosis in waste milk. J. Stabel^{*1}, USDA-ARS, National Animal Disease Center, Ames, IA.

A recent dairy survey conducted in 1996 by the National Animal Health Monitoring System suggests between 20 to 40% of dairy herds in the United States have some level of Johne's disease in the herd. This figure will continue to increase unless producers implement management regimes that will help control the spread of this disease within their herd. The neonatal calf is the target for infection with Mycobacterium paratuberculosis, the causative agent of Johne's disease. Calves become infected via exposure to the bacterium through contaminated feces, bedding, colostrum, and milk. Shedding of viable M. paratuberculosis has been documented in the colostrum and milk of infected dams. This study evaluated the efficacy of on-farm pasteurization to destroy M. paratuberculosis in waste milk fed to calves in order to circumvent this mode of transmission. In three replicate experiments, waste milk was experimentally inoculated with M. paratuberculosis and heated at 150degF for 30 minutes. No viable bacteria were recovered after 28 weeks of incubation. These results suggest that batch pasteurization of waste milk contaminated with M. paratuberculosis was effective at generating a clean product to feed to young calves.

Key Words: Mycobacterium paratuberculosis, Johne's disease, Pasteurization

777 Effect of environmental stressors on ADG, serum retinol and α -tocopherol concentrations, and incidence of bovine respiratory disease of feeder steers. N. K. Chirase*^{1,3}, L. W. Greene^{1,3}, C. W. Purdy², R. W. Loan³, R. E. Briggs⁴, and L. R. McDowell⁵, ¹Texas Agricultural Experiment Station, Amarillo and West Texas A&M University, Canyon, ²USDA/ARS, Bushland, TX, ³Texas A&M University, College Station, ⁴USDA/ARS, Ames, IA, ⁵University of Florida, Gainesville.

Environmental stressors are frequently encountered in confined animal feeding operations. An experiment was conducted to determine the effect of Micotil[®] and feedyard dust exposure on ADG, serum vitamins A (Vit A) and E (Vit E) concentrations, and incidence of bovine respiratory disease (BRD) of feeder steers. One hundred and twenty crossbred feeder steers (average BW 185 kg) were purchased in Morristown, TN and transported to Bushland, TX. One half of the steers received Micotil (1 ml/30 kg BW s.c.) in TN. Simulated dust storm was produced by having steers in an enclosed canvas tent. Calves were allotted randomly into 3 dust exposure groups: 1) Control (not exposed to tent or dust), 2) Tent (enclosed in tent without dust) and 3) Dust (exposed to dust suspension inside tent), and nested within Micotil[®] treatments. There were four dust application events each lasting 4 h. Calves were weighed and blood samples taken in Morristown (d -3), arrival (d 0) and every 7 d for 28 d. The data were subjected to the analysis of variance using the General Linear Models procedure of SAS. Transportation stress reduced ($P < 0.001$) serum Vit E concentrations from 7.10 to 1.95 ug/ml. There was no interaction ($P > 0.05$) between the antibiotic and dust treatments. On d-28, the mean ADG of tent and dust groups was lower ($P < 0.02$) than the controls (0.77 vs 1.26 kg/d). Similarly, the mean serum Vit E concentration of these steers was also lower ($P < 0.05$) than the controls (1.88 vs 2.11 ug/ml). Micotil[®] treatment sustained ($P < 0.001$) serum Vit A and E concentrations of steers. As incidence of BRD increased (0 to 6), serum Vit A and E concentrations decreased ($P < 0.001$) as well as ADG. These results suggest that environmental stressors decrease serum antioxidants corresponding with decreases in ADG.

Key Words: Steers, Simulated dust, Serum antioxidants

778 Influence of dietary antioxidant vitamins on performance of feeder steers exposed to simulated feedyard dust. N. K. Chirase*^{1,3}, L. W. Greene^{1,3}, C. W. Purdy², R. W. Loan³, D. R. George¹, and J. Avampato¹, ¹Texas Agricultural Experiment Station, Amarillo and West Texas A&M University, Canyon, ²USDA/ARS Bushland, TX, ³Texas A&M University, College Station.

Feeder cattle often encounter many environmental stressors such as dust. An experiment was conducted to determine the effects of short term (28 d) feeding of vitamins A (Vit A) and E (Vit E) on the performance of beef steers exposed to feedyard dust. Thirty six (36) crossbred feeder steers (average BW 260 kg) were allowed 28 d to recover from transit stress and sickness and assigned randomly into four groups of 9 steers. Steers were housed in pens equipped with calan gate feeders for individual feed intake measurement. The diets consisted of 1) Control (Vit A = 20,240 IU/kg DM; Vit E = 300 IU/kg DM) and 2) Antioxidants (Vit A = 60,700 IU/kg DM; Vit E = 760 IU/kg DM). The diets and dust treatments were arranged in a 2 X 2 factorial design. Steers were trained to feed from calan gates, adapted to diets for 14 d and assigned the following dust treatments: 1) Control (not exposed to tent or dust) and 2) Dust (exposed to dust suspension inside tent). Simulated dust storm was produced in an enclosed canvas tent. There were six consecutive daily dust events each lasting 4 h. Steers were weighed every 8 d. The data were subjected to the analysis of variance using the General Linear Models procedure of SAS. An interaction occurred between the dust and antioxidants for feed intake and ADG on d 8 and 17. Steers fed the control diet and not exposed to dust consumed less ($P < 0.08$) feed and gained less ($P < 0.05$) weight than all other groups. Although not significant ($P > 0.05$), the feed to gain ratio for steers not exposed to dust was 36% greater than those exposed to dust (8.0 vs 5.9). The feed to gain ratios of steers fed the control and antioxidant diets were not different ($P > 0.05$). These results suggest that short term feeding of dietary antioxidants during the receiving period to reduce oxidative stress requires additional investigation.

Key Words: Steer performance, Simulated dust, Antioxidant vitamins

779 Relative contribution of nitric oxide (NO)- synthase (NOS) isoforms to hepatic NO production following low-level in vivo endotoxin (LPS)-challenge in cattle. T. Elsasser*, S. Kahl, E. E. Connor, and D. Carbaugh, USDA, Agricultural Research Service, Beltsville, MD.

Nitric oxide, synthesized from arginine by different isoforms of NOS, mediates many aspects of inflammatory response to bacterial toxins. Type-II NOS, induced primarily in macrophages 4 to 6 h after LPS, has been identified in other cell types as well; Type-III NOS, constitutively present in several cell types, is modulated by cofactor availability. The present research evaluated the temporal relationship between increases in plasma nitrate (NOx, the stable breakdown product of NO) after LPS and relative activity of Type-II and Type-III NOS in liver. Calves were challenged with either 0 (saline, n = 6, CON) or 3 μ g/kg LPS (E. coli 055:B5, iv, jugular, n = 6, L) with serial blood samples obtained for plasma analysis. Plasma NOx increased after 3h ($P < 0.02$) and peaked at 6 to 8 h after a secondary rise initiating at 4 h post LPS. In a subset of calves (n = 4) liver biopsy samples were obtained 8 h after LPS for characterization of NOS isoforms by immunohistochemistry (IHC) and enzyme assay. Localized by IHC, both isoforms were present in CON; less than 5% of cells were positive for Type-II NOS while 36% of cells ($P < 0.002$ vs Type-II) immunostained for Type-III NOS. After LPS, Type-II positive cells increased to 18% in L (hepatocytes, Kupffer cells, and infiltrating monocytes). With the use of selective NOS-type inhibitors both isoforms were identified in CON (2.9% of total NOS activity - Type-II). Type-II activity (pmol citrulline/min/mg protein) averaged 0.052 and 0.445 (SEM = 0.12, $P < 0.002$) in CON and L, respectively. Type-III activity averaged 1.68 and 1.97 (SEM = 0.15, NS) in CON and L, respectively. While the activity of Type-II NOS increased 9-fold with LPS ($P < 0.01$), the relative contribution of Type-II to total NOS activity after this dose of LPS was 18.4%. The data suggest that early increases in plasma nitrate after LPS arise predominantly from Type-III NOS with secondary increases contributed from lower levels of Type-II NOS.

Key Words: Endotoxin, Cattle, Inflammation

780 Influence of estrus on somatic cell count in dairy goats. S McDougall* and M Voermans, Animal Health Centre, Morinsville, New Zealand.

The effect of estrus on the somatic cell count (SCC) in goats' milk was examined by inducing estrus in half of a group of 48 seasonally anoestrus dairy goats. Goats were blocked by infection status and ranked by SCC from the three preceding herd tests and then randomly allocated to three treatment groups: (a) an intravaginal progesterone releasing insert for 12 days and with equine chorionic gonadotropin (eCG) and dinoprost tromethamine 2 days before insert removal (Short; n = 12), (b) an intravaginal progesterone releasing insert for 17 days and with 500 i.u. of eCG on the day of insert removal (Long; n = 12), or (c) left as untreated controls (Control; n = 24). The bacteriological status of each gland of each enrolled goat was determined before and after synchronization (d -23 and d 13) and SCC and milk yield were determined on days -2, 0, 1, 2, 3, 4, 14, 25 where day 0 was the day of intravaginal insert removal. A general linear model was used to test the effect of treatment group on Log₁₀ SCC and milk yield on each day. The value on day -2 was used as covariate in all models. There was no difference in age, SCC or prevalence of intramammary infection preceding synchronisation among treatment groups ($P > 0.1$). The Short group were in estrus before the Long group who were in turn in estrus before the control group (1 (1-1) vs. 2 (2-2) vs. 11 (9-13) days, median days to estrus (upper and lower 95% confidence intervals) for Short, Long and Control groups, respectively; $P < 0.05$). The log₁₀ SCC was higher in the Short than Control group on days 1 to 4 (3.28 +/- 0.10 vs. 2.57 +/- 0.08; 3.17 +/- 0.11 vs. 2.71 +/- 0.08; 2.93 +/- 0.11 vs. 2.63 +/- 0.08; 2.95 +/- 0.12 vs. 2.55 +/- 0.09, mean and sem for Short vs. Control on days 1 to 4, respectively, all $P < 0.05$). Log₁₀ SCC of the Long group were higher than the Control group on days 2 and 4 (3.01 +/- 0.10 vs. 2.71 +/- 0.08; 2.84 +/- 0.11 vs. 2.55 +/- 0.09, mean and sem for Long vs. Control on days 2 and 4, respectively, both $P < 0.05$). There was no difference in milk yield on any day ($P > 0.1$) or in prevalence of intramammary infection between groups. This data indicates that estrus was associated with an increase in SCC and that the increase in SCC was independent of any change in milk yield.

Key Words: Goat, Somatic Cell Count, Estrus

781 Associations between porcine leptin and leptin-receptor marker genotypes and immune parameters. M.F.W. te Pas^{*1}, A.H. Visscher¹, E.J. van Steenbergen², E.F. Knol², K.H. de Greef¹, T.A. Niewold¹, and L.L.G. Janss¹, ¹ID-Lelystad, ²Institute for Pig Genetics.

Leptin is an adipocyte-secreted hormone that affects diverse traits like food intake, body fatness, reproduction, and immune response. Leptin acts through activation of the leptin-receptor on target cells. Leptin deficiency is associated with excessive fatness, suppressed reproductive function, and reduced immune function. Reduced leptin-receptor function is also associated with excessive fatness. Both leptin expression levels and leptin marker genotype has been associated with back fat thickness in certain, but not all, pig breeds. The relationship between leptin and leptin-receptor genotypes and immune parameters is still unknown. The purpose of this study was to evaluate the association between leptin and leptin-receptor genotypes and immune parameters. Ninety immune parameters were measured in 202 AI boars from 4 different lines from 2 pig breeding organizations. Immune parameters were grouped in 1) lymphocyte stimulation tests, 2) lymphocyte cell numbers, and 3) lymphocyte cell membrane markers CD4 and CD8. Pigs were genotyped for 1) a leptin marker as described by Stratil et al. (Anim. Genet. 28: 371-372), and 2) two leptin-receptor intronic PCR-RFLP#s. Associations were evaluated with several statistical models including models that evaluated the association of each individual marker genotype and the immune parameters separately, and models that included the genotypes and interactions of both genes. The results indicate that leptin marker genotypes show good association with the lymphocyte stimulation tests and the cell membrane markers. Leptin-receptor genotypes associated to lymphocyte stimulation tests, lymphocyte cell numbers, and cell membrane markers, but associations were less significant than for the leptin gene. Interactions between the leptin and leptin-receptor genotypes were shown for the cell membrane markers. The relation between pig health and leptin and leptin-receptor genotypes remains to be established.

Key Words: Pig, Leptin Genotype, Immune Capacity

782 Profiling intestinal microbial populations with the *cpn60* molecular diagnostic. J.E. Hill¹, A.G. Van Kessel^{*2}, R.P. Seipp¹, L. Hawkins¹, M. Betts¹, J. Marshall², and S.M. Hemmingsen¹, ¹National Research Council Plant Biotechnology Institute, Saskatoon, SK, ²University of Saskatchewan, Saskatoon, SK.

Conventional methods for identifying and quantifying microorganisms in complex communities such as those found in the intestine are costly, labour intensive, offer limited species differentiating capacity and fail to identify unculturable organisms. We designed a single set of degenerate PCR primers which can be used to amplify a target gene, *cpn60*, present, usually in single copy, in the genomes of all eukaryotes and eubacteria. We used these "universal" primers to characterize the microflora in pig intestine. Total genomic DNA was isolated from pig faeces by two different extraction methods and subjected to universal *cpn60* primer PCR at two different annealing temperatures. The resulting PCR amplicons were cloned, resulting in 4 libraries of partial *cpn60* sequences. To date, 266 randomly selected clones have been sequenced. Analysis showed the presence of 77 distinct sequences appearing in frequencies ranging from 1 to 50 out of 266. The majority of pairwise DNA sequence identities for the sampled sequences were between 50 and 70%, indicating that the sequences likely represent many different genera. A comparison of cloned sequences to a database of *cpn60* sequence data permitted the classification of library sequences into taxonomic subclasses, in some cases to the genus level, consistent with those identified in the intestine by classical methods. Preliminary data suggest that template extraction method and PCR parameters affect the composition and diversity of the resulting library. We are currently collecting sequencing data from 1800 additional library clones and are developing hybridization and realtime PCR approaches to quantitatively profile intestinal bacterial colonization. Profiling technology based on *cpn60* has significant potential to improve understanding of the interrelationships among intestinal colonization, age, nutrition, health status and animal performance.

Key Words: Intestinal Microbiology, *cpn60*, Molecular Diagnostic

783 Evidence for Transfer of Tylosin and Tylosin-Resistant Bacteria in Air from Swine Production Facilities using Sub-Therapeutic Concentrations of Tylan in Feed. J. A. Zahn^{*}, J. Anhalt, and E. Boyd, National Swine Research and Information Center, USDA-ARS, Ames, IA.

Macrolides are an important class of antibiotics used in human and veterinary medicine for therapy and prevention of diseases caused by Gram-positive bacteria, and as animal growth promotants. Tylosin belongs to the class of 16-membered macrolide antibiotics, and has been used exclusively in veterinary medicine for treatment of animal diseases or for enhancing animal growth rate. Antibiotic resistance studies have recently focused on tylosin residues and tylosin-resistant bacteria (TRB) in animal products or in effluent streams from animal production facilities as potential routes for transfer of antibiotic resistance to humans. However, these studies have not considered aerial transfer from point sources as a significant route in human exposure. This study quantified the concentration of tylosin and TRB in air from three mechanically ventilated swine (finisher stage) confinements using tylosin at sub-therapeutic concentrations ($20 \text{ g} \cdot \text{ton}^{-1}$) in feed. Tylosin residues and culturable bacteria in air at exhaust fans were trapped on absorbent resins or impinger samplers, respectively. Tylosin concentration was determined by high-performance liquid chromatography-electrospray tandem (MS-MS) mass spectrometry following solvent desorption of absorbent resins. The number of culturable bacteria and culturable, TRB were determined by plating on standard plate count agar containing no tylosin or $50 \mu\text{g} \cdot \text{mL}^{-1}$ tylosin, respectively. The mean concentration of TRB ($49,400 \text{ } 16,700 \text{ CFU} \cdot \text{m}^{-3}$) accounted for approximately 80% of the total culturable bacteria ($62,100 \text{ } 18,300 \text{ CFU} \cdot \text{m}^{-3}$) present in air streams from confinements, with *Corynebacterium* the predominant genus of TRB. The mean concentration of tylosin in the air from the three confinements was shown to be $8.1 \text{ } 5.3 \text{ ng} \cdot \text{L}^{-1}$ of exhaust air. Feeder operation, ventilation rate, and animal activity were shown to be the most significant variables influencing emission rate of tylosin and culturable TRB from the swine confinements. The results indicate that aerial transfer of antibiotics and antibiotic-resistant bacteria from swine confinements may represent an important, and previously overlooked mechanism for transfer of antibiotic resistance to humans and to the environment.

784 Evaluation of Mannan Oligosaccharide on the microflora and immunoglobulin status of sows and piglet performance. K. E. Newman^{*1} and M. C. Newman², ¹Venture Laboratories, Inc., Lexington, KY, ²University of Kentucky, Lexington, KY.

A number of studies have demonstrated improvements in production parameters and mortality with the inclusion of Mannan oligosaccharide (MOS) to the diet. Documented effects include increased macrophage activity and serum immunoglobulins. In addition, alterations in fecal bacterial populations have also been noted with MOS inclusion in the diet. Twenty-four sows were divided into two treatment groups by parity to evaluate the effect of MOS on fecal bacterial populations, sow colostrum immunoglobulin levels and piglet performance to weaning. All sows received a fortified corn-soy diet. Treated sows received 5-g MOS per day from approximately 14 days pre-farrowing throughout the lactation. Control sows received no supplementation (C). MOS treated sows had higher levels of IgM than untreated sows (440 vs. 316 mg/dl; $P=0.0366$). Colostrum IgG levels were also numerically increased in sows receiving MOS (4215 vs. 3565 mg/dl; $P=0.1615$). Colostrum immunoglobulin levels were also numerically greater 24-h post-farrowing in sows receiving MOS than unsupplemented sows (IgG 1572 vs. 1130 mg/dl; IgM 227 vs. 184 mg/dl). No effect of MOS supplementation was noticed on colostrum IgA concentrations. Piglet mortality was unaffected by treatment. Piglet weights were determined at 7, 14 and 21 days and greater when sows were supplemented with MOS than unsupplemented sows (Day 7: C - 3.14kg, MOS - 3.61kg; Day 14 C - 4.92kg, MOS - 5.62kg; Day 21 C - 6.57kg, MOS - 7.61kg $P<0.05$). Sow fecal bacterial concentrations were unaffected by treatment. The exact mechanism of the improved performance seen in the piglets from sows receiving MOS is not fully understood, but improved immune status of the piglets may provide an aid in performance by controlling sub-clinical problems. Further investigations on the nutrient profiles of colostrum may be warranted to better explain improved piglet performance.

Key Words: mannan oligosaccharide, immunoglobulin, sow

785 Biosecurity measures of spray-dried plasma protein in weanling pigs. J.M. Campbell*¹, B.S. Borg¹, L.E. Russell¹, J. Polo¹, and J. Pujols², ¹APC, Inc., Ames, IA, ²CRESA, Barcelona, Spain.

The experimental objective was to evaluate safety of spray-dried plasma protein after oral administration in weanling pigs by monitoring clinical, serological, and performance results. Thirty-six pigs (13.6 kg body weight) were randomly assigned to dietary treatments consisting of control (soybean meal) or 8% plasma. Diets were formulated to contain 1.20% lysine due to continuous administration for 2 months after weaning. Individual body weights and feed intake were determined on d 0, 21, 42, and 63 post-weaning. Clinical observations were monitored daily. Blood samples were obtained on d -14, 0, 21, 42, and 63 post-weaning for serological testing. Average daily gain was improved ($P < 0.10$) from d 22-42 and 0-42 due to plasma consumption compared

ASAS/ADSA Breeding and Genetics: QTL Detection and Mapping

786 Fine scale mapping of QTL using of linkage and linkage disequilibrium. T.H.E. Meuwissen*¹ and M.E. Goddard^{2,3}, ¹Institute fo Animal Science & Health, Lelystad, The Netherlands, ²University of Melbourne, Melbourne, Australia, ³Victoria Institute of Animal Science, Melbourne, Australia.

Genome wide scans for QTL in livestock populations have revealed many QTL carrying chromosomal regions. However, the size of these regions is rather large: $> 30\text{cM}$. Linkage disequilibrium has proven useful for the fine mapping of mono-factorial diseases in humans. A Quantitative Trait Loci (QTL) mapping method is presented that combines the information from linkage analysis and linkage disequilibrium mapping. The method is based on predicting an Identity By Descent (IBD) probability matrix between all haplotypes of the animals at the putative QTL position. By using this IBD-matrix as a correlation matrix between haplotypes, the variance associated with the putative QTL and the likelihood of the data can be estimated using REML variance component estimation. This likelihood can be maximised over all putative QTL positions in order to find the maximum likelihood position of the QTL. The matrix of IBD probabilities is predicted using 1) the identities of marker alleles in the region surrounding the QTL (linkage disequilibrium information); 2) recombinations within the marker haplotypes that occurred in the genotyped and pedigreed animals (linkage analysis information). The information on the IBD probabilities comes from two parts of the pedigree: 1) say 100 early generations where no pedigree and no genotyping information is available (but effective population size was assumed known); 2) say 2-5 generations where pedigree and genotypes are available. Background genes are accounted for by including a polygenic term in the REML variance component estimation.

Key Words: fine scale mapping, linkage analysis, linkage disequilibrium

787 Evaluation of statistical models and permutation tests for detecting gametic imprinting in QTL scans. H. K. Lee¹, J. C. M. Dekkers*², R. L. Fernando², and M. F. Rothschild², ¹National Livestock Research Institute, Korea, ²Iowa State University, Ames, IA.

Recently, De Koning et al. (PNAS, 2000) detected imprinted QTL in an F2 swine breed cross based on significance of paternal and maternal imprinting effects against a no-QTL model. They did, however, not test for deviations from Mendelian inheritance. Our objective was to develop and evaluate such tests. Breed cross regression interval mapping was implemented using the following QTL models: Mendelian (additive and dominance effects), full imprinting (separate maternal and paternal allele effects plus dominance), paternal imprinting (only paternal expression), and maternal imprinting. Tests of each model against the no-QTL model and tests of full imprinting against the Mendelian (Full/Mend), paternal and maternal imprinting models were used in a decision tree to determine presence and mode of inheritance of QTL. Chromosome-wise significance levels were derived by permutation (20,000 replicates). For the Full/Mend test, data were permuted by shuffling paternal against maternal coefficients within individual. Permutation test thresholds were compared to true values obtained from replicate (10,000) simulation of data under the null hypotheses (512 progeny from 8 F1 sires and 32 dams). The QTL was either fixed in alternate breeds or segregating at different frequencies (.7 and .3). The Full/Mend test had

to control pigs. Average daily feed intake and feed efficiency tended towards ($P > 0.10$) improvement. During the experiment, no clinical signs were associated with oral plasma consumption; however, control pigs had mild clinical symptoms and one death. Serological results of all blood samples from control and plasma treated pigs were negative for antibody presence against the following viruses: porcine parvovirus (PPV), Aujeszky's disease virus (PRV), porcine respiratory and reproductive syndrome virus (PRRS), and bovine viral diarrhoea virus (BVD). The plasma used in the study was devoid of titers for PRV, PRRS, and BVD, but positive for PPV. In summary, results indicate that oral administration of plasma had no adverse effects on clinical or performance parameters. Serological results indicate no transmission of disease from plasma for the period from a 14 to 63 kg pig.

Key Words: pigs, spray-dried plasma protein

higher F-value significance thresholds than tests against the no-QTL model. For fixed QTL, thresholds for Full/Mend derived by permutation underestimated simulated 10, 5, and 1% chromosome-wise type I error rates, but by less than 1.5, 0.6, and 0.3%. Simulation thresholds were slightly more stringent for segregating QTL. As a result, the permutation test underestimated simulated type I error rates slightly more ($< 1\%$). Similar work is ongoing to validate tests of full against paternal or maternal imprinting. In conclusion, statistical models and permutation tests can be used to determine presence and mode of inheritance of QTL, although true type I error rates may deviate slightly from desired rates. Supported by USDA CSREES # 00-52100-9610.

788 A Bayesian approach for constructing genetic maps when genotypes are miscoded. G. J. M. Rosa*^{1,2}, B. S. Yandell², and D. Gianola², ¹UNESP - Botucatu, SP/Brazil, ²UW - Madison, WI.

The increased availability of information on genetic markers has created opportunities for understanding quantitative inheritance and for developing novel strategies for genetic improvement in agriculture, such as exploitation of quantitative trait loci (QTL). A QTL analysis relies on having accurate genetic marker maps. At present, however, statistical methods for map construction ignore the possibility that molecular data are read with error. Often, there is ambiguity about at least some genotypes, and ignoring this phenomenon can affect inferences adversely. Here, a Markov chain Monte Carlo Bayesian approach is presented for constructing genetic maps (gene ordering and genetic distances) when there is some random miscoding of genotypes. A probability of miscoding is incorporated in the calculation of recombination events, assuming Haldane's mapping function. Samples from the joint (conditional) posterior distributions of recombination rates and gene order are obtained with the Metropolis-Hastings algorithm. Missing marker genotypes are imputed from Bernoulli distributions. Backcross data sets were simulated, with 100 or 300 individuals, genotyped for 5 loci (including some missing data), and with recombination rates between adjacent loci ranging from .02 to .18. Miscoding probabilities were 0, 2, 4 and 5%. Analyses were conducted ignoring or contemplating miscoding in the model. Results indicate that unless there is certainty that genotypes are coded correctly, it may be safer to use our alternative, robust, procedure, as it provides more reliable inferences about genetic maps. An analysis of *Brassica napus* is presented to illustrate how the procedure works in practice.

Key Words: Genetic map, Miscoding genotype, Bayesian inference

789 The extension of mixed model equations to finite normal mixture models for marker assisted analysis of quantitative traits. Yuefu Liu*, University of Guelph, Guelph, Canada.

The marker-based analysis of quantitative traits, such as marker assisted genetic evaluation, is characterized by the mixture model since the QTL genotypes are not observable. It is, therefore, important to develop a general statistical procedure for mixture model analysis. In this study, a set of mixture model equations was derived based on the normal

mixture model and the EM algorithm to analyze the data with mixture distributions. The derived equations are a generalization of Henderson's mixed model equations for mixture models. The mixture model equations were applied to marker assisted genetic evaluation with different parameterizations of QTL effects. The sire-QTL-effect model and the founder-QTL-effect model were introduced to illustrate the utilization of the mixture model equations. The potential advantages of the mixture model equations for marker assisted genetic evaluation were discussed. Comparing with mixed model equations, the mixed effect mixture model equations are flexible in modeling and shows desirable properties in estimating QTL effects.

790 Parameter estimation of epistasis effects using orthogonal marker contrasts. Yang Da*, *Department of Animal Science, University of Minnesota.*

The epistasis effects of two QTLs can be detected and mapped through their linked markers. Assuming marker A is linked to QTL 1 and marker B is linked to QTL 2, the marker genotypic effects can be obtained from the following model, $y = X\beta + Zm + \epsilon$, where $X\beta$ represents fixed non-genetic effects, $Z = nx9$ model matrix, $m = (AABB, AABb, AAbb, AaBB, AaBb, Aabb, aaBB, aaBb, aabb) = 9x1$ column vector of the genotypic effects of two-marker genotypes, and $\epsilon =$ random residuals including recombination residuals of the QTL value. Then, a QTL effect can be tested using an orthogonal marker contrast of $c_i m$, where c_i is one of the following eight contrasts: $c_1 = (1, 1, 1, 0, 0, 0, -1, -1, -1) =$ additive contrast for QTL 1, $c_2 = (-1/2, -1/2, -1/2, 1, 1, 1, -1/2, -1/2, -1/2) =$ dominance contrast for QTL 1, $c_3 = (1, 0, -1, 1, 0, -1, 1, 0, -1) =$ additive contrast for QTL 2, $c_4 = (-1/2, 1, -1/2, 1, -1/2, -1/2, 1, -1/2) =$ dominance contrast for QTL 1, $c_5 = (1, 0, -1, 0, 0, 0, -1, 0, 1) =$ additive additive contrast, $c_6 = (-1/2, 1, -1/2, 0, 0, 0, 1/2, -1, 1/2) =$ additive dominance contrast, $c_7 = (-1/2, 0, 1/2, 1, 0, -1, -1/2, 0, 1/2) =$ dominance additive contrast, $c_8 = (1/4, -1/2, 1/4, -1/2, 1, -1/2, 1/4, -1/2, 1/4) =$ dominance dominance contrast. Based on the above contrasts, analytical formulae are derived for estimating QTL locations and the size of each epistasis effect.

791 The effect of the number of loci on genetic evaluations in finite locus models. L.R. Totir*, R.L. Fernando, and S.A. Fernandez, *Iowa State University, Ames, IA.*

Several traits of interest are known to have low heritability, suggesting a non-additive gene action. Best linear unbiased prediction (BLUP) methods, although extremely efficient under additive gene action, have computational problems for large pedigrees under non-additive gene action. Multibreed data further increases the complexity of this problem. Finite locus models have been investigated recently as an alternative to infinitesimal models for genetic evaluation. A finite locus model can easily accommodate non-additive gene action even for multibreed data. Given a finite locus model, Markov Chain Monte Carlo (MCMC) methods can be used to estimate the posterior mean of genotypic values. Successful application of MCMC methods for genetic evaluation depends, among other factors, on the number of loci assumed in the model. In order to investigate the effect of the number of loci on genetic evaluations obtained with finite locus models, purebred as well as multibreed data were simulated for a 20-locus model. For a small pedigree, genetic evaluations obtained by best linear prediction (BLP) were compared to those from 1, 2, and 3-locus models. For BLP evaluations, the required parameters are the first and second moments of the joint distribution of the genotypic and phenotypic values. These moments were calculated from the gene frequencies and genotypic effects used in the simulation. For finite locus evaluations, the required parameters are the gene frequencies and effects for each locus in the analysis model. These were defined such that they yield the same first and second moments as the 20 locus model. For the 1, 2, and 3-locus models, exact posterior means were calculated using SALP, a segregation and linkage analysis computer program. As the number of loci increased, the finite locus genetic evaluations were closer to the BLP evaluations. Evaluations from the 2-locus model provided a good approximation to those from BLP. The improvement brought by the use of 3 loci was limited. So far only up to 3-locus models have been considered, which is the upper limit for

SALP. An MCMC sampler, known as ESIP will be used to investigate models with more than 3 loci in order to find the model that yields robust results and is still computationally efficient.

Key Words: Finite locus model, Markov Chain Monte Carlo, Best linear unbiased prediction

792 Accuracy of marker assisted selection using a mixed model method. Mathew A Chrystal*, Yang Da, Leslie B Hansen, and Antony J Seykora, *Department of Animal Science, University of Minnesota.*

The accuracy of marker assisted selection (MAS) was evaluated using a mixed model method and simulated data with known true QTL effects and marker-QTL distances. Correlation between the predicted marker effects and the true QTL values (r_1) was compared with the correlation between the phenotypic value and the true QTL values (r_2) for heritabilities (h^2) ranging 5% 30%. Also, the frequency of the favorable QTL allele in the selected population based on MAS is compared to that based on phenotypic selection for heritabilities ranging 5% 30% and for percentage of selected individuals (PSI) ranging 5% 30%. The correlation between the predicted marker effects and the true QTL values were substantially higher than that between the phenotypic and true QTL values, particularly when heritability is low. For example, for $h^2 = 30\%$, $r_1 = 0.726$, $r_2 = 0.548$; for $h^2 = 5\%$, $r_1 = 0.718$, $r_2 = 0.224$. Furthermore, MAS results in higher frequency of the favorable QTL allele in the selected population than phenotypic selection. Let $p_1 =$ frequency of individuals with the favorable QTL allele using MAS, and $p_2 =$ frequency of individuals with the favorable QTL allele using phenotypic selection. For the same PSI value of 5%, $p_1 = 0.996$ and $p_2 = 0.961$ if $h^2 = 30\%$, and $p_1 = 0.973$ and $p_2 = 0.728$ if $h^2 = 5\%$. For the same heritability of 5%, $p_1 = 0.973$ and $p_2 = 0.728$ if PSI = 5%, and $p_1 = 0.948$ and $p_2 = 0.630$ if PSI = 30%. In summary, MAS is most helpful when phenotypic selection is least effective, i.e., when heritability is low and the percentage of selected individuals is high.

793 Improved resolution of the porcine-human comparative genetic map. G. A. Rohrer*, S. C. Fahrenkrug, E. M. Campbell, J. W. Keele, and B. A. Freking, *USDA, ARS, U.S. Meat Animal Research Center, Clay Center, NE, USA.*

The last comprehensive porcine genetic map published by the MARC contained 1,042 loci and spanned an estimated 98.6% of the genome. Unfortunately, development of a high resolution human-swine comparative map was not possible as only 46 loci were associated with protein coding sequences (genes). Since that time, most marker development at MARC have been focused on increasing the number of genes represented on the porcine genetic map. Many of these markers were developed by screening porcine genomic libraries for specific genes and then identifying microsatellite markers within the identified clones. Our recent research emphasis has been to map genetic markers associated with porcine expressed sequence tagged (EST) sequences developed at MARC. Some ESTs were mapped using informative microsatellite markers identified within the sequences. Most ESTs have been mapped by identification of single nucleotide polymorphism (SNP) markers. In total more than 200 gene associated loci have been genotyped across the MARC reference population since the last published map, increasing the number of comparative anchor loci to nearly 250. Based on these gene assignments inferences about the conservation of synteny and gene order during the evolution of man and pigs can begin to be developed. In general, the predicted chromosome location of a gene has agreed with bi-directional ZOO-FISH results. The degree of conserved gene order varies widely across different chromosomes. In particular, SSC X appears to have an identical gene order as HSA X, while the gene orders within the conserved syntenic segments of SSC 5 and HSA 12 are quite different. Some ESTs have not mapped to the predicted porcine chromosomes which may be caused by incorrect determination of the human orthologue or previously undetected chromosomal rearrangements. Our efforts in mapping porcine genes has increased the marker density of the porcine genetic map as well as significantly improved the resolution of the porcine-human comparative map. The improved comparative map facilitates use of the human map to select positional candidate genes in QTL studies.

Key Words: Pig, Gene mapping, Comparative map

794 Effects of the Porcine Melanocortin 4 Receptor gene on growth rate, feed conversion and carcass composition of pigs sired by PIC337 or PIC408 boars. S. Jungst*¹, E. Wilson¹, M. Rothschild², C. Booher¹, T. Pastor¹, B. Fields¹, and G. Plastow¹, ¹PIC USA Franklin, KY, ²Iowa State University, Ames.

Camorough 22 and 24 sows were inseminated with semen from PIC337 (N=9) or PIC408 (N=10) boars to produce pigs to examine the effects of the Melanocortin 4 Receptor (*MC4R*) gene. Boars were randomly selected within line and their *MC4R* genotypes were unknown. Fifteen pigs were allotted to pens with either 13.4 or 8.4 m² of floor space during the growing - finishing period. Pigs were allotted to pens so each sire line and *MC4R* genotype was represented in the finisher pens. A total of 718 pigs from 102 litters were started on test. Objectives were to: 1) estimate *MC4R* additive effects, 2) determine if the marker effect was the same in each sire line and 3) determine if the gene effects were different for the two floor space allowances. SAS PROC MIXED was used to complete the analyses. Fixed effects for sire line, dam line, sire line x dam line, *MC4R* genotype, floor space and sex were included in all models. Boars nested within sire line and sows nested within dam line were included as random effects. Average daily gain, feed intake and feed conversion were adjusted for on-test weight. Carcass traits were adjusted for carcass weight. Sire line x *MC4R* and floor space x *MC4R* interactions were not detected for any trait (P>.10). The *MC4R* genotype that reduced fat thickness was deemed the favorable genotype. *MC4R* additive effects were -13 g/d for average daily gain (P<.10), -.07 kg/d for feed intake (P<.05), -.6 mm for real-time backfat (P<.05) and .7 mm for real-time loin depth (P<.10). Additive effects were .11 kg (P<.05), .09 kg (P<.05), .04 kg (P<.10) and -.06 kg (P<.10) for ham, loin, shoulder and belly weight, respectively. *MC4R* additive effects were -.5 mm for carcass backfat thickness and .2% for primal percentage (P<.05). These results confirm and extend the initial findings of Kim *et al.* (2000 Mamm. Gen. 10 p131-135). This gene can be used to produce leaner and more efficient pigs.

Key Words: Pigs, *MC4R*, Growth

795 Genetic relationships between insulin-like growth factor-I and performance traits in two lines of purebred swine. K.G. Lahti*¹, K. Bunter², J. Mercer¹, and S. Clearkin³, ¹Bell Farms, Wahpeton, North Dakota, ²University of New England, Armidale, NSW, ³PrimeGRO Pty. Ltd., Thebarton, South Australia.

Insulin-like growth factor-I (IGF-I) measured in the blood of weaning piglets is a suggested predictor of feed efficiency and carcass performance. Blood card samples were collected for IGF-I analysis in the nursery of a breeding company nucleus from 606 Landrace (LA) and 600 Large White (LW) piglets at 27 to 36 days of age. Samples were from 377 boars and 829 gilts, weaned at an average of 17 days. IGF-I assays were performed by PrimeGRO Pty. Ltd. Some pre-selection of boars for castration and feeder pigs for sale occurred before pigs began performance testing at 90 to 101 days of age. Valid daily feed intakes were measured on 124 boars with Osborne Industries Feed Intake Recording Equipment (FIRE feeders) and used to calculate feed conversion ratios (FCR). Pigs completed testing at 160-183 days of age, with weights and real-time ultrasound measurements of last-rib backfat (BF) and muscle depth collected on all pigs to compute gains and lean tissue growth rate (LTGR). Data were analyzed using SAS PROC GLM and ASREML. For LA and LW, univariate estimates of heritability were respectively, .09(.04) and .13(.04) for FCR, .44(.12) and .59(.11) for IGF-I, .38(.02) and .37(.02) for BF, and .26(.02) and .24(.02) for LTGR. Genetic correlations obtained with bivariate analyses of IGF-I with BF were .49(.15) and .54(.14), with FCR were .50(.38) and .59(.40), and with LTGR were -.25(.18) and -.20(.18) for LA and LW. The large, positive genetic correlations between IGF-I and BF indicate that animals with high IGF-I at weaning are more likely to be fatter at finishing. This is consistent with the strong positive genetic correlations found between IGF-I and FCR, and moderate negative genetic correlations between IGF-I and LTGR. Despite low numbers of feed records, results correspond in size and magnitude with previous studies. IGF-I may be a useful tool for early selection of boars and for obtaining increased accuracy of breeding values for feed intake and efficiency.

Key Words: Insulin-like Growth Factor-I, Swine

796 Interval mapping detection of QTL influencing lactation patterns in Holstein cattle. S. L. Rodriguez-Zas*, B. R. Southey, H. A. Lewin, and D. W. Heyen, *University of Illinois, Urbana, IL.*

Quantitative trait loci (QTL) affecting the shape and scale of the lactation curve of production and health indicators in dairy cattle were located using microsatellite marker data. Information on 46 genetic markers distributed across bovine chromosomes 3, 6, 7, 14, 21 and 22 was available from a total of 475 sons in three Holstein families. This information was combined with protein and somatic cell score (SCS) monthly records following a granddaughter design. A nonlinear mixed effects model was used to portray the lactation curve patterns. The probability of receiving either QTL allele from the grandsire was computed at 1cM intervals using an interval-mapping approach. Estimates of the putative QTL effect were obtained at the most likely position and significance values were adjusted for multiple testing. The implemented approach uncovered QTL associated with considerable variation of the lactation patterns. Some positions were associated with significant variation of various descriptors of the lactation curve. For example, a QTL located 69-79 cM on chromosome 6 was associated with variation on both the shape and scale of the protein lactation curve in one family. Other QTL exerted their effect on one or two curve parameters, such as a QTL located 61 to 71 cM on chromosome 3. Detected QTL can be used in marker assisted selection schemes to modify lactation patterns for more efficient production. This innovative approach enhances the understanding on the genetic control of the different aspects of the lactation curve and can be applied to other longitudinal traits.

797 A genome scan to identify quantitative trait loci affecting economically important traits in an elite US Holstein population. M.S. Ashwell*, C.P. Van Tassell, and T.S. Sonstegard, *USDA, ARS Gene Evaluation and Mapping Laboratory.*

Quantitative trait loci (QTL) affecting economically important traits were studied for eight Dairy Bull DNA Repository large US Holstein grandsire families using the granddaughter design. A total of 155 microsatellite markers located throughout the bovine genome were selected for the scan. Effects of marker alleles were analyzed for 22 traits including traits for milk production, somatic cell score, productive life, conformation and calving ease. Permutation tests were used to calculate empirical trait-wise error rates. A trait-wise critical value of P = 0.1 was used to determine significance. Twelve chromosomes (BTA) had significant marker-trait associations identified from within- and across-family analyses. Two chromosomes (BTA6 and 14) had significant effects on milk composition traits and BTA7 had a significant effect on somatic cell score. Significant effects on conformation traits, especially rump angle, were found on 8 bovine chromosomes (BTA4, 9, 12, 14, 16, 18, 22 and 27). The QTL identified in this genome scan may be useful for marker-assisted selection to increase the rate of genetic improvement on traits such as disease resistance and conformation traits associated with fitness while maintaining or accelerating genetic improvement for production. Before incorporation in marker-assisted selection programs, these potential QTL must be validated in other populations or newer generations of the original families. Validation studies are underway for QTL affecting dairy form and protein percentage on BTA27 and 6, respectively.

Key Words: Quantitative Trait Loci, Conformation traits, Dairy cattle

798 Detection of quantitative trait loci for functional and conformation traits in a whole genome scan in dairy cattle. H Thomsen*¹, N Reinsch², M Schwerin³, G Erhardt⁴, and E Kalm², ¹Department of Animal Science, Iowa State University, Ames, ²Institut fuer Tierzucht und Tierhaltung, D-24098 Kiel, ³Forschungsinstitut fuer die Biologie landwirtschaftlicher Nutztiere, D-18196 Dummerstorf, ⁴Institut fuer Tierzucht und Haustiergenetik, D-35390 Giessen.

A granddaughter design, consisting of 16 German Holstein grandsires and 872 sons, was used to locate quantitative trait loci (QTL) that affect functional and conformation traits in dairy cattle. The data was part of the granddaughter design of the joint German QTL research effort of AI organisations, breeding organisations and several institutions of animal breeding. Grandsires and sons were genotyped for 247 microsatellite

markers, 8 SSCP polymorphisms, 4 protein polymorphisms, and 5 erythrocyte antigen loci covering the whole genome. De-regressed breeding values were available for 29 traits, including 20 conformation, 2 fertility, 4 birth, 2 workability, and 1 longevity trait. After determining the most likely marker haplotypes for all grandsires based on the genotypes of their sons, multi-marker regression analysis of the trait data was used to scan the genome for QTL. Chromosome-wise and experiment-wise significance thresholds were determined by permutation test. The test statistic exceeded the genome-wise significance threshold with a type I error of less than 10% for the following traits and chromosomes: rump width on chromosome 1; feet and legs, foot angle, teat placement, udder, and udder depth on chromosome 6; calving difficulties on chromosome 8;

teat length on chromosome 13; rate of stillbirth on chromosome 18, and milking speed and temperament on chromosome 29. All QTL on chromosome 6, that exceeded the genome-wise significance threshold, were located around 88 cM. QTL for rump width on chromosome 1 may have an effect on calving difficulties. QTL for udder traits on chromosome 6 and 13 may affect somatic cell score and mastitis resistance. If there are no unfavorable correlations with other economic traits, marker assisted selection using markers associated with these QTL can be applied.

Key Words: whole genome scan, quantitative trait loci, conformation and functional traits

ASAS/ADSA Growth and Development: Conjugated Linoleic Acid (CLA) in Milk Production, Growth, and Health

799 Conjugated linoleic acid (CLA) and lipid metabolism in lactating cows. D. E. Bauman^{*1}, L. H. Baumgard, B. A. Corl, E. Matitashvili, D. G. Peterson, J. W. Perfield II, and M. A. Madron, ¹Cornell University.

The uniqueness of CLA in ruminant fat relates to biohydrogenation of unsaturated fatty acids by rumen bacteria. The major CLA isomer is *cis*-9, *trans*-11 and recent work with animal models has established that this isomer is anticarcinogenic when provided as a natural component of food. Although some CLA is of rumen origin, the major source in lactating cows is endogenous synthesis via Δ^9 -desaturase from *trans*-11 C18:1, another biohydrogenation intermediate. Thus, fat content of CLA is a function of rumen outflow of CLA and *trans*-11 C18:1, plus tissue activity of Δ^9 -desaturase. Investigations of these aspects have identified dietary manipulations, regulatory processes and animal differences that can impact the CLA content of ruminant fat. Under certain conditions, the initial step in linoleic acid biohydrogenation is altered so the isomerization results in production of *trans*-10, *cis*-12 CLA. This CLA isomer affects lipid metabolism during growth and lactation. Across a range of diets a curvilinear relationship exists between the increase in milk fat content of *trans*-10, *cis*-12 CLA and the reduction in milk fat yield. Thus, rumen biohydrogenation can result in the formation of *trans*-10, *cis*-12 CLA, and possibly other unique biohydrogenation intermediates that are potent inhibitors of milk fat synthesis; we refer to this as the "biohydrogenation theory" of milk fat depression. *Trans*-10, *cis*-12 CLA is a potent inhibitor of milk fat synthesis with 3.5 g/d (0.016% dietary dry matter) resulting in a 25% reduction. Yields of all milk fatty acids are reduced, but effects are especially pronounced on those fatty acids originating from *de novo* synthesis and Δ^9 -desaturase activity. Although specific mechanisms are not well defined, recent investigations indicate that exogenous *trans*-10, *cis*-12 CLA causes substantial reductions in mammary tissue mRNA abundance for key enzymes associated with *de novo* fatty acid synthesis, uptake of preformed fatty acids, fatty acid transport and esterification, and plasticity of milk fat.

Key Words: CLA, fat, milk fat

800 The use of rumen-protected conjugated linoleic acid to reduce milk fat percentage in lactating dairy cattle. M.A. Sippel^{*1}, J.P. Cant¹, and R. Spratt², ¹University of Guelph, Guelph, Ontario, ²Agribands Purina Canada, Woodstock, Ontario.

The use of conjugated linoleic acid (CLA) has been shown to reduce milk fat secretion in dairy cattle. A rumen-protected source of CLA is required for commercial feed applications. To test the ability of different rumen-protected CLA sources to induce milk fat depression, four Holstein cows (avg. 77 DIM, 40.9 kg/d milk, parity 2.25) were randomly assigned to treatments in a 4 x 4 Latin Square design. Treatments were a control diet (0 g CLA/d), CaCLA salt providing 50 g CLA/d, GRAS-coated providing 50 g CLA/d, and liquid CLA oil providing 50 g CLA/d. Periods were 3 weeks of adjustment and 1 week of sampling. The CaCLA and liquid CLA oil caused 23.4 and 23.9% depressions in milk fat content, respectively, without affecting milk, protein or lactose yields, or dry matter intake. In a second experiment, CaCLA was fed to provide 0, 25, 50, 75 or 200 g CLA/d. Ten Holstein cows were divided into two 5 x 5 Latin Squares by parity number; square 1 multiparous (avg. 110 DIM, milk yield 35.9kg/d, parity 2.3), square two primiparous (avg. 103 DIM, milk yield 29.3kg/d). Periods were 3 weeks of adjustment, followed by 1 week of sampling. Milk fat content averaged 3.48, 2.84, 2.53, 2.47 and 2.19 % as CaCLA intake increased from 0 to 200 g CLA/d. Milk yield

was reduced by 2.19 kg/d on the 200g CLA/d treatment relative to the control. There was no effect of treatment on dry matter intakes or milk protein and lactose percentages. There was no significant difference in response due to parity. Feeding the CaCLA salt source to provide 25 to 75 g CLA/d was effective in decreasing milk fat percentage without affecting other production variables.

Key Words: conjugated linoleic acid, milk fat, rumen protection

801 Milk fat synthesis in dairy cows is progressively reduced by increasing amounts of *trans*-10, *cis*-12 conjugated linoleic acid (CLA). Lance H. Baumgard^{*}, Jodi K. Sangster, and Dale E. Bauman, Cornell University.

CLA supplements containing a variety of isomers reduce milk fat yield in a number of species. We have recently identified *trans*-10, *cis*-12 as the CLA isomer responsible for inhibiting milk fat synthesis in dairy cows (Baumgard et al. Am. J. Phys. 278:R179). Our objectives were to establish a dose-response relationship between *trans*-10, *cis*-12 CLA and milk fat synthesis, and relate effects on milk fatty acid composition to the potential mechanism of action. Multiparous Holstein cows in late lactation were used in a 4 x 4 Latin square design where treatments consisted of four doses of *trans*-10, *cis*-12 CLA: 1) 0.0 g/d, 2) 3.5 g/d, 3) 7.0 g/d, and 4) 14.0 g/d. Over the 5d treatment intervals doses were continuously infused into the abomasum as a convenient experimental means to avoid possible alterations by rumen microbes. Milk fat yield was decreased 25, 33, and 50%, and milk fat concentration was reduced 24, 37 and 46% when cows received 3.5, 7.0 and 14.0 g/d of *trans*-10, *cis*-12 CLA, respectively. Feed intake, milk yield and milk protein content and yield were unaffected by treatment. Milk fat content of *trans*-10, *cis*-12 CLA averaged < 0.1, 1.5, 3.2 and 7.0 mg/g from cows receiving 0.0, 3.5, 7.0 and 14.0 g/d of *trans*-10, *cis*-12 CLA. Comparison of milk fat composition and synthesis revealed that reductions were most extensive for *de novo* synthesized fatty acids (short and medium chain) when cows received the two highest doses, but at the low dose (3.5 g/d) decreases in *de novo* synthesized fatty acids and preformed fatty acids were similar. Changes in milk fatty acid composition also indicated that Δ^9 -desaturase was inhibited at the two high doses of *trans*-10, *cis*-12 CLA, but relatively unaffected by the low dose. Overall, results indicate that *trans*-10, *cis*-12 CLA is a potent inhibitor of milk fat synthesis. A hyperbolic dose response curve was observed and even the low dose of *trans*-10, *cis*-12 CLA (0.016% of dietary intake) dramatically inhibited milk fat synthesis (25%).

Key Words: CLA

802 Mechanisms for conjugated linoleic acid-mediated reduction in fat deposition. Harry Mersmann^{*}, USDA/ARS Children's Nutrition Research Center, Department of Pediatrics, Baylor College of Medicine.

Potential mechanisms for the decreased fat deposition observed after oral administration of conjugated linoleic acids (CLAs) to mice, rats, hamsters, humans, and pigs will be reviewed. Most mechanisms are based on experiments with rodents or rodent-derived cells. In intact mice, there is an increased metabolic rate, but not in rats or sows. There is a decreased respiratory quotient in mice and rats, suggesting increased fat oxidation. Bovine milk-fat synthesis is decreased. Rat adipocyte size is smaller, but cell number is unchanged. In mice, there is increased adipocyte apoptosis. In 3T3-L1 preadipocytes, a clonal cell line derived from rodents, CLAs decrease proliferation. Differentiation

of these preadipocytes is diminished by CLA in two laboratories, but increased in a third. In contrast to the rodent-derived cells, CLAs did not inhibit proliferation in either porcine or human preadipocytes. In both porcine and human preadipocytes, CLAs acutely increased lipid deposition, but lipid content quickly reached a plateau. Peroxisome proliferator-activated receptor gamma (PPAR γ) and PPAR alpha, key transcription factors in adipocyte differentiation and lipid metabolism require an activating ligand; CLAs are ligands for both PPARs. The concentration of PPAR γ mRNA increases during adipocyte differentiation. In both porcine and human CLA-treated preadipocytes, the increase in PPAR γ mRNA concentration was minimal, suggesting differentiation was not markedly increased. The primary CLA isomer in ruminant tissues is cis 9, trans 11-CLA. Most synthetic CLA preparations contain a considerable amount of trans 10, cis 12-CLA, in addition to 9,11-CLA. The 10,12-CLA is responsible for the body composition changes in mice and for the decreased bovine milk-fat synthesis. The two CLA isomers equally reduced lipid deposition in porcine preadipocytes, whereas there is both evidence for a preferential effect of 10,12-CLA or no isomer distinction in human preadipocytes.

Key Words: Conjugated linoleic acid, Fat deposition, Adipocyte differentiation

803 Dietary conjugated linoleic acid (CLA) influence the lipogenic enzyme activities in adipose tissue and liver of rabbit. C. Corino¹, J. Mourot², G. Pastorelli¹, and V. Bontempo^{*3}, ¹University of Milan/Italy, ²INRA, Saint-Gilles/France, ³University of Molise, Campobasso/Italy.

A study was conducted to determine the effect of conjugated linoleic acid (CLA) synthesized from sunflower oil on lipogenic enzyme activities of adipose tissues and liver of rabbit. Thirty-six NZW rabbits, half male and half female, averaging 1.80 kg LW, allotted within weight and sex to a randomised complete experimental design, were fed ad libitum conventional pelleted diets supplemented with different CLA or sunflower oil levels: 0.5 % sunflower oil (C), 0.25 % sunflower oil and 0.25 % CLA (T1), 0.5 % CLA (T2). CLA oil contains 65 % CLA isomers (Conlino, Inc., Detroit Lakes, Minnesota 56502 USA). The rabbits were slaughtered at 2.8 kg LW. Acetyl-CoA-carboxylase (CBX) activities, expressed as nmol H-CO₃⁻ incorporated min⁻¹g⁻¹ were lower T than in C animals both in perirenal (T1= 3.14; T2= 6.34; C= 7.62; P< 0.01) and interscapular (T1= 5.40; T2= 4.98; C= 8.51; P< 0.01) adipose tissues. Glucose-6-phosphate-dehydrogenase (G6PDH), expressed as μ mol NADPH formed min⁻¹g⁻¹ resulted higher in perirenal adipose tissue of rabbits fed CLA (T1= 12.88; T2= 15.33; C= 9.3; P< 0.01). The lipogenic activities of liver was not influenced by the diet. The present study indicates that lipogenic enzyme activities are modified by dietary CLA and that are differently regulated on adipose tissues and liver of the rabbit. These results are consistent with the lower fatness of CLA fed rabbits and with the different lipogenic activities of tissues in rabbit.

Key Words: Dietary conjugated linoleic acid, Rabbit, Lipogenic enzyme

804 Performance and lipid deposition in broilers fed conjugated linoleic acid. L. Badinga*, K. T. Selberg, C. W. Comer, and R. D. Miles, University of Florida, Gainesville Florida.

With the broiler industry's major thrust in further processing, a major research challenge is to identify dietary components that reduce carcass fat deposition at economically reasonable levels of dietary protein. The objective of this study was to determine if a diet supplemented with conjugated linoleic acid (CLA) alters hepatic lipid metabolism in broiler chicks. Ninety-six 1-d-old male chicks of a commercial strain were weighed and allocated randomly to either CLA (n = 48) or control (n = 48) diets. On the basis of 63.6% CLA in the CLA source obtained from BASF Germany, the CLA mix was utilized at 7.86% of the diet to meet the assigned CLA concentration of 5.0%. The control diet was supplemented with corn oil to adjust the concentrations of total fats at 7.86% in both diets. At 3 wk, birds were weighed and feed intake measured. Twenty-four birds were randomly selected from each dietary treatment group and killed by cervical dislocation. Samples of livers and thigh muscles were collected and stored at -80C until subsequent determination of dry matter, fat and protein contents. Broilers fed CLA had smaller body weights (692.2 \pm 7.6 g < 862.2 \pm 7.6g) and grew at slower rates (30.9 \pm 0.4 g/d < 39.3 \pm 0.4 g/d) than chickens fed corn oil. Although CLA feeding significantly reduced feed intake (913.6 \pm 10.8 g < 1043.8 \pm 10.8 g), the overall feed conversion was better for

the control (feed:gain = 1.27 \pm 0.01) than the treated (F:G = 1.41 \pm 0.01) group. The total liver lipid content was 25% lower in CLA-fed birds compared with corn oil-fed birds. CLA feeding increased lean tissue (+ 1.6%) and reduced fat (- 30%) contents in thigh muscle. This resulted in significant increase (+ 45%) in lean : fat ratio in broilers fed CLA. Results provide convincing evidence that CLA supplementation increases lean tissue deposition at the expense of fat accretion in broilers and may provide a novel strategy for decreasing carcass fat and enhancing the quality of poultry meat.

805 Conjugated linoleic acid (CLA) in growth and development:Mechanisms involving immunity and prostanoids. Mark Cook*¹, ¹University of Wisconsin-Madison.

Mechanisms of immune-induced wasting or decrease rates of gain suggested that during the immune response, the cytokines, interleukin 1 (IL-1) and tumor necrosis factor (TNF) are released to up regulate immune and inflammatory cell activation. However, collateral damage caused by these cytokines includes decreases in rates of gain, muscle wasting, reduced feed efficiency, and anorexia, among other physiological changes. Effective approaches to reduce cytokine-induced suppression of growth have focused on removal of the immune stimulus or immune suppression. Both strategies improve animal growth, but with apparent drawbacks. Evidence that cytokines induced wasting of muscle through the stimulation of prostaglandin synthesis in skeletal muscle led us to explore an alternative method of growth stimulation in an immune challenged environment. CLA is a structural derivative of the precursor for prostanoids reported to be involved in muscle wasting and immune response down regulation. When chicks, mice, and rats were fed CLA, then immune challenged with endotoxin or TNF, significantly less depression of growth and feed intake was observed compared to linoleic acid fed animals. Even end-stage disease wasting associated with an autoimmune disease was reduced 50%. Studies showed that CLA actually enhanced a number of immune endpoints relative to controls. To determine if CLA was having an effect on prostanoid synthesis, a sensitized guinea pig (pg) model was used. A method involving the use of HPLC tandem mass spectrometry allowed us to examine antigen-induced release of 15 different lipid mediators, including prostaglandins (PG) and leukotrienes (LT), from lung, bladder, and trachea. Basal (nonstimulated) PG and LT were not affected in CLA fed pg in all tissues tested. While antigen challenge increased the release of all PG and LT in control fed gp, all PG and LT release was inhibited in all tissues from CLA fed gp. CLA regulation of antigen-induced PG and LT was not due to fatty acid changes in the phospholipids, and did not effect the antigen-induced increases of cyclooxygenase-2 (COX-2) protein in the tissue. We postulate that CLA is regulating COX-2 enzyme activity. COX-2 regulation could explain the beneficial effects observed in CLA fed animals.

806 Dietary conjugated linoleic acid (CLA) influence the immune response in weanling piglets. V. Bontempo*¹, C. Corino², D. Sciannimanico², and S. Magni¹, ¹University of Molise, Campobasso/Italy, ²University of Milan/Italy.

The aim of this study was to determine the influence of conjugate linoleic acid (CLA) supplementation of piglets diets on some immune response parameters. Forty-two weaned piglets, 45 days old and 12.44 1.96 kg L.W., were fed diets containing different levels of CLA and sunflower oil (SFO): 0 % CLA and 1% SFO (C); 0.5 % CLA and 0.5 % SFO (T1); 1 % CLA and 0 % SFO (T2). CLA oil contained 65 % CLA isomers (Conlino, Inc., Detroit Lakes, Minnesota 56502 USA). Blood samples were withdrawn from all the piglets at 0 d and 28 d from the beginning of the experiment and analysed for serum lysozyme (Lys), total Immunoglobulin of G class (IgG), and α -1 acil glycoprotein (AGP). Lys (T2= 1.86 μ g/ml, T1= 1.77 μ g/ml and C= 1.39 μ g/ml, SEM= 0.09; P< 0.01) and IgG (T2= 2075 mg/dl, T1= 1930 mg/dl and C= 1548 mg/dl; P= 0.05) were improved by CLA dietary supplementation. No dietary effects were observed on AGP. These results support the view that CLA may influence the immune response. The lack of effects on AGP may be related to a reduction of PGE₂ production which down-regulates cytokine release and AGP release.

Key Words: Dietary conjugated linoleic acid, Weanling piglets, Immune response

807 Effects of dietary conjugated linoleic acid (CLA) on growth, carcass characteristics and meat quality of heavy pigs. C. Corino¹, V. Bontempo*², S. Magni¹, G. Pastorelli¹, R. Rossi¹, D. Sciannimanico¹, and J. Mourou³, ¹University of Milan/Italy, ²University of Molise/Italy, ³INRA, Saint-Gilles/France.

A study was conducted to determine the effect of conjugated linoleic acid (CLA) synthesized from sunflower oil on growth, carcass characteristics and meat quality of heavy pigs. Thirty-six pigs, half barrows and half females, averaging 97 kg L.W., allotted within weight and sex to a randomized complete experimental design, were fed diets supplemented with different CLA levels: 0.5% lard (C), 0.25% lard and 0.25% of CLA (T1), 0.5% of CLA (T2). CLA oil contained 65% CLA isomers (Conlinc, Inc., Detroit Lakes, Minnesota 56502 USA). The pigs were slaughtered at 172 kg L.W.. No significant differences were observed on ADG, FI, FE, dressing percentage, backfat thickness, pH and color of loin and

ham. Fatty acid composition of ham fat was significantly affected by dietary CLA. Higher levels of saturated fatty acids (C=38.5^A, T1=43.7^B and T2=41.2^B SEM=0.754), lower levels of monounsaturated fatty acids (C=46.7^A, T1=42.1^B and T2=43.7^B SEM=0.854) and higher CLA content (C=0.54^A, T1=1.01^B and T2=0.92^B SEM=0.107) were observed on fat of pigs fed CLA. These data suggest that conjugated linoleic acid have no effects on growth performances, carcass characteristics and meat quality of heavy pigs during the last fattening period. The influence of CLA on fatty acid composition of ham adipose tissue may be very important from a technological point of view for the higher content of saturated fatty acids and from a nutritional point of view for the higher CLA content.

810 Effect of feeding a raw soybean hull-corn steep liquor pellet on the metabolism and performance of lactating dairy cows. J. M. DeFrain*¹, J. E. Shirley¹, E. C. Titgemeyer¹, A. F. Park¹, and R. T. Ethington², ¹Kansas State University, Manhattan, ²Minnesota Corn Processors, Inc.

Eighteen multiparous Holstein cows (148 ± 35 DIM) averaging 41.5 kg/d ECM were used in six 3 × 3 Latin squares with 28-d periods to evaluate the effect of a raw soybean hull-corn steep liquor pellet (SHSL) on the performance of lactating dairy cows. Cows were blocked by pretreatment BW and ECM and assigned to control (C), SHSL (20% of diet DM), or pelleted raw soybean hulls (SH, 15% of diet DM). C contained 30% alfalfa hay, 15% corn silage, 34% corn, 9.3% whole cottonseed, 5% soybean meal (SBM), 2% fish meal, 0.5% blood meal, 1% wet molasses, and 3.2% vitamin/minerals. SHSL replaced 6.2% alfalfa hay, 3.7% corn silage, 6.6% corn, 3.3% SBM, and 1.7% expeller SBM replaced solvent SBM to maintain similar dietary RUP levels. SH replaced 6.2% alfalfa hay, 3.7% corn silage, and 5.1% corn. Diet CP % and energy density (Mcal/kg NEL) were 16.6 and 1.78, 16.3 and 1.73, 17.1 and 1.71 for C, SHSL, and SH, respectively. DMI of cows fed SHSL were similar to C and SH, but cows fed SH consumed more (P < 0.05) DM than cows fed C. Milk and ECM were similar for cows fed SHSL and SH, but lower (P < 0.05) for those fed C. Production efficiencies (ECM/DMI) were not affected by diet, but CP output in milk/CP intake was highest (P < 0.05) for cows fed SHSL and similar between those fed SH and C. Milk fat percent and SCC were similar for cows fed SHSL and SH but higher (P < 0.05) for those fed C. Milk fat yield and milk protein percent were not affected by diet, but feeding SHSL and SH increased (P < 0.05) milk protein yield, MUN, and PUN. BW, BCS, milk N distribution, and glucose, NEFA, and triacylglycerol in plasma were not influenced by diets. Cows fed SHSL and SH had higher (P < 0.05) total alpha-amino N in plasma, but individual amino acids in plasma were similar. SHSL can replace a portion of the forage, grain, and SBM in diets for lactating dairy cows without decreasing production.

Key Words: Soybean hulls, Steep liquor, By-product

811 The impact of feeding a raw soybean hull-corn steep liquor pellet on induced subacute ruminal acidosis in lactating cows. J. M. DeFrain*¹, J. E. Shirley¹, E. C. Titgemeyer¹, A. F. Park¹, and R. T. Ethington², ¹Kansas State University, Manhattan, ²Minnesota Corn Processors, Inc.

We used four ruminally cannulated, multiparous Holstein cows (690 kg; 21 kg/d milk) in a 2-period cross-over design to determine the impact of feeding a raw soybean hull-corn steep liquor pellet (SHSL) on induced subacute ruminal acidosis (SARA) in lactating cows. Cows were fed control (30% alfalfa hay, 15% corn silage, 34% corn, 9% whole cottonseed, 5% soybean meal (SBM), 2% fish meal, 0.5% blood meal, 1% wet molasses, and 3.5% vitamin/minerals) or SHSL (20% of diet DM) diets as TMR. SHSL replaced 6.2% alfalfa hay, 3.7% corn silage, 6.6% corn,

3.3% SBM, and 1.7% expeller SBM replaced solvent SBM to maintain similar dietary RUP levels. Periods were 15 d (10 d adaptation, 2 d for pre-challenge measures, and 3 d of SARA challenge). During d 7 to 12 cows were fed once daily at a common DMI (3.2% of BW) dictated by the cow consuming the least. Cows were fasted 12 h prior to the first SARA challenge. For each SARA challenge (d 13, 14, and 15), cows were offered 75% of their daily diet at 0600 h. The remaining 25% of diet DM was replaced by ground corn which was mixed with orts remaining 2 h after feeding and placed into the rumen at that time. Rumen fluid was collected before and 3, 6, 9, and 12 h after feeding during d 11 to 15. Ruminal pH declined linearly with time after feeding (P < 0.01), and this decrease was greater during the SARA challenges (P < 0.01). Ruminal lactate was essentially 0 on d 11 and 12 and increased linearly (P < 0.05) with repeated SARA challenges. Concentrations of total ruminal VFA increased linearly (P < 0.01) after feeding, and increases were greater on challenge days than on d 11 and 12. There were no differences due to SHSL inclusion. These data suggest the model used to induce SARA was successful and the partial replacement of alfalfa, corn silage, corn, and SBM by SHSL did not influence the response to SARA challenges.

Key Words: Acidosis, Soyhulls, Steep liquor

812 Relative nutritive value of dried versus wet brewers' grain for dairy cows. T. R. Dhiman¹, M. S. Zaman*¹, I. S. MacQueen¹, and H. D. Radloff², ¹Department of Animal, Dairy and Veterinary Sciences, Utah State University, Logan, UT 84322-4815, ²A-L Gilbert Company, Oakdale, CA.

Twenty-four lactating cows (699 41.1 kg BW; 56 25.3 days in milk) were used to study the nutritive value of dried and wet brewers' grain for dairy cows. Twenty intact and four cows fitted with a rumen cannula were blocked according to milk yield and randomly assigned to two treatments. Each treatment had ten intact and two cows fitted with a rumen cannula. Cows were fed a total mixed ration (TMR) twice a day containing either dried or wet brewers' grain at 15% of the dietary DM. The diet contained 43% forage and 53% concentrate. The experimental design was a switch back with two periods. Each period was 5 wk. First 2 wk in each period were considered as an adaptation to the diets and data from the last 3 wk were used for treatment comparisons. Total duration of the experiment was 10 wk. Once a week milk samples were analyzed for chemical compositions. Ruminal pH, ammonia-N and VFA concentrations were measured in the rumen-cannulated cows. Dried and wet brewers' diets contained 68.0 and 66.5% DM; 16.9 and 16.9% CP; 40.4 and 42.0% NDF; 24.4 and 24.5% ADF, respectively. The feed DM intake were 25.4 and 24.8 kg/d and 3.5% fat corrected milk (FCM) yield 39.8 and 40.1 kg/d for cows fed dried and wet brewers' grain, respectively. Cows fed dried or wet brewers' grain had similar (P > 0.05) feed intake, milk yield, energy intake, milk composition, feed efficiency (FCM/DMI), ruminal pH, ruminal ammonia-N and ruminal total VFA concentrations. The results suggest that the performance of cows fed either dried or wet brewers' grain at 15% of dietary DM was similar when the TMR had the same amount of DM. The storage of wet brewers' grain for a lengthy time is always a concern especially in summer. However, based on milk yield response and drying cost, it might be beneficial to feed wet brewers' grain in areas close to the brewery.

Key Words: Cow, Brewer's grain, Milk

813 Effects of mechanical treatment of high-moisture rye and wheat grains on ruminal fermentation and nutrient digestibilities in steers. K.-H. Sdekum¹, A. Schrder¹, C. Idler², T. Hoffmann², M. Klein¹, and C. Frll², ¹University of Kiel, Germany, ²ATB, Potsdam, Germany.

In maritime climates cereal grains are often harvested at dry matter (DM) concentrations below 86% that prevent direct storage as food or feed ingredient. Airtight storage without additives of high-moisture, rolled grain containing > 80 and < 86% DM has emerged as a low-cost alternative to additive-supported storage. We studied effects on nutrient digestibilities and ruminal fermentation in steers of mechanical treatments applied to wheat and rye grains after storage. Wheat and rye grains were harvested at approximately 82% DM, rolled and stored airtight in a bunker silo. Each grain type was fed in three different physical forms to six mature, ruminally cannulated steers: Rolled prior to storage (ROLLED), ROLLED plus ground prior to feeding in a mill with a 6-mm sieve, and ROLLED plus ground prior to feeding in a mill with a 3-mm sieve. Steers were fed at 1.3 times maintenance energy requirements on forage:concentrate diets (30:70, DM basis) containing > 45% starch twice daily at 0700 and 1900 h. Wheat and rye were fed in two separate trials each according to a replicated 3 × 3 Latin square design. The same 30:70 forage:concentrate diet containing a dry-ground wheat-and-rye (50:50) mix (88% DM) was fed to the same group of six steers in a separate trial. Across all trials, organic matter (OM) and starch digestibilities were not affected ($P > 0.10$) by grain type or mechanical treatment. Average whole-tract OM and starch digestibilities were 80 and 99%, respectively. As a general observation, ruminal pH values were above 6.0 for almost all hours during the 24-h cycle. On an average, ruminal pH was 0.2 pH units higher with the wheat than with the rye diets, indicating a more rapid fermentation of rye. Grain source affected ruminal pH values more than did mechanical treatment. Rolling high-moisture wheat and rye grains prior to airtight storage appears sufficient to ensure complete starch digestion while maintaining a favorable ruminal environment.

Key Words: Cereal grain, Digestibility, Ruminal fermentation

814 Dehydrated bermudagrass pellets (DBP) produced with swine lagoon effluent as a substitute for cottonseed hulls (CSH) in diets for backgrounding steers. M.H. Poore*, B.A. Hopkins, and G.A. Benson, *North Carolina State University, Raleigh.*

Production of DBP might be an option for removing high quality forage from swine sprayfields. This trial evaluated two batches of DBP (2 and 4 wk maturities) for growing cattle. Respective nutrient concentrations for the 2 and 4 wk were; CP, 19.7 and 16.5; NDF, 66.3 and 66.9; ADF, 32.6 and 35.7; and nitrate ion, 1.20 and 0.89%. Fifty-six steers (initial wt 294 kg) were individually fed for 84-d. The control diet was (DM basis) 25% corn silage (CS), 25% CSH, 20% corn, 18.5% soybean hulls (SH) and 10.7% soybean meal (SBM). Each source of DBP was substituted for 1/3, 2/3 or all the CSH to make 7 diets (control, 1/3 2 wk, 2/3 2 wk, 3/3 2 wk, 1/3 4 wk, 2/3 4wk and 3/3 4 wk = diet 1, 2, 3, 4, 5, 6 and 7, respectively). SH and SBM were adjusted to maintain CP at 13% and NDF from roughage at 43%. Substituting 2 wk DBP for CSH resulted in a linear (L, $P < .01$) and quadratic (Q, $P < .03$) effect on DMI while 4 wk had no influence (10.3, 11.0, 10.1, 8.9, 9.9, 10.1 and 9.8 kg/d for diet 1, 2, 3, 4, 5, 6 and 7, respectively). Average daily gain response to 2 wk was L ($P < .04$) while the response to 4 wk was both L ($P < .08$) and Q ($P < .05$); 1.91, 1.86, 1.74, 1.72, 1.65, 1.68 and 1.71 kg/d for diet 1, 2, 3, 4, 5, 6, and 7, respectively). Feed efficiency showed a Q response to 2 wk ($P < .05$) while the response to 4 wk tended ($P = .16$) to be Q (.186, .171, .173, .196, .167, .168 and .174 for diet 1, 2, 3, 4, 5, 6 and 7, respectively). An economic analysis was conducted assuming a value of .110, .138, .22, .039 and .088 \$/kg for CSH, corn, SBM, CS and SH, respectively, and an initial and final cattle value of 1.76 and 1.56 \$/kg shrunk wt. Assuming no value for the DBP, return over feed cost response was L to 2 wk ($P < .01$) while for 4 wk the response was both L ($P < .01$) and Q ($P < .03$), showing the DPB had value. Calculated value of DBP was .058, .193, .140, -.063, .027 and .113 \$/kg in diet 2, 3, 4, 5, 6 and 7, respectively. This study showed that DPB has potential in this type of diet, especially at the higher inclusion levels.

815 Effects of replacing dietary high moisture corn with dried molasses on production of dairy cows. G. A. Broderick* and W. J. Smith, *U.S. Dairy Forage Research Center, Madison, WI.*

Eight primiparous and 40 multiparous (8 with rumen cannulae) Holsteins were blocked by parity and DIM, randomly assigned to 4 blocks of 12 and fed TMR containing (DM basis): 40% alfalfa silage, 20% corn silage, 8% soybean meal, 2% added fat, 1% minerals and vitamins, and 18% CP. Dietary sugar was varied by replacing rolled high moisture shelled corn (HMSC) with dried molasses. The 4 diets were: 0% molasses, 29% HMSC; 4% molasses, 25% HMSC; 8% molasses, 21% HMSC; or 12% molasses, 17% HMSC. Cows were fed the 0% molasses diet for a 2-wk covariate period, experimental diets for 8 wk, then the 0% molasses diet for another 2 wk covariate. Milk yield and DMI were measured daily. Yield of milk components was determined one day in both covariates and every 2-wk in the 8-wk trial. Rumen sampling was in trial wk 4 and 8. The statistical model included block and covariate average. LS means are reported below. There was a linear increase in DMI and linear decreases in milk/DMI and milk N/NI with increasing dietary sugar. There were quadratic responses in yield of FCM and fat, and rumen NH₃, with increasing sugar; FCM and fat yield maxima and rumen NH₃ minimum occurred at about 6% molasses. Several cubic responses were noted that were related to similar milk and protein yields at 0 and 8% molasses. Replacing readily fermented starch with dietary sugar primarily increased fat yield.

816 Effects of pea silage as a forage source in high concentrate diets on ruminal metabolism and total tract nutrient utilization of steers. S. G. Wielgosz*, A. F. Mustafa, D. A. Christensen, and J. J. McKinnon, *University of Saskatchewan, Saskatoon, Saskatchewan, Canada.*

A study was conducted to determine the feeding value of pea silage (PS) relative to alfalfa silage (AS) and barley silage (BS) in high concentrate diets of beef steers on ruminal fermentation and total tract nutrient utilization. Nine steers, six of which were equipped with ruminal cannulae were used in a randomized complete block design. Finishing diets were formulated to contain 90% barley-based concentrate and 10% forage, which included either PS, AS or BS. All diets were formulated to be isonitrogenous. Steers fed PS and AS as forage sources had a similar dry matter (DM) intake (average 11.5 kg), which was greater ($P < 0.05$) than that of steers fed BS (9.5 kg). Total tract digestibility of DM and gross energy was higher ($P < 0.05$) for steers fed PS (80.9 and 80.0%, respectively) than for those fed AS (78.6 and 77.9%, respectively) or BS (77.6 and 77.0%, respectively). Forage source had no effect on total tract digestibility of crude protein, neutral detergent and acid detergent fiber. Ruminal pH was higher ($P < 0.05$) for steers fed PS relative to steers fed AS or BS while ruminal ammonia nitrogen concentration was higher ($P < 0.05$) for steers fed PS and BS compared with those fed AS. Total ruminal volatile fatty acid concentration was not affected by forage source. However, molar proportions of acetate and butyrate were higher ($P < 0.05$) while that of propionate was lower ($P < 0.05$) for

steers fed PS and BS relative to steers fed AS. It was concluded that the inclusion of PS as a forage source in finishing diets of beef steers can increase feed intake and improve nutrient utilization when compared with AS and BS.

Key Words: Pea Silage, Nutrient utilization, Ruminant metabolism

817 Prediction of the in vivo digestibility of grass silage from gas production kinetics. P. Huhtanen^{*1}, M. Ots², S. Ahvenjrvi¹, and M. Rinne¹, ¹*MTT Agrifood Research Finland*, ²*Estonian Agricultural University*.

The objective of this study was to compare in vivo OM (OMD) and NDF digestibility (NDFD) determined in sheep and those predicted from in vitro gas production data using a rumen model. Fifteen silages were made from 1st cut timothy-meadow fescue sward at different stages of maturity over three years. The rate and extent of gas production was measured using computerized gas monitoring system with pressure transducers and electric valves to release overpressure. Triplicate incubations of 72 h were made using 500 mg samples of the whole forage and NDF residue. Kinetic parameters were estimated using two-pool Gompertz model. Potential NDF digestibility (pNDFD) was determined by 12 d in situ incubation in nylon bags. Rumen digestibility of digestible NDF (RDpNDFD) was predicted using a two compartmental rumen model assuming a 50 h retention time in the fermentation compartments. In vivo NDFD was predicted as pNDFD × RDpNDFD. In vivo OMD was estimated from the predicted NDFD and applying the Lucas equation for cell solubles (OM-NDF). Total gas production (TGP) was not correlated ($R^2=0.001$) with in vivo OMD (range 61.3-83.2%). However, there was a good relationship between TGP and in vivo NDFD ($R^2=0.90$), and between TGP and pNDFD ($R^2=0.94$). Based on the Lucas equation, the true digestibility of cell solubles was 100% and metabolic faecal OM output was 96 g per kg DMI. A combination of predicted NDFD and parameters from the Lucas equation for cell solubles was a good predictor of in vivo OMD ($Y = -0.74 + 1.003X$, $R^2=0.99$; se.est 0.85). This approach was better than using kinetic parameters estimated for the whole forage ($Y = -5.50 + 1.092X$, $R^2=0.99$; se.est 1.41). Gas production method is a useful tool to estimate digestion kinetic parameters to be used in rumen models to predict in vivo NDFD and OMD of silages. The results suggest that using NDF rather than whole forage in incubations predicts feeding value of forages more accurately.

Key Words: Forage Digestibility, Gas Production, Modelling

818 Comparison of Novartis corn silage hybrids for yield, nutrient traits, and lactational performance by high producing dairy cows. E. D. Thomas¹, C. S. Ballard^{*1}, P. Mandebvu¹, C. J. Sniffen¹, M. P. Carter¹, and J. Beck², ¹*W. H. Miner Agricultural Research Institute, Chazy, NY*, ²*Novartis Seeds, Inc., Golden Valley, MN*.

Novartis N29-F1 (N29-F1), a dual-purpose 90-d relative maturity corn hybrid, and Novartis NX3018 (NX3018), a 90-d relative maturity leafy corn silage hybrid planted in replicated 15.2 × 351-m plots were compared. Parameters measured from N29-F1 and NX3018, respectively, prior to ensiling were DM yield (t/ha): 14.7, 13.7 (SE=0.69; $P=0.407$); 30-h in vitro true DM disappearance (IVTDMD) (%): 77.8, 79.9 (SE=1.04; $P=0.228$); 30-h IVNDFD (%): 49.2, 53.9 (SE=1.13; $P=0.044$); starch (%DM): 40.6, 37.0 (SE=1.34; $P=0.202$); and NDF (%DM): 39.6, 41.6 (SE=1.33; $P=0.405$). Plant fractions expressed as a proportion of whole plant on DM basis for N29-F1 and NX3018, respectively, were grain: 53.4, 49.8 (SE=0.88; $P=0.005$); leaves: 10.2, 12.3 (SE=0.21; $P=0.0001$); and stalks: 22.5, 25.1 (SE=0.81; $P=0.026$). The IVTDMD for plant fractions on DM basis for N29-F1 and NX3018, respectively, were grain: 97.6, 98.9 (SE=0.14; $P=0.022$); leaves: 71.6, 77.4 (SE=0.85; $P=0.041$); and stalks: 42.7, 53.4 (SE=2.68; $P=0.107$). The lactation study was conducted as a crossover design with two 28-d periods. Nutrient parameters of N29-F1 and NX3018 corn silages, respectively, used in the lactation trial were NDF (%DM): 40.6, 40.7; starch (%DM): 35.6, 34.6; IVTDMD (%): 77.0, 81.1; and IVNDFD (%): 45.7, 55.3. Thirty-eight mid-lactation multiparous Holstein cows (7823.0 DIM; 47.28.87 kg/cow average daily milk yield) were blocked and assigned randomly to one of two TMR containing on DM basis approximately 26% N29-F1 or NX3018 corn silage. The TMR which were formulated using the CPM Dairy[®] nutrition model, had a forage to concentrate ratio of 44 to 56%, and contained 36.5% NDF, and 17.8% CP

on DM basis. Cows were group-fed TMR for ad libitum intake. Measurements collected from the cows fed N29-F1 and NX3018 corn silage-based TMR, respectively, were milk yield (kg/d): 45.1, 46.6, (SE=0.45; $P=0.024$); 3.5% FCM yield (kg/d): 47.2, 48.9 (SE=0.61; $P=0.059$); milk fat (%): 3.90, 3.89 (SE=0.078; $P=0.973$); milk CP (%): 3.08, 3.06 (SE=0.012; $P=0.222$); SCC (×1000/ml): 143, 215 (SE=33.9; $P=0.991$); and body condition score: 3.09, 3.12 (SE=0.022; $P=0.332$). The average daily DMI across treatments was about 28.2 kg/cow. In conclusion, NX3018 was more leafy and more digestible in vitro compared to N29-F1, and cows that were fed NX3018 produced more milk than cows fed N29-F1.

Key Words: corn silage hybrids, DM yield and digestibility, dairy cow and milk yield

819 Crop processing and chop length effects in brown midrib corn silage on dry matter intake and lactation performance by dairy cows. E. C. Schwab^{*} and R. D. Shaver, *University of Wisconsin, Madison, WI*.

Brown midrib-3 corn silage was harvested at three-quarter milking stage of maturity using a crop-processing harvester with rolls set at 2 mm clearance (PR) or unprocessed (UP). Theoretical lengths of cut (TLC) were 13 and 19 mm for unprocessed corn silage treatments (13UP and 19UP), and 19 and 32 mm for the processed corn silage treatments (19PR and 32PR). Corn silage treatments were stored in four separate silo bags. Dry matter, NDF, and ADF concentrations (DM basis) of the corn silage treatments averaged 39%, 37%, and 23%, respectively. Mean particle size of 13UP, 19UP, 19PR, and 32PR corn silage treatments were 9.7, 12.0, 9.7, and 10.8 mm, respectively. Twenty-four multiparous Holstein cows averaging 102±17 DIM at trial initiation were used in a replicated 4 × 4 Latin square design with 28-d periods. Orthogonal contrasts were used to evaluate TLC (13UP vs. 19UP and 19PR vs. 32PR) and crop processing (19UP vs. 19PR) effects. Diets formulated to contain 18% CP were fed twice daily as a TMR comprised of 40% respective treatment corn silage, 20% alfalfa silage, and 40% concentrate (DM basis). The DM, NDF and ADF concentrations (DM basis) of the four treatment diets averaged 56%, 26%, and 16%, respectively. Increasing TLC reduced ($P < 0.05$) DMI in unprocessed (25.5 kg/d for 19UP vs. 26.6 kg/d for 13UP) and processed (25.1 kg/d for 32PR vs. 25.9 kg/d for 19PR) corn silage treatments. Chop length did not affect milk and 3.5% FCM yields or milk protein percentage and yield. Crop processing did not affect DMI or milk yield, but there was a trend ($P < 0.10$) for reduced 3.5% FCM in the 19 mm TLC processed corn silage treatment (40.6 kg/d for 19PR vs. 41.8 kg/d for 19UP). Milk fat percentage (3.11 vs. 3.35%) and yield (1.35 vs. 1.43 kg/d) were reduced ($P < 0.05$) by crop processing of the 19 mm TLC corn silage treatment. In this trial with brown midrib corn silage fed to mid lactation dairy cows, there were no benefits from crop processing or increasing TLC on DMI or lactation performance.

Key Words: crop processing, chop length, corn silage

820 Neutral Detergent Fiber Concentration in Corn Silage Influences Dry Matter Intake, Diet Digestibility, and Performance of Growing British and Holstein Steers. K.E. Tjardes^{*}, D.D. Buskirk, M.S. Allen, and R.J. Tempelman, *Michigan State University, East Lansing, MI*.

Twelve British (237 ± 13 kg) and 12 Holstein (235 ± 15 kg) steers were used to determine if a corn silage-based diet high in NDF depresses DMI as steers increase in body weight and to determine if a diet high in NDF has the same influence on British and Holstein steers. Steers were randomly assigned to individual slatted-floor pens and used in a crossover design consisting of six 14-d periods. Experimental diets contained corn silage from a normal hybrid (low-fiber; LF) and its male-sterile counterpart (high-fiber; HF). The LF and HF diets contained 33.8 and 50.8% NDF. The HF diet reduced ADG (0.99 vs 1.15 kg/d; $P < 0.01$) and consistently decreased steer DMI during each period ($P < 0.01$). Holsteins consumed 14.4% more DM, and gained 14.3% faster than British steers ($P < 0.01$). There was a fiber level × breed interaction ($P < 0.10$) for efficiency of gain. British steers receiving HF were more efficient than British steers consuming LF (0.188 vs 0.173); however, Holsteins consuming LF were more efficient than those receiving HF (0.186 vs 0.174). The HF treatment increased total-tract digestibility of NDF and ADF (9.4 and 8.4%; $P < 0.01$), but reduced digestibility of DM and GE (4.6

and 4.5%; $P < 0.01$), and decreased DM intake 20.5% ($P < 0.01$). Holsteins had similar digestibility of DM and GE, but had greater DE intake ($P < 0.01$) when compared to British steers. Change in DM digestibility was negatively correlated to change in DMI ($r = -0.48$; $P < 0.01$) for LF vs HF within British steers, but not Holsteins ($P = 0.42$). There were fiber level \times breed interactions for digestibility of NDF and ADF ($P < 0.10$). When comparing Holstein to British steers, digestibility of

NDF and ADF was 4.1 and 3.4% lower for LF, but was only 1.1 and 0.6% lower for HF, respectively. Results from this trial suggest that high NDF corn silage diets may reduce intake of both British and Holstein steers by physical fill, and this reduction in DMI continues as steers increase in body weight from 240 to 330 kg.

ASAS/ADSA Ruminant Nutrition: Fiber

821 Measuring neutral detergent fiber in feeds and forages. D. R. Mertens^{*1} and D. Sauvant², ¹*US Dairy Forage Research Center, Madison, WI*, ²*INRA-Institut National Agronomique, Paris-Grignon*.

Neutral detergent fiber (NDF) is an important characteristic for measuring the nutritive value of feeds and forages. For ruminants, fiber can be defined as the indigestible or slowly-digesting components of feeds that occupy space in the gastrointestinal tract, which indicates that fiber can be determined only by the animal. Measurement of fiber is a compromise between the theoretical concept and the utility of using chemical methods to isolate and measure fractions that closely resemble it. The method used to isolate it, in effect, defines a specific type of fiber; therefore, it follows that fiber methods must be followed exactly to obtain results that are valid and reproducible. The NDF method was originally designed to measure fiber in forages and has acquired the reputation of being variable and difficult to use with other feeds. However, the greatest source of variability in NDF is related to various modifications and alternative procedures. In addition, laboratories sometimes modify fiber methods for convenience or speed without understanding how these changes affect results. Many factors can affect the determination of fiber and it is important to understand the conditions and steps in fiber methods that must be followed closely to obtain accurate results. Among these are: subsampling, drying, grinding and amount of the sample, standardization of reagents, pretreatment with acetone, removal of starch and nitrogen contamination, timing and temperature of refluxing, soaking, washing and transferring of fibrous residues, type of filtration vessel, method of weighing, and correction for ash or protein. Use of heat-stable amylase to remove starches and sulfite or proteases to remove nitrogen have significant impact on NDF determinations. They also affect soluble carbohydrate estimates that are calculated by difference. The amylase-treated NDF (aNDF) method, which uses both amylase and sulfite, solves most of the problems associated with measuring NDF, and with appropriate modifications can be used to measure fiber in protein, starch, pectin and fat-containing materials.

822 Fiber requirements for finishing beef cattle - a commercial feedlot perspective. R.S. Swingle*, M.E. Branine, and K.K. Karr, *Cactus Feeders and Cactus Research, Ltd., Amarillo, TX*.

It is generally accepted that dietary fiber is necessary in diets for finishing beef cattle to maximize net energy intake above maintenance and to lessen the risk of metabolic disorders. Fiber functions primarily to assist in maintaining ruminal pH above a critical threshold. Therefore, fiber requirements must be considered in the context of the physical nature of the fiber, fermentability of diet organic matter and meal size and frequency. Finishing diets typically contain only minimal fiber (5 to 15% roughage on a DM basis) and a high concentration of readily fermentable organic matter, which magnifies the importance of feeding management for influencing feed intake patterns to minimize daily fluctuations in ruminal pH. Concepts used to optimize NDF in diets for lactating dairy cows may be useful for refining fiber requirements for feedlot cattle but have not been tested extensively. Progress in this area is hindered by a lack of consensus on appropriate response criteria for assessing fiber status and a paucity of fiber equivalency values for diet formulation. Effects of fiber source, fiber level or organic matter fermentability treatments on rate of gain might be a practical indicator of fiber adequacy under research conditions due to the direct relationship between rate of gain and net energy intake. Because particle size distribution is a major determinant of fiber effectiveness, establishing the critical particle length for fiber in finishing diets and a more complete catalogue of particle size distributions and variation in common diet ingredients would be useful. Economic and operational realities continually provide

incentives to minimize fiber in finishing diets; the challenge is to develop procedures that will more precisely determine the minimum level that is compatible with production and economic objectives of specific feeding operations.

823 Digestible fiber from forages for lactating cows. M. S. Allen*, M. Oba, and J. A. Voelker, *Michigan State University, East Lansing*.

Coarse dietary fiber benefits lactating cows through selective retention of digestible organic matter in the rumen, more consistent supply of absorbed fuels within a day, and moderation of ruminal pH. However, energy density of neutral-detergent fiber (NDF) is lower and forage NDF is more filling than other dietary components; diets with high forage NDF can reduce energy intake by mechanisms related to ruminal distention. Forage NDF that is highly digestible is less filling and allows greater energy intake. Distention becomes a dominant mechanism limiting feed intake as milk yield increases, thus response to increased in vitro NDF digestibility is positively related to milk yield of cows. Maximum extent of digestion of forage NDF is negatively related to NDF lignification and is determined by environmental conditions during growth, plant genetics, and maturity at harvest. Digestibility of NDF in vivo is further determined by ruminal retention time and rate of digestion. Rate of NDF digestion is limited by low ruminal pH, high starch diets, and availability of nutrients for microbial growth. Although digestibility of forage NDF measured in vitro or in situ is positively related to feed intake and milk yield within a forage family, grass NDF digests and passes from the rumen more slowly than legume NDF and is therefore more filling despite its generally higher digestibility. Digestibility of NDF measured in vitro or in situ is negatively related to the filling effects of NDF, but is not necessarily an index of energy content. Forages with higher in vitro NDF digestibility allow greater DMI for cows with fed intake limited by physical fill, but reduced ruminal retention time decreases differences in NDF digestibility in vivo. Although DMI and NDF digestibility are positively related, DMI by cows is less limited by distension in the gastrointestinal tract as NDF digestibility increases, and therefore diminishing returns are expected for DMI. This presentation will discuss factors affecting NDF digestibility of forages, measurement and prediction of NDF digestibility, and benefits of highly digestible forage NDF.

824 Empirical modeling of ruminal pH from dietary NDF and mean particle size. D. Sauvant^{*1} and D. Mertens², ¹*Institut National Agronomique Paris-Grignon - INRA*, ²*US Dairy Forage Research Center*.

Accurate prediction of rumen pH is a challenge in ruminant nutrition. Numerous experiments have studied some aspects of the effects of the chemical and physical characteristics of fiber on ruminal pH. The results of these studies were combined for a meta-analysis of fiber-related factors affecting ruminal pH. Two databases were compiled, the first one consisted of trials where NDF content was the experimental factor and its mean value was $< 50\%$ DM (35 publications, 46 experiments, 120 treatments; NDF = $32.2 \pm 6.2\%$ DM (mean standard deviation or sd). The second database consisted of data from experiments where dietary mean particle size (MPS) was the primary experimental factor (12 publications, 19 experiments, 51 treatments; MPS = 2.59 ± 1.48 mm). Ruminal pH were similar between the two bases (pH = 6.16 ± 0.30 , $n = 120$ and pH = 6.25 ± 0.32 , $n = 51$). A GLM model of variance-covariance was used for statistical analysis that allowed relationships

across (global) and within (local) experiments to be investigated. Variance analysis was between experiments, and covariates were either NDF content or MPS. The interactions between experiments (E) and covariates were also tested (either E*NDF or E*MPS). For the NDF database, the interactions between experiments and NDF were significant ($pH = 5.25 + 0.028 \text{ NDF} + E*\text{NDF}$, $n = 120$, $R^2 = 0.98$, $rsd = 0.09$). The response of pH to dietary NDF was greater when the experimental mean ruminal pH was low than when experimental pH was high. For instance, $dpH/dNDF = 0.037$ when mean pH = 5.8 and = 0.018 when mean pH = 6.5. There were also significant interactions between experiments and MPS ($pH = 5.67 + 0.24 \text{ MPS} + E*\text{MPS}$, $n = 51$, $R^2 = 0.98$, $rsd = 0.07$). The pH response to MPS variation was more pronounced in experiments when mean pH was low. For instance, $dpH/dMPS = 1.14$ when mean pH = 5.8 and = 0.21 when mean pH = 6.5. These analyses indicate that both NDF and MPS influence ruminal pH and that the sensitivity of rumen pH to these two factors is greater when rumen pH is less than 6.0.

825 Effect of different particle size distribution of oat silage on feeding behavior and productive performance of dairy cattle. C. Leonardi*, L.E. Armentano, and K.J. Shinnors, University of Wisconsin-Madison.

Twenty lactating Holstein cows (5 primiparous and 15 multiparous) were used in an incomplete Latin Square, with five treatments and three periods of 21 days each. Diets contained 25% corn silage, 25% oat silage and 50% grain mix (DM basis). The five treatments tested in the experiment were: Long Oat Silage (LOS), Medium Oat Silage (MOS), Fine from Long Oat Silage (FLOS), Fine from Medium Oat Silage (FMOS), and Half LOS plus half FLOS (LFLOS). LOS and MOS silages were obtained directly in the field (2 vs. 8 knives on the harvester). FLOS and FMOS were obtained by chopping LOS and MOS just prior to feeding. The mean particle size (MPS) of the diets was 4.35, 4.46, 5.19, 5.39, and 6.68 mm for FMOS, FLOS, MOS, LFLOS, and LOS respectively. MOS was designed to provide similar MPS of LFLOS, but narrower particle size distribution. Sorting is expressed as (MPS of the intake/ MPS of the diet) x100. Treatments were tested for linear and quadratic response, utilizing the MPS of the intake to calculate the contrast coefficients. No quadratic response was observed. The primary effect was a linear decrease of DMI, milk yield, and milk protein yield with longer oat silage. Feeding longer particle size increased time spent eating, ruminating and chewing per kg of DMI. Increasing particle size increased sorting. LFLOS was similar to MOS with the possible exception of eating time.

826 Partitioning in vitro digestibility of corn silages of different particle sizes. D.R. Mertens*¹ and G. Ferreira², ¹US Dairy Forage Research Center, Madison, WI, ²Universidad Catolica Argentina, Buenos Aires.

In vitro apparent (IVDMD) and true DM disappearances (IVDMT - using neutral detergent extraction) of 32 diverse corn silages were determined to partition digestion into in vitro digestible NDF (IVdNDF) and digestible neutral detergent solubles (IVdNDS) and to study the factors affecting these fractions. Dried silages were fermented whole or after grinding through 4 or 1-mm screens for 24 h in a rotating jar in vitro system. For whole silages, ranges in variables were: IVDMD, 45-78%; IVDMT, 59-83%; IVdNDF, 5-30%; and IVdNDS, 24-63%. Results for 4 and 1-mm ground silages were similar and ranges were: IVDMD, 59-82%; IVDMT, 68-85%; IVdNDF, 10-33%; and IVdNDS, 37-68%. Range in estimated TDN by the NRC summative equation (63-75%) were narrower than IVDMD. Digestible NDF accounted for 10 to 50% of IVDMD regardless of physical form, indicating that neutral detergent solubles (NDS) were the primary contributor to DM digestibility. When corrected for ash, the relationship between IVdNDS and NDSom had a slope 0.98 and intercept of zero for 1 and 4-mm silages with $R^2 > 0.95$. The relationship for whole forages was similar, but R^2 were lower and residuals were large. For 1 and 4-mm silages, R^2 were improved by the addition of total starch and IVDMD of corn grain, indicating that starch affects IVdNDS. Residual deviations were reduced for whole silages by including the proportion of DM in starch from particles >4.75 mm and silage DM. For all materials, IVdNDF was related to aNDF or aNDFom and ADL or the ratio of ADL:aNDF. For 1-mm silage, $IVdNDF = 0 + .6[aNDF - 4.5(ADL)]$, $RMSE = 2.14$. The regression coefficient for aNDF was similar for 4-mm and whole silages, but the coefficient for ADL was larger (5.1 to 8.2). The TDN summative equation agreed with 4-mm IVDMD; however, it tended to over predict dNDF and under predict dNDS (dCP + dNFC + dEE) compared with IVdNDF or IVdNDS. Improved equations for predicting corn silage digestibility will require coefficients for starch content, particle size and availability and refined relationships between ADL and dNDF.

Key Words: TDN, Fiber, Digestibility

827 Effects of pretrial milk yield on feed intake, production, and feeding behavior responses to forage particle size by lactating cows. G. M. Burato*¹, J. A. Voelker², and M. S. Allen², ¹University of Padova, Italy, ²Michigan State University, East Lansing, MI.

Forage particle size can affect dry matter intake, chewing activity, digestibility, and yield and composition of milk for lactating cows. However, it is not known if cows varying in milk yield respond differently to differences in particle size of forages in their diets. Thirty-two Holstein cows (152 ± 78 DIM; 684 ± 71 kg BW; 2.79 ± 0.66 BCS; mean \pm SD) received two diets according to a crossover design with 16 d periods. Milk yield averaged 36.6 kg/d and ranged from 24.1 to 49.3 kg/d for the 14 d prior to initiation of treatments. Diets had similar composition (DM basis: 30.8% NDF, 20.9% ADF, 19.8% CP, 23.4% starch) and differed only in the particle size of alfalfa hay (28% of dietary DM). The long diet (L) contained coarsely chopped alfalfa hay, whereas the same hay was chopped twice through a hammer mill (3.2 cm mesh screen) before being included in the short diet (S). Both diets were offered ad libitum (5% orts) as a TMR. Different DM percentages were found for L and S diets on upper (11 vs. 0%) and middle sieves (32 vs 35%) and in the bottom pan (57 vs. 65%) of the Penn State separator. Treatments had no effect on DMI, milk yield, milk fat, milk protein, change in BW or BCS, or on total chewing or rumination time per day. Eating time increased for L treatment (229 vs. 202 min/d, $P < 0.001$). Cows across the range of milk yield responded similarly to treatments. No effects of pre-trial milk yield on response to diet particle size (L-S) were observed for DMI, milk yield, or percentages of milk components. The ratio between the NDF retained by each sieve of the Penn State separator for orts and the corresponding fraction in the original diet showed that selection against coarse NDF (upper plus middle sieves) increased with pre-trial milk yield for the L diet ($R^2 = 0.23$, $P = 0.02$). This feeding behavior response reduced the original difference in particle size between

the experimental diets. Selective feeding behavior, as well as the relatively high dietary NDF concentration used in this experiment, resulted in no effect of diet particle size on feed intake and milk production.

Key Words: Lactating Cows, Forage Particle Size, Feed Selection Activity

828 In situ digestibility and ruminal retention time of feed particles with functional specific gravity higher or lower than 1.02. A. N. Hristov*¹, S. Ahvenjarvi², P. Huhtanen², and T. A. McAllister³, ¹Department of Animal and Veterinary Sci., University of Idaho, Moscow, ID 83844-2330, ²MTT Agrifood Research Finland, FIN31600 Jokioinen, ³Agriculture and Agri-Food Canada, Lethbridge Research Centre, Lethbridge, AB T1J 4B1.

Ruminal content was separated into particles with functional specific gravity (SG) higher or lower than 1.02 (HP and LP, respectively) and their mean ruminal retention times (MRT) and indigestible neutral detergent fiber (iNDF) concentrations were compared. Whole ruminal contents from two lactating cows fed an all-grass silage diet were separated into HP and LP in NaCl solution (SG = 1.02) and washed through a 200-micron mesh (HP and LP) and a 38-micron mesh (HP only). Whole grass silage (WGS) was labeled with lanthanum, HP with erbium and LP with dysprosium. In a crossover study with four Ayrshire cows and two diets (100% grass silage and 50% grass silage:50% concentrate), labeled HP, LP and WGS were pulse dosed simultaneously into the rumen and whole ruminal contents were sampled 20 times over the next 72 h to determine markers MRT. Fractions arising from wet-sieving HP and LP were incubated in situ to determine iNDF contents. Diet did not affect ($P > 0.05$) ruminal MRT of labeled particles. The MRT of LP (22.5 h) was shorter than that of WGS (29.2 h, $P < 0.05$) or HP (28.8, trend at $P < 0.1$). The 0.038-, 0.08-, 0.16-, 0.315- and 0.63-mm sieves retained more ($P < 0.05$) dry matter from HP than from LP; the 2.5-mm sieve retained more ($P < 0.05$) from LP than from HP. Except for 0.16 mm, all sieve fractions from HP contained more ($P < 0.05$) iNDF than those from LP. Overall, HP had higher ($P < 0.05$) iNDF content than LP (45.3 vs 41.8%). Across SG, iNDF content increased ($P < 0.05$) with increasing sieve size up to 0.63 mm, and was lower ($P < 0.05$) in particles larger than 2.5 mm. This study indicates that ruminal particles with SG higher than 1.02 have higher iNDF content and tend to reside longer in the rumen than those with SG less than 1.02.

Key Words: Ruminal Particles, Specific Gravity, Digestibility

829 Differences among carbohydrates in yields of crude protein from in vitro fermentation with mixed ruminal microbes. M. B. Hall*¹ and C. Herejk¹, ¹Dept. of Animal Sciences, University of Florida.

The yield of microbial crude protein (CP) from carbohydrate fermentations was examined using trichloroacetic acid (TCA) precipitation of batch cultures. The medium contained ammonium bicarbonate, casein acid hydrolysate, and cysteine hydrochloride as nitrogen sources. Isolated bermudagrass neutral detergent fiber (iNDF) and 60:40 blends of iNDF and sucrose (Suc), citrus pectin (Pec), or corn starch (Sta) (375 mg of substrate organic matter (OM)/vial) were fermented in vitro in two separate fermentation runs with mixed ruminal microbes. Three fermentation tubes for each substrate were destructively sampled at 0, 4, 8, 12, 16, 20, and 24 h. Fermented samples were precipitated at a concentration of 19.4% TCA, and filtered to collect unfermented iNDF and precipitate. Collected residues were analyzed for CP as Kjeldahl N x 6.25. Microbial CP (TCACP) was estimated as TCA-precipitated CP corrected for the TCA-precipitated CP content of substrates at 0 h, and the mean of fermentation blanks from each hour. Medium pH did not decline below 6.49 in any fermentation tube. Heterogeneity of regression analysis of TCACP yield over time for iNDF vs. other substrates, Pec + Sta vs. Suc, and Pec vs. Sta indicated that the compared curves were not parallel ($P < 0.05$). The patterns of TCACP yield over time were cubic for iNDF and Suc, and quartic for Pec and Sta. The maximal yields of TCACP predicted from the regressions were Sta: 34.0 mg at 15.6 h, Pec: 29.9 mg at 13.5 h, Suc: 25.5 mg at 12.5 h, and iNDF:13.6 mg at 19.3 h. Comparisons of maximal yields based on the hour in which the measured mean yield was greatest for each substrate in each fermentation indicated that starch > sucrose = pectin > iNDF ($P < 0.05$). All substrates showed increases in TCACP to their maxima, followed by declines in TCACP. This likely reflects the relative dominance of microbe production or degradation about the point of substrate limitation. Unlike other substrates, Suc had no detectable lag, and presented

a much flatter TCACP yield curve than the other non-NDF carbohydrates (NFC). The NDF and NFC carbohydrates examined differed in both yield and pattern of yield over time of TCACP.

Key Words: nonfiber carbohydrate, microbial protein, rumen fermentation

830 Endogenous N-losses in the digestive tract of dairy cows; influence of low digestible fiber. W.J.H. Van Gestel*¹, G. Hof¹, J. Dijkstra¹, and S. Tamminga¹, ¹Wageningen Institute of Animal Sciences, Wageningen, The Netherlands.

In dairy cattle, about 30 % of the excreted nitrogen in feces and urine is considered to be of endogenous origin. The amount of fecal endogenous N (EN) loss likely depends on amount and composition of the diet fed. In the Dutch DVE/OEB protein evaluation system, a fecal EN loss of 8 g N per kg indigestible dry matter (IDM) is expected. This figure is derived from extrapolation of observed fecal N at various N-intake levels to a N-intake of 0. In this study, the influence of IDM passage on EN loss was investigated in a more direct way in a dose response set up, with IDM administered via two routes, and in two particle sizes. Four dairy cows, fitted with a dorsal rumen canula, were fed a basal ration of a mixture of grass- and maize silage, 1:1 on DM base, and concentrates according to individual requirements. In addition to this control diet (treatment 1), the animals received 3 kg of wheat straw as 0.5 mm particles infused in the abomasum (treatment 2) or orally (3) and as chopped straw orally (4) according to a 4x4 Latin square design. The extra fecal N, relative to the control, was corrected for indigestible N in the straw (ADIN, 1.51 g/kg DS) and undigested microbial N from straw fermented in the rumen (treatment 3 and 4), assuming that per kg unrecovered extra DM 24 g microbial N was produced, with a digestibility of 85%. The corrected extra N was considered the EN-loss due to the extra IDM. The addition of straw to the basal ration resulted in a significantly enhanced fecal excretion of DM (173% of the control) in treatment 2. The recovery of the extra DM was somewhat lower for treatment 3 and 4, due to rumen fermentation of the straw. There was a significant extra excretion of EN 3.4 - 6.0 (se 1.2) g per kg extra fecal IDM, which was also significantly lower than the expected value of 8 g per kg IDM. No significant differences were observed between treatments 2, 3 and 4. Therefore, EN loss due to IDM was not influenced by particle size and way of administration of the extra DM.

Key Words: Endogenous N, Dairy Cows, NDF

831 An investigation of feeding level effects on digestibility for diets based on grass silage and high fiber concentrates at two forage : concentrate ratios. F.J. Mulligan*, P.J. Caffrey, M. Rath, J.J. Callan, and F.P. O'Mara, University College Dublin.

The objective of this study was to investigate the effect of feeding level on diet digestibility at two forage : concentrate ratios for diets containing grass silage. Four rumen fistulated Holstein/Friesian steers were used in a latin square design comprising a 2 x 2 factorial arrangement of treatments. Treatments were maintenance (M) and 1.6-M feeding level and 500 or 850 g/kg dry matter (DM) soya hulls. Digestibility was determined by total collection and rate of digestion was determined in-sacco. Fractional soya hulls rumen outflow rate (k1p) and fractional solute rumen outflow rate (k1f) were determined using Cr-mordanted soya hulls and Co-EDTA. Increasing feeding level and soya hulls inclusion decreased the digestibility of diet DM, organic matter (OM), crude protein, neutral detergent fiber (NDF), acid detergent fiber (ADF) and gross energy (GE) ($P < 0.01$). As the interaction of feeding level and forage : concentrate ratio was significant for GE digestibility ($P < 0.05$), and approached significance for DM and OM digestibility ($P = 0.06$, for both), the depression due to feeding level was greater for 850 g/kg DM soya hulls diets and the depression due to soya hulls inclusion was greater for the 1.6M diet. The rates of digestion of slowly degradable soya hulls DM ($P < 0.05$) and NDF ($P = 0.07$) and grass silage DM and NDF ($P = 0.08$ and 0.09, respectively) were lower for high concentrate diets. Soya hulls k1p and k1f increased with feeding level but only the increase in k1f was significant ($P < 0.01$). Diet OM, NDF and GE digestibility were positively related to rumen pH six hours after feeding ($P < 0.01$; $R^2 = 0.50$ to 0.69). These results indicate that feeding level induced digestibility depressions are larger for high concentrate diets due to lower rumen pH values and lower rates of concentrate and forage digestion. These effects may cause important inaccuracies in rationing systems for ruminants.

Key Words: Digestibility, Intake, Forage : Concentrate Ratio

832 Effect of a targeted B-vitamin regimen on rate and efficiency of fast growing broilers from 0 to 49 days. M Coelho, W McKnight*, and B Cousins, *BASF Corporation*.

Nine thousand eight hundred, day old male Cobb X Cobb broilers were utilized in a 5x2 factorial design (10 replications/treatment) to determine the effects of five B-vitamins (riboflavin, pantothenic acid, niacin, B12 and folic acid) fortification levels (NRC, 2X, 4X, 8X and 16X NRC) and two levels of stress (low and moderate) on the performance of 0-49 day broilers. Diets were formulated to be isocaloric and isonitrogenous. The starter diet was fed in crumble form and the grower and finisher diets in pellet form. Across stress levels, broilers at 21 days had body weights of 645^e, 666^d, 693^c, 704^b and 715^a grams and corrected feed efficiency of 1.438^d, 1.410^c, 1.388^b, 1.376^{ab} and 1.371^a when supplemented with NRC, 2X, 4X, 8X and 16X NRC B-Vitamins, respectively. Carcass dry yield increased as vitamin supplementation increased (65.5^c, 66.3^{bc}, 66.7^{bc}, 67.5^{bc} and 68.5^a% for NRC, 2X, 4X, 8X and 16X NRC supplementation, respectively) and breast meat as percent of live weight also increased (16.12^d, 16.36^{cd}, 16.75^{bc}, 17.02^{ab} and 17.19^a% for NRC, 2X, 4X, 8X and 16X NRC supplementation, respectively). Fat pad as percent of live weight decreased with increased supplementation (13.08^d, 12.72^c, 12.55^{bc}, 12.31^{ab} and 12.17^a for NRC, 2X, 4X, 8X and 16X NRC supplementation, respectively). Under moderate stress, broilers fed 4X NRC had a \$0.17/bird advantage and 42X return over the NRC treatment birds. Broilers fed 16X NRC levels had a \$0.18/bird advantage and 10X (1000%) return over 2X NRC and \$0.13/bird advantage and 8X (800%) return over 4X NRC.

Key Words: Broilers, Vitamins, Performance

833 Impact of glutamine, Menhaden fish meal and spray-dried plasma on the growth performance and intestinal morphology of broilers. G.F. Yi*¹, G.L. Allee¹, J.W. Frank¹, J.D. Spencer¹, and K.J. Touchette¹, ¹*University of Missouri-Columbia*.

A 21-day trial was conducted to evaluate the effects of glutamine (GLN), Menhaden fish meal (MFM), and spray-dried plasma (SDP) on the growth performance and intestinal morphology of broilers. A total of 378 1-d-old male broilers were randomly allotted to one of nine treatments, with six replicate pens per trt and seven birds per pen. Trt 1 was a corn-soybean meal control diet. Trt 2 to 8 were 3%, 6%, or 9% MFM or 3%, 6%, or 9% SDP diets, and a 9% MFM + 3% SDP diet, respectively. Trt 9 was the control diet supplemented with 1% GLN. Body weight (BW), body weight gain (BWG), feed intake (FI) and gain:feed ratio (G:F) were used to evaluate the growth performance. At d 3, 7 and 14, villus height (VH), crypt depth (CD) and VH:CD ratio (CVR) of duodenum and jejunum were used to compare the intestinal morphology of broilers. Breast muscle weight and tibia ash was measured to evaluate the effects of MFM on breast muscle and tibia growth at d 21. From d 0 to 3, feeding 3% SDP improved the BW and BWG ($P < 0.05$) compared to broilers on the control diet. During wk 1, feeding 3% SDP improved BW and BWG relative to all the other dietary treatments except the 6% MFM diet ($P < 0.05$). At d 21, no significant differences were observed between BW, BWG, and FI among treatments ($P > 0.05$). At d 3, feeding 9% MFM or 1% GLN tended to decrease CD of both the duodenum and jejunum compared to the birds fed the control diet ($P < 0.10$). No significant differences between VCR of either duodenum or jejunum were observed at d 3, 7 or 14 after hatch ($P > 0.05$). There were no significant differences between breast muscle weight and tibia ash among treatments at d 21 ($P > 0.05$). These results suggest that additional research is needed to understand the role that these special ingredients may have in a prestarter diet for broilers.

Key Words: Broilers, Glutamine, Spray-dried plasma

834 Impact of glutamine, Menhaden fish meal and spray-dried plasma on the growth performance and intestinal morphology of turkey poults. G.F. Yi*¹, G.L. Allee¹, J.D. Spencer¹, J.W. Frank¹, and A.M. Gaines¹, ¹*University of Missouri-Columbia*.

A 21-day study was conducted to determine the effects of glutamine (GLN), Menhaden fish meal (MFM) and spray-dried plasma (SDP) on the growth performance and intestinal morphology of turkey poults. A total of 336 1-d male turkey poults were randomly allotted to one of

eight dietary treatments, with seven replicate pens per trt and six birds per pen. Trt 1 was a corn-soybean meal control diet. Trt 2 to 7 contained 3%, 6%, 9%, or 12% MFM, or 1.5% and 3% SDP, respectively. Trt 8 was the control diet supplemented with 1% GLN. Body weight (BW), body weight gain (BWG), feed intake (FI) and gain:feed ratio (G:F) were used to evaluate the growth performance. Villus height (VH), crypt depth (CD) and VH:CD ratio (VCR) of duodenum and jejunum were used to compare the intestinal morphology of birds at 7 and 21 days after hatch. From d 0 to 7, feeding 1% GLN improved the BW, BWG and G:F compared to birds fed the control diet ($P \leq 0.05$). Compared with the birds fed the control diet, the addition of MFM was 3% to 12% resulted in a linear increase ($P < 0.05$) in BW, BWG, and G:F, and SDP addition from 1.5% to 3% resulted in a linear increase ($P < 0.05$) in G:F. During wk 2, the addition of MFM resulted in a linear increase ($P < 0.05$) in FI relative to birds on the control diet. From d 0 to 14, feeding 1% GLN improved the G:F relative to all the other dietary treatments except the 12% MFM diet ($P < 0.05$). At d 21, there were no significant differences between BW, BWG, and FI among treatments ($P > 0.05$). Compared with the control diet, feeding 1% GLN improved the G:F significantly ($P < 0.05$). At d 7 or 21 after hatch, no significant differences were observed between the VH, CD, or VCR in the duodenum or jejunum among treatments ($P > 0.05$). These results indicate that these special ingredients may have a beneficial role in prestarter diets for turkeys.

Key Words: Turkeys, Fish meal, Glutamine

835 Apparent ileal digestibility of amino acids in soybean meal, Menhaden fish meal, catfish meal and spray-dried plasma in young broilers. G.F. Yi*¹, G.L. Allee¹, H.J. Liu¹, J.W. Frank¹, and J.D. Spencer¹, ¹*University of Missouri-Columbia*.

This trial was conducted to determine the apparent ileal digestibility of amino acids (AA) in soybean meal (SBM), menhaden fish meal (MFM), catfish meal (CFM) and spray-dried plasma (SDP) in young broilers. A total of 120 21-day-old male broilers (809±20 g) were randomly allotted to one of the four dietary treatments with six replicate pens per trt and five birds per pen. All birds were fed similar diets prior to being fasted for 20 h. Birds were then refed semi-purified corn starch diets for 5 h, where SBM, MFM, CFM or SDP served as the only AA source. Chromium oxide (Cr₂O₃ at 0.1% of diet) was supplemented as the indigestible marker. After refeeding, all the birds were killed to collect ileal digesta (the ileum defined as the portion of the intestine extending from the Meckel's diverticulum to the ileo-cecal junction). The AA and Cr₂O₃ content of the experimental diets and ileal digesta were measured to calculate the apparent ileal AA digestibility. The results indicated that among those four tested AA source, SDP had the highest AA digestibility while CFM had the lowest Lys, Met+Cys, Thr, Trp, Leu, Ile, Val, Phe+Tyr, Arg, His, Gly, Ser, Asp, Glu, Pro, Ala, essential AA, non-essential AA, and total AA digestibility ($P \leq 0.01$). Compared with SBM, MFM had higher Cys+Met, Leu, Thr, Ile, Val, Gly, Pro, Ala, essential AA, and total AA digestibility ($P \leq 0.01$). This research shows that the AA digestibility of SDP for young broilers is higher than all other tested protein sources. Compared to SBM, MFM was found to have higher digestible AA for young broilers, while CFM was found to be inferior to SBM.

Key Words: Fish meal, Ileal AA digestibility, Spray-dried plasma

836 Evaluating potential value-added sorghums for the poultry industry. A Johnson*, J Fulton, J Akridge, and M Latour, *Purdue University, West Lafayette, Indiana, USA*.

Sorghum is considered in broiler feed formulations in the regions where broiler and sorghum production overlap. Nutritionists have noted sorghum's variability of crude protein and essential amino acids (CP-EAA) as problematic in poultry diets. The sorghum industry is seeking opportunities to develop specialty hybrids that meet the needs of the poultry industry and ensure a long-term customer. One possibility is to address the main concern of many nutritionists about sorghum by reducing the variation of CP-EAA. Other possibilities that could be coupled with this reduction in variation of CP-EAA include an increase in the concentration of lysine and an increase in the CP-EAA levels. The expectation is that all three enhanced sorghums would result in more efficient broiler production through less waste of feed nutrients. The

benefits these enhanced sorghums might bring to the broiler industry could also be displaced by technology. The use of Near Infrared (NIR) grain analyzers would allow the mixing of rations using the actual nutrient profile of the ingredients. This process is expected to reduce the amount of wasted nutrients. This study estimates the effects on feed expenditures for five alternative scenarios: a BASE scenario (simulation with currently available sorghums), a sorghum hybrid with a reduced variation in CP-EAA (RV), a sorghum hybrid with RV and enhanced lysine concentration, a sorghum hybrid with RV and higher levels of CP-EAA (HPRV), and the adoption of NIR technology. The impacts of the enhanced sorghum and technology scenarios are determined by comparing estimated feed expenditures to the BASE scenario. The simulation model incorporates a least-cost feed formulation, stochastic CP-EAA levels of feed ingredients, and a broiler growth model. The simulation was run for each scenario for five years. Annual prices paid by poultry producers were used. The HPRV scenario was the only one that was in the efficient set for all three of the efficiency criteria used. This indicates that a sorghum hybrid that has increased levels of CP-EAA coupled with a reduction in the variation of CP-EAA holds the most promise for the broiler industry in terms of feed expenditure efficiency.

837 Effects of seed coat and plant color in sorghum on growth of broiler chicks. C. L. Jones^{*1}, J. D. Hancock¹, J. F. Pederson², C. W. Starkey¹, and D. J. Lee¹, ¹*Kansas State University, Manhattan, KS*, ²*USDA-ARS, Lincoln, NE*.

A total of 960 broiler chicks (1 d old) were used in a 14-d growth assay to determine the effects of seed coat (pericarp) and necrotic plant color on growth performance. Treatments in the experiment were sorghums with: 1) red pericarp/purple plant color; 2) red pericarp/tan plant color; 3) white pericarp/purple plant color; and 4) white pericarp/tan plant color. The 20 sorghum lines used in the experiment were 97% genetically identical except for those genes for pericarp and plant color. The sorghums were ground through a Prater Pulverizer[®] hammermill to a mean particle size of 600 microns and incorporated into diets with 1.2 % lysine, 1.1% Ca, and 0.5% available P. When the diets were fed to chicks, no differences were observed for ADG ($P > 0.36$) or ADFI ($P > 0.35$). As plant color was changed from purple to tan in the red pericarp sorghums there was little effect on gain/feed, but in the white sorghums, gain/feed tended to increase as plant color was changed from purple to tan (pericarp x plant color interaction, $P < 0.06$). In conclusion, pericarp and plant color did not affect ADG or ADFI of broiler chicks. But, there was a trend for improved gain/feed when white seed coat color was combined with tan plant color.

Item	Red/purple	Red/tan	White/purple	White/tan	SE
ADG, g	23.1	23.0	22.8	23.3	0.4
ADFI, g	32.6	32.7	32.9	32.2	0.5
Gain/feed, g/kg	709	703	693	724	9

Key Words: Sorghum, Food-quality, Chick

838 The effect of using different levels of tilapia by-product meal in broiler diets. L. E. Ponce and A. G. Gernat^{*}, *Escuela Agrícola Panamericana/Zamorano, Tegucgalpa, Honduras*.

The tilapia industry in Central America has grown significantly. Much waste is generated by the industry due to the fact that only the myomere muscles are removed (filleted) and commercialized. This portion constitutes approximately 36% of the entire fish, leaving the remaining 64% of the fish as waste lost during the various processing operations. This waste from the tilapia processing plant has the potential of being an alternative protein source in broiler rations. The objective of this study was to measure the effect of substituting different levels of tilapia by-product meal (TM) for soybean meal (SBM) in broiler diets. For the experiment 0, 10, 20, 30, 40, and 50% of the crude protein contributed by the SBM in broiler diets was substituted by crude protein from TM. The control and five levels of TM were used in a corn-soybean based diet and fed to chicks from 0-42 days. Chicks were identified and randomly allocated in a randomized complete block design. Body weight, cumulative feed consumption, feed conversion ratio, and mortality were determined on a weekly basis. At processing, carcass weights and yields were determined on a prechilled basis. Results show that the 10 and 20% TM group had significantly ($P \leq 0.05$) improved body weights from 14

to 28 d of age compared to the other treatments. No significant differences were found for the remaining 35 to 45 d body weights, cumulative feed consumptions, feed conversion ratios, mortalities, carcass weights or yields for any of the treatments. In conclusion, this particular TM can be used at levels up to 50% without negatively affecting bird performance or carcass quality.

Key Words: Tilapia, Tilapia by-product meal, Soybean meal

839 Nutritional value of wheat screenings for broiler chickens. G Audren^{*}, H Classen, and K Schwan, *University of Saskatchewan, Saskatoon, SK, Canada*.

Two trials were conducted to study the nutritional value of two wheat screening samples in broiler diets. Experiment 1 evaluated the chemical composition, energy, and amino acid digestibility of two wheat screening samples. Experiment 2 evaluated the performance of 1980 female broiler chickens, housed in straw litter pens, and fed different levels of the two wheat screening samples. In the latter study, the wheat screening samples replaced 0%, 25%, 50% and all of the wheat in diets fed to broilers. Each diet had 6 replications with 55 birds per replication. The metabolisable energy, protein content, and mean ileal amino acid digestibility were 3107 kcal/kg, 15.77%, 83.3%, and 3023 kcal/kg, 15.19%, 80.4% for the wheat screening samples 1 and 2, respectively. The samples contained 90.5% or 88.2% wheat and the major weed seed in both samples was wild buckwheat, which was 4.5% or 6.3% in samples 1 and 2, respectively. In the broiler feeding trial, no significant differences were found between the wheat diet and those containing wheat screenings with regards to growth, feed efficiency, and mortality. There were variations in the composition of wheat screening samples, however in this study, these variations did not significantly affect the performance of broiler chickens. Wheat screenings totally replaced wheat in balanced broiler diets without affecting performance.

Key Words: Broiler, Feed, Wheat Screenings

840 Use of cottonseed meal for broiler breeder pullets. N. M. Dale^{*}, J. L. Wilson, and A. J. Davis, *University of Georgia*.

The two major challenges facing producers of broiler breeder pullets are: 1) to prevent the accumulation of excess body weight, and 2) to maintain a reasonable degree of body weight uniformity in the flock. It is frequently difficult to maintain satisfactory flock uniformity while imposing the degree of feed restriction needed to maintain appropriate body weights during the rearing period especially when using soybean meal as the main dietary protein source. It is hypothesized that by using a less nutrient dense protein source, such as cottonseed meal (CSM), it may be feasible to restrict body weight gain in developing pullets without having to resort to extreme feed restriction. This should lead to improved flock uniformity. In a preliminary study, 8 replicates of 8 mixed sex Ross x Ross chicks were assigned to each of four dietary treatments: 1) a typical broiler starter diet, 2) a soy based pullet rearing diet, 3) a cottonseed meal (with added soapstock) based diet, formulated to the same nutrient specifications as #2, and 4) as #3, with soapstock-free CSM. After two weeks, body weights (relative to diet 1 were 75.1, 63.1, and 62.7%, respectively. Relative feed conversions were 131.5, 138.5, and 149.2%, respectively. These data confirm the potential of CSM in restricting growth. In a subsequent experiment, six hundred Cobb breeder pullets were reared to 2 weeks of age on a standard pullet starter diet. At this time, they were divided into two treatments of 300 pullets each and reared on pullet grower diets with either soybean meal (SBM) or cottonseed meal (CSM) as the major protein source. Feed was administered to both treatments so as to achieve the body weights recommended by the breeder. Pullets receiving the CSM diet gained less weight than those receiving the SBM feed, even though they consumed approximately 15% more feed than SBM controls. This led to an improvement in body weight uniformity.

Key Words: Broiler breeder pullets, Cottonseed meal

841 Comparison of broiler performance and carcass characteristics when fed B.t., parental control or commercial varieties of dehulled soybean meal. C.A. Kan*¹, H.A.J. Versteegh¹, T.G. Uijttenboogaart¹, H.G.M. Reimert¹, and G.F. Hartnell², ¹ID-Lelystad, P.O. Box 65, 8200 AB Lelystad, The Netherlands, ²Monsanto Company, 800 N Lindbergh Blvd, St. Louis MO 63617.

The nutritional value of diets containing solvent extracted dehulled soybean meal from (transgenic) B.t. soybeans and soybean meal from control and commercial lines of soybeans—all comparably processed—on broiler performance was evaluated and effect on carcass yield and body composition assessed. The following soybeans were included in the study: a non-transgenic soybean parental control line (A3237), two test lines (726 and 781) and seven commercial varieties (A1900, A2069, A2247, A2869, A3244, A4341 and A4922). The study lasted for 41 days and each treatment group consisted of ten replicate pens (5 with males and 5 with females) starting with 12 broilers and culled to 9 broilers per pen at 13 days. Day old sexed commercial Ross 508 broilers were used and bodyweight and feed intake were measured per pen at 41 days. At 42 days 4 broilers per pen were slaughtered and yields were determined. The carcasses were dissected later and cut-up yields of the valuable parts determined. Dry matter, protein and fat contents of breastmeat were determined on the excised material. Birds performed exceptionally well with body weights and feed conversion averaging over 2400 g and less than 1.60, respectively, at day 41. The data were analysed by an ANOVA procedure. There were no significant treatment x sex interactions. The effect of sex was (as could be expected) significant for some traits. All performance (final weight, feed conversion), carcass yield (weight, slaughter, evisceration, breastmeat, thigh, drumsticks, wings, remaining yields) and breastmeat composition (dry matter, protein and fat) measurements of broilers fed B.t. soybean meal were comparable ($P > 0.05$) to those fed their respective controls and the population fed commercial soybean meals. B.t. soybean meal is substantially equivalent to non-B.t. soybean in nutritional value.

Key Words: Soybean Meal, Nutritive Value, Broiler Body Composition

842 Evaluation of identity preserved soybean meal and amino acid density in broilers. R A. Swick*¹ and K. Huang², ¹American Soybean Association, Singapore, ²Gold Coin Services, Singapore.

A broiler study was conducted in Malaysia to compare performance of broilers fed diets containing identity preserved (IP) U.S. soybean meal (SBM) or commercially available (CA) SBM obtained from a local feed mill. Each meal was incorporated into diets containing 90%, 100% and 110% of NRC recommended minimums for amino acids (constant energy) resulting in a 2 x 3 factorial arrangement of treatments. Equal numbers of feather sexed Cobb 500 broilers were grown in 48 slatted floor pens (70 per pen) for an initial total of 3,360 birds. Analytical results of the SBM for CP (Kjeldahl), CF, DM, lys, met, thr, available lys, urease, protein dispersibility index, protein solubility in 0.2% KOH and initial predicted ME(n) were: IP- 49.8, 2.49, 88.3, 3.07, .72, 1.92, 2.86, .02, 28.7, 77.8, 2513; CA- 48.2, 2.01, 89.1, 2.96, .67, 1.88, 2.73, .02, 28.0, 76.4, 2506 respectively. Starter, grower and finisher diets were least cost formulated based on the nutrient values analyzed and prevailing local market prices for corn, corn gluten meal, meat and bone meal, SBM, palm oil, D,L-methionine, L-lysine HCL, L-threonine, vitamins and minerals. At 49 days, no differences were detected in performance of birds fed the different soybean meals ($P > .05$). Feed cost and feed cost per kg liveweight however, were less with the IP meal because of its higher nutrient levels. For amino acid density (across soybean meal sources), body weight (g) and feed conversion were: 90%: 2.228^a, 2.042^a; 100%: 2.443^a, 1.955^b; 110%: 2.465^a, 1.950^b. No SBM by amino acid density interactions were detected ($P > .05$). In conclusion, the results show that commercial diets should be formulated based on analyzed nutrient levels of SBM and that cost-performance should be considered before formulating with higher than recommended amino acid levels.

Key Words: Soybean meal, Identity preservation, Amino acids

843 Chemical analysis and feeding value of heat damaged soybean meal. Budi Tangendjaja*¹ and Robert A. Swick², ¹Research Institute for Animal Production, Bogor, Indonesia, ²American Soybean Association, Singapore.

An evaluation of soybean meals (SBM) collected from a heat damaged commercial shipment to Indonesia was conducted. Three distinct samples with colors of dark, tan and normal from the damaged shipment were compared to two other samples from a different shipment considered to be undamaged and of acceptable quality. SBM samples were analyzed chemically for proximate, protein solubility in 0.2% KOH (KOHPS), protein dispersibility index (PDI), urease activity, amino acids and available lysine (AL). Each SBM was incorporated into the same starter diet formulation and fed to broilers in battery cages from 0 to 3 weeks of age. There were 7 birds per cage and 7 cages per replicate with a completely randomized arrangement of treatments. Data was subjected to statistical analysis using the MSU-Stat program. SBM samples did not differ in proximate composition but KOHPS and PDI decreased as color became darker, from 75.4 to 72.3% and from 21.8 to 15.3% respectively. PDI was more affected by heat damage than was KOHPS. The darkest SBM was lowest in total lysine and threonine compared to undamaged SBM. Birds fed diets containing the darkest SBM had 15% less body weight (524 vs. 617g; $P < .05$) and 10% poorer feed:gain ratio (1.602 vs. 1.451; $P < .05$) after three weeks compared to those fed undamaged SBM. Feed:gain ratio was negatively correlated to total lysine (-.99) and AL (-.97). KOHPS and PDI were less strongly correlated to bird performance. In conclusion, feeding value of soybean meal is impaired by heat damage resulting in darkened color. Available lysine and PDI are useful measures of damage in commercial SBM samples.

Key Words: Soybean Meal, Broilers, Protein Dispersibility Index

844 Effect of storage time on the quality of different sources of soybean meal. B. Tangendjaja*¹, E. Wina¹, and R. A. Swick², ¹Research Institute for Animal Production, Bogor, Indonesia, ²American Soybean Association, Singapore.

An experiment was conducted to measure changes in quality of different sources of soybean meal (SBM) stored under tropical conditions. Samples of U.S. dehulled (USD), Brazilian dehulled (BD) and Brazilian non-dehulled (BND) SBM were collected and divided into 6 sealed polyethylene bags each containing 10 kg. One sample of each meal was stored in a warehouse under ambient conditions (ave 27° C and 60-85% RH) and the remaining five were stored in a freezer at -30° C. Each month one bag of each SBM was taken out of the freezer and allowed to be stored in the warehouse. At end of the 5 month period, the SBMs were analyzed for moisture, protein, fat, urease activity (UA), protein dispersibility index (PDI), protein solubility in 0.2% KOH (KOHPS), amino acids, digestible amino acids predicted by NIR, available lysine and 3 week broiler performance. PDI value decreased from 24-30% to 16-25% during 5 months storage but KOH PS did not change significantly. Moisture content increased slightly during storage but protein and fat did not. Total amino acids did not change during storage but digestible lysine predicted by NIR decreased at an average rate of -.019% per month. Individual decreases were: USD -.016%, BD -.025%, BND -.017% NIR digestible lysine per month. No differences in available lysine were detected. UA increased slightly during the 5 month period from 0.10-0.15 to 0.21-0.28 pH unit change. Each SBM sample was incorporated into a balanced diet and fed to 3 replicates of 7 birds per battery cage from 0 to 21 days. Body weight was not affected ($P > .05$) but feed:gain was negatively affected from 1.47 at time zero to 1.52 after five months storage under warm and humid conditions ($P < .05$). In conclusion, SBM quality decreases measurably during storage under tropical conditions. PDI and NIR digestible lysine are useful indicators of these changes.

Key Words: Soybean meal, Protein dispersibility index, Storage

845 Effect of heating solvent extracted soybean in the presence of cysteine or sulfite on ileal true digestibility of protein in broiler chicks. E.L. Miller*, Y.X. Huang, O.C. Fabb, B. Rayner, and S. Kasinathan, Department of Clinical Veterinary Medicine, University of Cambridge.

The objective was to test whether the previously demonstrated effect of cysteine (C) or sulfite (S) in increasing reactive SH and reducing the

heating time needed to reduce trypsin inhibitor (TI) content of soybean resulted in improved ileal true digestibility (TD) of protein. Petroleum spirit-extracted dehulled soybean (TI 58.4 mg/g DM) was adjusted to 780 g/kg DM and heated alone or with either sodium metabisulphite (11.8 g/kg DM) or cysteine (15 g/kg DM) for 25, 35, 55 or 75 minutes at 95°C. Reactive SH, determined by reaction with 4-vinyl pyridine and HPLC separation, was increased by C and S and decreased with heating time. Heating decreased TI 3.9 times faster in the presence of S but not of C. Each of these 12 preparations was included as the sole source of protein in diets formulated for chicks to provide 150, 200 or 250 g CP/kg diet. A diet with enzyme hydrolysed casein plus amino acids (E) as the sole source of protein at 200 g CP/kg diet was used to measure endogenous loss. Chromic oxide was the marker. The diets were offered to 3 cages of 3 chicks (E to 9 cages) ad libitum for 3 days (8 to 10 d of age). Food was removed overnight on day 10 and each cage was fed at timed

intervals ad libitum on day 11 for 4 hours before euthanasia with pentobarbitone sodium given intra peritoneum. TD was calculated as 1-slope of the regression of ileal N per g diet on diet N per g diet using diet E as a zero test dietary N level together with the 3 levels of each test material. TD (mean SEM) soybean alone 0.670.029, 0.780.037, 0.790.026, 0.870.009; +C 0.720.028, 0.860.023, 0.870.014, 0.860.018; +S 0.880.021, 0.890.014, 0.890.013, 0.880.010 at 25, 35, 55, 75 minutes respectively. TD of soybean alone increased with heating time to 75 minutes. The same maximum TD was achieved in 35 minutes with added C and in 25 minutes with added S. The TD achieved with added S was slightly but not significantly greater than the maximum achieved on heating soybean alone (difference 0.0250.0160, *t* 1.56).

Key Words: Ileal digestibility, Sulphite, Heat

AMSA Updates Session

846 Korean Pork 101. D.E. Burson^{*1}, D.B. Griffin², and W.N. Osburn³, ¹University of Nebraska, ²Texas A&M University, ³Michigan State University.

The changing economy and society in Korea combined with market liberalization is changing the Korean meat industry. Western style retailing is being adapted in Korea and has created a need for training. Therefore, the U.S. Meat Export Federation has established the Meat Education and Research Center (MERC) in Seoul, Korea to train butchers and meat retailers in the latest meat merchandising techniques. The National Pork Producers Council, the US Meat Export Federation, Korea, and meat scientists from the University of Nebraska, Texas A&M University and Michigan State University developed a train the trainer program, Korean Pork 101, for MERC instructors. Korean Pork 101 was designed to provide up to date information on pork quality, consistency and value. The course included topics of teaching and workshop methods, an overview of pork production in the U.S., pork quality, meat distribution and shelf life, fabrication value and merchandising, pork specifications, carcass fabrication and pork safety. The three day workshop was conducted with a series of lectures and discussion during an afternoon session and a laboratory demonstration in the evening. Approximately thirty instructors were trained and evaluations indicated that the program was valuable.

Key Words: pork, training, Korea

847 Advanced HACCP course update. N.G. Marriott^{*1}, ¹Virginia Polytechnic Institute & State University.

Since January 25, 2000 all inspected meat and poultry plants are required to have a food safety preventive program known as Hazard Anal-

ysis and Critical Control Points (HACCP). The American Meat Science Association (AMSA) and various professional members have been instrumental in the development of educational material, especially short courses, that has assisted the meat and poultry industry with the implementation of this food safety program. Regulatory requirements of HACCP plan assessment with an emphasis on verification and validation has been attributable to the International HACCP Alliance interest in the accreditation of an advanced HACCP course that will emphasize instruction about verification and HACCP plan validation. During 2000, the AMSA Continuing Education Committee accepted the challenge of the development of an advanced HACCP course to be accredited by the International HACCP Alliance. It was agreed that the content of this course would be developed by AMSA members. The AMSA Continuing Education Committee agreed upon a course content outline and one or more scientists for the development of this 2-day short course. It was decided that the course would be developed as PowerPoint presentations with appropriate handouts and supplementary materials that would be peer reviewed before the AMSA Continuing Education Committee would obtain accreditation from the International HACCP Alliance. The course content will become the property of the American Meat Science Association but available for members' use to present as a short course to the industry. More information about the course content will be discussed. Furthermore, a progress update of material development, peer review, accreditation by the International HACCP Alliance, and material availability to the American Meat Science Association membership will be provided.

Symposium on Concentrated Animal Feeding Operations Regarding Animal Behavior, Care, and Well Being

848 Physiological indicators of stress in domestic livestock. Donald C. Lay Jr.^{*}, *Livestock Behavior Research Unit, Agricultural Research Service-USDA, West Lafayette, IN.*

As with most mammals, domestic livestock will experience varying degrees of both psychological and physiological stress at some time during their life. The objective quantification of these stressful states and application of appropriate measures to limit excessive exposures to stressors is imperative. Proper management of an animal's exposure to stressors will maximize animal well-being and can have beneficial effects on animal production. Although scientists have recognized the deleterious effects of stress for more than 70 years, debates and questions on physiologically assessing its presence in humans and other animals continues to challenge researchers today. Because stress can be defined simply as any physiological change from homeostasis, traditional physiological measurements have relied on quantifying these alterations to homeostasis, such as deviations in heart rate, respiration rate, body temperature, and hormone concentrations. These measurements are still highly relied upon today. It is also well recognized that when these common alterations in baseline homeostatic mechanisms are dramatically altered, an organism's life strategies such as growth, disease resistance, and reproduction can be affected. Therefore, a great deal of research has concentrated on quantifying physiological alterations in these systems, such as

changes in growth and reproductive hormones, changes in populations of lymphocytes, and (or) outward signs of failure of these systems, such as low growth rates, infertility, and an increased number of diseased animals. An area of importance that has been relatively inaccessible are those changes that occur in the central nervous system. Because stress is commonly composed of both a physiological and psychological component, how the animal perceives the stress is critical to assessing its well-being. Physiological measures used thus far to assess the mental response to stress include neuronal activity and measurement of neurotransmitters. Scientists have done a good job of measuring all of these physiological alterations, unfortunately the underlying challenge that continues to confront scientists is how to define the degree of physiological change that translates into distress for the animal.

Key Words: Stress, Livestock, Well-being

849 Influence of stress on composition and quality of meat, poultry, and meat products. E. P. Berg^{*}, *University of Missouri.*

Stress experienced by meat-producing animals prior to slaughter not only influences lean and fat deposition, but also the physicochemical components involved in conversion of muscle to meat. Stressors that

trigger a physiological response can be short term (loud noise, unfamiliar environment, fighting, electric prod goading) or long term (sickness, dehydration, malnourishment, hot/cold stress). Postmortem metabolism in porcine and certain poultry muscles is more rapid than beef or lamb. Metabolism of intramuscular glycogen plays a primary role in the expression of unfavorable meat quality attributes such as dark cutting beef or pale, soft, and exudative (PSE) pork. The level and extent of post-mortem pH decline is glycogen dependent because anaerobic conversion of glycogen to glucose to lactic acid results in an acceptable (or unacceptable) ultimate meat pH. Activation of the sympathetic nervous system in response to a stressor results in mobilization of energy (glucose) from storage (glycogen). Prolonged activation may leave a lesser concentration of glucose available for conversion to lactic acid. The resulting meat will have a high pH (closer to physiological pH), a dark, dry appearance, reduced consumer appeal, a shorter shelf life, and (depending on duration) reduced levels of marbling. Activation of the sympathetic nervous system immediately prior to slaughter is particularly detrimental to swine and poultry. The fight or flight response initiates glycogenolysis and elevates heart rate, blood pressure, and muscle temperature. In this state, stunning and exsanguination will trap heat and lactic acid in the muscle as the system converts to anaerobic metabolism. The accumulation of lactic acid results in a rapid pH decline while the carcass temperature is high. This leads to denaturation and shrinkage of myofibrillar proteins that bind water, and to the development of PSE meat that has little consumer appeal and limited functional value in further processing. The entire meat production system must strive to produce a high-quality product that consumers will purchase repeatedly. Management techniques that reduce preslaughter stress are more easily controlled than postmortem chemical reactions.

Key Words: Stress, Meat quality, Meat production

850 The Free Farmed Program in the US and the Freedom Food Program in the U.K. Adele Douglass*, *Farm Animal Services, 236 Mass Ave., NE, #203, Washington, D.C. 20002.*

A presentation on the Freedom Food Program in the United Kingdom and a history of how the Free Farmed Program came about in the United States. A discussion of the Program description, what are the standards and the costs involved, what are the certification requirements, the assessments and the audits.

Key Words: Farm, Animal Welfare, Animal Behavior

851 Impact of public perception on current and future livestock and poultry production. G. J. Coleman*¹ and P. H. H. Hemsworth², ¹*Monash University, 2**University of Melbourne.*

It is well documented that there is a complex set of economic, political, social and personal factors which impact poultry and livestock production and marketing. It has, however, proven difficult to systematize current knowledge in this area. The aim in this paper is to identify the facets of public perception which impact livestock and poultry production practices and to suggest future impacts on the one hand and possible moderating strategies on the other.

Public perception comprises general attitudes and personal attitudes. General attitudes are those opinions which are collected by surveys and reflect peoples' opinions but, because they are not specifically directed to a particular behaviour, may not be expressed in a specific behaviour. It is useful to distinguish these public opinions from personal attitudes that an individual holds, which are derived from experience and which direct behaviour. Understanding this distinction and the differential impact of the two is important in predicting their effects on future poultry and livestock production and the relevance of education and regulation. Private attitudes are direct predictors of behaviour and are relevant to, for example, meat buying behaviour. General attitudes, on the other hand, influence politicians and regulatory bodies and lead to changes in trade policy and other regulations.

Sustainable poultry and livestock production requires economic viability, ecological viability and social acceptability. Social acceptability impacts on issues such as animal welfare, food safety, genetically modified foods and quality of life for the farmer/stockperson. These issues are likely to affect future production practices through consumer buying behaviour, product standards set by processors and retailers, international trade policy and welfare regulations. Many of these influences are outside the control of the poultry and livestock industries and are driven by special interest groups. Research needs to focus more on assessing

the attitudes and knowledge of the poultry and livestock industries in these areas, developing education programs which inform the public on these issues and developing industry strategies to proactively influence the direction of community opinion and government regulation.

Key Words: attitude, welfare, production

852 The effect of management practices on the stress response in livestock. J.L. Morrow-Tesch*¹, ¹*USDA-ARS Livestock Issues Research Unit, Lubbock, TX.*

Stress is a function of life for farm animals. When the biological cost of responding to a stressor becomes too great to overcome, the animal is in a state of distress. The biological response to stress is not a general one as originally proposed but is dependent on the individual's perception of the stressor. Many factors such as age and genetics influence the perception of a stressor. Because animals respond to a stress by changes in their behavior and physiology, we can measure the components of these changes and increase our understanding of how to manage stress in the animal's environment. Many animal management practices are stressful to livestock including handling animals; mixing, moving and regrouping; weaning; and castrating, dehorning, tail-docking and other painful procedures. Several research groups are focusing on ways to reduce the stress associated with these management practices which is important for enhancing animal well-being. Several examples of ways to manage stress in production systems include reducing social stress through hides (areas where pigs can place their heads to reduce aggressive contacts with pen mates) or olfactory cues, providing environmental enrichment and creating alternative production systems.

853 The FASS initiative to develop training materials on farm animal care. John McGlone*, *Texas Tech University.*

The public requires accountability in expenditure of public dollars in teaching and research. The USA Animal Welfare Act, the Public Health Service, the USDA and the Federation of Animal Science Societies (FASS) Guide for the Care and Use of Agricultural Animals in Agricultural Teaching and Research (Ag Guide, 1999) require that people who use animals be properly trained. While training materials have been available for users of laboratory animals for some time, training materials for those who use farm animals in teaching and research have not been available. The FASS board authorized a project to begin development of peer-reviewed educational materials late in 2000 and the first product of this effort was released in March, 2001. The materials in the first package – meant to cover introductory farm animal care topics – include a two-tape digital video, a CD with the Ag Guide and some sample questions to be used in the trainee evaluation. The tape's script was written by three authors (J. McGlone, J. Morrow-Tesch and C. Stull), produced by the FASS office and a local video production company and was reviewed by the FASS Animal Care, Use and Standards committee. More tapes are planned to cover each common farm-animal species. Development of a multi-media and web-based training program will be facilitated by capture of the video in digital format. Collaboration between FASS and The American Registry of Professional Animal Scientists (ARPAS) is underway to develop a certification program for farm animal workers.

Safety of Our Meat Supply: Assessing the Risks and Methods of Control

854 Risk assessment of pre-harvest food safety: a quantitative approach. S.A. McEwen*¹, ¹*Department of Population Medicine, Ontario Veterinary College, University of Guelph.*

This presentation will demonstrate how pre-harvest food safety risk assessment can be used to guide regulatory decision-making, help to establish policies and standards, and explore impacts of different risk-reduction options. The strengths, limitations and demands of risk assessment in the pre-harvest area will be discussed, using actual examples concerning *E. coli* O157:H7, and antimicrobial resistant bacteria.

We used a quantitative model to assess the benefit of measures implemented in the pre-harvest period that are aimed at reducing the contamination of beef carcasses with *E. coli* O157. Control measures that were assessed were based on either a reduction in herd prevalence of infection, reduction in opportunity for cross-contamination, reduction of concentration of *E. coli* O157 in fresh feces (by vaccination or other method), or a reduction in the amount of feces, mud and bedding ("tag") transferred from the hide to the carcass. Risk assessment is also being used in regulation of veterinary drugs, which will be the focus of the second example. FDA scientists have prepared and publicly presented a risk assessment on the human health impact of fluoroquinolone resistant *Campylobacter* associated with the consumption of chicken. Alternative approaches have been proposed and their strengths and limitations will be discussed.

Demands to enhance pre-harvest food safety continue to mount as microbial and chemical crises occur with amazing regularity around the world. Those concerned with managing risks at the farm level are often pressed to identify which risks can and should be addressed at that level, and at what cost. Risk assessment is gaining acceptance as a valuable tool because of the difficulty in making sound public health decisions in the face of complexity, uncertainty and varying scientific and public opinion. There is a compelling case for a decision-making process that is open and based on scientific evidence, economic analysis and wide consultation with due consideration of societal values.

Key Words: Risk assessment, Food safety, Pre-harvest

855 Pre-harvest Food Safety. J.E. Marion*, *National Chicken Council, Stuart, VA.*

The importance of food safety considerations prior to the slaughter of food animals has been recognized for centuries. It was first recognized that healthy food animals would yield safe food animal products if proper slaughter and processing techniques were followed. Diseases of animal origin that could be transferred to humans have been largely brought under control by vaccines, management, etc. during the past two centuries. During the mid-20th century, food animals were recognized as potential carriers of chemical residues, and programs are now in place to monitor and reduce such residues. More recently, food borne

organisms that affect humans, but not necessarily animals, are being targeted for reduction in numbers and incidence. A most recent foods situation involves bovine encephalopathy (BSE) in European cattle and its' possible relationship to a human form of the disease. All the above situations bring us to a full realization that food safety is a farm-to-table concept that demands programs beyond those for slaughtering and processing. We are compelled to consider all phases from pre-harvest to the consumers plate, and to consider related issues such as environment and waste management. The Hazard Analysis and Critical Control Points (HACCP) approach has been employed by industry and regulatory agencies to accomplish a reduction in food borne pathogens and to model meat and poultry inspection for food safety and wholesomeness aspects. HACCP in poultry plants appears to be successful and will likely be used in broader based programs from the farm to the table. HACCP and other programs will be discussed to illustrate progress in food safety, and to point out areas, especially in preharvest, that need attention. A specific industry program for pathogen intervention will be discussed.

Key Words: Food Safety, Slaughter and Processing Techniques, HACCP

856 Future directions for FSIS and food safety. K. Hulebak*, *USDA Food Safety and Inspection Service, Washington, DC.*

With HACCP now fully implemented nationwide, FSIS is developing a roadmap to enable it to build upon the improvements it has made so far in the safety of meat, poultry, and egg products. Next steps are being considered in many different areas. For example, FSIS has begun to consider and discuss with its stakeholders how the agency's chemical residue program might change as it becomes part of the HACCP approach to ensuring food safety. Through the Workforce for the Future initiative, FSIS plans to implement an ambitious human resource program emphasizing the further development of one of its most valuable resources—the public health professionals who work throughout the agency as inspectors, consumer safety officers, veterinarians, microbiologists, and lawyers, among others. Undertaking reviews of the scientific bases for performance standards will be another important activity within the coming several years. With respect to inspection, FSIS is pursuing a risk-based approach. Education initiatives all along the farm-to-table chain will play a role in FSIS' next steps. And research and risk assessment, the critical underpinnings of all of FSIS' regulatory activities, are receiving ever-increasing emphasis. FSIS is working to enhance its traditional relationship with USDA's Agricultural Research Service, is developing new relationships with USDA's Cooperative State Research, Education, and Extension Service, and is establishing a new Risk Assessment Center to spearhead new risk assessments for *Salmonella* Enteritidis, *Listeria monocytogenes*, and *E. coli* O157:H7. FSIS has initiated a wide-ranging dialogue with stakeholders to explore these next steps.

Soybeans in Monogastric Nutrition

857 Nutrient composition and processing of soybeans impact the nutritional value of resultant soybean meals. C. M. Grieshop* and G. C. Fahey, Jr., *University of Illinois, Urbana, IL/USA.*

It is vital that raw soybeans contain an optimal nutrient profile if the highest quality soybean meal is to be produced. Both soybean composition and processing conditions impact the nutritional quality of soybean meal. In a comparison of soybeans grown in a variety of locations around the world and representing diverse environmental conditions, significant differences in chemical composition (e.g. crude protein, amino acids, and lipid) were noted. These differences could impact the nutritional value of the resultant soybean meals. Little information is available on the impact of processing conditions (e.g. processing time and processing temperature) on the chemical composition and nutritional value of soybean meal. Soybean meals obtained from a large number of U.S. soybean processing plants varied in crude protein, lipid, and amino acid concentrations. Indicators of nutritional value (e.g. protein solubility in potassium hydroxide, urease activity index, and protein dispersibility index) are commonly used to rank soybean meals. United States soybean meals from many processing plants exhibited significant differences in these characteristics. Optimization of both soybean quality and

processing conditions is necessary to produce optimal quality soybean meal that will allow for maximal digestibility and growth performance of animals.

Key Words: Soybean, Soybean meal, Nutrient quality

858 Digestibility of amino acids in soybean meal for poultry. C.M. Parsons*, *University of Illinois, Urbana, IL USA.*

The digestibility of amino acids (AA) in well-processed soybean meal (SBM) for poultry is quite high, with mean digestibility coefficients being 90% or higher. Decreased digestibility of AA is usually due to either insufficient or excess heat processing. Inadequate heat processing results in decreased digestibility of all AA, whereas excess heating usually results in decreased digestibility of only Lys primarily. The reduction in Lys digestibility is due both to destruction of the AA and decreased digestibility of the Lys that is not destroyed. The protein efficiency ratio (PER) growth assay, slope-ratio growth assay and digestibility or balance assays such as the precision-fed cecotomized rooster assay or the chick ileal digestibility assay are all sensitive for measuring bioavailability or digestibility of AA in SBM. A great advantage of the digestibility assays is that all analyzable AA can be measured in the same assay.

When considering *in vitro* or laboratory assays for predicting AA digestibility or protein quality of SBM, the urease assay is good for detecting underprocessing and the KOH protein solubility assay is good for detecting overprocessing. A combination of the latter two assays is needed to ensure that SBM has neither been underheated nor overheated. The protein dispersibility index (PDI) assay may be superior to the urease and KOH assays as an indicator of minimum adequate heat processing of SBM. Determining the Lys concentration as a percentage of the CP may be a good initial indicator of possible overprocessing. Recent work indicates that near infrared reflectance spectroscopy (NIRS) and a new immobilized digestive enzyme assay (IDEA) may also be useful assays for predicting *in vivo* AA digestibility of SBM.

Key Words: Soybean meal, Amino acid digestibility, Poultry

859 Soybean meal quality:swine industry perspective. Keith Haydon*¹, ¹*Heartland Pork Enterprises, Inc.*

Soybean meal (SBM) in swine nutrition has long been the "gold-standard" protein that all other competitive proteins are measured and priced against. SBM provides an excellent amino acid (AA) profile of high true digestibility relative to the pigs' requirement when balanced with corn in a complete feed. The quantity and availability of energy, essential amino acids (EAA) and phosphorous (P) primarily drive SBM quality in the context of swine nutrition. Since energy is the most costly nutrient in swine feeds, the energy value of SBM is critical in formulating

cost efficient diets that provide optimum growth with minimal nutrient excretion and/or energetic losses. Dehulled SBM contains (by difference) approximately 32 to 35% carbohydrates in primarily oligosaccharide forms. Improvement in the digestibility of these components offers tremendous potential in improving the available energy in SBM. Defining the factors that can influence or that can improve the energy value of SBM is paramount to swine nutritionists. Considerable time and effort has been spent over the past 84 years in understanding the impact of required heat treatment of soybeans to neutralize the inherent anti-nutritional factors and their impact on AA availability. The use of protein dispersibility index alone or in conjunction with KOH protein solubility test provides an excellent means to predict adequacy of heat treatment during processing, but are not practical for use in large scale feed mills. Most swine nutritionists surveyed by the author routinely monitor moisture, protein and fiber in SBM. Many have AA analyses performed for quarterly or monthly baselines or predict AA levels from protein levels; however, rarely would they modify their matrix digestibility values based on compositional changes. Increasing the P availability in SBM could decrease diet cost and P excretion and increase dietary energy concentration. Many swine nutritionists consider SBM one of the most consistent quality (nutrient composition and availability) ingredients they use. Areas of concern or opportunity to improve SBM are energy value, consistent processing methodology across the industry and increased P availability.

Key Words: Soybean meal , swine, industry

Twinning Beef Cows

860 Experiences and management of twinner cattle. D. O'Kief*, *O'Kief Ranch, Wood Lake, NE.*

After graduation from the University of Nebraska at Lincoln and before returning to ranching at Wood Lake, NE, Dan O'Kief put his knowledge of reproduction in cattle to work managing Twinner cattle at the United States Meat Animal Research Center at Clay Center, Nebraska. In this symposium on twinning beef cows, Dan will discuss three primary areas related to twinning cow management. These include:

1. The critical period from calving to day three.
2. Improvement of reproductive management of twinning cows.
3. Meeting the mineral and energy demands of twinning cows.

Key Words: Cattle, Twinning, Management

861 Summary of the MARC genetics program to produce twinner cows. R. M. Thallman* and K. E. Gregory, *USDA/ARS, U.S. Meat Animal Research Center, Clay Center, NE.*

The U.S. Meat Animal Research Center (MARC) initiated a program to select cows for increased twinning rate in 1981. Cows that had produced multiple sets of twins were purchased from commercial producers (96 cows) or were transferred from other projects at MARC (211 cows). Semen from 8 Swedish Friesian and 7 Norwegian Red bulls whose daughters twinned more often than normal was imported. Other foundation sires included sons of foundation cows and one Pinzgauer and one Charolais bull whose daughters twinned at high rates in another project at MARC. The herd is 24% Pinzgauer, 18% Simmental, 17% Holstein, 14% Swedish Friesian, 9% Hereford and Angus, 10% Norwegian Red, and 8% other breeds. Current herd size is 300 cows, half calving in spring and half in the fall. Twinning rate (TR) currently averages 50%. Ovulation rate (OR) is used as an indicator trait and is measured by counting corpora lutea via rectal palpation over six to eight estrus cycles prior to breeding heifers for the first time to calve at 30 months of age. The heritabilities of TR and OR are 0.09 and 0.10, respectively, with a genetic correlation of 0.75. Predicted breeding values (PBVs) are computed using a multiple trait, repeated records model for TR and OR. Approximately 10 young bulls are progeny tested per year. Following measurement of their daughters' OR, the best sires are mated to females with the highest PBVs to produce candidates for progeny testing. Response to selection for TR has averaged 2.5% per year. Tissue samples for DNA have been obtained from animals in the herd in 1994 and thereafter. In addition, semen samples were available from most of the sires used prior to 1994. Two quantitative trait loci (QTL) for TR and OR have been identified on chromosome 7 (approximately 60 cM apart) and one on chromosome 5. These three QTL account for about 15% of the genetic variance and are used together with residual polygenic effects in a two-trait model

to compute marker adjusted PBVs, which have been used since 1998. Selection for TR has been effective, in spite of low heritability.

Key Words: Twins, Beef, Genetics

862 Reproductive, growth, feedlot, and carcass traits of twin versus single births in cattle. S. E. Echtenkamp* and K. E. Gregory, *USDA, ARS, RLH US Meat Animal Research Center.*

The production of fraternal twin calves presents a new paradigm in beef cattle management and production and affords an opportunity to increase both reproductive and economic efficiency. The first prerequisite for fraternal twins is twin ovulations. Breeding value for twinning was predicted by repeated measures of ovulation rate in yearling heifers and of twinning rate in the selected herd at the U. S. Meat Animal Research Center. Twinning rate increased 3% per year to an annual rate of 50 to 55%. Gestation length was shorter (275.6 vs 281.3 d; $P < 0.01$) and birth wt was smaller (38.2 vs 47.0 kg; $P < 0.01$) for twin vs single calves, respectively, but total birth wt (live) was increased 53.1% for twins. Respective weaning wt (200-d wt) were 231 vs 259 kg ($P < 0.01$). Number of calves weaned per cow calving was 0.92 for single vs 1.52 for twin births ($P < 0.01$); thus, total weaning wt was increased 47.4% for twins. Single male calves gained 74 g more per d than twin males from birth to 200 d, and 45 g more per d from 200 d to slaughter. Differences in carcass traits between twin and single males were small. Freemartins, 96% of the females born co-twin to a male, did not differ from normal females in growth traits, but freemartins had higher ($P < 0.05$) scores for marbling and a higher ($P < 0.05$) percentage of carcasses were USDA Choice or higher quality grade. Efficiency constraints to twins were increased ($P < 0.01$) incidence of retained placentae (28.0% vs 1.9%), of dystocia (46.9% vs 20.6%) and of perinatal calf mortality (16.5% vs 3.5%); difference in calf survival at 200 d was 14.3%. Dystocia of twins resulted primarily from malpresentation of one or both calves. Fertility was reduced 11.6% ($P < 0.01$) after a twin birth and 9.5% ($P = 0.06$) after a retained placenta, but the effect of twinning on fertility varied significantly ($P < 0.01$) among years and seasons. Collectively, twinning increased productivity at weaning by 54.2 kg or 28.3% per cow exposed at breeding.

Key Words: Twinning, Production, Cattle

863 Management of twinning cow herds. B.W. Kirkpatrick*, *University of Wisconsin-Madison.*

Many beef producers oppose twin birth for the perceived detriments associated with the trait. These include lower calf survival, increased dystocia (malpresentation), increased stillbirth, increased abortion, calf abandonment, retained placenta, lengthened interval from parturition to conception and freemartin heifers when born co-twin with a male. Some of these problems can be overcome with changes in management, others lack an obvious management fix and still others are of little practical significance. Management alterations which may be required for successful exploitation of twin birth include (1) pregnancy checks to determine twin versus single pregnancy, (2) adequate calving facilities and (3) early calf weaning. Determining whether a cow is pregnant with twins eliminates surprises at calving time in that cows at high risk for malpresentation are identified beforehand. In addition, cows gestating twins could be fed a higher plane of nutrition in recognition of the higher demands on them both during late gestation and subsequently while nursing twins. Adequate calving facilities are a necessity given the significant fraction of twin births which are malpresentations. Additionally, availability of calving pens facilities penning of cows with their twins which is sometimes needed to address potential calf abandonment problems. Early weaning is well documented to have beneficial effects on postpartum reproductive performance. Given the typically longer interval from parturition to conception for twin bearing cows, early calf weaning may help maintain adequate reproductive performance. Considering the remaining problems, there are no obvious alterations of management which will improve twinning-related problems with stillbirth, abortion or retained placenta. Freemartinism falls into the last category of something which is more a perceived than real problem. Given that absolute number of fertile females produced from a twinning system will differ little from a single-birth system, freemartinism is not a serious drawback of twinning in beef cattle.

864 Comparison of the profitability of single-calf with twinning cow herds. M. L. Thonney*, *Cornell University, Ithaca, NY.*

A spreadsheet available at <http://www.ansci.cornell.edu/courses/as360/lab/budget.htm> was developed to compare the profitability of cow

herds on 202 hectares (500 acres) of moderately productive forage land with three levels of twinning (1%, 50%, 90%) with or without 2 kg supplement (\$0.12/kg) for 90 days in early lactation expected to maintain fertility in cows with twins to the same level as cows with singles. Purchased hay was priced at \$0.07/kg and extra hay was sold at \$0.06/kg. Land was valued at \$741 per hectare (\$300/acre) and there were about \$62,736 of other capital items. Calf and replacement numbers were determined by twinning rate, fertility, and death rates. Carrying capacity was determined by monthly pasture and hay field productivity and energy requirements of cows with a 10% increase for twinning cows supplied by increased forage or mostly by the supplemental grain mix during early lactation. Cash expenses per cow included extra vet supplies and labor for calving twinning cows which increased as percentage of twinning cows increased (Table). All assets were assumed to be 100% owned. Net farm income accounted for \$8,115 depreciation as well as cash expenses and increased (Table) over single calf herds by 32 and 60% for 50 and 90% nonsupplemented twinning herds and by 61 and 113% for supplemented herds. After accounting for \$3,500 of unpaid family labor and about \$28,600 for possible return on equity, return to operator's labor and management ranged from a loss of \$8,946 for a single-calf herd with 1% twins to a gain of \$17,706 for a supplemented herd with 90% twins. These results show that properly managed twinning cow herds could significantly increase profitability over traditional single-calf cow herds.

Percentage of cows twinning (supplement?):	1 (no)	50 (no)	90 (no)	50 (yes)	90 (yes)
Cows	100	95	91	99	98
Open cows, %	5	10.5	14.9	5	5
Calf loss, %	3.8	11.8	15.8	12.2	15.8
Calves per cow	0.8	1.1	1.3	1.2	1.5
Replacements	15	20	23	16	16
Cash expenses, \$	19,802	21,607	22,137	22,429	23,522
Net farm income, \$	23,411	30,860	37,519	37,768	49,872

ASAS Horse Species: Historical Aspects of Equine Research—How We Got Here and Where Are We Going?

865 Historical aspects of equine nutrition. H.F. Hintz*¹, ¹*Cornell University.*

The modern horse was introduced to the North American continent in 1519. During the late 1800's and early 1900's a significant number of basic and applied studies were conducted on horse nutrition. Horse research was conducted at many experiment stations and even in territories such as Utah before they became states. However as the number of horses declined, research declined. By 1950, there were no research units at experiment stations dedicated to horse nutrition. As the popularity of horses increased in the 1960's nutrition units were established at several universities including the University of Florida, Texas A&M, University of Kentucky, Cornell University, and University of Minnesota. Research efforts have continued to grow, though not as great as some would like, and it appears the importance of the horse will continue to deserve research support.

Key Words: horse, nutrition, history

866 Effect of fasting on blood lipid concentrations in horses. N Frank*, J Sojka, and M Latour, *Purdue University, West Lafayette, Indiana.*

Triglyceride (TG) is exported from the liver in the form of very low-density lipoproteins (VLDL). This study examined the effect of fasting on plasma lipids, specifically VLDL. Four horses aged 13.5 + 3.9 yr were fasted or fed mixed grass hay (2.1% fat DM) *ad libitum* for a 36 h period beginning at 0800. Each horse served as its own control with a 7 d interval between study periods. Blood samples were collected every 2 h and plasma isolated. A density < 1.006 g/mL plasma fraction containing VLDL (and potentially chylomicron lipoproteins in fed horses) was

separated from plasma by ultracentrifugation. Components of VLDL including TG, total cholesterol (TC), free cholesterol, phospholipid (PL), and protein (PRO) were quantified. Plasma TG, TC, glucose, and NEFA concentrations were also measured. Total VLDL concentration was calculated by summing TG, TC, PL, and PRO concentrations. Repeated measures analysis revealed that fasting had a significant ($P < 0.10$) effect on VLDL concentration over time. Compared with fed horses, mean VLDL concentration was higher in fasted horses at 16 h and means differed significantly ($P < 0.05$) by 36 h. However, individual variation was observed. Fasting induced significantly higher VLDL concentrations in only two of the four horses. The percentage of TG in VLDL increased significantly ($P < 0.10$) with time in fasted horses. Plasma NEFA concentrations were significantly higher ($P < 0.001$) in fasted versus fed horses with mean (SE) concentrations of 299.9 (19.9) $\mu\text{mol/L}$ and 46.4 (2.1) $\mu\text{mol/L}$, respectively. Plasma TG, TC, and glucose concentrations did not differ significantly between groups. Results indicate that lipid-rich VLDL particles accumulate in the circulation of fasted horses, either as a result of accelerated secretion or inhibited clearance. Further studies are required to determine why individual horses respond differently to fasting. Potential contributing factors include body composition, endocrine status, genetic predisposition, and stress tolerance.

Key Words: Fasting, Lipids, VLDL

867 Plasma glucose responses of growing horses to different concentrate feeds. A. C. St. Lawrence*¹, L. M. Lawrence¹, S. H. Hayes¹, and M. Adams², ¹*University of Kentucky, Lexington, KY,* ²*Cooperative Research Farms, Guelph, ON.*

Fourteen horses (9 mos) were used to determine the effects of two concentrate feeds on glucose response to a meal. Initially, all horses received

a diet consisting of a control concentrate (16.9% CP, 10.3% NDF, 3.1% fat, 1.41% Ca, 1.0% P, 519ppm Fe, 184ppm Zn, 66ppm Cu) at 65% of the DE required for moderate growth, and ad libitum access to alfalfa hay. Following a 10-d period, the horses were fasted overnight and blood samples were collected immediately prior to a meal (25% of daily meal, .9-1.2 kg) and at 30-min intervals for 5 h after the meal was offered (B1). After B1, horses were blocked by age and assigned to treatment groups. Group C (n=7; 308 kg) continued to receive the control concentrate and Group F (n=7, 309 kg) received an isocaloric concentrate (16.1% CP, 16.5% NDF, 5.1% fat, 1.59% Ca, .96% P, 417ppm Fe, 155ppm Zn, 59ppm Cu). After 21 d, horses were bled (B2) following the same procedure as B1 except that each group received their respective dietary treatments as the test meal. To determine long-term effects of receiving diet F, horses were maintained on their respective diets for another 21-d and a third bleed was conducted (B3). In B3 all horses received the control concentrate as the test meal. Effects of diet on plasma glucose were determined by comparing areas under the response curve (AUC) and peak glucose concentrations between groups. Mean ADG was .53 kg and did not differ between groups. Differences in AUC were not observed between groups in B1, B2, or B3 ($P > .05$). Peak glucose concentrations were similar between groups during B1 and B3 but were lower in Group F during B2 ($P < .05$). The dietary component responsible for the differences in peak glucose between Group F and Group C is not clear. Both dietary soluble carbohydrates and dietary Zn have been implicated in altering glucose concentrations. The relatively small differences in soluble carbohydrates between diets may partially explain why differences in AUC were not observed in B2.

Key Words: Horse, Plasma Glucose, Diet

868 Fecal phosphorus excretion in yearling horses fed typical diets with and without exogenous phytase. M.T.M. Hainze*, K. A. Condon, J. A. Rush, R.B. Muntifering, and C.A. McCall, *Auburn University, Auburn, AL 36849.*

Phosphorus (P) returned to the environment in animal manures may detrimentally affect soil and water resources. Solubility of P returned to soil determines its rate and extent of assimilation by plants, which in turn affects P runoff and transport. Fecal P excretion was characterized in eight yearling geldings fed four typical diets differing in ingredient composition, with and without exogenous phytase. The experimental design was a 4 X 4 Latin square with repeated measures in which horses were fed Coastal bermudagrass hay at a rate of 1.5% of BW daily plus sufficient 12% CP sweet feed, 12% CP pelleted concentrate, whole oats or alfalfa cubes to meet NRC (1989) requirements for DE and CP. Phytase status represented a within-unit repeated measures factor. Each experimental period consisted of a 10-d acclimation to dietary treatments, 2-d fecal sampling, 7-d acclimation to exogenous phytase and another 2-d fecal sampling, followed by a 7-d diet changeover between periods. Diets were fed twice daily, and water and plain salt were available for *ad libitum* consumption. Phytase was delivered orally via syringe at time of feeding. When not being fed, horses were maintained in a drylot. Fecal samples were collected by rectal grab and were composited on an individual animal basis. Diet DM digestibility and fecal DM output were calculated by reference to AIA concentrations in feed and fecal DM. Fecal samples were analyzed for concentrations of total P and water-extractable P, and insoluble P was calculated as the difference between total and water-extractable P concentrations. Fecal output of total P, water-extractable P and insoluble P differed ($P < .05$) among diets, and total P excretion across all diets tended to be lower ($P = 0.16$) when phytase was administered (12.3 vs 13.8 g/d). Fecal output of total P, water-extractable P and insoluble P was 8.4, 3.0 and 5.4 g/d; 10.1, 3.9 and 6.9 g/d; 14.9, 5.3 and 9.6 g/d; and 19.0, 7.9 and 11.1 g/d, respectively, for diets containing oats, alfalfa cubes, sweet feed and pellets. Results are interpreted to mean that typical diets for horses, formulated to meet DE and CP requirements, can be expected to differ markedly with respect to quantity and solubility of P returned to the environment in feces.

Key Words: Equine, Phosphorus, Phytase

869 Passage rate of ingesta in Standardbred race horses. J. VandenBrink and J. H. Burton*, *University of Guelph, Guelph, Ontario, Canada.*

A trial was conducted on six Standardbred horses in race training to investigate the effects of training stress on rate of ingesta passage. Three

horses were in their early phase of training (low intensity (LI): jogging 4 miles per day, six days per week); three horses were race trained in 2:05 (minutes per mile) or less (high intensity (HI)). Two markers were used simultaneously to estimate passage rate: Cr-mordanted bran fiber to follow particulate matter; CoEDTA as a fluid phase marker. Mordanted fiber was fed in pellet form in one meal and CoEDTA was administered as a drench. Total fecal collection took place over 72 h commencing 6 h after marker administration. A 10 percent subsample of feces from each time period was retained for analysis of dry matter, Cr and Co. Feces were pooled over 3 hour intervals from 6 to 36 h and 6 h intervals from 36 to 72 h. Cr and Co were analysed in feces using atomic absorption spectrometry. Average fecal dry matter from all horses was 20.5 percent. Average mean retention times (MRT) for particulate matter as determined from Cr data were 30.7 h and 33.3 h for HI and LI horses respectively. Fluid phase had significantly lower retention times with MRT of 23.3 h for HI and 18.8 h for LI. Results indicate that particulate material was retained about 50 percent longer than the fluid phase.

Key Words: Rate of pasage, Standardbred race horses, Cr-mordanted fiber CoEDTA

870 Effects of melatonin implants on plasma concentrations of leptin and body weight in obese pony mares. P.R. Buff*, C.D. Morrison, E.L. McFadin-Buff, and D.H. Keisler, *University of Missouri-Columbia.*

Our objectives were to determine if subcutaneous melatonin implants would alter the diurnal rhythm of leptin secretion and subsequently alter body weight in obese pony mares. Seven ovariectomized and eight intact pony mares (initial weight 273.6 ± 17.9 kg) were used. Four mares from each group were implanted with 144 mg melatonin (Regulin[®], Sanofi, Watford, UK) and the remaining mares received no implant. All mares were allowed *ad libitum* pasture. Beginning at 10:00 h and 17:00 h plasma samples were collected every 15 minutes for one hour. This sampling protocol was repeated weekly from 7 July 2000 until 7 October 2000. Body weights were taken weekly following the 10:00 h blood sample. Plasma samples were analyzed for leptin using a double antibody homologous radioimmunoassay validated for equine leptin in our laboratory. The mean concentration of leptin from each of the 4 plasma samples was used for statistical analysis. Separate analyses for leptin were performed for 10:00 h and 17:00 h sampling periods to determine treatment differences. No differences in plasma concentrations of leptin were detected between melatonin implanted and non-implanted mares for the 10:00 h sampling period ($P = 0.62$). A significant treatment by day effect was detected for the 17:00 h sampling period ($P = 0.0012$), but post-test comparisons of the means resulted in no differences between treatment groups. No differences in plasma leptin levels were detected between ovariectomized and intact mares ($P > 0.7$). In contrast, plasma concentrations of leptin differed between morning (10:00 h) and evening (17:00 h) samples 22.07 ± 1.7 vs. 28.24 ± 1.7 , respectively; $P < 0.0001$). Treatment with melatonin had no effect on body weight change ($P = 0.09$). From these data we conclude that neither melatonin implants nor ovariectomy influences plasma concentrations of leptin in pony mares. However, differences in plasma concentrations of leptin were detected between the 10:00 h and 17:00 h samples, indicating that melatonin may not influence the diurnal pattern of leptin secretion.

Key Words: Equine, Leptin, Melatonin

871 Determination of pregnancy outcome of mares grazed on a non-toxic endophyte-infected tall fescue. B. J. Rude*, B. A. Warren, D. J. Lang, and P. L. Ryan, *Mississippi State University.*

Tall fescue infected with *Neotyphodium coenophilaum* (E+) is known to be toxic to late-term pregnant mares. A non-toxic endophyte-infected fescue (NTE+) has been developed for grazing cattle, but safety for pregnant mares grazing this new fescue is unknown. The objectives of this study were to 1) evaluate the toxicity risks of pregnant mares grazing NTE+, and 2) determine the persistence of NTE+. Fifteen mares were allotted to graze one of three pasture treatments: 1) Endophyte-free fescue (E-); 2) NTE+; and 3) E+. Five mares grazed on each of the paddocks from March 1 until 3 weeks post-partum. Urine was collected weekly from mares for ergot alkaloid analysis. Placental membranes were submitted for histopathology. Results indicated that only mares

grazing E+ exhibited symptoms of fescue toxicity which included agalactia (n=4 of 5), compromised delivery (n=2), retained placenta (n=3), and one mare aborted at 301 days gestation. Additionally, mares exposed to E+ had longer (P < 0.05) gestation (353 d) compared to those grazing NTE+ and E- (333 and 340 d, respectively). Mean urine ergot alkaloid content was greatest (P < 0.01) for E+ (38.5 ng/mg creatinine) compared with NTE+ and E- mares (5.9 and 3.4, ng/mg creatinine, respectively). Placental measurements showed increased (P < 0.03) thickening of the cervical aspect of the placenta in E+ (4.49 mm) compared with NTE+ and E- mares (1.58 and 1.57 mm, respectively). A difference (P < 0.05) was also seen for amnion thickness between E+ and NTE+ mares (2.37 vs. 1.0 mm, respectively). Pasture endophyte infestation rates were 2.3%, 63% and 91% in March and 1.5%, 92% and 91% in May for E-, NTE+ and E+ pastures, respectively. Of the infected tillers during May, 6% of the E- and NTE+ samples were positive for ergot alkaloids while 100% of the tillers in the E+ pasture were positive. Tall Fescue stands were 32 % for E-, 96 % for NTE+, and 95 % for E+ pastures in mid-March and 1 % (E-), 41 % (NTE+), and 27 % (E+) at the end of September, after a dry and hot summer (< 1 cm rainfall, 27 days > 37 C during July- September). Stand decline and survival in both NTE+ and E+ were related to soil type and landscape features. These findings suggest that NTE+ is a safe herbage for the grazing of late-term pregnant mares.

Key Words: Equine, Pregnancy, Non-toxic infected-fescue

872 Manipulation of the dopaminergic system affects prolactin but not LH secretion in anestrus and cycling mares. K. Bennett-Wimbush¹, B. Musolf², and D. Keisler³, ¹Ohio State University Agricultural Technical Institute, Wooster, Ohio, ²Cuyahoga Community College, Parma, Ohio, ³University of Missouri, Columbia, Missouri.

Previous research has shown that dopamine antagonists can hasten follicular growth and ovulation in transitional mares. The mechanism of action appears to be by modulation of prolactin and not FSH. However, the effect of dopamine antagonists on LH is unknown. The purpose of this study was to determine the effects of 2-bromo-ergocriptine (dopamine agonist) and perphenazine (dopamine antagonist) on prolactin and LH secretion during different reproductive stages. Six mares were used in a 3x3 Latin Square design experiment. Treatments included .375 mg/kg oral perphenazine (P), 0.08 mg/kg⁷⁵ 2-bromo-ergocriptine (B) intramuscularly (IM) or an equivalent volume of saline (S), IM. Each mare received all treatments once during anestrus, estrus and diestrus. Prior to treatment, each mare was fitted with an indwelling jugular catheter and pre-treatment blood samples were collected every 20 minutes for one hour, starting at time 0. After pre-treatment samples were collected, a single dose of either P, B or S was administered as described above. Blood samples were obtained every 20 minutes for 7 hours following treatment. Samples were analyzed for prolactin and LH via radioimmunoassays. Differences in mean prolactin (PRL), mean LH (LH), maximum prolactin (MAXPRL) and maximum LH (MAXLH) for cycle, treatment and cycle*treatment were tested using GLM. The relationship of prolactin and LH observed during this study parallels previously published works. Plasma PRL and MAXPRL were lower (p < .01) during anestrus (13.4 ± 7.3, 18.0 ± 9.0 ng/ml) when compared to concentrations observed during estrus (18.3 ± 9.8, 26.2 ± 13.1 ng/ml) or diestrus

(18.8 ± 9.3, 30.0 ± 14.1 ng/ml). As expected, plasma concentrations of LH and MAXLH were higher (p < .01) during estrus. Perphenazine treatment increased (p < .01) PRL and MAXPRL during all stages of the mares' cycles. PRL was 23.7 ± 9.3, 12.2 ± 5.6, 14.1 ± 7.0 ng/ml for P, B and S treatments respectively. Treatment with B did not significantly alter either PRL or MAXPRL when compared to the control (S). Similarly neither of the treatments had any effect on LH or MAXPRL. In conclusion, the dopaminergic system plays a key role in the regulation of pituitary prolactin secretion, but does not appear to regulate LH.

Key Words: Dopamine, Prolactin, LH

873 Temporal variables of the park walk and park trot of the Morgan Horse. M.C. Nicodemus^{*1}, K.M. Holt¹, and H.M. Clayton², ¹Mississippi State University, Mississippi State, MS/USA, ²McPhail Equine Performance Center, East Lansing, MI/USA.

During competition, two of the gaits performed by the Morgan Park Horse are the park walk and park trot. According to judging standards, the park trot is a definite 2-beat diagonal gait but the park walk can be either a 2 or 4-beat walk with both being snappy, collected, and cadenced. Distinguishing between these gaits can be difficult for the novice judge. Therefore, the objective was to clearly define the park walk and park trot. Frame-by-frame analysis was done on 5 Morgan Park Horses performing 4 strides of the park walk and park trot at Morgan Horse Nationals. The mean (SD) of the following stride variables were determined: stride duration, fore and hind stance durations, lateral and diagonal step intervals, and limb support phases. Both gaits demonstrated a diagonal footfall sequence (RH-LF-LH-RF) with short contact intervals between the hind and diagonal forelimb. In each park walk half-stride, the support sequence was: tripedal (2 hind and 1 fore), quadrupedal, tripedal (2 hind and 1 fore), and diagonal bipedal. In each park trot half-stride, the support sequence was: single hind, diagonal bipedal, single hind, and suspension. Both gaits demonstrated a diagonal footfall sequence with diagonal couplets. The park walk had walking support characteristics with trotting footfall characteristics, whereas the park trot was similar to the trot. The shorter stride duration, the lack of tripedal and quadrupedal support, and the inclusion of suspension in the park trot differentiate it from the park walk.

	Park Walk	Park Trot
Stride Duration (ms)	835 (60)*	673 (33)*
Fore Stance Duration (ms)	513 (14)*	316 (18)*
Hind Stance Duration (ms)	443 (22)*	232 (22)*
Lateral Step Interval (%)	50 (7)	51 (8)
Diagonal Step Interval (%)	4 (1)	6 (2)
Suspension (%)	NA	10 (2)
Hind Single Support (%)	NA	20 (4)
Diagonal Bipodal Support (%)	75 (1)	70 (3)
Tripodal Support (%)	20 (1)	NA
Quadrupedal Support (%)	5 (2)	NA

Table 1: Park walk and park trot temporal variables (mean, SD) with significant differences (P<0.05) between variables of the gaits indicated (*).

ASAS Nonruminant Nutrition: Growth Management and Sow Nutrition; Aquaculture

874 Effects of feed deprivation prior to slaughter on changes in body weight and stomach morphology of finishing pigs. C. M. Dodd*, D. L. Rader, J. D. Hancock, G. A. Kennedy, C. W. Starkey, C. L. Jones, and D. J. Lee, Kansas State University, Manhattan.

A total of 176 pigs were used to determine the effects of feed deprivation (none, 12 h, 24 h, and 48 h) prior to slaughter on changes in BW and stomach morphology of finishing pigs. The pigs were blocked by sex and weight and allotted to 16 pens with 11 pigs per pen. The pigs were fed a corn (mean particle size of 600 microns)-soybean meal-based diet (0.8% lysine, 0.6% Ca, and 0.5% P) for 36 d (from 92 kg until slaughter). The diet had 4% soybean oil, was fed in pelleted form, and was consumed on an ad libitum basis. For the feed deprivation treatments, feeders were removed from the pens. To end the experiment, the pigs were loaded onto a truck at 0000, shipped to a commercial meat pack-

ing plant, and killed at 0600. The pars esophagea of the stomachs were collected and scored on a scale of 0 to 3 (0 = none, 1 = slight, 2 = moderate, and 3 = severe) for keratinization and ulceration. The mean BW of all pigs at initiation of the feed deprivation treatments was 127 kg. At shipping (i.e., 48 h later), BW changes ranged from 1.5 to 5.4 kg as duration of feed deprivation was increased from none to 48 h (linear effect, P < 0.001). Also, hot carcass weight decreased as duration of feed deprivation was increased (linear effect, P < 0.04). Keratinization score increased from 0.44 to 1.77 as duration of feed deprivation was increased (cubic effect, P < 0.03). Ulceration score increased slightly (from 0.02 to 0.56) but the changes were negligible except for the 48 h treatment (cubic effect, P < 0.04). In conclusion, feed deprivation prior to shipping for slaughter decreased final BW and hot carcass weight. Also, keratinization of the pars esophagea increased as duration of feed deprivation was increased but changes in ulcer scores were minor.

Item	Hours of feed deprivation				SE
	None	12 h	24 h	48 h	
Shipping wt, kg	127.6	126.3	124.9	122.2	1.0
BW change, kg	1.5	-0.7	-2.7	-5.4	0.3
Carcass wt, kg	92.0	92.7	92.0	90.1	0.7
Stomach keratinization	0.44	1.29	1.35	1.77	0.10
Stomach ulceration	0.02	0.23	0.05	0.56	0.08

Key Words: Pig, Ulcer, Feed deprivation

875 Effects of induced stresses on productive performance and serum concentration of acute phase proteins in growing-finishing pig. C. Pineiro*¹, E. Lorenzo², A. Pineiro³, and G. G. Mateos⁴, ¹PigCHAMP Pro Europa, Spain, ²Proinserga S. A., Spain, ³Universidad de Zaragoza, Spain, ⁴Universidad Politecnica de Madrid, Spain.

The objective of the trial was to study the influence of two induced stressors (ambient temperature and stocking density) on serum levels of two acute-phase proteins (Pig-MAP and Haptoglobine) and productive performance of pigs. A total of 228 Landrace x Large White pigs of 60 ± 3 d of age and 18.2 ± 2.4 kg of weight were randomly distributed in three rooms (cold, control, and warm). There were three densities (1.25, 0.72, and 0.56 m² per pig) and two sexes (boars and females) and one replicate per each ambient temperature. The trial lasted 98 d. Feed intake and body weight were measured every 14 d and blood samples from two pigs per replicate were taken at random at the same time. Overall performance was excellent (ADG = 818 g and FC = 2.08) and no clinical signs of any disease were observed. At the end of the trial pigs stocked at 1.25 m² grew faster and had better feed conversion than pigs stocked at 0.72 or 0.56 m² (P < 0.05) but ambient temperature did not affect performance. Significant interactions were found among main effects. Pigs placed at 1.25 m² grew faster than pigs placed at 0.56 m² under cold (P < 0.05) but not under control or warm temperature. From 60 to 74 d females grew faster and had better feed conversion than boars (P < 0.05). Pig-MAP serum concentration in this period was greater in boars than in females (P = 0.06). From 116 to 158 d, growth rate of boars decreased with increased density (P < 0.01). Also boars had higher levels of Pig-Map than females (P = 0.06) but no differences among sexes were detected for Haptoglobine. In the same period, the levels of both marker proteins were the highest for overstocked pigs (P < 0.05). We conclude that environmental stresses might impair pig performance and that the concentrations of Pig-MAP and Haptoglobine can be used under these circumstances to detect losses in performance.

Key Words: Pigs, Environmental stressors, Biomarker proteins

876 Influence of slaughter weight on performance and carcass quality of fattening pigs. M. A. Latorre*¹, A. Fuentetaja², P. Medel¹, and G. G. Mateos¹, ¹Universidad Politecnica de Madrid, Spain, ²COPESE S.A. Segovia, Spain.

A total of 192 Pietrain*Large White x Landrace*Large White pigs of 75 kg of initial BW was used to study the influence of final slaughter weight (SW) on productive performance and carcass quality. There were six treatments arranged as a factorial 3x2 with three SW (115, 124, and 133 kg) and two sexes (castrated males and females). Each treatment was replicated four times and the experimental unit was formed by eight pigs penned together. All the animals received *ad libitum* a common diet based on cereals and soybean meal (2,415 kcal NE/kg and 0.70% total lys) throughout the test. No interactions were detected between SW and sex for any of the traits studied. At the end of the trial, pigs slaughtered at 115 kg grew faster and had better feed conversion than pigs slaughtered at 124 or 133 kg (843, 788, and 769 g/d; P<0.05, and 3.19, 3.24, and 3.48 g/g; P<0.01). Castrates ate more (2844 vs 2448 g/d; P<0.01), grew faster (848 vs 752 g/d; P<0.01), and had worse feed conversion (3.35 vs 3.26 g/g; P<0.05) than females. Carcass yield improved with increased SW (77.3, 77.7, and 78.6%, for 115, 124, and 133 kg SW, respectively; P<0.01). Also backfat and thickness of fat measured at the *Gluteus medius* muscle augmented with increased SW (22.1, 25.7, and 27.0 mm, and 15.3, 19.4, and 19.8 mm for 115, 124, and 133 kg, respectively; P<0.01). Castrated males had less carcass yield (77.4 vs 78.3%; P<0.01), were 23.7% fatter (P<0.01), and had 29.7% more fat at *Gluteus medius* (P<0.01) than females. The length of the carcass and the ham increased with SW (P<0.01) but sex did not influence any of these measurements. Increasing the slaughter weight of

both castrates and females up to 124 kg might help improve the carcass and meat quality of pigs destined to cured products.

877 Impact of daily energy intake on rate and composition of gain in pigs with high lean growth potential. J.F. Patience*¹, C.M. Nyachoti², R.T. Zijlstra¹, R.D. Boyd³, and J.L. Usry⁴, ¹Prairie Swine Centre, Inc., Saskatoon, SK, ²University of Manitoba, Winnipeg, MB, ³PIC USA, Franklin, KY, ⁴Heartland Lysine Inc, Chicago, IL.

While the response to changes in amino acid intake is becoming better understood, there is a paucity of information on energy effects on the modern pig. A total of 83 castrated male and 83 female pigs (PIC Camborough 15 X L65) were used to investigate the impact of declining daily energy intake on the rate, efficiency and composition of gain from 25 to 120 kg. Individually-housed pigs received a diet formulated to be non-limiting in amino acids, vitamins and minerals at 100, 93, 86, 79, or 72% of *ad libitum*. Pigs were killed at 25±2 kg (n=8 within sex) to provide baseline body composition and at 50±2 kg (n=3 within sex and treatment group), 75±2.5 kg (n=3), 100±2.5 kg (n=4) and 120±3 kg (n=5) to determine whole body protein, lipid, ash and water content. For each weight period until slaughter, rate of gain and feed intake were recorded; backfat and loin thickness were measured by real time ultrasound. A linear decline in ADG from 25 to 120 kg occurred as daily energy intake declined (P<0.05): 1.02 and 1.00; 0.94 and 0.90; 0.89 and 0.82; 0.78 and 0.73; 0.71 and 0.62 kg/d for males and females at 100, 93, 86, 79 and 72%, respectively. As daily energy intake declined from 8.8 (100%) to 6.4 (72%) Mcal DE/d in males and from 9.1 to 6.4 Mcal DE/d in females, total body protein at 120 kg increased from 15.0 to 17.4% of empty body weight in males and from 15.9 to 17.5% in females (P<0.05). Total body lipid declined from 27.5 to 20.7% in males and from 25.0 to 19.3% in females (P<0.05) while percent ash was unaffected (P>0.05). Empty stomach and intestine weights increased and then decreased in a quadratic (P<0.05) fashion as daily energy intake declined. Definition of body composition as influenced by energy intake is essential to the use of factorial models in estimating nutrient requirements of pigs.

Key Words: Pig, Energy, Carcass

878 Effect of high temperature and energy intake on energy utilization in growing pigs. L. Le Bellego*, J. van Milgen, and J. Noblet, INRA, St Gilles, France.

Eight blocks of five barrow littermates were used to study the effect of ME supply at thermoneutrality (23C; TN; four blocks) and under heat stress (30C; HS; four blocks) on composition of BW gain. Relative to *ad libitum* intake (100) at each temperature, ME levels were 100, 90, 80 and 70 % for TN pigs and 100, 91, 85 and 77 % for HS pigs. Feeding levels were adjusted daily according to BW. Animals were fed a corn, wheat, and soybean meal based diet providing 0.95 g of standardized digestible lysine per MJ NE. One littermate per block was slaughtered at the beginning of the experiment (24 kg BW) to measure initial body composition; the four remaining littermates were affected to the four ME levels. Pigs were penned individually and slaughtered at 65 kg. Gain of nutrients and energy were calculated according to the comparative slaughter technique. Data were analyzed according to a covariance model including the effects of block, temperature, ME intake and interactions. At the TN-100 ME intake (32.2 MJ/d), daily gains of empty BW, protein, lipid and energy were 1021, 166, 259 g and 16.4 MJ, respectively. At 26 MJ/d ME intake, (corresponding to HS-100 and TN-80), daily gains of empty BW, protein and energy were higher (P<0.05) in TN (901 g, 151 g and 13.14 MJ, respectively) than in HS (876 g, 143 g and 12.75 MJ, respectively). Daily lipid gain was similar at both temperatures (190 g). At 22 MJ/d ME intake, corresponding to TN-70 and HS-85), daily gains of empty BW and protein were higher (P<0.05) in HS (795 and 139 g) than in TN (755 and 124 g), whereas daily gains of lipid and energy were lower in HS (141 g and 10.61 MJ) than in TN (169 g and 11.01 MJ). These results demonstrate that the partitioning of energy between protein and lipid deposition in growing pigs is affected by both ambient temperature and feeding level. At similar ME intakes, protein gain is reduced directly by heat stress in *ad libitum* pigs while a severe man-imposed feed restriction at thermoneutrality affects protein gain more than the combination of a man- and temperature imposed feed restriction.

Key Words: Growing Pig, Temperature, Protein Gain

879 Compensatory feed intake and growth in pigs. J. van Milgen*¹ and J. Noblet¹, ¹INRA, St-Gilles, France.

Growing pigs may face temporary challenges, such as disease or seasonal heat stress that may be overcome later. The objective of this study was to determine the extent to which growing pigs may recover from a period of feed restriction. Eleven groups of two littermate barrows were used. At 35 kg, pigs were moved to individual pens and adapted to the experimental conditions for 4 d. One animal of each litter (A) had ad libitum access to feed throughout the experiment. Its littermate (R) received 60% of the anticipated voluntary feed intake for six d followed by 12 d ad libitum access to feed. This cycle of feed restriction and re-feeding was repeated three times (starting at approximately 40, 60 and 80 kg BW). Feed intake and feed refusals were determined daily whereas BW was determined at the beginning and the end of the experiment (after an overnight fast) and after every change in feeding level. After the third period, animals were slaughtered. During the restriction periods, feed intake averaged 1.66 and 2.90 kg/d for groups R and A, respectively. During the re-feeding periods, feed intake was equivalent for both groups during the first two periods (average 2.95 kg/d) but was considerably higher for group R during the third period (3.86 vs 3.27 kg/d). For the complete experiment (35 to 100 kg), average feed intake was significantly higher for group A (2.90 kg/d) than for group R (2.70 kg/d) but average daily gain was not different between groups (1.08 kg/d). Periods of feed restriction and re-feeding caused considerable variation in gut fill for group R and biased the calculated growth rates. These (average) growth rates for respectively R and A were 0.22 and 1.18 kg/d during the restriction periods, and 1.51 and 1.11 kg/d during the re-feeding periods. Due to the increased feed intake in the last period, animals in group R had greater gut fill and tended to have lower carcass weights (79.9 vs 82.5 kg). There was little difference in carcass composition between treatments. These results indicate that (partial) compensatory growth exists in fast growing pigs, but compensatory feed intake may only be effective in the later stages of growth.

Key Words: Pigs, Compensatory Growth, Compensatory Feed Intake

880 Effects of soybean meal from different sources on sow and litter performance during gestation and lactation. H. K. Kim*¹, H. S. Kim¹, Y. H. Park¹, I. S. Shin², H. S. Lee², and K. Y. Whang¹, ¹Korea University, ²American Soybean Association/Korea.

An experiment was conducted to study effects of the differently originated-soybean meals during gestation and lactation periods on sow and litter performance. One hundred and twenty crossbred multiparous sows (Yorkshire Landrace) were assigned to three dietary treatments and fed corn-soybean meal based diets containing the U.S. dehulled (USDH), Brazil, and India soybean meal (SBM) as a major protein source. Diets were formulated to meet the nutrient requirements (NRC, 1998). Sows were fed different diets during gestation, lactation and from weaning to estrus, according to physiological status. The ADG, ADFI and G/F did not differ ($P > .05$) among treatments in gestation period. In lactating period, ADFI, backfat change, and days of weaning-to-estrus were not different but body weight change was significantly different ($P < .10$). Number of born alive in the USDH treatment was higher ($P < .10$) than that in Brazil treatment. Also, litter weight at birth of the USDH treatment was greater ($P < .05$) than that of Brazil treatment. Litter weaning weights of the USDH, Brazil and India treatments were 56.10 kg, 52.93 kg and 54.42 kg, respectively. This experiment concludes that feeding a diet with the USDH to sows exhibits a better litter performance than feeding diets with Brazil or India SBM.

Item	USDHSBM	Brazil SBM	India SBM	SEM
Gestation				
ADFI, kg	3.07	3.06	3.08	0.005

881 Effects of dietary supplementation with mannan oligosaccharides on sow and litter performance in a commercial production system. P. R. O'Quinn*¹, D. W. Funderburke¹, and G. W. Tibbetts², ¹Cape Fear Consulting, LLC, Warsaw, NC, ²Alltech, Inc., Nicholasville, KY.

This trial was conducted to evaluate the effects of dietary addition of mannan oligosaccharides (MOS) on sow and litter performance in a commercial production system. The MOS used in this trial (Bio-Mos) was supplied by Alltech, Inc. Sows ($n = 509$ and 517 for MOS and control sows, respectively) were of PIC genetics with average parity and initial BW of 3.26 and 264 kg, respectively, and were fed MOS starting a minimum of three wk prior to farrowing (0.20% inclusion of Bio-Mos) and throughout the 21-d lactation period (0.10% inclusion of Bio-Mos). Diets were analyzed for mycotoxins: values for aflatoxin, T-2, fumonisin, DON, and ochratoxin were low and similar between diets. Sows were weighed upon entry into the farrowing house (d 112 of gestation) and at weaning, and litters were weighed at processing (approximately 30 h after birth) and at weaning. Addition of MOS did not affect ($P > 0.05$) sow weight loss, number born alive, stillborns, or mummified fetuses. Addition of MOS resulted in heavier ($P < 0.05$) litter birth and weaning weights. Average pig weight gain for the MOS and control pigs was 4.11 and 3.79 kg, respectively. Pre-weaning mortality was reduced ($P < 0.01$) by feeding MOS to the sows (9.09 vs 11.27% for the MOS and control sows, respectively). Concentrations of IgA, IgG, and IgM in pre-nursing colostrum samples ($n = 48$ and 42 for MOS and control sows, respectively) were increased by dietary addition of MOS. Concentrations of IgG showed the greatest response ($P = 0.007$; 5,853 vs 4,842 mg/dL) to MOS supplementation, followed by IgM ($P = 0.03$; 273 vs 241 mg/dL), and IgA ($P = 0.06$; 1,178 vs 1,097 mg/dL). The changes in composition of the pre-nursing colostrum samples may help explain the observed improvements in pig growth performance. In summary, the reduction in pre-weaning mortality coupled with the improvements in litter growth performance indicates that additions of mannan oligosaccharides may be beneficial in commercial sow herds.

Key Words: Sow, Litter, Mannan oligosaccharides

882 Effect of dietary levels of soluble and insoluble fiber on energy digestibility and nitrogen balance in gestating sows. J.A. Renteria*, L.J. Johnston, and G.C. Shurson, University of Minnesota, St Paul MN.

Gestating sows (12 nulliparous, NULL; 12 multiparous, MULT) were used to assess the effect of different levels of soluble (S) and insoluble (IS) fiber on energy digestibility and nitrogen balance. Experimental diets included: Control (C) - corn-soybean meal diet (1.59% S, 7.67% IS); High Soluble Fiber (HS) - corn-soybean meal-oat bran (34% oat bran, 3.19% S, 8.95% IS); High Insoluble Fiber (HIS) - corn-soybean meal-wheat straw (12% wheat straw, 1.46% S, 15.36% IS); and High Soluble/High Insoluble (HS/IS) - corn-soybean meal-sugar beet pulp (16% beet pulp, 3.20% S, 15.31% IS). Sows were randomly assigned to diets, and fed to meet their energy requirements according to the NRC model (1998), assuming 10 pigs per litter and 40 kg gestation gain. Total collections of feces and urine were conducted in 5-d periods at wk 5, 10, and 14 of gestation. Greater apparent digestibility of dietary gross energy (87.1 vs 86.2%; $P < .02$; SE = .34) and nitrogen (85.7 vs 83.1%; $P < .01$; SE = .63) was observed for MULT vs NULL females throughout gestation. There were no interactions between parity group and dietary treatments for the evaluated response criteria. Apparent digestibility of dietary energy throughout the evaluated periods was lowest for females fed HIS (82.7%) vs C (87.9%), HS (89.3%), and HS/IS (86.8%; $P < .01$; SE = .48). Apparent digestibility of dietary nitrogen throughout the evaluated periods was similar between C and HS (86.1 and 86.2%) but greater ($P < .05$; SE = .90) than HIS and HS/IS (82.8 and 82.8%). Apparent nitrogen digestibility but not energy declined ($P < .05$) as time on diet and gestation progressed. In conclusion, multiparous sows demonstrated a greater ability to digest fibrous diets than nulliparous females. Inclusion of insoluble fiber in diets for gestating sows depresses energy digestibility and nitrogen balance, but elevated levels of dietary soluble fiber do not influence these variables. Knowledge of specific dietary fiber components is necessary to accurately predict effects of dietary fiber on digestibility.

Key Words: Sow, Fiber, Digestibility

883 **Reproduction, conceptus growth and plasma reduced folates in sows in response to dietary supplementation with oxidized and reduced sources of folic acid.** A. F. Harper^{*1}, J. W. Knight¹, E. Kokue², Y. Toride³, and J. L. Usry⁴, ¹Virginia Polytechnic Institute & State University, ²Tokyo University of Agriculture & Technology, ³Ajinomoto Company Incorporated, ⁴Ajinomoto Heartland Incorporated.

The study was conducted to determine the response of sows to oxidized and reduced forms of supplemental folic acid in the diet. Yorkshire x Landrace gilts were mated and fed a standard corn-soy diet (0.57 ppm folacin) with no supplemental folic acid. On d 105 of gestation gilts were randomly assigned to one of four dietary treatments for the remainder of the study. Treatments included a diet with no supplemental folate (control), a diet with 2.1 ppm added folate from an oxidized monoglutamate form (MG), a diet with 2.1 ppm added folate from N5-Formyl-5,6,7,8-THFA (leucovorin) and a diet with 2.1 ppm added folate from a commercial organic source (Ajinomoto-PG). Breeding-gestation diets were fed at a rate of 1.8 kg/sow/d and lactation diets were fed ad libitum. Plasma samples for HPLC determination of reduced plasma folates were collected on d 105, at weaning, at mating and when the sows were sacrificed on d 45 after mating for the second parity. There were 19, 18, 18 and 22 sows for the control, MG, leucovorin and Ajinomoto-PG treatments, respectively. Supplementing folacin just prior to farrowing and during lactation had no effect on measures of sow and litter performance during the first parity ($P > 0.18$). Live fetuses at d 45 of gestation in parity 2 were 10.06, 12.23, 10.87, and 11.07 for the control, MG, leucovorin and Ajinomoto-PG treatments, respectively. Due to variability in the data the litter size advantage with added folate was not significant (added folates vs. control, $P = 0.15$). Fetal survival and placental size and protein content was generally unaffected by folate treatment. Reduced folates in sow plasma were 13.50, 13.58, 22.50, and 17.79 nM at weaning and 12.55, 19.29, 18.96, and 21.88 nM at mating for the control, MG, leucovorin and Ajinomoto-PG treatments, respectively, with the leucovorin treatment elevated significantly above the controls at weaning ($P < 0.05$) and the Ajinomoto-PG treatment greater than controls at mating ($P < 0.05$). In this study folate supplementation from oxidized or reduced sources of folate did not impact sow reproductive performance but the reduced sources (leucovorin and Ajinomoto-PG) appeared to increase circulating reduced folates at mating and weaning time.

Key Words: Sows, Folic acid, Reproduction

884 **Evaluation of pea ingredients for rainbow trout (*Oncorhynchus mykiss*) diets.** D.L. Thiessen^{*1}, G.L. Campbell¹, and P.D. Adelizi², ¹University of Saskatchewan, Saskatoon, SK, Canada, ²Whitewater Trout Co., Whitewater, CA, USA.

While nutrient digestibility data is available for whole peas (*Pisum sativum*), data is lacking for further processed pea ingredients in rainbow trout diets. Air classification of dehulled peas produces a concentrated product (50% CP, 20% starch) that may be beneficial in the continuing search for alternative feedstuffs suitable for salmonid diets. This study was undertaken to determine the effects of various milling and heat treatments on the nutrient and energy digestibility of pea ingredients in rainbow trout. The apparent crude protein, amino acid, acid ether extract, starch, energy and dry matter digestibility of raw/whole pea, raw/dehulled pea, extruded/dehulled pea (145°C, 620-740 psi) and autoclaved air-classified pea protein (125°C, 15 min) was determined. The ADC of each test ingredient was determined on diets in which 30% of a reference diet was replaced by each test ingredient. Experimental diets contained 1% acid insoluble ash as the indicator. Eighteen fish (300±15 g) per tank were adapted to the test diet (n=4) for 7 days with subsequent fecal collection for 4 days using a settling column. Results indicate that raw/whole pea protein was highly digestible (90.0%) in rainbow trout but the large starch component was essentially indigestible (14.3%), resulting in an ingredient with poor digestible energy (54.6%). Removal of the fibre-rich hull through dehulling had no significant effect on digestibility of raw peas ($P > 0.05$). Extrusion of dehulled peas increased crude protein, starch and energy digestibility (93.5, 100.7 and 78.4%, respectively; $P < 0.05$). Subsequent air classification and autoclaving of dehulled peas proved to be beneficial by concentrating the protein and removing the majority of the indigestible starch, ultimately producing an ingredient with exceptional protein and energy digestibility (94.6 and 87.0%, respectively; $P < 0.05$). Based on digestibility it was concluded that autoclaved air-classified pea protein is an appropriate aquafeed ingredient for salmonid fish.

Key Words: Peas, Digestibility, Rainbow trout

885 **Apparent nutrient digestibility of fishmeal and feather meal diets for juvenile Pacific white shrimp (*Litopenaeus vannamei*).** Zongjia Cheng^{*1}, K.C. Behnke², and W.G. Dominy³, ¹University of Idaho, Hagerman, ID, ²Kansas State University, Manhattan, KS, ³The Oceanic Institute, Waimanalo, HI.

A 35.8% CP shrimp diet containing 24.5% fishmeal (LT-94) was modified by substituting regular hydrolyzed feather meal (FTM), or a high digestible feather meal (FTMHD), at 33.3, 66.7 and 100% replacement for fishmeal on w/w basis. Additionally, synthetic amino acids (AA), L-lysine and DL-methionine, were added to FTM and FTMHD so that their total lysine and methionine contents were the same as in fishmeal. The modified FTM diets also were formulated to replace fishmeal at 33.3, 66.7 and 100% levels on w/w basis. Thirteen diets (including a fishmeal control diet) were fed to 936 shrimp (initial BW 1.77.75 g) for 20 d. Three aquaria/diet and 24 shrimp/aquarium were used. Cr₂O₃ was used as an inert marker. Results showed that the apparent protein digestibility (APD) for fishmeal diet was higher than FTM or FTMHD based diets for shrimp ($P < .05$). However, the apparent dry matter digestibility (ADMD) and apparent fat digestibility (AFD) of fishmeal were lower than those FTM or FTMHD based diets ($P < .05$). The APD, ADMD and AFD were 81.6%, 70.9% and 93.5%, respectively, for shrimp fed fishmeal diet. For those FTM or FTMHD diets, APDs varied from 51.7% for shrimp fed FTMHD plus AA replacing 100% fishmeal diet to 77.3% for shrimp fed FTMHD plus AA replacing 33.3% fishmeal diet ($P < .05$). ADMDs ranged from 63.7% for shrimp fed FTMHD plus AA replacing 100% fishmeal diet to 75.7% for shrimp fed FTMHD replacing 100% fishmeal diet ($P < .05$). AFDs ranged from 93.5% for shrimp fed FTMHD plus AA replacing 100% fishmeal diet to 96.8% for shrimp fed FTMHD replacing 66.7% fishmeal diet ($P < .05$).

Key Words: Apparent nutrient digestibility, shrimp, Fishmeal and Feather meal

886 **Apparent nutrient digestibility of fishmeal and poultry by-product meal diets for juvenile Pacific white shrimp (*Litopenaeus vannamei*).** Zongjia Cheng^{*1}, K.C. Behnke², and W.G. Dominy³, ¹University of Idaho, Hagerman, ID, ²Kansas State University, Manhattan, KS, ³The Oceanic Institute, Waimanalo, HI.

A 35.5% CP shrimp diet containing 24.5% fishmeal (FM, LT-94) was modified by replacing FM with two types of poultry by-product meal (regular, PBM; and petfood grade, PBMPG) at 33.3, 66.7 and 100% on w/w basis. Additionally, the PBM and PBMPG were defatted and fish oil was added back so that their oil contents were the same as the original samples. These modified meals were also used to replace FM at 33.3, 66.7 and 100% levels on w/w basis. Thirteen diets (including FM control diet) were fed to 936 shrimp of average BW 1.77.75 g for 20 d. Shrimp were stocked into 3 aquaria per treatment (diet) and 24 shrimp per aquarium. During the first 3 d, shrimp consumed their respective test diets, feces were collected on the 4th d of the Exp. Cr₂O₃ was used as an inert marker. Results showed that the apparent dry matter digestibility (ADMD), apparent protein digestibility (APD) and apparent fat digestibility (AFD) were 76.9%, 86.1%, and 94.9%, respectively, for shrimp fed FM diet. For the PBM diets, ADMDs ranged from 63.4% for shrimp fed PBM replacing 100% FM diet to 78.6% for shrimp fed defatted PBMPG replacing 66.7% FM diet ($P < .05$), APDs varied from 66.7% for shrimp fed PBM replacing 100% FM diet to 84.2% for shrimp fed defatted PBMPG replacing 66.7% FM diet ($P < .05$), and AFDs ranged from 94.8% for shrimp fed PBMPG replacing 33.3% FM diet to 97.2% for shrimp fed defatted PBMPG replacing 100% FM diet ($P > .05$).

Key Words: Apparent nutrient digestibility, Shrimp, Fishmeal and poultry by-product meal

887 Identification of factors that cause genotype by environment interactions between dairy production systems. N.R. Zwald* and K.A. Weigel, *University of Wisconsin - Madison*.

The objective of this study was to describe the production systems in countries that participate in international dairy sire evaluations, and to identify factors that cause variation in progeny performance between herds. Test day data from first lactation Holstein cows in Australia, Austria, Belgium, Canada, Czech, Estonia, Finland, Germany, Hungary, Ireland, Israel, Italy, the Netherlands, New Zealand, South Africa, Switzerland, and USA were used. These data included 233,673 herds, 16,403,413 cows, and 131,907,373 test day records from cows calving between 1/1/90 and 12/31/97. Herds were grouped into 5 quintiles for each of 11 management variables and 2 climate variables. Heritability of milk yield was calculated within each quintile of each variable, and genetic correlations between quintiles were computed. Genetic correlations less than unity and significant differences in heritability between quintiles were found for peak yield, average sire PTA milk, temperature, fat to protein ratio, days to peak yield, within-herd standard deviation of milk yield, and percent North American Holstein genes. Currently, differences in production systems between countries are considered in international sire evaluations. However, variation in management or climate within countries is ignored. We have identified some of the factors that cause genotype by environment interactions between individual herds. This research shows that it is more reasonable to define traits based on the production conditions in each herd, as opposed to defining traits based on country borders. Grouping herds on these variables should create international sire evaluations that are more appropriate for genetic selection decisions on individual farms, because each sire will receive a PTA for each unique production system. In addition, the number of unique production systems will likely be less than the number of countries, and this will lead to greater accuracy of parameter estimates and a more efficient international evaluation system.

Key Words: Genotype by Environment, International Evaluations

888 Genotype by environment interaction for milk production traits in Guernsey cattle. W.F. Fikse*¹, R. Rekaya², and K.A. Weigel², ¹*Interbull Centre, Uppsala, Sweden*, ²*University of Wisconsin, Madison*.

International genetic evaluations that use national genetic evaluation results as input need to acknowledge country borders. The current model for international evaluation treats each country as genetically separate trait, and assumes milk production to be similar within country, but different between countries. The use of unprocessed cow performance records does not require such restriction, and allows for other statistical models to consider genotype by environment interaction. First lactation records from 45,000 Guernsey cows in four countries (Australia, Canada, United States and South Africa) were used to detect and describe genotype by environment interaction for milk production traits. Five statistical models were considered: a) single trait across country, b) single trait across country with heterogeneous residual variance, c) multiple trait across country, d) multiple-trait herd cluster model, and e) reaction norm model. For the herd cluster model, herds were clustered into groups based on information on herd management, genetic composition and climate. Reaction norms describe the phenotype expressed by a genotype as a function of the environment, and are modelled by random regression on descriptors of production environment. The same variables to describe production environment were used in the herd cluster and reaction norm model. Gibbs sampling was used to make inferences about the parameters of interest, and models were compared based on Bayes factors and deviance information criterion. Posterior mean and mode for heritability for the single trait model was .33, and ranged from .25 to .40 for models b) and c). Genetic correlations between countries estimated with model c) were generally high (.87 - .92). Heritabilities obtained from the reaction norm model differed substantially depending on descriptive variable, and ranged from .10 to .50 in 'poor' and 'good' environments. Genetic correlations between extreme environments were between .80 and unity depending on environment descriptor. Both Bayes

factors and deviance information criterion indicated that country borders do not effectively distinct between production environments.

Key Words: International Genetic Evaluation, Guernsey, Lactation Records

889 Evidence for genotype by environment interaction in production traits of US Holsteins under grazing versus confinement. J. F. Kearney*¹, M. M. Schutz¹, P. J. Boettcher², and K. A. Weigel³, ¹*Purdue University*, ²*University of Guelph*, ³*University of Wisconsin*.

Grazing, as a form of low input dairying, has increased in popularity. However grazing herds tend to forego conventional US Artificial Insemination (AI) sires, in favor of sires proven in other grazing countries or novel breeds. The objective of this study was to investigate possible genotype by environment interaction in grazing versus confinement herds in the US. Grazing herds (GH) were defined as utilizing grazing for at least 6 months each year and were enrolled in Dairy Herd Improvement. A total of 414 GH in 14 states contributed 101,872 records of 24,451 AI-sired Holstein cows, calving from 1990 to 1999. Control herds (CH) were confinement herds of similar size in the same states. The CH had 144,863 records from 61,273 AI-sired Holstein cows. The performance of daughters in GH and CH was examined using linear regression of mature equivalent milk (MEM), fat (MEF) and, protein (MEP) yield on the 11-00 USDA Predicted Transmitting Abilities (PTA) of their sires for those traits. The model also included the fixed effects of herd, year-season, and age-parity. For GH or CH, regression coefficients were estimated for all records, for four random subsets, and for four subsets based on quartiles of herd average MEM. Average MEM was greater for CH (10,008 kg) versus GH (8602 kg). For GH, the coefficients of regression of MEM, MEF, and MEP on PTA were significantly less ($P < 0.01$) than 1 (the expected value), except for MEM and MEP in the highest quartile ($P > 0.2$) and MEP in one of the random subsets. In CH, MEF, and MEP were significantly less ($P < 0.01$) than 1, only for the lowest quartile. MEM was less ($P < 0.05$) than 1 in two of the random subsets and in the lowest and second highest quartiles. MEM, MEF, and MEP were all greater ($P < 0.01$) than 1 for the highest quartile. Results suggest that performance of cows in GH may not be predicted adequately by current US recording and genetic evaluation systems, but relationships may be due to both production level and management system.

Key Words: Genetics, Grazing, Genotype by environment interaction

890 Effects of genotype-by-environment interactions in conventional versus pasture-based dairies. P. J. Boettcher*^{1,2}, J. Fatehi¹, and M. M. Schutz³, ¹*University of Guelph, Canada*, ²*ANAFI, Cremona, Italy*, ³*Purdue University, West Lafayette, IN*.

The objective of this study was to evaluate effects of genotype-by-environmental interaction (GxE) on dairy traits among herds in Canada that practice intensive rotational grazing versus conventional methods that rely on stored feeds. The basic approach taken was to estimate the genetic correlation between phenotypes for a given trait expressed under the two different environmental conditions. Based on responses to questionnaires, 22 herds were selected for the grazing group. These herds were required to intensively graze their cattle for at least six months per year, during which pasture provided at least 70% of the forage in the cows' diets. In addition, herds were required to be enrolled in DHI and to record pedigree data. All herds were in either Nova Scotia or Ontario. The control (conventional) group consisted of 34 large free-stall operations. Data were DHI records from 1990 and later and consisted of 6749 lactations from 2817 cows in the grazing herds and 29,371 lactations from 12,774 cows in the control herds. Per cow production was greater in the conventionally managed herds (9947 kg milk) than in the grazing herds (9300 kg). Genetic correlations were estimated by multiple trait REML and a model that included fixed effects of age-parity and herd-year-season-parity classes and random effects of animal, permanent environment, and residual. Effects of GxE were minor, with genetic correlations of near 0.90 or greater. Genetic correlation was lowest for fat yield (0.88 with SE = 0.04). Genetic correlations for milk and protein

were 0.93 and 0.94, respectively. Heritabilities were greater for the yield traits in the conventionally managed herds, averaging about 0.37 versus 0.32 in the grazing herds. An equivalent analysis was performed for the conformation traits Frame and Capacity, Mammary System, and Feet and Legs, using data from approximately 12,000 cows. Genetic correlations for Mammary System (1.00) and Feet and legs (0.97) were near unity. The estimate for Frame and Capacity was slightly lower (0.90). These results demonstrate that effects of GxE are small between the two types of management systems analyzed and that sires will rank similarly when progeny tested in the two environments.

Key Words: Genotype-by-Environmental Interaction, Intensive Grazing

891 Method to establish average relationships among Holstein bull populations over time. B. Auvray^{*1}, G.R. Wiggans², F. Miglior³, and N. Gengler^{1,4}, ¹*Gembloux Agricultural University, Belgium*, ²*Agricultural Research Service, USDA, Beltsville, MD*, ³*Canadian Dairy Network, Guelph, Canada*, ⁴*National Fund for Scientific Research, Brussels, Belgium*.

Average relationship coefficients between groups of animals were calculated by repeating three calculation steps until convergence was reached. The first step was a stratified sampling of pedigrees. Second, relationships between animals in the sample were calculated, using the group relationships computed in a previous round for unknown parent relationships. Third, results were accumulated by group. Average relationship coefficients calculated in this way can be used for such purposes as to better understand the structure of a population, to more accurately calculate inbreeding coefficients, and to assign unknown parent groups using clustering methods. This method was applied to the pedigree data for the worldwide Holstein sire population. The data was derived from Interbull and North American pedigree databases. Groups were defined by year of birth, sex, and country. Average relationships between US and Canadian bulls increased across time from 0.02 in 1960 to 0.12 in 1999. The increase was continuous except for a plateau in 1992, followed by a slight decrease until 1995 when the trend to increase resumed. Average relationships across time comparing Canadian with European bulls and US with European bulls are quite similar. They increased from about 0 in 1963 to 0.10 in 1999. After a peak of 0.05 in 1966, the relationships dropped to 0.03 in 1976 before starting to increase again. For bulls born in 1996 in the US, Canada, and Germany (representing a typical European country), the average relationships were: 0.116 (Canada-Canada), 0.112 (Canada-USA), 0.1 (Canada-Germany), 0.101 (USA-USA), 0.101 (USA-Germany) and 0.084 (Germany-Germany). These results demonstrate the recent dramatic increase in relationships and inbreeding in the worldwide Holstein population, and show the power of this method of calculating relationship coefficients.

Key Words: Relationship, Holstein, Bull population

892 Possible global scale for ranking dairy bulls by blending national rankings. R.L. Powell^{*} and P.M. VanRaden, *Animal Improvement Programs Laboratory, Agricultural Research Service, USDA, Beltsville, MD*.

International genetic evaluations are computed routinely for dairy bulls using multi-trait across country evaluation methods. Separate rankings are provided on the scales of member countries, but a global scale also could be useful in marketing across countries and for use by non-member countries. National units of expression were removed by dividing the evaluation on each scale by the country's standard deviation. These standardized evaluations were weighted by each country's fraction of global cow numbers and blended into a global evaluation. That approach is predicated on interest in breeding for a world market, but other weights may be considered. Fractions of global cow numbers were estimated by the proportions from each country of all daughters of evaluated bulls in the international evaluation. For the Holstein evaluation, countries with the largest cow numbers included the United States (18%), Germany (15%), France (13%), New Zealand (10%), and the Netherlands (9%). Twenty one other countries accounted for 35%. Standard deviation of the global scale can be set to a constant and a fixed genetic base can be imposed simply by setting the mean of evaluations equal to the previous mean. Conversion formulas for the global scale to and from each country scale may be needed. Correlations of bull evaluations

on the separate country scales for protein averaged .976 within birth year. Correlations of the country scales with the global scale ranged from .955 to .995 with a mean of .988. Even with high correlations, there was reranking. The use of a global scale could ease the transition to an evaluation of data grouped and modeled by herd management and climate variables instead of national borders. Separate regional, country, or cluster rankings would still be needed to provide selection tools adapted to local conditions. Global evaluations would allow both participants and non-participants to select for a global market.

Key Words: genetic evaluation, international rankings, dairy cattle

893 Estimation of genetic correlations between countries and prediction of sire breeding values using individual animal performance records. K. A. Weigel^{*1}, R. Rekaya¹, N. R. Zwald¹, and W. F. Fikse², ¹*University of Wisconsin, Madison*, ²*Interbull Centre, Uppsala, Sweden*.

Our objective was to estimate genetic correlations between milk production in different countries and to predict international sire breeding values using individual animal performance records. Data included first lactation records of 16,403,413 Holstein cows that calved between January 1, 1990 and December 31, 1997 in 233,673 herds in Australia, Austria, Belgium, Canada, Czech Republic, Estonia, Finland, Germany, Hungary, Ireland, Israel, Italy, Netherlands, New Zealand, South Africa, Switzerland, and USA. Milk yield in each country was considered as a different trait. Genetic parameters and sire breeding values were estimated using a multiple-trait sire model that included the effects of sire, herd-year-season of calving, age at calving, milking frequency, and heterosis class. Heritabilities ranged from 0.25 in Finland to 0.34 in Israel. Genetic correlations between countries ranged from 0.77 between Estonia and both Ireland and Israel to 0.96 between Belgium and Netherlands and between New Zealand and both Australia and Ireland. Some correlations differed markedly from values that are now used in international sire evaluations. In particular, correlations of 0.94 or greater were found between Australia, Ireland, and New Zealand, all countries that rely heavily on rotational grazing. Correlations of 0.92 or greater were found between Belgium, Canada, Italy, Netherlands, and USA. Correlations between the intensively managed countries and the rotational grazing countries ranged from 0.82 to 0.88. Examination of the top 1% of bulls (N=665) on each country scale revealed that 556 bulls were selected in one country only, 861 were selected in at least five countries, 461 in at least 10 countries, and 107 in all 17 countries.

894 Simultaneous estimation of genetic correlations for milk yield among a large number of Holstein populations. H. Jorjani^{*}, *Interbull, Department of Animal Breeding and Genetics, Swedish University of Agricultural Sciences*.

Estimation of genetic correlations among all 26 Holstein populations participating in Interbull's international genetic evaluation of AI bulls is hampered by the large number of country combinations (325), the large number of bulls in the correlation estimation (>110000) and the low number of common bulls with estimated breeding values (proofs) in more than one country (about 110 country combinations had less than 20 common bulls). These problems have led to the current practice of estimating genetic correlations among smaller well-connected groups of countries rather than among all 26 countries in one single evaluation, which in its turn leads to the prolongation of the turn around cycle, multiple estimates of some country combinations, and more importantly the need for bending the resulting covariance matrix. Therefore, to find a subset of data that facilitates a simultaneous and speedy estimation process for all 26 populations without introducing bias is desirable. To achieve this, new methods of selecting well-connected subsets of data have been examined. These involved selection of data based on the bulls' number of proofs and two different measures of connectedness, namely, weighted and effective number of proofs, which are based on number and distribution of bulls' daughters across countries. These alternatives were used in combination with time edits, that is selecting the subset from all available bulls or only bulls born in the last 17 years, i.e. as is the current practice for estimation of breeding values. Results indicated that the estimated genetic correlations are very sensitive to even small

changes in the number of common bulls, probably because few bulls can potentially provide a significant amount of genetic links. Subsets selected based on different measures of connectedness resulted in higher average genetic correlations and larger number of correlations that are biologically sensible (>0.75). Time edit resulted in increased estimates among countries that share young bulls and decreased estimates among countries that rely heavily on the importation of old proven bulls.

Key Words: Connectedness, data subset, time edit

895 Alternative strategies for estimation of country sire variance in international evaluations of dairy bulls. F. Miglior^{*1}, P. G. Sullivan², and B. J. VanDoormaal¹, ¹Canadian Dairy Network, ²CGIL, University of Guelph, Guelph, ON, Canada.

Three alternatives were compared to estimate sire variances in Interbull evaluations. Sire variance estimates are used in international evaluations of dairy bulls to account for different scales of proof expression in each country. Currently these variances are estimated in MACE using all bulls that have daughters in at least 10 herds by country. This group includes locally sampled bulls and imported bulls first sampled abroad. Sire variances are estimated using approximate Mendelian sampling terms (MS), which have an assumed expected value of 0 for all bulls. While average MS of bulls sampled locally may be close to zero, MS of imported bulls tends to be positive, as only top proven bulls are imported in any country. A total of 59,657 Holstein bulls from ten major dairy countries were evaluated with MACE, based on genetic evaluation files and genetic correlation estimates used by Interbull in the November 2000 routine run. Sire variances were estimated for each country using MS of either: a) all bulls (the current Interbull procedure); b) only bulls sampled locally; or c) only bulls born in the last five years (1992-96). The last group included mostly first crop locally sampled bulls. Variances were estimated by birth year and across all years for each of the three data sets for milk, fat and protein yield. For protein yield, sire variances estimated using only locally sampled bulls ranged from -1% to -12% lower than variance estimated using all bulls. Sire variances estimated using bulls born in the last 5 years ranged from -8% to +9% of the variance estimated using all bulls. In order to quantify the impact of different estimates of sire variability on international evaluations, changes in bull rankings and bull proofs were also compared. A simulation study is required to identify the most accurate strategy to estimate sire variance in a MACE evaluation.

Key Words: International evaluations, sire variance estimation

896 Variance of effects of lactation stage within herd by herd yield. N. Gengler^{*1,2} and G.R. Wiggans³, ¹Gemblox Agricultural University, Belgium, ²National Fund for Scientific Research, Brussels, Belgium, ³Agricultural Research Service, USDA, Beltsville, MD.

First-lactation test-day yields from New York, Wisconsin, and California herds with low (<7257 kg), medium (9072 to 9525 kg), and high (>11,340 kg) annual milk yields were adjusted additively for age and lactation stage. Two random regression models with third-order Legendre polynomials for permanent environmental and genetic effects were used. The second model also included a random effect with the same polynomial regressions for 2-yr intervals within herd (herd-stage effect). Mean adjusted test-day milk yields were 35.4 kg (75,838 test days in 9108 lactations) for high-yield herds, 28.8 kg (74,845 test days in 8887 lactations) for medium-yield herds, and 25.6 kg (71,996 test days in 8490 lactations) for low-yield herds. Although estimated phenotypic variances also declined with herd yield, those variances were surprisingly similar for medium- and low-yield herds. Herd-stage effect on phenotypic variance was negligible. Heritabilities for high- and medium-yield herds initially decreased and then gradually increased across lactation stages. Maximum heritability (0.33, high-yield herds; 0.30, medium-yield herds) was reached from 200 to 300 d in milk. Heritabilities were lower for low-yield herds but increased rapidly (maximum of 0.22 at lactation end). Introduction of a herd-stage effect eliminated the heritability decrease in early lactation for high- and medium-yield herds and reduced the increase in late lactation for low-yield herds. Heritabilities generally were lower with inclusion of a herd-stage effect, which indicated that variances for this effect were partly considered genetic in the

less complete model. Herd-stage variances relative to phenotypic variance were highest at the beginning (12%) and end of lactation (7%) for medium-yield herds. Herd yield and stage had a large effect on variance size and change across lactation stages during first lactation and should be considered when accounting for heterogeneous variances in genetic evaluations.

Key Words: Heterogeneous variance, Test-day model

897 Lactation curves of milk production traits of Italian Water Buffaloes estimated by a mixed linear model. N.P.P. Macciotta^{*1}, G. Catillo², G. Pulina¹, A. Carretta², and A. Cappio-Borlino¹, ¹Dipartimento di Scienze Zootecniche, universit di Sassari, Italia, ²Istituto Sperimentale per la Zootecnia, Roma.

Aim of the work is the estimation of lactation curves of milk production traits of Italian water Buffaloes pertaining to different age classes and seasons of calving. Data were 4064 Test Day records of milk production traits (milk yield, fat and protein percentages) recorded on 534 Italian buffalo cows during the years 1986-1999 in a farm of the Istituto Sperimentale per la Zootecnia. Animals were grouped according to 6 level of age at calving and to 4 levels of season of calving. Data were analysed with a mixed linear model that included test date, age at calving, season of calving and stage of lactation as fixed effects plus a random animal effect associated with each lactation. Average lactation curves were estimated by solving for the effects of stage of lactation nested within age at calving and season of calving. Milk yield lactation curves of animals of different ages resulted clearly separated till 20 weeks from parturition, with buffaloes of 4-5 years having the highest curve. Peak yield occurred at around the 6th week of lactation in all age classes; buffalo cows of 2-3 years of age showed the highest persistency which, however, is markedly lower than in dairy cattle. No effect of age at calving could be observed for fat and protein percentages. Season of calving affected milk yield only in the first phase of lactation, with the lowest production levels for summer calvings; no effect could be observed on fat and protein contents. Actually, the inclusion of a TD effect accounted for much of the seasonal variation normally observed among buffalo cows calving in different seasons, in agreement with previous results obtained in dairy cattle. Average correlations among TD measures within animal or repeatabilities, calculated on the basis of the variance component associated to the random animal effect and of the residual variance, were 0.59, 0.31 and 0.36 for milk yield, fat and protein percentages respectively.

Key Words: Buffalo, Milk Production Traits, Lactation Curves

898 Heritability estimates for birth weight of exotic dairy breeds in Nigeria. O.T.F. Abanikanda^{*1}, O. Olutogun², A.O. Leigh¹, M. Orunmuyi³, and O.Y. Apena¹, ¹Department of Zoology, Lagos State University, Nigeria, ²Department of Animal Science, University of Ibadan, Nigeria, ³Department of Animal Science, Ahmadu Bello University, Zaria, Nigeria.

Genetic parameter estimates for traits are specific for a particular breed in a specified environment. Weight of calves at birth has been established to be the first and quickest index of some of the performance traits of cattle. The correlation of birth weight to other performance traits as weaning weight, milk yield and survivability has been well documented. This research aim at computing the heritability of birth weight of Holstein and Jersey breeds, calved and bred in the medium to high trypanosomiasis-risk zone of Southern Nigeria. The 475 Holstein calves used in this analysis are from 13 sires and the 39 Jersey calves are from 4 sires. Factors studied included year of birth, season of birth, sex of calf, parity of calf as fixed effects and the sire effect was used as random effect. The SPSS (1996) software was used for both the analysis of variance and the variance component estimation. The General Linear Model (GLM) for variance component estimation using the ANOVA method was used to estimate the variance components. The paternal half sib method of Henderson ($h^2 = 4\sigma_s^2 / \sigma_s^2 + \sigma_w^2$) was used to compute heritability for both breeds. In the Holstein calves, all factors except the parity were highly significant ($P < 0.01$), while only the sire effect was significant ($P < 0.05$) in the Jersey calves. The mean birth weight for the Holstein and Jersey calves are 32.59 ± 0.24 kg and 21.15 ± 0.44 kg respectively. In the Holstein breed, the males were 1.67kg

heavier than females and the highest birth weight was recorded in the late wet season. This seasonal variation in birth weight was due to the amount of precipitation recorded in those seasons as reflected in the availability of forage for the pregnant dams, which are rarely given supplemental feeds. and the h^2 for Holstein and Jersey was 0.49 ± 0.26 and 0.54 ± 0.35 respectively. The moderate to high heritability estimate obtained in these analyses implies that these breeds of animal could be maintained as purebred, despite the prevailing inimical environmental conditions.

Source	DF (Holstein)	MS (Holstein)	DF (Jersey)	MS (Jersey)
Year of birth	15	90.87**	6	8.27ns

ASAS/ADSA Extension Education: Beef

899 Performance comparisons between mature cows categorized by weight and frame score combinations that are enrolled in a cow herd performance testing program. S.R. McPeake*, W.T. Wallace, and L. Keaton, *University of Arkansas Cooperative Extension Service.*

Data from (n = 164) cows and their calves were analyzed to compare differences in performance levels between cows categorized by weight and frame score combinations. General linear model procedures were used to generate least squares means for dependent variables. Weight categories (WT) for the cows were small (< 500 kg), moderate (500 to 544 kg), large (545 to 590 kg) and extra large (> 590 kg). Frame scores (FS) represented included 4, 5, 6, and 7. Cow size (CS) included all possible combinations of WT and FS that were available in the data set. WT was significant ($P < 0.05$) for adjusted 205 day weight (WWT), cow efficiency (CE) and FS. CS was significant ($P < 0.05$) for WWT, CE, and body condition score of cows (BC). No significant differences were found between CS for muscle score (MS) of calves. As WT increased, WWT increased but CE decreased. Within WT, cows with larger frame scores generally had higher WWT with the exception of extra large cows. Within each WT, CE increased with FS with the exception of the extra large cows. Cow frame size and weight may need to be considered when matching cows to production environments.

Key Words: Beef cattle, Cow size, Efficiency

900 Designing and implementing a quality assured, source-verified feeder calf sale program. T. Nennich^a, C. R. Dahlen^b, C. M. Zehnder^b, L. R. Miller^b, G. C. Lamb^c, D. Kampmeier^d, and A. DiCostanzo^{*b}, ^a*Clearwater County Extension, Bagley, MN*, ^b*University of Minnesota, St. Paul*, ^c*North Central Research and Outreach Center, Grand Rapids*, ^d*Central Livestock Association, South St. Paul.*

A producer-driven quality assured, source verified feeder calf sale program was initiated to enhance marketing options for producers, to create a repeat-buyer feeder calf outlet, and to increase profitability and growth of the Minnesota beef industry. Several marketing agencies were interviewed according to marketing criteria producers wished to follow. A marketing agency was chosen and charged to set and promote sale dates, provide transportation, facilities and personnel to form outcome groups of cattle of similar color, frame and muscling, and to sell outcome lots within a regular sale date. Producers agreed to follow specific beef quality assurance (MBQA) procedures, and to background and process calves for disease prevention. Cattle were immunized against viral and bacterial diseases at weaning time and boosted against viral diseases 15 d before the sale. On the sale date, an experienced sale observer gathered cattle description, weight and price data on all lots sold. A regression equation was fitted to determine factors that had a significant ($P < .05$) effect on sale price. Color, muscling, sex, and health status were factors that influenced sale price in addition to weight and lot size. Steer MBQA lots sold better than other vaccinated steers or steers under no vaccination protocol 56% or 75% of the time for a total advantage of \$3 or \$13/head, respectively. Heifer MBQA lots sold better than other vaccinated heifers or heifers under no vaccination protocol 41% or 76% of the time for a total advantage of \$1.86 or \$12.21/head, respectively. Compared to single source lots, when a producer contributed up to 12 steers or heifers to a larger lot, the advantage of selling in larger lots

was \$.068/kg. Producers and the marketing agency were satisfied with the experience and have made a commitment to continue this endeavor.

901 Mississippi farm to feedlot program: carcass performance. W.B. McKinley, A.R. Williams*, J.N. Myers, A.G. Gardner, and E. Ward, *Mississippi State University, Starkville, MS.*

The objectives of the Mississippi Farm to Feedlot program are to evaluate production and carcass information of steers produced in Mississippi, and to provide educational information regarding retained ownership as a marketing alternative. Seven years (1993-1998) of data were collected and the effects of year of feeding (YR) and sire breed (SB) on carcass performance were evaluated. Sire breeds were classified into three breed groups, British Breeds (BB), European breeds (EB), and American breeds (AB). Carcass performance response variables included steer hot carcass weight (HCWT), back fat thickness (BF), ribeye area (REA), marbling score (MS), quality grade (QG), and yield grade (YG). Both YR and SB significantly influenced carcass performance. HCWT was greatest ($p < .05$) for steers in YR 5 and 6 (352 and 344 kg, respectively) compared to all other years. Steers in YR 1 had greater ($p < .01$) BF (1.52 cm) than steers in all other years. REA was larger for steers in YR 3 and 7 (87.09 and 87.07 cm²) and least for steers in YR 1 (79.04 cm², $p < .01$). MS was the highest in YR 5 at 396 and the lowest in YR 1 at 362 ($p < .01$). QG mirrored MS with steers in YR 5 having the highest QG and those in YR 1 the lowest QG (17.89 and 17.24, respectively, $p < .01$). YG was greatest in YR 7 at 2.86 and the lowest in YR 4 at 2.57 ($p < .01$). SB did not influence ($p > .05$) HCWT. However, SB did significantly influence all other carcass traits. BB and AB sired steers had greater ($p < .01$) BF (1.34 and 1.31 cm, respectively) than EB sired steers (0.97 cm). EB sired steers had larger REA (88.14 cm², $p < .05$) than BB and AB sired steers (83.39 and 82.16 cm², respectively). MS and QG were greater ($p < .01$) for BB sired steers (403 and 18.07, respectively). YG was lowest ($p < .01$) for EB sired steers at 2.4 compared to 2.76 and 2.89 for AB and BB sired steers, respectively. Overall, QG improved as the program progressed. BB sired steers exhibited the highest QG, while EB sired steers had the lowest YG.

Key Words: Cattle, Feedlot, Carcass

902 On farm/ranch HACCP - Is it time? W.J. Means*, *University of Wyoming, Laramie, WY/USA.*

Based on review of available literature, the objective was to determine if HACCP (Hazard Analysis Critical Control Points) could be efficaciously applied to livestock production systems to reduce the prevalence of *Escherichia coli* O157:H7 in beef products. HACCP involves prevention of hazards affecting food safety from production to consumption. Currently, HACCP application in relation to control of pathogenic food-borne bacteria extends to processing plants, retail outlets, and restaurants - not to the farm or ranch. Steps necessary for food borne illness (FBI) to occur include pathogen contamination of the food, abuse of the food, improper cooking, and consumption of the food in question by a susceptible individual. Measures that break the sequence of events, thus deterring FBI, may be considered critical control points (CCP's). Reducing the number of pathogens entering a food/meat processing facility in/on livestock could further decrease the pathogen load of finished raw or cooked product. However, prevalence of *E. coli* O157:H7 in individual animals/herds as well as factors affecting shedding of the organism

has received limited study. Seven reports indicate *E. coli* O157:H7 is present in 0.28 to 11.6% of dairy cattle with a herd incidence of 8.3 to 75%. Two studies indicate *E. coli* O157:H7 is present in 0.33 to 13.4% of feedlot cattle and can be found in 10% of feedlots tested. Factors that may be associated with prevalence of *E. coli* O157:H7 include age of animal, herd biosecurity, feeding regimen, manure handling practices, weaning, and fasting. It is clear that single-time-point sampling of beef and dairy herds is an inadequate method to determine *E. coli* O157:H7 prevalence and that more research is needed to describe the true animal/herd prevalence. Since management practices that can actively reduce carriage and shedding of *E. coli* O157:H7 are not clearly defined, it is unrealistic to apply HACCP principles to cattle production systems at this time. Continued research to identify on-farm/ranch CCP's is needed to decrease the pathogen load of cattle entering processing plants.

Key Words: HACCP, *E. coli* O157:H7, cattle

903 A bioeconomic model of the broiler chicken supply chain - simulation for extension. M. J. Zuidhof^{*1}, R. J. Hudson², T. Joro², and J. J. R. Feddes², ¹*Alberta Agriculture, Food and Rural Development*, ²*University of Alberta*.

A dynamic, deterministic bioeconomic model of the broiler supply chain has been developed with the objective of assisting the poultry industry with complex decisions. Because of biological variability and complex industry structure it is often difficult to optimize decisions, which may be defined as decisions that yield maximum economic benefit to the supply chain. The model spans five sectors of the broiler supply chain: feed, hatching egg production, hatchery, broiler production, and processing. Biological productivity is based on the genetic potential of each strain of bird used in the model. The model operates on a daily time step, and accrues production and associated costs daily. The model simulates daily hatchery, feed, and processing cycles. The length of the broiler cycle is determined by the length of time required to produce chickens for specific processing objectives, which can be set in the user interface of the model. In the broiler sector, production costs are accrued until the time of processing, after which costs are held constant. Prior to the onset of lay in the breeders, actual costs of chick production are undefined, so the model draws on a user supplied chick price. After 250 d of simulation, the model uses simulated chick cost, which drops with increasing breeder age as costs are spread over larger chick numbers. The cost reported on the last day of simulation represents the predicted costs if breeders are kept for the entire production cycle. The model is set to simulate 66 wk of production, the standard broiler breeder cycle length in Canada. Costs are reported in formats that are meaningful to each sector of the supply chain, and as the total cost per kg of meat produced by the supply chain. This is useful for analyses of the effects of specific supply chain management decisions, such as the choice of genetic strain, on costs at the level of each sector. This is important because although a decision may be optimal for the supply chain as a whole, it may not be optimal for all participants in the supply chain.

904 Profitability analysis model for assessing the relationship between feeder frame scores, feed efficiency and carcass merit. K.C. Olson^{*}, V.L. Pierce, R.L. Larson, E.P. Berg, and C.L. Loenzen, *University of Missouri*.

Problem Cow calf producers are facing a changing beef marketing system. To that end, their interest in animal performance beyond the point of weaning is gaining with tremendous speed. However, the ability of cow calf producers to identify characteristics of early life animal performance which later impact feed efficiency, health, and carcass quality and yield are limited.

Objective To determine the economic relationship between USDA frame scores, weaning weight and early post weaning health on feedlot performance and carcass grade and yield.

Data and Methods

Data from the Missouri Premier Beef Marketing program is used in the study. Complete data collected from 699 calves in the Premier beef program include USDA feeder frame score, weaning weight, feeding efficiency, and carcass yield and quality. A general backpropagation-estimated feedforward artificial neural network is developed to explain the relationships between the stages of the animals life in these systems. This model is contrasted to an OLS regression attempting to explain

the same relationship. Model parameters are then used to identify economic relationships between early life performance, frame scores, feed efficiency and USDA carcass merit values. Multi-variate distributions are assigned to model stochastic variables to assess the risk and reward trade-offs in the final analysis.

Conclusion Economic trade-offs are presented which demonstrate the ability and likelihood that a cow calf producer can project feed efficiency and carcass merit from feeder frame scores and weaning weight and early post weaning health and feeding efficiency. The list below shows how a group of 156 head of steers animals is tracked economically; 65 percent choice or better, average carcass value of 847 dollars, average animal cost to feeder of 529 dollars, average available to feeder 322 dollars, maximum available to feeder per head 544 dollars, minimum available to feeder 113 dollars, 92 of the 156 were profitable to the feeder leaving 19.35 dollars per head at the feedyard. This data is used with feeder grades to identify those animals that were profitable in the feedlot and determine associated relationships for use in the predictive model.

Key Words: Feeder Calves, Economics, Carcass

905 The use of early post weaning performance and quality data of feeder calves in determining the best marketing method for cow calf producers. R.L. Larson, V.L. Pierce^{*}, and K.C. Olson, *University of Missouri*.

Problem Cow calf producers are facing a changing beef marketing system. Producers have increased access to early post weaning performance and quality information on their calves. However, a system that allows producers to measure the economic trade-offs between these data and available marketing systems is largely unavailable in a user-friendly computerized decision tool.

Objective To evaluate the economic trade-offs between early post weaning performance and quality characteristics of feeder calves and develop a farm specific decision tool which allows producers to evaluate various marketing methods given likely feeding and carcass merit performance of their calves.

Data and Methods

Data from the Missouri Premier Beef Marketing program is used. This program coordinates a group of cow-calf operations with the objective of gaining market power by producing uniform, quality animals that can be traced from birth through slaughter. With this program, for example, 20 producers with 50 calves each can market 1000 calves in sorted potload size lots with similar health, genetics and management programs. Feedlot performance and carcass data can be fed back through the production chain to each cow-calf member producer to assist in making production and management decisions. Animals are commingled and developed during a short 45-90 day backgrounding period. Complete data collected from 699 calves in the Premier beef program include serial USDA feeder muscling scores, USDA frame score, weaning weight, feeding efficiency, and carcass yield and quality. An ordinary least squares multi-variate model is developed to explain the relationships between the stages of the animals life in these systems. Spreadsheet add-on tool At Risk is used with enterprise budgets to assess the impact of variable distributions on decisions regarding various marketing methods including commodity market sale, full and partial retained ownership.

Conclusion Producers can use this spreadsheet tool, based on actual calf performance data, to evaluate the likely performance of their feeder calves and thus determine the risks and reward trade-offs under various marketing scenarios.

Key Words: Feeder Calves, Economics, Decision Tool

906 The A.I.M. Program (Allied Inputs and Marketing): A Producer Cooperative that Reduces Production Costs and Increases Market Value of Calves. L. H. Anderson^{*}, J. T. Johns, K. D. Bullock, and W. R. Burris, *University of Kentucky*.

Small and medium-sized producers face tremendous production and marketing disadvantages due to the lack of economics of size. Approximately 85% of beef cattle operations in Kentucky consist of 50 cows or less. The University of Kentucky Beef Extension Team has developed a new program that encourages producers to form a production and marketing alliance. The focus of the A.I.M. (Allied Inputs and Marketing) program is to improve profitability of beef cattle production by allowing small and medium size beef producers to utilize economies of scale.

Two production alliances have been developed in Kentucky. One alliance has both a purchasing and marketing function and consists of 22 producers who own approximately 1500 cows (average size = 68 cows; range = 10-200). The second alliance is a purchasing alliance only and consists of 107 producers who own 6237 cows (average size = 58 cows, range 7-400 cows). Each member agrees to purchase only through the alliance. The alliance then requests bids from local vendors on products such as vaccines, dewormer, growth implants, mineral, preconditioning feed, semen, and estrus synchronization products like melengestrol acetate. Savings on these products have been tremendous. Purchase price of vaccines (respiratory disease complex, clostridial diseases, and reproductive diseases) have been reduced an average of 23.25% (range = 22-26%). Costs of deworming products decreased 24.0% while savings on growth promotants average 18%. Similarly, savings on mineral averaged 24.7%. Over the past two years, production costs decreased \$12-20 per cow due to the purchasing programs in these alliances. The cooperative marketing of the alliance cattle has increased net return \$28-37 per cow over the last two years in one alliance. Thus, return per cow has increased for \$40-57 per cow due to the production and marketing cooperative. Based on these results, participation in these alliances has increased profitability and sustainability of small and medium-sized beef producers.

Key Words: Beef, Extension, Marketing

907 Cow College: Implementation of an Intense, 9-day Educational Opportunity for Beef Producers in Kentucky. L. H. Anderson*, W. R. Buriss, K. D. Bullock, J. C. Henning, P. B. Scharko, D. W. Shepherd, J. D. Anderson, and C. W. Absher, *University of Kentucky*.

A renewed interest in profitability and an increase in nontraditional clientele have increased the need for more educational opportunities for producers. An instructional program was developed by the Kentucky Beef Integrated Beef Management Team to educate producers in all aspects of beef production. Cow College consists of 5 separate training sessions conducted from July to November. The first session discusses economics of the beef industry. Lecture material includes farm goal setting, record keeping, marketing, and the future market. Laboratory exercises discuss case studies in which producers are asked to make financial decisions using economic tools such as backgrounding spreadsheets. Producers also gain experience in the feedlot/packer industry by participating in the Packer-Feeder game. The second session focuses on beef cattle nutrition. Lectures regarding beef cattle nutrients, characterization of feedstuffs, planning both forage and nutritional programs and mineral supplementation. Laboratory sessions include body condition scoring, ration balancing and reading mineral and feed tags. The third session discusses herd health and cattle handling. Herd health programs, implanting, dehorning and castration are discussed and demonstrated. The basics of cattle handling are also taught. The fourth session focuses on breeding management. The basics of genetics, crossbreeding programs, bull selection, heifer selection, female reproduction, male reproduction and reproductive management are taught. Laboratory sessions provide opportunities to learn AI, pregnancy diagnosis, pelvic area measurements, BSE, and bull selection. The final session discusses end product. Students learn to calculate yield and quality grade of both live cattle and carcasses. Carcasses are fabricated and students also participate in a taste panel focusing on palatability of select versus choice beef. Since July of 1999, 32 producers have been trained. Herd sizes of these producers ranged from 10 to 900 cows and backgrounding operations ranged from 50 to 5000 calves. Most producers have indicated that Cow College was an outstanding program and session evaluations have averaged 8.6 (1-10, 1 being lowest).

Key Words: Beef, Extension, Education

908 Mississippi farm to feedlot: feedlot performance. W.B. McKinley, A.R. Williams*, J.N. Myers, A.G. Gardner, and E. Ward, *Mississippi State University, Starkville, MS*.

The objectives of the Mississippi Farm to Feedlot program are to evaluate production and carcass information of steers produced in Mississippi, and to provide educational information regarding retained ownership as a marketing alternative. Seven years (1993-1998) of data were collected and the effects of year of feeding (YR) and sire breed (SB) on feedlot performance were evaluated. Sire breeds were classified into three breed groups, British Breeds (BB), European breeds (EB), and American breeds (AB). Feedlot performance response variables included steer

final weight (FWT), final gain (FGN), final average daily gain (FADG), and final age at harvest (FAGE). Both YR and SB significantly influenced feedlot performance. FWT was greatest for steers in YR 5 at 548 kg ($p < .01$), intermediate for steers in YR 4 and 6, and the least in YR 1, 2, 3, and 7. FAGE was also greatest ($p < .01$) in YR 5, with steers averaging 532 d at harvest, whereas steers in YR 1 were significantly younger at harvest (460 d). FGN was highest ($p < .05$) in YR 4 and 6 (261 and 269 kg, respectively), and lowest in YR 3 and 7 (233 and 232 kg, respectively). FADG was highest ($p < .01$) for YR 4 and 6 (1.44 and 1.45 kg/d, respectively) and lowest for YR 2 and 5 (1.29 and 1.28 kg/d, respectively). FWT and FGN were not influenced ($p > .05$) by SB. However, SB did influence FADG with BB and EB sired steers exhibiting daily gains of 1.40 and 1.37 kg/d compared to 1.34 kg/d for AB sired steers ($p < .05$). SB also influenced FAGE with BB sired steers the oldest at harvest at 499 d, AB sired steers at 494 d, and EB sired steers were the youngest at 467 d ($p < .01$). Year of feeding significantly affected feedlot performance in all variables measured. There was a tendency for steers to be younger and lighter at harvest in the first three years of the program. SB significantly influenced FADG and FAGE. BB and EB sired steers had significantly higher FADG compared with AB sired steers.

909 Establishing a catfish off-flavor control program in Georgia. G. J. Burtle*¹, G. W. Lewis², M. Fowler³, and T. Cummings³, ¹*Animal & Dairy Science, University of Georgia, Tifton, GA 31793*, ²*Warnell School of Forest Resources, University of Georgia, Athens, GA 30602*, ³*Cooperative Extension Service, University of Georgia, Louisville, GA 30434*.

In 2000, more than 545,500 kg of channel catfish under production in Jefferson county, Georgia were off-flavor. Individual catfish ponds were sampled to determine the extent of the off-flavor problem. Ponds that had off-flavor catfish were not harvestable due to refusal of processing plants to purchase the off-flavor catfish. Twentytwo ponds ranging in size from 1.25 to 5.0 ha were found to have a few hundred to over 5,000 colonies per mL as blue-green algal species known to cause off-flavor in catfish. A leading cause of off-flavor in catfish, *Oscillatoria perornata*, was present in 40.9% of the ponds from 184 to 8,820 colonies per mL. That species produces methylisoborneol, the leading cause of catfish off-flavor. Control options included chemical treatments with copper containing herbicides, algae-eating fish, and special label extension for diuron herbicides. An emergency label extension under Section 18 of the Federal Insecticide, Fungicide and Rodenticide Act was applied for and was granted by USEPA. The label extension directly affected catfish valued at \$472,000 and indirectly affected 13 ponds containing catfish valued at \$682,000. A system of alternating copper containing chemicals with diuron herbicide was recommended for the catfish producers using county meetings, newsletter articles, and news releases.

910 Effectiveness of a volunteer association in conducting 4-H/youth extension activities. M.J. Wylie*, M.J. Miller, R.B. Housel, L.H. Pribek, and R.J. Antoniewicz, *University of Wisconsin, Madison, WI*.

A volunteer association can be highly effective in the planning and conduction of 4-H/youth extension activities. Yearly district and state events are critical to most extension youth programs yet the organizational details required can often overwhelm state specialists and county staff in this era of dwindling staff and increasing program needs. One way to effectively manage yearly events such as conferences and competitions is to empower volunteers. The Wisconsin 4-H Horse Association is the current organization that has evolved and expanded since its beginnings in 1965. Its purpose is "to plan, promote and execute educational programs in the area of horse science for Wisconsin youth and their leaders". It works in conjunction with county 4-H agents and state specialists and can serve as a model for other species and/or discipline volunteer associations. All currently enrolled 4-H Horse and Pony or Horseless Horse adult leaders are members and each of the six districts elects three directors. The association sponsors the following state events: clinics, hunt and dressage show, gymkhana, horse expo (educational events and show classes), and an annual leaders conference. A volunteer leader (all project areas) survey recently conducted in Wisconsin revealed the top reasons a person continues as a volunteer are: personal satisfaction, desire to serve community, friendships,

children still in program, and interest in specific project. A pre-survey of association directors revealed common reasons for volunteering were: enjoy working with youth and horses and a desire to contribute back to a program, which benefited them. Some of the challenges listed included trying to keep program costs minimal for leaders and youth, personal expense when attending association activities, and improving communi-

cation. Overall, directors consider the association to be highly effective in conducting 4-H/youth horse extension activities. These volunteers are examples of extremely dedicated individuals with a common interest - to offer youth quality educational programs.

Key Words: Volunteer association, 4-H/youth, Extension horse activities

ASAS/ADSA Forages and Pastures: Grazing

911 Evaluation of calf and forage production in rotational stocking systems for spring- and fall-calving beef cows. N. A. Janovick*¹ and J. R. Russell¹, ¹Iowa State University.

To evaluate two forage management systems, 24 spring-calving Angus-cross cows with calves were rotationally stocked in four 8.1-ha smooth bromegrass-orchardgrass-birdsfoot trefoil (SB-OG-BFT) pastures on April 22, 1999, and April 26, 2000. In a hay harvest (HH) system, spring-calving cows with calves grazed 2.03 ha for 58 d. Forage from the remaining 6.07 ha was harvested as first-cutting hay and incorporated into the rotational stocking system after 28 d. Over winter, cows were maintained in a drylot. In a first-last (FL) grazing system, six spring-calving cows with calves and 12 stocker cattle grazed paddocks in a rotational stocking system before six pregnant fall-calving Angus-cross cows for 55 d. In addition, forage from replicated 6.07 ha smooth bromegrass-red clover (SB-RC) and tall fescue-red clover pastures (TF-RC) was harvested as first-cutting hay and strip-grazed by spring-calving cows with calves and fall-calving cows for 50 d while stocker cattle grazed SB-OG-BFT pastures. Thereafter, stocker cattle were removed and spring- and fall-calving cows were again rotationally stocked in SB-OG-BFT pastures for 80 d. During winter, spring-calving cows grazed replicated 6.07 ha corn crop residues and stockpiled SB-OG pastures and fall-calving cows grazed stockpiled TF-RC pastures. Fall-calving and spring-calving cows were bred by natural service over 45 and 49 d in yr 1, respectively, and over 42 d in yr 2. No difference in average daily gains of spring calves and total growing animal production per hectare between systems was observed. Conception rates of spring-calving cows in the HH system were lower ($P < .01$) than spring-calving cows in the FL system in yr 1 and lower ($P < .01$) than fall-calving cows in the FL system in yr 2. Hay production per hectare did not differ between systems in yr 1, but was greater ($P < .05$) for the HH system than for the FL system in yr 2. Total perennial winter forage production per cow for the HH and FL systems were 1329, 4898 and 3272, 4681 kg DM in yr 1 and 2, respectively.

Key Words: beef cattle, rotational stocking, stockpiled forage

912 Liveweight and growth rate of cow-calf pairs grazing tall fescue pastures infected with either non-toxic (MaxQTM) or toxic endophyte strains. R.H. Watson*, M.A. McCann, J.A. Bondurant, J.H. Bouton, C.S. Hoveland, and F.N. Thompson, *The university of Georgia, Athens, GA.*

A trial was conducted to determine whether cow-calf pairs grazing tall fescue pastures infected with the non-toxic endophyte, MaxQTM, have better productivity than cow-calf pairs grazing tall fescue infected with the toxic, wild-type endophyte. Two 7.1 ha paddocks and two 7.3 ha paddocks were sown in tall fescue (*cv*: Georgia-5) infected with either the MaxQ or toxic endophyte. The 7.1 ha and 7.3 ha paddocks were stocked in early March with 15 and 16 cow-calf pairs respectively. The cow-calf groups were balanced for cow age, calving date, BW, and body condition-score (BCS). The pairs were grazed on their respective treatment pastures until the calves were weaned in late August. All cows and calves were weighed and blood sampled pre-treatment, and subsequently every 8 weeks, with a final weight recorded at calf weaning. Cows were visually assessed for BCS at these times. Blood samples were analyzed for prolactin as an indication of toxicosis. Serum prolactin levels were lower ($P < .01$) in cows and calves on toxic fescue (32 ng/ml, and 36 ng/ml respectively) than cows and calves on MaxQ fescue (94 ng/ml, and 101 ng/ml respectively). Cow BW and BCS were better ($P < .05$) at weaning in the MaxQ group compared with the toxic group (BW, 512 kg vs 486 kg respectively; BCS, 5.9 vs 5.3 respectively). Steer calves raised on MaxQ fescue had better ADG and weaning weights than all other groups of calves. Heifer calves raised on MaxQ fescue had better ADG and weaning weights than heifer calves raised on toxic fescue but were not different from steer calves raised on toxic fescue. The results indicate that grazing tall fescue infected with the MaxQ endophyte, as

opposed to toxic tall fescue, has the potential to eliminate toxicosis and greatly improve cow-calf productivity.

	Steer calves		Heifer calves	
	Toxic	MaxQ	Toxic	MaxQ
ADG (kg/d)	0.91 ^{a,b}	1.15 ^c	0.87 ^a	1.03 ^b
Weaning weight (kg)	226 ^{a,b}	260 ^c	207 ^a	230 ^b

^{a,b,c} Means on same row with different superscripts are different ($P < .05$)

Key Words: Cow-calf production, Toxic tall fescue, MaxQ

913 Non-toxic endophyte (MaxQTM) use for alleviating tall fescue toxicosis in stocker cattle. J.A. Bondurant*, M.A. McCann, J.H. Bouton, C.S. Hoveland, R.H. Watson, and J.G. Andrae, *The University of Georgia, Athens, GA.*

To address the problem of fescue toxicosis in grazing cattle, plant persistence-enhancing non-toxic endophytes from New Zealand have been incorporated into tall fescue cultivars grown in Georgia. The objectives of the present study were to determine animal performance and evaluate toxicosis in stocker steers and heifers grazing non-toxic endophyte-infected (MaxQTM), endophyte-free (EF), or toxic endophyte-infected (EI) tall fescue. Replicated (n=2) .809-ha tall fescue paddocks were established at the Central Georgia Branch Station near Eatonton, GA and at the Northwest Georgia Branch Station near Calhoun, GA with Jesup and Kentucky-31 tall fescue cultivars, respectively. Animals were stocked on the paddocks using put-and-take grazing management during four periods from Spring 1999-Fall 2000 that averaged 65 d each at Eatonton and 89 d each at Calhoun. Mean stocking rate at Eatonton was 7.1 hd/ha with no treatment differences ($P > .05$). At Calhoun stocking rate averaged 8.9 hd/ha and was higher ($P < .05$) on the toxic EI paddocks compared to the MaxQTM and EF paddocks. Forage available during grazing was approximately 3100 kg DM/ha at the central GA location and 1900 kg DM/ha at the northwest GA location. There were no differences ($P > .05$) seen among treatments for available forage with the exception that MaxQTM available forage levels were lower ($P < .05$) than toxic EI available forage levels during Fall 2000 at Calhoun. D-14+ serum prolactin was depressed ($P < .05$) on the toxic EI paddocks compared to the MaxQTM and EF paddocks during fall grazing at Eatonton and during both seasons at Calhoun. No differences ($P > .05$) were found in d-14+ rectal temperatures among the three treatments. ADG/hd and gain/ha were higher ($P < .05$) on the MaxQTM and EF paddocks than on the toxic EI paddocks in both trials. These results suggest that infecting tall fescue cultivars with non-toxic endophytes is a promising alternative for combating fescue toxicosis in stocker cattle.

Key Words: Tall fescue, Nontoxic endophytes, MaxQTM

914 Performance of beef cattle grazing endophyte-infected tall fescue or sod-seeded ryegrass. D.W. Sanson*¹ and D.F. Coombs², ¹Rosepine Research Station, ²Dean Lee Research Station, *LSU Ag. Center.*

Grazing endophyte-infected tall fescue was compared to grazing sod-seeded ryegrass in West Central Louisiana for two-years with mature beef cows. Seventy-six cows (551 kg) were randomized into four groups of 19 cows. Each group was assigned to 8.1 ha pastures that were subdivided into four 2 ha paddocks. Two pastures were previously established in endophyte-infected fescue along with bermudagrass and bahiagrass, while two bermudagrass/bahiagrass pastures were sod-seeded with ryegrass each fall. Cows were maintained on their assigned pastures throughout the year. Hay was available in the fall prior to calving when forage availability was not adequate for grazing. Cows, predominantly Angus, Simmental, and Hereford crosses, were exposed to Brangus bulls from late April to mid-June of each year. Conception rate was determined by rectal palpation in September. Calves were weaned in mid-October. The model for data analysis included treatment, year,

and the treatment X year interaction. In general, cow weight, cow weight change, or cow condition score were not affected ($P > .1$) by treatment, however, cows grazing ryegrass were heavier ($P = .04$) in September (600 vs 578 kg for ryegrass and fescue, respectively). Cows grazing ryegrass had higher ($P < .03$) condition scores (5.8 vs 5.6) prior to calving, however the difference was probably not of biological significance. Fall pregnancy rates were lower ($P = .03$) for cows that had grazed fescue (70.4%) compared to cows that grazed ryegrass (91.6%). Calves born to cows grazing fescue (38 kg) weighed less ($P = .02$) at birth than calves born to cows that grazed ryegrass (43 kg). There was no difference ($P > .2$) in calf weights at the end of the breeding season or at weaning due to grazing treatment. These data suggest a negative effect of grazing endophyte-infected fescue on pregnancy rates with mature beef cows under West Central Louisiana conditions.

Key Words: Fescue, beef cows, ryegrass

915 Effect of grazing tall fescue endophyte types on subsequent feedlot performance and carcass quality. S. K. Duckett¹, J. A. Bondurant¹, J. G. Andrae¹, J. N. Carter², M. A. McCann¹, T. D. Pringle², and D. R. Gill², ¹University of Georgia, Athens, ²Oklahoma State University, Stillwater.

Research was conducted to determine the effect of grazing tall fescue pastures with different endophyte types on subsequent feedlot performance and carcass quality of beef cattle. Cattle grazed tall fescue endophyte infected (TOXIC), free (EF), or non-toxic (MAXQTM) pastures for 84 d at the Central Georgia Experiment Station (CGES), Eatonton and 112 d at the Northwest Georgia Experiment Station (NWGES). Real time ultrasound measures of fat thickness (UFT), ribeye area (UREA), and intramuscular fat (UIMF) were collected at the end of grazing phase. Twenty-four crossbred steers from CGES and twenty-four Angus heifers from NWGES were transported to the Willard Sparks Feedlot (Stillwater, OK). At the feedlot, cattle were allotted by location, grazing treatment and pasture replicate to pens (4 hd/pen) and fed a high concentrate diet for 112 d. Cattle were weighed at 28-d intervals and pen feed intake data was recorded on a daily basis. Carcass data were collected after harvest. Data were analyzed with treatment, location and two-way interaction in the model. Interactions between treatment and location were non-significant ($P > 0.05$). MAXQTM and EF cattle gained 0.52 kg/d more ($P < 0.05$) than TOXIC during the grazing phase. UFT and UIMF were similar ($P > 0.05$) between grazing treatments. MAXQTM and EF cattle had larger UREA than TOXIC; however, UREA/cwt values were similar ($P > 0.05$). At the beginning and end of feedlot phase, MAXQTM and EF cattle were over 50 kg heavier ($P < 0.05$) than TOXIC. Feedlot ADG was similar ($P > 0.05$) among grazing treatments. Hot carcass weights were higher ($P < 0.05$) for MAXQTM and EF than TOXIC. Other carcass quality measures did not differ ($P > 0.05$) due to grazing treatment. Carcass value was higher ($P < 0.05$) for MaxQTM than TOXIC with EF being intermediate. Thus, TOXIC cattle did not compensate in the feedlot for lower gains attained in the grazing phase and remained lighter in weight than EF or MaxQTM throughout the feedlot phase.

Key Words: Fescue, Feedlot, Carcass

916 The Effect of Yeast (*Saccharomyces cerevisiae*) Mineral on Organic Matter Digestibility in Beef Cattle on Native and Fescue-based Pasture Grazing Systems. Dean Kobs* and Stephen Boyles, *The Ohio State University*.

Twenty cows were given ad-lib access to mineral mix (control) or yeast (Diamond V XP[®]) mineral mix over the course of a year. Organic matter (OM) digestibility of the pasture was measured by randomly sampling the forage base and collecting 10 fecal grab samples per animal over five days (at least two samples per day). The fecal collections were conducted at different times of the day and/or night to account for diurnal variation. The trial was conducted in the winter (December), and twice in the summer (June and August). In-vitro OM digestibility was measured in both forage samples and cow fecal samples (compiled within animal). The indigestible forage and feces were measured for acid detergent fiber (IADF). The IADF served as an internal marker to calculate OM digestibility. There was no significant difference between groups in both seasons. However, in both summer trials, there was a trend of increased June OM digestibility 47% vs. 43% ($P = 0.12$) and August OM digestibility 55% vs. 52% ($P = 0.14$) in the yeast-mineral supplemented

groups. The trend may imply yeast-mineral supplemented cattle have an increased ability to digest organic matter in the summer months.

Key Words: Yeast (*Saccharomyces cerevisiae*)

917 Effect of method of storage on protein and fiber fractions, and *in situ* digestibility of kikuyu grass (*Pennisetum clandestinum*) and guinea grass (*Panicum maximum*). J.R. Carpenter^{*1}, S.E. Ellis², and R.Y. Niino-DuPonte¹, ¹University of Hawaii at Manoa, Honolulu, HI USA, ²University of South Carolina, Columbia, SC USA.

Cattle production in tropical/sub-tropical regions is limited by the available pastures' ability to support growth, reproduction, and lactation due to their high moisture and fiber, and low protein and energy content. The objectives of this experiment were to determine the effect of method of storage (direct cut, wilted silage, haylage and hay) on protein and fiber fractions and their relationship to extent and rate of dry matter, protein and fiber digestion. Six-week old kikuyu grass (KG) and guinea grass (GG) were harvested, chopped, then wilted to various moisture levels before being stored as silage or haylage in replicated experimental silos or as hay. After 30 d, subsamples from each storage method were analyzed for DM, fiber and protein fractions, and *in situ* digestibility. CP, NDF, ADF, and cellulose (averaged across storage methods) were 14.7, 65.7, 35.6, and 25.2% for KG and 8.6, 70.1, 44.7, and 31.8% for GG, respectively. *In situ* extent and rate of digestion differed ($P < .05$) both between grasses and storage method. Extent of digestion for DM, CP, NDF, and ADF (averaged across storage methods) were 54.2, 65.3, 45.4, and 47.4% for KG, and 43.9, 70.9, 46.6, and 45.1% for GG, respectively. Rates of DM, CP, NDF and ADF tended to increase as moisture content decreased for GG, but the opposite trend was observed for KG. For both grasses, the proportion of hemicellulose to NDF and to cellulose decreased and cellulose to ADF increased with decreasing moisture content. The proportions of soluble N decreased and insoluble available N increased as moisture content of storage method decreased. Data suggest that the method of storing tropical grasses alters both the nutrient composition, particularly the protein and fiber fractions, and the rate and extent of *in situ* digestion.

Key Words: Tropical grass and Silage/Haylage, Protein and fiber fractions, *In situ* digestibility

918 Characterization of season and sampling method effects on forage quality in fescue-based pastures. T.M. Dubbs*, E.S. Vanzant, S.E. Kitts, R.F. Bapst, B.G. Fieser, and C.M. Howlett, *University of Kentucky, Lexington*.

Information describing effects of seasonal changes and sampling methods on measurement of forage quality is limited for fescue-based pastures. Eight continuously-grazed, .76-ha, fescue-based pastures were used to compare forage type, method of collection, and seasonal effects on forage quality in a repeated measures, split-plot design. Four pastures were interseeded with red clover during March 2000. Masticate (M; from 4 ruminally-cannulated steers) and hand-clipped (C) samples were collected every 28 days from May until October 2000. In general, interseeding red clover in tall fescue-based pastures did not contribute ($P > .10$) to differences in OM, CP, NDF, ADF, or protein degradability characteristics. Sampling method effects were not evaluated for protein degradability characteristics. Sampling method and season interacted ($P < .03$) for OM, CP, NDF, and ADF. Concentrations of OM were greater ($P < .01$) for C than M in all months and responded quadratically ($P < .01$) to month for both C and M (C: 93, 93, 94, 94, 94, and 93%; M: 91, 89, 87, 88, 87, and 89% for May-October). NDF (C: 69, 73, 75, 74, 72, and 63%; M: 66, 68, 66, 66, 65, and 62% for May-October) and ADF (C: 35, 39, 42, 38, 37, and 31%; M: 33, 35, 33, 34, 34, and 31% for May-October) were greater ($P < .01$) for C than M in all months except October ($P > .10$) and were described by quadratic ($P < .01$) responses across month, except for NDF with C, which was cubic ($P = .04$). Crude protein (C: 13, 11, 12, 13, 14, 17%; M: 16, 15, 18, 18, 18, and 18% for May-October) was lower ($P < .01$) in C than M in all months except October ($P > .10$) and was quadratic ($P < .01$) across months for C, and cubic ($P < .01$) for M. Within M, concentrations of A, B, and C protein fractions, determined from *in situ* analysis (uncorrected for microbial attachment), responded cubically ($P < .01$) to month, whereas protein degradation rate decreased linearly ($P < .01$) from May-October. Estimates of protein degradability responded cubically (72, 61, 64, 67, 65,

and 67% for May-October). In its first growing season, red clover interseeded into fescue pastures did not influence quality of diet selected by grazing steers. Differences between clipped and masticate samples were substantial until late season, when opportunities for selective grazing were minimal.

Key Words: Fescue, Season, Quality

919 Performance of high producing dairy cows with three feeding systems combining pasture and total mixed rations. F. Bargo*, L. D. Muller, J. E. Delahoy, T. W. Cassidy, and J. L. Amick, *The Pennsylvania State University, University Park.*

Forty-five Holstein cows [15 primiparous and 30 multiparous (6 rumen cannulated); 624 kg BW; 44.9 kg/d milk; 109 DIM] were used in a repeated measures design of 21 weeks to study the effect of three feeding systems on animal performance and rumen digestion. Cows were blocked by lactation number and DIM, and randomly assigned to three treatments: pasture + concentrate (PC); pasture + total mixed ration (TMR) (partial TMR; pTMR); and total mixed ration (TMR). Cows on PC and pTMR grazed a grass pasture offered at 30 kg DM/cow/d plus a corn-based concentrate (1 kg/4 kg of milk for PC and an amount to maintain a similar forage:concentrate ratio between PC and pTMR for pTMR). Cows on TMR were fed ad libitum with a nutritionally balanced TMR. Pasture, concentrate and TMR had 26.3, 15.2, and 16.6% CP; 49.9, 15.7 and 30.1% NDF, respectively. Total DMI was measured 4 times in all three treatments using Cr₂O₃ as fecal marker. The highest total DMI and milk production were obtained with the TMR diet, the lowest with the PC, and intermediate with the pTMR. Both the TMR and the pTMR treatments had a higher milk fat and protein percentage than the PC treatment. Cows on PC and pTMR gained less BW (27 and 40 kg, respectively) than cows on TMR (76 kg). Concentration of rumen ammonia N and MUN were significantly lower in TMR and pTMR treatments than in PC treatment. Rumen pH and total VFA concentration were not affected by treatments. The combination of pasture and TMR resulted in a higher milk production with a higher fat and protein content and a better dietary N utilization than the pasture plus concentrate combination.

920 Application of a pasture intake model in an educational package to enhance farmer uptake of pasture quality management technologies. S.J.R. Woodward* and M.G. Lambert, *AgResearch Limited, Hamilton, New Zealand.*

Accurate feeding of livestock on pasture depends on a farmer's ability to estimate the quantity and quality of the feed components on offer, and then to predict what animals will eat while grazing. An educational package was developed to better enable New Zealand sheep and beef farmers to manage pasture quality on-farm. The package was designed to promote farmers' (1) understanding of pasture quality, (2) measurement of pasture quality on-farm, (3) prediction of animal responses to pastures with an estimated quality, and (4) management of pasture quality for feeding livestock to achieve pre-determined performance targets. Part of the objective was achieved by constructing a computer-based decision support tool, Q-Graze. A farmer enters field estimates of pasture quality, along with stock and grazing management information, and Q-Graze then predicts changes in herbage mass and quality, intake, and liveweight gain responses of animals. This allows the farmer to check that liveweight gain targets will be met, and if not, to alter his or her grazing plan accordingly. Predicting grazing behavior, intake, and liveweight gain is complicated because of the dynamic interplay between pasture mass and quality, intake rate and composition, rate of digestion, and animal energy metabolism. Mathematical models are the most appropriate tool for simulating these interactions. Underlying Q-Graze is

a pasture intake model that calculates bite size, bite composition, bite handling time (including ruminating), and energy intake rate. The ratio of energy intake rate to animal energy demand is used to determine the animals' instantaneous feeding effort (the time derivative of grazing time plus ruminating time). This allows the seamless integration of four constraints to intake: satiation, digestive capacity, resting requirements, and cessation of feeding when net energy assimilation rate falls below zero. Daily dry matter and energy intakes can then be calculated, and used to predict animal growth. The successful application of this pasture intake model is possible because it is embedded in a user-friendly software tool (Q-Graze). Use of Q-Graze by farmers during its development allowed them to shape the software, and contributed to their learning about pasture quality.

Key Words: Decision support software, Sheep, Beef cattle

921 Using *in sacco* and *in vitro* incubations to determine the digestion and fermentation kinetics of fresh forages. J.L. Burke*^{1,2}, G.C. Waghorn¹, L. G. Barrell^{1,2}, I. M. Brookes², G.T. Attwood¹, and E. S. Kolver³, ¹AgResearch, ²Massey University, ³Dexel Ltd, New Zealand.

The objective of this study was to estimate the nutritive value and digestion kinetics of New Zealand forages using *in sacco* and *in vitro* incubations. Initial studies using three fresh forages (*Trifolium repens*, *Lolium perenne* and *Lotus corniculatus*) indicated that mincing was a more suitable preparation for incubation than either freeze drying and grinding or chopping to 6-mm lengths. Digestion kinetics were determined on 23 contrasting fresh forages following mincing to a particle size similar to chewed material. Forages (2.5 g wet) were incubated *in vitro* at 39°C for 24 h with McDougals buffer, rumen liquor (obtained from a Friesian cow fed good quality lucerne hay) and cysteine sulphate reducing agent. Triplicate bottles of each forage were removed after 0, 2, 4, 6, 8, 10, 12 and 24 h of incubation and sub-sampled for ammonia, VFA and pH determination. 100 mm x 100 mm dacron bags containing 30 g of each forage were placed in the rumen of the cow. Duplicate bags were removed at 0, 2, 6, 12, 24 and 72 h, hand-rinsed in cold water, dried at 60°C for 48 h and residues were analysed by NIRS to estimate nutrient content. Kinetic parameters of DM and nutrient disappearance over time were predicted by fitting data from bag residues to a non-linear model (Orskov and McDonald, 1979). Estimates of DM solubility (%DM) and fractional DM degradation rates (h⁻¹) were: temperate grasses (48, 0.09); legumes (42, 0.14); tropical grasses (29, 0.06); silages (45, 0.10); herbs (40, 0.25). High nitrogen legumes released up to 43% of plant-N over 24 h. Low nitrogen tropical grasses released a maximum of 8% of the plant-N after 6 h, and losses of plant-N decreased thereafter. These data will be used as a scientific basis for formulating forage-based rations in which the components complement each other in terms of their digestion and fermentation characteristics. Such rations may then be incorporated into New Zealand grazing systems to optimise the nutrient supply for high-producing dairy cows.

922 Condensed tannins in legumes increase milk production of dairy cows. S.L. Woodward*, E.B.L. Jansen, and P.J. Laboyrie, *Dexel Ltd, Hamilton, New Zealand.*

New Zealand dairying relies on ryegrass (RG)-white clover pastures. *Lotus corniculatus* is an alternative legume species which, when grazed by lactating dairy cows, results in higher milk yield than either RG or white clover. It was thought that condensed tannins (CT) contributed to this increase. CT (phenolic compounds in some legumes including *Lotus*) bind to plant proteins and reduce microbial degradation of soluble protein to ammonia. This increases non-ammonia nitrogen flux to the abomasum and small intestine, and absorption of amino acids from the small intestine. Three indoor feeding trials were conducted to determine what proportion of milk yield and milk composition changes were due to CT in *Lotus*, and what proportion was due to factors common to all legumes. Friesian dairy cows in mid- to late-lactation (125-226 days in milk) were fed either RG or *Lotus*, and were drenched with either polyethylene glycol (PEG) solution or water. CT bind to PEG in preference to plant proteins thereby rendering the CT inactive. Comparing cows on RG (21.4%DM; 17.4% crude protein; 10.7 MJ ME/kg DM; 0% CT) or *Lotus* (16.0%DM; 23.7% crude protein; 11.6MJ ME/kg DM; 2.63% CT) diets with CT-inactivated cows (+PEG) allowed effects of CT in *Lotus* to be quantified. Higher milk yield of cows fed *Lotus*

was due to a combination of legume factors (higher intake and forage quality), and CT effects, which contributed 42% of the increase in yield. CT also contributed 65% of the increase in milk protein concentration and 100% of the increase in conversion efficiency, but did not contribute to the increase in intake or decrease in milk fat concentration. *Lotus* has potential as a forage for dairy cows, although its low herbage yield compared with traditional forages necessitates further investigation of management options for inclusion of *Lotus* into the farm system. Table: Means (30 cows) and SEDs of combined data from all three trials.

	RG	RG+PEG	Lotus	Lotus+PEG	SED

923 Nutrient composition of forages in Arkansas, 1985-1999. G. V. Davis*, M. S. Gadberry, and T. R. Troxel, *University of Arkansas Cooperative Extension Service, Little Rock, AR.*

The objective of compiling a statewide forage database was to determine the average nutrient composition and variability of forages produced in Arkansas. The database consists of 11,592 forage samples (10,246 hay, 1,001 pasture and 345 silage) collected from 1985 to 1999. Forage samples were analyzed for 1 to 15 nutrients. These included DM, N, ADF, NDF, P, K, Ca, Mg, Na, S, Fe, Mn, Zn, Cu and Se. The mean \pm SD CP and TDN levels (% DM) of bermudagrass (n = 3,007), fescue (n = 904), mixed grass (n = 2,394) and all hays (n = 8,316) were, respectively; 12.4 \pm 3.5, 60.0 \pm 6.2; 11.2 \pm 3.0, 53.8 \pm 4.7; 11.1 \pm 3.1, 52.9 \pm 4.7; and 12.0 \pm 3.8, 56.8 \pm 6.6. For beef cows and calves, TDN was deficient in a higher percentage of hays (P < 0.05) than CP. Bermudagrass hay contained greater (P < 0.05) levels of CP and TDN, but lower (P < 0.05) levels of P and Mg than fescue or mixed grass hays. Fescue and mixed grass hays did not differ (P > 0.05) in CP, ADF, NDF or TDN concentrations. Mixed grass hay contained greater (P < 0.05) levels of Ca but less (P < 0.05) S than bermudagrass. Fescue hay had less (P < 0.05) Cu and Zn than bermudagrass or mixed grass hays. Sodium was the most deficient mineral in all hays. Only 6 to 10% of the hays analyzed for Na contained adequate levels for beef cows and calves. Trace minerals Se, Cu, and Zn were deficient in 60, 52 and 41% of the samples, respectively.

ASAS/ADSA Growth and Development: Ruminant Growth and Mammary Development

925 Effects of a dairy calf starter containing yeast culture on daily grain intake, weight gain, structural growth, and rumen development in dairy calves. K. E. Lesmeister* and A. J. Heinrichs, *The Pennsylvania State University, University Park, Pennsylvania.*

The effects of supplemental yeast culture on daily grain intake, weight gain, structural growth, and rumen development were analyzed using 75 Holstein calves (38 male and 37 female) fed one of three grain starters containing a yeast culture (*Saccharomyces cerevisiae*, Diamond V Mills, Inc.) at 0 (C), 1% (1Y), or 2% (2Y) of the ration in a randomized block design. Calves were placed on trial at 2 1 d of age and maintained on trial for 42 d. A non-medicated milk replacer (20% CP, 20% fat) was fed in two equal feedings totaling 10% of birthweight until abrupt weaning at 35 d on trial. Grain and water were provided daily on an ad-lib basis, with grain intake (GI) being measured daily. Measurements of bodyweight (BW), wither height (WH), hip height (HH), hip width (HW), and heart girth (HG) were recorded at 0, 7, 14, 21, 28, 35, and 42 d on trial. Incidences of scours were recorded daily (DS). Two calves per treatment were slaughtered at 42 d, weights of empty stomach compartments (CE) were recorded, and rumens sampled for analysis of papillae length (PL), papillae width (PW), wall thickness (WT), and papillae/cm² (PC). No differences were observed between sexes for all variables. Average daily GI was greater (P = 0.029) for 2Y (0.687 kg/d) than for C (0.602 kg/d). Average daily gain was numerically greater for 2Y (0.340 kg/d) compared to C (0.304 kg/d) and 1Y (0.287 kg/d). Average daily change in HW was greater (P = 0.013) for 2Y (0.064 cm/d)

A lower percentage of the hays were deficient in P, Ca, Mg and S. Fe, Mn and K were deficient in 2% or less of the hays. Wheat, ryegrass, legume-grass and fescue pastures tended to contain greater levels of CP and TDN than the other pasture forages analyzed. Bermudagrass, corn, and sorghum-sudan silages contained greater (P < 0.05) levels of TDN than the other silages. This information was provided to county Extension agents, cattle producers, and cattle-related industries to promote forage testing by cattle producers and provide general feeding recommendations whenever a forage test was unavailable.

Key Words: Hay, Pasture, Forage composition

924 Frontal grazing for cattle management on annual ryegrass pasture. H. Lippke*¹, T. D. A. Forbes¹, R. V. Machen², and B. G. Warrington¹, ¹*Texas Agricultural Experiment Station, Uvalde, TX,* ²*Texas Agricultural Extension Service, Uvalde, TX.*

An experiment was conducted to develop a modified frontal grazing system (FGS) based on center pivot irrigation machinery and to compare that system to a traditional continuously stocked management system (CGS) with respect to (a) ADG by yearling steers grazing ryegrass (*Lolium multiflorum*) and (b) livestock production/unit land. In the FGS, a break wire was attached to the towers of the outer 98 m of a 244-m center pivot. Concentric rings of temporary fence restrained lateral movement of the steers, while a manually advanced back fence restricted the cattle to a 15 to 20-degree arc of the circle. Pivot towers were advanced at a rate such that 30% of the ryegrass leaf lamina remained with the ungrazed plant residue. The CGS was lightly stocked initially at 593 kg animal weight/ha. The FGS was initially stocked with 1038 kg animal weight/ha. With the onset of spring growth, cattle were added to both systems so that at the mid-point of the 156-d grazing season, the CGS and the FGS supported 1094 and 1989 kg animal weight/ha, respectively. As an additional measure to control forage growth, 25% of the CGS and 20% of the FGS was de-stocked during the month of March, harvested as high-moisture hay, and restocked in mid-April. Average daily gain for steers on the CGS (1.22 kg) was greater (P < .01) than ADG for steers on the FGS (1.08 kg). Animal production/unit land was greater (P < .01) for the FGS (834 kg/ha) than for the CGS (668 kg/ha). If the animal production potential of the hay harvested from these systems is included, the FGS again produced more (P < .01) gain than the CGS (873 vs 746 kg/ha). Frontal grazing offers instant flexibility in cattle management and sufficient promise of higher productivity to be further evaluated in comparison with an array of stocking densities under continuous grazing.

Key Words: Grazing system

than for C (0.052 cm/d). A trend (P = 0.128) for PC from the caudal ventral rumen wall was also observed between C and 2Y (938.75 vs. 711.06 papillae/cm²). No treatment differences were observed for BW, WH, HH, HG, DS, CE, PL, PW, and WT. These data suggest that the addition of yeast culture in a dairy calf grain starter at 2% of the ration positively influenced average daily grain intake, ADG, hip width, and rumen papillae/cm².

926 Calf serum IgG concentrations affects weaning performance. R. C. Vann* and J. F. Baker, *University of Georgia, Tifton, GA/USA.*

The objective of this study was to determine if calf serum IgG concentrations at 24 h of age affects growth performance to weaning. Calves were born in January or February in two consecutive years and weighed monthly beginning in March until weaning in early September. Colostrum samples were collected from Angus (n=94) and Polled Hereford (n=38) cows at the Tifton location and crossbred (n=112) cows at the Alapaha location within 8 h after parturition and serum samples collected from their calves at 24 h of age. The serum and colostrum immunoglobulin (Ig) concentrations were determined using radial immunodiffusion (RID) kits. Calf serum IgG concentrations were classified as Superior (S) Ig concentration (above 1600 mg IgG/100 ml), Average

(A) Ig concentration (between 400 and 1600 mg IgG/100 ml) and inferior (I) Ig concentration (below 400 mg IgG/100 ml). Failure of passive transfer (FPT) rate (IgG concentration below 800 mg IgG/100 ml) in the first year at the Tifton location was 19.4% and at the Alapaha location 12.5%, however, the FPT rate in the second year was 38.6% at the Tifton location and 32.9% at the Alapaha location. The FPT rate for the two years combined was 34.1% at the Tifton location and 28.6% at the Alapaha location. Data were analyzed by Proc MIXED using a model that included fixed effects of dam breed, year, and FPT class. Covariates included were cow IgG, cow IgM, cow IgA, birth weight and birth day of year. The effects of birth weight, birth day of year and FPT classification were significant for periodic weights and weaning weight. Breed of dam did not have a significant effect on colostrum or calf IgG concentration. Weight gains from March to weaning followed a linear trend, however, at the March weight the S calf group were 3 kg heavier than the A group and 7 kg heavier than the I calf group, and at weaning the S calf group were 14 kg heavier than A group calves and 29 kg heavier than the I calf group. Calves in the A and S FPT groups were significantly heavier at all weigh periods and at weaning compared to calves in the I FPT group.

Key Words: Beef calves, Immunoglobulins, Growth

927 Plasma IgG concentration in neonatal calves in response to a colostrum supplement or colostrum replacer and addition of deoxycholic acid. J. D. Quigley*, C. A. Kost, and T. M. Anspach, *APC Company, Inc., Ames, IA.*

Absorption of IgG from the intestine of neonatal calves is influenced by the milieu in which the IgG are presented. The presence of excess protein or selected ions may affect absorption of IgG during the neonatal period. Bile salts are powerful emulsifiers that affect absorption of fats, vitamins and other compounds and may influence IgG absorption. Our objective was to determine if deoxycholic acid (DOCA) affected IgG absorption in calves fed a colostrum supplement (CS) or colostrum replacer (CR). Holstein bull calves ($n = 33$) were removed from the dam within 10 min of birth, weighed, and fed 454 g of a commercially available CS (Lifeline Nutritional Colostrum Supplement, APC Company; 10% IgG) or an experimental CR (20% IgG) containing IgG extracted from bovine plasma. The CR and CS were mixed in a blender with 1.9 L of water per feeding. In addition, 0 or 2 g of DOCA were added at each feeding. Calves were fed by esophageal feeder at 1 and 8 h of age. Intake of IgG was 90 and 187 g for CS and CR, respectively. Jugular blood was collected at 0.2 and 24 h of age and analyzed for IgG by turbidimetric immunoassay and total protein by biuret. Plasma IgG and total protein at 0 h were unaffected by dietary treatment and were 0.4 g/L and 4.57 g/dL, respectively. Addition of DOCA had no effect on any parameter measured. Plasma IgG at 24 h in calves fed CR was higher ($P < 0.001$) than in calves fed CS (13.6 vs. 8.0 g/L); however, plasma protein was not different (4.99 vs. 4.98 g/dL). Plasma IgG at 24 h in calves fed CS and CR ranged from 4.8 to 12.9 and 9.9 to 17.5 g/L, respectively. Apparent efficiency of IgG absorption was similar between CS and CR and was 33 and 30%, respectively. Relationship between plasma IgG and total protein at 24 h varied by treatment. For CS, regression equation was plasma IgG (g/L) = $4.92 \times$ plasma protein (g/dL) = 16.5; $r^2 = 0.77$. For CR, regression equation was plasma IgG (g/L) = $5.38 \times$ protein (g/dL) = 12.5; $r^2 = 0.59$. The CR used in this study effectively prevented failure of passive transfer in neonatal calves; however addition of DOCA did not influence IgG absorption.

Key Words: calves, colostrum, immunoglobulin

928 Intake, growth and efficiency of calves fed milk replacers containing whey protein concentrate or alternative animal proteins. J. D. Quigley*, C. J. Kost, and M. L. Miller, *APC Company, Inc., Ames, IA.*

Protein ingredients in calf milk replacers (CMR) contribute significantly to the overall cost of the product and alternatives to dried skim milk and whey protein concentrate (WPC) have been evaluated extensively. Spray-dried hydrolyzed red blood cells (SDHRBC) and bovine plasma (SDBP) have been compared to CMR containing WPC. However, the effects of SDHRBC and SDBP in the same formulation have not been determined. Our objective was to compare the performance of calves fed CMR based on WPC or SDHRBC alone or in combination with SDBP. Holstein bull calves ($n = 120$) were purchased from area dairies or sale barns and were assigned to receive CMR containing WPC, or 10% of the

formula as SDHRBC or 10% SDHRBC plus 4% SDBP. All CMR were formulated to contain 23% and 21% of DM as crude protein and ether extract, respectively. Calves were housed in individual hutches and fed 454 g/d of CMR reconstituted to 12% DM for 24 d. Commercial calf starter and water were available throughout the study. Mean BW on d 0, 28 and 56 were unaffected by treatment and were 48.1, 58.5 and 89.5 kg, respectively. Mean intake of DM from CMR from d 0 to d 24 was 413 g/d; intake of calf starter and water were 1308 g/d and 3.6 L/d, respectively from d 0 to 56. Mean fecal scores, days scouring and days treated tended to be higher in calves fed SDBP, although much of the increase in veterinary treatments occurred during the last 2 wk of the study. Mean fecal scores were 1.65, 1.64 and 1.72 in calves fed WPC, SDHRBC and SDBP, respectively. Mean days with scours were 5.5, 5.3, and 8.3, respectively. There were few differences in physical characteristics of the CMR and acceptance by the animals was excellent. Spray dried bovine plasma may be included in CMR formulations containing SDHRBC.

Key Words: calves, milk replacer, intake

929 Economics of dairy heifer growth programs. C.A. Wolf* and M.J. VandeHaar, *Michigan State University, East Lansing, MI/USA.*

Interest in rapid growth rates for replacement heifers occurs because breeding date, and subsequent calving/lactation, is determined by size. General agreement exists that heifers should be bred when they are 340 to 380 kilograms regardless of age. Given the weight standard, a heifer that grows at a faster rate will achieve the breeding size at a younger age. Accelerated growth rates, gains over 900 grams/day, put heifers at risk for impaired mammary development and have been found to be detrimental to milk production with declines of 5 to 48 percent in the first lactation. The potential advantages of reduced age at first calving include decreased feed costs and lower overhead while the potential disadvantages include lower milk production and the cost of increased planes of nutrition. The tradeoff between potential savings in heifer raising costs and milk production loss is examined in a basic economic model using parameter values from the dairy science literature. The analysis uses 20, 22 and 24 months age to first calving. In a short-run framework, facility and enterprise size variables are held constant and the cost change is driven by the feed costs determined using least-cost rations. Least cost rations indicate that total feed costs decline from 22 to 24 months age at first calving but are essentially constant and may even increase marginally when heifers are grown at rates required to calve at 20 months relative to the 22 month scenario. The savings in feed cost are small enough that even a five percent decline in milk yield in the first lactation will off-set the savings. In a long-run analysis accelerated heifer growth implies less need for facilities and other infrastructure associated with the heifer enterprise and overhead costs decline with age to first calving. Sensitivity analysis is used to compare the changing heifer enterprise costs with milk income loss values using data from the economics literature. The results indicate that milk yield loss is the important factor in the short-run while fixed cost changes substantially affect the long-run heifer growth rate decision.

Key Words: Heifer growth, Economic analysis

930 Effects of added rumen undegraded protein (RUP) and bovine somatotropin (bST) administration on mammary gland growth in prepubertal dairy heifers. A. V. Capuco*¹, G. E. Dahl², D. L. Wood¹, and R. A. Erdman², ¹USDA-ARS, Beltsville, MD, ²University of Maryland, College Park, MD.

The objective of this study was to test effects of added rumen undegraded protein (RUP) and recombinant bST administration on growth of mammary glands of dairy heifers from 90 d of age until 10 mo of age (peripubertal). Thirty-two Holstein heifers (90 d of age) were used in the experiment, eight of which were slaughtered at 90 d, prior to being assigned to treatment. The remaining twenty-four heifers were randomly assigned to one of four treatment groups. Treatments consisted of added dietary RUP (2% RUP, 14.9% CP, DM basis) and 0.1 mg of bST/kg BW/d applied in a 2 x 2 factorial design. Twelve heifers (3 per treatment) were slaughtered at 5 and 10 mo of age. Mammary parenchymal growth was not affected by RUP or bST treatment ($P > 0.1$). Total parenchymal mass increased from an average of 16 g to 364 g, and parenchymal DNA from 58 mg to 1022 mg from 3 mo to 10 mo of age, respectively. Total parenchymal fat increased from 82 g at 3

mo to 618 g at 10 mo of age. Furthermore, the number of mammary epithelial cells likely was not affected by diet or bST because neither total parenchymal DNA nor the lipid content of parenchyma was affected by treatment ($P > 0.1$). Results suggest that mammary parenchymal growth was neither enhanced nor inhibited by RUP or bST at the feeding rates employed in this study.

udder half (10 mo)	Treatment ¹				
	Control	bST	RUP	RUPbST	SE

931 Physiological responses and growth rates of dairy heifers when raised from birth to weaning during hot weather. Tomas Belloso^{*1}, R.A. Bucklin¹, H.H. Head¹, M.J. Hayden¹, A.N. Garcia¹, M.S. Gulay¹, and F. Baccari², ¹University of Florida, Gainesville, Florida, ²Universidade Estadual de Londrina, Londrina-PR, Brasil.

Objectives were to evaluate effects of hot weather on physiological responses, hormone concentrations, and growth rates of newborn heifers from birth to weaning. Twelve heifers were assigned to each of three housing systems by d-3 of age. These were in calf barn without (H1) or with fans (H2), and outside calf-pens (H3). Approximately equal numbers of heifers with low (C1, <5.0 g/dl) or high (C2, <5.0 g/dl) levels of total plasma protein on d-3 of age were in each H. Fans provided air movement across heifers in H2. Heifers were fed milk replacer twice daily through d-42 then once daily until weaned (d-49). Water and dry feed (>15%CP) were available free choice and intakes measured once or twice daily, respectively. Body weight and height at withers were measured when assigned and then once weekly. Blood samples were collected twice weekly, plasma harvested and frozen until analyzed for concentrations of somatotropin (ST), insulin (INS), insulin-like growth factor-1 (IGF-1), triiodothyronine (T₃), and thyroxine (T₄). Rectal temperature (RT) and respiration rate (RR) were recorded one day a week over a 24-h cycle at 0700, 1100, 1500 and 1900, and at 0700 h. Mathematical models included H, C and H*C. Highest and lowest mean RT (39.81±0.04 and 38.71±0.03) and RR (66.7±1.71 and 35.33±1.68) were at 1900 h and 0700 h, respectively; daily trends followed daily ambient temperature. Significant effects of H were detected only for T₃ (H1>H2,H3) and mean daily water intake (2.8, 2.5 vs. 3.5 L/d). Differences were detected among C groups. Calves in C2 had greater mean daily water intake ($P < 0.0119$) and DMI ($P < 0.0404$). They grew faster than heifers in C1 (0.265 vs. 0.239 kg/d, $P < 0.0415$; and 6.1 vs. 4.3 cm increase, $P < 0.0517$). They also had significantly higher mean concentrations of T₃, T₄ and INS in plasma. No significant interactions (H*C) were detected except for RR; it was greater in C2 except for H1. Importance of providing newborn calves with colostrum and growing heifers with water and feed free choice during summer months was confirmed. Increased water consumption by heifers, especially in H3, likely allowed them to dissipate greater heat load and to maintain body temperature, physiological responses and growth rates the same as heifers in H1 and H2.

932 Analysis of cell proliferation in the prepubertal bovine mammary gland. S. Ellis^{*1} and A.V. Capuco¹, ¹USDA-ARS-GEML Beltsville, MD 20907.

The focus of this research was to investigate the growth and development of the prepubertal ruminant mammary gland. Detailed histologic analyses were conducted to characterize the proliferation of mammary epithelial cells and to determine how each of the mammary cell types contribute to mammary development. Holstein heifers were slaughtered at 2, 5, and 8 mo of age to provide tissues for this study (n = 3 per age group). Each heifer was injected intravenously with bromodeoxyuridine

(BrdU, 0.5 mg/kg body weight in pH 8.5 saline) 2 h prior to slaughter to label S-phase cells. After slaughter, mammary parenchymal tissue samples were collected from peripheral, medial, and cisternal parenchymal regions. Tissues were then fixed, embedded, and sectioned at 0.9 μm. Sections were immunohistochemically labeled to detect BrdU and stained with a mixture of Azure II and basic fuchsin. Current models of mammary development in rodents suggest that a population of small, basally located, lightly-staining cells (SLC) function as mammary stem cells. In the present study, three distinct levels of cytoplasmic staining were observed in mammary epithelial cells: light, intermediate, and dark. As in the rodent mammary gland, BrdU-positive SLC were observed in all parenchymal zones. BrdU-positive SLC were also observed in contact with the ductal lumen, in contrast with the current rodent model. BrdU labeling was also observed in cells with intermediate and dark cytoplasmic staining. Preliminary results from these analyses reveal both similarities and distinctions from the current model of mammary epithelial cell proliferation in murine mammary glands. The results of these analyses provide critical insight into the cell types involved in ruminant mammogenesis. This information will aid in the development of therapies that improve prepubertal mammary development and increase the return on investment in replacement heifers.

933 Leptin receptor expression in the bovine mammary gland and other tissues. L.F.P. Silva^{*}, M.J. VandeHaar, M.S. Weber, and G.W. Smith, Michigan State University, East Lansing, MI.

The effect of leptin on food intake and energy metabolism relies on leptin receptors (Ob-R) located in the central nervous system. Several peripheral actions of leptin have also been reported, and Ob-R mRNA has been detected in peripheral tissues of human, rodent, pig and sheep. We believe leptin may modulate mammogenesis in heifers. Thus, our objective was to characterize Ob-R expression in mammary and other tissues of prepubertal dairy heifers. We used reverse-transcription PCR to detect Ob-Rb, the long splice variant which has an intracellular signaling domain essential for leptin's weight-reducing effects, and Ob-Ra, a short isoform with unidentified signaling capabilities. Ob-Rb mRNA was detected in all tissues examined: hypothalamus, pituitary, heart, spleen, liver, lung, ovary, testis, skeletal muscle, subcutaneous adipose tissue, primary mammary epithelial cells, mammary extra-parenchymal adipose tissue, a bovine mammary epithelial cell line (MAC-T) and mammary tissue (parenchyma + stroma) from a heifer two months after puberty. However, in contrast with reports in other species, expression of Ob-Ra was detected only in bovine liver, pituitary, subcutaneous adipose tissue and spleen. The partial deduced amino acid sequence (134 a.a.) for bovine Ob-Rb shared 92, 78, 73 and 68% similarity with the reported Ob-Rb sequences for ovine, swine, human and rat, respectively. The partial amino acid sequence (91 a.a.) for Ob-Ra shared 90 and 80% similarity with the human and rat Ob-Ra, respectively. The widespread tissue distribution of Ob-Rb in the growing heifer suggests that leptin may potentially have a direct action on peripheral tissues. Immunocytochemical staining of bovine mammary epithelial cells and MAC-T cells using a specific antibody to Ob-R revealed that Ob-R protein is also expressed in bovine mammary parenchyma. The presence of Ob-Rb mRNA and Ob-R protein in the mammary gland supports the concept that leptin may play a direct role in mammary parenchymal development.

934 Postnatal nutrition and fatness affect plasma leptin concentration in neonatal sheep. R.A. Ehrhardt¹, P.L. Greenwood^{*2}, R.M. Slepatis¹, A.W. Bell¹, and Y.R. Boisclair¹, ¹Cornell University, Ithaca, NY, ²NSW Agriculture Beef Industry Centre, Armidale, NSW, Australia.

Effects of birth weight and postnatal nutrition on plasma leptin concentration were investigated in male Suffolk x (Finn x Dorset) lambs from birth to LW 20 kg. Lambs of low (meanSD 2.290.34 kg, n=28) and high (4.840.45 kg, n=20) birth weight were individually fed a milk replacer diet in amounts that promoted rapid (ad lib, ADG 350 g, n=20) or slower (restricted, ADG 150 g, n=20) growth, and slaughtered at selected LW from 5 to 20 kg. Blood plasma was obtained from selected lambs at birth, every second day from birth to slaughter, and during frequent

sampling one day prior to slaughter. At birth, plasma leptin concentration did not differ between low and high birth weight lambs (meanSEM 4.10.3 vs 3.80.3 ng/mL, respectively). During the first week of postnatal life, plasma leptin was higher in small compared to large newborns (4.10.1 vs 3.60.2 ng/mL, $P < 0.05$) and tended to be higher in ad lib compared to restricted fed lambs (4.10.2 vs 3.6 0.1 ng/mL, $P = 0.07$). By week 2 of postnatal life, plasma leptin was significantly higher in the ad lib group (4.60.2 vs 3.70.2 ng/mL, $P < 0.005$) but was not affected by birth weight. Overall, during rearing to 20 kg LW, plasma leptin concentration was greater in ad lib than restricted lambs ($P < 0.001$) but was not significantly affected by birth weight. The effect of plane of nutrition increased with LW; ad lib lambs had leptin concentrations that were twice those of restricted lambs at 15 kg LW (6.01.0 vs 3.10.2 ng/mL), and 3-times greater at 20 kg LW (8.20.5 vs 2.80.2 ng/mL). Although plasma leptin concentration was related to both mass of body fat ($r = 0.614$, $P < 0.001$) and percentage of body fat ($r = .624$, $P < 0.001$), body fatness was not sufficient to explain the effect of plane of nutrition. This was particularly evident as the lambs reached 20 kg LW, when ad lib lambs were only 16% greater in body fatness than restricted lambs yet had plasma leptin concentrations that were 3 times greater than restricted lambs. Collectively, these data suggest that plane of nutrition independent of its effect on body fatness, is a major factor regulating plasma leptin concentration during early postnatal growth in sheep.
